Cholera has not yet disappeared (says the Naples correspondent of the *Times*, writing on the 5th instant), and quarantine at Nisida, and fumigation at every landing-place, are in full force. The cases for the last four days have been 14, 9, 10, 14, while the deaths have been 5, 9, 8, 13. During the week which closed yesterday there were 96 cases and 77 deaths. From this great fatality it is evident that the malady is of a severe type, and if it has not spread so widely and rapidly as might have been expected, it must be attributed to the sanitary measures which have been so promptly adopted, and to the energy and unwearied activity of the authorities. A few cases of cholera have appeared in the province of Caserta, six having been registered up to October 1, and two deaths, but the coast of the bay and the islands are "clean."

WHAT'S A "ROOKERY."

Some complaints were recently made at an inquest by Dr. Lankester on the unsanitary state of Mitre-court, John-street, Smithfield, which the coroner said was "a disgraceful rookery." Dr. Gibbon, the Medical Officer of Health for Holborn, visited the court on the day following the inquest, and has reported the result of his visit to the Vestry. He found that the room in which the deceased child died had been cleansed and limewashed four months previously, and that the closet, water-cistern, and dust-bin were in good order. Dr. Gibbon admits that the court is narrow and rather confined, but is not prepared to recommend the closing of the court, because there never has been any amount of preventable disease which would justify such a course. Dr. Gibbon felt it necessary to write to Dr. Lankester to ask him what meaning he attached to the word "rookery," and to specify the sanitary defects that he observed. In reply, the coroner informed him that the court was "structurally unfit for human habitation in consequence of the narrowness of the passage leading to the houses, and the single rooms had no ventilation. He did not go into the three other houses, but seeing them full of dirty children he thought the court might with great propriety be called a rookery." The court consists of four houses, containing twenty-five adults and twenty-one children. With the exception of the family in which the deaths occurred, Dr. Gibbon thought the children clean and healthy-looking. The rooms, with this one exception, are not dirty or over-crowded. In this room there were 250 cubic feet of space to each adult, reckoning the two children under three years of age as one adult. The Works Committee recommended that in future, where the conduct of the Board was likely to be inpugned, Dr. Gibbon attend the inquiries.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

The first meeting of the eighteenth session of the above Society was held at the Royal Kent Dispensary, Greenwich-road, on Friday, October 3rd, at eight p.m.; Dr. Ralph Gooding, President, in the chair. The following gentlemen were elected office-bearers for the ensuing session, 1873-74:—*President:* Frederick Moon, M.B. *Vice-Presidents:* John Anderson, M.D.; John Prior Purvis, M.R.C.S. *Council:* John Moulden Burton, F.R.C.S.; William Carr, M.D., F.R.C.S.; William Lockhart, F.R.C.S.; J. W. Walker, M.D.; Charles Nind, M.R.C.S.; Ralph Gooding, B.A., M.D.; J. N. Miller, M.D. *Treasurer:* Prior Purvis, M.D. *Secretary:* Harry Knight Hitchcock, M.R.C.S. *Librarian:* J. B. Saundry, M.R.C.S., L.R.C.P. Dr. Moon then took the chair as President, and proceeded to deliver an inaugural address. The next meeting will be held on Friday, November 7, at the Royal Kent Dispensary, Greenwich-road, at eight p.m. precisely. Mr. William F. Teevan, B.A., F.R.C.S., will read a paper on "Retention of Urine, Causes and Treatment."

MANCHESTER ROYAL SCHOOL OF MEDICINE, INCORPORATED WITH THE OWENS COLLEGE.

After the address, introductory to the medical session, by Professor Arthur Gamgee, M.D., F.R.S., on Wednesday, the 8th inst., the following scholarships and prizes were distributed by George Southam, F.R.C.S., Director of Medical Studies. The School award of Scholarships and Prizes, session 1872-73.—Third Year's Scholarship, value £20—H. M. Lightoller, Chorley; First Prize, value £5 5s.—W. Smith, Ashton-under-Lyne; Second Prize, value £3 3s.—F. Newsham, Great Eccleston; Third Prize, value £2 2s.—C. E. Smith, Preston. Second Year's Scholarship, value £15—T. Anningson, Burnley; First Prize, value £5 5s.—J. J. K. Fairclough, Northenden; Second Prize, value £4 4s.—F. H. Grosholz, Altrincham; Third Prize, value £3 3s.—H. Burton, Manchester; Fourth

Prize, value £2 2s.—No award: Certificate of Merit—T. Gallimore, Rusholme. First Year's Scholarship, value £10—S. Harris, Higher Ardwick; First Prize, value £5 5s.—H. Tomkins, West Gorton; Second Prize, value £4 4s.—J. H. Wylde, Stretford-road; Third Prize, value £3 3s.—E. Jackson, B.A., Whalley Range; Fourth Prize, value £2 2s.—J. Newton, Heaton Chapel; Certificate of Merit—A. K. Ludlam, Salford. Dumville Prize in Surgery, value £20—F. W. Jordan, Manchester. Platt Exhibition in Physiology, value £25—C. E. Richmond, Manchester. Certificates of Honour, 1872-73.—J. Buxton, W. H. Clarke, G. F. Coles, J. J. K. Fairclough, G. Fitton, F. H. Grosholz, J. Hampson, J. W. P. Hosking, G. Kisby, G. L. Lennon, J. E. Looker, W. S. Merriman, J. Priestley, G. T. Schofield, W. W. Settle, J. B. Stelfox, H. Tomkins, W. H. Vickerstaff, W. Walker, V. A. Wartenburg, J. T. Watts, W. Whittaker, W. Wood, F. H. Worswick.

LIVERPOOL MEDICAL INSTITUTE.

On Thursday, October 9, the President of the Liverpool Medical Institute, Dr. John Cameron, gave a *conversazione* to the members and other gentlemen, the guests numbering about two hundred. The entire suite of rooms was thrown open, and the walls hung with a choice collection of pictures that were lent by their owners for the occasion. In the library there were exhibited a great number of most elegant specimens of porcelain and other ware, mostly of English manufacture, and of various dates, so as to illustrate the development of the art in England. Ancient books, microscopes, modern physiological instruments, and a series of the rarer and more recent pharmaceutical preparations, forwarded by Messrs. Abraham, Delf, and Syme, were also present for examination. A short address of welcome and introductory to the work of the session was given, at nine o'clock, by the President, in the large theatre.

VERBA NON FACTA.

The *Oswestry Advertiser* observes, on the appointment of the Medical Officer of Health for Newton, that "£20 a year cannot be regarded as much more than a nominal salary for a professional man, but we may hope that Mr. Cockburn Smith, who has been appointed Medical Officer of Health, will discharge the duties *eon amore*, and win something better than money. The medical profession has earned an honourable distinction by the readiness with which many of its members labour for the welfare of mankind with slender hopes of reward, and the delight which they take in a pursuit that has for its object the alleviation of human sorrow." Whatever disadvantages the members of our profession labour under, they cannot complain of the want of eulogy and a wordy appreciation of their services. Whether in Parliament, in the pulpit, in the press, or in society in general, compliments are showered upon them to any extent. It would be well for the profession if the adulation were accompanied with something like substantial reward for their self-sacrifice and their disinterested labours in the cause of the public welfare.

PROSECUTION OF ADULTERATORS.

We agree with the remarks of Mr. S. A. Brooks, made at the Clerkenwell Vestry last week on a matter brought before them connected with the office of analyst, that if they left it to the Vestry to prosecute parties who adulterated their goods, he was afraid the thing would go by favour, for no vestryman would be prosecuted on the recommendation of a committee. It should be left to the analyst to prosecute before the police magistrate, independently of the authority of the Vestry. The analyst should be unshackled, and have absolute control and discretion over these prosecutions against offenders under the Act.

CAN IT BE TRUE?

Owing to the practice of sending (says the *Gloucester Journal*) the washing from the infirmary to be done by the prisoners at the gaol, a female warder died there a few days since from typhoid fever. Inquests, it is stated, have been held upon prisoners who were alleged to have contracted fatal diseases by contact with the infirmary clothes, and in more than one case juries have added to their verdicts recommendations that the practice alluded to should be discontinued, but it has been persisted in. We should hope the above statement cannot be correct. That the recommendations from the coroner's court should not have received proper consideration from the governing bodies of the infirmary, and the practice complained of still continued, is almost incredible. This is a case which demands the immediate attention of the authorities. We trust they are able to exculpate themselves from, apparently, great neglect and a grave responsibility.

PUBLICITY *versus* ADULTERATION.

The South London Grocers' Association has addressed a letter to the Bermondsey Vestry, complaining that the names and addresses of shopkeepers whose articles had been analysed were published in the newspapers. The Association was of opinion that the names being given in cases where the articles were pure gave those interested an undue advantage over the tradesmen whose articles had not been tested. The Vestry decided that they had no right to interfere with the press, to whom the letter should have been addressed. As the whole object of the Adulteration Act is the prevention and punishment of fraud on the part of the purveyors of articles of food and drink, we think the publication of the names of the defaulters is absolutely necessary for carrying out the purposes of the Act.

DISCRETION THE BETTER PART OF VALOUR.

The Local Government Board, after having investigated the circumstances which led the St. Pancras Guardians to suspend Dr. Purcell, one of the medical officers of the parish, has superseded the decision of the guardians. After some high words of protestation and threats of defiance at the rebuff thus administered, the guardians ultimately and wisely, although reluctantly, decided "to let the matter drop." Consequently Dr. Purcell has resumed his duties. We have always contended that a medical officer's position and reputation are safer in the hands of a Government board than of a board of guardians. This is a case in point.

POOR-LAW MEDICAL RELIEF.

From a return prepared by order of the Poplar Board of Guardians, it appears that the number of persons supplied with medicines from the several dispensaries in the Union had greatly diminished during the past five years. The numbers of cases dealt with in 1869 at these establishments were as follows:—Poplar, 8624; Bow and Bromley, 5327; South District, 2231; whilst during the twelve months ended at Michaelmas last the respective numbers were 4933, 2198, and 932. We believe this satisfactory diminution of the number of applications for medical relief is due to a more stringent inquiry into the real necessities of the applicants.

SURELY A QUIBBLE!

A firm of grocers of extensive business in Liverpool have been fined £5 and costs for selling tea which was found to be adulterated with 6 per cent. of metallic substance. For the defence it was argued that tea as sold in the leaf was neither food nor drink within the meaning of the Act of Parliament. The magistrate over-ruled the objection. Notice of appeal was given by the defendants.

ALLEGED CURE OF LEPROSY.

THE *Friend of India* reports that the Madras surgeon in medical charge of the penal settlement at Port Blair believes he has made a valuable discovery in the cure of leprosy. He is of opinion that leprosy can be cured by the oil of the gurjun tree. Every leper in the settlement is, it is stated, being cured fast of this loathsome disease. In no case has there been the slightest failure, and the disease has been arrested at every stage.

FROM ABROAD.—TRANSFUSION IN CHOLERA—THE SULPHATES AS A CAUSE OF EPIDEMIC GOÎTRE—VACCINATION OF ERECTILE TUMOURS—SMALL-POX AT BICÊTRE DURING THE SIEGE.

DR. STADTHAGEN, Physician to the Shed Hospital at Moabit, Berlin, communicates (*Berlin. Woch.*, September 22) a case of cholera in which he performed transfusion with success. The patient, a woman 29 years of age, was brought to the hospital on August 26 with her two children, her husband having died shortly before of cholera. Prodromic diarrhœa had set in the day before, and during the night had become excessive and watery, and was soon accompanied by vomiting. On her admission at 10 a.m. she exhibited all the signs of a commencing collapse. Her skin was flaccid and cold to the touch, and the face and extremities were covered with cold sweat. The thermometer stood at 36° Cent. in the axilla, and 38° in the anus. Folds of the skin only slowly recovered themselves. Pulse 90, and small. The abdomen was flattened and fluctuating to pressure, but nowise tender. The abundant stools had the characteristic rice-water appearance, as had the matters which were vomited. Great thirst. From time to time there were cramps, and the patient complained of a sense of constriction of the chest and of painful pressure at the epigastrium. In spite of all means employed, the collapse continued to increase, and when seen at 8 p.m. the change in her countenance told plainly of the extremity which she had reached. The extremities and lips were cyanotic, and the pulse and second sound of the heart could no longer be perceived; the temperature, too, had sunk to 35·4° in the axilla, and 37° in the anus. No urine had been passed for fifteen hours, and the stools came away unconsciously. In consequence of this condition of the patient, and of the great mortality that had attended the commencement of this epidemic, a very bad prognosis was delivered, and it was determined to have recourse to transfusion. About 180 grammes of defibrinated blood were injected into the median basilic vein by means of Uterhart's syringe. The operation was performed without any obstacle, the patient being scarcely sensible of it. While the blood was being propelled, the pulse, which had almost disappeared, could again be plainly perceived. An equable diffusion of bodily heat was also sensible to the hand, the peripheric parts therefore having had their temperature much raised. One hour afterwards the temperature was 36° in the axilla and 37° in the anus; the appearance and general feeling of the patient undergoing corresponding improvement. At first several stools and vomiting of colourless matters still continued, but gradually diminished in number, and then assumed a bilious colour. The reaction, though slow and delayed during several days, yet met with no disturbance, the diarrhœa and nausea continuing for some time. The temperature during the three following days varied from 36·2° to 36·8°, and only on the evening of the fourth day reached more than 37°. Some highly albuminous urine was first passed after three days of anuria, and the first solid stool took place on the tenth day. The woman was discharged well on September 7.

In a second case the operation was tried without a good result. The patient, thirty-four years of age, had been passing rice-water stools for fifteen hours, and all the cholera symptoms were developed in a high degree. Neither the pulse nor the second sound of the heart could be perceived. During and immediately after the injection of blood the pulse could again be felt, and there was a temporary amelioration in other symptoms. The patient, however, died twenty-four hours after the transfusion.

In reference to the epidemic of goître which has broken out among the young soldiers at St. Etienne (*Medical Times and Gazette*, Sept. 27, p. 372), Dr. Bergeret has just made a communication to the Académie des Sciences, pointing out the influence of the sulphates in the production of this disease. He states that before the year 1835 all the inhabitants of Saxon in the Valais were either goîtrous or cretins. They then drank water derived from a bank of gypsum, which on analysis was found to furnish one gramme of sulphate of lime per litre, beside some sulphate of magnesia. In 1835 the potable water was derived from a spot situated far above the bank of plaster; and since then goître has much diminished. The children are no longer subject to it, and before long the disease will probably have disappeared.

But how does this fact go to explain the occurrence of goître at St. Etienne, where the water is of such excessive purity that photographers use it in place of distilled water? It is, in fact, rain-water which falls on the primary rocks of Mount Pilate. The cause is to be sought for in the excess of sulphates which gain access to the circulation through an exaggerated muscular "detrophia" induced by forced exercise. In fact, as long since observed by M. Chevreul, in order for the health of an adult to be maintained good he should weigh the same at the same hour every day—that is to say, that the anatomical elements, the tissues and organs, should receive assimilable principles of an equal weight to that of those which are destroyed, in order to maintain the animal heat and to execute the mechanical work imposed upon them. If what is received does not equal what is expended, consumption or anæmia takes place. This is what is observed in the goîtrous soldiers in barracks who are subjected to excessive work and who are not fed proportionally to the amount of force they are called on to expend. It is a phenomenon which presents some analogy to what was observed among the French labourers engaged during the construction of the Du Nord Railway, and later in certain factories. On the other hand, we know that when a muscle is employed with force and continuity, or when it is submitted for a certain time to the action of a continuous electrical current, such muscle, burning its own substance, becomes acid, and that the acids produced are the sulphuric and phosphoric, at the expense of the sulphur and the phosphorus contained in albuminoid principles. Under the conditions of excessive work, then, a man has circulating in his blood an abnormal amount of sulphates, absolutely the same as if he had drank water loaded with gypsum. This is what has occurred to the soldiers in the barracks suffering from goître. In support of this theory, M. Bergeret cites analyses of urine showing that the sulphates precipitated are three or four times more abundant during the existence of goître than in the normal state.

M. Larrey, in relation to goître in young soldiers, observed that it as well as enlargement of the cervical glands were formerly of much more frequent occurrence than at present, the cravat having been substituted for the stiff military stock formerly in use.

M. Blot brought the subject of vaccinating erectile tumours before a recent meeting of the Société de Chirurgie. He observed that since he had undertaken the vaccinations performed at the Académie de Médecine, a week did not pass without the parents or medical attendants of infants bringing them to have vaccination of erectile tumours performed. To

pretend to cure an erectile tumour in this way is to commit an error. Blood flows away, and the vaccine does not take, or, if it does take, a small cicatrix and nothing else is the result. Erectile spots (*taches*) may be thus cured, but for erectile tumours vaccination is insufficient, and may give rise to serious hæmorrhage. M. Tillaux stated that he had cured a true erectile tumour the size of a nut by vaccination, traversing the tumour in the direction of its long axis by a fine needle, followed by a thread imbued with the virus. Another thread was then passed in a direction perpendicular to this. M. Sée had cured an erectile *tache* by surrounding it with a circle of vaccinal punctures made in the sound skin. M. Marjolin was of opinion that vaccination should always be first attempted, whatever may be the seat, extent, or depth of the erectile tumour. In a tumour of two centimètres in diameter he makes from thirty to forty vaccine punctures with an excessively fine needle, sliding the skin over the tumour before puncturing. M. Desprès related the case of his own child, who was born with an erectile tumour at the end of the little finger. At the end of six months, as it was increasing rapidly, a simple vaccinal puncture was made at its most projecting part, and this sufficed to effect a cure. M. Chassaignac agreed with M. Blot, for to vaccinate in these cases is only to lose time and expose the patient to the danger of erysipelas. When a cure is accomplished, this is not brought about by the vaccine virus, but by the consecutive inflammation. M. Blot, however, did not wish to speak so absolutely as this, for superficial slight *taches* may be cured by vaccination. But it is not suited for voluminous, deep-seated tumours. If out of fifteen punctures only three or four take, some other means must be resorted to; and M. Blot much dreads erysipelas in new-born infants. M. Marjolin, when he stated that he applied vaccination in all cases, did not mean that it always succeeded. But the inflammation which accompanied the vaccinal evolution ought to be utilised; and when but partial success was obtained, there would be a better chance for any other procedure, or a spontaneous cure may result. M. Guéniot has frequently met with a slight vascularisation of the dermis of the eyelids or lips in new-born children. A large proportion of these *taches*, however, disappear spontaneously within the first six months. M. Tarnier has also observed this vascular development disappearing spontaneously, and which is not of the nature of an erectile tumour. Many of these infants present no *tache* during the first few days after birth; then a red elevation appears, which increases, especially in breadth, the vessels being very minute. In the process of spontaneous cure a whitish tissue appears on the centre of the *tache*, and gradually replaces the red tissue. These cases should be watched for some months, and if the *tache* increases, in place of disappearing, vaccination should be tried.

Professor Colin, of the Val-de-Grâce, communicates an interesting paper to the *Révue Scientifique* (October 4) on the utility of wooden hospitals for the reception of patients in epidemic variola. He founds his suggestions upon the experience he has derived from the treatment of 8000 soldiers the subjects of variola during the siege of Paris, and who were accommodated at the Bicêtre Hospital. He examines into what are the results of so large an agglomeration, first on the patients themselves, and then on those in attendance upon them and on the surrounding population.

1. When one considers the immense amount of purulent discharges that are produced in variolous patients distributed over sixty wards, each containing from twenty-five to thirty beds, it is obvious that if anywhere the atmosphere ever becomes saturated with contagious germs it must have been so at Bicêtre. And yet this assemblage of so large a number of cases does not seem to have aggravated the affection; and the mortality did not exceed that observed in the Val-de-Grâce and other ambulances. This is but a new proof that in diseases of a distinctly specific virulent nature, having, so to say, their evolution determined beforehand, the fate of the patient depends much more on the energy with which the contagious germ has impressed itself upon him than upon the circumstances of the medium amidst which he undergoes the disease. Would the same innocuity have been observed if, in place of small-pox, typhus, dysentery, or wounds had been the affections to be treated? One accident of the disease, ophthalmia, seemed to have been aggravated by this concentration of cases, and consequent emanation of pathological products.

2. The *personnel* of Bicêtre, nearly two hundred in number, suffered little from variola—one alone dying from it. Of forty medical attendants, none took the disease, in spite of the negligence of most of them in respect to vaccination. Still more remarkable was the complete exemption of forty *religieuses* who lived in the centre of the hospital, and tended the patients day and night. It would seem, therefore, that a mass of variolous patients, shut up in an establishment, does not render the transmission of the disease much more certain. On the contrary, there is probably a certain degree of immunity produced by the very fact of a long sojourn in the midst of these variolous patients, and that there is more danger of contagion for persons merely visiting these patients than for those living close to them.

3. The vicinity of Bicêtre was incontestably noxious to the garrisons quartered near it, and which were in communication with the military staff quartered in the centre of the hospital. The same may be said of soldiers billeted in some adjoining houses, near which the patients had to pass on entering and leaving the hospital. But the germs of the disease seem to be incapable of being transported far; and a fort about a hundred mètres distant from Bicêtre, with which it had no personal communication, remained free from the disease. This shows that there is no necessity for such establishments for the reception of variolous patients being placed at a great and inconvenient distance from inhabited parts of a town. These facts are confirmed by analogous observations made by the leading physicians of Paris.

In M. Colin's opinion, there is no disease so suitable for the application of the hutting system of construction of hospitals; and if during the siege of Paris a sufficiency of huts had been erected in advance, or the dearness of wood had not afterwards prevented their construction, he would gladly have availed himself of them. It is true that such constructions protect less from the vicissitudes of weather than do ordinary hospitals; but of all serious diseases variola is that which, within certain limits, best withstands such vicissitudes. And while the temperature of sheds cannot be raised in winter sufficiently to allow of our placing the wounded in them during this season, this consideration does not apply to cases of variola. Not only would this mode of construction enable us, in imitation of the Americans, to destroy by fire hospitals that had become contaminated, but it would easily admit of change of site when this for economical or sanitary reasons had become desirable. The speed with which such erections can be raised during an epidemic, and removed after its cessation, is an additional advantage.

Prevention of Tormenting of Horses, etc., by Flies.—M. Rochard, a veterinary surgeon, describes a simple and economical means of preventing the suffering which is induced in horses and other animals by the persecution of flies; and which our provincial readers will probably be induced to try. It consists in painting with a pencil the insides of the ears, or other parts liable to be bitten, with a few drops of empyreumatic juniper oil (*huile de cade*). Insects will not approach the parts so painted, and the cost of the oil is trifling. —*Journal de Connaissances Méd.*

CLINICAL REMINISCENCES.—No. III.

By PEYTON BLAKISTON, M.A., M.D., F.R.C.P., F.R.S.

Hysteria.

Those who have passed the greater part of a long life in medical practice must have seen numerous cases of hysteria in which almost every form of disease to which the human frame is heir was simulated.

An endeavour to lay down a code of laws by which a young practitioner would be enabled to distinguish between an attack of inflammation and its hysterical shadow would be attended with about as much success as the efforts of Sisyphus. I shall, however, touch on a few cases presenting peculiar features, and carrying with them a moral.

One of the commonest forms is that in which disease of the spine is simulated, of which the following case furnishes an instance:—About thirty years ago I was summoned to a single lady, twenty-nine years old, who was on a visit in the neighbourhood. I found her suffering from what was supposed to be disease of the spinal column. She could not put her feet to the ground. She had been nine years under the care of a medical man at Bath of some notoriety, and had been treated by him for disease of the spine. She had been repeatedly leeched, cupped, and blistered, and on each side of the spine were marks left by the use of moxas, actual cautery, etc. On careful examination not a trace of disease was to be discovered in any one of the vertebræ—no thickening, no absorption, no anchylosis,—and perfectly normal motion existed throughout the column. Mr. Hodgson, having met me in consultation, came to the same conclusion. Yet this poor lady had been kept in a recumbent position till she had lost the use of her legs, had from time to time been tortured by most painful remedies, for the cure of a disease which never existed; whilst her slender means had been reduced by the sum of 700 guineas, which she had at different times paid to her medical adviser. And the man who had thus acted escaped scot-free! whilst a poor man, whose family was starving, would be severely punished for stealing a loaf of bread. Some mild tonic medicine was given, and she was ordered to endeavour to regain the use of her legs by the aid of crutches. Some months afterwards, having a consultation at Clifton, I went over to Bath, and saw her with the late Mr. John Soden. She was then getting on very well with her crutches. I heard of her about two years since as being seen regularly at church; but I could not learn whether she had regained complete use of her legs.

About the same time I was sent for to see the wife of a collier butty, near Dudley. She had been attended by a medical man in the neighbourhood for sixteen years, during which time she had never left her bedroom. He had been treating her for "disease of the back," and made some excuse for not meeting me in consultation. On more than one occasion he had salivated her, and had received from her husband sums of money which had caused a serious drain on his resources. I could not find a trace of disease about this woman, although she seemed enfeebled both in mind and body. Had I told her this, of course she would have disbelieved me, and probably have gone on in the same manner she had been doing for these sixteen years. So I told her I knew perfectly well the nature of her complaint, and how to cure it; that she would never get well so long as she remained confined to her bedroom; and that medicine would be ordered for her which would give her power to leave it, and that in three or four days' time she must do so. She protested that it would be impossible, but was told that unless she promised faithfully to make the effort she should not be prescribed for. She promised; some quinine pills were ordered for her; she went downstairs in three days, and made a rapid and complete recovery. A few months afterwards I found this person playing the same trick, and I then exposed him.

Cases in which the medical attendant is himself deceived are far from uncommon; occurring occasionally when he is a man of some age and experience. Some years ago I attended a young lady, aged 18, living in the neighbourhood of Birmingham, in a well-marked attack of hysteria, from which she recovered. Three years afterwards she had inflammation of one knee, and her medical attendant had come to the conclusion that the leg must be amputated; but before this was fully determined on it was decided that a consultation should be held on her case, and Mr. Hodgson was asked to see her. But as his engagements would not allow of his doing so at that time, her friends preferred my seeing her to calling in a fresh surgeon who was a perfect stranger to her. I found her knee excessively painful, particularly to the touch; much swollen, with some fluctuation, but not, as it appeared to me, caused by fluid in the joint. I at once recognised the inflammation as being of an hysterical character, such as I had seen two or three times in the Birmingham Hospital. The medical man in attendance was past middle age, of sound judgment, and in large country practice, but he had never seen an hysterically inflamed knee. The friends were told that possibly amputation might not be necessary, and that an effort would be made to save the leg, although a stiff joint might remain. Some cold lotion was applied, and some medicine given, the exact nature of which I do not remember. In a week's time Mr. Hodgson accompanied me, when we found the inflammation much reduced, and he agreed with me as to the nature of the affection. Curiously enough, owing to her obstinacy, she had a stiff joint for about eighteen months. Eventually, however, she recovered the perfect use of her leg, was soon after married, and has now a grown-up family.

There is another class of cases in which the hysterical simulation of disease after a certain time is succeeded by the real disease. A single lady, aged 26, had for four or five years exhibited symptoms of hysteria in various forms, but there was almost always some cough, and she became very thin, which, however, might in some degree be accounted for by the existence of a pernicious habit which she had doubtless contracted and had practised some years, as there was reason to believe. The chest was repeatedly examined, but no physical signs of disease were detected, although she had every appearance of being consumptive. After an absence of six or seven months she applied for advice, suffering from cough and expectoration, which appeared for the first time. It was then ascertained that a tubercular cavity existed in one lung. The disease spread rapidly, and she sank.

A lady, separated from her husband on account of her eccentric but not immoral conduct, the mother of three children, was placed under my care in preference to being sent to an asylum, to which a strong objection existed on the part of her friends, although it would have been more suitable to her case. In addition to her eccentricity of manner and conversation, it was supposed that her lungs were delicate, and that a residence on the south coast might be beneficial to her health. With the exception, however, of a dry cough—which is very common in cases of hysteria—I never could detect any physical sign of disease in the lung. One marked feature in her case was a habit of feigning diseases. On one occasion she complained of pain in the abdomen, and violent retching and vomiting came on. The pulse was quiet, and there was no other disturbance of the system. On inquiries being made amongst the druggists, it was ascertained that she had purchased antimonial wine, so at my next visit she was informed that the vomiting and other symptoms she had recently had were caused by antimony, at which she feigned great surprise, as "she had never taken any medicine other than had been prescribed for her." She was told that the druggist had possibly made a mistake, and that the medicine must be discontinued. The vomiting forthwith ceased. On another occasion an eruption was produced by means of some irritating drug she had procured, and she was treated in a similar manner. She was thus led to understand that, although her practices were known and would be thwarted, she would not be exposed or treated harshly, and she ceased to practise them. But she took every opportunity of conversing with a neighbouring clergyman, and whoever else she could get to listen to her, telling them the most extraordinary tales about her ailments and her friends, which had not the slightest foundation in truth. One or two persons were told of her peculiar state of mind, but as everyone could not be told, and it was not thought desirable to shut her up, I advised her removal to a smaller place at some distance off, where she was placed in the family of a trusty and judicious medical man. She had not been there long when she had an attack of hæmoptysis, which was followed by another in a few months, when undoubted signs of pulmonary phthisis developed themselves, and she died from the effects of a bloodvessel bursting into a tubercular cavity. It may be supposed by some persons that in this case phthisis had commenced before the appearances of the symptoms of hysteria, but as I myself carefully and fre-

quently examined the lungs, and as there was not the slightest acceleration of the circulation, I feel satisfied that such was not the case.

In another case—that of a young lady aged 21—I was for a long time doubtful whether phthisis and hysteria were not co-existent, for I detected from the first some dulness on percussion and prolonged expiratory sound and vocal resonance in a small spot under the right clavicle; but as month after month, and year after year, these physical signs never altered, I came to the conclusion that they resulted from an attack of congestion or inflammation during childhood, and that hysteria was the sole complaint under which the patient laboured. She is now about forty-seven years old, is in good health, has the care of a widowed brother's children, and rejoices in her work.

I now come to a class of cases in which hysterical mania was joined with exaltation of the sexual passion; and I enter on it because such cases sometimes furnish a valuable lesson to the younger members of our profession.

A young lady, aged 18, came under my notice, having occasional attacks in which her reason was affected and her conduct was very strange. I found that these attacks were of an hysterical character, that they occurred at the menstrual period, and were attended with more or less of nymphomania. After a time the attacks became more prolonged, till they ran into each other, so that it was found necessary to place her under constant observation and control. In about two years' time they gradually shortened, but it was always necessary to keep a strict watch upon her during the menstrual period. About ten years afterwards a younger sister was attacked in a similar manner, but in her case the duration of the attack never exceeded three or four days, and between times she was sensible and in every way well conducted. I need hardly remark that in this and similar cases I never remained one moment in the room unless another female, if possible a married woman, was present. In the two following cases more painful results took place:—

About thirty years ago I was sent for to a distance to see a young lady, who was eighteen years of age, and was said to be in a strange state which caused her friends much anxiety. I found her not merely in a state of hysterical mania, but affected with nymphomania in a marked degree. It was clear that she was not in a fit state to be left where she was, and therefore I at once removed her and her maid in my carriage, and placed them in a lodging with a trustworthy person on whom I could depend. A surgeon of eminence was joined with me in attendance, and the patient was removed to a farmhouse, the occupiers of which were known to him. An old female relative came to reside with her, and the strictest orders were given that she should never be left one moment alone. Matters progressed much as usual for some months, when, on one of my visits, I observed symptoms which caused me some uneasiness. I immediately conferred with my colleague, and in a few days we visited her together, and came to the conclusion that there were strong grounds for supposing her to be pregnant, and yet at first we could find no evidence of her ever having been left unwatched. It appeared, however, that her relative had left her for a fortnight, during which time she sent for the maid for three or four days, the patient being left under the care of the farmer's wife, the mother of a large family, and well acquainted with the nature of the case. After a certain time it proved that our suspicion was well grounded, and that she actually was pregnant. She was immediately sent off to a first-rate asylum. Neither I nor my colleague, however, felt ourselves to be in a very comfortable position, as the friends knew of no other man ever having been in her company. Still, it was known that she had never been seen by either of us except in the presence of her relative, her maid, or the farmer's wife. The whole affair was mysterious. Luckily, after a short time, the wife of the medical gentleman who kept the asylum elicited the truth from her. It appeared that the farmer's wife was in the habit of rising before her husband to look after her household work, and that on one or two occasions, during the absence of the maid, our patient had got into his bed, and so become pregnant. Our annoyance and distress, as well as that of her family, was not diminished by knowing that we could not punish the scoundrel without publishing the disgrace of one of the highest families in the country. There was no improvement in her state after her confinement, and she remained for years and died a confirmed maniac.

Another case was that of a widow lady, aged 32, the mother of a small family. In her case, however, the symptoms of nymphomania predominated over those of hysterical mania. She was at once removed to an asylum, a step the necessity for which had been imposed upon me by the remembrance of the last-mentioned case. Here she was occasionally visited by a brother and sister, when her conduct and conversation appeared quite rational, so that after a time they entreated me to consent to her removal, and on my declining to do so, their language became violent and offensive. On her being removed, therefore, I washed my hands of the case, and pointed out to them what they might expect, for which I received little thanks. She had not been removed many months before she was found to be pregnant, and circumstances of a most painful nature came to light. She was sent back to the asylum, where she remained and died a few years afterwards. As much that occurred could not be concealed from observation, the misery produced in her family can be better imagined than described.

These cases disprove the correctness of the supposition, not uncommonly entertained, that the state of a patient in such instances is improved by gestation and parturition. Somewhat allied to the last class of cases are those in which there is a morbid craving for examinations, injections, etc., and which it has been thought has in some cases led to the too frequent use of the speculum; but no object would be gained by detailing such cases.

In my work on "Diseases of the Heart" I have recorded two remarkable cases in which hysteria simulated heart disease, so I will not refer to them here.

When in Paris, in 1832, I sometimes heard discussions respecting mesmerism as employed in cases of hysteria; and in 1835 M. Jules Cloquet told me he had removed a breast from a female who had been placed in a state of mesmeric trance, and who, on recovering from it, was not aware of any operation having been performed. In 1839, Mr. Hodgson mentioned his having seen some persons put under the influence of mesmerism by Dr. Elliotson, at the North London Hospital. He told me how the effect was produced, and by what means the subjects of it were restored to their natural state. At that time a large number of patients were in the habit of coming to my house twice weekly for gratuitons advice; and amongst them were some young women whom I thought, from Mr. Hodgson's description of those he had seen in London, were the sort of persons likely to be successfully acted on by mesmerism. Accordingly, on the entrance of a young woman suffering from hysteria, I commenced making some passes as I had been instructed to do, and in a short time, to my utter surprise, she suddenly fell down and remained in a perfectly unconscious state until she was restored to her senses, by my placing my thumbs on the inner edge of her eyebrows, and quickly drawing them across the eyebrows two or three times.

On another occasion I requested a friend to engage the attention of a young woman, and whilst this was being done, I made a few passes behind her, which she could not possibly see, and she too dropped as if she had been shot. I may mention that none of those who were operated on knew what was going to be done, nor had they ever heard of mesmerism. My astonishment was great, but it had not reached its height. Amongst my patients was a girl seventeen years old, who lived in a state of double consciousness, or, in other words, was subject to fits of a kind of hysterical mania. Her natural and hysterical state each had their separate memory, and were never confounded in her mind the one with the other; so that when she was questioned in either state about something that had occurred in the other state, she was frequently not only puzzled but annoyed, and burst out crying. She was naturally a quiet and rather reserved girl, but in her hysterical state she was the reverse—full of fun and mischief, restless and active,—but there was no impropriety in her conduct. She was more than once kept upwards of twenty-four hours under mesmeric influence, when her nose was actually burnt by the strength of ammonia which did not produce the slightest effect on her, and pins were introduced into her arms and legs with a like result. Bits of silver paper were also placed on different parts of the body, but none ever stirred from the spot whereon they had been placed. And now comes the most extraordinary part of the story. Whenever, after having been mesmerised, she was aroused out of the trance in a short time, she invariably was found to be in the maniacal state; but when left half an hour or upwards, and then aroused, she was always found to be in her natural state,—so that it was possible in this manner to restore her to her natural state. Something of the nature of mesmeric influence was thus revealed to us,

and shown to resemble that of opium—being first exciting and then sedative.

Now, whatever inferences may be drawn, here are the facts, and they were witnessed by all the leading medical practitioners of that day in Birmingham, and by some non-professional gentlemen, none of whom previously knew anything at all about mesmerism. It was decreed, however, that it should not, in my hands at least, become a therapeutic agent, for on employing it on a girl subject to epileptic fits I found their frequency and severity increased rather than diminished. On another occasion, a medical man residing on the opposite side of the street in which I lived having related what he had seen at my house to his wife, who was a highly hysterical subject, she asked him to send her to sleep, and he did so. In a short time he sent me a hurried message, begging me to come over as he could not awaken his wife out of a mesmeric trance into which he had thrown her. On my endeavouring to arouse her in the usual manner, a nervous and convulsive twitching of the muscles of one side of the face took place, and it was some time before she came quite round. For some months her hysterical symptoms were much exaggerated. Thus, finding mesmerism an uncertain and somewhat dangerous agent, I ceased making experiments with it, and never resumed them. Whilst I was making them I saw nothing of clairvoyance, as it is called,—of persons under mesmeric influence seeing objects through opaque substances or blindfold, or answering questions addressed to them; I simply learned that persons of a certain constitution, or in a peculiar state of health, could, by the motions of the hand of a second party, whether seen or not, be thrown into a kind of coma in which they were totally insensible to pain, and in one particular instance could by this means be restored from an hysterical to a natural state.

I wish it were in my power to throw any additional light on the treatment of hysteria, which would seem to be involved in as much obscurity as its nature and causes. In many cases the most successful treatment has seemed to be more moral than medical. Drugs that have seemed useful in some cases, have not produced the slightest effect in others, apparently similar. When, however, there has been reason to suspect the existence of congestion of the ovaries or neighbouring parts, a leech applied to the vulva, and the use of cold enemata and hip-baths, have certainly had very beneficial results. But change of scene and of occupation, when practicable, have done more good in my experience than any medical treatment whatever.

A GENERAL HOSPITAL FOR THE BRIGADE OF GUARDS.

[COMMUNICATED.]

We hear from a very good source that, in connexion with the inquiry into the position of the officers of the Guards with regard to the Line, that of the Medical Department is also to be investigated. Some time ago we drew attention to a suggestion made by Surgeon-Major Logie of the Blues, senior Surgeon of the Household Cavalry, for establishing a general hospital for the whole brigade of Guards. During this inquiry we trust this excellent idea will not be forgotten. Mr. Logie does not wish to change the present system of hospital management *in toto*, nor does he suggest any interference with either the appointment of medical officers or removal from their regiments; but he throws out this idea, that in the event of war it be thoroughly understood that the very instant regiments of the Guards are ordered to the field, then the medical officers of those regiments shall be entirely at the disposal of the principal medical officer in the field; for, as he justly says, what can it matter whether the signature is Surgeon of the 100th, Irregular Horse, or Guards? Neither does he suggest the expense of a change of uniform, stating that the red cross is quite sufficient for all field purposes. We rather think that this idea—of making it known to the whole Medical Department that those engaged in campaigns should consider themselves a general staff for the time being—would have answered all requirements, instead of doing away with the regimental system, which has always worked so well and so happily.

NÉLATON AS A SURGEON.

By Professor A. DESPRÈS.

We extract the following appreciation of M. Nélaton's characteristics as a surgeon, by M. Desprès, from a recent number of the *Révue Scientifique*:—

"Nélaton, one of the illustrations of French surgery, has just succumbed to a long and painful malady, attacks of which he suffered from during three years. Like Mirabeau and Dupuytren, he died of an affection of the heart. By the unanimous agreement of the surgeons of all countries, he was a model clinical teacher, and the Faculty of Medicine has rarely possessed a more lucid professor or one more apt to make good pupils.

"Auguste Nélaton, born in Paris in 1807, after years of solid work as *interne* of hospitals, where he was a pupil of Dupuytren, received his doctor's degree in 1836. After being appointed a hospital surgeon and *agrégé* of the Faculty, he encountered the *concours* once so brilliant, and was in 1851 one of the last professors chosen by its agency. His 'Traité de Pathologie Externe,' which he had then begun, and the brilliant commencement of his professorial career, obtained for him honours, practice, and reputation. The Academy of Medicine opened its doors to him in 1856, and in 1867 the Academy of Sciences summoned him to fill the place of Jobert de Lamballe. In 1868 the dignity of Grand Officer of the Legion of Honour and also that of Senator were accorded to him in recompense for his attendance on the son of Napoleon.

"Beyond the first volume of the 'Traité de Pathologie Externe,' Nélaton has written but little, so that he leaves very few works; but what he has done of these himself bears the impress of precision and good sense, that are scarcely to be found elsewhere than in Boyer's 'Traité de Chirurgie,' which Nélaton declared an imperishable monument. The chapters on phlegmons, amputations, fractures of the forearm, senile gangrene, together with the general observations on dislocations, contained in the second volume, are pages that have never yet been surpassed. Surgery, indeed, owes much to Nélaton. He it was who taught us that a ligature placed on a wound, even when suppurating, was preferable to any distant ligature in secondary hæmorrhage. The investigation of naso-pharyngeal polypi and their treatment, whether by the palatine button-hole or by electrolysis; the application of the preliminary suture before opening the intestine in enterotomy; the regularisation of lithotrity and pre-rectal lithotomy; the diagnosis of retro-uterine hæmatocele, of abscess and tubercle of bone, together with a crowd of other points, such as cricoidean laryngotomy—*i.e.*, opening the larynx through the cricoid, and excising a segment of this,—these are some of the different surgical procedures to which Nélaton's name has become attached. All these modifications have proved successful. They were first published in their theses by the pupils of Nélaton, and were at once accepted, possessing as they did that practical character which is always requisite to secure the durability of new procedures.

"All this, it is obvious, does not constitute any great discovery. It is rather, if we may so term it, perfected surgery. Nélaton, in fact, had the great merit—possessing much good sense and a reflecting mind—of being able to amend, correct, and complete anterior surgical conceptions. He knew how to disengage parasitic precautions or formalities from good procedures faultily presented, and to render these practicable. Caring little for theories, the spirit of which he, however, analysed with wonderful clearness, it was only the attempt which attracted him; but when he had made this, he rapidly seized any defective point of an operation, and at once rendered it applicable by means of a modification which everyone present declared it was easy to make, while forced to admit that until then it had never been discovered. This class of surgical conceptions explains the enormous success which Nélaton met with in practice—a success which, 'like all durable vogues in our country,' has always been legitimised by a real talent. Those who were pupils of Nélaton have learnt of him two things—the precious art of diagnosis in which he excelled, and the therapeutical indication. Here the surgical qualifications of Nélaton were quite remarkable. Never would he operate on his patients during his visits, always leaving time for reflection. If he felt in any doubt, he practised on the dead body the operation he was about to perform, and frequently

then conceived a modification (always a happy one) in his original plan of procedure. It may be said that Nélaton always operated at the proper time, and just as he should operate, never exceeding the limit he had proposed to himself. And thus in the eyes of his assistants he was often looked upon as fortunate in his operations; but when his pupils had become practitioners they easily recognised the fact that success in surgery oftenest waits on those who neglect no precaution and abandon nothing to chance. Possessed of these faculties, Nélaton was enabled to captivate that European surgical practice which, while it wore him out, imparted its glory."

GERMAN ASSOCIATION FOR THE ADVANCEMENT OF NATURAL SCIENCE AND MEDICINE.

(*From our Special Correspondent.*)

WIESBADEN MEETING, SEPTEMBER, 1873.

(*Continued from page* 423.)

ADDRESS BY PROFESSOR VIRCHOW.

On the Natural Sciences: their Relation to the Moral Edueation of Mankind.

PROFESSOR VIRCHOW commenced his address by reminding his audience that he had already handled a similar subject at their Hanover meeting before the Austrian war, and again in Rostock a second time and from another point of view before the war with France. He was proud to be able to say that after both these occasions history had speedily confirmed the views which he had expressed. It was not more than a year after their war with Prussia before the Austrians began to comprehend that even Romanism, the foundation of the old Austrian constitution, had become the cause also of its downfall. His Rostock address was not everywhere agreeably received, yet only a year afterwards Germany was in possession of the ecclesiastical laws. In renewing the theme to-day he had a kind of recognition of the correctness of his choice in the esteemed address of the delegate of the Government, who had publicly acknowledged in the previous sitting how much value the Government attached to the natural sciences on account of their practical utility. This fact was certainly already known to scientific men; but what they wished, and what the Government had not yet granted, was a greater amount of influence—and that all the more at the present moment when the old supports of the State were being cleared away.

Hitherto, said Virchow, the moral education of man has been universally in the hands of the Church; she was recognised as the guardian of the conscience, and accordingly it seemed as if she must be the peculiarly-called teacher of mankind. The conscience has been considered as something innate, as an inward divine voice—the judge of good and evil. Modern science, however, holds that the conscience is not an innate possession, but something acquired. The former view of conscience has led to the recognition of the Church as its guardian. The Church early adopted the commandments of the outward or prescribed morality, which have reached us from former periods of culture in distinctly formulated laws, and so far have become the best foundations for the later traditions. These were, however, only outward commandments. The Ten Commandments, for example, of the Jewish and Christian religions correspond more or less to outward morality only, and furnish a useful treatise for human society and a certain security of their relations. But these outward commandments do not found that inward morality which endows the individual with the power of setting himself right even in the most difficult cases of the "conflict," for they supply no standard by which it may be decided. Now, an increase in the number of conflicts is a necessary consequence in the States of the present day with their great complexity. The more simple the political and social relations, the less cause there is for conflicts, as may be seen by studying the uncivilised nations of the present day. Virchow here referred to Wallace's description of the Indian Archipelago. When this observer declares that the morality among these savages is as high as that of the great mass of the English population, or even higher, he forgets (said Virchow) that the morality of which he speaks is only external, transmitted in the form of settled laws, and so forming the basis of education in the simple circumstances of the people. If one sets oneself the problem of the moral education of a population moving on so complex a basis as the Europeans do, one must avail oneself of other means than the vulgar signification of a simple race or village, which might apply even in South America.

The Church has not taken the trouble to do this: she has applied the principle of education to individuals who are truly morally free. This is indeed the great reproach which we must lay against the Church. Virchow would not refuse to grant that in perfectly simple, primitive political conditions the outward moral code, as it had established itself in the various laws, might be sufficient. If, however, with the advancing development of these political conditions the complexity of the social conditions was more and more developed, then there arose the conflict—that primeval opposition which in more recent times has been abundantly expressed in the phrase, "knowledge opposed to belief." Twice have we had this contest already in the history of our own religious development. It first took place as the result of the dogma of the Tree of Knowledge which should remain forbidden to man, and which, when it became accessible to him, brought after it the fall. The second occasion was when Pope Innocent III., in 1215, interdicted the study of the scientific writings of Aristotle, which until that time formed a regular constituent of theological education. And the heretical study still continuing even among the monkish orders formed for its extirpation, the Pope widened the breach with science still more by still more strict prohibitions. The Church remained stable, and science continued to advance.

We are now living to see the State compelled to retake from the hands of the Church what she has improperly administered. For the State has begun to observe that with this simple outward morality a man is not able to advance. Nevertheless, there is no State that can substitute the political code for the ecclesiastical. Legislation cannot advance so rapidly that, exactly as culture is developed, it can express the steps of this development in definite legal paragraphs. On the contrary, the modern State, which developes the idea of a State most completely, is compelled, in order to compass this development, to give way simultaneously to the individual. "As the individual freedom (which we ought to claim for ourselves as a genuine German right) spreads, we must of course also demand that the individual development amongst our people be founded upon moral principles which are ever becoming broader and more profound."

The speaker now passed on to the proof of the law which he had laid down in the beginning of his address: that conscience is to be considered as a product of development—as an organic production. The opponents contend that the conscience is an internal voice which indicates to a man whether something is good or evil. Now, there is nothing either absolutely good or absolutely bad, but only something relatively good or relatively bad. The good and the bad as such (as absolute) cannot, therefore, be an object of science. A poison may be a valuable drug; the fishes which we represent as the ideal of innocence are such beasts of prey that we might represent them as the very expression of evil. This preying in the whole of nature—this necessity of living at the expense of other lives—is *the evil*. Nor can any man divest himself of this wicked necessity which lies in his nature—of living at the cost of other beings. All human culture is accomplished over corpses; every advance in society is bought with abundant sacrifices—sacrifices not only of those who voluntarily, but much more frequently of those who involuntarily, succumb to the new culture.

To the question, How has man become further developed with this original badness—this diabolical part of his nature—according to which he must purchase his existence at the expense of other organic beings?—there cannot yet be returned any unanimous reply. Here the speaker introduced two subjects by way of illustration—first, the practice of cannibalism as a stage in human development; and second, the occurrence of war between civilised nations in the present day. Under the second head, and in reference to the late Franco-German war, Virchow declared that in France, in spite of all ecclesiastical influence, no moral code had been created which embraced the principle of general love among men—this first and greatest principle of Christianity.

Only by better application of the sciences in the schools can an advance be made here. Two kinds of things have to be distinguished—first, the recognition of things themselves, including a much better acquaintance with human nature; and, secondly, what must be attained by the people of all

grades, and by all classes of the schools—unity of method. By this has the tradition of 2000 years in the field of medicine been broken; and by the admission of scientific method into medicine an enormous change has been wrought in it since the first decennium of this century.

This striving after truth is to be taken as the peculiar object of the moral education of mankind. There are (continued Virchow) two kinds of truth as far as most men are concerned—an objective and a subjective truth. The speaker here discussed at considerable length the question of objective and subjective impressions—optical and auditory,—of delusions, illusions, and visions; and pointed out, in reference to the last mentioned, that they may occasion the greatest political excitement, as they are doing at this very moment in France—stirring European society to its very foundations, and threatening to bring the most terrible of all wars in its rear. Our duty in this state of matters is very manifest: we must strive with every means in our power that a really large number of men may take a great step, and be able to separate a subjective from an objective truth. Such false interpretations of the impressions of the senses have in many other directions caused the most extreme confusion in the moral principles on which the education of mankind should have been founded. For example, there was the false representation that the earth stands still and the sun moves round it,—a delusion which has led to the greatest moral errors, inasmuch as the earth was made the centre of the universe, and man the highest product of the world—the first peculiar object of creation. The idea of the peculiar design of the world was thus entirely misrepresented. The same has to be said of the idea of superiority of race, which was so conspicuous among the Jews and ancient Greeks, and persists to the present day, even in England, as Virchow discovered when he paid his visit to London.

Returning to the consideration of the growth of true morality, Virchow would explain it by evolution. All systematically advancing development of the forms of organic nature, and its philosophical contemplation speak in favour of the theory of evolution; and in moral relations also all the development which we see in the world is in favour of the growth and increase of inward morality—the strengthening of instinct into inward morality. What a man brings with him into the world is very little—the ability of receiving mental impressions, and the ability of setting these in mutual relation. This estimation of the mental impressions with each other is innate, because the organism on which this ability depends is present in the newly born child. Now begins the development. New impressions are being continually received, from month to month new experiences are added; presently the instincts become developed, and from these come the passions as years advance. Now, as common sensation is related to the several sensual instincts, so is conscience to the several moral instincts. As long as the moral instincts move in the direction of the pleasant and agreeable, so long will it be easy for the simplest man to hit upon the right. It is different, however, when in certain circumstances instinct must be opposed—when, in a word, it is important to rule oneself. This self-government is possible only by exercise; the moral instincts are developed only by practice. Their practice must be made more prominent in the education of man; thus only can man become more and more fitted to understand the processes without and within him, and then, when the conflict comes, to make the right moral choice with quickness and certainty. The bare outward morality is not sufficient for this. This effect can never be produced without exercise; moral practice alone can promote it. It is therefore necessary that the scientific man should declare that the experience furnished by advances of science is to lie at the foundation of moral theory and of moral practice too.

In conclusion, Virchow said: Most of our churches answer the question, "Wherefore is man created?" by saying that it is a matter of a return to God, to the source of light—a return which, according to the ecclesiastical interpretation, constitutes the final end of all knowledge in the peaceful contemplation of the highest truth. Men of science have also a creed—that mankind is destined ever to press nearer to the light of truth; to behold truth and to advance in truth is also our highest happiness. That the Church calls the contemplation of the final end of all knowledge, the most perfect happiness, can assuredly not satisfy us. We repudiate this doctrine; it is in absolute conflict with every view of the scientific man and with human nature itself: it is perfectly inhuman. It is in work that consolation lies. "And as we—I repeat it expressly—as we have a creed, so we have a sign also by which the true man of science shall always be recognised and must; and the sign is this, that he will never be weary in that striving after truth. Thus only does he earn the name which Linné has given to his sex—the name of *Homo sapiens*,—otherwise must he be called *Homo credulus*."

MANCHESTER ROYAL SCHOOL OF MEDICINE.

ABSTRACT OF THE INTRODUCTORY ADDRESS.

The Introductory Lecture was delivered in the Chemical Theatre on October 8 by Professor Arthur Gamgee; Mr. T. Ashton presided. There was a large attendance of professors of the College and the general public. The gallery was appropriated to the students, who conducted themselves in the usual boisterous manner previous to and for some time after the entrance of the lecturer and the chairman, and it was not until the latter had expressed his intention of clearing the gallery that order was restored.

The Chairman, in introducing Professor Gamgee, said he had no doubt that the reputation which the Professor had gained in Edinburgh would be greatly increased by the work which he was about to do in that College. He came to devote the whole of his time and talent to the interests of that school; and he (the Chairman) hoped to see the time when it would be as celebrated for its results in investigation as in teaching. There was no doubt that to that end they must have not only one professor but many, who would be able to devote their time and energies to the interests of the profession.

Professor Gamgee said, in looking forward with hopefulness to the future of the Medical School in its connexion with Owens College, he would be the last to refrain from offering a tribute of praise to the founders and promoters of what might now be called the old medical school of Manchester. It was to the honour of the teachers of medicine in this city that they succeeded in establishing in Manchester the first of the numerous provincial schools of medicine; that in the face of obstacles of all descriptions, often at great personal sacrifices of time and money, they laboured with very considerable success to further the spread of medical education. Now that the older was being merged into the newer and larger institution, it would be ungraceful and unjust on his part were he not to refer to a few of the men whose names were most honourably associated with the past teaching of medicine in Manchester. First to be named was the late Mr. Jordan, who very early in the century became a teacher of anatomy and physiology in this city, and whose lectures were first delivered in the provinces, and were recognised by the medical corporations as qualifying for examination the students who attended them. In 1825 Mr. Turner organised the Pine-street school, and gathered around him teachers, amongst whom were the illustrious Dalton, Sir J. Bardsley, and many others of distinction. In 1850 the Cheetham-street school, among whose teachers were the late Mr. Dumville, Dr. Watts, and Mr. George Southam, was established; and in 1858 the two schools were amalgamated. To the energy and devotion of one of the teachers in particular (Mr. Southam) the success of the Manchester School had for many years past been greatly indebted, and but for him the union of the Medical School with Owens College might not have been effected. Professor Gamgee proceeded with a review of the progress of medicine from the time of Hippocrates, in order to show that the study of medicine had at all times been influenced by the study of science. Glancing, towards the conclusion of his paper, at the present and past history of the famous medical schools of modern Europe, he said the system of centralisation which had been pursued in France since the days of the First Empire had produced as marked an effect in stifling the scientific ardour as in enervating the political energies of the nation. Enforced dependence had been fatal to progress, and the attempt to centralise the intellectual power of France in Paris, for the glory of the capital, had proved as fatal as would be an attempt to concentrate in one focus the commercial enterprise of this or any other country. The Germans had perceived the mistake of centralisation, and in many departments of science had clearly asserted for themselves the right to hold the first place. The first cause of their progress was to be found in the very perfect system of education pursued in the gymnasia of Germany, which as a consequence led to the average medical student possessing a

greater amount of both literary and scientific knowledge than was the case with us. The second and most potent cause lay in the fact that in the numerous universities of Germany learning met with opportunities of development which did not exist elsewhere. The most ardent enthusiasts of the German unity must admit that the intellectual success of this country was greatly owing to the jealous fidelity with which the elements of German greatness had been developed in the separate centres of the fatherland, and pre-eminently in its universities. In them the greatest encouragement had always been given to the most intellectual men to devote themselves to the acquisition of learning; not merely to become acquainted with what was already known, but to lead in the path of scientific discovery. It was the scientific knowledge acquired in the physiological laboratories of Germany which had chiefly led to the pre-eminence which we were obliged to acknowledge. German physicians had, in these laboratories, learned the methods of inquiry which, when applied to medicine proper, tended every day more and more to raise it from the condition of an art to that of a science. If facts had compelled the cheerful admission that we had much to learn from abroad, it was none the less true that contemporary British physicians had good reason to reflect with pride on the success with which they had sustained the heritage of fame transmitted by Linacre, Harvey, and Sydenham. With the instinctive sense of the useful and industrial acquisitiveness which characterised our countrymen, the best fruits of foreign investigators had been gathered up and assimilated by British physicians, who, science and practice combined, were, he was inclined to think, still not second to the physicians of any other country. What we did want, and what we were happily growing day by day more alive to, was a wider development of schools of science wherein competent men should have the opportunities essential for research, and young men might be trained in those tastes and habits of mind which were of the very essence of successful intellectual pursuit. Now that the wealth of such great industrial centres as this city was being utilised for the highest educational purposes, it was not too much to hope that on the scene of the labours of Dalton and Joule that school might grow to exemplify once more that happy combination and adaptation of resources which had so often placed Englishmen in the van of literary and scientific progress as of manufacturing and commercial enterprise.

REVIEWS.

Lectures on Practical Pharmacy. By Barnard S. Proctor, Lecturer on Pharmacy at the College of Medicine, Newcastle-upon-Tyne. London: J. and A. Churchill. Pp. 399.

There were few books, perhaps, more wanted in this country than a good one on practical pharmacy,—and this not only to the chemist, but also to the practitioner; for since the old system of apprenticeship has been abandoned, men whose life-long business it is to prescribe drugs have few opportunities of practically handling them or of compounding them, and so learning by experience which is the form in which a medicine is best exhibited. Even among otherwise well-skilled physicians there is often a lack of this particular kind of knowledge, chiefly arising from the universal use of hospital pharmacopœias; and the power of writing a neat prescription in good Latin seems to have gone with that old-fashioned polished learning we are nowadays taught to despise. Since the institution of examinations among pharmaceutical chemists, the want of such a book as this must have been severely felt, for no book of the kind was readily available save the excellent American work by Parrish, and that was not very easily come at. That there was wanted some such book as the present will therefore, we suppose, be readily conceded. The question is, Does the present volume meet the necessities of the case? To us it seems that it does so very well, while it has a freshness about it which is very pleasing. The earliest chapters deal with such subjects as drying, comminution, solution, crystallisation, precipitation, diffusion, evaporation, distillation and sublimation, filtration, and percolation. After such preliminary matters are disposed of, Mr. Proctor proceeds to give a critical account of the pharmacopœial preparations, commencing with the powders. Here some very good critical remarks are made on the various officinal products. After the powders come the pills. These, as is well known, are nowadays often kept in the form of powder, instead of the old-fashioned pill-mass, the powder only requiring the addition of some water to make it coherent enough for use; but so many order their pills wholesale from a pill-maker, supplying him with their own formulæ, that the former plan is mainly to be recommended only because you can be more certain of the purity of the drugs used. The liquors or officinal solutions are next considered, and so in due order are the other pharmacopœial preparations, with sound and judicious comment; after which the more complex processes of dispensing are considered. And this leads us to a matter of equal importance to prescribers and dispensers—viz., doubtful prescriptions. Mr. Proctor gives us some interesting examples, as when a mixture is ordered containing sixteen drops of almond mixture and eight ounces of prussic acid. This, on the face of it, is a transposition. Again, we have an example of the excipient, and so actually of the quantity of medicine ordered, being omitted. We have instances of contractions or old names used in a doubtful kind of way, as "mur. hydrarg.," which may mean either calomel or corrosive sublimate. Here is a somewhat doubtful substance—"tinct. mel. vesicatoriæ"—"mel." being almost invariably honey, and no vesicating honey being in existence; it really is, however, a contraction of the old name—meloe vesicatoria—given to the Spanish fly. "Acid. hydroc." may mean either prussic or hydrochloric acid; "inf. sen.," infusion of senna or senega; "potass. sulph.," the sulphate or sulphuret; and so on. These are examples of culpable carelessness. Such, too, are instances where powerful remedies are given and then some substances added which would be sure to precipitate them. One of the most important of these errors, and one perhaps more frequently committed than any other, is prescribing the double chloride and iodide of mercury (made by mixing corrosive sublimate with iodide of potassium) along with a vegetable preparation containing an alkaloid; for the alkaloid is immediately thrown down, and the mixture rendered valueless.

An exceedingly interesting lecture on reading prescriptions, with examples as nearly as possible *fac-similes* of the original, next follows. These prescriptions are of all shades of difficulty and sometimes of ambiguity, but not very many are examples of good penmanship. Four lectures on the pharmacy of certain special drugs conclude the volume. The drugs so considered are cinchona, opium, aloes, and iron, and the remarks are often very interesting. Some of our readers may remember an article on aloes which appeared in these columns some years ago. It was then esteemed—and we have no reason to alter our opinion of it—one of the most valuable contributions to our knowledge of that drug which had ever appeared. This furnishes a text for some remarks by Mr. Proctor; for the pharmacy of aloes is a very difficult subject, and anything of value as regards it would be only too gladly received. But meantime we must take leave of Mr. Proctor, heartily commending his book as being both interesting and valuable.

FRANCE.

Paris, October 13.

Cholera at the Academy of Medicine—Fauvel on Cholera—Dr. Ball on the Etiology and Pathology of the Disease—Dr. Liouville on the Propagation of Cholera—Decline of the Epidemic—Discussion on Septicæmia at the Academy of Medicine—Death of Count de Flavigny and of M. A. F. Passy—Professors at the School of Medicine.

The subject of cholera, so far as the discussion of the matter is concerned, is closed at the Academy of Medicine, but the whole affair has been made over to a commission of academicians, whose report has not yet been published. Dr. Fauvel, who, it will be remembered, was to respond to Jules Guérin's arguments, did so last Tuesday week, and I must say the latter was treated rather cavalierly by the *ex-conférencier*, as he is maliciously designated by his adversaries (referring to the part he took in the international conference that took place some few years ago at Constantinople, in order that measures might be taken to prevent the incursion of cholera into Europe). Dr. Fauvel, as if to form an exception to the rule that the French are generally given to more talk than work when any grave question is laid before them, opened his discourse with the

suggestion that the time was inopportune for discussion, and added that when an enemy is in a place we should not discuss, but act. But, if he entered into the field of arguments, it was to protest against the theory enunciated by Dr. Lecadre, of Havre, and supported by Dr. Guérin, that Asiatic or malignant cholera may be developed spontaneously at any time and at any place, and that the disease is not necessarily generated by importation. This, M. Fauvel said, he could not pass over in silence, and opposed to it the conclusions of the Constantinople conference, which were formulated as follows: —"That the cholera is an exotic disease, contagious, and of Indian origin, having at different periods invaded Europe; that it is importable from one place to another, solely by human peregrinations, and producing epidemics of greater or less duration, and more or less fatal, and which, once extinguished in our clime is not reproduced unless by fresh importation." 2. "Cholera thus propagated was never engendered in any part of Europe that had no communication with another part where the disease had not reigned." 3. "An epidemic of cholera never took less time to spread than that materially necessary for the removal of human beings from one place to another." This form of cholera, M. Fauvel continued, should not be confounded with what is termed "cholera nostras," which is a benign disease, which is engendered by certain circumstances, is confined to the locality where it breaks out, and disappears with the local circumstances which produced the disease. M. Fauvel then dwelt upon the advantages of quarantines, to which, he said, for reasons best known to themselves, the English were not very favourable; and when it was objected that quarantines were far from sufficient to prevent the ingress of the disease, as there were other inlets by which it may find its way, the worthy doctor replied that by closing even one entrance the chances of the invasion of the disease are diminished. The discussion having been here closed, M. Guérin was precluded from giving in his rejoinder, but, with reference to certain gratuitous assertions made by his adversary, to the effect that his (M. Guérin's) observations were concocted in his study, and were not the result of clinical experience, M. Guérin of course retorted that his observations were taken at the bedside of patients in private and hospital practice, and that during the epidemic of 1832 he scarcely passed a single night in bed. Thus ended this discussion at the Academy of Medicine, but the other learned bodies have taken it up, and the question is still being ventilated, but not to much purpose from a practical point of view.

Dr. Ball, who is acting for Professor Béhier at the Hôtel-Dieu, has occupied three long lectures on the etiology and pathology of cholera, and, after having traced the disease to its origin in the delta of the Ganges, went through its geographical distribution, which he said always coincided with the peregrinations of man. Dr. Bal llooks upon cholera as a zymotic disease, and as each virus has its own habitat or vehicle (the pus in small-pox and the lymph in vaccinia), the intestinal dejections seem to be the media in which the cholera germs are developed and multiplied. Hence the importance of totally destroying everything that was once in contact with these germs, either by chemical reagents or by fire itself; and this would, perhaps, explain the *rationale* of Dr. Blanc's treatment of cholera by the administration of the chloride of aluminium and of chloralum (both powerful disinfectants and antiseptics) by the stomach and rectum, the former of which he also adds to the excrements so as to destroy the germs in their habitat. Dr. Ball is a confirmed believer in the contagiousness of cholera, and says that its propagation or transmissibility cannot be explained in any other way. Here I may observe that in the French school the terms infection and contagion are employed synonymously, and consequently in using the word "contagiousness" both the terms are included. Dr. Ball thinks that although the digestive tube is the habitat as it were of the choleraic poison, yet the lungs are the principal *viæ* of infection, as it is well known that of all mucous membranes the capacity of that of the air-passages for absorption is very great. He thinks also that drinking-water as a means of propagating the disease has been greatly exaggerated, as it has been proved that choleraic matter containing the poison when introduced into the stomach is almost inert, as its virulence is destroyed by the gastric juice, unless the dose ingested be excessive, but, if the smallest quantity be injected subcutaneously, death is almost instantaneous. This has been amply confirmed by experiments on man and animals. In the former case a French physician swallowed a certain quantity of the dejections of a choleraic patient without suffering any other inconvenience than slight nausea—more, he thought, from the nastiness of the idea than from the effects of the poison itself; and, only very recently, a German physician, Dr. Obermeier, of Berlin, so well known for his works on typhus, fell a victim to his audacious courage, by inoculating himself with the blood of a patient suffering from cholera, from which he died in seven hours, most deeply regretted by his colleagues and a large circle of friends. This is certainly carrying the love of science to an unwarrantable extent, as I do not think it necessary to sacrifice human life for experimental research, while there are animals which are, as it were, predestined for such purposes. M. Charles Robin, the eminent histologist of Paris, performed some years ago a series of experiments with choleraic dejections on dogs and rabbits, which produced the same results as those obtained by the above experimenters; and it may be remembered that the experiments tried by Dr. Shortt, the great ophiologist of India, with the venom of serpents, produced similar results—that is, negative by the stomach, and certain death by inoculation.

Dr. Liouville, Chef de Laboratoire at the Hôtel-Dieu, has just begun a series of researches on the mode of propagation of malignant cholera, which may prove interesting to your readers. On September 23 he examined with a microscope of the greatest power some filtered water contained in a well-stoppered glass jar of the capacity of a litre (20,000 drops), and found no appreciable living organisms in it. He then added to this water one drop of the intestinal evacuations of a patient affected with cholera. With the same microscope he had examined the choleraic liquid, and discovered in it the presence of a great quantity of vibriones—some very active—of a round form (microzymata), while others were long and eel-like. He then added this "pathological dross," as he termed it, to the 20,000 drops of filtered water which was altogether uninhabited, and, having well corked the bottle, he let it rest for six days. On September 29 he found, with the aid of the microscope, that one drop of this solution contained a great number of vibriones (of the same appearance) of various sizes, moving about like eels. These little corpuscles were also very active. The colour of the water was slightly changed, which seemed saturated with the same animated elements as those found in the choleraic evacuations. This would show the extraordinarily prolific nature of these microscopic animals; for, be it observed, it was only one drop of the choleraic liquid that was added to the 20,000 drops of filtered water. But these infusoria or animalcules are also found in other pathological conditions, such as simple diarrhœa, enteritis, continued fever, etc., and, wonderful to relate, the vibriones that have been looked upon as being the specific agents in the pathogeny of cholera, have been found in the intestines of healthy individuals, but who had come by their death by accidents. This, I am sure, will not discourage Dr. Liouville, who, with his usual zeal and energy, intends performing a series of experiments with this infected fluid on animals, the result of which he hopes ere long to be able to submit to one of the academies of Paris. It is to be desired that he will make haste, for the edification of the anti-germ theorists of cholera and other zymotic diseases.

With reference to the isolated cases that occurred in the hospitals, which it was attempted to show originated spontaneously, and were not the result of importation or contagion, I endeavoured, in my last, to prove to the contrary; but how the disease reached the patients I was then unable to answer. I have, however, since had a clue as to the manner in which the infection took place—which seems to put the question beyond all doubt. Hospital patients in Paris are allowed to receive the visits of their friends only twice a week—viz., Sundays and Thursdays. The first hospital case of cholera, I may here remark, occurred on Friday, September 5, the day following the visiting day, when it is likely the germs of the disease, which were clearly traced to the family which had arrived in Paris some days previously from Hamburg *viâ* Havre, were in all probability conveyed by the visitors to the hospital.

If we may judge from the casualties in the past week, the present epidemic of cholera is evidently on the decline—at least, as far as Paris is concerned,—and, it is reported, the same may be said of Havre, where in France the disease first broke out about a month and a half ago. The last weekly return ending October 6 gives a mortality of 51 in hospital and town practice, whereas the week preceding it was 66. But notwithstanding this diminution in the mortality, great fears are entertained that the epidemic is not stamped out; that the disease is merely lurking about ready to break out afresh

when the conditions necessary for its development present themselves.

At the last meeting of the Academy of Medicine the subject for discussion has been changed from that of cholera to that of septicæmia, or more correctly speaking the latter has been resumed. The champion this time is M. Colin, Professor of Pathology at the Veterinary School of Alfort, near Paris. The discussion promises to be a most interesting one, but whether the subject will be satisfactorily solved is another question. M. Colin has not yet fully entered into the subject-matter of his thesis, but he has said sufficient to show that he is not in favour of the doctrine of Dr. Davaine, whose opinion may be thus stated:—All putrid matter, the blood putrified outside the economy, or modified in the vessels under the influence septic diseases, may produce the pathological condition termed "septicæmia" in man and animals. To which M. Colin replied in a few words by way of preface, intending at the next meeting to resume the subject. According to experiments performed by M. Colin on certain domestic animals, he has come to the conclusion that the pathological condition known under the name of septicæmia is not the constant and invariable effect of blood putrified in the air or altered in the organism. He considers it due to a morbid reaction furnished by certain animals, but which the greater number do not furnish in experimental conditions. Thus, as regards the rabbit, it is a matter of pure idiosyncracy, and the error of M. Davaine consist in having too much abused a reagent which is far from offering the guarantee desired. In other words, Mr. Davaine has drawn his conclusions in proceeding from the particular to the general, and his theory is defective from its very foundation.

The death of the Count de Flavigny and that of M. Antoine Frederic Passy is announced. The former was well known for the service he rendered since the war to the Society of Help to the Wounded, of which he was president. M. Passy, member of the Institute, was one of the founders of the Society lately formed in Paris for the Suppression of Intemperance, and a member of the Society for the Protection of Children, of which he was one of the committee of management.

The School of Medicine is to be reopened on the 15th inst., but the lectures will not begin before November 4. The following is a list of the professors who are to lecture for the winter session, with the subjects to be treated of annexed to their names:—MM. Gavarret, Medical Physiology; Damaschino (acting for M. Axenfeld), Medical Pathology; Sappey, Anatomy; Chauffard, Pathology and General Therapeutics; Wurtz, Medical Chemistry; Dolbeau, Surgical Pathology; Lefort, Operative Surgery; Robin, Histology; Lorain, History of Medicine and Surgery; Brouardel (acting for M. Bouilland), Clinical Medicine at La Charité; G. Sée, Clinical Medicine at La Charité; Bchier, Clinical Medicine at the Hôtel-Dieu; Laségue, Clinical Medicine at La Pitié; Richet, Clinical Surgery at the Hôtel-Dieu; Gosselin, Clinical Surgery at La Charité; Vernouil, Clinical Surgery at La Pitié; Broca, Clinical Surgery at La Clinique; Depaul, Accouchements at La Clinique; Roger, Diseases of Children.

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, October 7.

Changes in the Staff of the Hospitals and Schools—Dublin Industrial Exhibition—Lectures on Sanitary Science—Assault upon a Medical Man.

There is no doubt that the opening of the approaching medical session in this city will be signalised by the occurrence of a number of changes in the staff of many of our schools and hospitals. In the school of the Royal College of Surgeons the Professorship of Chemistry has been vacant since the lamented death of Dr. William Barker, who for several years most ably filled this important chair. Three favourites may be mentioned among the candidates for this appointment—namely, Drs. Emerson Reynolds, Charles A. Cameron, and Edmund Davy, the present Professor of Medical Jurisprudence in the College. The election is fixed for the 24th inst., but it would be difficult to forecast the result, owing to the peculiar method of conducting the election which holds good at the College. Seven members of Council are chosen by lot, and on them alone devolves the responsibility of making the appointment by a majority of votes. In the Ledwich School, the lectureship on the Theory and Practice of Medicine, vacant since the death of Dr. Henry Eames last March, has been filled by the appointment of Dr. A. Wynne Foot, Physician to the Meath Hospital and County of Dublin Infirmary. No more admirable selection could have been made, as Dr. Foot has given abundant proofs of ability as a scientific, practical, and clinical teacher since his appointment to the Meath Hospital.

Within the past few days two of the first hospital surgeoncies in Dublin have been declared vacant by the resignation of Dr. Robert Adams, Surgeon to the Queen in Ireland, and of Professor Robert W. Smith. In losing the services of these gentlemen the Richmond Hospital has indeed sustained a double loss, but in each case this was unavoidable; you have already noticed the sad illness which has fallen upon Professor Smith. Happily Dr. Adams still enjoys good health, but the weight of more than fourscore years has urged him to place his resignation in the hands of the Board of Governors. The services of both distinguished gentlemen are secured as honorary surgeons. Among the candidates for these highly-prized appointments may be mentioned Drs. Corley, Surgeon to Jervis-street Hospital; James Stannus Hughes; Yeo, Assistant-Physician to the Whitworth and Hardwicke Hospitals; R. J. Harvey, Lecturer on Comparative Anatomy in the Carmichael School of Medicine; W. Thomson, Assistant-Surgeon to the Richmond Hospital; and Mr. Gogarty. The election is to take place on Thursday, the 16th inst., and the result is looked for with much interest by the profession. In the School of Physic in Ireland two chairs are likely to be vacated shortly, owing to the continued illness of the present Professors, Dr. R. W. Smith and Dr. Robert Law. The former, as Professor of Surgery in Trinity College, is also Surgeon to Sir Patrick's Dun's Hospital, and the latter is Physician to the same Hospital by virtue of holding the post of King's Professor of Institutes of Medicine. Lastly, Mr. T. P. Walshe has resigned the Surgeoncy to Jervis-street Hospital, and has been succeeded by Mr. Kane, son of Sir Robert Kane, the well-known chemist.

The executive of the Dublin Industrial Exhibition have published a syllabus of a course of twelve lectures on Sanitary Science, to be delivered in the theatre of the exhibition on every Tuesday and Friday (commencing with to-day) until completed. The lecturer's name is well known to your readers—Charles A. Cameron, M.D., Professor of Hygiene to the Royal College of Science, and Analyst to the City of Dublin. The subject-matter of the lectures is very well arranged, and there is but little doubt that the course will be as largely attended by ladies and gentlemen as was a similar one this time last year. I give a list of the subjects to be dealt with:—The atmosphere, ventilation, the heating and lighting of dwellings, atmospheric dust, contagion and disinfection, water, the skin and hair, clothing and exercise, food, digestion, stimulants (alcohol, tobacco, etc.), unsound and adulterated food. Indeed, the institution of this course of lectures is only one way in which the great and increasing interest in the science of sanitation now displayed by the public is being expressed. Lately one of our leading and most influential daily papers—the *Freeman's Journal*—issued a sanitary commission to inquire into the existing state of Dublin. Thirteen reports were sent in, the character of all of them being essentially practical. The existence of evils was proved by a recital of facts, and the means of preventing or of checking these evils were indicated. Meanwhile, the Dublin Sanitary Association continues its most useful labours, which have already begun to bear really good and permanent fruit; witness the increased activity of the Public Health Committee of the Corporation. We are even to have a floating hospital for imported cases of cholera ready on November 6, and the old powers of the Corporation *in re* the widening of streets, etc., are sought to be revived. At the same time, we must believe that it has been, under Providence, due much more to the cold and wet summer which we have experienced here than to any action taken by our health authorities to abate the atrocious nuisances which crop up in every part of Dublin, that we have so far escaped a visitation of cholera.

October 13.

Last Friday a most unwarranted assault was committed upon Dr. George Johnston, the Master of the Rotunda Lying-in Hospital, under the following circumstances. At 5 p.m. on that day a Mr. Mulvany, a dentist, of 4, Christchurch-place, Dublin, commonly known as "Dr. Mulvany," called upon Dr. Johnston, and complained that his wife (then a puerperal patient in one of the private wards of the Rotunda Hospital)

was being neglected. Dr. Johnston at once accompanied Mr. Mulvany to the ward, where they found two nurses in attendance. It appeared that Mrs. Mulvany had been attacked by pain some short time before, and the nurses were engaged in applying warm fomentations and other remedies. Notwithstanding, her husband repeated that she was being neglected, and, on Dr. Johnston asserting that he had himself visited her that day, became noisy and violent. It was pointed out that such conduct was calculated to harm the patient, and a request was made that he should leave the ward. On refusing to do so, Dr. Johnston caught him by the arm and turned him towards the door. Mulvany not only resisted, but proceeded to assault Dr. Johnston violently, cutting his temples with a poker and dislocating one of his fingers. He subsequently had his wife removed from the Hospital. On Saturday the case was brought before Mr. C. J. McDonel, the magistrate presiding in the Northern Divisional (Police) Court. After going fully into the circumstances, Mr. McDonel committed Mulvany for trial at the approaching Commission, accepting bail for his appearance—himself in £25, and one surety in an equal amount.

GENERAL CORRESPONDENCE.

PHYSIOLOGICAL LABORATORIES.

Letter from Mr. Arthur Gamgee.

[To the Editor of the Medical Times and Gazette.]

Sir,—On the occasion of the opening of the new buildings of Owens College, Sir James Kay-Shuttleworth, Bart., referred "to the establishment in the College of the first laboratory in England for physiological research." Although I regretted exceedingly the error into which the speaker had fallen, and wished to have it in my power to correct it, I felt that on an occasion of so formal a character, when no speeches were made except by those called upon for the purpose by the President of the College, the Duke of Devonshire, it would have been scarcely becoming had I, unasked, risen to vindicate the honour of the physiological laboratories of Edinburgh, Cambridge, and London. To the part which these laboratories have taken in what I may term the revival of the study of experimental physiology in England, I hope to direct very marked attention in the introductory address to my class of practical physiology, which I shall deliver in this College on Thursday, the 23rd inst.

I am induced to address you this letter in order to explain what has, I believe, by some been considered unaccountable negligence in failing to correct a statement prejudicial to the position of British physiology.

I am, &c., Arthur Gamgee.

The Owens College, Manchester, October 14.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, October 1.

E. J. Tilt, M.D., President, in the Chair.

John Goldsmith, M.D., Worthing, was elected a fellow of the Society.

Mr. T. Eyton Jones read a paper on a case of Vesico-Vaginal and Recto-Vaginal Fistula. The patient was seized with labour pains on Saturday night, and remained in labour until 5 p.m. on Tuesday afternoon, when a medical gentleman was called in, who delivered her by forceps. Ten weeks after her confinement she came under Mr. Jones's care, who discovered great swelling and redness of the labia. At the vaginal entrance were two apertures—the anterior small, barely admitting the little finger, apparently entering the bladder; the posterior covered by a red, velvety-looking mucous swelling, through which the forefinger entered with ease, and apparently consisting of the vagina and rectum dilated into one cavity, and containing in it the closed mouth of the uterus. She could retain neither her fæces nor urine, and the catamenia have never since reappeared. Two years and a half after this disastrous confinement she suffered excruciating pain for a fortnight, at the end of which she parted with the phosphatic calculus, one inch in circumference, and two inches in length, which had formed in the bladder or urinary passage. Venesection has to be performed every two months to relieve the severe headache caused by catamenial suppression.

Dr. Heywood Smith thought that the paper, to be of any use to the Society, should state accurately the exact present state of the parts. It did not appear, from the case as then read, that it was hopeless as regards any operative interference, and it seemed to him that an attempt should be made to remedy a state of things so deplorable.

Dr. Aveling considered that at all events some effort should be made to restore the patency of the cervical canal of the uterus.

A note by Dr. J. Braxton Hicks was read, "On the Muscular Subsurrus in relation to the Fœtal Heart-Sounds." The author wished to call the attention of the Society to a point with regard to the diagnosis of pregnancy and the life of the fœtus by means of the existence of the fœtal heart-sounds which he had not unfrequently observed in the course of his practice, but which he did not remember to have seen in print, and summed up his observations as follows:—First, that the number of vibrations of the abdominal muscles in a state of half-suspension can be distinctly counted, watch in hand. Secondly, that their number and sound are so like those of a very rapid fœtal heart that they may be mistaken for them.

A paper by Dr. J. Matthews Duncan was read, "On the Spontaneous Separation of the Placenta when it is Prævia." The author did not in this paper enter on the subject of hæmorrhage, desiring to keep in view only the mechanism of separation of the placenta when prævia. He pointed out that during labour every portion of the surface of the body of the uterus underwent contraction, and that it was probably to the same extent over the whole of it. But the lower part of the body of the uterus was greatly expanded during labour, and contraction could there be only in the meridianal or longitudinal direction. The contraction of the uterus in early labour did not separate the placenta, wherever it might be inserted, whether prævia or not. A small amount of the whole expansion of the cervix, or an early stage of it, when there could be very litte contraction, was sufficient to detach partially the placenta. He arrived at the conclusion that the placenta when prævia was separated by expansion, not by shrinking or contraction, of the uterus. At present it was universally held to be separated by uterine contraction. The paramount errors of authors such as Simpson and Barnes were in supposing that the placenta might be attached to the cervix even near the external os, which it never was; and in not rightly apprehending the behaviour of the cervix during labour. The process of detachment by expansion will go on till the internal os is dilated to a diameter of about four inches, and this may occupy a great part of the whole duration of the labour. Study of the shape of the lower uterine hemispheroid showed that a meridian leaves the vertex or centre of the internal os uteri in a direction nearly at right angles to the uterine axis; and that, after it has described an arc of one and a half or two inches, it becomes nearly parallel to it. At about two inches and a half from the vertex the diameter of the uterine cavity is four inches. There is no need for any considerable expansion beyond a diameter of four inches, which is reached at a meridianal distance of two inches and a half from the centre of the internal os uteri. Expansion beyond this would produce very slight extension of uterine surface, and consequently slight detaching power, which would probably be counterbalanced by placental expansibility. Dr. Matthews Duncan pointed out that this was the measure of the spontaneously-detaching area, and criticised the various other measurements that authors had made. He showed that Barnes's estimate of three to four inches from the os uteri must be far too great. The circle of latitude two inches and a half from the vertex marking this limit was the line, insertion of placenta within which constituted placenta prævia. Complete detachment of the placenta was to be explained by a study of the production of a caul and of those cases in which the placenta was perforated by the advancing fœtus. Finally, Dr. Duncan called attention to the analogous detachment of the decidua around the internal os, which had been described by Dr. Haussmann, of Berlin.

Dr. Barnes expressly denied that he was open to the charge of committing the error imputed to him by Dr. Duncan of stating that the placenta was ever attached to the os uteri externum. He had taken special pains to insist that

the cervical canal had nothing to do with gestation. He had even sent to Dr. Duncan years ago a tracing of a drawing made by himself from a pregnant uterus showing the separate cavity of the cervix. With regard to the remaining statements of Dr. Duncan, they would be found to be simply repetitions in other words of Dr. Barnes's published account.

Dr. Aveling believed the Society was much indebted to Dr. Matthews Duncan for his accurate and scientific description of the spontaneous separation of the placenta when prævia. We could not be too minutely particular on a subject of such importance; and he believed with the author, that there were many illustrations to be found in our midwifery works which gave the student an erroneous view of the relative conditions of the body and cervix of the uterus during pregnancy and parturition.

Dr. Edward John Tilt read a paper, "On the Diagnosis of Subacute Ovaritis." The author suggested that the undervaluing of the part played by subacute ovaritis as a source of disease in women partly depended on the lamentable facility with which many practitioners, wherever there was pain in the ovarian region, inferred the existence of ovaritis, partly on account of the real difficulties of diagnosis, of which he gave some remarkable instances. He intimated that another reason might, however, be found in the difficulty of making examinations in young unmarried women. He had found that the most frequent sexual diseases during this period of life (between fifteen and twenty-five) were subacute ovaritis and inflammation of the neck of the womb. When the disorders of menstruation resisted good hygienic and medical treatment, he believed they were generally due to subacute ovaritis and cervicitis. The symptoms of cervicitis he described to be the habitual painless passing of a moderate amount of muco-purulent vaginal discharge, with habitual pain in the back; those of subacute ovaritis were constant dull pain deep in the ovarian region, much increased by firm pressure, and extending to the thigh and leg; mammary symptoms, disturbed menstruation, and hysterical phenomena. The positive sign of subacute ovaritis was the finding of an ovoid, smooth, or slightly indented lump beside the womb or in Douglas's pouch, pressure upon which, caused by the practitioner's finger or during coitus, caused an overpowering and sickening sensation of pain and debility. It might be necessary to confirm this diagnosis by a rectal or recto-vaginal examination. The author expressly stated that it would sometimes occur to a practitioner making a first vaginal examination, that, instead of finding any ovarian disease as he expected, he would detect cervical disease; and in other cases subacute ovaritis would be found when the symptoms would lead him to expect cervical inflammation. He concluded by describing the line of conduct to be adopted by the surgeon for the management of each of the three classes, and sketched the treatment most likely to cure them.

Dr. Barnes thought that many ovarian symptoms had their origin in uterine displacement.

Dr. Wynn Williams concurred in Dr. Barnes's opinion. He had rarely met with a case of ovaritis without some uterine complication, unless caused by direct violence. He believed the uterine mischief preceded the ovarian, and his experience taught him that on the removal of the uterine ailment the ovarian soon subsided. The same remarks applied to the ovary as to the testicle. Orchitis was seldom met with without previous inflammation of the urethra. He had frequently relieved ovarian symptoms by introducing a stem into the uterus, and he had under his care several unmarried females wearing stems and shields who could not be persuaded to have them removed, dreading a return of their sufferings.

Dr. Heywood Smith believed the best way of using the double touch was to use the forefinger of the right hand for the vagina and the middle finger of the same hand for the rectum; the left hand was thus left free to make pressure on the hypogastric region. With regard to what had been stated as to ovaritis being associated with or consequent upon flexions or other morbid states of the uterus, he must say that he frequently found patients suffering from ovaritis in various stages unconnected at all with any flexions or misplacements of the uterus or with any metritis.

Dr. J. J. Phillips said that his experience was that so-called subacute ovaritis was a very frequent cause of dysmenorrhœa, and he believed that this ovaritis frequently existed independently of any uterine flexion or peculiar conformation of the cervix uteri. It was very common to find a swollen, hyperæmic, probably inflamed ovary as the only evidence of disease in cases of dysmenorrhœa. The fact stated by Dr. Barnes, however, could not be controverted, that in a large class of cases dysmenorrhœa was due to uterine flexion or some uterine abnormality; and by appropriate treatment not only was the pain relieved, but also the congested state of the uterine appendages. A suitable selection of cases was, however, important, for some of the most troublesome cases of ovaritis and perio-ophoritis had their origin in mechanical interference with the neck of the uterus by incision or dilatation.

Dr. Gervis remarked that the truth might be between the two views which had been expressed, and that while primary subovaritis was probably rare, yet it might certainly continue to exist as a result of various uterine affections—such as chronic endometritis and mechanical dysmenorrhœa—after these affections had been cured.

Dr. Tilt, in reply, stated he had always taught that mechanical obstructions to the menstrual flow and uterine malpositions required special treatment, but he intentionally omitted to treat of them in the present instance because they were not of very frequent occurrence between the ages of fifteen and twenty-five, whereas he had come to the conclusion that subovaritis and cervicitis were then common and were often treated as diseases of menstruation. He did not think that the analogy between the testicle and the ovary should be pushed too far, because the testicle was not subject to any monthly process similar to ovulation.

OBITUARY.

JOHN MURRAY, M.D.,

Has suddenly passed away from among us at an age when everything seemed opening up before him, and before the promise of his early manhood was half fulfilled. No sadder story has it been our lot to tell, and to the many friends of the deceased to whom this will be the first intimation of his illness, our tidings will bring deep and heartfelt sorrow. Though young in years, Dr. Murray had by his happy disposition, his kindness and good-nature, endeared himself to a host of friends, to whom his untimely end will be a real and personal loss.

The story of his life is soon told, for though he had lived long enough to make his mark in many ways, still his deeds were rather of that private or semi-public kind which make little noise though of mighty influence. Dr. Murray was born in Aberdeen, where his father has long practised as a highly esteemed advocate. His education was mainly acquired in the Gymnasium in that city; and when old enough, he passed as a private student into the Arts classes of the Aberdeen University. Having spent one or two years in preparation, he began the study of Medicine, which he subsequently pursued, partly in the University of Aberdeen, partly in that of Edinburgh. He was a steady and industrious student, in no ways remarkable at that time—for he began the study of medicine very early—save for an ardent love of natural science. In this he was perhaps fostered by the fact that his father possessed an unusually good collection of shells, birds, and other objects, all calculated to stimulate a youth in the pursuit of such knowledge. After graduating in medicine in Aberdeen and London, Dr. Murray spent some time abroad in the great schools of Paris and Vienna, becoming afterwards attached to the Middlesex Hospital, first as House-Physician, and afterwards as Pathologist and Medical Registrar, finally becoming Assistant-Physician. Here he had field for work of a thoroughly congenial kind, and, in the series of hospital reports issued in conjunction with Mr. Henry Arnott, he made a most decided impression—their workmanship was of the first order. It was, however, mainly as a Volunteer Surgeon and in his capacity of assistant editor of the *British Medical Journal* that Dr. Murray was best known. His connexion with the London Scottish Rifles brought him into intimate contact with many old friends from the North, and enabled him to make many new ones, for he ever loved to turn to Scottish men and things, and even in the local politics of his native city he took here in London a keen interest. Of his work and doings as assistant editor of the *British Medical Journal* it is not for us to speak, but for years he has sat by us, as we worked side by side, a loyal and honourable rival in journalistic work. A

week ago he began to ail, and he complained of sore throat. This gradually became worse, till he and his friends became alarmed. Signs of œdema set in, and before anything could be done, so suddenly did serious symptoms develope, he was almost dead. But his trachea was opened, and after twenty minutes' artificial respiration he revived. At first he improved rapidly, but signs of a general and deep-seated change in his tissues and organs began to manifest themselves, his lungs became gorged, and he sank to rest—another victim to the horrible struggle of a London life. Dr. Murray was a strong and active man, ever eager for work, often seemingly going out of his way to do the work of others. Latterly, to all the weight of his daily avocations have been superadded the duties of Dean to Middlesex Hospital School; and there can be no question that, though at the time the work did not seem to hurt him, it was more than any man could stand with impunity, and so when disease came it found him unable to bear up against the brunt of its attacks.

Words cannot express the sorrow of his friends, for Dr. Murray had so endeared himself to men of his own time that he seemed more like a brother than a mere ordinary acquaintance. Under any circumstances, one plucked out of their midst in such a way must leave an affecting blank; but to many he was much more—he was the centre of a social circle as kindly as is to be found in the ranks of our profession, and to all such his loss is something we can hardly put in words. His deeds may look small on a sheet of paper, but were each kindly act and word of encouragement to his struggling juniors, each courteous deed to his brethren, professional or otherwise, here recorded, we should have a monument which in the eyes of the right-minded would far outweigh deeds often held up to honour and glory. How inadequate these lines are none know better than do we, and we almost wish we had limited ourselves to the simple statement which will bring sorrow to many—that "John Murray is dead."

(*From a Correspondent.*)

Undoubtedly Dr. Murray's great characteristic was his unbounded kindliness, the feeling and thoroughness with which he could throw himself into the wants and interests of others, and his readiness to take upon himself to do anything which he saw and felt ought to be done, but which, apparently, it was nobody's duty in particular to do. I have seen this frequently in him. This was strongly marked in connexion with any public or semi-public matter—to wit, the enthusiasm and determination he showed in working up an organisation of the medical officers of the rifle corps, in order, first, to get the War Office to properly equip corps with ambulance requisites, etc.; and, secondly, to resist, and ultimately get repealed, the Act requiring medical officers of corps to attend officers and their families at some trivial fixed rate. Again, the regularity with which he worked for the East London Children's Hospital when it was first started and in its early stage was of great service to that institution. Then the determination with which he exposed the want of proper accommodation for fever and other infectious diseases in Aberdeen, and the abuse of sending such cases into a general hospital, resulted in the grant of land and building for a fever hospital. The unselfishness and untiring efforts he showed under Dr. Frank in the ambulance hospital near Sedan were such as to bring him to the notice of Loyd-Lindsay and others, who afterwards rendered him considerable help in his canvass at the Middlesex Hospital. His career at the Middlesex Hospital commenced in 1866 as Physician's Assistant, after giving up which he became Medical Registrar, and was appointed to the *British Medical Journal* staff. Last year he began to share the lectures on Pathology with Dr. Cayley, and this year he became Dean. The energy he has shown in the duties of Dean during the few months of office has been very considerable; it was no doubt due very much to him that there is a larger entry than usual, and his kind and genial manner to the students promised to make him one of the most popular of deans, as he was one of the best friends of the students. At the Hospital he will be missed by all classes and in all the capacities he occupied. Another great point with him was his strong opinions as to women's rights. He considered women were unfairly treated in life, and in this matter, as in every other, he was always willing and anxious to lend a helping hand to redress a grievance. There is no doubt that besides sacrificing much time and labour he has expended much money upon movements he has initiated for the redress of things he thought wrong and unjust.

It may be questioned, I think, whether there is another man in London of any profession, and of his age, who has anything like the number of friends—the large circle of acquaintances—Murray had. This circle was immense, not only in town, but in the country, and in fact abroad too. And few, if any, would have drawn to his sick rooms so many inquiring friends, had his illness been less sudden. As it was, the bad news of his condition soon spread, and a large number of members of the profession were constantly at hand.

I have heard it said in the last few days that he possessed in a remarkable degree the "enthusiasm of humanity," and this is quite true. Always thinking and speaking well of others, others did the same of him; and though he knew so many, still these were not to him indifferent acquaintances, but real friends, who had a downright good feeling for him.

I may mention, too, that only last Monday he went to Petworth for a meeting of the south-eastern branch of the British Medical Association. While at Petworth he went over the county prison, and (as another instance of the fascination which all social and public matters possessed for him) he inquired very closely into the discipline of the place, and the effect of that discipline on the mental and moral characters of the prisoners. He deplored at the time, and once or twice during the day afterwards, the hardening inhuman influence the continued isolation of prisoners must produce.

These few remarks I send in the rough, but much might be written upon the life and character of a man who young was a good clinical physician, a true gentleman, and a frank, warm-hearted, and trusty friend.

At the post-mortem examination were found œdema of the epiglottis and arytæno-epiglottidean folds as low as the upper vocal cords; the pharynx intact; the tonsils not distinctly enlarged; but great congestion of the pillars of the fauces and of the mucous membrane of the trachea below the opening. The incision had divided the cricoid and first ring of the trachea, and by one side of the opening the mucous membrane was sloughing and of ashy-grey colour. The lungs were œdematous, and the upper lobe of right lung collapsed.

ARCHIBALD DYMOCK, M.D., M.R.C.P.

We have to record the death of Archibald Dymock, M.D. Edin., M.R.C.P. Lond. and Edin., which took place at his residence, South-street, Louth, Lincolnshire, on September 17, after a long and painful illness, aged 62, leaving a widow and a large family to mourn their irreparable loss. He was the eighth son of the late William Dymock, writer to the Signet, Edinburgh, and was educated at the High School, and at the age of eighteen entered at the University of Edinburgh, where he studied under Alison, Christison, and other distinguished professors who adorned the Edinburgh School at that period. He was the favourite pupil and clinical clerk of Dr. (now Sir) Robert Christison, and greatly assisted him in the compilation of his work on "Granular Degeneration of the Kidneys." He received his degree as Doctor of Medicine before he was quite twenty-one, and was immediately offered and accepted the post of resident physician to the present Earl of Carlisle, with whom he remained rather more than a year, at Castle Howard, Yorkshire. After that period he returned to his native city and commenced practising as a physician, and was attached as physician to the North-Western Dispensary. During that period he contributed several valuable papers to the *Edinburgh Medical and Surgical Journal*; amongst the number were one on Poisoning by Arsenic, on Puerperal Convulsions, etc. In the summer of 1843 he left his native city, and settled at Louth, Lincolnshire, where he soon obtained a large consulting practice, not only in Louth, but the whole of North Lincolnshire. He was a justice of the peace for the borough of Louth, and a trustee of King Edward's Grammar School in that town. He was Physician to the Louth Dispensary, and Consulting Physician to the Lincolnshire Convalescent Home. He was equally kind and courteous to both rich and poor, and was beloved by a large circle of friends of all denominations for his kind and amiable disposition. His body was interred in the cemetery on the 21st ultimo by the side of his deceased son, Thomas Graham Weir Dymock. The hearse was preceded to the grave by the officiating clergy and the whole of the local medical practitioners, with the mayor, and the magistrates. The pall was borne by the warden and five assistants of King Edward's Grammar School, and followed by his sorrowing and afflicted widow and family.

WILLIAM GARDEN, M.D. Aberdeen,

Died at Alford on the 22nd ult., at the age of 63. Dr. Garden was a son of the late Mr. George Garden, farmer, Bandley, Alford. He studied at Aberdeen, and, after taking the degree of M.D., practised for some time at Bandley. He took to agricultural pursuits, and rented the farm of Mains, at Balfling, at which he resided until some time ago, when he removed to the village of Alford. He furnished evidence to the Assistant Commissioners on the "employment of children, young persons, and women in agriculture, 1867." Dr. Garden, though retired from medical practice for years, took an active part in the public affairs of the district, and held several local public offices.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Oct. 9:—

Kane, Patrick, Sawley, near Derby.
Matthews, Arthur, Harwich.
Young, George Wm., Mile End-road.

The following gentleman also on the same day passed his Primary Professional Examination:—

Treves, Frederick, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Cameron, John, M.B., Edin.—Assistant Medical Officer, Crichton Royal Institution, Dumfries.

Manall, Thos., M.B., C.M. Edin.—Assistant to the Extra-Physicians of the Sick Children's Hospital, Edinburgh, *vice* Dr. Renton, resigned.

BIRTHS.

Campbell.—On October 9, at 16, Wellesley-terrace, Liverpool, the wife of W. Macfie Campbell, M.D., of a daughter.

Canton.—On October 13, at Camden Villa, Southsea, the wife of G. Anderson Canton, M.R.C.S., of twins.

Clapton.—On October 14, at 6, Lansdowne-villas, Lee, the wife of Edward Clapton, M.D., of a son, stillborn.

Maunsell.—On October 7, at Newland Villa, Victoria-road, Aldershot, the wife of T. Maunsell, M.D., Royal Horse Artillery, of a son.

MARRIAGES.

Cartwright—Hudleston.—On October 13, Mark Cartwright, eldest son of T. Cartwright, Esq., of Poppleton, York, to Rosa Elizabeth, youngest daughter of the late John Hudleston, M.D., of 21, Gloucester-place, Portman-square.

Chancellor—Downs.—On October 7, at the parish Church, Stockport, Herbert Chancellor, Esq., of Old Broad-street, London, second surviving son of George Chancellor, Esq., Chessington Hall, Surrey, to Fanny Maria, elder daughter of George Downs, M.D., of Stockport.

Dean—Caswall.—On October 8, at the Church of St. Nicholas, Leeds, Kent, Harry Stewart, younger son of Benjamin Dean, of Acton, to Helena Mary, third daughter of the late Charles Caswall, M.R.C.S., of Tunbridge, Kent.

Finch—Mitchison.—On October 7, at St. Saviour's, Paddington, Charles, son of the late Charles Denver Finch, M.D., of Tulse-hill, to Maria Amelia, eldest daughter of the late G. B. Mitchison, Esq., and granddaughter of Mrs. Mitchison, of 23, Warwick-road, Maida-hill.

Grace—Day.—On October 9, at the church of St. Matthias, West Brompton, William Gilbert Grace, fourth son of the late Henry Mills Grace, M.R.C.S. Eng., of Downend, Gloucestershire, to Agnes Nicholls, daughter of W. Day, Esq., 19, Coleherne-road, S.W.

Jackson—Whytehead.—On October 9, at Lastingham, Yorkshire, Thomas Boyes, youngest son of Hugh William Jackson, Esq., of Riston Grange, to Jane Elizabeth, second daughter of Henry Yates Whytehead, M.D., of Crayke.

Prior—Whitaker.—On October 9, at Dalston Wesleyan Chapel, Edward Thomas, youngest son of Samuel Prior, Esq., of Greenwood-road, to Marianne, eldest daughter of the late J. Summs Whitaker, F.R.C.S., L.S.A., of Betah Cottage, Kingsland.

Wooncock—McO'Connor.—On September 23, at Haysville, Ontario, Canada West, Francis Dealtry, second son of the late Edward Woodcock, Esq., of Springfield, Wigan, to Matilda Louisa, eldest surviving daughter of Maurice McO'Connor, M.D., of Haysville.

DEATHS.

Betts, Agnes Mary, daughter of G. Harvey Betts, M.D., at Shanklin, Isle of Wight, on October 10, aged 19.

Borrett, James, M.D., M.R.C.S. Eng., at Clifton, on October 10.

Howitt, W.. F.R.C.S. Eng., L.S.A., J.P. for county of Lancaster, at his residence, Fishergate-hill, Preston, on October 7, aged 63.

Murray, John, M.D., M.B., C.M., M.R.C.P. Lond., M.R.C.S. Eng., at 42, Harley-street, on October 15, aged 30.

Nichol, Robert, M.D., M.R.C.S. Eng., L.S.A., at Denmark-hill, after a few hours' illness, on October 13, in his 49th year.

Woodhouse, Louisa, wife of R. T. Woodhouse, M.D., at Reading, on October 7, aged 76.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

Bideford Union.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Charles W. Hole, Clerk to the Guardians, on or before October 20.

Carlisle Dispensary.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

Guest Hospital, Dudley.—Honorary Surgeon. Applications, with testimonials, to Mr. E. Poole, Secretary, on or before October 31.

Kent and Canterbury Hospital.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to the Board of Management, before October 28.

Liverpool Dispensaries.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before October 29.

Queen's College, Galway.—Professor of Materia Medica. Applications, with testimonials, to the Under-Secretary, Dublin Castle, on or before October 27.

Royal Free Hospital.—Senior House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before October 29.

St. Peter's Hospital.—House-Surgeon. Candidates must attend personally, with their testimonials, on Monday, October 20, at 4 p.m.

Unst, Shetland.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

West London Hospital, Hammersmith.—House-Surgeon. Candidates must be duly qualified, and attend at the Hospital on Monday, October 20, at 10.30 a.m.

Wilts Pauper Lunatic Asymum.—Medical Superintendent. Candidates must be duly qualified and registered. Applications, with testimonials, to Mr. A. G. Meck, Clerk to Committee of Visitors, Devizes, on or before October 28.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bridgwater Union.—Mr. G. F. V. Bent has resigned the Second District; area 8504; population 5040; salary £70 per annum.

Castle Ward Union.—Mr. James Marr has resigned the Ponteland District and the Workhouse; area of District 17,677; population 2002; salary £15 per annum; Workhouse salary £30 per annum.

APPOINTMENTS.

Brentford Union.—Robt. G. Burton, M.D. Edin., L.R.C.S. Edin., to the Seventh District.

Epping Union.—Trevor Fowler, L.K.Q.C.P. Ire., L.R.C.S.I., to the Epping District.

Henstead Union.—John B. Pitt, L.R.C.P. Edin., F.R.C.S. Eng., L.S.A., to the Workhouse.

Langport Union.—Thos. L. Tims, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A., to the Workhouse.

Neath Union.—John H. Davies, M.R.C.S., L.S.A., to the First Eastern District.

Saffron Walden Union.—Robert Clement Pritchard, L.F.P.S.G., L.S.A., to the Fourth District.

Shiffnall Union.—James Sherwin Greene, M.R.C.S.E., L.S.A., to the Prior's Lee District; John Emilius Mayer, F.R.C.S., L.S.A., to the Sheriffhales District.

Wantage Union.—Robert Murdoch, M.B., L.R.C.P. Edin., L.R.C.S. Edin., to the Ilsley District.

Weymouth Union.—Hauteville Flown John Sterling, M.R.C.S.E., L.S.A., to the Overmoigne District.

Royal College of Surgeons.—At a meeting of the Council, on Thursday, the 16th inst., Mr. Thomas Rivington Wheeler, L.S.A., a member of the Court of Examiners of the Society of Apothecaries, of the Ferns, Sundridge, Sevenoaks, was admitted a Fellow of the College, his diploma of Membership bearing date May 10, 1843; and at the same meeting of the Court, Mr. George Annger Michell, L.S.A., of Redruth, J.P. for the county of Cornwall, was elected a Fellow, his diploma of Membership bearing date April 14, 1835.

We regret to hear that Dr. Lyle has had an attack of paralysis, caused by blood-poisoning contracted in the discharge of his duty as one of the medical officers of the parish of Paddington.

News from Hawaii (late Sandwich Islands) states that leprosy is making fearful ravages not only among the Chinamen and natives, but also the Europeans of the most respectable classes. From New York we hear that the yellow fever is abating at Shreveport; 600 persons have died of the epidemic.

The Medical Society of London will meet for the first time at their new premises, Chandos-street, Cavendish-square, on Monday, October 20, when Dr. Richardson will read a paper "On Organic Stricture of the Æsophagus: a recast of Clinical Observation."

Naval Medical Supplemental Fund.—At the quarterly meeting of the Directors of the Naval Medical Compassionate Fund, held on the 14th inst. (Sir Edward Hilditch, Inspector-General, in the chair), the sum of £86 was distributed among the various claimants.

Liverpool Royal Infirmary School of Medicine.—The new buildings which have recently been added to the School of Medicine in Dover-street, Liverpool, have been formally opened by Mr. John Torr, M.P. The principal additions and alterations are—a pathological and anatomical museum, a chemical laboratory with a private laboratory and class-room attached, and a physiological laboratory. The old building has to a great extent been remodelled; the dissecting-room has been considerably enlarged, and adjoining it a room has been fitted up with osteological preparations, skeletons, plates, and preparations illustrative of elementary anatomy. A demonstrator's room opens into the dissecting-room, and every convenience in the way of lavatory and dressing-rooms is provided. The old museum has been converted into a library and reading-room for the use of the students. These extensions and improvements, including the amount of existing contracts for work not completed, have involved an expenditure of £5326—a sum which, in consequence of the advance in the cost of labour and of almost everything used by builders, is largely in excess of the amount which the lecturers at the commencement of their undertaking were led to believe would be required. The committee have entered into a contract for fitting up the parts of the museum required immediately, but the fitting up of the gallery has been postponed.—*Builder*.

Absence of Cholera-Panic in Paris.—"The old proverb is right—'We get accustomed to everything'—even to the cholera. Look at what has been going on in Paris during the month since when the Indian scourge has passed its walls. Not the slightest particle of fear; not a single desertion; no habit discontinued; the same receipts at the *Fille de Madame Angot*; numbers sent away when M. Faure sings at the opera; and a brilliant assembly to welcome back the Italian singers. When we compare the effect produced on the Parisian population by this fifth cholera invasion with that of those preceding it, we cannot help exclaiming, 'How things are changed!' Have we become more courageous or less impressionable? I incline to the latter opinion, for I cannot prevent myself from believing that a population which has been spectators of the disasters of war and the horrors of the Commune, and whose very existence has been menaced by famine, bombardment, and civil war—such a population, I say, must have become singularly inured, or rather remains indifferent, to all calamities of a minor importance. It is true that up to the present time the epidemic has not been very bad. May this frightful monster, this pathological sphinx, which defies alike the investigations of science and the resources of art, speedily leave us, to return no more! May France, already so unfortunate, be spared the ravages which the cholera has produced in other parts of Europe, especially Hungary, where in some months it sacrificed 120,000 victims out of a population of 14,000,000. This is about double the mortality which each cholera epidemic has ever produced in France, with a population about twice as numerous."—*Union Méd.*, October 11.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The obituary notice of Dr. John Miller, which appeared in the number of September 6, is an obituary notice of Dr. John R. Miller, Inspector-General of Hospitals, etc., and not of Dr. John W. Moore Miller, of Southsea, author of articles on "Public Health," "Drainage," etc. The latter gentleman is, we are happy to state, alive and well.

A Metropolitan Teacher.—The return is published in another column. The additional numbers in both classes will appear next week.

Mr. A. M. Bawtry, York.—Osteo-plastic fillings are most of them chiefly composed of oxide of zinc and chloride of zinc, specially prepared and subjected to powerful hydraulic pressure.

Alpha.—We know none such.

A Third-Year Student.—Write at once to the President, enclosing a certificate of ill-health, when no doubt he will allow you to register next week.

Godolphin.—The Oxford examinations for the first or scientific part, and for the second or practical part of the examination for the degree of Bachelor of Medicine will be held early in December. Candidates names should be sent to the professor before November 15.

Lorton.—The statistics of 1870 show that the percentage of suicides in the United States was 3·06 per 100,000. In 1860 it was 3·02, and in 1850, 2·01.

S. P. W.—The suggestion is a good one, and shall have attention.

A Medical Jurist has called our attention to the fact that it is due to the honour of medical coroners that they were foremost—indeed, the first—to insist upon the necessity of having an accused person present at an inquiry at which his reputation and possibly his life might be concerned. We cheerfully admit the truth of our correspondent's statement. The late Mr. Wakley, the Coroner for Middlesex, was the first to insist upon the importance and justice of this proceeding. He contested the point with his usual ability and perseverance. His successor, Dr. Lankester, has invariably acted on the same principle. It seems surprising that lawyer-coroners have never attempted to carry out a principle of law and justice, which is equally consistent with common sense. The late decision in Dublin, by Mr. Justice Fitzgerald, is a high compliment to Medicine *versus* Law in the election of coroners. We hope this fact may be taken advantage of in future elections of judges who exercise so important an influence upon the safety and welfare of society.

A Doctor's Log.—No. V.

(*Continued from page* 373.)

The first day in the Indian Ocean very unsatisfactory. No abatement of blazing sun; steamy, dirty feeling; nausea; languid torpor, disinclination to move—indeed, to do anything but drink and sleep during the day, varied by tossing, depression, and misery at night. The thermometer only 88° in cabin, 85° in hospital, 90° in the lower troop deck when the ports are closed. The men very healthy; still about fourteen in Hospital, but no fever, ophthalmia, or sunstroke. Several women rather ill—relapses of sea-sickness; and the children incline to bilious remittent fever, possibly contracted in Malta harbour, encouraged off Suez, developed in the Red Sea. Remission in the morning, exacerbation at night; offensive excretions; tendency to vomiting, jaundice, and abdominal distension, dirty tongue, rigours, chills, burning skin, incessant thirst, occasional diarrhœa, sometimes lienteric. Indian diet, lime-juice, dilute nitro-hydrochloric acid, quinine in the morning, aconite when the fever is about to commence, friction and inunction over various parts of the body, swabbing out the throat included in the treatment. If this is wrong, it should be remembered that books are not accessible, that these patients and diseases are treated in the tropics every day on the move, and that doctors feeling heat much the same as other people, our brains are addled by the sun. One night a soldier's wife taken ill; the messenger brings no light; difficult work groping in the dark for clothes; next tumbling over soldiers lying between decks or bumping against others sweltering in hammocks. Eventually reach the women's quarters, where about 100 are arranged in dinner-waggon bunks. The lower of the two shelves better adapted for mothers with children; no chance of tumbling out. The upper more airy, suitable for women without incumbrances. One woman with six children has three bunks. Several have three, four, and even five children wonderfully comfortably put up under the circumstances—the husbands, of course, sleeping with the bachelors. The atmosphere was far purer than any married quarter barrack or hospital ever visited on an oppressive summer night. The patient, suffering from hæmorrhage, received medicine, was tended by another woman (a qualified midwife), and the necessary beef-tea and brandy provided without delay. Next morning she is moved into hospital, and the soiled bedding thrown overboard and replaced, the expense (about £2) falling on the troops generally.

One suggestion here: when soldiers embark, one woman of experience should be told off to superintend, or at all events to nurse, in the women's hospital, the expense (possibly not exceeding three guineas at the utmost) divided amongst the married men. One unrecognised woman engaged herself as nurse to a lady, concealing the fact of advanced pregnancy. When the mistress was ill and sea-sick, and the children required every attention, the maid gives birth to a child, and for days cannot be moved out of the cabin. *En passant*, there are twenty-one ladies on board, the wives of colonels and field officers, with their husbands. The others doubled up, three, four, and seven in cabins, according to situation. How they dress and do not lose valuable jewellery, with servants, stewards, and others prowling about, is a great mystery.

Beyond sea-sickness and dyspepsia induced by overdoses of chlorodyne, by all accounts very little to complain of. One young officer has a terribly swollen face. Several cases of rheumatism—more of neuralgia—caused by sleeping on deck. From information received, the ladies, all things being considered, are wonderfully quiet, instead of fighting about a squalling baby introduced into a cabin, or the thousand-and-one red rags of contention incidental to the coopiug up of strangers. According to statistics, about this period of the voyage everybody would be delighted by a tread on the tail of their coat. The Red Sea would spoil the most amiable temper. Even theatricals have their objections in the excitement, hurry-scurry, not to say scrimmaging, about parts, creating bones of contention, specially in a hot climate.

It may not be out of place to say a few words of financial importance. We pay 3s. 6d. a day for messing, including breakfast, lunch, dinner, and tea, the Government paying the rest. Sometimes the total may be ten or even fourteen shillings a head, according to weather or appetite of passengers. The allowance of beer and port at starting, and of claret after, very liberal—sherry also; but of course there are extras—the amount reduced to a minimum by those economical. The water is extremely palatable and apparently innocuous, obtained by condensation and filtration. Daily thirty-eight tons of sea-water can be condensed by Normaudy's process, then twice passed through animal charcoal on Captain Creasy's principle. And I believe before this patent was adopted a bucketful of grease, oxide of iron, and refuse would be found in the tanks during a month's cruise. In the Suez Canal, where the Red Sea mixes with the Bitter Lakes in the current towards the Mediterranean, the amount of salt, the extreme density, involves increased expenditure in condensation. As a rule, seven tons of distilled water are produced by one ton of coal.

February 13.—Unfortunately in a medical publication serial matter reluctantly must be kept in the background, otherwise more might be said descriptive of the theatricals; the daily life; the curious anecdotes; the excitement about the conversion of one of the nigger stokers, to the delight of the chaplain, who feels hurt at incredulity, and the locking of cabin doors when the enlightened stoker is about; of the Christy minstrels, who, hired at an enormous expense, perform for the first time out of London—Mr. Johnson, Bones, and the rest of the troupe quite at home in the Indian Ocean. But to the text: Admire to-day Benham's cooking range, capable of providing for 2000. Visit Mr. Knibbs, who, in his cheerful manner, states that the engine-room to-day is 112°, the stoke-hole 110°, the

Sea-water 76. Find that in the men's hospital, when returning with invalids, there are sometimes 34 in-patients, 117 attending, and that the mortality commences in the Mediterranean. Look in to Mr. Souter at the paymaster's office, who, ever courteous and obliging, lends a printed description of the ventilation on Dr. Edmunds' system, difficult to explain in a few lines. There are five ordinary tube and cowl ventilators, to act by the wind in a general way, but at other times steam-jets are introduced, forcing out the foul air, and to close the vacuum cold fresh air rushes in—to the best of comprehension,—care being taken to prevent condensed water being included. Dr. Edmunds adds double-acting ventilating shafts and gunwale ventilation; but I must get some man to explain it *in toto*, then try again to simplify details on paper. Anyhow, the system answers very well. And before the matter is forgotten it should be noted that the condensed and filtered water is very palatable and refreshing—so good and pure that at present I rely upon it as the chief weapon in the treatment of infantile fevers. Came across a case of hyperlactation to-day—three years and two months,—yet the mother wonders she is ill, and thinks that plenty of brandy, wine, and stout would set her up; also a primipara suffering from obstipatio about twelve days, and far advanced in pregnancy. The condition must be relieved, yet for her to be confined at the last on board ship, at Bombay, or on the journey up country, will be extremely inconvenient, not to say hazardous. If conscription and no marriage, what a cheap effective army probably we should have! To the best of recollection, Frederick the Great violently objected to the marriage of soldiers, refusing the privilege even to field officers, unless the lady came up to a certain standard, yet conferred a certain *brevet* of respectability on certain camp followers.

COMMUNICATIONS have been received from—

Dr. Burman; Dr. J. Cameron; Dr. George Scott; Dr. Stevenson; Mr. H. K. Hitchcock; Dr. Philip Foster; Dr. W. M. Campbell; Dr. Vinen; Mr. J. H. Jackman; Dr. Webster; Dr. Peddie; Mr. C. J. Fox; Mr. H. Morris; Mr. J. Chatto; Dr. Foster; Dr. Aveling; Mr. T. M. Stone; Dr. C. Handfield Jones.

BOOKS RECEIVED—

Roberts's Handbook of the Theory and Practice of Medicine—Erichsen on Modern Surgery—Jordan's Surgical Inquiries—Sympson's Letters concerning the Lincoln County Hospital—Broken Gleams, by C. Miller—On the Education of the Imbecile, by Dora Greenwell—Proceedings of the Twentieth Annual Meeting of the Medical Society of North Carolina—Whitmore's Monthly Report on the Health and Meteorology of the Parish of St. Marylebone—Transactions of the Medical Society of the State of Pennsylvania. vol. ix., part 2.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Gazette des Hôpitaux—Allgemeine Wiener Medizinische Zeitung—Pharmaceutical Journal—Manchester Evening News—Gazette Hebdomadaire—Lincoln Gazette—Medical Press and Circular—Birmingham Morning News—Bulletin Général de Thérapeutique—Lancester Guardian—Journal de Médecine—New York Medical Journal, August and September—O Correio Medico—Le Mouvement Médical—La Tribune Médicale—Le Progrès Médical—La France Médicale—New York Druggist—Philadelphia Medical Times, September 20 and 27—Monthly Review of Dental Surgery.

APPOINTMENTS FOR THE WEEK.

October 18. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

Association of Medical Officers of Health, 7½ p.m. Dr. Letheby, "On the Right Use of Disinfectants."

20. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Dr. Richardson, "On Organic Stricture of the Œsophagus—a Recast of Clinical Observation."

21. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Pathological Society, 8 p.m. Mr. McCarthy—Traumatic Separation of the Epiphysis of the Great Trochanter; Recent Fracture of the Atlas and Odontoid Process of the Axis. Dr. Dowse—Foreign Body in the Crico-Thyroid Pouch; Traumatic Degeneration of the Spinal Cord. Dr. Peacock—Aneurism of the Aorta forming a Large External Tumour. Dr. Greenhow—Large Hydatid Cyst of the Liver. Dr. Silver—Obstruction of the Common Bile-duct; Two Specimens of Diseased Liver. Mr. Nutt—Photograph of a remarkable Vesical Calculus. Dr. Cayley—Psammoma of the Dura Mater.

22. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Hunterian Society (London Institution), 8 p.m. Mr. McCarthy—Specimen of Imperforate Anus and Colles's Fracture.

24. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·67 in. The highest was 29·95 in. on Sunday evening, and the lowest 29·40 in. on Tuesday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON DUST-INHALATION AS A CAUSE OF LUNG DISEASE.(a)

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

(*Continued from page* 430.)

Robert G., aged 42, a tall Yorkshireman. Family healthy and long livers, but one brother, a typefounder, died of phthisis at the age of thirty-six. When sixteen years of age he was apprenticed to a baker, and though well at first, exposure to flour-dust, sulphurous fumes from the coal, and sudden changes of temperature gradually developed lung disease. He had cough, night sweats, loss of flesh, purulent expectoration, and hæmoptysis. He improved in the country, and returned to baking, but was soon forced to give it up; and at the age of twenty-three his health was so bad that he was advised to cross the Atlantic. He gained flesh and strength at New Orleans, and then went to St. Louis, where the winters were very severe, and he had several attacks of bronchitis. Went into the interior, among the pine forests on the Jackson River, north of Ohio. For eight years remained well—riding, driving, shooting, and looking after trotting and racing stables. During the second autumn and winter of the war had eight months of camp life as groom and valet to an officer of the 117th Illinois Regiment. Had diarrhœa, ague, fever, jaundice, and other local maladies; and one winter, in Ohio, when the thermometer stood at 18° Fahr. below zero, got a cough. Found the climate, on the whole, good, being very cold in winter and very hot in summer, but spring and autumn delightful, the sky being clear and the air dry. Returned to England in 1867; became groom at the hunting stables of a sporting nobleman, where he had to do much dusty chaff-cutting, and was admitted to the Brompton Hospital, where, after thirteen weeks of treatment, he returned to work as coachman in a private family. Last year had a return of cough, and was again admitted as an in-patient in March. Gradually improved for nine weeks, then caught fresh cold, with severe cough, dyspnœa, and some fever.

The physical signs of the chest have been variable. On admission, on the right side there was crepitation throughout, and on the left the same crepitation sounds were heard over the upper third of the chest in front.

May 9.—Right side: Crepitation extended to the third rib. The left side was free in front, but a little crepitation was heard in the acromial region behind.

June 27.—The resonance throughout perfect. Right side: Crepitation loud, superficial, and diffused, extending nearly to the angle of the scapula, though intermixed with natural vesicular breathing; below this the breathing normal. Left side: Fine distant crepitation in front to the axillary margin.

Millstone dressers and stonemasons occupy an intermediate position between these extremes. The case of James N. which follows illustrates this class well:—

James N., aged 42, when admitted into the Richmond ward three months ago under my care, was threatened with delirium tremens. He had the appearance of a hard drinker, and confessed to a partiality for beer and spirits.

History.—Since twelve years of age, when he had measles, subject to cough. During the last three winters the breath has been specially short, particularly in the morning, when he coughs up half a pint of thick phlegm, sometimes streaked with blood. After leaving school he began life as a silk handkerchief printer. He left this in 1850. Then he took to stoking locomotive engines, but the coal-dust choked him. He then took to the building trade, and was chiefly employed in stonemasonry because his breath was not good enough for carrying bricks up ladders, and he caught cold when exposed in the bricklaying trade. Found stone-facing work very trying to the chest in consequence of the dust inhaled. Three years ago, after working with bath-stone, which is the worst as being the most dusty stone, he was laid up with cough, dyspnœa, and expectoration, and this has continued ever since. Pulse 92; respirations 32.

On examining the chest it is seen to be much expanded, moving *en masse*. Respiration chiefly diaphragmatic. There is a depression at the scrobiculus and a swelling at the left clavicle—a callus following fracture (he says that three trains went over him, smashing his collar-bone and cutting off his finger-top). On percussion the chest is hyper-resonant below the right clavicle and in the axilla (but the area of hepatic dulness is increased); behind the chest is resistant, though hyper-resonant. At the left apex in front percussion is slightly dull. On auscultation—Right side: breathing nearly normal, somewhat harsh, with sibilus and scattered crepitation in the axilla. Left side: Vesicular murmur replaced by superficial crepitation, varying from day to day. Here and there towards the axilla the vesicular murmur unaltered. Heart sounds diffused, impulse heaving. When admitted the heart's action was very tumultuous, and the man was very shaky from drink. He could not sleep until chloral was given him in fifteen-grain doses. Effervescing ammonia with ipecacuanha wine gave no relief, except in easing expectoration; nor did ether and ammonia. When the bronchial surfaces are dry, dyspnœa is urgent; when secretion is free, breathing is easy. Quassia, iron, ether, and strychnia seemed to do good, and cod-liver oil. He has gained ten pounds in weight—from 10 st. 0½ lb. to 10 st. 10¾ lbs.—but has varied lately from a renewed attack of bronchitis, to which he is always very prone.

July 1.—Went out on pass yesterday and returned drunk next day, having prolonged his absence without leave.

The particles of millstone are as hard and irritating, or very nearly so, as those of steel or iron, and it is from the dressing of the millstones, more than from the flour-dust, that millers suffer.

Bakers who have to deal with highly-dried flour—*biscuit*-flour—the men employed at Robinson's and Polson's flour factories, for instance—suffer more than those who work with the common flour used by ordinary bakers. Bakers often complain more of the sulphur fumes from the ovens, and the long hours, than of the flour; and sudden great alternations of temperature serve greatly to increase the unhealthiness of this trade.

It has been observed that the Sheffield grinders and Staffordshire potters are very reckless and careless of consequences. As those who live in an atmosphere of carbonic acid fail to observe a degree of closeness unbearable to those coming from the open air, so workers in dust take no notice of an atmosphere so full of dust as to be perfectly choking to the inexperienced; nor do they, as a rule, apply for treatment until disease is firmly established and dyspnœa urgent.

Bakers, on the other hand, are a poor anæmic set, and often come under treatment at our hospitals—general and special—before any decided bronchial or pulmonary mischief has set in. They look pallid and miserable, although their lungs are sound; whereas the grinders often retain a good digestion and remain fleshy when extensive disease exists. Their chests are generally emphysematous, and the abnormal sounds are loud and extensively diffused. The healthy complexion, skin, and general appearance make one unprepared to find evidence of so much pulmonary disease. The dyspnœa, however, is usually greater than in phthisis, and the cough more constant, ringing, and spasmodic.

Instead of giving a general epitome of the physical signs, the most satisfactory way appears to me to be to bring the case before you first by a brief description, and then give you an opportunity of a personal examination. The cases now under my care in the Hospital afford fair illustrations of the points referred to.

I have to thank Mr. Bartlett, our indefatigable Assistant Medical Officer, for drawing my attention to the following cases:—

Mary H., aged 35, admitted under Dr. Pollock into Montgomery ward. Has been employed at Carter's seed warehouse in Holborn for years. The work given to women is chiefly sifting seed—a very dusty employment. Hours of work from 8 a.m. till 8 p.m., and often till 11 p.m. She and many others are often ill, chiefly, it is thought, from the effects of the inhalation of dust. They rarely place anything over their mouths; the dust induces sneezing and coughing, with expectoration.

Symptoms.—Cough of a loud, tearing, spasmodic character, with expectoration at first frothy, now purulent; considerable dyspnœa. When in St. George's Hospital two months ago was almost confined to bed, but now sits up daily; is gaining strength.

Physical Signs.—Right subclavian region dull and crepitant

(a) Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

to the fourth rib; dull, with diffused crepitation to base. Left supraspinous fossa dull, with tubular breathing and scattered crepitatiou.

In this case the disease appears to have begun with bronchitis, arisiug partly at least from dust-inhalation, but has goue on to consolidation and commencing softening on the right, with scattered mischief on the left side. The apices are chiefly affected, and there is now some decided tubercular mischief present.

G., aged 28, a driller, now in Richmond ward under my care, says that when he took to drilling—a work in which metallic particles are dispersed through the workshop—he was ill, and subject to cough and shortness of breath; his previous occupation having been chopping wood for fire-lighting. Was admitted under the care of Dr. Quain three years ago. His shoulders are very round, and the chest is emphysematous, being resonant all over, but crepitant at both apices, with sibilus aud prolonged expiration. Every morning there is much wheeziug, but after expectorating half a piut or a quarter of a pint of frothy sputa the breathiug is less oppressed. He has obtained benefit from counter-irritation, and is gaining in weight.

I regret that I have no opportunity of placing before you specimens of the changes that take place in the lungs, for we have not lately had a post-mortem examination in a case of this kind; and even when patients die of this form of disease, the lung has often passed on to general disorganisation with formation of cavities. It is rare, in fact, to meet with a fatal case until advanced destruction of lung has occurred.

Instead of morbid specimens I have brought down some beautiful drawings in Lebert's work, and also in Carswell's, which illustrate very well the melanotic chauge which takes place in lung and in gland in many of these cases.

It is not easy to show in a drawing the thickened and hypertrophied walls of the bronchial tubes which result from the chronic inflammation set up by the particles of dust lodged in the mucous membranes. The tubes are narrowed, partly from thickening of their mucous linings, and partly by exudation matters which encroach on the adjacent lung substance. This thickening obstructs some of the smaller bronchi, and leads to collapse of the air vesicle iu which they terminate, and it appears probable that particles of fine dust may find their way into the minute air-cells themselves, and set up changes similar to those which occur in the air tubes.

The material which is exuded may also obstruct the vessels, and cut off the supply of blood, so that atrophy of the tissues occurs; local congestions follow, leading often to hæmoptysis. The dyspnœa aud dusky hue of the face may be attributed to the extensive alteration of large tracts of lung by fibroid or exudation matter. Fibroid phthisis in one of its forms may be traceable to inhaled irritants, for the inflammatory products resulting from irritation or subacute inflammation have a property of slow contraction, and hence the expansile power and elasticity of the lung becomes slowly crippled. Nodules, often nigrated, are scattered throughout the lung, and these undergo cretific change or calcification, and give to the lung a mottled appearance. Not unfrequently the nodules are encysted, and fibrous prolongations extend from these cysts into the substance of the lung; the thickening being greatest in the septa, on the pleural surfaces, and along the course of the bronchial tubes. The fibrous depositions about the pleura are the result of unchecked subacute pleurisy. This is apt to escape notice unless the patient is carefully watched and the chest examined; even when there appear no marked signs of increased discomfort, it is not unusual to fiud loud creaking souuds extending over a considerable portion of the side and lasting for days or weeks.

Dilated bronchial tubes are frequently met with. The mucous membrane lining the bronchial tubes is found to be congested and sometimes ulcerated. The bronchial glands are enlarged often to the size of nuts, are perfectly black, gritty on sectiou, and similar black-current-like deposits are often scattered through the lung (*vide* Lebert). Tubercular deposits appear to dry up in the presence of the black matter surrounding them, cicatrices become black, and the walls of cavities are black too. In old age there is a great increase of pigment in the lung. Chronic congestion leads also to the same result (*vide* Carswell's plates), aud auy abiding irritation may be aloue adequate to the production of melanotic change. But besides this, there are in the lungs of coal-miners deposits of carbou, in which silica may be detected. Indigo and tobacco may be also found in the lungs of indigo-makers or snuff manufacturers. The signs of emphysema are constant.

After this account of the pathology, a very hopeful prognosis cannot be anticipated. Eveu when removal from the cause of the malady is possible, the disease is very apt to run its course. Our prognosis may, however, be *favourable* in some seemingly bad cases, and *vice versâ*. In the class in which the chest is large, expanded, and emphysematous, with clear normal or hyper-resonant percussion, spasmodic breathing, and violent tearing cough, the cough and spasm may be relieved, and great, perhaps permanent, amendment take place—the prognosis being favourable in proportiou as the asthmatic element is most marked. The *unfavourable* cases are those in which the chest is flat and contracted, the percussion dull, and the symptoms masked. These are often cases in which there is an hereditary tendency to chest disease, aud the patients would probably have become phthisical in auy indoor occupation. The poor sufferer works on uncomplainingly till the pulmonary degeneration is so advanced that life cannot be maintained.

The *treatment* is in the main that which we employ iu lung disease from other causes. Counter-irritants are certainly of value, the croton-oil liniment (known by the out-patients at this Hospital under the euphemistic name "Brompton itch") being probably the best of these.

Small blisters certainly give relief in the acute stages, and a few leeches when the pleura is affected. But the pleural inflammation is generally subacute, and leads to adhesions and effusion of lymph rather than fluid.

When there is much dyspnœa and blueness of lips and finger-nails, remembering that the oppressiou, with dull, heavy pain is due to pulmonary engorgement, we may relieve the circulation by occasioual emetics. When we bear in mind the pathology of the disease, we are prepared to expect more benefit from tonics than from auy other plan of treatmeut; and experieuce confirms this view.

Much relief may be also giveu by promoting secretion in cases in which the cough is dry and irritative. Antimony, chloric ether, and soda inhalations are serviceable in this way.

The prophylactic treatmeut differs with every trade. To the metal-worker the magnetic gauze respirator is of service; but the injurious particles are frequently portions of the grindstone, and these may escape the magnet. An ordinary gauze respirator or silk handkerchief may be used, or Dr. Marcet's charcoal respirator. Fans should be employed to carry off the dust from the workers, and the stoves should be in buildings distiuct from those in which the potter moulds his clay; for the sudden transition from hot to cold places is an undoubted element in the maintenance, if not in the causation, of lung disease among potters. In the stove-rooms there is not only dust and a hurtfully hot, dry air, but there is also much coal-dust; and this probably accounts for the marked nigration in the lungs of potters.

Let me, in conclusiou, beg you carefully to examine the patients uow introduced.

Medical Names of Streets in Paris.—We who are so much more disposed to blame than to praise the Paris municipal authorities which have succeeded each other during the last half-century, should bear in mind the homage which they have rendered to Medicine during that period by giving to the streets names that are cherished by science and the medical profession. We should indeed be ungrateful to complain on this head; for if our researches are exact there are thirty-seven of the public streets that bear such names, and certainly no other science or art has been so liberally dealt with. Here is an alphabetical list of such streets:—Alibert, Ambroise Paré, Antoine Dubois, Bichat, De Blainville, Broussais, Cabanis, Chomel, Corvisart, Cuvier, Desgenettes, Duméril, Dupuytren, Esquirol, Fagon, Ferrus, Fourcroy, Galvani, Guy de la Brosse, Guy Patin, Hallé, Harvey, Jenner, Larrey, Magendie, Mazet, Papin, Pinel, Quesnay, Rabelais, Richerand, Vauquelin, Velpeau, Vésale, Vicq d'Azyr.—*Union Méd.*, Oct. 18.

Richmond Surgical Hospital, Dublin.—On Thursday, the 16th inst., William Thornley Stoker, M.D., Surgeon to the City of Dublin Hospital, and William Thomson, M.D., House-Surgeon to the Richmond Surgical Hospital, were elected Surgeons to the above institution, in the room of Robert Adams, M.D., Surgeon to the Queen and Regius Professor of Surgery in the University of Dublin, aud Robert W. Smith, M.D., Trinity College, Professor of Surgery, both resigned.

ORIGINAL COMMUNICATIONS.

CASES OF HEART DISEASE AFFORDING EVIDENCE RESPECTING THE ACTION OF DIGITALIS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

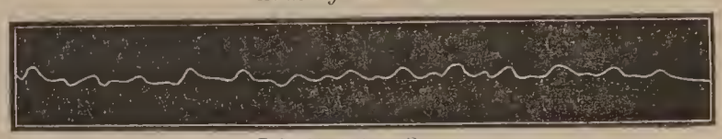
(*Continued from page* 432.)

Case 3.—*Obesity, Dyspepsia, Flatulence, Enteralgia, copious Urie Acid Deposit in Urine, very Feeble Action of Heart—Benefit from Digitalis, and especially from Sea-Air.*

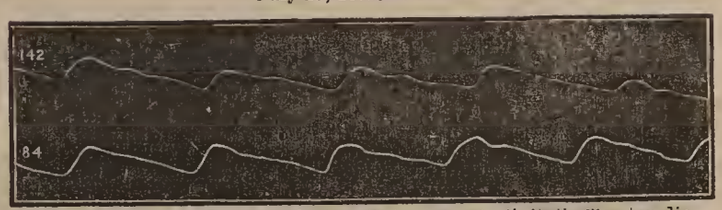
E. Sh., widow, cook, aged 38, admitted July 27, 1872. Had miscarriage and flooding severely eight years ago; had much anxiety five years ago. Has not felt well on and off for four years. She used to be very thin, but has got very stout the last year or two. Now and then her face and legs have swelled. Tongue pretty clean. Has always a nasty taste in her mouth, at times bitter. Bowels very costive. Meat suits her best in the way of food; liquid ingesta blow her out like a bladder; she cannot take sugar, it turns acid immediately. Catamenia regular, but are very pale, and only last about one day; has sickness sometimes for a week before the flow. Lips anæmic. Cardiac impulse scarcely to be felt. First sound of heart extinct, or nearly so; second heard as a rapid pit-pat; every now and then a complete pause occurs. Says her breath is so short that it takes her half an hour to walk up a flight of stairs. Urine of dark colour, red, with brownish sediment; darkens greatly when boiled with nitric acid; is not albuminous. Her weight was 156 lb. Ordered—Spt. ammon. co. ℥xx., pot. bicarb. gr. xx., inf. cascarillæ ℥j. ter die.; ferri redacti. gr. j. in pil ter die. Meat, toast for bread, no sugar or potatoes. By August 12 her breath was much better; the first sound of her heart was much improved in quality. September 2: Suffering from shortness of breath and so-called spasms of the abdomen (pains). The belly, she says, becomes as cold as ice when these attacks come on. She has often had them before during the last two years. Urine, two or three days ago, deposited much uric acid. Heart's action very quick; no first sound audible—only the second; now and then an interval of complete silence occurs. Pt. c. mist. c. tinct. cinchon. ʒj. ad ℥j. September 9: Wakes up from sleep in alarm, and in a dripping perspiration. Urine the other day was acid, and deposited much uric acid; it is to-day pale and neutral. Ferri et quinæ citratis gr. x., tinct. nucis vomicæ ℥x., spt. chlorof. ℥x., aq. ℥j., ter die. She continued this till the 19th, when it was changed for ammon. carb. gr. v., tinct. cinchon. ʒj., dec. cinchon. ℥j., quater die, with ferri carb. sacch. ʒss., ter die. She had been ailing with hysterical disorder, shooting pain at region of heart, and abdominal "spasms," with considerable deposit of uric acid in urine. She continued to take the last-prescribed remedies till October 25; but no ground was gained. She was then ordered tinct. digitalis ℥v., aq. ʒij., ter die, which she took till the 30th, when the dose of digitalis was increased to ℥x. bis die, with ferri et quinæ citratis gr. v. On this treatment more benefit was obtained than on any previous. The report on November 22 is that she has slept better the last three weeks than she has for two years. Instead of lying in bed, as she has hitherto, she is now sitting up, and takes food well. The urine, however, continued almost constantly to deposit much uric acid. Medicine was omitted on December 2, and on the 7th she went to a convalescent home at Dover, where I heard on January 9 that she had improved much, and had not been obliged to keep her bed a day. I saw her again on February 26, three days after her return from Dover. She was looking very well. The pulse was irregular and unequal, but of tolerable size, and pretty distinct. She had been taking a prescription sent her for ammon. carb. gr. iv., tinct. digitalis ℥x., dec. cinchon. ℥j., ter die, and ferri carb. sacch. gr. xx. ter die, but not quite regularly. She was seeking a situation in service. Her urine was examined on September 16 and on November 25, with respect to its acidity—a notable deposit of lithic acid being present on the first occasion, and a copious sediment of lithates on the second. On September 16, 100 cc. of the urine contained an amount of acid equal to 9·264 grains of oxalic acid; on November 25, 100 cc. of urine equal to 15·44 grains of oxalic acid. The latter amount was therefore more than half as much again as the former. Probably the lithates were mingled with numerous minute uric acid crystals, so that there was no material difference between the two deposits. If we assume that the total urine passed during twenty-four hours was equally acid, and adopt Parkes's mean of 1500 cc. for its quantity, we should have a total acidity of 139 grains of oxalic acid on the first occasion, and of 231 grains on the second—a prodigious excess over the figures given by Parkes, which vary from 29 to 61 grains of oxalic acid as representing the total twenty-four hours' acidity.

In this patient some grave change had taken place in the normal vital chemistry, the consequences of which appeared to be a tendency to formation of fat, to an excessive production of acid, and to neuralgic disorder. It is a question whether the heart's muscle had undergone fatty degeneration, or whether its action was only depressed by deranged innervation. I incline to think both states existed and concurred in causing the very remarkable feebleness of the circulation. The uric acid sediment was probably due not so much to excessive production of this constituent as to over-acidity of the urine which determined its precipitation. The icy coldness of the belly occurring in the attacks of enteralgia is noteworthy, as well as the simultaneous existence of profuse perspiration in other parts. The enteralgia seems to have caused a morbid activity—an irritation—of vasal nerves in the district related to the suffering part, while those of the rest of the surface were in a state of paralysis. The non-occurrence of anything like articular rheumatism should also be noted in reference to the habitual over-production of acid in the system. Digitalis was not only well borne, though I gave it at first with much hesitation, but was positively of more benefit than any other medicine administered. It was, however, far excelled by a residence at the seaside, which certainly produced remarkable improvement. Unfortunately I omitted to inquire into its effect upon the production of uric acid sediment.

Tracings in Case 3.



July 29, 1872.—Pr. 58.



October 30, 1872.—Pr. 84 and 142. Taking tinct. digitalis ℥v. ter die.

The tracing taken July 29, with a pressure of only 58 grammes, contrasts strongly with those taken October 30, when small doses of digitalis had been administered about five days, the pressure used for the latter being 84 and 142 grammes. The latter show that the left ventricle was acting more regularly and exerting much more force. I am of course aware that greater degrees of pressure will often produce a better-developed tracing than weaker, but I believe this point was not overlooked in making the observations.

Case 4.—*Dilatation and Hypertrophy of Heart—Extensive Dropsy—Great Distension of Jugulars—Much Benefit from Digitalis with Iron or Blue-pill—Autopsy.*

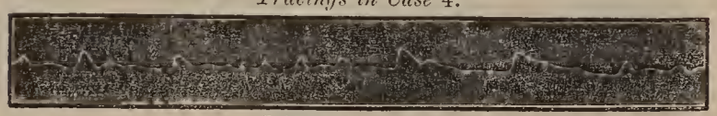
E. B., aged 68, admitted July 1, 1872. Says she enjoyed very good health until three weeks ago, when dropsy set in and soon became very considerable. The pulse was about 80, weak, small, and irregular. The rhythm of the heart was very irregular—every now and then there occurred a number of brief hurried beats; the first sound was weak, the second more distinct; the impulse was tremulous, scarcely perceptible; the dulness area was unduly extended to right and left. Both external jugulars were very greatly distended. There was evidence of œdema in the lower posterior parts of the lungs, much more extensive in the right than in the left; this increased considerably towards the close. The urine was of sp. gr. 1020, sometimes contained a little albumen, but did not deposit renal epithelium or casts to any notable amount. The girth of the abdomen was at one time forty inches; under treatment it was reduced for a time to thirty-two. The anasarca of the lower limbs also lessened very greatly. She left

the hospital much improved on November 11. The remedies employed were chiefly digitalis and iron, the former either in combination with liq. ferri muriat., or liq. ferri peracet., or with pil. hydrarg., and pulv. scill., the iron being given separately. She was readmitted January 31, 1873, having got worse the last three weeks. The pulse was too weak to be counted. The lungs were much engorged at their lower parts. There was much anasarca, and both hands and feet became covered with purpuric spots and patches, extending subsequently to the elbows. Digitalis given by the mouth failed to benefit, nor was a lotion of the same or subcutaneous injection more effectual. The latter caused much prostration and sickness. The urine was tested three different times, was not found albuminous, but was red and scanty. She was tapped March 31, and ninety-six ounces of semi-opaque straw-coloured fluid were drawn off. This fluid deposited nothing when left to stand for several days; all that could be seen in it with the microscope was some droplets of oil. She died some hours after the tapping.

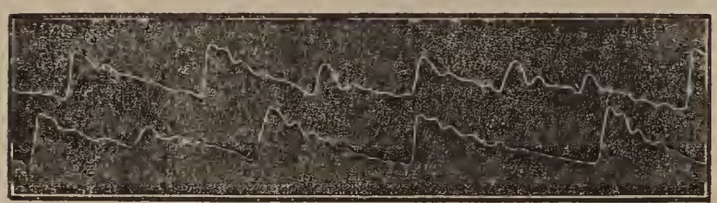
Autopsy.—Heart weighed fifteen ounces, was moderately dilated, valves sound. Lungs were semi-consolidated; highly œdematous throughout. There was old tubercle in the right apex, which was much indurated and blackened. The kidneys weighed together ten ounces; were much fissured and indented at many parts of the surface; the cortical tissue was much wasted in these situations; the cortical tubes were opaque, their epithelium more highly fatty; the Malpighian tufts pretty normal; the matrix thickened, but not condensed—at any rate, in all parts; the straight medullary tubes were normal. The liver was firm, weighed fifty-six ounces; capsule at anterior part thickened, much congested; Glissonian sheaths thickened. Cells plexiformly arranged; some contained yellow pigment, some fat; they seemed wasted.

It is interesting to compare the tracing taken on July 4 with those of September 25, when some material improvement had been obtained. The first, taken with a weak pressure (fifty-six grammes), shows a very low rise, great inequality of beats, and great irregularity of rhythm; the second shows a much higher rise, less inequality and irregularity. The higher rise is the more noteworthy as the pressure employed was double what it was on the first occasion. It cannot be doubted that the left ventricle projected a larger quantity of blood on the second occasion than on the first. The absence of albumen from the urine on four different occasions, when the kidneys were undoubtedly diseased, is very noteworthy. Recent experience to the same effect has made me more suspicious than ever of the existence of latent renal mischief in refractory or obscure cases.

Tracings in Case 4.



July 4, 1872.—Pr. 56.



September 25, 1872.—Pr. 112.

Case 5.—Dilatation and Hypertrophy of Heart, with Mitral Regurgitation—Alarming Asthenia—Speedy Improvement with Digitalis.

E. M., aged 34, married, no children, admitted September 2, 1873. Had rheumatic fever five years ago; was very ill then. Was in-patient here with broncho-pneumonia and mitral mischief two years ago. Ill this time three weeks; had short breath and swelling of legs first. Now (September 10) she has semi-orthopnœa, congestion of liver, nausea, and occasional vomiting; loss of appetite. Left back, fairly good breathing and resonance; right, dulness in lower half, very little breathing, and some moist râle. Heart's impulse extensive, marked in epigastrium, and at fifth left space both inside and outside vertical line; also in second and third left spaces. Dulness area extends up to second left space and to median line, and a little beyond left vertical line. Sounds at mid-sternum are a pit-pat, are louder at epigastrium, and at normal site of apex-beat on left side are marked by breath-sound; no distinct murmur can be heard anywhere, though the breathing often simulates it. Pulse in both wrists so small and weak that it can hardly be felt. Two days ago had no appetite; she was then taking tinct. ferri muriat. ℥x., inf. digitalis ʒij., aq. ℥j., 4tis horis. Hyd. chlor. gr. j. and ext. coloc co. gr. j. has been given each of two last nights, and she is to-day better; has eaten a nice dinner. Since the 9th the iron and digitalis have been left off, and she has had acid. muriat. ℥ij., spt. chloroformi ℥x., aq. ℥j. ter die. Has had simple diet—milk and fish; took to-day boiled mutton and custard; since the 3rd has had brandy ℥iv.

11th.—Seemed better this morning, but has become much worse since about noon. Pulse scarcely to be felt; no tracing can be got. She seems to be in grave danger of dying speedily from asthenia of the heart. Respirations 24. I ordered tinct. digitalis ℥xv. at once in brandy-and-water, and then ℥x. 2dis horis till 8 p.m.; afterwards ℥x. 4tis horis.

12th.—4 p.m.: Looks cheerful and smiling; says she is wonderfully better; passed a very good night; has taken her food well to-day; had no sickness; says that some parts of yesterday she was unconscious. Pulse 63, a little more distinct. Brandy has been given freely to eight or ten ounces a day. Pt.

13th.—Slept well until 5 a.m.; then was very ill for three hours; her heart quite stopped every now and then—once it stopped so long that she tried to call the nurse, but could not. Says that her heart is beating all right now. Pulse pretty distinct, 80, unequal.

15th.—Urine pale, alkaline, not albuminous, much increased in quantity. Pulse 69, quite distinct. Taking food well; had a very good night. Ferri carb. sacch. gr. xx. bis die.

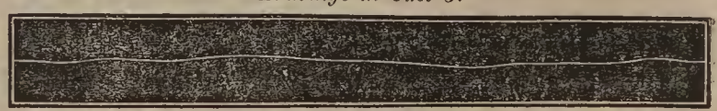
16th.—Slept well until 6 a.m.; then woke faint and distressed; was sick, had ℥xx. of tinct. digitalis, but vomited it. Has rallied again, and her pulse is fuller and gives a more ample tracing than it has yet done. Has not taken food so well to-day. Digitalis omitted, iron continued.

17th.—Better to-day; pulse good and distinct; a well-marked systolic murmur heard at apex both to-day and yesterday.

30th.—Has gone on improving steadily up to this date, taking ferri carb. regularly, and tinct. digitalis some days.

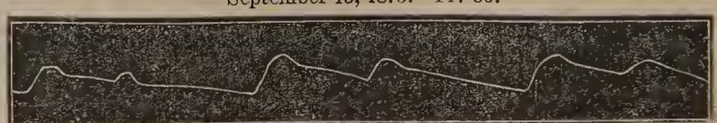
There is no question that the administration of nearly 100 minims of tinct. digitalis in about thirty hours coincided with a vast improvement in this woman's state. It is, however, true that four to six ounces more brandy were given at the same time than she had taken before, and some of the result may have been due to the alcohol. Yet, at the very least, it is plain that the drug did not weaken the heart's action, and I suspect few will admit that the additional dose of brandy made all the difference. The tracings show a most marked improvement in the pulse in the course of two days under the medication, and I cannot but hold the opinion that life was really preserved by this remedy. There occurred, however, after this great rally had taken place two attacks of faintness, the last of which *may* have been due to the digitalis having been too long continued. This, however, seems very doubtful, as both the attacks came on in the early morning after a long sleep, when the nervous forces generally, and that of the heart's centres in particular, were likely to be languid and depressed. The first attack certainly cannot be imputed to the digitalis, as the patient went on improving while still taking it. After the second, however, I thought it right to let her try to do without it, and I admit that no ground was lost by the change. It was interesting to find the murmur become audible as the heart gained strength.

Tracings in Case 5.



September 11, 1873.—Pr. 56 (?).

September 13, 1873.—Pr. 56.



September 16, 1873.—Pr. 56.

To conclude: I hold (1) that digitalis is the remedy for cardiac asthenia, especially of the enlarged and dilated heart; (2) that the existence of fatty degeneration in the heart does not forbid its administration; (3) that its effects should be carefully watched, and that if the patient cannot be frequently seen it is well to make him omit the remedy at intervals, as every third day.

THE TREATMENT OF GONORRHŒA BY LOCAL REMEDIES ONLY;

WITH COMPLICATED CASES SO TREATED.

By PHILIP FOSTER.

Some most eminent authorities having condemned the use of injections in the first stage of gonorrhœa, I feel that I am simply discharging a duty in recording how exceedingly successful, during an extended trial, this mode of treatment has proved in my hands. That cases do occasionally occur, as Case 2, in which the immediate use of injections would not be prudent, I willingly admit, but experience has assured me that the great majority of cases may be thus treated with the most perfect safety and success. Where mischief has followed this mode of treatment,—and I have seen instances of it, although not in my own practice,—I believe it to have arisen from injections of too powerful and irritating a nature having been used. My success in the treatment of this complaint I consider mainly attributable to the use of very mild injections: at first, say one or two grains of sulphate of zinc to the ounce of water, strengthening or changing them in a few days if necessary. And here let me distinctly state that it is not to any particular form of injection,—for one will frequently answer where another has failed,—but to the principle of treatment itself that I wish to direct attention. Three or four days of this treatment usually suffice to effect a cure, but I consider it advisable, and always recommend, that it should be persevered with for a few days after the discharge has entirely ceased. The occurrence of gleet and stricture would, I believe, be exceedingly rare after this mode of treatment.

I beg to observe that the following are not selected cases, but the only complicated ones that have come under my care since I commenced my present mode of treatment. Case 1 is inserted because it illustrates the mischievous effect of strong and irritating injections—the reason, I believe, of local treatment having fallen into disrepute.

Case 1.—Mr. —— called upon me, complaining of great pain and uncasiness in the urethra, especially when passing water. The meatus looked red and irritable, and there was a slight glairy discharge issuing from it. He had the day before consulted a surgeon at Manchester, where he resides, who had prescribed an injection of nitrate of silver, gr. j. ad ℥j., to be used three times a day. He said that this injection, which he has used twice, had made him decidedly worse. I ordered an injection of sulphate of zinc, gr. j. ad ℥j., to be used six or eight times a day. The next day he wrote to inform me that all the symptoms had entirely disappeared, and I have since heard that there has not been any return of them.

Case 2.—In this case the whole penis was exceedingly swollen, and there was great constitutional disturbance. Ordered antimony and saline aperients, sugar of lead lotion, rest, and low diet. A week of this treatment having sufficed to get rid of the swelling and fever, an injection of sulphate of zinc, gr. j. ad ℥j., was directed to be used four times a day. As, however, a week passed by and the discharge still continued, although the zinc had been increased to gr. ij., cupri sulph. gr. j. ad ℥j. was substituted for the zinc. On the fourth day after commencing with the copper the discharge had completely ceased, and the patient has remained quite well.

Case 3.—This commenced as an ordinary case of gonorrhœa. An injection of zinci sulph. gr. ij. ad ℥j., was prescribed four times a day. On the third day the patient was decidedly better, but on the fifth inflammation showed itself in the left testicle. The injection was at once discontinued, and the usual remedies for orchitis were commenced with. On the fourth day, the orchitis having disappeared, the injection gr. j. ad ℥j. was resumed, and in a week the patient was quite well. This patient, whom I have not seen since, informed me that he had suffered from inflammation in the same testicle during a previous attack of gonorrhœa, although he had not then been treated by injection: so that the orchitis cannot be reasonably attributed to the injection.

Leeds.

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,

Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, etc., etc.

(*Continued from page* 324.)

Having stated, as clearly as the difficulties of the subjects will allow, something of the nature of snake-poisou, of its effects upon the blood, and the symptoms it produces, together with the results of injection of ammonia into the veins, I proceed now to detail all the cases of snake-poisoning in the human subject that have been treated in this manner.

Case 1 occurred in the practice of Dr. J. C. Dempster, and was communicated to me as follows:—

"Beechworth, November 15, 1868.

"Sir,—I beg to inform you that on November 11 an adult male came under my care for treatment of the bite of a black snake (Pseudechys porphyriacus). He was bitten at about 8 a.m., and after several minutes had elapsed he sucked and incised the wound. Prior to this, however, he had felt very giddy. I did not see him for more than an hour afterwards, and treated him in the usual way with brandy, ammonia, scarifying the wound and applying ammonia. He, however, fell into the stage of stupor, and when I was called to him at midday we could not rouse him. I therefore injected liq. ammoniæ fort. into the saphena vein, and also hypodermically. This affected him at once, and after the second injection he woke up and became sensible. His pupils—which had before been very sluggish—acted well, and his pulse rose from 56 to 70. After this he progressed well. I certainly attribute his recovery to the injection of the ammonia, of which I injected about twelve minims. Yours truly,

"John C. Dempster, M.D.

"G. B. Halford, Esq., M.D."

This case, occurring in the practice of an accomplished surgeon, excited great hopes of an antidote having been discovered. Knowing that not only the popular mind, but even the professional, is constantly looking in that direction, I felt it my duty to write, November 17, 1868, to the *Melbourne Argus*, explaining that I regarded the injection of ammonia as only a mode of treatment, as the following extract will show:—"Should further experiment encourage the adoption of this treatment in snake-poisoning, it must never be forgotten that ammonia cannot destroy the poison. It may build up as fast as the poison pulls down. Mixing freely with the blood, and being eminently volatile, it does its work speedily, and is as speedily used up; consequently it must be replaced by fresh injections as often as required."

Subsequent events, as will be seen, lead me still to adhere to this opiniou.

Case 2.—The second case which I have to record is valuable principally for the fact that it was closely observed by three medical practitioners — Messrs. Arnold, Wooldridge, and à'Beckett—as well as by myself. Mr. Arnold's account is as follows:—

"At about 11 a.m. on Monday, November 30, 1868, Mr. John Brown, station-master at Elsternwick, was bitten on the third finger of the right hand. Two punctures were clearly visible, from which the blood flowed. Symptoms: Pain in the finger, wild appearance of countenance, stiffness of the legs. Applied a ligature above the bite, employed suction to the wound, and took sixpennyworth of brandy. At 1 p.m. felt drowsy and unable to attend to his duties. As he did not feel alarmed, his friends had great difficulty in persuading him to go to town for advice. Feeling somewhat better at Balaclava (four minutes' journey), he declined to proceed further. Whilst conversing with Mr. McPherson, the latter noticed his manner resembled that of a person labouring under the effect of drink—speech affected, drowsiness. He was then brought, almost against his will, to my residence—five minutes' walk. About half-way he complained of feeling very weak. On his arrival he was completely prostrated, and shortly after paralysis of the lower extremities set in, with indistinct vision, sluggish dilated pupils, weak pulse, cold perspiratiou, and vomiting. The punctures from the bite were still distinct. Treatment:

Excision of the bitten part; firmer ligature. In a short time symptoms of coma commenced; when roused with difficulty he had great trouble in recognising his wife. Considerable swelling was noticed about the upper lip. Treatment: Gave brandy —in all about six ounces—with great difficulty; sal volatile half an ounce, in divided doses; mustard poultices to the chest and feet. Galvanism, which greatly roused the patient; the moment it was suspended the comatose symptoms returned; at the same time it was evident this artificial restorative would ultimately fail, coma becoming deeper and deeper. At 5.30 p.m. Mr. Wooldridge and Professor Halford came to our assistance. Coma has been entirely absent since the time Professor Halford injected ten minims of liq. ammoniæ fortior, mixed with twenty of distilled water, into the superficial radial vein. This was the turning-point, I am fully satisfied, to the saving of the man's life."

Mr. à'Beckett's account is as follows:—

"On the afternoon of Monday, November 30, I was requested by Mr. Arnold to see a patient of his who, some hours before, had been bitten by a snake at Elsternwick. On arriving at the house I found the patient lying on a sofa in a semi-conscious state, and as I entered the room he vomited a small quantity of brandy and water which was being administered to him. On examination I found the surface of the body cold and clammy, the pulse slow and very weak, the face pale, and the pupils sluggish and dilated. Hearing that the bitten part had been excised, liq. ammoniæ fort. applied locally, and also a ligature above the bitten part, besides brandy and spt. ammon. aromat. having been given internally without much benefit, I suggested that Professor Halford should be immediately sent for to employ his injection of ammonia, and in the meantime to use galvanism and continue the administration of brandy and ammonia. The plan was immediately carried into effect with the following results:—On commencing the galvanism the colour returned to the face, the pulse became stronger, and the insensibility diminished; the patient at this time presenting the symptoms of incipient intoxication rather than those of narcotism. When the galvanic current was interrupted he fell into his former state. He continued in his condition for about an hour, at the end of which time the galvanism seemed to lose its good effect, the symptoms of coma slowly but surely coming on. His pulse varied, being sometimes moderately good, at others all but gone; he could with difficulty be roused, and his feet became cold. We then applied a mustard poultice to the epigastrium, and flannels wrung out of hot water and mustard to the feet. About this time Dr. Halford and Mr. Wooldridge arrived, and we determined upon injecting ammonia, as we considered the case to be desperate. I would state that an attempt to walk the patient about the room, so far from being attended with any good results, seemed to prostrate him utterly, complete paralysis of the lower extremities having now succeeded to the previous weakness and impaired sensation in the legs. The effects of the operation performed by Dr. Halford were wonderful, the patient reviving at once, consciousness returning, the pulse becoming full, and the pupils acting readily to the stimulus of light. This relief of the symptoms was persistent, and the patient, though experiencing extreme debility, has gradually advanced to convalescence. I will end the account of this highly interesting case by stating my firm conviction that the injection of ammonia saved the man's life."

Mr. Wooldridge's account is as follows:—

"The symptoms of this case at 5.30 p.m. were—corneæ insensible to the touch; pupils possessed only of the minutest power of contraction, and considerably dilated; limbs paralysed; pulse of large volume, weak, and about 70; countenance rather approaching a livid hue, features swollen; breathing rather slow. In two or three minutes after the injection the patient awoke as from a deep sleep. The countenance was expressive of great surprise. The pupils contracted and dilated again and again, and then settled down into pupils of ordinary size. He answered questions deliberately and coherently; in fact, the coma was replaced by consciousness, and the declining functions of life resumed almost at once their normal activity, leading this poor fellow onwards to the happy termination of his misfortune in complete recovery."

I will only add one or two remarks to these accounts. I ascertained from those who brought the patient from the railway-station to Mr. Arnold's that before he reached that gentleman's house he had become insensible, and, in fact, remembers nothing of what occurred after this time until he became conscious soon after this little operation. This shows how deep must have been the impression produced upon the sensorium by the snake-poison—as great, indeed, as accompanies severe concussion of the brain, and sometimes alcoholic drunkenness. The swollen features are a very frequent result of snake-poisoning, depending partly upon the paralysis of the muscles of expression, distension of the veins, and serous exudation. In the case of adder-bite which I attended in London the punctures on the finger could scarcely be seen, but the man's face, fauces, and tongue became in a few hours so swollen and œdematous as to threaten suffocation. I adopted as treatment free leeching and fomentations to the neck with great relief. The bite was followed by the most extensive ecchymosis of the arm and side of the trunk; no swelling of the glands.

It has been objected to the value of this case that the snake was nearly dead. Against that we have the evidence of the two punctured wounds from which blood was flowing. The species of snake was hoplocephalus superbus (copper-head).

These two cases—those of Dr. Dempster and of Messrs. Arnold and à'Beckett—drew from me at the time the following observations:—The fact of recovery in these cases is of little statistical value; but of great value is the fact that, coinciding with the diffusion of the ammonia throughout the system, force is manifested. Visual consciousness and its result, contraction of the pupil, are presently succeeded by general consciousness and its resulting acts. Animal life is restored; in other words, the bitten man now responds to the forces which surround or are brought to play upon him.

Case 3.—Of this case I have failed to get any authentic account, but it was well spoken of in the New South Wales papers. Dr. Irwin, who treated the case "by injection of ammonia into a vein above the wrist with a syringe," soon after died.

Case 4.—At Moyston a man was bitten by a tiger snake (hoplocephalus curtus) at 4 p.m. Forty minutes afterwards he was attended by Dr. O'Grady, but by this time the patient had swallowed a bottle of brandy. Twenty-five minims of liq. ammon. fort. diluted with water were injected into a vein in the arm, and brandy and ammonia given at intervals of every half-hour till recovery. As the treatment of this case also included galvanism and constant walking about, I wrote to Dr. O'Grady for more information, and the result of his observations was, in his own words, that "but for the injection of ammonia the man would have died."

About this time many violent letters appeared in some of the colonial newspapers denouncing the new treatment—most of them by anonymous authors, and displaying little knowledge of the first elements of physiology and medicine; others were from medical men whose previous readings had taught them the poisonous effects to be expected from injecting ammonia into the veins. One of these gentlemen thus wrote—"For my part, I would rather be bitten by a dozen snakes than have a drachm of strong ammonia injected into my veins." Another—"It was a happy idea, indeed, to think of introducing the antidote at once into the poisoned blood, and so preventing the usual fatal consequences. At the same time it is well known that the injection of fluid into the blood is in itself attended with some danger, especially should air happen to be introduced, or the inner coats of the veins get inflamed and form matter producing pyæmia or purulent poisoning of the blood. It is my decided conviction that the inhalation of ammoniacal gas, largely diluted with common air, into the lungs would be equally successful with its injection into the veins, and not likely to be attended with the same injurious results."

I had previously assured myself that any amount of air included in the small syringes could have no injurious effect on a man. I had frequently injected with these syringes nothing but air two and three times over in the jugular vein of dogs without any harm following. I had also fortified myself on this subject by reference to the writings of the late Dr. John Reid, who quotes Nysten and Magendie on this subject. The first author states that from two to three cubic inches of air rapidly thrown in are necessary to kill a small dog, and from six to seven cubic inches a large dog. Magendie says that he once threw, with all the force and celerity he could, forty to fifty pints of air into the veins of a very old horse without his dying immediately, though he sank at last. The usual quantity necessary to kill a horse was three inflations of the lungs.

As regards the inhalation of ammonia, I had tried it, but,

as I had expected, found it impossible to be borne. In fact, as I have before stated, my endeavour was to avoid in its administration both the stomach and the lungs.

Case 5.—Dr. Bennett, of Smythesdale, states—"Between 10 and 11 a.m., December 25, 1868, a messenger arrived requiring my immediate attendance on a girl named I. M., aged 14 years, who had, when drawing water from a hole, been bitten on the extremity of the last phalanx of the little finger of the right hand by a tiger snake (hoplocephalus curtus) which had coiled itself round the cord of the ascending bucket. On arriving, I found that the mother had excised the bitten part, had put a ligature round the finger, and had given about two ounces of gin. The girl was being walked about between two women. Her countenance was swollen and dusky, cornea glassy and insensible, stupor complete; pulse small, breathing slow. I could only partially and with great difficulty rouse her and obtain incoherent muttering in reply to a question. When the support given by the two women was withdrawn, she sank on to the floor. I injected fifteen drops of liq. ammoniæ into the median vein of the injured arm. In a few minutes she became conscious and violently excited, laughing, crying, singing, biting, and throwing herself about so much as to require two people to restrain her. After this, with occasional small doses of ammonia and brandy in water, she thoroughly recovered. About 4 p.m. of the following day I received a message to go to Black-hill, as the same girl had been bitten by a black snake—most probably a dark specimen of tiger snake (hoplocephalus curtus). At 4.20 p.m. I arrived at the house, and the mother told me that the girl and a younger sister when in or near the garden saw a snake basking; the younger one ran back to the house and informed the mother, who immediately went to the spot, having on the way seized a clothes-prop; she called to her daughter to get out of the way, upon which the girl took a few steps on one side to where a gum-bush grew, took hold of a branch, and when bending it down to break it the mother saw two snakes rise from under the bush, one of which seized the girl's hand. The mother excised the bitten part, put on a ligature, and gave about two ounces of gin with two drachms of spt. ammoniæ aromat. left from the previous day. I found no symptoms of poison present; there was a wound on the last phalanx of the ring-finger of the left hand, which I washed with the solution of ammonia, and as a matter of precaution injected fifteen minims into a vein at the elbow, but, wishing to see the efficacy of the injection, I administered nothing whatever internally. In five minutes I asked her if she felt anything unusual. She replied, 'No; excepting a burning pain on the inside of the arm,' in the course of the basilic vein. In another five minutes the same train of nervous symptoms set in as occurred yesterday, but not so violent." After this only a little quieting medicine was needed for her perfect recovery.

It is certainly very remarkable that in this case a girl should have been bitten on two following days, but, according to Dr. Bennett, there was no doubt about the fact, the mother being a very sensible and firm woman. Tending to the probability of the account is the following from a local paper:—

"The locality in which the M—— family resides appears to be infested in an extraordinary manner with snakes. On the day previous to the girl being bitten, her mother killed one close to the door of their dwelling; and on the same evening, I. M. found another in one of the beds, which escaped into the bark roof of the building. It is reported that shortly before nearly a dozen were seen at one time near an abandoned hole in the vicinity."

In this case there is evidence of a great impression having been made on the mind of the girl, as shown by the hysterical symptoms following; but that which is of special interest in the present inquiry is the fact of her having by the injection of ammonia been brought almost instantaneously from a state of helplessness to one of active muscular exertion, the people who were formerly required to support being now required to restrain her.

Case 6.—A young man was bitten by a snake at Mornington. A great deal of brandy had been given, so that by the time he reached Mr. Lane, the surgeon, he was perfectly insensible, with the pupils dilated and fixed. My friend and colleague, Professor Wilson, happening to be in the neighbourhood, assisted Mr. Lane, and watched carefully for the results of the treatment. Thirty minims of liq. ammoniæ (B.P.) were injected into the basilic vein. In eight seconds the pupils began to contract to the stimulus of light, and he presently became conscious. Then followed some tetanic spasms of the muscles of the neck and arms; but these subsided in a few hours.

This case is valuable, as showing the instantaneous recovery from the coma. I am inclined to think that the spasms of the muscles were not brought on by the injection, nor were they the effects of the snake-poison, but were caused by reflex acts due to his having been made to swallow some of the ammonia almost undiluted. I had previously seen a man exhibiting some very remarkable reflex symptoms, amongst which was perfect fixedness of the eyeballs, from swallowing very strong ammonia.

IN

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

ABSCESS OF CHRONIC NATURE IN THE ROOF OF THE PROSTATIC PORTION OF THE URETHRA, GIVING RISE TO THE CLINICAL SYMPTOMS AND PATHOLOGICAL RESULTS OF ORGANIC STRICTURE OF THE URETHRA—PERITONITIS.

(Under the care of Mr. HEATH.)

[For notes we are indebted to Mr. ARTHUR KEMPE.]

THOMAS H., aged 44, was admitted on September 6.

History.—The patient is an actor, lately a lay brother in the Haverstock-hill Priory. Has always been accustomed to drink a great deal—generally whisky. Family history good. Scars of old chancres on the penis, and of buboes on the groin; the prepuce has been slit up. Three years ago he began to feel incontinence at night, which continued for a considerable time before any dribbling took place during the day. He is unable to assign any cause for this, but puts it down to his weak state of health. Three weeks ago he took cold during a journey to Liverpool, and noticed blood in his urine. From the account given of his urine, he has probably had chronic cystitis for years. Has lately been very thirsty, and his stomach has rejected food. Thinks he is thinner than he was a year ago. While at the Priory his habits were necessarily regular, but since that time he has led a dissipated life. When at Liverpool, three weeks ago, he confesses to having drunk a large amount of spirits.

On admission (5 p.m.) urine was dribbling from his penis, and he was altogether in a very low and filthy state. Tongue dry, brown, hard, and cracked. Temperature in axilla 100·4°; pulse 88. Urine slightly acid—sp. gr. 1008; no albumen: no colour on boiling with potash, but with Fehlyn's solution a yellowish precipitate is thrown down. Turbid precipitate consists of pus and amorphous material; no casts. No ascites; no enlargement of the liver. A swelling in the right lumbar region. No cough; hiccough very severe. No diarrhœa; no constipation. Examination per rectum reveals no enlargement of the prostate. Rectum full of fæces.

September 6.—On admission catheter was passed, and bladder emptied; three-quarters of a pint was drawn off; two hours after twenty-six ounces were drawn off. Scrotum was dusted over, and a bed-urinal put between his legs.

7th.—Tongue moist and furred; temperature 98·6°; respiration 48; pulse 80. This morning there is diarrhœa, and some distension of the abdomen, not painful on pressure. Distressing hiccough partially relieved by sucking ice. Water passed into urinal during the night not more than six ounces. Water at 10 a.m. drawn off with catheter, one pint. At 7 p.m. only four ounces of urine could be drawn off, none having passed into the bed-urinal. The urine was followed by drops of unoffensive blood and stained pus-liko matter to the extent of half an ounce. Hiccough worse; diarrhœa continues. On pressing below right ribs a mass is felt lying over the region of the kidney. The pressing does not cause pain. Respiration about 50; temperature 98°.

8th.—Hiccough still continues, but not quite so violent; diarrhœa less. Two ounces of urine were drawn off at 10.30 a.m.

9th.—Urine passed on September 8 gives no precipitate with Fehlyn's solution. On examination of the patient yesterday morning he was in a very stupid condition, answering slowly and irrationally. His sclerotics had a faint icteric

...markably prominent. Liver-dulness begins tint; ... border of sixth rib in nipple line, and ends at two fingers' breadth above margin of the ribs. Abdomen full—nowhere tender. Patient lying on his back has dulness in both loins as far as about the seventh cartilage—resonant in front. Patient lying on either side, the flank which is uppermost becomes resonant, and the dulness increases on the other side. Defæcates and urinates continually in his bed; fæces are of a very light colour; skin cold and clammy. At 11.30 pulse scarcely perceptible; abdomen appears fuller; is not quite conscious, and is very dull when spoken to. Died at 4.30 p.m.

Post-mortem, twenty-four hours after Death.—Rigor mortis slight. On opening the abdomen a considerable amount of turbid yellow fluid was contained, reaching about the level of the seventh cartilage. The apex of the bladder was seen to project above the pubes, adherent (as was afterwards found) by recent lymph to the omentum, which was dragged down beneath the small intestines. Peritonitis was most strongly marked in the pelvis when the fluid was purulent, and there were numerous flakes of yellow lymph. There was also considerable peritonitis over the outer surface of the spleen, for which no cause could be discovered. The liver was first removed, and found apparently healthy, and, though not reaching the margin of the ribs by two fingers' breadth, was about normal size. The right kidney was in normal position, somewhat enlarged; the pelvis, though large (admitting the thumb), was not distended; both ureters were dilated, not excessively so. Kidneys, bladder, and rectum removed together. On slitting up the urethra no stricture was discovered; but immediately behind the bulb, or just at the apex of the prostate, was a small sac in the roof of the urethra, burrowing forwards on the right side for about half an inch, containing perhaps a quarter of a drachm of purulent fluid; walls were thick, and evidently of old standing, and no communication existing between this and the urethra, which must have caused some obstruction to the passage. Bladder immensely hypertrophied, muscular walls being an inch thick; at the apex was a large sacculus, exactly in the position of the adherent omentum; the walls here were as thin as paper, and in a sloughly condition; no actual perforation found. In other parts the lining of the bladder was fasciculated, and of a reddish-black colour. The lining of the ureters and pelves of the kidneys were inflamed. In the pelvis of the right kidney was some phosphatic deposit: both contained stinking urine. Substance of the kidneys pale and swollen; capsule stripped off readily; in it the vessels were prominent. On the surface of the kidney were numerous white spots, size of pin-heads, of doubtful nature. Surface of the kidneys smooth in some parts, of a dark red colour. Both kidneys larger than natural. Spleen tough and fibrous, rather large; old adhesions in both pleuræ. Lower lobe of left lung pneumonic throughout; rest of lung healthy. Lower lobe of right lung congested, œdematous, not pneumonic; rest of lung healthy.

BIRMINGHAM GENERAL HOSPITAL.

CONSTITUTIONAL SYPHILIS—CHRONIC GENERAL MENINGITIS—LATER, FORMATION OF A NODULE COMPRESSING THE LEFT MIDDLE CEREBRAL ARTERY, CAUSING ATAXY AND DEFECTIVE SPEECH, AT FIRST IN FITS, THEN PERMANENTLY—SLIGHT AND TEMPORARY PARALYSIS OF THE FACE—SOFTENING NEAR THE CORPUS STRIATUM.

(Under the care of Dr. RUSSELL.)

THE case which follows affords an interesting example of one of the three ways in which Dr. Hughlings-Jackson has stated that syphilis may produce hemiplegia. The diagnosis of syphilis, as deciding the nature of the disease, was made easily enough from the patient's physical condition and antecedents; and, this part of the diagnosis being effected, distinct significance was given to the early symptoms of the case, which accorded entirely with the post-mortem appearances in indicating the course of that inflammation and thickening of the membranes of the brain which form a frequent element of the intracranial disease occurring in connexion with the introduction of the syphilitic poison. During the chief part of the patient's history there was no evidence of localised disease other than that certain portions of the dura mater became the seat of greater activity of the morbid process, and in some degree coincided with the locality of the chief pain. Symptoms which pointed to localised disease only appeared at a late period, and doubtless marked the formation of the mass which compressed the middle cerebral artery, or at least the period of its active interference. The three ways in which syphilis produces hemiplegia specified by Dr. Hughlings-Jackson are—(1) paralysis following a convulsion, (2) blocking of a syphilitic artery (in hemiplegia the middle cerebral)—it may be without convulsion or loss of consciousness,—and (3) a nodule growing in the motor tract, in which case the hemiplegia may come on gradually. The second of these ways existed in my case, only that the artery was blocked from without, though its coats were thickened. I place the case in the rank of hemiplegias, although the paralysis was of the slightest character, and confined to the face; the obstruction in the artery being partial only, the effect of the obstruction was apparent chiefly in the change effected in speech. It will be observed that at first the defect of speech occurred in separate attacks, but perfectly distinct in their character from the "fit" from which the patient had previously suffered, and in which the intellect was temporarily and repeatedly deranged. It is remarkable that the convulsive (epileptic) fits, which constituted the first symptoms noticed by the patient, ceased during the time when the active changes in the membrane were going on, although the surface of the convolutions was involved in the adhesions which were then formed; the fits which then took place were of vertigo, simply followed by active delirium.

In respect of the gradual formation of the functional defect, the present case rather belongs to Dr. Jackson's third class than to the second, the cause of the defect being of the same kind with that quoted in the third class, not sudden obstruction, as would be likely to occur in the condition belonging to the second class. It is worth noting that ataxy of articulation was the first change in speech; afterwards, as the compression increased and the damage extended more widely, words were lost—confirming Dr. Jackson's hypothesis.

I think it worth while to prefix to my case a few notes of another case, probably very similar in its character, because it affords an interesting illustration of the duration to which the disease may attain. The patient has frequently been under my observation, though not under my care. A medical friend who attended him gave me the report twenty years ago, and from it I can condense the following notes. The patient is still alive:—

Case 1.—The patient had constitutional syphilis in 1837-38. He was then 31 years of age. He was treated by mercury. He had hemicrania in 1838, cured by iodide of potassium, and again in 1842, when the pain was more severe and recurred with greater frequency. All remedies then failed to relieve him. Towards the close of 1842 he had confusion of thought, left ptosis, and numbness of the cheek. He was considerably improved by local bleeding and salivation. In the following January he had three seizures in five days of inability to find words, and then fell into a lethargic condition with general convulsions, ending in complete coma. Again in June the pain returned, with occasional double vision, confusion of thought, and impairment of mental power. Then followed in September continuance of pain seated in the *left*(a) parietal region, and sudden left hemiplegia, with rigid flexure and numbness of the arm. Partial recovery was attained in the course of a fortnight by the aid of mercury, and since that period to the present the arm has remained partially paralysed and nearly useless. But again the pain in the right parietal region returned, again being checked by mercury. During the following three years he had attacks of pain five or six times in the course of each year, relieved always by mercury, each of two or three weeks' duration. The mental faculties continued much impaired. He kept his bed a large part of each day, and was in a mere automatic condition. In 1847 he began to improve in this particular, and became able to walk about, and by degrees to occupy himself. He has never since encountered any return of serious cerebral symptoms, but has remained in a low mental condition, capable of little intellectual effort, and quite excluded from taking part in the business of life, yet retaining much keenness of observation and correctness of judgment. He is now about 68 years of age, having been the subject of this disease for thirty-five years.

Case 2.—T. M., aged 37. His family history was satisfactory. His habits had been very dissolute. He had a venereal

(a) The *right* parietal region is afterwards spoken of; probably the above is an error.

sore at the age of sixteen; he married at twenty-one, and his children presented a very interesting illustration of the manifestations of hereditary syphilis. We found in his throat an extensive cicatrix, the result of destructive ulceration, with perforation of the soft palate. When aged 32 he lost his teeth rapidly without any decay, and at present his upper jaw is edentulous with the exception of one canine tooth, the alveolus having been absorbed. We could gain no evidence of his having been salivated. He had his first fit (a complete epileptic attack) about two years before coming under my care, and was unable to work for several weeks subsequently. Three months after, a second and much milder one occurred. Five weeks before I saw him he was attacked one morning with pain over the occiput; in the afternoon he had another fit, and was confined to bed the next day. The occipital pain recurred, coming on suddenly and lasting an hour; it was accompanied with giddiness. The pain has been so severe that he has kept his wife awake at night with his cries. There was pain also in the region of each frontal eminence, like the other pain occurring in sudden paroxysms. His nights at this time were disturbed by very vivid dreams. Both the pain and the disturbance of sleep were much relieved by iodide of potassium. When he first came under my notice, early in March, 1869, he had the appearance of a healthy man. Mr. Arthur Bracey then examined his eyes by the ophthalmoscope, and found the right optic disc very indistinct, the vessels obscured; in the left eye the disc was grey and anæmic, and the outline also rather indistinct. The man read with the right eye No. 4 Jaeger easily, and No. 1 with difficulty; with the left eye only No. 16. The pupils were normal as to size and contractility; the ocular muscles were intact; taste was good; smell was impaired, probably by the disease in the throat; hearing was perfect. He took iodide of potassium in full doses (up to gr. xv.) from April 5 until September 20, and improved considerably; but on the last-mentioned date it was noted that, although he had been quite free from fits of unconsciousness, he was suffering from paroxysms of vertigo. In these attacks he did not lose consciousness, but became violent; in the intervals his intellect was clear. The pain in the left frontal region continued. After this period slight fits of "mithering" continued to recur, and a note made on December 7 states that during the preceding week he had been attacked repeatedly with loss of articulating power (ataxy), but without any fit: "he tried, but could not bring out his words." He also described independent attacks in which "the right side of the face went," and the entire face became very red and burning, and tears rolled down his cheeks. In a week afterwards he was described as sitting the day round without speaking, complaining of his head, and talking in a disorderly manner, "asking for contrary things to what he desired—*e.g.*, brushes for pocket handkerchief," etc. He was found on one occasion, probably after a fit, with the right side of his face "drawn." He was now taken into the Hospital (December 20, 1869). He was then discovered to have partially lost the function of speech as well as that of articulation; he would go through a great part of a sentence correctly, but almost always came to some word which he miscalled or replaced by gibberish. The defect was manifested still more clearly in reading, many words in a sentence being altogether unintelligible. The defect increased rapidly. "It says things that I shown such different tones," when asked to describe the state of his eyes; but added in correction, "They are chiefly things that there is anything about." —"I feel lost and low the last two years," in reply to "How are you?" He was seldom correct in stating the time, and often miscalled an object. Sometimes he retained the last word spoken, and when he had correctly named "a knife," he applied the same term in succession to a pen and to keys, but to a shilling, shown next, "It is money, sir." In his spoiled sentences the word "fares" was often prominent (he is a cab-driver). He wrote his name rightly, but a sentence written from dictation from a book immediately after began with his residence (therein expressing the residuary and automatic thought), and then declined into nonsense. Some tendency to right ptosis and to convergence of the right eye was observed, but no other defect in the face. His intellect speedily deteriorated: he filled the kettle with coal, and did other automatic acts, and finally became perfectly torpid, not opening his eyes, the lids of which were glued with mucus. He had a fit on January 27 in which the right arm alone was shaken, and died on the 30th.

Post-mortem Examination.—The brain was generally and firmly adherent to the dura mater, so as to be removed with the greatest difficulty. The adhesions were particularly dense in the left temporal and left occipital regions, where the dura mater was of an opaque yellow colour. The adhesions extended to the base, retaining the brain very strongly. The dura mater was greatly thickened, especially around the torcular and in the left regions, as mentioned already. The longitudinal sinus was quite open, but a dense mass of dura mater lay over its termination. The arteries at the base required to be dissected with care from the arachnoid. Especially was this the case in the left Sylvian fissure, where the middle cerebral artery at its origin was identified with the matter constituting the adhesion; its walls also were much thickened. A dense yellow gumma the size of a horsebean lay in the fissure and compressed the left middle cerebral artery by surrounding it. A similar mass lay upon the insula, closely connected with the superficial layer of cerebral tissue. The masses consisted entirely of granular matter and of small irregular nuclei intermixed with larger groups of fat globules. The middle cerebral artery was obstructed by a non-adherent plug of colourless fibrin; its walls were thickened beyond the point of compression; it was quite empty, except that a small quantity of blood existed in one or two of its finer branches. All the other arteries were quite pervious. A small cavity about half an inch in diameter, not lined with membrane, lay just outside the anterior extremity of the left corpus striatum; the surface of that body and the adjacent white matter were soft. The surface of the brain, chiefly on the left side, was probably soft, but it was too much injured during extraction for satisfactory examination of the convolutions. The cerebral nerves were healthy, though they were engaged in the thickened arachnoid. The cord and its membranes were healthy. The other organs were healthy; there were no other evidences of visceral syphilis.

Medical Times and Gazette.

SATURDAY, OCTOBER 25, 1873.

THE CONJOINT EXAMINATION SCHEME.

The reception of the short Act of last session, giving the University of London the power to combine with the two Royal Colleges and the three other English Universities in the formation of a Conjoint Board of Examiners, has brought the well-worn subject of the Conjoint Examination Scheme again prominently before the notice of the Council of the Royal College of Surgeons. We believe we are right in stating that

an effort will be made by the Society of Apothecaries in the ensuing session of Parliament to obtain like powers of co-operation with the University of London. It therefore becomes our duty as medical journalists to re-open the consideration of a topic of which, we believe, a large proportion of the profession, as well as ourselves, are quite weary.

We have always maintained, and do maintain, the principle that an equal examination for all desirous of practising medicine in any part of the United Kingdom is theoretically a desirable thing. It would give all practitioners a broad and common basis of attainments, and would insure the public the possession of at least a minimum of knowledge by those who have legally a right to practise. These are the great arguments for altering the present state of things, and introducing a radical change in the laws which since the passing of the Medical Act have governed admission to the medical profession. On the other hand, the experience of the last five years has shown that there are enormous difficulties in the way of obtaining perfect and unreserved co-operation amongst the existing examining bodies of any one of the three kingdoms, and that it is practically impossible to obtain in the present state of the law any conjoint action between the medical authorities in England, Scotland, and Ireland. Moreover, a closer comparison of the advantages which would be reaped by a one-portal or three-portal system with the advantages of corporate action, scientific standing, and incentives to emulation offered by the present institutions, has led some of the more sagacious and wiser of our leaders to the opinion that even the probable benefits of conjoint examining boards may be purchased too dearly, and that the inevitable result of their establishment will be to injure permanently, and probably ultimately to sweep away, the historical corporate bodies which have during a long period worthily represented medical science and art. No arrangement can be a permanent one which would assign to the Royal Colleges revenues from the fees of candidates for admission into the medical profession whom they no longer examine. To grant the Royal College of Surgeons a large percentage of the money paid by a medical student for his diploma, who is examined for that diploma, not by the College, but by a separate body of examiners, and to make the fee of the candidate a large one, in order to admit of the payment to the College, is an arrangement which in a few years will be held by a profession so taxed an indefensible abuse, and the Government of the day will be besieged by medical and educational associations to sweep away such an impost upon the fruits of knowledge. What better pretext for a Liberal Minister, with a smattering of science, willing to do a popular thing, could be offered to annex the Hunterian to the British Museum than that of relieving an effete corporation at once of the expense, responsibility, and glory of possessing and supporting it?

Those junior members of the Council of the College of Surgeons who are anxious to transfer the duty of examining candidates for its surgical diplomas to a separate and irresponsible Board, and expect to maintain that College and its great collections out of the earnings of the Board, seem to us, to say the least, to be assuming enormous responsibility. Supposing the clumsy mechanism of a committee of reference and an independent examining board were set in motion to-morrow, for how many years would it last, and how long would the College obtain a sinecure income from its product? When the College is no longer the *Alma Mater* of the great bulk of English surgeons, is it likely to maintain its present prestige? When it has once laid aside its functions, will it ever be permitted to assume them again?

There are other views of this question which at least point the necessity for caution. Whatever conjoint board may be formed in England, no conjoint board will be set up in Scotland. Even if the Apothecaries' Society be ultimately one of the co-operating English authorities, there will still be the Scottish Colleges and Universities and the Glasgow Faculty offering the English students access to the profession at a cheaper expenditure—at least of money, and probably of brains. Already the annual exodus of medical students to the North is as established as the exodus of sportsmen. How will the ranks be swollen when all portals in England are shut but one, and that is guarded by a thirty-guinea entrance-fee, a large portion of which will be paid to institutions which have discarded their duties and thrown away their privileges. Again, those who know best the state of the existing law still maintain that the proposed action of the Colleges in this matter is *ultra vires*, and that there must be fresh legislation before any change can be effected. Do the advocates for a conjoint examination scheme hope to obtain the required powers from a weakened Government, already accused by the leader of the growing Opposition of "worrying" every profession? and are they willing to hand over the remodelling of the medical profession to Messrs. Stansfeld, Lowe, and Ayrton?

The General Medical Council is now at least doing its duty. Examinations are visited by competent visitors, and we may expect that the general standard will be improved in every part of the United Kingdom. Would it not be at least wiser to wait and see the effects of these visitations before the old medical institutions of the country are sacrificed at the shrine of a visionary and unattainable uniformity?

ASPIRATION.

I.

Aspiration, as now so generally used both in medicine and surgery, has been a plant of slow growth, though suddenly starting to maturity. The importance of using a small trocar in opening collections of purulent fluid has long been known and insisted on by many, though the opposite has been also generally maintained; but then the difficulty arose of getting a dense fluid through a narrow opening, and so a certain limit was, as it were, imposed on the dimensions of the canula. The application of the syringe to the hypodermic injection of remedies, the consequent possibility of using needles of small size, and the fact that the use of such needles gave rise to (comparatively speaking) little inconvenience, probably aided in maturing the idea embodied in modern aspiration. Nevertheless, the principle of aspiration was acted upon in this country long before the modern appliances were invented. Thus, Dr. W. Roberts, of Manchester, made use of syphon-power in tapping abdominal collections of fluid long before anything like a syringe had been used in a satisfactory manner for the purpose. Probably the first to successfully use a syringe for tapping collections of matter was Dr. Bowditch, of Boston, and he was thereby enabled to convert a very fatal malady—perinephric abscess—into one easy of relief. But undoubtedly it is to Dr. Dieulafoy, of Paris,(a) we are mainly indebted for developing the method, which he has done with a skill and boldness meriting the highest praise; all the more so, inasmuch as he seems to have been ignorant of much that had been done before him. The method, however, has so much to recommend it that we think it well to give a kind of outline sketch of the various uses to which it may be applied, endeavouring as well as we can to indicate those for which it is most suitable from those less adapted for its use.

The great merit of Dr. Dieulafoy's instrument is, that it is capable of being used as an exploratory as well as an evacuating instrument; and, as used by him, it seems to us that the instrument is as good as can be made. Here

(a) "A Treatise on the Pneumatic Aspiration of Morbid Fluids: a Medico-Chirurgical Method of Diagnosis and Treatment of Cysts and Abscesses of the Liver, Strangulated Hernia, Retention of Urine, Pericarditis, Pleurisy, Hydrarthrosis, etc." By Dr. Georges Dieulafoy, Gold Medallist of the Hospitals of Paris. London: Smith, Elder, and Co. Pp. 394.

in this country it has tended to develope too much in one direction, for in the instrument now generally manufactured only one kind of vacuum is used, and certain advantages of the original instrument have been somewhat prematurely abandoned. In Dieulafoy's original instrument we simply had this: a syringe so contrived as to be in some part transparent, which was double-acting, such as most stomach-pumps are made—that is to say, capable of drawing in fluid at one orifice, and expelling it at another; and the piston was so constructed that it could be fixed at any point, whilst by means of stopcocks the interior of the piston could be converted into a vacuum before applying it in any way. The needles were exceedingly fine trocars, with canulæ or needles hollow and pointed like the needles of a hypodermic syringe, these latter being used for exploratory purposes. Suppose, let us say, a patient had an hepatic swelling, the nature of which could not be readily made out; one of these exploring needles would be attached by means of an indiarubber tube to the syringe already exhausted, and, introduced into the side gradually by a screw-kind of motion, thus it would be made to pass inwards until the wall of the abdomen was penetrated and the tumour pierced. That being so, and the suction-power of the exhausted syringe being, by turning the stopcock, rendered active, the moment any collection of fluid is reached that moment it is drawn into the syringe and makes itself perceptible at once—to the eye by its general appearance, and to the hand by its warmth. The appearance would speedily tell what kind of cyst we had reached, and of course the nature of the tumour. After emptying the syringe when full, the vacuum could be renewed either directly or indirectly—that is, either before or after opening the stopcock on the tube leading to the sac to be emptied. Of course if the doubtful tumour were solid no fluid could escape, but the size of the needle is too small to set up any mischief. If, however, we wanted to tap a collection of fluid whose existence was well known—say a purulent collection in the pleura, or an over-distended bladder—we might proceed thus. Selecting a fine trocar and canula, we would push it into the collection of fluid, withdraw the trocar, and, as the first drops of fluid appeared, apply the tube and exhausting syringe to the extremity; after which, by working the piston, we could directly withdraw the fluid, without any previous vacuum being made. Moreover—and this is a matter of importance,—supposing a small plug of lymph obstructed the fine orifice of the canula, we could, by a back-stroke of the syringe, eject it from its position, and so free the opening. Another matter of some importance is this: the extremity of the canula, being blunt, would not injure the expanding lung pressed against it. Now the instruments are generally so made that only the previously exhausted receiver can be employed, and the needles are for the most part those spoken of above as exploring needles, not of the nature of trocar and canula. As only the already formed vacuum can be employed, only the indirect suction-power of this, and not the direct suction-power of the syringe, can be used; and no back-stroke is possible so as to free the canula from any obstruction. Moreover, the trocar and canula, being more rigid, are more easily introduced than the exploring needle, which is also blunter, and so gives rise to more pain. For this reason we imagine that a return to the former model might be considered as in a certain number of instances advisable. In whatever form used, there can be no doubt but that the aspirator is a most valuable engine both for diagnosis and treatment, the more especially as both can be in many cases combined.

The official *Staatscourant* of Holland states that some sporadic cases of cholera occurred in that country last week, but there appears to be no fear of an epidemic.

THE WAR ON THE GOLD COAST.

There are few things more trying than inaction after a period of excitement. Since the time when it became manifest that we had actually commenced a war on the Gold Coast to within a fortnight ago, active preparations and hot discussions kept the circumstance prominently before us; but for the last two or three weeks, whilst waiting for the final demands from Sir Garnet Wolseley—which will once more set all the different departments of the Government in a state of bustle,—there has been positively nothing to chronicle.

The present outbreak has been very generally spoken of as a "doctors' war," from the peculiarly unhealthy nature of the climate in which the hostile operations will have to be carried on; and whilst fully acknowledging the grave responsibilities which are likely to fall to the medical branch of the service in the forthcoming expedition, we still confidently anticipate that, so far as the Medical Department is concerned, the public will not be disappointed. The line-of-battle ship *Victor Emmanuel* is still in the hands of the fitters in Portsmouth Dockyard, and every care is being bestowed upon her to render her the most serviceable and efficient hospital-ship ever despatched from these shores. The large and peculiar boats which have been provided by the authorities to contend with the heavy surf which constantly breaks upon the West Coast of Africa off Cape Coast Castle, should prove an easy and safe means for the transference of the sick and wounded from the shore to the ship; and once on board the floating hospital, under the charge of a strong medical staff, many of the dangers incidental to a hospital building upon the hot and malarious littoral will be avoided. It is further rumoured that none but the very gravest cases will be retained on board the *Victor Emmanuel*, swift and commodious vessels being retained in readiness to bring home the sick and disabled men with the least possible delay.

It will thus be seen, from these few items of intelligence as to one portion of the preparations, that the Medical Department is fully alive to the grave nature of the duties expected of it; and taking into consideration the rapid strides which modern science has made in the treatment of disease, whilst remembering that the present is by no means the first campaign which England has found it necessary to undertake in unhealthy climates, we look hopefully forward to a result anything but in accordance with the gloomy forebodings which ushered in the first announcement of hostilities against the Ashantees.

We believe the other West India Regiment will certainly be despatched from Jamaica to the seat of the war; the number of men-of-war in those waters will also be strengthened to insure a strict blockade of the Coast, and to prevent the landing of muskets and ammunition for the use of our foes, from sharp traders who, so long as there is profit to be made, are perfectly indifferent on the score of national interests.

The next mail, which is now due, will doubtless bring the result of Sir Garnet Wolseley's local inquiries and observations; and until such time as this is made public, we cannot pretend to anticipate the further course of events.

THE WEEK.

TOPICS OF THE DAY.

The Vice-Chancellor of the University of London, in forwarding a copy of the Medical Amendment Act (University of London) passed at the close of the last session of Parliament, to the Council of the Royal College of Surgeons of England, by the provisions of which Act the University is now ready to join in the preparation of a scheme for a conjoint medical examining board for England, has requested to be informed whether the College is disposed to accept the co-operation of the University in the object. The letter and enclosures were discussed at a meeting of the Council of the College on the 16th inst., when a resolution was adopted expressive of the

satisfaction of the Council that the authorities of the University of London were now enabled to join in the preparation of the scheme; that the Council cordially invited the co-operation of the University in carrying out the scheme; and suggesting that the Senate should elect two representatives of the University, one in medicine and one in surgery, as members of the Committee of Reference appointed under the scheme already approved by the Universities of Oxford, Cambridge, and Durham, and the Royal Colleges of Physicians and Surgeons. Copies of the scheme, approved by the above medical authorities, together with copies of the two reports from the Committee of Reference, were ordered to be sent to the Vice-Chancellor, with a view to their consideration by the Senate of the University.

We believe we are correct in stating that it has at length been decided that the medical appointments to the new brigade depôts are to be held for a period of three years. This intelligence will no doubt prove satisfactory to many gentlemen who have been hesitating as to whether it would be to their advantage to apply for or to accept these posts. Since their inauguration, the number of these brigade depôts originally in working order has been slowly increased, and little by little the whole of them, about seventy in all, will be rendered available for the reception of troops. It remains to be seen whether the formation of these military centres in the different counties and districts will have the effect of popularising the service throughout the country. If the number of recruits at present presenting themselves is not shortly increased, and a check placed upon the wholesale desertions daily taking place, it will become imperative upon the authorities to take some stringent measures for increasing the supply of men, or the exigencies of the State will once more raise the question of compulsory service on the model of that system which is adopted in Germany and other foreign countries.

The newspapers have recently reported the death of Dr. Smethurst, of Old Bailey notoriety. Since his two years' imprisonment for bigamy it seems that Smethurst resided with his lawful wife in a house in Onslow-square, where he died. His death was so sudden that an inquest was considered desirable. Disease of the kidneys and other organs was discovered, and the jury returned a verdict of "Death from natural causes."

DR. MURRAY'S FUNERAL.

It having been resolved by his relations to take Dr. Murray's remains to his native Aberdeen for interment, a company assembled at the Euston Station on Monday evening, there to receive the coffin and escort it to the train, as striking as could well be conceived. There were men of all grades and ages in the profession, from grey-haired veterans to young men entering on their medical studies—men and women of all classes—hospital nurses and hospital patients,—all joined together in a desire to do honour to the deceased. And in their sadness it must have been no little comfort to his relatives to see how generally Dr. Murray had been esteemed and valued. A short, simple, but impressive service was held over the remains, and, covered with chaplets of flowers, the funeral waggon went to take its place in the night express, to reach Aberdeen on Tuesday afternoon. Steps have already been taken, and a committee is in process of formation, to collect subscriptions for the purpose of erecting a memorial bust and tablet to his memory in the scene of his too brief labours—the Middlesex Hospital,—but of this more will be said hereafter. Meanwhile it may be of interest to many that some excellent photographs of the ordinary size have recently been taken by Fradelle and Marshall, 230, Regent-street, and may be obtained from them. These gentlemen have also fortunately been able to include Dr. Murray in their admirable series of larger photographs of medical celebrities.

ROYAL COLLEGE OF SURGEONS.

The following is an abstract of the unconfirmed minutes of the meeting of the Council on the 16th inst., with the exception of those portions already published in the *Medical Times and Gazette*:—A letter was read from Mr. John Flint South, resigning his office as a member of the Council. The resignation having been accepted, it was resolved unanimously—"That the Council desire to convey to Mr. South the expression of their regret at the cause of his resignation of the office of member of Council, and their sense of the deep interest he has uniformly taken in the affairs of the College, as evinced by his constant efforts to promote its welfare." The President stated that the vacancy occasioned by the resignation of Mr. South would be filled up at the annual meeting of the Fellows in July next for the election of members of the Council. The President reported that the term of five years, for which period Mr. Hilton was elected a member of the Board of Examiners in Dental Surgery, expired on the 15th inst., and that at the next ordinary meeting of the Council the election would take place of a member of the Court of Examiners in such vacancy. The arrangements for the Dental School and Dental Department of King's College were approved. A letter from Mr. Francis Fowke, the General Secretary of the British Medical Association, was read, enclosing the following resolution, signed by Sir William Fergusson, Bart., as President of the Association;—"Moved by Dr. Sibson, F.R.S. (London), seconded by Dr. Steele (Liverpool), and resolved unanimously, 'That the cordial thanks of the British Medical Association be given to the President and Council of the College of Surgeons for their splendid hospitality in giving a reception at the College of Surgeons on the occasion of the forty-first annual meeting of the Association.'" The consideration of Dr. Humphry's motion was postponed.

MEDICAL SOCIETY OF LONDON.

On Monday last, October 20, the Medical Society of London commenced its second century in the new premises, No. 11, Chandos-street, Cavendish-square. There was a very large attendance of Fellows, and the proceedings were characterised by a freshness and vigour that gave promise of a long-continued life to the old Society. The President, Dr. Habershon, opened with a short address commenting on the prospects and future of the Society, which was warmly received, and at once put the meeting in good spirits. Dr. Richardson followed with a carefully written paper on "Organic Stricture of the Œsophagus," being a recast of his own clinical observation of this disease. A very interesting debate then took place, in which Dr. Semple, Mr. Mason, and Mr. A. E. Durham took part. The new building proves admirably adapted to its designed purpose, and the Society may be congratulated on making so successful and important a change.

FURTHER INFORMATION REQUIRED.

The Medical Officer of the Cardiff Union reported to the Guardians that the effect of the milk supplied to the Workhouse on patients and infants was so deleterious that the officials had been compelled to get a supply of Swiss condensed milk. It does not appear that under these circumstances the Medical Officer or the guardians made any reference to the Adulteration Act or the powers it gave over vendors of adulterated articles of food. This statement is most unsatisfactory, and it is incumbent on the Medical Officer to furnish a report of the actual condition of the milk complained of. Nothing is more likely to bring an Act of Parliament into disrepute than loose and unconfirmed statements. If the milk were really impure and adulterated, it was the bounden duty of the Guardians to prosecute the vendor. It, moreover, would be satisfactory to know what were the "deleterious effects" said to have been produced by the milk.

KLEPTOMANIA.

Dr. Rogers, Medical Officer to the Westminster Infirmary, has made a representation to the Commissioners in Lunacy, and to the Visiting Justices to the Coldbath-fields Prison, as to the treatment of one William Weightman, a mechanic, who has been imprisoned there. It would appear that on the morning of his discharge, the wife applied to the relieving officer of the workhouse for his admission on the grounds of his insanity. Dr. Rogers, on seeing the man, came to the conclusion that from his paralysed condition and mental infirmity he had been deranged for some period. He therefore sent for the wife, who stated that her husband had become much changed since last November, up to which time he had been a respectable, hard-working mechanic; he became moody and melancholy, and neglected his work. One evening last February, between five and six o'clock, he suddenly put his foot upon the board of a poulterer's shop, and at much risk to himself took a hare off the topmost hook, put it under his arm, and walked quietly down the street. He was followed by the shopman, who gave him into custody, and he was taken before Mr. Newton, at Marlborough-street, who sentenced him to a month's imprisonment with hard labour. On his discharge from prison, at the latter end of March, his mental condition became so much worse that his wife was about to apply for his admission to the workhouse, when she learnt that he was again in custody, he having gone into a shop where he was well known, and in the presence of the shopman took down a pair of trousers, which he walked off with. He was followed, given into custody, taken before Mr. Knox, and committed for trial; and although the wife tried to get a hearing as to the state of his mind, she was rudely repulsed from the court. He was sentenced to six months' hard labour, which time he fully served, no one appearing to have recognised his mental condition. The lunatic has been visited by Dr. Blandford, of Grosvenor-street, who has certified that he is paralysed, and that, in his opinion, his mental infirmity has been of some duration.

UNHEALTHY DWELLINGS.

Our contemporary, the *Pall-mall Gazette*, in an article on "Adulterated Houses," observes—

"In no one respect are our sanitary legislation and administration so defective as they are with regard to houses. The medical officers of health never make a report which does not condemn a number of houses, sometimes whole streets, as unfit for human habitation. They have been doing this for years past, and it would be an interesting subject of inquiry, how many of these condemned houses are still inhabited. Occasionally a vestry makes a raid upon some of the worst—or perhaps, to put it more accurately, upon those among the worst which are not the property of vestrymen—and some faint semblance of a clearance is effected. But the aggregate of unwholesomeness is not, we suspect, much reduced by these intermittent displays of sanitary virtue, and about the better class of houses, as to which doctors and sanitary engineers give such discouraging evidence, nobody troubles himself at all. These evils, and all the consequences which flow from them, will go on unchecked until we have the courage to apply to the sellers of houses the same law which has lately been applied, with such good results, to the sellers of milk and groceries. The man who sells or lets a house should be held answerable for that house being free from any additions injurious to health. It is not proposed that every house should be a miracle of sanitary engineering; all that is required is that a few simple and well-understood sanitary appliances, which can never be omitted without great danger to health, should be prescribed as indispensable adjuncts to every inhabited house. The law does not allow grocers to sell poisons under the name of spices, and there is just as much need that it should no longer allow builders and landlords to sell fever-traps under the name of houses. The greater, because more dangerous, adulteration should be forbidden as much as the lesser."

SPURIOUS TEA.

A report from the Sanitary Committee was laid before the Commissioners of Sewers for the City of London at their meeting, held on Tuesday last, in reference to the allegation that a large quantity of spurious tea was at present in bond in the City of London, and intended to be sold for consumption by the public. The report stated that the Committee had ascertained that during the year 1872 the quantity of tea of different sorts imported into this country was 180,000,000 lbs., and they had reason to believe that at the present time there was a quantity of tea in bond amounting to 40,000,000 lbs. so grossly adulterated as to be wholly unfit for human consumption. The Committee had also reason to believe that of the quantity of tea annually imported into this country 70 per cent. was not tea at all, but consisted of leaves of plants of different sorts. The Committee expressed an opinion that the only remedy for this state of things was to appoint inspectors to examine every cargo of tea brought to this country upon the arrival of the ship, and that the "chops" should be examined by a portion being taken indiscriminately from some of the chests. The Committee also recommended that her Majesty's Government should be communicated with, and that it should be asked to introduce a Bill into Parliament upon the subject. The report was agreed to, and ordered to be printed. It is to be hoped that the recommendations of the Committee will be carried out with promptness and vigour. The Committee appear to have conducted their inquiries in a satisfactory and exhaustive manner, and they are entitled to the commendations of the community for having exposed a most gigantic fraud.

VACCINATION IN MADRAS.

A letter in the *Indian Statesman* from Madras says:—"The system pursued by the Vaccine Department in Madras is worthy of a passing note. On specified days the various suburban districts of the town are visited by the perambulatory staff, consisting of the vaccinator and his or her clerk armed with a register and a bundle of tickets. But the chie, attraction of the invading party is its *avant courrier*, who flourishing a sonorous bell with one hand, and exhibiting an attractive bag of coppers in the other, invites all and sundry to bring their children to be inoculated at the premium of one anna a head. At a fee of eight annas per diem a victim is obtained to accompany the procession and disseminate his or her lymph to candidates for the coppers, and on a promising crowd being assembled a suitable spot is selected and the distribution of pice and vaccine virus takes place contemporaneously. Now and then, an urchin upon whose arms a previous operation had been bunglingly performed managed to elude the vigilance of the registrar and to submit himself a second time to the vaccinator for the sake of the anna; and clearly the whole affair is looked upon as a purely business transaction, in which vaccination is regarded as a trifling punishment by means of which to earn a copper. Indeed, out of a tolerably large crowd I had the curiosity to watch the other day under the vaccinator's hands, I was struck with the large proportion of boys and girls who had long passed infancy, who evidently presented themselves of their own accord with the supreme object of acquiring possession of the bellman's coppers."

PROFESSOR FLOWER, F.R.S.

The many friends of the indefatigable Conservator of the Hunterian Museum will regret to learn that his health has been so seriously affected by close application to his duties, that at the last meeting of the Council of the College of Surgeons it was unanimously resolved to relieve him at once from work by giving him leave of absence for six months. Professor Flower will leave in a few days for Egypt, where it is to be hoped he will regain his health.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

The annual stated meeting of the College was held, pursuant to charter, on St. Luke's Day, Saturday, October 18. An election for Fellowship—the first since the memorable visitation of the College, at which voting by ballot was declared to be illegal—took place by open voting. Four Fellows were elected—namely, J. Hawtrey Benson, M.B.; Robert Cryan, L.K.Q.C.P.I.; George F. Duffey, M.D.; and John William Moore, M.D. On the same occasion the following officers for the ensuing year were elected:—*President:* James F. Duncan, M.D. *Vice-President:* Henry Kennedy, M.B. *Censors:* Henry Kennedy, M.B.; Robert D. Lyons, M.D.; W. B. Jennings; Walter G. Smith, M.D. *Registrar:* J. Magee Finny, M.B. *Treasurer:* Aquilla Smith, M.D. *Examiners in Midwifery:* John Kingland, M.D., and Lombe Atthill, M.D. *Professor of Medical Jurisprudence:* Robert Travers, A.M., M.B. *Representative on the General Medical Council:* Aquilla Smith, M.D. *Agent to the Trust Estates:* Charles Uniacke Townshend. *Law Agent:* Charles Woodward, B.A.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

At the annual meeting of the College on the 15th inst. the following office-bearers were elected for the ensuing year:—*President:* James Simson, M.D. *Treasurer:* John Gairdner, M.D. *Secretary:* Robert Omond, M.D. *Librarian:* Archibald Inglis, M.D. *President's Council:* James S. Combe, M.D.; Andrew Wood, M.D.; James Dunsmure, M.D.; William Walker; Henry D. Littlejohn, M.D.; Patrick H. Watson, M.D.; *ex off.*, John Gairdner, M.D. *Examiners:* Archibald Inglis, M.D.; James Dunsmure, M.D.; Peter David Handyside, M.D.; James D. Gillespie, M.D.; Henry D. Littlejohn, M.D.; Patrick H. Watson, M.D.; David Wilson, M.D.; John Smith, M.D.; D. M. C. L. Argyll Robertson, M.D.; Joseph Bell, M.D.; Thomas Annandale; William Stephenson, M.D. *Assessors to Examiners:* William Brown; James Spence: John Gairdner, M.D.; William Walker. *Conservator of Museum:* James Bell Pettigrew, M.D. *Clerk:* James Robertson. *Officer:* John Dickie. *Assistant to Conservator:* James Grandison. Dr. Andrew Wood was unanimously re-elected representative in the General Council of Medical Education and Registration of the United Kingdom for the period of three years from the 8th inst.

PHOTOGRAPHS OF SKIN DISEASES.

Some photographs of skin diseases have been forwarded to us under the title of the "Photographic Clinique of the British Hospital for Diseases of the Skin," edited by Balmanno Squire, M.B. It would be unfair not to give these photographs a word of commendation, for they are far superior to anything of the kind heretofore published, and may justly claim to be considered works of art. One we have just received—a picture of rodent ulcer—is really exceedingly good. It has always struck us that in selecting subjects for such illustrations and pictures the wants of the practitioner have not been duly considered; we have, as a rule, either very unusual or very intractable forms of disease, whereas it is the intermediate group which would best repay such consideration. We trust Mr. Squire will take the hint as far as this series is concerned.

INSANITARY STATE OF SANDHURST COLLEGE.

The War Office authorities have acted with praiseworthy promptitude in issuing an order for the appointment of a special committee, under General Napier, Director-General of Military Education, to inquire into the sanitary condition of this College. A visit to the College on Saturday last has led to a recommendation that it should be immediately quitted by the students, which has been acted on. One case of typhoid fever has been reported. Upon whom rests the responsibility of allowing the College to get into an insanitary state?

FEVER IN A "MODEL HOUSE."

In consequence of the continued prevalence of fever in the "Model House" in Mason-street, Millwall, the Board of Guardians drew the attention of the Poplar Board of Works to the fact, and requested the immediate attention of the sanitary authorities. The inspector has since reported that he could discover no nuisance on the premises, and that the Board of Works had no power to interfere in respect to the structural arrangements of houses. Is the undiscovered cause of this fever in this "Model House" to remain a mystery? We should hope not, but that further inquiry will be made.

AN EXAMPLE FOR CORONERS' JURIES.

At the adjourned inquest which took place before Dr. Gill last week in the case of Bernard Burns, charged with the manslaughter of his daughter in Belfast, the prisoner was not produced, and, after a good deal of evidence had been given, the jury refused to return a verdict, because the accused had not been produced. Subsequently the jury passed a resolution strongly condemning the conduct of the authorities. We think the jury acted in a spirit of justice and consistency which should be an example to jurymen placed in a similar difficulty.

BISHOP MCDOUGALL, F.R.C.S.

From the *London Gazette* of Friday last we learn that her Majesty the Queen has been pleased to grant unto the Right Rev. Francis Thomas McDougall, D.C.L. (sometime Bishop of Labuan), the place and dignity of a Canon of the Cathedral Church of Winchester, in the vacancy occasioned by the decease of Dr. William Wilson. The new Canon passed his examination and was admitted a Member of the Royal College of Surgeons of England on June 3, 1839, and was elected a Fellow on July 25, 1854.

REGISTRATION OF STUDENTS.

Since the publication of the annual return of gentlemen pursuing their studies in this metropolis, in the last number of the *Medical Times and Gazette*, the gross number has been increased to 1641, including 39 gentlemen studying for the licence in Dental Surgery of the Royal College of Surgeons.

WESTMINSTER HOSPITAL.

On October 14, Mr. G. Legge Pearse resigned office as Surgeon to the Hospital. Mr. Richard Davy, the senior Assistant-Surgeon, has applied for the post; consequently, a vacancy occurs in the list of Assistant-Surgeons. The nomination is fixed for October 28.

UNWHOLESOME WATER.

Mr. Donkin, the analyst appointed by the county of Oxford under the Adulteration Act, reports that of eleven samples of spring and well water submitted for analysis the greater number were found to be unsafe for drinking purposes.

FROM ABROAD.—TREATMENT OF NÆVUS BY VACCINATION—DR. VACHER ON THE MORTALITY OF PARIS IN 1872.

In continuation of the discussion at the Paris Société de Chirurgie on the treatment of nævus by vaccination, noticed in our last (p. 441), M. Depaul insisted upon the necessity of distinguishing between nævi and the *taches* which are so constantly met with in new-born infants, and which generally disappear spontaneously. These, therefore, require no treatment. Erectile tumours, properly so called, he said, may

almost certainly be cured by vaccination, wherever they may be seated, providing that they are of small dimensions, not exceeding a franc in size. When they are of a more considerable dimension, as that of a two-franc-piece, for example, they cannot be completely cured by vaccination, although they may be ameliorated. M. Depaul makes from ten to twelve punctures in the surface of the little tumour; and he has practised this operation more than 150 times without ever meeting with any more hæmorrhage than could be readily arrested by the application of a compress wetted with cold water. This mode of treatment is especially useful for erectile tumours situated on the upper eyelid. In these cases there supervenes at the time of the vaccinal eruption an enormous swelling of the eyelid, which alarms the friends, but which is dissipated in from ten to twenty days. M. Trélat agreed with M. Depaul as regards the efficacy of vaccination for erectile tumours and the trifling character of the hæmorrhage that results from the punctures, but he is not of the same opinion with him concerning *taches*. These do not always disappear spontaneously, and they may, at the end of several months or even years, become transformed into erectile tumours of a serious character. They should therefore always be attentively watched. M. Trélat is of opinion that the action of vaccination in the cure of these tumours depends much less upon the surgical traumatism which it gives rise to than on a special process set up by the involution of the vaccinal eruption, and by the mode of cicatrisation of the pustules. M. Desprès stated that Nélaton in large erectile tumours traversed their base by a seton soaked in vaccine virus, while he treated the smaller tumours by simple vaccinal punctures.

Dr. Vacher, the well-known medical statistician, has communicated to the *Gazette Médicale* (October 4 and 11) an interesting paper on the "Sanitary Condition and Mortality of Paris during 1872." In this he observes that in normal times, when there is nothing to disturb the regular increase of population, the annual mean number of births is 54,000, and that of deaths 45,000, being an excess of 9000 of the former. The normal immigration of provincials and foreigners introduces a contingent of 18,000 individuals, the two sources together thus leading to an annual increase of about 26,000. This regular increase, deduced from what took place during the period of 1860-70, ought, if the sad events of 1870-71 had not occurred, to have brought the population at the census of 1872 up to very nearly 2,000,000 inhabitants. The official statements, however, fix it at only 1,799,250, or with the addition of the garrison at 1,851,792, showing a considerable deficit, the causes of which it may be of interest to examine.

The *Bulletin de Statistique Municipale* informs us that the deaths in 1870 rose to 73,563, exceeding the annual mean by 28,500. In 1871 the mortality rose to 86,760 (or, according to an account derived from the *pompes funèbres*, to 99,945), or an excess of 41,800—the two years furnishing an excess of 70,300 deaths. The same increase also took place in the rest of France; for the mean annual excess of births of 123,000 was converted in 1870 into an excess of deaths of 103,000, and in 1871 of 419,000. So that besides its other disasters France sustained during these two years a diminution of population of more than 500,000 from excessive mortality. Nor is this all, for there was also a great decrease of births in Paris in 1871, the mean annual natality sinking from 54,000 to 37,410—giving a deficit of 16,500. This deficiency of births occurred especially in August, September, and October, 1871, the corresponding periods of conception being December, 1870, and January and February, 1871—the time when the population of Paris was exposed to the most rigorous privations.

Besides these two chief causes of the diminution of population, other secondary causes have to be taken into account. For example, the German population has diminished from 30,000 to 5000, and an emigation towards the provinces has, at all events temporarily, replaced the immigration hence. This will no doubt be only transitory, for the same fact was observed during the period 1848-51. The population of Paris, which in 1846 had been 1,053,897, had diminished by 1851 to 1,053,262; but it soon recovered itself, so that by 1856 an increase of 120,000 had occurred.

The number of deaths registered in Paris amounted to 40,489, occurring in a population of 1,851,792, being a considerable diminution on the annual mean of 45,000. It is to be remarked, however, that after great epidemics or excessive mortalities there is almost constantly a diminution in the number of deaths; and, as M. Besnier has shown, such diminution applies to all the prevalent diseases, and not as might be supposed to the absence of any one of these in particular. All diseases participate in the diminution just as they participate in the increase in times of excessive mortality; and M. Besnier lays down the rule that the physician in his prognosis and treatment ought never to lose sight of the prevailing level of the general mortality. Comparing the mortality of Paris in 1872 with that of other capitals, it is found that it holds a most satisfactory position. Thus in 1872 that of London was 21·4 per 1000; Paris, 21·9; Brussels, 22·6; Vienna, 31·8; Berlin, 32·3; New York, 34·5; Florence, 34·8; and Rome, 37·7.

Passing to the details of the special causes of death, it is found that 897 deaths resulted from typhoid fever, 2266 from pneumonia, 8104 from phthisis, 1514 from bronchitis, 1348 from croup and laryngitis, 537 from puerperal affections, and 182 from variola. As usual, *phthisis* heads the list by far, sweeping off, as it does, a fifth of the Parisian population. The small number of deaths from *variola* confirms the observation just made as to the diminution of mortality observed in the years following the explosion of epidemics. In 1870-71 small-pox carried off in Paris no less than 15,421 persons, and proved far more murderous than the fire of the enemy or the civil war—the number of deaths from wounds amounting to 4862, 1512 being due to the first siege and 3350 to the period of the Commune. The disease, indeed, ravaged not only Paris but entire Europe, snatching 7876 victims in London in 1871, 958 in Brussels, and more than 8000 in Berlin. For the whole of France it is no exaggeration to place the number of deaths it has caused at 200,000. Of the 537 deaths from *puerperal affections*, 195 took place in the town and 342 in the hospitals. But the number of deliveries which took place in the hospitals amounted only to 6730, while those *à domicile* exceeded 47,000—that is to say, childbed mortality was only 4·1 per 1000 *à domicile*, and was 51 per 1000 in hospital, or thirteen times greater. Moreover, while each delivery *à domicile* costs the municipality 21 fr., the expense at the Maternity varied from 47 fr. to 72 fr. per patient! The same observation applies to most, if not all, the diseases that decimate the population—viz., that the mortality of the Paris hospitals, even those most sumptuously provided for, very much exceeds that observed in the most miserable dwellings of the faubourgs.

In 1872 there occurred 797 *suicides* in Paris, so that the chance is greater for the life of a Parisian being terminated by voluntary death than by typhoid fever or phthisis. Large as the number is, it still indicates improvement in moral conditions, for in 1869 it amounted to 1100. M. Vacher long since made the remark that one effect of political revolutions was to diminish the number of voluntary deaths; and the observation is verified by what occurred in 1830, 1848, and still more in 1870. From September 1, 1870, to September 1, 1871—that is, during one of the most tormenting of periods—the suicides sank to 447, a figure so exceptionally small that it is only to be met with by going back half a century, when the population of Paris was scarcely a third of what it now is. These facts

forcibly contradict the assertions of those who declare that an increase of suicides is connected with and coeval with the spread of democratic opinion. M. Vacher is much more disposed to refer it to the feverish speculation and thirst for gold which have prevailed during the last thirty years. Besides the 797 actual suicides there were 231 unsuccessful attempts. The most common means employed was hanging, which took place in 234 suicides. Drowning was resorted to in 100 cases, precipitation in 58, shooting in 77, "white arms" in 50, and poison in 41.

RECOLLECTIONS OF NÉLATON.

By Professor DIDAY.

We extract the following passages from an interesting article by Professor Diday, contained in the *Lyon Médical* of the 12th instant:—

The career of Nélaton has set a problem to many excellent judges which they have had to confess their difficulty in solving. "The true psychical position of the man being given," they say—"how is his success to be explained?" Well, for those who witnessed the commencement of his career nothing is more easy. Such as you have seen him at his apogee, with that rare combination of a consciousness of power and a manifestation of kindness so happily united and spread over his honest face, by such also my recollections of youth bring him to my mind. From 1832 he already "counted" among us. In the waiting-room of the Hôtel-Dieu, amidst the future great men of every calibre, who from night to morning were noisily proclaiming themselves in that legendary *rez de chaussée*, the entrance of "Auguste" always produced an effect. At first sight of him one felt attracted by I do not know what charm, already mingled with a kind of respect, towards this young man of mild yet firm bearing, with so modest yet so assured an aspect. Anyone who had at that time predicted for him one day the popularity of Dupuytren would have been met with no denial from any of us. I may here rectify a biographical error. All who have written on Nélaton declare that he was a pupil of Dupuytren. Now, it is certain that he was a very frequent and a very assiduous attendant upon the lectures of the senior surgeon of the Hôtel-Dieu, and I can testify that he appreciated with the fullest admiration the method and the profound yet simple instruction of the illustrious professor. But he was never one of Dupuytren's *internes;* for, although inscribed for admission among these for 1835, Dupuytren's illness and death prevented his ever serving under him.

This deference which Nélaton obtained from us without ever seeking for it manifested itself under all circumstances. I recollect one amongst a thousand. One day a man was brought in with a dangerous hæmorrhage. The *interne* on duty was present, and he alone had to do with the case. But as Nélaton happened to be there, by an instinctive movement all others made way for him, and he was requested to perform the necessary operation, which he did with a dexterity that had already become remarkable.

Follow him in his career and you find him met in the same manner by the judges of his merits as by his comrades; and this, be it noted, without any steps whatever being taken on his part, a single request being proffered, or even the most legitimate exhibition of his titles to attention being made. His inaugural thesis, "Sur les Tubercules des Os," in 1836, was a revelation. Two years later he presented himself at the *concours* as an *agrégé* in surgery. There his success *à priori* seemed but doubtful; for, by the traditions of the Faculté de Paris, these posts, though offered for *concours*, are ordinarily destined for the *fils de la Faculté*—those who have become successively attached to it, first as anatomical assistants, and then as prosectors. These are regarded as their appanage, which they have a right to count upon. They do count upon them, and generally the event justifies them in doing so. Nélaton had none of these titles, and he was not recommended by even the smallest book nor by the smallest private course of lectures. Therefore, he, of his competitors, who possessed all these antecedents and that joined to real merit and an exceptional talent for exposition, flattered himself that he should have an easy triumph. Nélaton thought so too, and would have felt well satisfied to obtain any one of the four vacant places. He presented himself, rendered somewhat awkward in appearance by his very modesty, and spoke, certainly not as an orator, but as a man of study, and especially as a man of sense; and at last, of all of us, he was the only one who was astonished at his being proclaimed first among the elected.

This period corresponds to continuous and indefatigable labour, which at a later period yielded its fruits to Nélaton, but the immediate result of which is yet another of the significative characteristics of his moral nature. He worked, and worked hard, but others reaped the honour. Continually some new-fledged author, some candidate not too far advanced or even some professor from whom the editor of a *dictionnaire* had extorted the promise of an article, sought out our friend. His advice was sought, and he presented a memoir—I say presented, for he never dreamed of accepting any lucre for his complaisance. At certain epochs this became an *exploitation* on a large scale. In 1844, for example, when in a *concours* all the candidates demanded Nélaton's advice on their theses, he had not the courage to refuse any of them. Nay, so willingly did he lend himself to these demands that at the last hour he was obliged, in order to satisfy them all, to pass the night in the printing-office.

The same qualities to which he owed his first success obtained for him some years after what was then called the field-marshal's bâton of our profession—a chair *obtained by concours* in the Faculty of Paris. The very non-militant life of this candidate, his almost utter want of show of scientific work done, his reserved manner, and unpolished speech, would have damaged any other but him in such an arena—now closed, but once the theatre of so many brilliant passages of arms. But neither the spectators nor the jury allowed themselves to be deceived. "Celui-là, on sait, qu'il sait," said a good judge—a true expression, which supplied the motive and justification of his nomination. But was there not also a secret prompting? If we are to believe the intimate chronicle of this last *concours*, the absence of certain qualifications had, under the circumstances been of more service to Nélaton than those which he had given proof of possessing. "Oh! as for that one," exclaimed a professor, "we may safely nominate him; he is not cut out for practice."

The professor to whom this calculation was attributed, himself an experienced clinician, had not much reason to applaud his own prognosis in this case. Nélaton's professional soon equalled his professorial success. I cannot here repeat all the marvels of his double career, so brilliantly accomplished and so superabundantly complete. What strikes me and what I wish to note is that Nélaton always continued such as we had known him—meriting his celebrity, while avoiding to proclaim it. Just as his pupils felt themselves attracted by his words, without show or pretension, to him who in searching with them taught them the art of finding, so also were his patients seduced by that half-smile of affectionate assurance and visible sincerity which seemed to say to them far better than in phrases, "I have searched out your disease, and am able to cure it. Why tremble? Do I look uneasy?" This man, so thoroughly true, and so indulgent for all and everything, was unjust towards himself. His good fortune astonished him. "It seems to me that I am in a dream," said he to me one day in 1863, when showing me the sumptuous *salons* of his hotel. "I am quite ashamed of the money I gain," he has been many times heard to repeat.

After adverting to the affection borne by Nélaton towards his provincial brethren, and especially for those of the Lyons school, M. Diday thus concludes—

"May this *souvenir*, the sincerity of which it is pleasant to me to attest, be my excuse for this imperfect sketch. It would be easy for me to complete it, and I might try to render it interesting; I prefer to leave it instructive. May not the analysis of the elements which have concurred for the elevation of Nélaton, and the exhibition of the conditions by which he acquired his fortune and renown—alike legitimate,—prove of service to his successors, as well as to all those who aspire to become such? If I have succeeded in throwing a few rays of light on their path, I shall be compensated for any sadness which I have felt in the task. A consolation, indeed, already has offered itself to me, and that is derived from this thought—born of my subject—namely, that the age which has produced a man at once so great and so simple cannot be so much the slave of pomp and appearance as it has been represented to be, and that knowledge is certain to triumph over charlatanism whenever it resolves never to avail itself of any of its arms."

LETTERS ON THE SOUTH OF FRANCE.

(*From a Foreign Correspondent.*)

AIX-LES-BAINS (SAVOIE).

AIX, although not usually looked upon as the South of France, may be so considered, both from its situation and its climate. It is distant from Lyons only a few hours' journey towards the Mediterranean, and under a degree of latitude which gives it a touch of the blue sky of Italy. The climate of Aix is mild in winter. Chestnuts and fig-trees flourish, and snow seldom falls.

We passed some weeks in Aix, and it seemed to us that the climate had much analogy with that of Pau. Here, as in Pau, strong wind is not frequent, and the invalid can be benefited by sound sleep. For many ages the waters of Aix have been successfully used in the treatment of chronic rheumatism in the form of vapour-baths, ordinary baths, and douches. Their utility is incontestable in many cases of anchylosis and chronic ulceration. During the late war they worked wonderful cures of wounds.

Dr. Brachet, a military doctor who was especially charged with the treatment of the wounded in Aix, attributes to its waters a remarkable power of facilitating the expulsion of bone fragments.(a) How far these properties of the waters of Aix are to be attributed to their chemical composition, especially to the sulphuretted hydrogen contained in them, we do not seek to determine; common water, perhaps, of the same temperature, and used in the same manner, would produce similar effects. But the particular apparatus used at Aix, and the experience of the doctors and persons employed in its application, are not to be found everywhere.

We take this opportunity to make a remark concerning watering and climate stations in general. When once a place of this kind has a name, it does not matter in what manner, for being very useful in a particular disease, it has a great chance of really acquiring this property. In the same way, a doctor who has once the reputation of being very clever, has a good chance of becoming so. Why is this? In the first place, trust is a wonderful auxiliary in every medical case. A patient who believes that he is going to a place where he is likely to be cured has made the first step towards health. But there is another reason. When once a place has the reputation of being a specific against a disease, the consequence will be that a great number of patients afflicted by the same disease will flock thither. The medical men of the place will therefore be driven to pay special attention to the treatment of that disease, and will acquire particular experience and skill in this direction. In fact, the place soon becomes a school for specialists. Resources of every kind will also be provided as soon as they contribute to the treatment of such disease; and even if the virtue of the place should be at first purely illusory, it will become real by means of art. At Aix, for instance, where rheumatic patients predominate, the attendants have acquired a proverbial perfection in the art of *douching* and *massage* (shampooing). M. Brachet possesses besides a splendid constant-current galvanic battery, an example which deserves to be imitated by his colleagues. For chest invalids and sufferers from other kinds of exhaustion there is facility for obtaining milk of different kinds and from the various species of mammalia.

We have mentioned some affections in which the waters of Aix are useful. These waters may do good service, however, in many other maladies. Their use is evident in every case where perspiration and congestion of the skin are indicated. It is also scarcely necessary to add that they possess the therapeutical power of all sulphuric waters in the treatment of syphilis, skin diseases, and chest complaints. In this respect they are analogous to the waters of the Pyrenees. The waters of Aix are, besides, very rich in active elements, especially in sulphuret of sodium. The waters of Challes (a place in the environs), which are frequently used at Aix, contain more sulphur than any waters of the Pyrenees. To this may be added that the elevation of Aix is only 240 mètres above the sea; whereas Cauterets, Eaux Bonnes, etc., are much higher. This is a great virtue of Aix, especially for sufferers from the chest, who are generally incommoded by a too great rarefaction of the air.

For the treatment of tuberculosis Aix has been warmly recommended in an interesting book by the late Dr. Berthet—"Aix-les-Bains, ses Thermes" (Chambéry, 1862). Dr. Berthet must have been a man of much intelligence and talent for observation. In his own case he experienced much good from the inhaling and drinking cure. Many of the innovations he proposes in his book have since been carried out at Aix.

Aix itself possesses three kinds of mineral water—four, if we add that of Challes, in its close neighbourhood. In the town are two very warm sulphurous springs, which feed the baths and inhalation cabinets of the great establishment. One of these springs is improperly called "Source d'Alun," being simply a sulphurous water. At a quarter of an hour's distance from the town there are cold sulphurous springs in a park called Marlioz. These also are used for baths and inhalations. Every half-hour an omnibus leaves Aix for Marlioz. The park of Marlioz is beautiful. There is a restaurant for general refreshment, and a farm where fresh milk can be obtained at any hour in the day.

We see, then, that a cure in Aix as regards baths, douches, and inhalations can be equally made with cold and warm water. It must be remarked that the warm cure requires especial care, particularly in bad weather, for the patient is obliged to go through the cold to reach his home after its application. He is generally wrapped in blankets, and carried in a chair closely curtained on all sides. Still it is of course quite impossible to shut out the air altogether and prevent its entry into the bronchial tubes. It would be desirable that an hotel were connected with the bathing establishment, in order to prevent this risk to the patient.

The bathing establishment itself is well organised, and affords a curious arsenal of apparatus for douching, inhaling, etc. In the inhaling cabinets ingenious contrivances are made to bring the air in contact with a very large surface of water. To inhale the hot vapour is very soothing to the bronchi, and it acts as a powerful expectorant. The sulphuretted hydrogen mixed with this vapour may have some good effect upon diseased lungs.

At Marlioz the air of the inhaling apartments is charged with sulphuretted hydrogen, produced by cold mineralised water. Here the atmosphere is said to be too irritating for some patients. Aix, in fact, deserves notice as possessing the most valuable therapeutic resources.

Here, too, nature is picturesque. Excursions to Chambéry, Annécy, and Grande Chartreuse may be easily made. There are also steamers plying on the lake of Aix for those who prefer water to land. Ostensibly there is no gaming table, but there is . . . a *cercle*, or club, with very suspicious-looking little green tables! There is one want, however,—the absence of good public music in Aix. The military band of Chambéry alone plays there, and that only twice a week.

The general administration of Aix, as well as the medical men, are most fraternally and generously disposed towards those of the profession. Medical men have the whole cure gratis, even to the use of the omnibus to Marlioz, and free admission for themselves and families to the Casino and Cercle upon being presented by a doctor of the establishment.

(a) See "Traitement des Blessés aux Eaux d'Aix-les-Bains," par le Dr. Brachet, Chirurgien-Major, etc. (Paris: Chaix et Cie.).

ON ENDOCARDITIS IN RELATION TO ERYSIPELAS OF THE FACE.

By Dr. JACCOUD,

Professeur Agrégé à la Faculté de Médecine de Paris.(a)

IT was at La Charité, in 1866, that I observed the first example of cardiac complication occurring in the course of erysipelas of the face. As since then cases have multiplied, each year furnishing me with a more or less rich contingent of facts, I am able, without temerity, to reject the idea of a mere coincidence, and free myself from that prudent hesitation which should prevail with every observer in the interpretation of a new pathological complexus. The following year, at the St. Antoine Hospital, I taught my pupils to inquire into the condition of the heart in spontaneous erysipelas with the same solicitude as in articular rheumatism, eruptive fevers, typhus, or the puerperal condition. In 1868 and 1869, at the Municipal Maison de Santé, I verified new examples of these morbid manifestations; and in the first edition of my "Traité de

(a) *Gazette Hebdomadaire*, 1873, No. 25.

Pathologie" I incidentally indicated them by representing the thermic curves in a case of severe erysipelas accompanied by endocarditis. Later still, my conclusions, based upon a larger number of facts, became wider and more firm; and, in 1872, I was able, in my "Clinique de l'Hôpital Lariboisière," to sum up in the form of propositions all that observation had then taught me concerning the clinical relations of erysipelas of the face and acute cardiac phlegmasia.

Nevertheless, these relations are, it would seem, as yet but little known; and, at all events, their vulgarisation is not proportional to their importance, and I believe that it will be useful to call attention to them in a few words. One of my most distinguished pupils, M. Sevestre, is preparing a work on the subject, *in extenso;* and I now wish simply to enumerate the fundamental facts with the object of diffusing to a greater extent these new clinical ideas, and to secure for my conclusions the priority to which they appear to me to have a right. These, then, are the propositions which my observations allow me to formulate, being, with some additional development, the same that I have published in my "Clinique de la Lariboisière."

Erysipelas of the face should be placed among the acute diseases which present phlegmasias of the heart among the number of their possible determinations. This possibility is realised only in a small number of cases, and in this respect it resembles typhoid and the eruptive fevers. *Endocarditis* is by far the most common form of this heart-affection. By its chronological relations with the exanthem, which it may exceptionally precede or follow, by its relative frequency, and by the uniformity of its characters, this endocarditis proves itself to be a true determination of erysipelas, and not the capricious effect of a chance hazard. It scarcely ever gives rise to the subjective symptoms of primary endocarditis. Scarcely does it induce in some cases an unexpected rise of temperature. It does not announce itself, and is only recognised when it is deliberately sought for. In fact, it has no other positive signs than the phenomena of auscultation corresponding to the seat of the phlegmasia. The endocarditis affects the left auriculo-ventricular orifice, and is a *mitral endocarditis*. Once, in a woman twenty-six years of age, it coincided with a tricuspid endocarditis, the lesions being found, at the autopsy, more marked on the right than on the left side. In no case has the inflammation ever been seated at the arterial orifices.

By reason of its seat, the endocarditis of erysipelas gives rise to the physical signs of acute mitral insufficiency; and it is characterised, with or without *frémissement* on palpation, by a systolic souffle at the apex. The souffle may trench on the *petit silence*, but I have never found it modify the second normal sound. As the other symptoms of endocarditis are usually absent, the diagnosis rests entirely on the verification of the souffle, the characters of which I have indicated. This fact imposes extreme reserve on clinical judgment, for just as we should err in default, and should allow the endocarditis to pass unperceived if we neglected to practise auscultation day by day, so we should err by excess if we attributed to acute endocarditis every souffle that may be heard in the subjects of erysipelas. Here are the rules which have guided my appreciation. I do not regard as significative, or, in other words, I do not impute to acute endocarditis, any souffle that does not correspond to the following conditions:—It must be systolic and at the apex; it arises during the course of the erysipelas or some hours before; it is independent of the thermic degree of the fever which it may survive; the patient has never been affected by articular rheumatism or by pleuro-pulmonary inflammation; and the erysipelas is not actually complicated by pleurisy or pneumonia. In this way may be avoided the causes of error which might lead the judgment astray. The first conditions eliminate the anæmic and the febrile souffles, and the others prevent the fault being committed of attributing to the erysipelas an endocarditis really depending on some other morbid condition. The rigorous observation of these rules guarantees the justice of the diagnosis in the cases in which the autopsy is wanting; and it is because I have never departed from this severity of appreciation that I have been enabled to affirm the pathogenic relations of erysipelas and endocarditis, although, with the exception of two cases, my observations have been purely clinical.

In my lectures at the Lariboisière, I indicated the evolution of this endocarditis in the following terms:—"The erysipelatous affections of the heart may prove fatal during the period of the existence of the disease, but when this actual danger has passed away, they (with the exception of myocarditis) ordinarily terminate in complete resolution. I have not yet seen a single case in which the endocarditis of erysipelas became the point of departure of a persistent valvular lesion. If further observation confirm this negative fact, this endocarditis would be, in this point of view, a much less serious affection than that of rheumatism." Observation, whose teachings I thus reserved, no longer allows me to form so favourable a judgment. I have seen this year a man, twenty-seven years of age, affected by endocarditis during the course of erysipelas of the face, retaining, after his perfect recovery, a systolic souffle at the apex which left no doubt as to the persistence of mitral insufficiency. Consequently, the endocarditis of erysipelas is liable to the same prognosis as that of rheumatism. It may, as it ordinarily does, terminate in complete resolution; it may prove fatal during the acute stage; and it may leave in the valves definite traces of its passage. When, therefore, we are investigating a valvular lesion, it is necessary to inquire concerning anterior erysipelas, just as it is to inquire concerning rheumatism, eruptive or typhoid fevers, or acute diseases of the respiratory apparatus.

Pericarditis is a far more rare affection in erysipelas, and never goes beyond the stage of dry pericarditis, revealed by more or less extensive friction sounds, with or without the *bruit de galop*. It never continues after the termination of the erysipelas, and I have never observed it alone, unaccompanied by endocarditis. For these reasons, it is of far less importance than this latter affection.

Myocarditis, which is still more rare, may accompany endocarditis or exist alone. It can be suspected only when paretic failure of the heart succeeds to a disordered agitation of the organ; and its existence can only be affirmed by an autopsy. This myocarditis, which doubtless is always fatal, and which may furnish the explanation of the unexpected fatal termination of some cases of erysipelas, has not, in my opinion, the same signification as endocarditis. It is no longer a true determination of the erysipelas, but the direct result of the excessive elevation of the temperature—a hyperthermic myositis. The two patients (men of twenty-seven and forty-five years of age) at whose autopsies the initial changes due to myocarditis were exhibited, had both presented a temperature far in excess of that usually observed in erysipelas. Analogous cases, concerning surgical erysipelas, were published by Ponfick in 1868. I need dwell no longer on facts of this kind, which relate only to fatal erysipelas, and are entirely exceptional. The demonstration of endocarditis and endopericarditis occurring in erysipelas of the face in non-rheumatic individuals, is that which constitutes the importance of my observations, and the object of this paper. The clinical and theoretical interest of the facts is, I believe, sufficiently great to justify the persistence with which I have called the attention of my colleagues to them.

REVIEWS.

Surgical Diseases of Infants and Children. By M. P. Guersant, Honorary Surgeon of the Hôpital des Enfants Malades, Paris, Honorary Member of the Société de Chirurgie, etc. Translated from the French by Richard J. Dunglison, M.D. Philadelphia: Henry C. Lee. London: Trübner and Co., 60, Paternoster-row. 1873. Pp. 354.

A book on the surgical affections of early life from one whose authority in such is so generally recognised as is that of M. Guersant is sure to be welcomed by the profession in this country. This volume consists of short essays on the surgical diseases most frequently met with in children. It has been no part of the author's intention to deal exhaustively with the whole of infantile surgery; he desires rather to put on record his views on certain subjects as they have been expressed in his clinical lectures at the Hôpital des Enfants from 1840 to 1860. The reader will find a great deal omitted that he might, perhaps, have expected to meet with, for all those rarer diseases and malformations which occur on an average but once or twice to any one surgeon are not touched upon. Still there is much to detain the attention of the practitioner as well as of the student in these pages. The subjects discussed are those of which the author is evidently well capable of judging from his own practical experience of them, and the descriptions of diseases are clear and concise. There is, however, no attempt at arrangement in the contents of the book; after reading to the end of a chapter on cervical adenitis, we

come upon one on phimosis, followed by another on fractures. Polypus of the rectum is side by side with hypertrophy of the tonsils, and so on throughout there is the same absence of anything like grouping. This is due, perhaps, to the fact that these chapters were originally delivered in the form of clinical lectures, and are now published in the same order in which they were addressed to the students attending M. Guersant's class. But this does not at all affect the subject-matter of the chapters. We will now proceed to mention one or two points in detail; and first we must allude to some very valuable remarks in Chapter I. on the manner of performing operations on the young. The three subjects discussed are important ones—viz., (1) the preparation of the patient, (2) the performance of the operation, and (3) the after-treatment.

In writing under the second heading the author rightly draws great attention to the fact that operations on children are more difficult than in adults, and that a more exact knowledge of anatomy is requisite, because, as the spaces are smaller and the regions of less extent, it is needful to exercise greater caution in incisions, and to limit them to smaller dimensions. Further, as children do not bear pain and long operations well, it is desirable to operate quickly; and for this reason also a most positive anatomical knowledge should be possessed by the surgeon, in order that he, in acting rapidly, might act with confidence.

The subject of tracheotomy in croup receives considerable notice. M. Guersant condemns the operation as a rule when the patient is below the age of two years. The number of successful operations performed prior to that period is, he feels assured, very small. But while evidence of the disease being of a general character, as shown by false membranes in the nose, behind the ears, in the vulva, or on a blistered surface, is a strong contra-indication, false membranes when limited to the air-passages themselves, even though they extend to the trachea and bronchi, do not constitute an objection to the operation. It no doubt would be admitted, however, by the author that the subsequent extension of the inflammation and false membrane along the air-passages below the opening is a most frequent cause of death after tracheotomy for croup.

The method of operation is most minutely dwelt upon, and decided preference is given to the double canula advocated by M. Trousseau. The author states that of the thirty-two children first operated upon, in which the simple canula was used, only two were saved. He considers a dilator indispensable in the operation. The one in use at the Hôpital des Enfants is "devoid of hooks at its extremity, and furnished with a spring which may be opened by pressure, and not by separating the branches."

A clear account of the symptoms of rectal polypi in children, and of the treatment employed by the author, is given in Chapter VII. They are, he thinks, generally formed by a mucous follicle which has increased in volume and become hypertrophied. They are generally found attached by a pedicle just above the sphincter, though in some autopsies he has discovered them as high as the cæcum.

Chapter X., on "Vesical Calculus—Lithotomy—Lithotrity," is one of great interest. We are here informed that "the study of 140 cases of calculus enables me to decide that age makes no difference in the physical and chemical constitution of these foreign bodies. . . . Their form and volume have varied not less than in the adult, for we have extracted some as small as a pea and others as large as a hen's egg." In speaking of lithotrity, M. Guersant says he cannot repeat what he wrote in 1828—"Lithotrity is impracticable in children under five years of age." His experience at the present time is favourable to this operation at all ages—even in children fifteen or eighteen months old, without regard to sex. In cases in which, from the size, hardness, or adherence of the stone, or when more than one is present, lithotrity is unfavourable, lithotomy must be resorted to, and among the various methods of this operation he likes best the bilateral.

In Chapter XV. the operation of hare-lip is described. The author disapproves of the universal employment of twisted sutures, and advocates Thierry's needles, made of iron, with a movable lance, which, when once removed, enables a little screw to be slid on, which may be tightened or loosened at will. When these needles are not used, the plan resorted to by M. Guersant, and also by his successor M. Giraldès, is to pass interrupted sutures of double silk or a silver thread by means of a curved needle.

In Chapter XXV. the subject of "Caries of the Vertebræ" (Pott's disease) is treated of; and in Chapter XXVI. some very valuable remarks are made on "Congenital Imperforation of the Anus and Intestines." When speaking of Amussat's operation for this deformity, the very important difference in the anatomical relations of the kidney in the adult and in the child are alluded to. In the adult we only meet with the inferior extremity of this organ, whereas in the new-born the kidney passes considerably beyond the external border of the quadratus lumborum muscle, and even descends into the iliac fossa.

In the treatment of foreign bodies in the air-passages (Chapter XXVIII.), M. Guersant, all other means failing, would resort to laryngotomy if he thought the body was in the larynx, and to tracheotomy if in the trachea or bronchial tubes.

The treatment of cancer of the eye has been very unfavourable in the hands of the author. Cures have been but of very slight duration, even when the eye has been removed at the commencement of the disease. Relapses have most frequently taken place before the formation of the cicatrix or within one year or eighteen months afterwards, and then the fatal progress has been very rapid.

Cancer of the testicle (Chapter XXXIII.) is no less fatal, the prognosis no less certain. In all cases but one, which was lost sight of, a recurrence was met with. The author has not seen cancerous tumours of the testicle produce ulceration of the scrotum, "neither have we seen chimney-sweeper's cancer, which is more common in England than with us."

In Chapter XXXVI., "On Hypospadias and Epispadias," we find the following remarks:—"Until these later days surgeons restricted themselves to advising the use of bandages and of apparatus to guide the flow of the urine to avoid irritating the skin of the neighbouring parts. More recently Gerdy at first proposed to pare the edges of the skin and afterwards unite them by sutures. Roux of Toulon, Nélaton, and Richard had the idea of performing an autoplastic operation by taking flaps of the skin from the anterior portion of the abdomen to form the anterior wall of the bladder, and to make also walls for the canal of the urethra, divided with the skin and a scrotum. These experimental operations, being painful in the execution and very difficult, have rarely been performed, and have sometimes been followed by death or incomplete results. They do not appear to us worthy of our advocacy, and we can only say that they are not dictated by sound surgery." We think these remarks are too sweeping when read by the light of some of the cases operated upon by our countryman John Wood. If it is true the results have been incomplete, it is also true they have been very beneficial in some instances.

We might extend our references and observations to the whole seventy-three chapters had we the space at our command; but we must conclude this notice of an excellent little volume by saying, as we did at the commencement, that it contains a large amount of useful practical information, and records the experiences of a surgeon well able to give instruction on the subjects he treats of. The English and American readers too may be congratulated upon what appears to be a faithful and simple translation of the original text, without either note or comment by the translator to interfere with the impressions the author's own words are intended to convey.

Lectures on Madness in its Medical, Legal, and Social Aspects. By Edgar Sheppard, M.D., M.R.C.P., Professor of Psychological Medicine in King's College, London, and one of the Medical Superintendents of the Middlesex County Lunatic Asylum at Colney Hatch. London: J. and A. Churchill. Pp. 186.

It is not our rule to criticise lectures or communications which have appeared in our own columns, nor should we have done so on the present occasion had it not been for some sharp comments directed not to the matter but to the manner of the book, which substantially consists of the lectures Dr. Sheppard published in this journal. It is hardly fair to deal with the mere surface of any man or thing sound and honest at heart, however awkward it may seem; but on the present occasion there is not even such an excuse, for the language, though striking, is not the less clear on that account; and allowance must always be made for the difference between a spoken and a written discourse. This is, for instance, specially notorious in the matter of sermons: a preacher may deliver a discourse which seems to his hearers singularly striking, but which, when printed, loses all the *vis viva* it derived from the man's

lips. We would beg our readers, therefore, to look into the substance of these lectures. Dr. Sheppard is a man well skilled in his profession, and who has had a long experience as an alienist. To a shrewd man the mass of human waste congregated in such an Asylum as Colney Hatch must be full of instruction; and though it may be impossible to single out individual cases, the broad generalisations and conclusions of such a man are worth listening to.

An Introduction to Pathology and Morbid Anatomy. By T. Henry Green, M.D. Lond., M.R.C.P., Lecturer on Pathology and Morbid Anatomy at Charing-cross Hospital Medical School, and Senior Assistant-Physician to Charing-cross Hospital. Second Edition.

The present edition of Dr. Green's excellent little manual may be looked upon as a very decided improvement on the last. A considerable quantity of new matter has been added, and many new and beautiful wood engravings, which are of especial value in a work of this kind, which cannot always be studied with the aid of actual specimens. The most important additions have been in the domain of tubercle and pulmonary phthisis, to which Dr. Green has devoted much care and attention. The views here expressed are substantially those advanced in our columns some time ago in some papers by Dr. Green. A chapter has also been added on septicæmia and pyæmia. Altogether we are in a position to endorse the encomiums we formerly passed on the volume, as being the best we could put in the hands of the student.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

October 6.

Enlargement and Opening of the School of Medicine—List of Successful Students.

More than usual interest has been attached to the commencement of the present winter session at the Liverpool School of Medicine, in consequence of its being made the occasion for formally opening the extensive additions which have recently been made to the School premises. These additions comprise a new museum, sixty feet in length by thirty in breadth, two chemical laboratories and a balance-room, a large physiological laboratory, a new and most commodious lecture theatre, an injecting-room, a boiler-house, corridors and water-closets, and an increase in the size of the dissecting-room to nearly twice its former dimensions. The museum has a handsome Grecian *façade*, in keeping with the design of the original building. It is well lighted from the roof, and has a light iron gallery running all round it. The floor of the gallery is of thick ground glass, while that of the museum itself is of encaustic tiling. The larger chemical laboratory in which the students perform their practical work is fitted up with great care and completeness, and affords every facility to the student for the prosecution of a most important and interesting branch of his curriculum. The most interesting addition of all, however, is probably the physiological laboratory, which seems quite a model of completeness, and is surpassed by very few, if any, of the metropolitan schools. It is of an oblong form, well lighted from the roof, and has running down it lengthwise two very long parallel benches, at which the students will work. Underneath the smooth and solid tops constituting the benches are series of drawers for instruments, and cupboards for the microscopes; while let into the tops at regular intervals are basins, with an ample water supply from taps connected with horizontal pipes, which run the whole length, a foot or two above the basins. The width is sufficient for students to work on both sides, so that there is accommodation for a great number. Each pair of workers is provided with a small case, containing some half a dozen liquids, such as carmine solution, glycerine, etc. On one side of the room are glass cases for the general instruments used by the lecturer and demonstrator, while at the farther end are a daïs and desk, from which directions can be given so as to be seen and heard by all in the laboratory. There is no doubt that, under the able management of Dr. Caton, this will become, as it deserves to be, one of the most useful and attractive departments of the School.

The room formerly occupied as a museum is now fitted up as a reading-room and library for the students. Dr. Inman, Consulting Physician to the Royal Infirmary, and formerly a lecturer at the School, has just presented to the library 200 volumes of recent works in medicine, surgery, etc.; while it is indebted to Dr. Vose for a handsome donation in money. Another very important addition for which the creation of the new premises has allowed space is a bone-room. This adjoins the dissecting-room, and is fitted up with a great number of good osteological preparations, with skeletons and plates, and cannot fail to be of the greatest possible advantage to those who are entering on the study of anatomy, to whom a constant reference to the parts of the skeleton is so essential.

The premises were formally opened by J. Torr, Esq., M.P., in the presence of a very large number of medical and other gentlemen from the town and neighbourhood; and after the opening an adjournment was made to the large theatre of the Medical Institution (kindly lent for the occasion), where the introductory address was delivered by Dr. Caton, and the prizes afterwards distributed by Mr. Torr to the successful students, of whom the following is a list:—*Winter Session.*—Exhibitioners: Messrs. T. L. Roberts, J. Lewtas, G. G. S. Taylor, and J. Marmon. Third year subjects: Messrs. G. W. Joseph, silver medal; R. N. Pughe, silver medal; and G. G. S. Taylor, bronze medal. Second year subjects: Messrs. W. F. Shain, silver medal; J. Bark, bronze medal; S. F. Bigger, 1st hon. certificate; A. L. Douglas, 2nd hon. certificate; and E. S. Wood, 3rd hon. certificate. First year subjects: Messrs. J. T. Smith, silver medal; W. H. Wright, bronze medal; W. Gruggen, 1st hon. certificate; and W. Latham, 2nd hon. certificate. *Summer Session.*—Second year subjects: Mr. F. C. Gresham, bronze medal. First year subjects: Messrs. J. Twinem, silver medal; W. Gillibrand, bronze medal; and W. Townson, hon. certificate. Comparative Anatomy and Zoology: Messrs. R. H. Jones, prize; and H. Pilkington, hon. certificate.

I am happy to state that the health of the town continues good, and that no new case of cholera has been introduced.

FOREIGN AND COLONIAL CORRESPONDENCE.

AUSTRIA.

Vienna, October 6.

To-day the first meeting of the private International Conference takes place. The subjects consist in an examination of the exhibits in the Sanitäts Pavillon, and in especial the consideration of the best mode of transporting wounded men. This question will not be decided by a mere examination of the various waggons and ambulance carts, brancards, and sanitary trains, but an actual trial will be made, and a vote subsequently taken. To-morrow we go to Vöslau, the members of the Conference travelling by the sanitary train, when they will see in actual operation the manner in which the transport of wounded men takes place, and form a conclusion as to what is the best way of supporting them. This is a most important matter, and will give rise to an animated discussion. A dinner will be cooked *en route* in the kitchen attached to the train, but not for the delectation of the members of the Conference, who are to be regaled by Professor Billroth in the Hotel Back at Vöslau, where we shall also have the pleasure of listening to the sweet music of Strauss's band, conducted by the distinguished musician himself.

The Empress Augusta of Germany has taken the most lively interest in this sanitary exhibition and in the Conference; it is to her that its installation is mainly, or indeed altogether, due. She has written a letter to Dr. Wittelshöfer, the President of the Sanitary Division of the Exhibition, in which she expresses her thanks to him, together with Professor Billroth and Baron Mundy, for the work they have so well carried out, and her great wish to see the Society whose emblem is the Red Cross perfected and extended, and the sphere of female usefulness as well in peace as in war turned to advantage.

I will not describe the contents of the sanitary pavilion in detail. There are of course many surgical instruments. One case contains what, without much exaggeration, might be described as a collection of bullet-extractors from the time of Hippocrates down to the present day. Bartolomæus, Ambrose Paré, and Garengeot are represented by forceps of rather a clumsy construction, while representing most recent times are several kinds of electric bullet-forceps and extractors. Every

species of bandage and splint finds a place. Also the various methods of applying plaster-of-Paris bandages, models of transport waggons, artificial limbs, specimens illustrating the effects of gunshot injury of bone, photographs of the victims of military science and the triumphs of surgical skill, are largely illustrated.

There is a large French train of eight carriages, elaborately fitted up, and in the surgeon's carriage even luxuriously. Besides isolated carriages from Hamburg, Dresden, and Munich, there is a German train, less elaborate than the French, but I should say equally efficient; it is, in fact, a train which saw much actual service and did good work during the late war.

The first sitting was opened by an excellent speech by the President (Professor Wittelshöfer), who concluded by asking the meeting to call Langenbeck by acclamation to preside over them.

Langenbeck, on taking the chair, alluded to several matters of interest, and feelingly spoke of the sudden death of the Grand Duchess Helena of Russia, who first during the Crimean war brought a woman's aid to the sick and wounded Russians; he also spoke very warmly of Nélaton. After the election of Professor Esmarch, Count Serrurier, General Baumgarten, and Professor Dummreicher as V.P.'s, Baron Mundy and Professor Billroth addressed the meeting as to its scope and objects. Professors Volkmann, Fischer, Roth, Neudorfer, and several other members joined in an animated discussion on the various forms of brancard. It was decided to practically test them before coming to any decision.

Tuesday, the second day of the Conference, was spent in the most agreeable manner possible. A discussion, without decided result, having taken place, we started from the Exhibition grounds, in a long train of eighteen carriages, fifteen being sanitary waggons of the various constructions exhibited in the Sanitäts Pavillon, and the rest ordinary passenger carriages. The carriages communicated with each other by a central passage throughout the train, and it was therefore easy to inspect all the arrangements, and try the relative amount of comfort experienced whilst lying on the different forms of bed and stretcher. The more securely and firmly fixed they were, the more comfortable they appeared to be to me. Those resting on springs or swung in slings afforded a too great freedom of motion, which would, I think, be severely felt by a wounded man. I concluded that, had I myself a broken leg or thigh, I would greatly prefer being transported in what Baron Mundy calls the "*suspension fixe.*" Our experiments were scarcely finished ere we reached Vöslau, the district of one of the best Austrian wines. The weather was beautiful; the scenery is hilly and wooded, and the slopes and plains are all vine-clad. The Hotel Back is on a terrace commanding a superb view. Professor Billroth entertained some eighty guests in what was simply a princely fashion, and the refined gold was gilded by the music of Strauss's band, conducted by the famous Johann himself. Billroth, in a few well-chosen and eloquent words, welcomed his guests: "I greet you, gentlemen," he said (pointing towards the terrace), "with the beautiful scene around us, I greet you also with art (turning towards Strauss), I greet you, in fine, *in Austria with Austria;*" and then the band struck up "The Beautiful Blue Danube," and the effect was electrical. Langenbeck proposed another toast: "I am sure," he said, "everyone here present has been a pupil of Ricord. Let us drink his health. *Moi, le vieux disciple du jeune maître*, do so with all my heart." "Yes," said Ricord, in reply, "I am young, it is true, *mais ce n'est pas ma faute!*"

The voting on the various questions takes place to-day. There will be an almost complete uniformity of opinion; and the official account shortly to appear will form an important document, which cannot fail to arouse public attention and be followed by practical consequences.

After the discussion yesterday morning a trial of the ambulance waggons and *cuisines volantes* was made in the Hippodrome, in the presence of the Archdukes Wilhelm and Karl Ferdinand. Baron Mundy explained various details to their Imperial Highnesses, and the members of the Conference, from the president downward, became for the moment a corps of volunteer sick and wounded, and essayed for themselves the merits of the different waggons. I will not trespass on your space or on your readers' patience by entering into the discussion of those merits here. Those interested will have an opportunity of examining the results arrived at in the report shortly to be issued in a complete form.

To-night (Thursday, 10th) the Archduke Wilhelm, who is the Grand Master of the rich and powerful Teutonic Order, entertains at dinner some of the members of the Conference; and so will end one of the most interesting and agreeable *réunions* at which I have had the good fortune to assist.

WILLIAM MAC CORMAC,
Wien, October 10. Surgeon to St. Thomas's Hospital.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY.

FRIDAY, OCTOBER 10.

P. HEWITT, President, in the Chair.

DR. TILBURY FOX exhibited a living subject affected with Parasitic Sycosis. The patient had been sent to Dr. Fox the day before by his medical man, and on being requested to do so, readily consented to exhibit himself. The disease began at the outer angle of the mouth six months ago by a patch of eruption having all the characters of ordinary ringworm of the surface (tinea circinita). This patch gradually spread until it invaded the whole of the left cheek, the left upper lip, and the left half of the chin. The spreading edge of the patch was always red, very well defined, and herpetic; whilst the central portion became pale, and desquamated slightly. The use of remedies destroyed the disease about the cheek, and the malady now consists of a red, slightly scaly surface, occupying the left half of the upper lip, a little of the right half of the same, and the whole of the left side of the chin. In addition, there are eight or nine small tubercular swellings, one of which is slightly pustular in aspect, and scattered here and there over the diseased area. These lumps began to come about a month since. The hairs in the site of these little tubercles lie loose in the follicle; they come away very readily; they are swollen, lustreless, opaque, and loaded with fungous elements. The man, in addition, has a small circular patch possessing all the characters of ordinary ringworm in the middle of the chin beneath the jaw. Dr. Fox said that he had only met with two cases of this parasitic sycosis within the last few years. As Hebra denied its occurrence, he thought it important to bring the case under the notice of the Society. He further pointed out the unsymmetrical character of the disease, the origin of the latter from common ringworm, the slow development and indolent character of the small tuberculous swellings, and the absence of any decided suppuration, as points of diagnostic interest; the common non-parasitic sycosis furnishing contrasts in these particulars, no less than in the presence of diseased hairs in the one and not in the other. Dr. Fox placed under the microscope specimens of the hairs invaded by the mycelium of the fungus (microsporon metographytes) and also of the root sheath, in which the conidia (or spores) were seen in abundance.

Dr. DUFFIN said this form of skin disease was rare; he had only seen one case. The patient, a German tailor, had a large patch on his chin, and another on the right side of the face. In some parts there were pustules, in others the skin was only red, but in both spores were found. The Vienna physicians maintained that the malady was rare; the Parisian said it was common. At one time Hebra held it to be fictitious, but had now modified his opinion.

Dr. THEODORE WILLIAMS brought forward three cases of Spasmodic Asthma treated by Chloral. The first was that of a married woman, aged 23, who came from the Isle of Man, where, during the last nine months, she had suffered from asthma of so severe a character as to confine her to her bedroom for four months. Various remedies had been tried in vain. On her arrival in town, Dr. Williams did not at first pursue active treatment, hoping that the change of climate might give relief. The fit, however, coming on as usual, chloral was given in twenty-grain doses. After the first dose, she fell asleep for an hour; after the second, she slept a whole night; and a few more rendered her breathing quite clear. The drug was then omitted, and the patient remained free from asthma for more than a week. The second case was that of a lad, aged 16, who had been subject for six years to attacks occurring once a week and lasting three days. Chloral was given during a severe paroxysm, with the result of causing sleep and immediate relief to the breathing. He remained in the Brompton Hospital free from attacks, in spite of several threatenings of

dyspnœa, which were always averted by the timely administration of chloral. The third patient was an unmarried woman, aged 27, with a history of asthma of two years' standing; the attacks occurring every morning, lasting two or three hours, and often recurring in the forenoon. During a very severe one, which occurred in the Brompton Hospital, a variety of drugs were tried with little effect. Chloroform inhalation gave some relief, but caused cardiac intermission. Hypodermic injection of morphia did good, but her increasing lividity precluded its continuance. Chloral was then given in twenty-grain doses, and the first dose induced slumber and easy respiration. The drug was continued in smaller doses for upwards of two months, during which time the attacks seldom recurred, and, when they did so, were extremely mild. Once the chloral was omitted, and the asthma immediately returned, but ceased on resuming it. All the cases were complicated by catarrhal symptoms, and in the third case there was considerable emphysema, which diminished during the patient's stay in the hospital. Biermer, of Zurich, had already used chloral extensively in these cases. Dr. Theodore Williams's own experience, founded on upwards of twenty cases, was decidedly favourable to its use in spasmodic asthma. In only two cases had any bad symptoms arisen.

Dr. Southey said that the patient who had been under his care was of a markedly hysterical temperament, and any little occurence in the ward brought on an attack of asthma. In one bad attack he gave her nitrite of amyl, which seemed to benefit her; but he was not too sure about its efficacy, and it was not a remedy to leave in unskilled hands. In such cases he thought stimulants did most good; and chloral, he thought, would be found most beneficial when the disease was most purely neurotic.

Dr. A. P. Stewart said that chloral seemed to have a decided effect in these cases, but in many he thought it risky and uncertain. In some instances it did well for a time, and then, for no reason at all apparently, it began to disagree, and its use was followed by extreme depression of the circulation to a most alarming extent. In others the same happened after long use. In many cases no doubt it was very good, but he would be strongly disinclined to order it several times a day. Often it gave rise to severe itching, so as to destroy rest, as well as to severe irritation about the eyes. He thought bromide of ammonium in large doses better in every way.

Mr. Nunn had seen some cases of asthma, almost like suffocative attacks, produced by food—in one patient by rice.

Dr. Williams did not think chloral a stimulant, and in one case stimulants properly so-called had been given largely before the chloral. He had seen no mischief arise from its use. The cases he thought mainly due to damp.

Dr. Southey read the account of a case of Chronic Bright's Disease in a young man, aged 21, the subject of syphilis. The patient had had scarlet fever when a child, and had suffered with dysentery several years previously. The first symptom which led to his admission into St. Bartholomew's Hospital was erysipelatous inflammation of the left ankle, following a trivial injury. His urine was loaded with albumen, but was always excessive in quantity; its daily average was fifty ounces, but on many days more than seventy ounces were passed. His temperature was invariably at or above normal, and he presented very trivial anasarca during his illness. Generally his appetite was good, but at times he suffered in the morning sickness, and had severe colicky pains. Among the anomalous symptoms noted were the following:—Bright red patches of erythema came out on different portions of his body, sometimes on the face, at others on the trunk and limbs; they were attended by febrile symptoms, and coppery-coloured stains marked their situation for a while. Their disappearance was usually attended with the most profuse perspirations or critical sweats. These rashes, as well as transient mottlings of the arms and legs, and sudden transitory attacks of acute pain in calves, loins, and back, were attributed by Dr. Southey to the syphilitic poisoning, of which there was further confirmatory evidence in amygdaloid cervical glands, and scars of old buboes in both groins. After being two months under observation, during all which time the microscopical characters of the sediment of his urine varied very little, fatty and granular casts of varying size being always present, although never in large quantity, he was suddenly seized with rigors of a most severe kind. His temperature rose to 103·2°; he complained of general pains in different parts of his body, and especially of headache, localised behind his ears. This was followed by profuse sweating, which afforded some relief. For three successive days these ague-like attacks were repeated. The abdomen then became tympanitic and tender, and acute peritonitis supervened, to which he succumbed after a few days; his temperature gradually rising to 106°, which it reached twelve hours before death. At this high temperature he passed into an insensible state, with protruded eyeballs, dilated pupils, and stertorous breathing; but up to this period his intellectual faculties had never been clouded, and he never exhibited any epileptic convulsions. The necropsy revealed old as well as recent peritonitis, large and soft liver and spleen, large pale fatty kidneys, the pair together weighing seventeen ounces and a half. All the viscera were examined by iodine, but did not furnish any amyloid reaction.

Dr. Silver asked if the kidneys had been tested, as in almost every respect the case was a typical one of amyloid kidney. Such forms of disease usually occurred after syphilis. The quantity of water passed was very large, the amount of albumen considerable, and the specific gravity was also frequently considerable, whilst there was no dropsy and little tendency to uræmia.

Dr. Williams asked what was the nature of the liver and kidney changes.

The President said it was not very common to have constitutional symptoms with scars in the groins. Were there no enlarged glands? He now had a case under his care where there were two kinds of sores and two kinds of glandular enlargement. He had also seen a similar case previously. Scars did not, as a rule, indicate the existence of syphilis.

Dr. Southey said the liver was large and granular. The kidney had all the marks of intratubular change. He thought the case differed from amyloid kidney in the quantity of albumen and specific gravity of the urine passed.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, October 14.

Dr. C. J. B. Williams, F.R.S., President, in the Chair.

Mr. Henry Lee communicated a case of Imperfect Development of the Circular Muscular Fibres of the Rectum and Vagina. The case is one in which a large accumulation of fæces occurred in the lower bowel. It formed a tumour, which extended six inches above the pubes, and was five inches broad. The perineum was deficient, and also the circular muscular fibres of the lower part of the rectum and vagina. These two passages opened in common. The rectum and vagina were always relaxed, and the uterus very imperfectly developed.

Mr. W. Spencer Watson related a case of Idiopathic Hyalitis, with Acute Inflammation of the Vitreous Humour of both Eyes. A man, aged about thirty years, a coal-porter, was seized with dimness of vision, which increased so rapidly that in the course of a few days he could not find his way across the room without a guide, his aspect being characteristic of amaurosis. The ophthalmoscope revealed an uniformly distributed turbidity of both vitreous humours. The diagnosis was uncertain, the patient being a free drinker, and having smoked to excess; he had also an ulcer of a suspicious nature on one leg, but no other traces of anything like constitutional syphilis, and no appearance or history of any other disease. Under a course of mercury, rapidly administered to the extent of rendering the gums spongy and tender, vision rapidly improved, and was completely restored in ten days. The progress of the case (taken in connexion with the simultaneous healing of the ulcer on the leg) points to syphilis as the origin of the disease. It is concluded from this case that inflammation of the vitreous may occur, independently of injuries, without any iritis or choroiditis, and without any impairment of the retina. The rarity of the affection and the very rapid improvement under treatment make the case remarkable.

Mr. Henry Lee said he wished to make a remark on one point in the paper. It was implied that increased action was necessary for repair. But when increased action was going on in one part, there was a diminution in another; so he would say, a diminution of activity in the hyaloid, not an increase, cured.

Mr. Cooper Forster said the author of the paper doubted the presence of syphilis because no scars were found on the penis. If found, they would only indicate one kind of sore; and their absence was no proof that the patient had not had

syphilis. He thought the abuse of tobacco had more to do with producing hyalitis than syphilis.

Mr. SPENCER WATSON, in reply, said there was no enlargement of the glands of the groin. He thought the hyalitis was due to syphilis: he had never seen the excessive use of tobacco produce it; its action was rather upon the nerves. He agreed with the remark made by Mr. Lee, that increased action was not necessary for repair.

OBITUARY.

THE LATE DR. THURNAM, DEVIZES.

(*Communicated.*)

By the sudden death of this able and highly respected physician, on September 24 last, the Wilts County Asylum sustained a loss which will not be easily replaced.

Dr. Thurnam was born at Ludcroft, near York, on December 28, 1810. As his parents belonged to the Society of Friends, his education was of a private character; but to the excellence of it, it may in justice be said, the pupil was a living testimony.

After passing through the required course of medical study he became a Member of the Royal College of Surgeons of England in 1834. In the same year he was appointed the Resident Medical Officer of the Westminster Hospital, which office he held till 1838, when he was chosen as the Superintendent of the Retreat near York. In 1843 he became a L.R.C.P., and in 1846 M.D. of King's College, Aberdeen. That during the above periods he distinguished himself by the zeal and ability with which he cultivated various branches of medical science there is ample proof. Amongst others may be cited the various published memoirs which he contributed on different pathological subjects, more especially those on partial and spontaneous aneurism of the heart, to the great merits of which all writers on cardiac diseases of that period, whether in this country or on the Continent, have borne testimony.

During his residence at the Retreat, he published in 1841 the "Statistics of the Retreat," and in 1843, "Observations on the Statistics and Treatment of Insanity." Of this latter work it was stated, at the time of its publication, that in its application of the numerical method to the subject of insanity, "we may appeal to Dr. Thurnam's work as an example of the interesting and novel results which may thus be deduced, and which, though they might be suggested by ordinary individual experience, are only capable of being established as facts by calculations founded on a large number of observations. Those only who, like ourselves, have been somewhat extensively engaged in statistical researches, will be able fully to appreciate the amount of labour and care which is required to insure the accuracy which throughout characterises Dr. Thurnam's work." Before referring farther to the chief scene of his labours, we think it will not be out of place here to remark that, though he evinced so much assiduity in the pursuit of strictly medical subjects, it was by no means to the exclusion of other branches of scientific research. As a Fellow of the Society of Antiquaries, Dr. Thurnam, by his joint editorship of "Crania Brittanica," his "Observations of British and Gaulish Skulls," and by various contributions to the different journals on allied subjects—by all these he had earned for himself no mean degree in the domain of archæology and antiquarian lore. In the Wilts Archæological Society, as a member of the council, he had in different ways rendered valuable service. In the annual excursions of the Society he was not unfrequently looked to as an expositor of the objects of interest which were being visited.

In 1849 he was selected by the magistrates of the county of Wilts as the suitable and proper person to whom to entrust the management of first establishing and afterwards of superintending their asylum, which was opened for the reception of patients in 1851. The ability manifested and the success which attended his labours in this important undertaking may be considered as having fully justified their choice. What evidences of painstaking diligence and high conscientiousness he had shown in the pursuit of medical science were the more manifestly developed in the discharge of the duties which he had thus undertaken. It is hardly doubtful whether in this aspect of his varied labours he did not belong to the "countless numbers" referred to by the Premier at the late meeting of the Medical Association, who "are true martyrs of humanity, exhausting themselves in a ceaseless unnoticed anxiety for those whose sufferings they seek to alleviate." It is well known to the writer that not only was Dr. Thurnam much respected as well as beloved by the poor patients in the midst of whom he spent so large a portion of his life, but in the difficult duty of governance his patience and tact in settling disputes which from time to time might occur won for him the title of the "peace-maker," or, as one of his *employés* recently expressed himself on the same subject, "he ought to have been a judge." His practice on such occasions was such as might well be followed by others under similar circumstances. He would allow each to state his case, and then appoint a time a few hours later, on that or the following day, when he would hear them more fully, and decide the point in hand, thus allowing time for the passions of each to subside. By these means, we have understood, he uniformly succeeded.

For some time previous to his death he had complained of headache and drowsiness, but which he had hoped that change and rest would prove adequate to remove. Not having been able to effect his purpose, but expecting to do so shortly, he remained at his post to the last; and even on the morning on which he died he had been into the wards of the Asylum to attend to some sudden call of duty. Even his last words evinced the possession of his faculties immediately previous to an apoplectic seizure which soon terminated his existence.

Dr. Thurnam has left a widow and three sons, with whom we know a large number of friends, both lay and professional, deeply sympathise. Of him it might be truly said that he died beloved and lamented. Both attendants and patients (*i.e.*, those of the latter who were in a condition to comprehend what had occurred) evinced most sincere grief at their unexpected loss.

W. HOWITT, F.R.C.S.

On Tuesday, William Howitt, of Fishergate-hill, Preston died at the age of 63. Since April last the deceased gentleman had been ill, and his demise makes the third death in the family since 1869; for in November of that year his eldest daughter died; in 1870 Mrs. Howitt, his wife, died; and now we have to record his decease. Mr. Howitt was a native of Lancaster, having been born there in August, 1810. He was educated at Lancaster Grammar School; and on completing his tuitional course there he remained for a time with his father, who followed the medical profession in the county town. Afterwards he went to London, where he studied for the same profession; then he proceeded to Paris with a similar object in view; and in 1835 he came to Preston, and started practice on his own account. Mr. Howitt, who was a Fellow of the Royal College of Surgeons of England, continued in active practice in the town up to about 1867; and till the period of his final illness he held the appointments of certifying surgeon to the factories of the town, and district surgeon to the London and North-Western and the Lancashire and Yorkshire Railway Companies. On January 5, 1870, he qualified as a magistrate for the County of Lancaster; and in that capacity he was always on the side of judicious management and sound economy. For many years he acted as a guardian for Preston; on two occasions he was chairman of the board; and up to the time of his death he held the office of vice-chairman of that body. In religion Mr. Howitt was attached to the Church of England; in politics he was a Liberal; but during recent years he virtually withdrew altogether from the turmoils of party and the conflicts of the "isms." During his illness his medical advisers were Dr. Fernside, Dr. Brown, Dr. Dixon, of Preston, and Dr. Southam, of Manchester. The remains of Mr. Howitt were interred in Preston Cemetery. The funeral, in accordance with a previously expressed wish, was of a very private and unostentatious character.

THE following grace passed the Senate of the University of Cambridge on the 16th:—"That, on the recommendation of the Local Examinations Syndicate, a student, though he is above the age of sixteen, may be admitted to the examinations for students under that age, provided that he produces a certificate signed by a graduate of the University, or a member of the medical profession whose name is on the Medical Register, that such graduate or member believes him to be *bonâ fide* intending to become a medical student; and that the names of students admitted under this condition and satisfying the examiners be sent to the Registrar of the General Medical Council, but that the ordinary certificates be not granted to such students."

MEDICAL NEWS.

THE QUEEN'S UNIVERSITY IN IRELAND.—The annual meeting of the Senate for the purpose of conferring degrees, honours, and diplomas was held in St. Patrick's Hall, Dublin Castle, on the afternoon of Thursday, October 16. The chair was taken by Sir Dominic Corrigan, Bart., M.D., M.P., Vice-Chancellor of the University. From a statement in the Vice-Chancellor's introductory speech, it appeared that in the twenty-three years of the existence of the University the degree of B.A. had been conferred upon 795 candidates, that of M.D. on 635, and that of M.Ch. on 250 candidates. The following degrees in Medicine and Surgery were subsequently conferred :—

DEGREE OF M.D.

First Class.—Aurelius Victor Maybury, Cork.

Second Class.—Robert Clements, Belfast; Louis Richard Dawson, Belfast; Edwin Hemsted, Belfast; Roger Macauley, Galway; Michael Walsh, Galway.

Third Class.—Michael White, Galway.

Passed.—Ringrose Atkins, M.A., Cork; Robert Talbot Beamish, Cork; John Lane Corbett, Cork; Henry Corby, B.A., Cork; Francis E. Davis, Belfast; Richard J. Drury, B.A., Galway; Robert Kerr Eccles, Belfast; A. Mathewson Edge, Belfast; William Irvine Faulkner, Belfast; John E. Vaughan Foss, Cork; Thomas J. Gallwey, Cork; Alfred J. Gilmore, Belfast; Joseph Henry Gormley, Galway; John Wilson Hamill, Belfast; Richard Heath, Belfast; Benjamin R. Jagoe, B.A., Cork; Edward H. Kelly, Belfast; William Young Kingston, Cork; Richard R. Leader, Cork; Charles H. MacCartic, B.A., Cork; Charles E. M'Glinchy, Belfast; Hugh M'Millen, Belfast; James Moran, Cork; John Morris, Galway; Jarlath J. Mullen, Galway; Edward J. Murtagh, Cork; John William Nicholls, Galway; William Pearson, Cork; Charles M. Plowmau, Cork; Caleb K. Powell, Cork; Richard Frith Quinten, B.A., Belfast; Joseph Robertson, Belfast; Edward Shipsey, Cork; Carew C. Howard Smyth, Cork; Michael Sweetman, Cork; William E. Warren, B.A., Galway; John Forsyth Wilson, Galway.

DEGREE OF M.CH.

George W. F. Armstrong, M.D., Cork; Ringrose Atkins, M.A., Cork; Philip Lambert Benson, M.A., M.D., Cork; John Lane Corbett, Cork; Henry Corby, B.A., Cork; Francis E. Davis, Belfast; Louis Richard Dawson, Belfast; William Irvine Faulkner, Belfast; Thomas J. Gallwey, Cork; Michael Gillespie, B.A., M.D., Galway; Alfred J. Gilmour, Belfast; A. Joseph Andrew Gormley, Galway; Richard Heath, Belfast; Edwin Hemsted, Belfast; Benjamin Richard Jagoe, B.A., Cork; David Johnson, M.D., Belfast; Edward H. Kelly, Belfast; William Young Kingston, Cork; Richard R. Leader, Cork; Hugh M'Millen, M.D., Belfast; John Andrew Malcomson, M.D., Belfast; Aurelius Victor Maybury, Cork; William Molloy, M.D., Belfast and Cork; Douglas Mullen, M.D., Galway; Jarlath J. Mullen, Galway; John William Nicholls, Galway; William Pearson, Cork; Charles M. Plowman, Cork; Caleb K. Powell, Cork; Richard Frith Quinteu, B.A., Belfast; Edward Shipsey, Cork; William Simpson, M.D., Galway and Belfast; Carew C. Howard Smyth, Cork; Michael Sweetman, Cork; Michael Walsh, Galway; William Edward Warren, B.A., Galway; John Wheeler, M.D., Cork; Michael White, Galway; John Forsyth Wilson, Belfast; Alexander Wylie, M.D., Belfast.

Diplomas in Midwifery were granted to—

George W. F. Armstrong, M.D., Cork; Ringrose Atkins, M.A., Cork; J. Laue Corbett, Cork; Louis Richard Dawson, Belfast; Robert Kerr Eccles, Belfast; Thomas J. Gallwey, Cork; Michael Gillespie, B.A., M.D., Galway; Alfred J. Gilmour, Belfast; David Johnson, M.D., Belfast; Edward H. Kelly, Belfast; William Young Kingston, Cork; Richard R. Leader, Cork; Hugh M'Millen, M.D., Belfast; Aurelius Victor Maybury, Cork; William Molloy, M.D., Belfast and Cork; John James Morris, Galway; Douglas Mullen, M.D., Galway; Jarlath J. Mullen, M.D., Galway; John William Nicholls, Galway; Richard Frith Quinten, B.A., Belfast; William Rutherford, M.D., Galway; William Simpson, M.D., Galway and Belfast; Carew C. Howard Smyth, Cork; Michael Sweetman, Cork; Michael Walsh, Galway; John Wheeler, M.D., Cork; John Forsyth Wilson, Belfast; Alexander Wylie, M.D., Belfast.

Prize in Composition, limited to the competition of undergraduates in medicine—

Prize awarded for the essay signed "Hermes Trismegistus," to Daniel Wilson, of Queen's College, Cork.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meeting of the College held on Tuesday, Wednesday, and Thursday, October 14, 15, and 16, the following candidates obtained the licence to practise Medicine :—

Bourke, George Deane.	Kelsall, Edward William.
Horne, Patrick.	Stoney, George Legge Buchanan.
Kelly, Michael James.	Wolfenden, Joseph Hines.

The diploma in Midwifery was granted to—

Bourke, George Deane.	Stoker, William.
Kelly, Michael James.	Stoney, George Legge Buchanan.
Kelsall, Edward William.	Wolfenden, Joseph Hines.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, October 16 :—

Eastall, Henry Francis, Shooter's Hill-road, S.E.
Waller, William Bevan, Milner-square, Islington.

The following gentleman also on the same day passed his Primary Professional Examination :—

Crawshaw, Benjamin, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

LUSH, W. J. H., M.R.C.S. Eng., L.R.C.P. Ed., L.M.—Medical Officer to the Fyfield District of the Andover Union, *vice* Mr. Hammond, resigned.

MILITARY APPOINTMENTS.

WAR OFFICE.—MEDICAL DEPARTMENT.—Surgeon Thomas Ramsay, to be Surgeon-Major, *vice* William Henry Price, placed on temporary half-pay. Surgeon William Temple, M.B., V.C., to be Surgeon-Major, *vice* Robert Watson, placed on temporary half-pay. Surgeon William Kippen Stewart, M.D., to be Surgeon-Major, *vice* Alexander Richmond, retired on temporary half-pay. Surgeon James Joseph McCarthy, M.D., to be Surgeon-Major, *vice* Joseph Salkeld Johnstone, M.D., retired on temporary half-pay. Surgeon Usher Beere Eaton, M.D., is placed on temporary half-pay. The restoration to full-pay of Staff Assistant-Surgeon Alexander Neill, which appeared in the *Gazette* of August 15, 1873, is cancelled.

ARMY HOSPITAL CORPS.—Apothecary to the Forces Francis Dancy Hamilton, to be Lieutenant of Orderlies.

BIRTHS.

CALTHROP.—On September 1, at Patialah, Punjaub, India, the wife of C. W. Calthrop, M.D., Sanitary Commissioner, of a son, who survived his birth only a few hours.

CAREY.—On October 12, at Weston-super-Mare, the wife of Sanger Carey, M.D., Surgeon-Major 24th Brigade Depôt, of a son.

CARMICHAEL.—On October 13, at 42, Northumberland-street, Edinburgh, the wife of James Carmichael, M.D., of a son.

HOFFMAN.—On October 18, at Fulham, the wife of H. W. Hoffman, M.B., of a daughter.

JONES.—On October 20, at Grange House, Bromley, Kent, the wife of Alfred Orlando Jones, M.D., of a son.

KERR.—On October 18, at Markyate Street, near Dunstable, the wife of Norman S. Kerr, M.D., F.L.S., of a daughter.

THOMAS.—On October 15, at 97, Bradford-street, Birmingham, the wife of William Thomas, M.B., F.R.C.S., of a daughter.

WALL.—On October 19, at 2, Burlington-road, St. Stephen's-square, the wife of Reginald Bligh Wall, M.R.C.S., of a daughter.

MARRIAGES.

BEAUMONT—PERFECT.—On October 13, at West Malling, Kent, Robert W. Beaumont, Staff Surgeon H.M.S. *Northumberland*, to Jane (Jeannie), daughter of the late George Leopold Perfect, M.D., and stepdaughter of Thomas Harvey Lowry, M.D.

DAVIES—ALLEN.—On October 16, at St. Stephen's, Avenue-road, St. John's-wood, David J. Davies, Esq., of Liverpool, to Elizabeth Annie Lawrence, eldest daughter of David John Allen, M.D., of Wellington House, St. John's-wood.

GRELLET—HANSCOMBE.—On October 16, at Shillington, Beds, Charles John Grellet, M.R.C.S., of Hitchin, to Martha Ann, only daughter of the late William Hanscombe, Esq., of Pirton Grange, Herts.

DEATHS.

DOWARD, JAMES, Inspector-General of Hospitals, Madras Army (retired), at Haddington, on October 18.

GILBERT, ANNA MARION, widow of the late Henry Gilbert, M.R.C.S., of Kensington, at St. Wilfrid's Haylands, Ryde, the residence of her son-in-law, the Rev. Stuart Scholefield, on October 16, aged 60.

GODWIN, JAMES, M.R.C.S. Eng., L.S.A., at Twyford, near Winchester, after a short illness, on October 3, aged 42.

GORDON, CHARLES ALEXANDER, aged 18, serving on board the *Penlomond*, second son of Deputy Surgeon-General C. A. Gordon, M.D., C.B. The ship was last spoken on October 11, 1872, in lat. 8° N., long. 25° W.

HARRISON, AMELIA ECKFORD, widow of the late John Harrison, M.D., at Hampstead-lane, Highgate, on October 16.

MUGGERIDGE, ELLEN GRICE, wife of Henry Harris Muggeridge, M.R.C.S. Eng., L.S.A., of Norfolk-terrace, Bayswater, W., on October 14.

RENDLE, SOPHIA, wife of Edmund Rendle, M.D., at 6, Buckland-terrace, Plymouth, on October 18.

STOKES, HELENA SARAH, youngest daughter of William Stokes, M.D., at 5, Merrion-square North, Dublin, on October 18.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CHERTSEY, EPSOM, REIGATE, AND DORKING.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to Mr. Francis H. Beaumont, Buckland Lodge, Reigate, on or before November 1.

DALTON-IN-FURNESS DISTRICT LOCAL BOARD.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to F. H. Clark, Clerk, Dalton, on or before October 31.

GOOLE AND SELBY UNIONS.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to the Clerk to the Guardians of the Selby Union, or or before October 30.

GUEST HOSPITAL, DUDLEY.—Honorary Surgeon. Applications, with testimonials, to Mr. E. Poole, Secretary, on or before October 31.

HALIFAX INFIRMARY.—Assistant House-Surgeon. Candidates must possess one qualification. Applications, with testimonials, to the Chairman of the Medical Staff, on or before October 28.

KENT AND CANTERBURY HOSPITAL.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to the Board of Management, before October 28.

LEEDS PUBLIC DISPENSARY.—Senior Resident Medical Officer. Candidates must be duly registered. Applications, with testimonials, to Mr. John Horsfall, 31, Albion-street, Leeds, on or before November 6.

LIVERPOOL DISPENSARIES.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before October 29.

METROPOLITAN DISPENSARY AND CHARITABLE FUND.—Physician. Candidates must possess a Diploma from a British University, and also be Fellows or Members of the Royal College of Physicians, London, or undertake to become so within six months after election. Applications, with testimonials, to the Secretary, before November 15.

QUEEN'S COLLEGE, GALWAY.—Professor of Materia Medica. Applications, with testimonials, to the Under-Secretary, Dublin Castle, on or before October 27.

RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY.—Resident Medical Officer. Candidates must be doubly qualified and registered. Applications, with testimonials, to the Secretary, 13, Cavendish-street, Ramsgate, on or before November 9.

ROYAL FREE HOSPITAL.—Senior House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before October 29.

SWANSEA UNION.—Medical Officer of Health for the Rural Parishes in the Union. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to G. B. Haynes, Clerk, 5, Fisher-street, Swansea, on or before November 1.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WILTS PAUPER LUNATIC ASYMUM.—Medical Superintendent. Candidates must be duly qualified and registered. Applications, with testimonials, to Mr. A. G. Meek, Clerk to Committee of Visitors, Devizes, on or before October 28.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Plomesgate Union.—Mr. N. F. Hele has resigned the Aldborough District; area 7425; population 2774; salary £40 per annum.

APPOINTMENTS.

Belford Union.—Lewis G. Broadbent, M.D. Aberdeen, M.R.C.S.E., L.S.A., to the Eastern District.

County of Kent.—Henry Letheby, B.M., and Charles M. Tidy, B.M., as Analysts.

Easingwold Union.—Tertius D'Oyley Pain, L.S.A., to the Alne District.

Neath Union.—John H. Davies, M.R.C.S. Eng., L.S.A., to the First Eastern District.

A NEW wing is to be added to the City Lunatic Asylum, at Stone, at a cost of £9000.

MR. A. W. BLYTH, of Worcester, surgeon, has been elected Medical Officer of Health for the district of Martley.

THE fever in Memphis, New York, has so much subsided that the quarantine restrictions have been withdrawn.

THE epidemic of small-pox is very serious at Rio. The disease is generally prevalent throughout the empire.

THE guardians of Rotherhithe are about to erect an infirmary for the sick-poor of St. Olave's Union at a cost of £12,000.

WE regret to learn from India that Dr. Lang, Assistant-Surgeon to one of the regiments in Cachar, was drowned while bathing on the 12th ulto.

NINE hundred and thirty-eight cases of cholera had been reported at Berlin from the breaking out of the epidemic up to the 13th inst. Of these 628 were fatal, 223 recovered, and 87 remained under treatment.

A HOT spring, marking 90° Fahr., has been discovered (says the *Swiss Times*) in the neighbourhood of Schams, in the Grisons, and near to the saline spring of Tarasp—another spring of the same character as the latter.

THE Governor of Malta reports that the health of the island and its dependencies was good throughout the year 1872. The deaths were 3326.

DR. TIDY'S report of the health of Islington for the five weeks ending September 27 states that the death-rate was only 15·2 per 1000 as compared with 20 per 1000 for the whole metropolis.

THE return of deaths in the Punjaub, registered in the week ending August 23 last, states that the usual autumnal increase in sickness has begun. This is most marked in the districts from Lahoro southwards. The mortality in large towns is also on the increase. Only two deaths were registered from cholera during the week; they occurred in the rural circles of Ludiánah and Jhelam. Of these nothing is known; but from accounts just received from Gurgáon it would appear that the disease is not yet extinct there, as was hoped, but has made its appearance in two other towns there—namely, Mazaffra and Firozpúr. In the former, between August 28 and September 2, eighteen cases and two deaths were reported, while in the latter thirty-four cases and fourteen deaths occurred between September 1 and September 5. It has also broken out in the town of Nizám-ud-din, only a few miles from Delhi, where twenty cases and seven deaths have been reported.

LEEDS SCHOOL OF MEDICINE.—The number of new students who have entered the Leeds School this year is twenty-eight. The total students attending now is ninety-five.

CLINICAL SOCIETY.—At the meeting of the Clinical Society on Friday evening, October 24, papers will be read by Sir William Gull on "Anorexia Hysterica" and on "A Cretinoid State superveuing in the Adult," and Dr. Guinier, of Montpellier, will show a new method of "Gargling the Larynx," illustrating this upon himself.

MR. JOHN FLINT SOUTH.—This gentleman, whose resignation of his seat in the Council of the Royal College of Surgeons was accepted at the last meeting, was admitted a Member of the College so long ago as August 6, 1819—before some of the present members of the Council were born. He was one of the first of the Honorary Fellows, having been elected December 11, 1843. He had previously—viz., in 1841—been elected a member of the Council, conjointly with Mr. Arnott; in 1844 he was appointed Hunterian Orator; in 1849, with Mr. Cæsar Hawkins, he was elected a member of the Court of Examiners; and in 1851 he received the highest honour his colleagues could offer him—viz., the President's gown; he was re-elected to this high office in 1860. With Mr. South the life-membership of the Council expires.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.—The general annual meeting for the election of officers for the session 1873-74 was held in the College hall, Kildare-street, on the evening of Wednesday, October 15. The chair was taken by Dr. James Duncan, President elect of the College. The report of the Council for the past year was read by Dr. G. F. Duffey, Honorary Secretary, and referred to the prosperous condition of the Society; to the lamented death of Henry Eames, M.D., who had for four sessions filled the post of Honorary Secretrary; and to the papers read during the past session. The following office-bearers were subsequently elected by ballot:—*Council:* Lombe Atthill, M.D.; J. Hawtrey Benson, M.B.; Thomas Fitzpatrick, M.D.; Arthur Wynne Foot, M.D.; Samuel Gordon, M.B.; T. W. Grimshaw, M.D.; Thomas Hayden, F.K.Q.C.P.I.; George Johnston, M.D.; Henry Kennedy, M.B.; James Little, M.D.; Alfred H. McClintock, M.D.; J. W. Moore, M.D. *Honorary Secretary:* George F. Duffey, M.D.

THE CHOLERA IN THE PARIS HOSPITALS.—Between September 4 and October 16 inclusive there were treated in the thirteen civil hospitals and hospices of Paris 352 cases of cholera. Of these, 94 were discharged and 211 died, leaving 47 still under treatment. In relation to the high mortality (69·18 per cent.), it is to be remembered that many of the patients were dying or seriously ill of other diseases when attacked by cholera. The mortality from cholera in Paris, taken altogether, is about 50 per cent.

OUR FRENCH CONTEMPORARIES.—The *Révue Scientifique* gives a very interesting account by Professor Cornil of the annual meeting of the British Medical Association, and of the gracious reception accorded to the foreign *savants* by the public institutions and private individuals. Some amusing mistakes are made in the orthography—and titles especially—in commenting on the fine speech of "Lord Gladstone," in Lincoln's-inn, where "Mons. Fergusson" presided, and amongst the guests was "M. Creetchett" (for Critchett). The current number of the *Gazette Médicale*, in giving an account of the medical institutions in this country, publishes the result of the examinations at the College of Surgeons, showing the severity of the examiners, or the weakness of the students, and pays a well-deserved tribute to MM. John Chatto and T. M. Stone, the latter of whom the writer states, with some surprise, has held office since 1832. With the museum and library Dr. C. Delvaille is greatly pleased.

A NEW HEALTH-RESORT.—In climate, Ajaccio (says the correspondent of the *Times*) is said to resemble Mentone more than any other of the Rivieran stations, but its insular situation renders it less close and stuffy, and at the same time insures for it a more equable temperature. The following thermometrical readings were taken at Ajaccio some years ago, and during a season said to be exceptionally severe:—In October and November the tem-

perature varied from 55° to 66° Fahrenheit; in December, January, and February from 52° to 60°; in March from 54° to 64°; and in April from 60° to 70°. The thermometer from which these observations were taken was placed in a window with a north-eastern aspect, and his (the correspondent's) own experience led him to credit the statement that they represent the Corsican temperature in an unfavourable season. During his stay there (from February to May) very little rain fell, and there was generally bright sunshine, and during the month of March they had uniformly perfect weather, altogether without rain, and free from harsh winds. In the first half of April they had, it is true, squally and very unpleasant weather, but after that they had a return of the same splendid climate which they had in March, though, of course, with an increased temperature. As to fever and malaria, there is no doubt that during the summer months, and in the lowlands, they exist to a very serious extent; but perfect safety is to be obtained, even in the summer, by moving up to a mountain residence. And what is more to the purpose, between this time (October) and the middle of June fever does not exist at all at Ajaccio.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Marais, Honfleur.—Enclosure received.

Phthisical Pleurisy in 1818.—Matthews, in his "Diary of an Invalid," has the following entries:—"The Place, Naples. March 6: Seized with an acute pain in the side. 9th: Decided pleurisy; summoned an English surgeon to my assistance; high fever; copious bleeding. Owe my life, under heaven, to the lancet, whose repeated application was necessary to relieve me from the intolerable distress under which I had been gasping for some days." Matthews, whose "Diary" is still one of the most readable of books and one of the best guides to Italian art and antiquities, travelled because phthisical. The bleeding evidently did not hurt him.

Gaol Fever.—One example of this plague was given in May, 1750, when Sir Samuel Pennant, Lord Mayor, Baron Clark, Sir Thomas Abney, Judge of the Common Pleas, the Under-Sheriff, many counsel, jurymen, and others died of a putrid fever brought into the Court of the Old Bailey by the prisoners confined in the foul air of Newgate. "Since that time," says Pennant the historian, "every precaution has been taken to keep the Court airy." He should have lived to witness the trials of the Claimant. Black Assizes (so called from the fatal effects of gaol fever on judges and persons in Court) are, we believe, reckoned by the dozen.

An Appeal.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Having been Medical Officer of Swymbridge, North Devon, nearly sixteen years (my appointment being an annual one), the Board of Guardians, without any notice or provocation whatever, elected another medical man (five miles distant) at the expiration of the Michaelmas quarter. Being 73 years of age, with a delicate wife, I make this appeal to the medical profession, hoping I shall receive sympathy in my trouble by their subscribing whatever they may feel disposed to do in order to assist me towards my future succour, having nothing to fall back on, the salary having been so low. I appeal *in pro formâ pauperis.* Highly respectable gentlemen can testify to the truth of this assertion by a reference to the editors or to me. Subscriptions will be thankfully received by the editors of this journal. I am, &c., Jno. Hawkes Jackman.

Swymbridge, Barnstaple, North Devon, October 14.

Expectant.—Since the foundation of the Queen's University of Dublin, 635 students have received the degree of Doctor in Medicine, and 250 of Master in Surgery.

Inquirer.—The value of the annual produce in meat in the United Kingdom (according to the estimate of Mr. John Algernon Clarke, before the House of Commons Select Committee), amounts to £75,000,000, or a little more than 30s. per acre; 47,000,000 acres are under all kinds of crops, fallow and pasture.

A. L., St. Bartholomew's.—You will find the exact dates of both examinations in the *Medical Times and Gazette* last week; and the amount of fees at both hospitals in our Students' Number.

An old Guy's Student and a Fellow.—In addition to the vacancy caused by the resignation of Mr. South, we believe Mr. Hilton's term of office will expire; he will of course offer himself for re-election into the Council of the College of Surgeons, as his colleagues could ill afford at the present crisis to lose his valuable experience in collegiate matters.

W. W., jun.—Yes. There is a species of insanity known by the epithet *notional*, in which, as well as in *delirium tremens*, there is frequently no general depravation of the reasoning and comparative faculties, but where the disease consists entirely in the patient mistaking the objects of his thought or imagination for real and present existences.

Thurley.—The time for the examinations at Cambridge for the degree of Bachelor of Medicine has recently been altered, and will in future take place twice annually, commencing on the Thursday following the first Monday in December, and in the Easter Term on the Thursday next but one preceding the general admission to the B.A. degree.

Philo.—Dr. Francis Bernard was chief physician to King James the Second.

Quackery.—According to the official returns just published, the stamp duty on patent medicines in the year ended March 31 last amounted to £95,812 19s. 7d. Surely for such a comparatively paltry sum it is disgraceful to a paternal government to endorse with their stamp quack medicines, many of which have been proved to be dangerous, and in some cases even fatal.

Tubes for Vaccine Lymph.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In using the capillary tubes for vaccination, there are sometimes difficulties both in charging them with lymph and in their application economically. I have found a simple and effective, as well as cheap, remedy for these difficulties (which may possibly have been dealt with by some such contrivance before). A tube of about a quarter of an inch calibre, but may be a little more or less, and about a couple of inches in length, with a split cork inserted at one end, so that when free the cork is in two longitudinal pieces—one of which has along its plane surface a shallow groove (as by a careful angular cut with a long knife), so as to, with the other ungrooved half in apposition, hold a capillary tube, of which about one-eighth of an inch projects at the smaller end of the cork, and the rest of the length of the capillary tube at the other end of the cork. The smaller end of the cork being then stuck into the tube enough to hold it *in situ*, with the capillary tube in the relative position to the cork as above mentioned, it is then obvious that either for drawing up lymph by the pressure of the air (by the mouth) when the capillary force is insufficient, from the capillary tube being too large in calibre (as some are in most of the bundles supplied)—*i.e.*, by inhalation at the open end of the tube described; or, on the other hand, for exuding(a) *economically* the lymph without danger to the operator, either from puncture from glass or from virus,—both such purposes are by such means facilitated. The tube may be of any material, but glass is the cleanest to deal with. Possibly a bit of fine indiarubber tube might do, and without a cork, by merely pinching the tip of the capillary tube *pro tem.* in the distal end of the indiarubber tube. The tube I enclose is from a cigarette called "Bijou," with Alexander's patent crystal-carbon tube, a box of which can be had for a shilling, with either ten, twelve, or fourteen cigarettes; and these tubes would last pretty well a lifetime.

P.S.—Since writing the foregoing I have tried a bit six inches long (price 2d.), of fine indiarubber tube, and it answers well and has some advantages, such as mobility when using; but I prefer, on the whole, the glass tube and split cork. I am, &c.,

14, St. Jean d'Acre-terrace, Stoke, Devonport. R. W. Woollcombe.

The Medical Department.

The following memorial has just been forwarded to Simla for transmission:—

Unto the Right Honourable the Secretary of State for War, War Office, London.

This, the Memorial of the Surgeons-Major and Surgeons of the Medical Department of her Majesty's British Army at present serving in ——

Humbly sheweth,—1. That with every desire to co-operate with the authorities in carrying out the new system of medical organisation which it has been deemed necessary to establish in the army, your memorialists regret to find that the Army Medical Warrant of the 1st March, 1873, has, in certain respects, materially injured their prospects. Your memorialists had looked forward with confidence to the appearance of the above Warrant, believing that, whatever further privileges and advantages her Majesty might be graciously pleased to confer on them, none of the rights and privileges granted by previous Warrants would be withdrawn. In cherishing this hope, your memorialists, as members of a Department having the health and physical efficiency of the army in their keeping, trust that they may not be deemed unreasonable.

2. That such of your memorialists as have been suddenly deprived of appointments with regiments in consequence of the new Warrant, and thereby pecuniarily injured, are, we consider, entitled to compensation.

3. That whilst a Controller, Deputy-Controller, and Assistant-Controller rank, respectively, on appointment, as Major-General, Colonel, and Lieutenant-Colonel—according to date of commission—the corresponding grades in the medical department of Surgeon-General, Deputy Surgeon-General, and Surgeon-Major, after twenty years, are accorded *lower* relative rank.

4. That Clause 5 affects your memorialists injuriously, depriving them of the precedence and privileges conferred by the Royal Warrant of the 1st October, 1858—namely, as to the presidency of mixed committees, and of departmental or relative army seniority in choice of quarters when doing duty with regiments.

5. That the word "necessarily," as used in Clause 6, will have the effect of depriving the Surgeon-Major of forage, as guaranteed by the Warrant of 1858. A *trained charger* is absolutely necessary to enable a Surgeon-Major, with troops under arms, to discharge his duties efficiently.

6. That a charger is equally necessary for the Surgeon of the Department for the efficient discharge of the duties when with troops under arms.

7. That the principle adopted in Clause 12, of making selection for promotion the rule instead of the exception, is, in our humble opinion, likely to open a door for patronage, which, however carefully exercised, may, in many instances, act injuriously to faithful and efficient officers.

8. That this selection being, by Clauses 12 and 21, placed in the hands of the Commander-in-Chief, instead of those of the head of our own profession in the army (who is best fitted to form a just opinion as to our respective professional abilities and claims to advancement), is, we would respectfully submit, erroneous in principle, and not likely to prove beneficial either to the Department or the Service.

9. That whilst the officers of the Indian Medical Department obtain the actual rank and pay of Surgeon-Major after a total service of twelve years, the officers of the British Medical Department serving in India are not insured even the mere *local* rank (which carries no pay) after completing that amount of service. We are of opinion that the local rank should be conferred upon the Surgeons of the British Medical Department after a total service (on full pay) of twelve years; and, further, that Surgeons should be promoted on the completion of fifteen years' full-pay service; or, if not thus promoted, that they should receive 17s. 6d. per diem, as guaranteed to the late Assistant-Surgeons of that length of service.

(a) I have exuded above twenty-five deposits of fluid from one capillary tube with this contrivance. It would be useful in the country or abroad, where fresh capillary tubes either uncharged or charged are not always at hand.

10. That if Clause 15 is made universally applicable to holders of regimental appointments—the late Surgeons and the Assistant-Surgeon—at the date of the Warrant, considerable pecuniary loss will accrue to many.

11. That the principle of retaining administrative and executive medical officers after the ages of sixty-five and fifty-five respectively cancels Clause 11 of the Warrant of October, 1858, and will act prejudicially by impeding promotion in the Department.

12. That, in consequence of the decreased value of money, and the greatly increased cost of the necessaries of life, the retired daily pay of medical officers has become insufficient—the half-pay of a Surgeon-Major being only from 12s. to 16s. 6d. after twenty years', and from 16s. 9d. to 20s. after twenty years' full-pay service; but these higher rates are only granted to him when worn out and unfit for further service.

13. That the present indefinitely prolonged tenure of administrative appointments deprives the junior ranks of a fair and reasonable prospect of promotion, and of the increased advantages attaching thereto.

14. That whilst all other officers of the British Service in India or elsewhere seldom experience any difficulty whatever in obtaining ample periods of leave for various purposes, the officers of the British Medical Department serving in India and elsewhere are not only not allowed more than six months' leave for the recovery of the most seriously impaired health, but are denied anything like sufficient leave for professional improvement or attention to private concerns. This grievance has pressed long and most severely upon your memorialists, and is felt all the more acutely from the fact of all other officers being treated so very differently.

15. That the position in the Regimental Army List of the names of the Surgeons-Major, who are now virtually departmental officers, appears to us no longer necessary, the more especially as the position accorded them therein is neither befitting the members of a great and learned profession, nor such as to promote self-respect or efficiency.

16. That our position at mess is also irksome and anomalous. Mess being regarded as a parade, we, as so-called non-combatant officers, are placed there, as regards precedence and authority, junior to the latest promoted non-commissioned officer or last appointed sub-lieutenant, should these happen to be the senior so-called combatant officers present. As to the band, we are in a similarly unprivileged condition, although to both these institutions our subscriptions are only exceeded by those of the Lieutenant-Colonel of the regiment.

17. That we regard the continued appointment of military men to the post of Governors of General Hospitals in the army as causing needless expense to the public, and a chronic condition of irritation and discontent in the Department, which considers its own superiors much better qualified for the due administration and discipline of such hospitals. We are given to understand that this reform has already been successfully effected as regards the General Hospitals of the Royal Navy.

18. That, whilst all other departmental officers, and even all regimental staff officers, receive a considerable staff salary in additiou to the pay of their rank, the Surgeon-Major in charge of a regiment draws nothing but the bare pay of his relative rank.

19. That, as regards the additional duties imposed upon your memorialists by Clause 6 of the Special Circular of March 6, 1873, they are of opinion that they ought not to be required to undertake them unless provided with a sufficient staff of specially trained subordinates, and an adequate charge allowance in consideration of the increased work and responsibility, as is customary in all other departments.

Wherefore for these reasons your memorialists pray—

1. That the privileges guaranteed by previous Warrants be restored.

2. That compensation be granted such of your memorialists as have suffered (or may suffer) pecuniary loss by summary removal from regiments in consequence of the Warrant.

3. That the relative rank of Surgeon-General, Deputy Surgeon-General on appointment, and of Surgeon-Major, after twenty years, be that of Major-General, Colonel, and Lieutenant-Colonel respectively, according to date of commission.

4. That the benefits conferred by Clause 17 of the Royal Warrant of October 1, 1858, as regards presidency of mixed committees, and relative rank in choice of quarters when doing duty with regiments, be restored.

5. That the forage allowance guaranteed by the Warrant of October 1, 1858, be restored.

6. That a similar allowance be granted to the Surgeons when with troops under arms.

7. That promotion in the executive ranks be, as hitherto, chiefly by seniority.

8. That selection for promotion be entirely vested in the head of our own profession in the Army.

9. That Surgeons of our Department serving in India be granted the local rank of Surgeon-Major after twelve years' total service; and that all Surgeons be promoted after fifteen years' full pay service; or, if not thus promoted, that they receive a daily pay of 17s. 6d. as guaranteed to Assistant-Surgeons of that standing by a former Warrant.

10. That, as regards Clause 15, vacation of regimental appointments by their incumbents—the late Surgeons and Assistant-Surgeons—at the date of the Warrant be optional for a term of five years from such date, as guaranteed in Director-General's Letter No. 20270/15, dated August 17, 1870, which states—"that the scheme for reorganising the Department will not, if approved, affect any regimental officer, nor alter his position in his corps, for at least five years."

11. That, as regards age retirements, Clause 11 of the Warrant of October 1, 1858, be carried out in its integrity.

12. That increased retiring allowances be granted for the reasons hereinbefore stated, according to the following scale—namely, at twenty years, 20s. per diem, with 1s. extra for such additional years up to twenty-four years, after which no increase unless promoted to the Administrative ranks.

13. That the tenure of the appointment of Surgeons-General be, under no circumstances whatever, extended beyond five years.

14. That the grievous deprivation of leave, from which your memorialists have hitherto suffered so severely, be redressed, and that they be treated, as regards leave for the recovery of their health, for professional improvement, and for attention to private affairs, in the same liberal spirit as other officers are.

15. That the names of the Surgeons-Major be no longer inserted in the regimental list, and that they, being *purely departmental* officers, be regarded as such, and in no sense whatever as regimental.

16. That all medical officers be in future exempted from compulsory attendance at regimental messes and subscription thereto, or to regimental bands, as is the case with all other departmental officers.

17. That the appointment of military men as Governors of Army Hospitals be abolished, and that these offices be reserved for meritorious officers of the Medical Department invested with the necessary powers.

18. That all officers in medical charge of regiments and batteries be granted charge allowance, like all other departmental officers holding charges.

19. That an efficient staff be provided for carrying out, under the supervision of the senior medical officer, the additional duties enumerated in Clause 6 of the Special Circular of March 6, 1873, and that he be granted an adequate allowance to compensate for increased work and responsibility.

And your memorialists will ever pray. (Signed by)
56 Surgeons-Major,
157 Surgeons.

213 Total signatures.

Number of Surgeons-Major and Surgeons actually serving in India (according to last quarterly Army Lists), 306; minority not signing, 93.

Mortimer.—There are somewhere about 1000 medical officers in the army.

Antony, Drury-lane.—Various opinions are entertained respecting the reptile that inflicted the fatal sting on Cleopatra. The aspic of the ancients is the *Coluber Naja*, called by the Arabs *nascher*, and classed by Lacepède as the Egyptian viper.

A Doctor's Log.—No. VI.

(*Continued from page* 456.)

February 14.—One or two cases of sprains and contusions, dyspepsia, bronchitis, amongst the officers, the latter depending on careless exposure to the night air. Some want iodine paint and arnica applied to bruised limbs, but No!—bearing in mind previous experiences. On one occasion an officer's wife, the mother of a large family, contracted erysipelas through using arnica: her eyes closed, dangerous fever, deposition in joints, her life in danger, followed by long and tedious convalescence. On board ship, too, poultices of linseed-meal and mustard too often induce greater susceptibility to cold. Take up a pamphlet to read that in Bengal out of 34,287 men—divided into total abstainers, temperate, and intemperate,—the percentage of daily sick in each class was represented by 3, 5, and 80; the deaths of total abstainers 1, of temperate 2, and of intemperate 4 per cent. Just the old story. And when one remembers the sieges, campaigns, and expeditions—for instance, to the North Pole and the Red River,—my intention is to raise to the utmost individual protest against the spirit ration. In the revised instructions for the guidance of troops arriving at Bombay it is stated that men will exchange their rations for liquor unless prevented, will eat unripe fruit, bad pork or vegetables, rancid bacon or native sweetmeats, will drink the first water they come across, ignoring filtration, besides exposing themselves bareheaded to the sun, or sleeping at night on damp ground or in heavy dew. There are endless minute directions about cholera, cautions to medical officers to inspect stores for which they are responsible, to take receipts for everything, to look after the water, food, and drains, bedding, straw, encampments, etc.; but the most important information is that the pay of Assistant-Surgeons runs from £31 to £45, Surgeons from £78 to £82, and the remote grade of Surgeon-Major from £105 to £109 a mouth: very satisfactory but for the heavy expenditure—the rupee only providing a shilling's worth,—the many luxuries, however costly, which become necessaries in India. The Indian Ocean becomes pleasant—the atmosphere, excepting in the cabin at night, very tolerable; the sea as smooth as the Serpentine. It is said that the *Serapis* during a cyclone here was for eight hours on her beams ends, at an angle of thirty-eight degrees, the fury of the gale intensified by lightning and rain, the furnaces partially extinguished; and the passengers imagined their last hour had come.

Excepting porpoises at Gibraltar, seagulls, a solitary jackal in the desert, and a few camels strung, the tail of one fixed to the nose of another, have met nothing, not even a shark or flying fish. Thinking over the whole voyage, the parade on a cold winter morning at Woolwich (the day after the Emperor's funeral), the band playing "Auld Lang Syne" on the road to the railway—the special train to Portsmouth—the confusion on board—the removal of the gangway—the cheers of those on shore, whilst the vessel led us reluctantly away—the last glimpses of the Isle of Wight and gradually of England, which never looked so lovely before—the dreary feeling after, and the storm in the Bay of Biscay flit through the mind;—and, as a doctor, one cannot help thinking of the diseases to be treated, very probably endured, before long, namely—cholera, dysentery, diarrhœa, sunstroke, malaria, intermittent and remittent fevers, insanity, cerebral, hepatic, renal, splenic, and cardiac affections. The diseases of women are reported most difficult; a voyage to England, visits to Drs. Gream, Tilt, Graily Hewitt, Bennett, Oldham, Barnes, and last but not least Mr. Spencer Wells, required. Children, too, will give plenty of work—anxious and often unsatisfactory,—but having taken out every book on this branch, and had practical experience, hope to turn the latter to account. It is stated that the Indian people have all the appointments, all the private practice, and that if an Assistant-Surgeon becomes promoted, and is supernumerary, his pay remains stationary, the promotion ignored. Hear that surgery and diseases of the eye bring in good incomes to the Indian practitioners, but that their expenses are very heavy.

16th.—The beginning of the end. Subscription-lists for stewards, band, and a regimental charity; great entertainment in the evening,—dancing, songs,—followed by three cheers for the Empress of India (that is to say her Majesty the Queen), and then three cheers for Captain Grant and the first lieutenant. Note to-day that a dressing-gown, serge suit, postage-stamps, a lamp, two forage-caps, comfortable shoes, and one or two books descriptive of the journey should be included amongst necessaries. Mothers are advised to bring out different varieties of infants' food—specially Ridge, Hard, and Robinson's—also a small medicine-chest, there being such a run on quinine, opium, podophylliu, ipecacuanha, Warburgh's tincture, and the mild mercurial preparations—else the chance of the remedies being old or adulterated. Bromide of potassium, colchicum, turpentine, antimony, acetate of lead, chloroform, carbonate of ammonia, chlorodyne, castor oil (all at times valuable), might be concentrated into small space. No medical officer should be without a catheter, a penknife, a pair of scissors, needles and thread. Common-sense appliances and adaptations will tide over many emergencies, but, should the occasion require, there is no substitute for the catheter. The hypodermic syringe, too, how valuable when other things fail! Learning lessons daily will be the excuse for harping on certain points forced on attention.

Let me urge upon officers—for instance, medical officers—the necessity for the very strongest boxes; also to have their names and destination painted large and legible—written directions or paper labels useless. Also look after your boxes yourself—trust no one. A most valuable box was sent from London to Woolwich for transfer to Portsmouth, and, but for-

the merest accident, it would have remained in a baggage-shed in England whilst the owner, when 1000 miles up country in India, would have discovered and felt the loss. Everything is reported to be very dear, so that it is economical to hring out things. One officer going up country will have to pay £120 for extra haggage; in the long run he considers it worth his while. We disembark, according to rumour, in full dress as at home—gold-laced jacket, red-striped overalls, belts, sword, sabretache, substituting a white helmet with a gilt spike for the busby. A flying-fish appeared in the hospital through the port, very probably anxious for advice gratis, and was promptly cooked for the sergeant's dinner. It is stated since the opening of the Suez Canal some new curious fish have appeared—there an unknown breed. Those who have bathed in the Bitter Lakes complain of the pungency of the salt. The *Serapis* stuck there on one trip, and before they could get her off many tons of coal and baggage had to be transferred to lighters. Just now the sunsets attract even the oldest travellers, resembling a blazing circular ruby rapidly sinking helow the horizon. At night the stars and planets eclipse the most hrilliant fireworks, rivetting the attention of the singers, the dancers, the happy young couples, the depressed, crusty old hachelors. The Southern Cross, Orion, and Venus specially beautiful; but although the motto of the vessel runs "Heaven's light our guide," the sailors take but little interest in this particular. To-night, talking to one of them, he tells of the sharks about Panama; how that men are afraid to put their feet in the water, and an old scoundrel, well known by certain marks, and nicknamed "Jacky Jones," has been about there for years. A warrant officer states that when the thermometer stood at 80° Fahr. at Bermuda, in three days he was at Halifax, when it stood at 3°. I wonder if this is true. In 1861, during the *Trent* affair, the cold crossing some of the lakes in sleighs was very intense, yet very hracing. The sailors say the *Serapis* never had a cooler passage. What must it be in the really warm weather?

APPOINTMENTS FOR THE WEEK.

October 25. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

27. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. (Clinical Night.) Mr. Churton (of Erith), "A Case of Suppurative Pericarditis" (with specimen). Mr. A. E. Durham (Surgeon to Guy's Hospital), "A Case of Foreign Body in the Pleura accidentally introduced through Opening made for Empyema, and successfully removed." Dr. Routh, "A Case of Stone impacted in Kidney" (with specimen). Dr. Purcell, "Specimen of Calculus in the Pelvis of Kidney."

28. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Royal Medical and Chirurgical Society, 8½ p.m. Dr. Miller Ord, "On a Case of Duchenne's Pseudo-hypertrophic Muscular Paralysis." Dr. C. J. B. Williams (President), "On the Acoustic Principles and Construction of Stethoscopes and Ear-Trumpets."

29. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

30. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

31. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·75 in. The lowest was 29·42 in. on Monday at noon, and the higest 29·98 in. on Friday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 hy the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Duhlin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

ON METHOD IN SURGICAL DIAGNOSIS.

A Lecture delivered at University College Hospital.

By PROFESSOR ERICHSEN,

Senior Surgeon to the Hospital, and Holme Professor of Clinical Surgery in the College.

Gentlemen,—It is my intention to-day, as preliminary to the course of clinical surgery, to direct your attention to the subject of surgical diagnosis. Now, when you are called to a patient who is suffering from an injury or labouring under a disease, the first point that you have to determine is what is the matter with that patient; and the determination of that point is, in ordinary professional language, called making the diagnosis of the case. How are you to make that diagnosis? This is not a matter that can be effected by any intuitive instinct; but there is a certain method to be adopted just as there is in conducting a treatment.

The importance of effecting a correct diagnosis is this: that the treatment must necessarily be entirely founded upon the diagnosis; and according as the diagnosis is more or less correct, so will your treatment be more or less rational. If the diagnosis is correct, the treatment will be removed from that blind empiricism that deals only with symptoms which are effects, and not with the disease or injury itself which is the cause of these symptoms.

In effecting a diagnosis you may look upon a patient very much in the same way as a lawyer looks upon a reticent witness in the box. You have a something before you which is not disposed to tell the truth. It is your business to elicit that truth; and just as a skilled counsel employs a certain method which experience has taught the members of his profession will tend to elicit that truth—experience confirmed, perhaps, by his own sagacity and natural instinct—so the surgeon employs a certain method to elicit the truth which the patient is unable to reveal, willing as he would be, perhaps, to do so, and which the disease cannot tell us. In making a diagnosis you will find that you have to employ both your senses and your judgment. In fact, a diagnosis is effected by a method of observing; and observation is nothing more than the application of the senses, tempered, modified, and improved by the judgment. The mere use of the senses will not enable you to effect a diagnosis. You may see and not be able to observe. You may hear and not be capable of understanding. You may touch and be unable to feel. You learn how to effect a diagnosis by the combined influence of study and practice. Mere study will not give it to you. No man, however much he might consult books, and however learned he may be in surgery, could possibly through the force of that book-learning be able to distinguish elasticity from fluctuation. No practice, however great it may be, is capable of explaining to the surgeon the nature of a complicated injury or disease the first time he sees it. You must combine the two. You must study in order that you may know what you may expect to find, and this you learn from that concentrated experience of your predecessors, which is to be found in works, or which is to be heard in lectures; and you are enabled to find what you may expect to meet with by the cultivation of your senses. It is therefore by that combined influence of study and of practice, of judgment and of sense, that a diagnosis is at last effected.

In effecting a diagnosis you will find that the patient will present two distinct classes of phenomena, and it is very important to bear in mind the distinction and the difference that exist both in kind and in importance of those two classes of phenomena. He will, in the first place, present a series of phenomena which are recognisable by the surgeon himself, however unable the patient may be, from his injury or disease, to explain them. These phenomena are commonly called *objective*, and they are described, or ought to be described, in surgical language as "*signs*." Let me give you an illustration. A man is brought into the hospital unconscious, with a laceration of his scalp, with a depression of his cranium, and with bleeding from the ear. He is unable to tell you a single word as to his condition; but you recognise this at once by the local signs just mentioned, coupled with the more general signs perhaps of dilated pupil, of stertorous breathing, with heavy, slow pulse. Those are the signs that he presents, and those signs are unmistakable by the surgeon. They indicate at once, without a word from the patient, without the necessity of putting a question to anyone, what his actual condition is.

But there is another series of phenomena presented by the patient which are of less importance than those that I have just mentioned, and that series of phenomena goes by the name of "*symptoms*." They are *subjective*—that is to say, they are not recognisable by the surgeon, but they are dependent upon the statement made by the patient. The surgeon can form no judgment of them except so far as the patient tells him. A man, for instance, comes to the hospital complaining of a violent pain in his head. You cannot possibly determine whether he has got that pain or not, except by his own statement. He tells you he has, and you must take it that he has got it, especially if he presents other phenomena that are corroborative of that statement. Such a pain is a symptom, and there are many of these that are met with. They are all dependent upon the statement of the patient, and they are all incapable of proof by the surgeon, except so far as his reliance on the patient's statement is concerned, whatever be the value of that as a matter of proof. You will therefore see that there is an immense difference in point of value as well as in kind between a sign and a symptom. But there is a further difference between the two. A sign indicates not only the fact of a lesion, but it indicates the very nature of that lesion in the majority of cases. It is, or it may be, the lesion itself. A symptom merely indicates the fact of there being a disturbance of some kind, but it does not indicate more than that. It in no degree shows what the nature of that disturbance may be. In making a diagnosis, then, always bear in mind the difference of value between signs and symptoms, between the objective and subjective phenomena presented by the patient.

The objective phenomena—those that I have just been mentioning as signs—are cognisable to the surgeon through the medium of his senses, and he judges of them by the sense of sight, of touch, and of hearing. The other senses are of little value in surgery. Now, the senses necessarily vary in acuteness in different people; but the mere acuteness of sense has nothing to do with the power of observation through that sense. The power of observation is a matter that is learned by practice, and that is often possessed, and that in a remarkable degree, by people who may not be quite so acute in some of their senses as others. You must educate, in fact, your senses, however perfect they may naturally be, in order to obtain accuracy in diagnosis.

Now let me tell you what you may learn by those different senses when they are properly educated. In the first place with regard to the sense of sight. Always employ that; always look at your patient; always strip him; always examine the injured or diseased part with your eye; look at it—look at it carefully. From want of this simple precaution, many a patient has been mistreated. I have known, for instance, a patient treated for typhoid fever, who, in reality, had a great carbuncle on his back which had never been looked at and never been seen. You may actually find a patient suffering from a broken bone, and the injured limb has never been looked at by the practitioner who was called to see the patient. Always look at the part that has been complained of, and in the case of many general constitutional conditions examine the whole of the surface of the body. For by the sense of sight you get an enormous amount of important information rendered unconsciously by the patient himself, every portion of which is objective—is a sign—and hence is of the greatest value in diagnosis. You look, for instance, at the patient's countenance. You immediately see whether he is healthy or cachetic; whether he is strumous or sanguine. You at once take an inventory, as it were, of his whole constitutional condition by the simple aspect of his face. You judge of the patient by looking at his attitude. The extreme restlessness of exhausting disease or the depression of septic disease is at once recognisable by the sight. The expression, not only of the countenance, but of the whole body, will often indicate to you almost unmistakably the nature of the disease under which the patient is labouring. A person, for instance, with peritonitis, the result of strangulated hernia, lies flat upon his back with his knees drawn up, and with his face drawn in a somewhat agonised expression.

But not only do you judge by the general aspect of the patient, more or less of his general constitutional condition, or of the malady or injury under which he may be labouring, but you must also examine carefully the attitude of the part

of the body that is complained of, and you will at once see in many cases what is the real nature of the injury from which he suffers. The attitude of a patient, for instance, with a fractured clavicle is quite peculiar and characteristic. The way in which he supports the injured limb by the elbow with the opposite hand, the manner in which he inclines his neck and head over to the injured side, are all almost unmistakable evidences of the nature of the injury he has met with. The attitude of the lower extremity in fracture of the neck of the femur is equally characteristic. The attitude of the hand in a case of impacted fracture of the radius is equally unmistakable. In that way, by examining the attitude of the limb, you determine almost unmistakably and at once the very nature of the lesion from which the patient is suffering.

But you ascertain many other things by looking at the patient. You determine, for instance, the questions of relative size of a part: if there is swelling, you see that; if there is shortening or lengthening, you determine those points. In doing so, you should always measure and examine the corresponding sides—or parts rather. You should always examine the two opposite limbs—the sound limb and the diseased or injured one,—and measure one in relation to the other, and compare one with the other. You do this because sometimes there will be congenital malformation or accidentally acquired deformities of limb that may, unless this precaution be taken, mislead you as to the character and extent of the lesion. Then, again, by means of the sense of sight you determine whether the part is transparent or is solid. You have a tumour of the scrotum, for instance; you examine it by transmitted light, and you see at once whether the light passes through it—whether it is transparent or not,—and your diagnosis is founded almost at once upon the determination of that single fact. Or, again, you notice by sight whether there is undulation—the wave of a liquid in a part,—and a variety of other important matters as to colour, as to the extent and depth of wounds, as to the condition—the progress that is being made towards recovery.

But, in addition to sight, or next, perhaps, to the sense of sight, the most important sense to the surgeon (in determining the presence of objective phenomena, of signs) is that of touch; and that sense may be equally educated with the sense of sight. What is known, or what was known formerly, in the profession as the "*tactus eruditus*," can only be acquired by long practice. By the touch the surgeon, as it were, can see more deeply into the interior of the body than the organ of vision can carry him; and there is a light, so to speak, at the end of each finger of a skilful surgeon that penetrates the cavities of the body and that throws its ray through the skin into the solid tissues beneath it, clearing up much that would otherwise be obscure. The surgeon, with a skilled touch, is able in this way to derive the most accurate information as to the condition of parts that he cannot see.

Make it a rule of practice in surgery always to touch and handle a diseased part. Do not content yourself with simply looking at it, but always handle the diseased part or limb, and in that way you will frequently get most important information. In a case of erysipelas, for instance, you may simply see a uniform blush upon the surface; but handle the part, and you feel a deep, doughy, infiltrated, or semi-fluctuating sensation, indicating at once the existence of deep-seated mischief in the planes of cellular tissue lying perhaps between the muscles of the limb. So with the touch you determine a great number of special points of the first importance. In cases of injury, for instance, you ascertain by the touch—by handling the part—whether a limb presents the sensation of crepitus, of crackling or grating of broken bone; you determine by handling the parts whether a joint is out of place or not. The general swelling around it, perhaps, would prevent your ascertaining this by the eye alone; but, by comparison with the opposite limb, you learn by the sense of touch whether the bony points are in their true relations or not. By the sense of touch, too, you determine that most difficult point in surgery—whether a tumour contains fluid, or whether it is a semi-fluctuating elastic but solid body; whether you have, indeed, undulation and fluctuation, or mere elasticity. You determine, by the sense of touch, the texture, the consistence of many parts—whether a tumour is hard or whether it is soft, whether it is smooth or whether it is nodulated; whether a surface is unbroken in the interior of the body, or whether it is ulcerated. In a variety of ways, then, you determine points of the utmost importance by the sense of touch.

So, also, by the sense of hearing you ascertain a good deal. But the sense of hearing is of minor moment, as a rule, to the surgeon than it is to the physician; and in surgery you will find that the sense of hearing and the sense of touch go together in a somewhat remarkable manner, so that it is often very difficult to say whether you feel a thing or whether you hear it. Take as an instance the grating of a broken bone. You put your hands upon the limb, and you feel it most distinctly, and you think you hear it. It is very doubtful in many cases whether you actually hear it or do not; but at all events the sense of hearing goes with the sense of touch in many of these cases in a way that is very puzzling; it is somewhat difficult to dissociate the two. It is the same with the crackling in a chronically inflamed joint, or that peculiar crepitation that you have along the sheath of an inflamed tendon. It is difficult to tell in touching it whether you hear the sound or whether you feel the peculiar crackling or crepitation as the case may be. In many cases, however, the sense of sound is of the utmost importance. I set aside all those case of exploration of the chest which are common to the physician and the surgeon, and about which I wish to say nothing; but in purely surgical cases I cannot give you a better illustration of the value of the sense of hearing than what is elicited in the case of a hernia, about the nature of which you are doubtful, whether it is strangulated or whether it is simply irreducible. You hear the bubbling sound of the returning gas, and you know at once that the gut cannot be strangulated—that it is simply irreducible. In the case of stone in the bladder you hear the stroke of the sound against the stone, and you determine its existence in this way by the sense of hearing more than by the sense of touch. It is, indeed, a rule in surgery never to believe that there is a stone in the bladder unless you actually hear that it is there by the stroke or click of the sound against it. In that way the sense of hearing becomes a most important auxiliary to the surgeon.

These three different senses—the sense of sight, the sense of touch, and the sense of hearing—are all supplemented, rendered more acute, and the sphere of their action greatly extended, by the ingenuity of the surgical mechanism; and we have a number of instruments which we daily employ in surgery, the sole object of which is to extend the sphere of information derivable from these senses, or to render them more acute in the determination of what they seek. With regard to vision, for instance, we have two sets of instruments by which its aid is greatly extended, and by which a vast amount of information can be obtained, which could not otherwise be elicited by the sense of sight. We have specula of all kinds, the object of which is to separate the walls of narrow or deep cavities, like the rectum or the vagina, and, by throwing a stream of light into the bottom of these, to enable the surgeon to see what is the condition of parts removed several inches from the surface of the body. We have reflectors of different descriptions, the object of which is to throw a stream of light into the interior of the body, and to enable the surgeon by this artificial light to see the condition of more deeply seated parts which would be beyond the reach of his vision under ordinary circumstances. The ophthalmoscope, the laryngoscope, the endoscope, the auroscope are all instruments of this kind, and all constructed upon this principle.

Then, with regard to the sense of touch, we have other instruments which enable you to propagate the sense of touch through long and narrow and tortuous channels, through which the finger could not by any possibility be introduced, or to the bottom of which, if introduced, it could not reach. These instruments are probes and sounds of various kinds. By introducing a probe through a sinuous channel you come down to the exposed bone or to a foreign body like a bullet. By introducing a sound into the bladder you examine by the touch the interior of the organ, which you could not reach in any other way.

In order to improve the sense of hearing we have also two sets of instruments. We have the stethoscope, which is employed by the surgeon as well as by the physician; and we have also instruments the object of which is to increase the sound of the part that is touched. We have, in point of fact, a sort of sounding-board. There is an instrument, for instance, a sounding-board, that is adapted by some surgeons to the end of a sound, and which greatly increases, by its vibrations, the sound produced by the contact of the end of the metallic instrument with the foreign body in the bladder.

In these various ways these different senses are supplemented, and their range and sphere of action are greatly increased by

the employment of various surgical instruments; and a very large number of those which we employ are constructed designedly for the purpose of improving our methods of diagnosis.

So much, then, for the methods to be employed in the determination of the signs of the objective phenomena presented by the patient; now for the mode of estimating the value of the symptoms.

(To be continued.)

ON THE RIGHT USE OF DISINFECTANTS.(a)

By H. LETHEBY, M.B., M.A., etc.,

Professor of Chemistry in the College of the London Hospital; Medical Officer of Health and Public Analyst for the City of London; and President of the Society of Medical Officers of Health.

I am induced, gentlemen, to bring this subject under your consideration for the purpose of removing the many dangerous fallacies which beset it, and of arresting, if possible, the unblushing quackery which disgraces it. A glance, indeed, at the so-called sanitary literature of the day will show how boldly and how confidently the use of certain inert bodies is recommended to the public as powerful disinfectors The danger of this, gentlemen, cannot be over-rated; for when by such means undue confidence is placed in the disinfecting power of an agent which fails in its purpose, the result is not merely a waste of materials and a loss of valuable time, but it is also a serious danger to the public. Therefore it is that we should be most careful in the selection of disinfectants—using those only which are known to be effective. It is necessary also that we should be thoroughly conversant with their several modes of action, and that in applying them we should be guided by rational principles suggested by the scientific aspects of the subject.

It is hardly necessary to say that the question in all its relations is very large and extensive; for by the term "disinfection" I mean the removal, or neutralisation, or destruction of that which is offensive to the senses or hurtful to the body, limiting it of course to those cases where offensive effluvia, or noxious matters, or specific contagia are the subjects of treatment; and here I may remark that, although the questions before us are undoubtedly connected with the difficult problems now occupying the attention of physiologists, pathologists, and chemists as to the origin of infusorial life, and the cause of specific infectious maladies, as well as of organic decomposition, yet it is at the same time sufficiently independent of these abstruse inquiries as to be capable of very effective practical treatment at our hands, without much reference to the conflicting theories of genesis. To us, indeed, it is of little importance, except for the scientific elucidation and explanation of our empirical facts, whether the manifestations of life in a decomposing liquid be the *cause* of putrefaction and fermentation, or the *effect* of it: and whether it comes "*ex vivo*"—that is, from pre-existing life, as the Biogenists, the Homogenists, and the Panspermatists believe; or "*de novo*," as the Abiogenists, the Heterogenists, and the Non-Panspermatists maintain. Nor does it concern us in our practical treatment of the subject whether each distinct kind of spontaneous organic decomposition and each specific form of infectious disease are the results of the vital manifestations of special germs—differing in each case—or whether they are caused by the molecular movements of organic matter in peculiar states of decay; for that which we aim at, and which we undoubtedly are able to accomplish, is the destruction or prevention of the hurtful thing which causes offence or produces disease. And as in many cases this is associated with the changes incidental to organic decomposition, it may be effected in one of four ways—as, first, by strengthening the affinities of organic substances, and thus enabling them to resist decay; secondly, by so acting upon them with chemical agents as to produce new compounds which are not susceptible of organisation or decay; thirdly, by hurrying on the changes of decomposition and oxidation, so that the particles may quickly arrive at their final stages of decay, and be brought to rest; and, fourthly, by the use of special agents which are found to have specific powers of disinfection.

(a) Read at the meeting of the Society of Medical Officers of Health on Saturday, October 18, 1873.

As examples of the first of these methods of preventing decay I may allude to the effect of cold and to the desiccation of organic matters.

As instances of the second I will refer experimentally to the coagulation of albuminous matters by alcohol, creosote, the mineral acids, and most mineral salts.

Under the third head are the oxidising influences of chlorine, hypochlorous acid, permanganate of potash, and atmospheric air, aided by water and porous substances.

And as examples of the fourth method of disinfection I may allude to sulphurous acid, to carbolic and cresylic acids, and to the volatile oils.

The relative values of these several disinfecting substances have again and again been tested by experiment. As far back as the year 1858 I entered very fully into the question of their action on sewage; but very recently they have been examined by Dr. John Dougall, of Glasgow, and Dr. Crace Calvert, of Manchester, with the view of ascertaining their respective disinfecting powers, as tested by their action on protoplasmic and fungus life, and on vaccine lymph. I have tabulated the principal results of these experiments, and submit them to you for examination. Let us therefore discuss them in the order in which they are there placed:—

1. The Mineral Acids.—These are *Sulphurous Acid*, *Nitric Acid*, *Hydrochloric* or *Muriatic Acid*, *Sulphuric Acid*, and *Chromic Acid*. This is the order in which Dr. Dougall found they prevented the development of infusoria in infusion of hay, in urine, and in a mixture of beef-juice and egg albumen—sulphurous acid being the least effective, and chromic acid the most; for in the first case as much as one part of sulphurous acid in 117 of water was required to prevent such life during six days, while in the last case as little as one part in 2200 of water was sufficient. A like conclusion was arrived at when a solution of one part of the substance in 500 of water was used with a little beef-juice or egg-albumen. Dr. Crace Calvert, however, found that sulphurous acid was more powerful in its action than nitric or sulphuric acid when used in the proportion of one part in a thousand of solution of albumen, for in the case of sulphurous acid it required eleven days to produce vibrio life and twenty-one days for fungus life, there being no putrid or mouldy odour for more than forty days; whereas with the like proportion of nitric or sulphuric acid the existence of such life was observed on the ninth and tenth days. In all cases the addition of these acids in small proportions, as from 1 to 2 per cent., to putrid matters swarming with animalcules immediately arrested life. In like manner the vitality of vaccine lymph was completely destroyed by the vapours of these acids. It would seem, therefore, that they are all powerful disinfectants, and this accords with experience; for as far back as the year 1773 Guyton Morveau, one of the most distinguished chemists of France, recommended muriatic-acid vapour as a means of disinfecting hospitals; and in 1797 Dr. Carmichael Smith obtained a Parliamentary grant of £5000 for the successful use of nitrous fumes in the disinfection of our prisons. But sulphurous acid enjoys a reputation of much more ancient date. Homer tells us that Ulysses, after destroying the suitors, fumigated the rooms in which the bodies lay, as well as the rest of the palace, with the fumes of "pest-averting sulphur." Ovid, too, in the "Fasti" speaks of the cleansing and purifying power of sulphur; and Pliny, in his "Natural History," says "that brimstone is employed ceremoniously in hallowing of houses, for many are of opinion that the perfume and burning thereof will keep out all inchantments—yea, and drive away any foul fiends and evil spirits that do haunt the place." The Chinese have always attached considerable importance to the action of burning sulphur as a disinfectant, and have from time immemorial used pastilles of sulphur for internal fumigation, and squibs and crackers for external.

In the act of generating the gas by burning sulphur in atmospheric air, thirty-two parts of it by weight combine with the same weight of oxygen to produce sixty-four parts of sulphurous anhydride, which occupies precisely the same bulk or volume as that of the oxygen consumed. The density of the gas is considerable, for its specific gravity is 2·247, or very nearly twice and a quarter that of atmospheric air; a cubic foot of the gas, therefore, weighs a trifle less than 1206 grains, and it takes 603 grains of sulphur and a cubic foot of oxygen, representing five cubic feet of air, to produce it. Its chief characteristic is its powerful odour; for as little as one part or volume of the gas in 100,000 volumes of air is readily discoverable by the nose; nine parts of it in 100,000

of air are disagreeable, and provoke coughing; twenty parts of it in that quantity of air are powerfully irritating; and forty-three parts of it in 100,000 of air, or rather more than four parts in 10,000 of air, are actually irrespirable, and a much smaller quantity than this will rapidly kill plants. Water absorbs from forty to fifty times its bulk of the gas, and produces a solution of powerful antiseptic and disiufecting properties. The same is the case with the combinations of the acid with alkalies forming the sulphites and bisulphites.

2. The Organic Acids—as *Carbolic*, *Cresylic*, *Acetic*, *Picric*, and *Benzoic Acids*—are all disinfectant and antiseptic. According to Dr. Dougall, the most powerful of them is benzoic acid, for as little as one part of it in 533 of water will prevent the appearance of infusorial life, whereas as much as one part of acetic acid iu 125 of water is necessary for this purpose. Carbolic acid occupies an intermediate position, for it requires one part of the acid in 267 of an organic solution to arrest the development of animalcules for six days; moreover, according to Dr. Dougall, the addition of one part of carbolic acid to 200 parts of a solution swarming with infusoria had no injurious action on them, although the like proportion of picric or benzoic acid was immediately fatal to them. So also with respect to vaccine lymph: air saturated with the vapour of carbolic acid at ordinary temperatures had no destructive effect on its vitality after exposure thereto for twenty-four hours; and even wheu mixed with the lymph in the proportiou of 1 per cent., and allowed to dry, the activity of the virus was not impaired. Pettenköfer, indeed, has shown that although carbolic acid will arrest the development of ferment cells, it does not destroy their vitality; for if after such treatment they are freely diluted with water, they again start into activity. Its antiseptic power, however, is evidently great; for, according to Dr. Crace Calvert, the presence of one part of the acid in 1000 of an organic solution will check decomposition aud prevent the appearance of vibrio or fungus life for more than forty days. At the Morgue in Paris, where the acid has been freely used, Dr. Devergie found that in hot summer weather one part of carbolic acid (No. 5, which contains 85 per cent. of carbolic and cresylic acids) in 1900 of water, freely applied to the dead bodies, completely prevented putrefaction; and even wheu diluted to the extent of one part in 4000 of water the effect was most marked. In my own experiments in the city of London I have noticed that a very small quantity of carbolic acid in the sewers prevented decomposition, and that a solution of 1 per cent. of it upon meat arrested putrefaction.

Specimens of the acid are upon the table, there being several varieties of it in commerce for different purposes. The pure acid is a camphor-like solid, which fuses at 95° F. and boils at 366° F., the boiling point of cresylic acid, with which it is commonly associated, being 397°. It is not very soluble in water—only to the extent of about 3 per cent.—but it is freely soluble in alcohol, ether, and glycerine. It has no acid reaction on litmus paper, although it combines with the alkalies to form salts. A good test, indeed, for the purity of carbolic acid is the solubility of five parts of it in one part of caustic soda dissolved in ten of water. You have seen its powerful coagulating action on albumen, and I hardly need say it is an energetic caustic.

The commercial preparations of it are—1, the pure crystals for medical use; 2, the fluid crystals of the British Pharmacopœia strength for surgical purposes; 3, the loose crystals for disinfection; and No. 4 and No. 5 for commoner purposes. The last-named variety, as prepared by Messrs. Calvert and Co., is guaranteed to contain 85 per cent. of carbolic and cresylic acids, free from tar oils and sulphuretted hydrogen, and this is well suited for all the commoner kinds of disinfection. It may be used in the proportion of half a pint of the acid to two gallons of water, and if the odour is objectionable, the purer quality, No. 4, may be employed. Other preparations of it are "*the powder*" (carbolate of lime), which should contain at least 15 per cent. of acid as shown by the neutralisation of the lime with hydrochloric acid; "*McDougall's fluid carbolate*," which is the acid in neutral combination; "*Cliff's antiseptic liquid*," which is a solution of the acid in soft soap; "*Westerton's patent zymotic fluid*," which is a mixture of carbolic acid, pyroligneous acid, and ether, with a little scent; and there are several kinds of carbolic acid and coal tar soaps. But it is best to avoid these nostrums and rely on the action of the pure or nearly pure acid.

3. The Alkalies—*Lime*, *Potash*, *Soda*, and *Ammonia*—are not very powerful disinfectants unless they are used in a somewhat concentrated state, when they are useful for detergent purposes and for the destruction of organic matter. Cream of lime, for example, as well as a strong solution of potash and soda, may be advantageously employed in cleansing rooms, stables, cattle-sheds, slaughter-houses, etc.; and powdered lime, sprinkled freely about cellars, church vaults, cattle lairs, etc., will absorb moisture, carbonic acid, etc., and help the oxidation of organic matters. Added to sewage in the proportion of from ten to twenty grains per gallon, it combines with the carbonic and phosphoric acids, forming a flocculent precipitate which rapidly subsides, and carries with it all suspended matters as well as a notable proportion of soluble organic matter. It likewise kills the infusoria of the sewage, and checks the decomposition of it for several days.

4. The Haloids.—The most important of these are *Iodine*, *Chlorine*, *Chloride of Lime*, *Chloride of Zinc*, *Chloride of Aluminium* (*Chloralum*), and *common Salt*. *Iodine* is not of much practical importance, although it has been recommended for use in the sick-chamber. *Chlorine*, however, is a powerful disinfectant, and has been used with considerable success from the time (1791-92) when Fourcroy, the distinguished French chemist, proposed it as a fumigating agent. It is easily prepared by adding black oxide of manganese to strong muriatic acid—using about a quarter of a pound of the former to half a pint of the latter in a basin or dish,—frequently stirring the mixture, and, if possible, heating it. It is also produced by the gradual addition of muriatic acid to permanganate of potash (Condy's fluid); and this, indeed, is very like the preparation now advertised under the name of *chlorozone*—the muriatic or hydrochlorous acid having been added in comparatively small proportion. Chlorine is a heavy gas, its specific gravity being as nearly as possible two and a half times that of atmospheric air. It is extremely irritating, and, like sulphurous acid, cannot be effectively and safely used in the sick-chamber except for sweetening the air, as the quantity necessary to disinfect is irrespirable. The same is the case with chloride of lime, when its acid (hypochlorous) is set free by carbonic or muriatic acid, as it must be to become an effective aërial disinfectant. In proper proportions, however, both of these agents are powerful disinfectants, as they not only check putridity and the development of animalcules in organic solutions, but they also kill such creatures when added in the proportion of about 4 per cent., and they destroy the vitality of vaccine lymph. Like other agents which favour oxidation, they actually promote decay and the generation of infusorial life when used in small proportion. To disinfect with chlorine, therefore, or with hypochlorous acid, the chamber must be vacated, so that the air may become charged with at least 1 per cent. of these agents, and then the destruction of the miasm or contagium is insured. A solution of chloride of lime in the proportion of one pound to two gallons of water (5 per cent.) is useful for washing floors, etc., but it must be used cautiously for the disinfection of clothing, as solutions of this strength act injuriously on animal tissues, although they are not so hurtful to vegetable fibres.

Chloride of Soda (Labarraque's liquid) is a compound homologous with chloride of lime, and it enters into the composition of Watts's chlorinated soap; but, as it rapidly undergoes decomposition, the antiseptic power of the soap is *nil*.

Chloride of Zinc (Sir William Burnett's fluid) is a liquid which ranges from 1309 to 1594 of specific gravity—the former containing about 30 per cent. of the chloride, and the latter about 54. Its action is evidently due to its power of coagulating albumen, and of absorbing ammonia and sulphuretted hydrogen. Used in the proportion of one part of the chloride to 300 of water it instantly destroys infusorial life, and even when diluted so as to contain but one part in 1000 of an organic liquid it checks decomposition, and prevents the appearance of animalcules and fungi for more than forty days. Its chief use, however, is as a disinfectant of fæcal matters; for it has no power as an aërial disinfectant, and is too corrosive in its action for textile fabrics.

Chloride of Aluminium or *Chloralum*, which is a solution containing about 15 per cent. of the salt, appears, from the researches of Dr. Dougall, to be powerfully antiseptic, for when used in the proportion of only one part of the substance to 933 of water it prevented the development of animalcules for six days. Dr. Crace Calvert also found that an organic solution containing one part of chloralum in 1000 of the solution did not exhibit vibrio life until after ten days. In another experiment, however, with albumen and starch-paste—each containing 2 per cent. of the substance—decomposition with

offensive odour began in nine or ten days; and in my own researches I found that putrefactive decomposition could not be prevented with less than 4 per cent. of the substance. In the illustrations before you, you will notice how ineffective it is in checking putrefactive decomposition. Moreover it is not an aërial disinfectant, and is therefore worthless in a sick-room; and with regard to its deodorising power it manifestly does not contain anything which is capable of absorbing putrid miasms. Like common alum, however, and crude sulphate of alumina, it is a good precipitating agent for sewage, and when combined with the action of lime it thoroughly defæcates such matters.

5. Mineral Sulphates—as *Sulphate of Zinc, Sulphate of Iron, common Alum*, and *Sulphate of Copper*, as well as the waste solutions of metallic salts from wire-working, iron-galvanising, lacquering, etc.—are useful disinfectants when the object is to coagulate albuminous matters and to destroy living organisms, as well as to neutralise offensive miasms. Each of these substances will prevent the manifestation of infusorial life in organic solutions containing from one to four parts of the salt in the 1000; and a solution composed of from one to two pounds of the substance in a gallon of water is a good disinfectant of drains and of fæcal matters directly they are discharged from the body. Mudie's disinfectant is sulphate of iron or green copperas, which is the cheapest of all these substances. None of them, however, can be advantageously used as aërial disinfectants, as they are not in any case volatile.

6. *Permanganate of Potash* and *Chlorozone* are both oxidising agents, and do not appear to exert much action on vital manifestations, but they are very active in the destruction of dead organic matter. The use, therefore, of these agents in the sick-room as disinfectants is altogether fallacious, for we have no reliable evidence of their power of destroying contagia. The sheet, indeed, saturated with Condy's fluid, which is recommended to be hung up in the sick-chamber, will quickly, like other dead organic matter, decompose the fluid and render it inert. This property, however, of attacking and oxidising dead and decaying organic matter gives it value as a means of purifying potable water, and for this purpose it is alone useful. The same may be said of chlorozone, for the small quantity of free chlorine present in it is not capable of much energy of action.

7. The Volatile Oils—as *Camphor, Turpentine*, etc.—are probably effective to some extent, for we not only perceive that they hinder the development of animalcules and fungi, but they also generate ozone; for ages, indeed, these substances have enjoyed a high reputation as trustworthy disinfectants and deodorisers. They are the correctives universally employed in religious worship, and from time immemorial they have entered into the composition of the ointments of the high priest and the incense of the altar. Among eastern nations the practice of fumigating the house with costly spice and rich-smelling drugs has been contemporaneous with history. During the middle ages, when the plague, the black death, and the sweating sickness decimated the cities of Europe, immense importance was attached to these agents as disinfectants. The advice of the learned Dr. Caius, who wrote of the sweating sickness in 1552, was to "have always your handkerchief perfumed with a mixture of spices for your nose and your mouth, both within your house and without, and in your mouth a piece either of setwel or of the root of *Enula campana* well steeped before in vinegar roseate, or a mace, or berie of juniper. In want of such perfumes, as before said, take of myrrh and dried rose-leaves, of each a like quantity, with a little frankincense, for the like purpose, and cast it upon the coals, or burn juniper and their berries." Until very recently, too, the practice in our criminal courts was to lay a bunch of rue on each side of the prisoner, to prevent the spread of contagion brought from the infected gaol. Now, it is a curious fact, as I will show you experimentally, that the oxidation of perfumes and volatile oils is generally accompanied with an active ozonisation of the atmosphere—indeed, Professor Paolo Mantegazza, of Pavia, who has carefully investigated this subject, says that this is a very convenient method of obtaining ozone: for under the influence of light (especially solar light) and air the essential oils, even in small quantities, will ozonise comparatively large proportions of atmospheric oxygen. It may well be, therefore, that the volatile oils and essences deserve the reputation they have so long enjoyed as purifying agents; and that the recommendation of Empedocles, to plant aromatic and balsamic herbs about your house as preventives of pestilence, is supported by scientific as well as empirical facts. Moreover, as benzoic acid is a large constituent of the incense used in the Latin and Greek churches, it is possible, looking at its antiseptic powers, that this also may be useful as a disinfectant.

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Resident Medical Officer to the London Fever Hospital.

No. XI.

(*With Photo-lithographic Plates.*)

Dicrotism: its Production; conditions determining its Intensity—Varieties of the Pulse in Acute Disease—The Pulse in Typhus.

In approaching the consideration of the pulse in acute diseases, it will be necessary first to consider some points connected with the physiology of the circulation, more especially those bearing upon the production of dicrotism. One of the earlier papers in this series (No. III., *Medical Times and Gazette*, March 2, 1872) was devoted chiefly to this subject; but since that was written it has been found necessary, owing to more extended experiments and further observation, very materially to alter the views therein expressed. An apology is therefore necessary for a conclusion too hastily arrived at, after investigating only one side of the case, however strong that side appeared to be in experimental proof.

The hydro-dynamic problems of the circulation form some of the most complicated in physiology, and their extreme difficulty alone would afford excuse for many errors. It was stated in the paper above mentioned that dicrotism was produced by, and was dependent upon, a condition of high arterial tension; it is on this most important point that it has been found necessary to alter the views then entertained.

The experiment previously related of placing an elastic bag at the commencement of the aorta, in a schema formed of comparatively inelastic tubing (of which the tracing had previously been non-dicrotic), and by this means immediately producing dicrotism, no other condition having been changed, appeared to prove—as, indeed, it did—that the dicrotic wave owed its origin to the elastic recoil of the aorta. But further than this, it was shown that by constricting portions of the schema representing the capillaries, or by increasing the rapidity of the contractions—either proceeding increasing the tension in the system of tubes representing the arteries—the dicrotic wave was increased. This result seemed as conclusive as the previous one. In further experiments on straight and more elastic tubing, however (many of them made conjointly with my friend Dr. Galabin, who has especially advocated the present view in his highly interesting paper "On the Cause of the Secondary Waves of the Pulse," read before the British Medical Association at its recent meeting), it was found that dicrotism was more readily produced when the the tension was reduced to a minimum, such as in a straight tube of large calibre with an unconstricted outlet. Other experiments also proved the dicrotic, or some wave exactly resembling it, to exist, even when the aortic valve had been removed. Dr. Galabin has carried these observations still further, and has shown that when a straight tube of equal calibre throughout is used a reflected wave is produced, which originates at the distal end of the tube, and travels from the periphery towards the centre. He has found, however, in a more mechanically correct and still more simple schema, composed of bifurcating tubes, that the same law of the coincidence of dicrotism with low tension remains true.

These results, so utterly contradictory, naturally present many difficulties in their explanation. It is certain, from observations on animals, on the human subject under abnormal conditions, and on the schema with an elastic aorta, that the aorta is greatly dilated by the influx of blood produced during systole, and that immediately this action ceases it is followed by the contraction of the elastic coat. This contraction is surely the result of a distinct mechanical power (that of elasticity), and is not merely the result of the inertia of the arterial walls as argued by Dr. Galabin (in opposition to the view of its production as the result of their elasticity), and

must necessarily produce a second or dicrotic wave in the pulse. If this be the case, the elastic recoil of the aorta must be admitted as the prime origin of the dicrotic wave. Doubtless, as stated in the paper above referred to, the recoil from the closure of the aortic valves is one component of the dicrotic wave, but it is only a secondary one, and would scarcely have existence were it not for the elastic contraction of the aorta. The conditions under which this wave becomes most developed are somewhat difficult to ascertain; while discussing them, it must be remembered that they do not resolve themselves into a question of high or low tension occurring in a system of tubes of unvarying elasticity, but the relaxed or contracted state of the muscular walls of the arteries must also be taken into account; and, according as one or the other condition obtains, the walls enclosing the blood-column become more or less elastic, or rather their innate elasticity is permitted to act with greater freedom. The dicrotic wave appears to vary in intensity, chiefly with the variations in these conditions—*i.e.*, it is more intense when the muscular walls are relaxed, it is less so when they are contracted; or, in other words, it is more intense with a highly elastic tube, less so with a more rigid one.

In the normal state, with the muscular coat of the arterial wall healthy and of good tone, or more especially in Bright's disease, when they are hypertrophied and acting more powerfully than usual, the pulse is non-dicrotic and the condition is one of so-called "high-tension"; while in fevers, or other conditions where the vaso-motor nerves are poisoned and the muscular coat is inactive and relaxed, the pulse is dicrotic, and the condition has been called that of "low tension."(a)

That the muscular coats of the smaller arteries have power to resist the distending tendency of the heart's contraction is proved by the well-known fact that it possesses the power of contracting if a small artery be completely divided, and so arresting hæmorrhage—in this case overcoming that portion of the force of the heart's systole which reaches it by its own power of contraction. This of course is only true of the small arteries, and could not take place were it not that the blood-pressure diminishes in inverse proportion to the distance from the heart.

If it be admitted, therefore, that, given a healthy condition of the muscular coats of the arteries, their tonic contraction being of good power, the heart has not power to distend them beyond limits regulated by themselves, it follows that in those conditions accompanied by good muscular tone, or in Bright's disease, the space afforded in the arterial system for the reception of the blood thrown into it during the systole of the heart is at a minimum. The blood-tension must in these cases be high. The aorta, which is distended greatly during the heart's systole, has not the opportunity to contract and empty itself sufficiently to regain a condition of rest or non-distension, the pressure in front being too great for it to completely overcome before the next systole occurs, which therefore finds it still more or less distended; such contraction as it does make is made slowly and gradually, and is only able to maintain the constant onward flow and produce a marked fulness of the vessels during diastole. The movement is not sufficiently sudden to form a wave superimposed upon, and travelling more quickly than, the ordinary blood-current. Distension is sudden and complete after each systole, but the corresponding contraction during diastole is gradual and incomplete. The dicrotic wave under these circumstances is not only imperfectly formed, but the high tension of the arterial walls through which it passes obstructs its progress, and tends to obliterate it.

On the other hand, under conditions by which the arterial muscles are relaxed and inactive, either owing to bad tone, or in a more excessive degree to reflex paralysis from poisoned blood, or from nerve derangement, the space afforded for the blood in the arterial system would be greatly increased, while the opposition to its onward movement would be correspondingly diminished; in other words, low arterial tension would exist. Under these circumstances, the elastic walls of the aorta are at liberty to act more freely. After distension during the cardiac systole they contract during diastole more completely and more suddenly, by virtue of their elasticity, the pressure to be overcome being diminished. This more complete contraction of the aortic walls produces a larger dicrotic wave, which, owing to the decreased lateral pressure or "tension" of the blood-column, encounters less resistance to its onward movement.

Following the dicrotic wave there is often seen another small wave or secondary dicrotism. Occasionally, in very slow pulses with relaxed arteries and low tension, it becomes strikingly developed. This is probably due to an oscillatory or vibratile movement of the arterial walls occurring in their efforts to regain their equilibrium. It is to this wave that I should prefer to apply Dr. Galabin's theory of the inertia of the arterial walls.

So far this discussion of the pulse, or rather its most important feature in the febrile state—namely, dicrotism—has been chiefly theoretical, and with only its physiological import in view. Its clinical meaning must now be examined, its value as a symptom and an aid to prognosis in fever investigated.

One of the first questions which demands an answer when considering the clinical importance of dicrotism, is whether or not the development of this wave bears any exact relative proportion to the temperature of the patient. It has been sought by some to show that it does bear a very close relation; but this assertion is incorrect, and for the purpose of controverting it, several tracings coexistent with high temperature, and showing various degrees of dicrotism, have been placed at the commencement of the accompanying plate. But inasmuch as a high temperature often indicates a severe condition of fever, so hyperdicrotism affording the same indication often accompanies it. In the same manner a medium temperature indicates a mild degree of fever, and is coincident with only moderate development of the dicrotic wave.

The pulse of the febrile state may assume either the sthenic or the asthenic type,—in other words, it may be non-dicrotic or dicrotic. The former of these conditions is the rarer, and will not be much discussed in the present paper, but be reserved for a future occasion, when it will be shown to be coincident with a certain vascular condition, and to give rise to a well-known series of pathological conditions more usually referred to renal disease. The latter, or asthenic, type is the form which is generally found in fevers.

Fig. 1, Pl. ix., is an example of the non-dicrotic or sthenic form of pulse, occurring in this instance in a case of erysipelas on the second day of the disease, the temperature being 103°. A pressure of three ounces was used, and it required very much more to extinguish the pulse. The pulse in erysipelas usually assumes the sthenic form, especially in its early stages; when exhaustion supervenes, or should the condition become in any degree pyæmic, the pulse will become dicrotic. This character, however, may be altered by treatment. All mild forms of surgical fever, after operations, etc., occurring in healthy individuals resemble this form of pulse closely. It is a pulse which feels full and strong and well sustained to the finger; it does not vary from the normal form of pulse except in being harder, quicker, and a little larger. Persons who in health possess dicrotic pulses probably have the dicrotism correspondingly increased in this condition; otherwise it is a pulse occurring under the conditions of health, with an increased rapidity and increased force of the heart's contractions; the vessels are full, and the muscular walls of good tone.

The effect of loss of blood on this form of pulse is well seen in Fig. 2, Pl. ix. This tracing was obtained from a man who had lost an immense quantity of blood during an operation for the removal of a naso-pharyngeal polypus performed on the previous day. His temperature had risen, and it was now 102·4° F.; the condition of surgical fever was therefore present. The extreme dicrotism which manifested itself was due probably both to the diminished quantity and quality of the blood; the watery blood probably acting in great measure as poisoned blood in relaxing the arterial walls. The diminished quantity perhaps accounts for the peculiar character of the dicrotism—namely, the sharpness of the angles, and the strikingly vertical upstroke of the dicrotic wave. It is a noteworthy fact that during the few succeeding days, though the temperature each day increased, the dicrotism daily diminished, proving distinctly that the dicrotism was not due to the febrile but to the anæmic condition.

Even in the most severe cases of surgical or traumatic fever, when the patient is actually moribund, the pulse is often non-dicrotic. This may possibly be due to the much enfeebled action of the heart, which has not power to distend the aorta

(a) Bernard, by his differential manometer, has proved the influence of the vaso-motor nerves through the arterial muscular coat on the tension of the blood-column. On introducing the mouth-pieces of the instrument into the two facial arteries of a horse, the mercury stood at the same level in each arm of the instrument; but on division of one of the cervical sympathetic nerves, the mercury instantly rose on that side, indicating a diminution in the tension of that vessel.

and produce a recoil; but doubtless the vascular condition of unrelaxed arteries also exists.

An instance of this may be seen in Fig. 3, Pl. ix., obtained from a man suffering from traumatic fever and shock accompanying extremely severe contusions produced by a fall from a height. His temperature was 104°. He died on the following day (the fourth after the accident), his pulse never becoming dicrotic.

Fig. 4, Pl. ix., is an instance of hyperdicrotism occurring in a case of surgical, or rather suppurative fever, with a temperature of 103·5°, following an amputation through the thigh, the patient being moribund. Death ensued on the following day.

Fig. 5, Pl. ix., represents the pulse in a case of pneumonia which terminated fatally two days afterwards, the temperature at the time being 105·2°. The pulse possessed the same characters during the four days he was under observation. The non-dicrotic character was in this case again due in some measure to an overtaxed and failing heart, but, as in the case previously mentioned, the arterial condition cannot be absolved; for in the last stage of heart disease, when the ventricle is greatly dilated and rapidly failing, the pulse is often hyperdicrotic; and again in typhus, when the heart is very greatly affected, and death ensues from exhaustion of this organ, the pulse may be hyperdicrotic. (*Vide* Fig. 21, Pl. ix.)

The contracted arteries perhaps formed the chief factor in the sum of pathological causes of death; for by their contraction the difficulty of the circulation and labour of the heart would be materially increased. Thus the knowledge of this condition may afford the most valuable indication for treatment. In those cases in which the muscular walls are contracted, veratria and aconite may be indicated; and in those in which the arteries are extremely relaxed, digitalis may prove of advantage. It is perhaps to the absence of this rule for treatment, and to the indiscriminate use of these powerful drugs, that they have chanced to be wrongly used in some cases when the results have proved disappointing.

Fig 6, Pl. ix., affords an instance of relaxed walls and low arterial pressure occurring in pneumonia. Far more dicrotic tracings might have been selected, as the pulse sometimes assumes the condition of hyperdicrotism in an extreme degree; but in this case dicrotism occurs in a pulse requiring considerable pressure—*i.e.*, four ounces. This is comparatively rare in dicrotic pulses, and the pulse may be regarded as a transitional one, for in pneumonia I believe it to be more frequently non-dicrotic; and it is to this fact possibly that the advantages lately ascribed to the exhibition of veratria or aconite have been due. The full, hard pulse of pneumonia has been noticed by the older writers, so also has the "*contracted*" pulse. Sir Thomas Watson in his classical work, speaking of the advisability of the occasional use of the lancet, says that in those cases of high fever accompanied by a "*hard, firm pulse*," blood may be taken till it becomes "*softer*," "or, if it were *contracted*, till it becomes *fuller*." These were the directions usually given, and more elaborate means of clinical observation appear to prove their truth.

Passing from these general observations, which apply to the pulse in all febrile conditions, when it varies with the constitution of the patient, the nature of the disease, and its intensity, the character of the pulse in some of the specific fevers may be noticed. It bears a certain character in each. Typhus may be said to possess a malignant form of pulse, remarkable either for its extreme dicrotism or its failing heart.(b)

Figs 7, 8, 9, and 10, Pl. ix., were obtained from a mild case of typhus occurring in a man aged 25. The patient came under observation on about the twelfth day of his fever. Fig 7 represents his pulse on the morning of that day; his temperature was only 103·1° F., and his general condition indicated a mild attack. His pulse was extremely hyperdicrotic, but there is no loss of percussion, rounding of the angles, or other indication of a failing or overtaxed heart.

Fig. 8, obtained on the fourteenth, and Fig. 9 on the fifteenth days of his fever, which had now passed its crisis and was abating, indicate an excited but powerfully acting heart, the tracing being obtained on each occasion with a pressure of four ounces, which is extremely high, and gives the best prognosis in typhus. It is thus, as a gauge of the power of the heart's action, which is the greatest source of danger in typhus, that the sphygmograph affords assistance in these cases. So long as the tracing affords indications of a heart so well capable of performing its work, little need be feared for the patient. Fig. 10, obtained two days after the one preceding it, shows how rapidly the pulse resumes the normal character.

The six tracings (Figs. 11 to 16 inclusive) placed next on the plate illustrate the pulse of another case of typhus, rather more severe than the last, occurring in a woman aged 25. She came under notice about the eleventh day of her fever. On the twelfth day the tracing reproduced in Fig. 11 was obtained. On this day her temperature was higher, and the indications afforded by her pulse worse, than on any other day of her illness. Her temperature at the time the tracing was obtained was 104°. The pulse is by no means a severe one for typhus, although it is very hyperdicrotic and the apices are somewhat rounded. The latter feature indicates some failing of the heart's action, and is the most serious characteristic of the pulse. The dicrotism may be far more excessive, and even assume the monocrotic form, and yet be consistent with recovery.

A monocrotic pulse is merely a hyperdicrotic pulse which is so rapid that the primary upstroke becomes superimposed upon the dicrotic wave, which has not time to travel to the radial before the more rapidly transmitted primary wave of the succeeding cardiac contraction overtakes and absorbs it, as one often sees a small wave of the sea merged into the larger one which has overrun it. The dicrotic wave in these instances is probably a small and slowly travelling one, as the lower the tension the slower the transmission of these secondary waves; and the more feeble the heart's contraction, the less the aortic recoil and the smaller the dicrotic wave.

Fig. 12, obtained on the thirteenth day of the fever, shows a higher upstroke, indicating a more forcible contraction. In this tracing the dicrotic wave is almost obliterated; all that remains of it is the slight rise visible before the commencement of the upstroke. The meaning of this absence of the dicrotic wave is extremely doubtful; I can form no theory that will satisfactorily account for it. One thing appears certain—it is not identical with the true monocrotic pulse.

In Figs. 13, 14, and 15, obtained on the fourteenth, fifteenth, and sixteenth days of the fever respectively, the dicrotic wave is seen gradually to increase in size, while the temperature subsides in the same relative proportion. Fig. 16 was obtained on the nineteenth day of her fever, the first on which her temperature reached the normal point. It is remarkable how perfectly and how quickly the pulse recovers itself. This tracing is in all respects perfectly normal, both the tone of the arteries and the power of the heart being apparently good. It is hard to believe that the heart suffers as much as some writers represent—it would appear to be only overtaxed for the time being, and its failing action may be due merely to a temporary mechanical condition, and not to an actual organic change, though in extreme cases this may also exist; for if in all severe cases the heart underwent more or less fatty degeneration, it could scarcely recover itself in so incredibly short a space of time as to give a perfectly healthy tracing on the first day of the return of the temperature to the normal standard.

Figs. 17 and 18, Pl. ix., were obtained from a man, aged 51, who, while convalescing from acute rheumatism, contracted typhus. His age, and his previous attack of rheumatism, united to secure the most unfavourable condition for his heart. He was admitted into the London Fever Hospital on the fifteenth day of his fever. His pulse on the following day is reproduced in Fig. 17: the upstroke is oblique, the percussion-wave absent, the apex rounded, and the respiratory line undulating; occasionally, also, the rhythm is irregular—there is every indication, in fact, of a failing heart. The area of cardiac dulness was increased, and the sounds were extremely feeble, but no bruit was audible. The base of the right lung had become pneumonic, and this complication may account for the absence of dicrotism—the artery feeling to the finger small and contracted, instead of large and relaxed. His condition was hopeless from the time of admission. On the next day, the seventeenth of his fever, his pulse was much more feeble, smaller, and more irregular, as indicated in Fig. 18. After this his temperature rapidly fell; on the succeeding day his pulse could not be felt, nor a tracing obtained, on account of the constant subsultus, and death occurred the same evening.

Figs. 19, 20, and 21, Pl. ix., were obtained from a man aged

(b) Unfortunately it is impossible to obtain tracings of all cases of typhus, and often some of the most interesting series are spoilt by the condition of the patient, as the disease advances, not permitting a tracing to be obtained, owing either to the violent delirium or to the constant subsultus.

32, who was a hard drinker and had contracted typhus. His pulse on the first day he came under observation (about the thirteenth of his fever) was a fairly good one, though the upstrokes were slightly oblique and the apices a little rounded. It was only fully dicrotic, and the pressure employed was three ounces, indicating a heart acting with good power, though the commencement of the contraction was not so sudden and forcible as usual. His temperature was only 102·9°. On the following day his condition was considerably worse: the upstrokes were much more oblique, and the apices quite round; the dicrotic wave was diminished. It still, however, required the same pressure to develope it—though the heart's power was evidently failing. By auscultation the sounds were found to be feeble, the first sound being almost inaudible at apex.

The pulse on the succeeding day had assumed an inevitably fatal form, represented by Fig. 21—the upstrokes as sloping as the downstrokes; all angles obliterated; each contraction of the heart varying in power from the preceding one; the pulse altering its character at each pulsation, being sometimes not fully dicrotic, at others hyperdicrotic, and at another monocrotic; the respiratory line is undulating. This great change in his heart and in the prognosis of the case, be it noticed, is not indicated by the temperature, which remained almost stationary, being on this day 103°. Death occurred on the following day. The last two cases are good examples of death produced by failure of heart, and not by intensity of fever.

SNAKE-POISONING IN INDIA.

Communicated by J. FAYRER, C.S.I., M.D., F.R.C.P.

(*Continued from page* 251.)

Second Instalment of the Report of the Committee appointed by the Government of India to investigate the Subject of the Treatment of Snake-poisoning by Artificial Respiration. (The following gentlemen form the Committee:—Dr. Ewart, President, Dr. Mackenzie, and Mr. Vincent Richards.)

Experiment 6.—July 15.—A dog was bitten by a cobra at 7.17 a.m; the temperature was then 102·4°. 7.25 a.m.: Temperature 101·8°. 7.40 a.m.: Convulsed; temperature 101·6°. 7.43 a.m.: Commenced artificial respiration; the pupils were dilated, and the animal was much convulsed. The pupils gradually assumed their natural appearance, and convulsions ceased. The dog shakes its ears when a fly settles on them. 8.8 a.m.: Temperature 101·4°. 8.30 a.m.: Temperature 101·3°; the pulse is beating steadily and well, 100; respirations 36. 9.30 a.m.: Temperature 101·2°; respirations 28, much too slow; pulse 200, strong and regular; the usual response to the galvanic current. 10.30 a.m.: Temperature 100·2°; respirations 36; pulse good, 144. 11.30 a.m.: Temperature 100·2°; respirations 32; pulse 112, very strong; same response to the galvanic current. 12.30 p.m.: Temperature 98°; respirations 32. 1.10 p.m.: Heart ceased to beat, five hours twenty-seven minutes after the commencement of artificial respiration. This was not at all a satisfactory experiment. Blood coagulated after death.

Experiment 7.—July 16.—A dog was bitten by a cobra at 8.25 a.m; the temperature was then 103·2°. 8.35 a.m.: Temperature 103·4°. 8.44 a.m.: Temperature 103°. 8.50 a.m.: Commenced artificial respiration; the pupils were at first dilated, but afterwards became natural. 9.5 a.m.: Temperature 103°; pulse 136; respirations 60; applied heat. 10 a.m.: Temperature 101·6; respirations 40; pulse beating very rapidly; no response to the galvanic current. Noon: Pulse 190; temperature 105·5°; respirations 42; pupils dilate by galvanism. 1 p.m.: Respirations 44; pulse 180; one pupil only dilates by galvanism; temperature 105°. 2 p.m.: Respirations 42; pulse 172; temperature 104°; no response to galvanism. 3 p.m.: Respirations 44; pulse 190; femoral cannot be felt; temperature 103·8°. 4 p.m.: Temperature 104·4°; respirations 40; femoral artery beating very rapidly; no response to galvanism. 5 p.m.: Temperature 104·7°; respirations 36; pulse 200; no response to galvanism. 5.30 p.m.: Temperature 104·2°; respirations 36; pulse about 200, and pretty strong. 7.30 p.m.: The heart is beating rapidly, but pretty forcibly; respirations 44; temperature 104·2°; no response to galvanism. The blood coagulated after death. We were kindly assisted by Dr. O'Brien.

Experiment 8.—July 18.—A dog was bitten by a snake at 8 a.m.; the temperature was then 101·6°. 8.15 a.m.: The temperature has risen to 102°. 8.20 a.m.: Temperature 102·4°. 8.30 a.m.: Temperature 102°. 8.52 a.m.: As the bite was considered a doubtful one, the dog was now bitten by another cobra. 8.58 a.m.: Temperature 102·5°; convulsed. 7.5 a.m.: Artificial respiration was commenced; temperature 102·5°. 9.20 a.m.: Temperature 101·6°; the heart did not begin to beat so well as usual: respirations 44; applied heat. 10.20 a.m.: Temperature 101·1°; pulse 100, pretty strong; respirations 40. 11 a.m.: Temperature 101·6°; pulse very quick and weak; respirations 56; same response to galvanism. Noon: Temperature 103·2°; pulse 160, very irregular; respirations 44; passes water in response to the galvanic current. 1 p.m.: Respirations 36; temperature 104·2°; pulse very quick and weak; a few drops of urine pass on applying galvanism. 2 p.m.: Temperature — °; respirations 36; pulse beating rapidly and without force; no response to the galvanic current. 3 p.m.: Temperature 104·2°; respirations 44; pulse beating rapidly; no response to the galvanic current. 4 p.m.: Temperature 103°; respirations 36; pulse beating very rapidly, and is extremely weak. 4.20 p.m.: Heart ceased to beat, seven hours and fifteen minutes after the commencement of artificial respiration. The blood in this instance was fluid, and did not properly coagulate. This snake bit more viciously than ever we saw a snake bite.

Experiment 9.—July 19.—A middling-sized dog was bitten by a cobra at 8.20 a.m. 8.28 a.m.: Passed a stool. 8.30 a.m.: Temperature 104·2°. 8.45 a.m.: Fell over. Temperature 104·8; pulse 132°; respirations 36. 8.55 a.m.: Commenced artificial respiration. This dog was scarcely convulsed at all at the time, but it appeared quite dead. 9.5 a.m.: Temperature 105°; respirations 44; pulse 134, pretty strong. Slight convulsions have occurred since the commencement of artificial respiration. The pupils are now natural. 10 a.m.: Temperature 103°; respirations 44; heart beating very rapidly, and with but little force. Noon: Respirations 40; heart beating extremely rapidly, and without force; temperature 105°; passes water in response to the galvanic current. 1 p.m.: The heart can scarcely be felt beating; temperature 104°. 1.10 p.m.: Heart ceased to beat, in four hours fifteen minutes. The blood coagulated after death. This dog was the smallest yet operated on. Dr. O'Brien assisted us.

Experiment 10.—July 21.—A dog was bitten by a cobra at 7.52 a.m.; temperature previous to the bite 103°. 8.10 a.m.: Temperature 102·8°; much purged. 8.20 a.m.: Convulsed. 8.23 a.m.: Commenced artificial respiration. The pupils, from being widely dilated, became perfectly natural, convulsions ceased, and sensibility returned; sensibility lasted for an extraordinarily long time—viz., from 8.23 a.m. until 9.12 a.m., when it ceased; temperature 102°. 10 a.m.: Heart beating quickly and very forcibly; respirations 50; temperature 100·8°. 11 a.m.: Heart and respirations the same; temperature also the same; pupils dilated by galvanism. 11.30 a.m.: Belly all at once became tympanitic. The bases of the lungs are evidently congested. Heart has been beating very irregularly. Noon: Temperature 104°; heart beating very strongly though slowly; respirations 48; heart, pupils, and bladder respond to galvanism—the heart especially. 1 p.m.: Exactly the same in all respects. 2 p.m.: Temperature 104°; respirations 44. 3 p.m.: Respirations 46; pulse very rapid and weak; temperature 105°. 4 p.m.: Respirations 44; temperature 100·8°; pulse 190. 5 p.m.: Temperature 103·3°; respirations 48; pulse strong, 200; pupils dilate very slightly in response to galvanism. 6 p.m.: Temperature 102·9°; respirations 48; pulse strong, 200; pupils only slightly respond to galvanism. 8 p.m.: Temperature 103°; heart beating very rapidly and tolerably strongly; respirations 48. 10 p.m.: Temperature 103°; pulse 160; respirations 48; no response to galvanism. 11 p.m.: The same. Midnight: Temperature 103°; respirations 48; heart beating very rapidly. 1 a.m.: Heart beating very feebly; respirations 44; temperature 105°. 1.25 a.m.: Heart ceased to beat, seventeen hours and two minutes after the commencement of artificial respiration. Blood coagulated after death. Dr. O'Brien assisted.

Experiment 11.—July 3.—A dog was bitten by a cobra at 7.50 a.m.; temperature 103°. 8 a.m.: Temperature 104°. 8.38 a.m.: Convulsed. 8.40 a.m.: Commenced artificial respiration. 9.10 a.m.: Temperature 101·1°. Had a sharp convulsive movement; is now perfectly senseless; heart beating slowly and irregularly; passes water and the pupils dilate on the application of galvanism. 10 a.m.: Temperature 101°;

respirations 40; pulse 176; the usual response to galvanism. 11 a.m.: Temperature 102·7°; pulse 152; respirations 52. 1 p.m.: Respirations 44; pulse 160; temperature 102·5°; response to galvanism as usual. 3 p.m.: Temperature 103·2°; respirations 44; pulse 120; galvanism causes urine to pass. 5 p.m.: Temperature 103°; pulse small and weak, 200; respirations 44. 6.30 p.m.: Temperature 106·2°. 8 p.m.: Heart beating very rapidly; respirations 44; temperature 103°. From this time the heart's action gradually became weaker, until it ceased at 11.30 p.m. The blood was fluid when taken from the body; one hour after death it rapidly coagulated. Dr. O'Brien assisted.

Experiment 12.—July 24.—A dog was bitten at 7.50 a.m. 8 a.m.: Temperature 103·4°. 8.23 a.m.: Again bitten by another snake, as we were in doubts about the efficacy of the first bite. 8.30 a.m.: Affected; commenced artificial respiration. 9 a.m.: Temperature 102·5°; applied heat; pulse weak and irregular, 64. 11 a.m.: Respirations 36; temperature 102·8°; pulse 200; response to galvanism. 1 p.m.: Pulse 180; temperature 103°; respirations 38. 3 p.m.: Pulse 140; temperature 103·2°; respirations 36; response to galvanism. 6 p.m.: Pulse 200; temperature 102·6°; respirations 32. 8 p.m.: Pulse 136; respirations 36; temperature 100·2°. 10 p.m.: Temperature 103·2°; pulse 160; pretty good respirations, 28; had passed water; no response to galvanism. 11.20: Heart ceased to beat, fourteen hours and fifty minutes after the commencement of artificial respiration. Blood coagulated. Assisted by Dr. O'Brien.

Half a drachm of the saliva of dog No. 11 was injected hypodermically into a pigeon. The bird died on the morning of the second day.

Ten drachms of the saliva of dog No. 11 were injected into the femoral vein of a dog. The result was great prostration and a gradual fall in the temperature.

(*To be continued.*)

A CASE OF

ACUTE PLEURISY RESULTING QUICKLY IN EMPYEMA — OPERATION — RECOVERY.

By GEORGE SCOTT, M.D.,
Physician to the Royal South Hants Infirmary.

W. H., AGED 40, a short, stout, robust-looking man. States that he has all his life enjoyed very good health, having only occasionally suffered from trifling ailments. His present illness dates from Monday evening, June 2, 1873, when he had a very severe rigor. I saw him for the first time on June 4. He was then complaining of pain in the head and back, want of appetite, and thirst. His tongue was very foul. Pulse not high: between 80 and 90 in the minute. I prescribed some saline mixture to be taken every three hours.

At 1 a.m. of June 6 he was seized with a very severe cutting pain in the right side, just above the liver. A dose of opium was given, and a sinapism was applied externally to the painful part. At noon on the same day I detected a loud friction-sound at the lower part of the right lung, where he complained very much of severe pain, particularly on taking a deep inspiration. Tongue still very foul. I ordered six leeches to be applied immediately, and subsequently linseed-meal poultices to the painful part. ℞. Calomelanos gr. iij., pulv. ipecac. gr. ij., pulv. opii gr. vj., cons. rosarum q. s.; divide in pilules xij., una omni quartâ horâ sumenda.

June 7.—Pain in right side much relieved by leeches. A distinct to-and-fro sound is heard to-day over the cardiac region. ℞. Pulv. rhei, pulv. jalapæ, āā ʒ ss., podophyllin gr. ij., sodæ bicarb. ʒij.—M.; divide in pulveres iv., unus omni mane sumendus.

9th.—Pain in the right side better. There is considerable dulness on percussion at the lower part of the right lung, together with diminished respiratory sound and diminished vocal thrill at the same part, thus indicating effusion into the cavity of the right pleura. Omittantur pilulæ calomelanos, etc., et ℞. Potassæ nitr. ʒj., spt. æther nitr. ʒiij., aquæ cinnamonii ad ʒxij.—M.; cochl. magnum quater in die sum. Contin. pulv. rhei, etc., omni mane; to have no solid food, but liquid nourishment *ad libitum*, such as beef-tea, milk, yolks of eggs, etc.

12th.—Pulse 92; temperature 100·2°; respiration 36. Condition of patient is much the same as at last report.

14th.—11.15 a.m.: Pulse 90; temperature 100°; respiration 34. He complained this morning of an acute pain in the left side, just below the heart. This was considerably relieved by a mustard poultice. A friction-sound is heard on the left side of the chest posteriorly, just about the spine of the scapula, also in the axillary line and in front of this. Tongue foul. Urine more copious. Sumat æger pulv. rhei, etc., statim.

15th.—10.30 a.m.: Pulse 114; temperature 101·8°; respiration 44. Bowels moved five times since last visit. Tongue still foul. Friction-sound on the left side heard the same as yesterday. To-and-fro murmur over the cardiac region still distinct. Sumat ægar pulv. rhei, etc., cras mane.

16th.—12 noon: Pulse 106; temperature 100·8°; respiration 40. Bowels freely moved by powder; urine copious, high-coloured, and thick with lithates; tongue foul; sweating profusely. Friction-sound still distinctly heard on the left side posteriorly below the spine of the scapula, and very loud anteriorly, just below, and a little external to, the left nipple; at the latter spot the friction can be felt by the hand placed on the chest. On the right side of the chest posteriorly there is absolute dulness on percussion as high as the level of the fifth dorsal spine; above this there is slight dulness up to within one inch of the apex. The breathing is very indistinctly heard over this absolutely dull portion, and the vocal thrill is here quite absent. Above the level of the fifth dorsal spine the breathing is heard, and the vocal thrill can be felt, although neither so distinctly as on the left side. He lies chiefly on his right side. The to-and-fro murmur over the cardiac region can scarcely be heard to-day, and the heart-sounds are indistinct and muffled. When the patient is lying on his right side the respiration is thirty-nine in the minute; when on his left side it is forty-three in the minute. Diet consists of from one to two quarts of beef-tea, about one pint of milk, four or five eggs, a little farinaceous pudding, etc., and a dessertspoonful of brandy four times in the twenty-four hours.

17th.—11.15 a.m.; Pulse 100; temperature 101·9°; respiration 40. Bowels well open; urine not quite so copious; sweating profusely. Mr. Mott saw the case with me to-day, and we determined to try a little longer the effect of medicines in causing the absorption of the fluid in the right pleural cavity, but if we saw no improvement by the end of the week (June 21), to resort to paracentesis. To take double dose of the nitrate of potash mixture—*i.e.*, one ounce four times a day.

18th.—12.30 p.m. (noon): Pulse 106; temperature 101·3°; respiration 35. Passed a good night. Bowels freely open; stools rather offensive; urine in fair quantity; tongue rather cleaner. Has still profuse sweats. Anteriorly on the right side the dulness in the middle and in the mammary lines extends up to about one inch above the nipple; in the axillary line almost up to the apex of the axillary fossa. Normal breathing is heard anteriorly at the apex of the right lung, but hardly at all below this. The friction-sound is not heard on the posterior part of the left side to-day, but it is so distinctly in the axillary line below the level of the nipple. A slight to-and-fro sound is heard over the cardiac region, and the heart-sounds themselves are still rather muffled. Continue mist. potassæ nitr., etc.

19th.—4.30 p.m.: Pulse 102; temperature 101·5°; respiration 40. Slept well. Tongue foul; bowels freely open; urine more copious—at least two quarts since last visit. Friction-sound on left side and to-and-fro sound over the cardiac region have disappeared; heart-sounds are still somewhat muffled. Sumat æger pulv. rhei, etc., cras mane.

20th.—1 p.m.: Pulse 106; respiration 36. Slept very well. Not quite so much sweating; tongue still rather coated; heart-sounds heard distinctly to-day, a bellows-murmur accompanying the second sound; bowels freely open; urine of normal appearance, and measuring about two quarts in the last twenty-four hours.

21st.—5 p.m.: Pulse 102; temperature 101·3°; respiration 42. Not so well to-day, although he did not sleep badly last night; he complains of pains in the legs, shortness of breath, weakness, and a sensation of tightness across the abdomen. Sweats more than ever. Bowels moved only once since last visit; urine about one quart in the last twenty-four hours; tongue still a little foul. Messrs. Mott and Ware saw the patient with me again this afternoon, and physical signs showing that the right pleura was more than half full of fluid (below the level of the fifth dorsal spine there was absolute dulness both anteriorly and posteriorly), and the genera

symptoms—dyspnœa, sweatings, exhaustion, etc.—becoming more urgent, we determined to relieve the man at once by tapping. Accordingly, the patient being in a sitting posture, I plunged into the seventh intercostal space, midway between the sternum and spine, a trocar and canula an eighth of an inch in diameter (the latter provided with a tap), withdrew the trocar, fitted on Bowditch's syringe, and drew away about a pint and a half of bland, creamy pus. I experienced some little difficulty in doing this, owing to the thickness and flakiness of the matter. Once, when the canula seemed to be stopped up, I reversed the action of the syringe, and injected two or three teaspoonfuls of luke-warm water into the pleural cavity, with the effect of again clearing the tube, and thus enabling me to get away as much pus as I did. The wound was closed by a pledget of lint secured by strapping, and the patient was put back to bed. He required a few doses of brandy to keep him up during the operation, which, on the whole, he bore very well. To have two or three ounces of brandy in the twenty-four hours. Diet as before. Continue mist. potassæ citr., etc., et sumat aeger pulv. rhei, etc., cras mane.

22nd.—10.15 a.m.: Pulse 104; temperature 101·4°; respiration 42. Rested well last night. Sweatings profuse, although not quite so much so as before. Tongue still foul.

23rd.—2 p.m.: Pulse 106, of fair strength; temperature 101·4°; respiration 37. Did not sleep very well last night. Not so much sweating. Bowels freely open; urine thick with lithates, and not quite so copious—about two to three pints in the twenty-four hours; tongue still foul. Friction-sound is again heard at the base of the left lung posteriorly. Heart-sounds normal. Decubitus still chiefly on the right side. He is sometimes a little delirious at nights. ℞. Pulv. rhei, pulv. jalapæ, āā ʒ ss., podophyllin gr. iij., sodæ bicarb. ʒ ij.—M.; divide in pulveres vj., unus omni secundo mane sumendus.

24th.—1.30 p.m.: pulse 106, of fair strength; temperature 100·7°; respiration 36. Has slept a great deal since last visit. Bowels freely open; urine rather high-coloured, about three pints in the last twenty-four hours; sweatings more copious than yesterday; tongue coated. Friction-sound is still heard on the left side posteriorly at the base of the lung. Diet as before, but he evinces some disinclination to take as much as he has hitherto done.

25th.—12 noon: Pulse 116; temperature 102·6°; respiration 34. Slept well last night; is very sleepy during the day also. Sweatings very profuse. Percussory and auscultatory sounds are much the same as they were before the tapping on the 21st inst.—viz., dulness posteriorly is absolute up to about the level of the fifth dorsal spine; laterally almost up to the apex of the axillary fossa and anteriorly up to one inch above the nipple. For some distance above this level the dulness is considerable; in fact, it is only at the apex of the right lung that the resonance is normal. The breathing is very indistinctly heard over the right lung below the level of the spine of the scapula, and gradually diminishes downwards until at the base it is scarcely heard at all. Below the level of the nipple, anteriorly and posteriorly, the vocal thrill is totally absent on the right side. Diet as before, with the addition of a little minced mutton-chop.

26th.—Pulse 126; temperature 102·8°; respiration 40. Passed a fair night. Sweating still very profusely; skin almost covered with sudamina; bowels freely open; urine about two quarts. He is beginning to feel rather a disinclination for food. Altogether he feels worse to-day.

27th.—11 a.m.: Pulse 120; temperature 101·9°; respiration 40. Bowels freely open; urine about one quart; tongue still rather foul. Had no meat yesterday, but takes his food better to-day. Omittatur mist. potassæ nitr., etc., et ℞. Ac. sulph. dil. ʒ ij., inf. gentianæ co. ad ℥ xij.—M.; cochl. magnum ter in die ante cibum sumendum. Contin. pulv. rhei, etc., omni secundo mane.

28th.—11 a.m.: Pulse 116; temperature 100·1°; respiration 34. He was very bad yesterday afternoon and evening—suffered much from dyspnœa and extreme prostration. This morning at 12.30 he was so weak that a dessertspoonful of brandy was administered every hour for several hours in succession. This rallied him considerably. Sweatings most profuse and exhausting. Diet as before, but eggs have been increased to seven or eight in the twenty-four hours. Tongue coated; bowels freely open; urine copious.

29th.—10.45 a.m.: Pulse 122, of fair strength; temperature 100·9°; respiration 38. Tongue still coated; sweatings are still very profuse; appetite better.

30th.—12 noon; Pulse 118; temperature 99·2°; respiration 38. Heart-sounds normal. Sweatings profuse.

July 1.—2 p.m.: Pulse 124; temperature 102·3°; respiration 46, while he is lying on the back. Not so much sweating. Sleeps a great deal. Tongue still rather foul. Diet less fluid. Had some mutton and a wing of a chicken yesterday for dinner.

2nd.—11 a.m.: Pulse 122; respiration 36. Has slept a great deal since last visit. Tongue cleaning. Considerable sweating. On percussion, absolute dulness begins on the right side—anteriorly, one inch above the level of the nipple; posteriorly, at the level of the fifth dorsal spine. Left side normal. Heart-sounds normal.

3rd.—4.30 p.m.: To-day, in the presence of Messrs. Mott, Ware, and Hobley, the patient sitting in an arm-chair, I plunged a large trocar about a quarter of an inch in diameter into the seventh intercostal space in the old wound made on June 21, and there flowed away in the course of a few minutes rather more than a quart of pus of slightly offensive odour. I afterwards enlarged the opening with a narrow probe-pointed bistoury to the extent of one inch and a half, withdrew the trocar, and put in an indiarubber drainage-tube of about a quarter of an inch in diameter, and by the side of this an elastic catheter of slightly smaller calibre. These having been secured by strapping, the patient was put back again to bed. The drainage-tube was long enough to reach to a vessel placed on the floor. The ether spray was used to freeze the skin before cutting. The patient bore the operation well. Continue diet and medicines as before.

4th.—11.15 a.m.: Pulse 114; temperature 99°; respiration 36. Slept pretty well last night, and seems none the worse for the operation of yesterday. About half a pint of matter has come away by the tube. Still has profuse sweatings. Bowels not moved since last visit. About one quart of urine since yesterday afternoon. Tongue not quite so foul. By injecting water through the elastic catheter, the fluid escapes easily by the drainage-tube, and thus washes out the pleural cavity effectually. This is to be repeated every day. He lies comfortably and almost constantly now on the left side.

5th.—8 p.m.: Pulse 112; temperature 99·9°; respiration 36. Slept very well last night. Bowels open; not so much sweating; no pain in affected side. About a quarter of a pint of matter has come away by the tube. Appetite pretty good; had meat and a small quantity of vegetable for dinner. Complains of a feeling of tightness across the bowels. ℞. Olei ricini ℥ ss. cras mane sum.

6th.—3.30 p.m.: Pulse 110, rather weak; temperature 99·5°; respiration 32. Slept pretty well. Bowels have acted twice since castor oil, and the sensation of tightness of the abdomen is much relieved. Urine copious. Only about two ounces of matter have come away by tube. Tongue not quite so foul. Meat diet as before. ℞. Pulv. rhei, pulv. jalapæ, āā ʒ ss., podophyllin gr. iij., sodæ bicarb. ʒ j.—M.; divide in pulveres vj., unus omni secundo mane sum.

7th.—11.15 a.m.: Pulse 112; temperature 100·9°; respiration 36. Slept very well. Only about one ounce of matter has come away by tube. Tongue cleaning. Appetite improving rapidly. To have meat two or three times a day.

8th.—12.30 (noon): Pulse 112, of good strength; temperature 100·6°; respiration 30. Tongue almost clean. About one ounce and a half of matter has come away by the tube since yesterday. On percussion, dulness posteriorly begins on the right side at the level of the sixth dorsal spine, but it is only slight all the way down to the base of the lung. Anteriorly on the same side absolute dulness begins in the mammary line about one inch below the nipple; in the axillary line it begins on a level with the nipple. On auscultation the breathing is heard on the right side posteriorly pretty distinctly all the way down, but diminishing in loudness downwards. The breathing is distinctly heard on the anterior part of the right side of the chest. The vocal thrill is felt on the right side pretty much as on the left.

10th.—5.15 p.m.: Pulse 112; temperature 100·3°; respiration 30. Scarcely a tablespoonful of discharge has come away by the drainage-tube to-day. Tongue clean. Sweats very little.

12th.—1.15 p.m.: Pulse 106; temperature 99·4°; respiration 26. Patient is getting on very well. Sleeps well at night; feels stronger; appetite very good—eats meat three times a day. I took out both tube and catheter yesterday, and substituted two smaller elastic tubes. These latter came out either last night or this morning, and hardly any dis-

charge has come away from the opening in the side. Endeavouring to pass a small silver probe into the latter, it did not enter more than one inch and a half in any direction. I did not replace the tubes, but merely plugged the opening as deeply as possible with a long narrow piece of lint, and covered the latter with a larger piece as a dressing to the unhealed wound, and then secured the whole with strapping. This dressing is to be repeated every day until the wound is healed. Meat diet as before. To have half a tumblerful of porter at dinner, and only one ounce of brandy besides in the twenty-four hours.

14th.—11 a.m.: Pulse 106; temperature 100·4°; respiration 28. Patient is up to-day; he sat up for a short time yesterday and the day before also. Feels that he is gaining strength. Bowels act once a day regularly; urine copious; appetite very good; tongue a little coated. On examining him with the chest bare, the right side looks shrunken. On a level with the ninth rib in the axillary line the right side measures fourteen inches and a quarter, the left side measures fifteen inches and a quarter. He is gaining flesh a little. Seems in very good spirits. No discharge from side. Auscultatory and percussory signs much the same as on the 8th inst. Sumat æger pulv. rhei, etc., cras mane. Continuatur mist. ac. sulph. dil., etc.

16th.—11.30 a.m.: Pulse 110, of fair strength; temperature 99·5°; respiration 30. Tongue a little foul. Appetite not quite so good. ℞. Pulv. rhei, pulv. jalapæ, āā gr. x., podophyllin gr. j., sodæ bicarb. ℈j.—M.; ft. pulvis statim sumendus.

18th.—2 p.m.: Feels better. Powder taken on the 16th inst. acted pretty well. Tongue still rather foul. Appetite not quite so good as it has been. ℞. Mist. aperient. ℥ij.; ft. haustus cras mane sum.

21st.—Better; pulse 108; wound in side healed.

25th.—4.30 p.m.: Pulse 112; tongue foul. Stomach is evidently out of order; complains of want of appetite. ℞. Pulv. rhei, pulv. jalapæ, āā ℈ij., podophyllin gr. iij., sodæ bicarb. ℥j.—M.; divide in pulveres vj., unus omni nocte sumendus. Contin. mist. ac. sulph. dil., etc.

29th.—Not getting on well. Breathing is short, and pulse quick. Nevertheless, he was out to-day from 7 a.m. until 11 a.m. without feeling much fatigue. Powders have acted pretty well; motions offensive. Tongue still foul; and appetite not good. There is considerable dulness over the lower half of the right lung anteriorly and posteriorly, beginning at the level of the nipple. Breathing is indistinct over this dull part, but it is still audible—less so, of course, as one approaches the base; vocal thrill is here also diminished. On a level with the ninth rib in the axillary line, the right side measures fourteen inches and three-eighths, the left side measures fifteen inches and a half. On a level with the eighth rib in the axillary line, the right side measures fifteen inches and three-quarters, the left side measures sixteen inches. Sumat æger pulv. rhei, etc., hâc nocte. ℞. Mist. aperient. ℥vj.; pars quarta hausti omni secundo mane sumenda. Has a pint of porter and a little brandy daily.

August 2.—2 p.m.: Pulse 112; respiration 33. Does not feel so well. Complains much of weakness, although he goes out every day. Tongue very foul, although the bowels are very freely opened by the medicine; appetite bad. Sweated a little last night. Omit. mist. aperient. et mist. ac. sulph. dil., etc., et ℞. Pulv. rhei, pulv. jalapæ, āā ℈ij., podophyllin gr. iv., sodæ bicarb. ℥j.—M.; divide in pulveres vj., unus omni tertia nocte sumendus. ℞. Potassæ nitr. ℥j., spt. æther nitr. ℥iij., aquæ cinnamonii ad ℥xij.—M.; cochl. magnum quater indies sum.

9th.—Not doing well. Seems low-spirited, and says he is very weak and has no appetite. Feels sick occasionally, and has retching at times. Says he has great difficulty in taking the nitrate of potash mixture. To take only two doses of the latter in the day instead of four. Bowels open.

11th.—Yesterday afternoon the wound in the right side (over the seventh intercostal space) broke open, and discharged about a quarter of a pint of pus. Linseed-meal poultices have been applied ever since, and the side is still discharging pus freely. Opening admits a probe readily, and to the depth of three inches. Pulse is of good strength—90 in the minute when he is lying down, and 104 when he is sitting up. Has a little cough occasionally. Appetite not much better. Linseed-meal poultices to be continued to the side. The nitrate of potash mixture to be taken four times a day.

12th.—12.15 (noon): Pulse 88. Slept well last night. Cough troubles him a little at times. Vomited once yesterday. Side is discharging freely; about half a pint of pus has come away since last visit. Opening in cicatrix is larger—it is now about half an inch long. Has had a great deal of sweating since last visit. Tongue still very foul; appetite a little better; bowels open. Continuatur mist. potassæ nitr., etc., et sumat æger pulv. rhei., etc., statim. To omit porter, and to take half an ounce of brandy with water twice daily.

14th.—Pulse 100. Tongue much cleaner. Coughs very little now. Appetite better. Side is still discharging pretty freely.

16th.—1 p.m.: Pulse 94, of fair strength; respiration 26. Feels much better. Tongue almost clean; appetite still improving; bowels rather relaxed; no cough whatever now; side has healed up again; no discharge since yesterday morning. Omit. mist. potassæ nitr., etc., et resumat. mist. ac. sulph. dil., etc.; sumat æger ℥ ss. olei jec. aselli indies.

18th.—Much the same as at last report. Went to Ventnor to-day for change of air.

September 22.—I saw the patient this morning. He looks well and has gained flesh considerably since last report. He can walk easily and without fatigue seven or eight miles in the day. On examination of the chest there is slight dulness on percussion on the right side below the level of the lower angle of the scapula, both anteriorly and posteriorly, and here the respiratory sound is not quite so audible as in the corresponding situation on the left side. Vocal thrill is about the same on both sides. On a level with the ninth rib in the axillary line the right side measures fifteen inches and a quarter; the left side measures sixteen inches. On a level with the eighth rib in the axillary line the right side measures fifteen inches and three-quarters; the left side measures sixteen inches and one-eighth.

Remarks.—From the fact of my seeing this patient before the physical signs of inflammation of the pleura were present, I was thus enabled to ascertain precisely the time when the attack of pleurisy began. I saw the man on June 4 and June 5, but it was until the 6th of that month that a loud friction-sound was heard at the lower part of the right lung. Effusion into the right pleural cavity quickly took place, and, as above reported, the patient was in such a condition on June 21—*i.e.*, fifteen days after the commencement of the pleurisy—that it was deemed advisable to perform paracentesis thoracis. The fluid evacuated was, much to my surprise, found to be purulent. The wound was closed again after the operation. When, however, on July 3 I tapped a second time and enlarged the opening in the side, leaving the latter patent, the cavity soon contracted, and the patient made what may be considered a rapid recovery. The only untoward circumstance was that the wound closed somewhat prematurely and the matter collected again to a small extent; but when this was spontaneously evacuated on August 10 the patient soon regained strength, and was quickly convalescent. I may here repeat what I said on a former occasion,(a) that in performing paracentesis thoracis it is advisable to use as large a trocar as is possible and safe, as very small ones are apt to become blocked up by flakes of lymph, blood-clot, or thick pus, and even under the most favourable circumstances render the operation longer and more tedious than there is any occasion for. When one is certain of the presence of fluid in considerable quantity in the pleural cavity, a good-sized trocar can be as safely used as a very small one.

Southampton.

The Cholera in Paris.—The progress of cholera during the preceding week, if it has not been considerable, does not give us any hope of a speedy cessation. The cases, without being much more frequent, still continue very fatal—a circumstance we must bear in mind in appreciating the probable phases of the epidemic. We wish to be neither alarmists nor optimists. Paris is evidently still under the influence of a cholera epidemic—an epidemic which up to the present time is not very serious in relation to the number of cases, but is so with regard to the relative number of deaths.—*Union Méd.*, October 23.

Lime-water in Stings of Bees or Wasps.—M. Dauverne states as the result of numerous trials that the pain and suffering caused by these may be immediately assuaged by the application of lime-water—a remedy which may always be prepared at once by the aid of a little quick-lime and a glass of water.—*Union Méd.*, October 25.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASES UNDER THE CARE OF MR. BRYANT.

Case 1.—*Dislocation of the Head of the Femur on to the Dorsum Ilii in a boy aged* 6.

George M., aged 6, was admitted on March 20, 1871, into Guy's Hospital with a fracture of the left leg, having been run over by a cart. The fracture was a simple one, and was put up in splints. Ten days after his admission something was found wrong about his right hip, and on Mr. Coote's attention being drawn to it, a well-marked dislocation of the head of the femur backwards and upwards was discovered. Chloroform was given, and reduction readily effected by manipulation, flexion, adduction, rotation outwards, and extension. A good recovery followed.

Case 2.—*Dislocation of Right Femur into Foramen Ovale in a girl aged* 14—*Reduction by Manipulation.*

Jane H., aged 14, was admitted into Guy's Hospital under Mr. Bryant's care on June 8, 1871, with serious injury to her right hip. She had received it the day before her admission on getting out of an omnibus; her right leg being caught and drawn outwards and backwards. She has been unable to walk since the accident. On admission, the girl on standing held her right leg forward with the foot pointed; the pelvis was much tilted upwards on the opposite side, the anterior superior spinous process of the ilium being three inches higher on the left than on the right side. Posteriorly the fold of the buttock had entirely disappeared. The head of the femur could be felt beneath the adductor muscles. Mr. Bryant pronounced the case to be one of dislocation into the thyroid foramen. He reduced it with the greatest facility, with the patient anæstheticised, by simply flexing the thigh and then adducting it.

Case 3.—*Dislocation of the Femur on to the Dorsum Ilii in a boy aged* 14—*Reduction.*

Joseph S., aged 14, was admitted into Guy's Hospital on August 2, 1871, under Mr. Bryant's care, with a severe scalp wound and a dislocation of his hip after a fall off a dock of many feet. The dislocation was clearly one backwards and upwards on to the dorsum. It was at once readily reduced, after chloroform was given, by manipulation, flexion, adduction, rotation outwards, and extension. A good recovery ensued.

Case 4.—*Paralysis of Muscles supplied by the External Popliteal Nerve, and severe Pain in the course of its Distribution, the result of the Contraction of a Cicatrix.*

George S., aged 41, came under my care at Guy's Hospital on May 21 for severe pain down the front and outer side of his left leg and foot, with almost complete paralysis of the extensor muscles. The pain was at times very severe, and the paralysis had been gradually coming on for some years, following an injury sustained twelve years previously about the head of the fibula, which had caused a severe wound in the part. On examination Mr. Bryant found a dense cicatrix over the head of the fibula, and about two inches round it, tightly binding down the external popliteal nerve to the bone. Pressure on the spot excited severe pain. A free vertical division of the cicatrix on its anterior and posterior borders gave immediate relief, and when seen six weeks afterwards he was free from pain and well in all respects.

Case 5.—*Cancer of Femur after Cancer of Breast.*

Sarah E., aged 41, was admitted into Guy's Hospital under Mr. Bryant's care on March 19, 1871, with a fracture of the left thigh-bone. It appeared that she had been in the Hospital nine months before, under Mr. Poland's care, for cancer of the left breast, which was then removed. She left the Hospital, and soon experienced what were called rheumatic pains, which prevented her getting out of bed without assistance. On the day before her admission she was removing from her bed to a chair, with the aid of her daughter, when she felt her left leg give way. She thinks she slightly twisted it. On admission, a distinct fracture of the left femur is readily detected at the junction of the middle and lower third. The limb was put up in splints at once. The patient died on April 6, having gradually sunk. After death a cancerous nodule was found in the bone at the seat of fracture, as well as in the ribs, vertebræ, liver, kidneys, spleen, etc. There were also many in the seat of the operation in the left breast.

MIDDLESEX HOSPITAL.

BURSAL SWELLING AT THE OUTER MALLEOLUS CONTAINING MELON-SEED-LIKE BODIES.

(Under the care of Mr. HULKE.)

Bursal swellings of the sheaths of the flexor tendons, containing loose bodies, which are common enough on the wrist and in the hand, occur much less frequently in other situations, and are but seldom met with in the foot. Many of the solid, loose bodies—which were mostly flattened ovals—had a small projection at one end of the longest axis, the vestige of a shrunken stalk. Their structure was cellular, the interior consisting of cells resembling those of cell-cartilage, overlaid externally by others of a more flattened pavement-epithelium-like form. The history pointed to a chronic sub-acute inflammation, excited by sprains, as their origin.

A tall, weakly servant-girl, aged 18, was admitted into Queen ward, January 28, 1873, having behind and below the outer malleolus an elongated, elastic, fluctuating swelling, not tender when handled, not painful when going down, but very painful in walking, and accompanied with a feeling of great weakness, rendering her unable to stand securely on this foot. It moved with the perouei tendons when these muscles were put in action. The girl dated the swelling from a severe sprain three years ago, which was followed by much swelling of the ankle, and which laid her up for several weeks. Some time after she again sprained this ankle, and the swelling never quite disappeared. Blistering and compression not producing any decrease of the swelling, the bursal nature of which was evident, a valvular opening was made into it under an antiseptic spray, and a large number of solid, melon-seed-like, gristly bodies were let out together with a little glairy mucus. The bursa proved multilocular, and other compartments of it were subsequently evacuated; these contained only a viscid albuminous substance. All the punctures healed immediately. Firm compression was afterwards made, and she left on the 17th of the following month, much relieved.

BURSAL TUMOUR OVER GREAT TROCHANTER.

(Under the care of Mr. MORRIS.)

[Reported by Mr. Lewis, House-Surgeon.]

Bursal tumours over the great trochanter are said sometimes to be common in men, such as soldiers, who are in the habit of lying much upon their side, on the ground or on hard benches. In the following case the tumour, evidently of bursal origin, could not have been produced in this manner, as neither the man's occupation nor his history pointed to such a cause:—

John H., aged 48, a French polisher, was admitted into Forbes ward on September 2 with a tumour over the left great trochanter. He stated that his business necessitated his being on his feet all day, and that he had not been in the habit of lying on the left side, nor has he subjected that part of his body to an excessive pressure. The tumour has been forming for two years. The first symptom was a feeling of grating when the hand was applied on the outer side of the left great trochanter, especially during walking. It has not increased much for the last twelve months, but has grown very painful.

On admission there was in the position mentioned above an oval swelling, with its long axis in length of limb, and measuring three inches by two. It was hard, and slightly movable upon the bone. When quiet in bed he did not suffer much, but on moving it caused him pain.

On September 3 chloroform was administered, and the tumour was removed. An incision eight inches long was made along the axis of the limb, and the skin was reflected back on each side. The tumour was found beneath the fascia, and on the insertion of the gluteus medius and tendon of the gluteus maximus, and upper part of the origin of the vastus externus. After removal it was divided, and it was then seen to be composed of a very dense thick-walled cyst of fibro-cellular structure, with only a very minute cavity the size of a hazel-nut, which contained a few drops of semi-solid creamy-looking fluid. There is little doubt that this cavity had gone on contracting

by the gradual thickening of the walls, as the tissue immediately surrounding the cavity had no appearance of softening or degeneration.

LONDON HOSPITAL.

PECULIAR SPASMODIC MOVEMENTS IN A SUPPOSED MALINGERER—INSANITY (?)—SUICIDE: SUFFOCATION PRODUCED BY A PIECE OF RAG PUSHED INTO THE MOUTH—WITH REMARKS.

(Under the care of Dr. RAMSKILL.)

The patient (J. B., aged 57, dock labourer) said—and he made this statement calmly and clearly—that "about a fortnight before admission into the Hospital, one day whilst in the dock urinal, he was seized with violent shaking of his head, arms, and legs, which he was unable to control. He was found in this condition and taken home to bed, and during the same evening and following days had several similar attacks. He never lost consciousness, but has become deaf in his right ear." He seems to have met with more than one accident, and about eighteen months ago he fell down a ship's hold (twelve to fourteen feet). He was in consequence stunned, but soon recovered. Whilst in the Hospital it was observed that he was a muscular, well-made man. He was civil and quiet, giving very little or no trouble to the nurse. His usual position in bed was upon his back, with his hands lying across his chest. He seemed to take no interest in what went on in the ward; but this was attributed to his partial deafness; but his somewhat expressionless face changed to a smile on receiving any little attention. His only peculiarity was that he remained each day in the water-closet until called out, but during the last few days of his life he was frequently seen staring at the ceiling and moving his lips. The so-called convulsive attacks came on at irregular intervals in the day, and continued generally one or two minutes; they varied greatly as to the part affected. Sometimes his head would be moved from side to side, and with partial rotation; the shoulders and chest were also moved to some extent. In other seizures he rapidly and violently rubbed one arm with the opposite hand, or he moved one leg up and down very quickly. All the movements were made with very great rapidity, and so violently that on two or three occasions he was thrown off the bed. After each seizure his face was flushed and his body sweating profusely. He also appeared much exhausted and only semi-conscious—in fact, it was impossible to rouse him sometimes, even with pinching his skin or pulling his limbs for two or three minutes.

A day or two before his death, however, his manner altered: he became restless; he went to the bedside of a patient who was lying near, and said he was going to do something which would benefit him; he then seized the patient's throat and almost choked him. It was then found necessary to place him in another room. In the evening the nurse noticed that he was placing a piece of rag in his mouth, but did not suspect his object, and shortly afterwards he was found dead.

The post-mortem examination clearly showed that he had committed suicide. A metal crucifix, three inches in length, was found pushed far back into the commencement of the pharynx, and besides this, and pressing firmly upon it, was a piece of rag which filled up the mouth completely. The lungs were greatly congested, the right side of the heart much distended, whilst the left ventricle was firmly contracted, indicating that death was due to suffocation.

In speaking of this case, Dr. Ramskill remarked—"Probably all physicians have occasionally found it difficult to determine whether a patient was malingering or not; and this is especially so in hospital practice, where it not unfrequently happens that little or no collateral evidence showing the state of the patient previous to his admission into the hospital can be obtained, and we cannot confidently accept the patient's own statements as to his symptoms. Moreover, it may happen, as in this case, that the symptoms are so odd, so unlike the recognised symptoms of disease, and so manifestly under the patient's will, that we are led to conclude that the patient is feigning. As regards the patient in question, the rapid movements of his head and arms, from side to side and backwards and forwards, were totally unlike the convulsive movements of epileptiform seizures, the movements of chorea, or other well-recognised disease. It was, moreover, noticed by several of us that he could execute these movements when requested to do so. One day I said to him 'Now let us see the movements,' and at once his head was thrown in a rapid manner from side to side and in various other directions, and the action continued for some minutes. He did not seem to be mentally affected; day by day, when spoken to, he answered questions rationally, and gave an intelligible account of his health and doings. His statements, his manner of speaking, and his conduct in the ward until just before his death, did not lead us to regard him as insane; in fact, it was the opinion of several persons that he was malingering, and this opinion was further strengthened when it transpired that he had seemingly an end to gain in deceiving us. He said that he had received an injury whilst working in the dock, and he had in consequence claimed compensation from the dock company. It was true that he had made a claim on the company, for one of their inspectors called to make inquiries respecting his condition. His conduct a day or two before, and the manner of his death, at once suggested that he was insane; and, on making inquiries, the Catholic priest who had known him said that 'some time before the patient came into the Hospital he had noticed him loitering about his church in a singular manner, and he asked the patient why he did so; he replied that he had seen the devil, who had told him that he was to have a fit.' The priest's statement, tending to show that this patient had delusions, taken together with the act of self-destruction, would probably convince many persons that he was insane; and the case is instructive, as showing that there may be suicidal tendencies and at the same time no noticeable mental disturbance, at least whilst the patient is under medical observation, and the only indication of disease may be extraordinary spasmodic movements. In all cases of supposed malingering we have to inquire if the patient be healthy—simply feigning illness to obtain something he desires—or if he has cerebral disease with disordered ideas (may be delusions), and his actions therefore be simply the expressions and attendants of his ideational disturbance. At first sight, these two classes might seem to be totally different, and, so to speak, completely separated from one another, especially if we regard this question from an abstract or metaphysical point of view. If, however, we consider it from a physiological basis, then it is evident that the difference is one of degree only. For the mere fact of a patient feigning disease evidences that his conduct and ideas are so unlike those of mankind at large that they are abnormal, and must be the result of abnormal cerebral action. This abnormal cerebro-mental action, with its attendant symptoms, may be consequent on impressions the brain has received from circumstances which occurred a few days, weeks, or years before, or it may depend upon some inherited defect in the brain itself. Nevertheless, in such a case the absence of the objective signs of disease, the history of the patient, and his conduct, are such that no one would regard him as insane or suffering from other disease. In the other class of cases not only does the one act feigning disease betray mental disorder, but other actions of the patient denote cerebro-mental disorder. It may be, as with this patient, that there are spasmodic movements and delusions, and these denote that there is great cerebro-mental disturbance. It is, however, to be recognised that the mental disorder is much greater in the one class of case than in the other, and a medical man is called upon to estimate the degree of disorder. Experience shows that there are various degrees of difference. Some persons feign disease, and their actions are such that perhaps no one would regard them as suffering from disease; others seemingly feign disease, and opinions differ as to whether the patient is mentally unsound or not. This occurs in not a few hysterics. In other cases the patient is urged by some hallucination to perform certain acts, and state things which seemingly are intended to mislead: such a person is considered to be insane. Persons, therefore, disagree in opinion because they begin by looking at the case from different standpoints—each observer having his own mental conception as to what is a diseased and what is a healthy mind; and we disagree because we cannot look at the case from each other's standpoint. And, again, we fail to satisfy some persons because they expect us to make broad lines of separation and difference between malingering mental disorder and insanity; and we cannot do so, because they do not exist in nature."

In the Manchester Royal School of Medicine, now incorporated with "The Owens College," during the present session 1873-74 the total number of students registered amounts to 138, inclusive of thirty-eight new entries.

SATURDAY, NOVEMBER 1, 1873.

SIR HENRY HOLLAND.

The public and the profession alike will be pained and surprised to hear of the death of Sir Henry Holland. Only the other day the papers told us that he was present at the trial of Marshal Bazaine; and we have been so accustomed, through a very lengthy series of years, to hear of his long journeys, of his visiting every historical and well-known place, and of his presence at every important scene and event, that we had almost ceased to think of him as mortal; and he is probably one of the very last men one would have expected to hear of as having succumbed to a cold caught on a journey. Yet we learn that his unexpected and almost sudden death was caused "by a cold caught on his journey home from Paris." Distinguished as a physician, a traveller, and an author; known as a man of mark so far back as the early days of the Peninsular War; and wondrously active in mind and body to the last—his death, on his eighty-sixth birthday, will make a blank that will be very widely felt and mourned. His career was, indeed, a very remarkable one. Eminent as was his position as a physician, he was still more distinguished for his knowledge of the world and his rich experience of men and things. He had been brought into close contact with all or almost all the most important events and personages of the century. He may be said to have begun his medical career as travelling physician to the unfortunate and unhappy Caroline of Brunswick, then Princess of Wales, and was the most important and effective of the witnesses for the defence at her trial when Queen Caroline; while for more than twenty years before his death he was one of the Physicians-in-Ordinary to her Majesty Queen Victoria; and he was present, as we have before mentioned, though not in the character of a witness, at the trial of Marshal Bazaine now being carried on at Versailles. He visited the battle-field of Vittoria immediately after Wellington's victory there, and he witnessed the entry of the Allied Armies into Paris; and he was present in America during the Civil War, and rode over the battle-field of Gettysburg. He was well acquainted with Madame de Staël, counted among his personal friends six Presidents of the United States of America, and was the physician and friend of six Prime Ministers of Great Britain. Indeed, when one reads—and who has not read?—the charming and extremely interesting "Recollections of a Life" which Sir Henry Holland gave to the world in his eighty-fourth year, it seems as if he had known as patient and friend almost every person of note and celebrity of the age. Yet he did not attain eminence by such means as are commonly held to be the necessary steps to success in our profession. He never was attached to any hospital in London; he took no active part in, and was rarely if ever seen at, any of our medical societies; and he was not a teacher or lecturer in medicine, nor by any means widely or popularly known as a medical author, though his "Medical Notes and Reflections," published in 1839, and his book "On Mental Physiology," are remarkably able, valuable, and suggestive works. How, then, may his early and remarkable success as a physician be explained? His success was as rapid as it was great and lasting. We must refer our readers to another part of our pages for some details of his life, but it may be worth while to give a few moments to the consideration of the question we have asked above. The first thing to be noticed is, we think, that Sir Henry Holland never knew the pressure and harass of pecuniary anxieties. His father's circumstances and liberality enabled him to spend in constant travelling the years between 1811, when he took his M.D. degree, and 1816, when he settled in London; and protected him when he did so begin to seek practice from all need of care or dread lest expenditure should outrun income. Then comparatively very few men had in those days travelled to such an extent, and with such boldness, active interest, and intelligent purpose as he did; and his reputation as a traveller was so high that it gained him the Fellowship of the Royal Society in the very year (1816) in which he began his professional career in town. Besides the celebrity thus acquired, he had during his travels made the acquaintance of very many able and prominent men, whose friendship was of great service to him. For four years after commencing practice he also annually visited Spa professionally, and these visits, he has himself told us, were of great use in making him known to a host of notabilities, among whom were the Emperor Alexander, the Duke and Duchess of Cumberland, Wellington, Londonderry, and the Prince and Princess of Orange; and his unfailing habit, throughout his life, of devoting two months of every year to foreign travel, did no doubt in some degree help to widen and keep up his professional reputation. But we suspect that the most powerful cause of his success was his connexion with the Whig party. We do not mean to say that he was an active politician, but while at Edinburgh he made the acquaintance of the remarkable circle of great and brilliant men then to be found in the modern Athens, and through them he became connected with the *Edinburgh Review* and the leading Whigs. This connexion probably, at least, helped to procure him his appointment as Physician to the Princess of Wales, and the clearness, honesty, and boldness of his evidence at her trial, when Queen, made him a very prominent and (with "the Queen's party") a very popular man. He very early gained the friendship of Lord Holland, and was a constant and welcome visitor at Holland House, and he married a daughter of Sidney Smith. All these things were undoubtedly of great weight and service in introducing him, at the very outset of his career, to practice of a high class. They gave him the opportunities that most men have to wait much longer and toil much more arduously for. But, we need not say, they did not make him successful, though they put success in his way. He was ready and fitted to grasp and profit by his opportunities. He was a learned, able, and skilful physician, and a man of high culture and fine perception, of varied and extensive acquirements, and of high social

qualities, and a clever and well-known writer, and was endowed with rare bodily as well as mental vigour.

No one can read his "Recollections of a Life" without being convinced that, if his life was exceptionally happy and prosperous, he was a man of exceptional character and qualities. He could not else have gained and kept the friendship and confidence of the crowd of celebrated men and women whose names occur in that remarkable volume. We suppose that no physician "falling upon days like these" will ever reach to eminence through the same influences and by the same paths that Sir Henry Holland did, but like qualities of mind and character will make opportunities and insure success under different circumstances. We fear it would be of little use to recommend to others Sir Henry's restrictions as to work and his long yearly holidays. To very many, or most, these are made impossibilities by those stern necessities of daily bread-winning, of which Sir Henry knew nothing. But undoubtedly his early and faithfully kept determination to limit his professional gains, and to take an annual two months' holiday, very largely helped him to preserve the activity and buoyancy of mind and the bodily vigour that enabled him when more than eighty to write his "Recollections of a Life" and to undertake and enjoy journeys of thousands of miles.

ASPIRATION.

II.

We might fairly divide our subject into two parts—viz., the use of aspiration as a means of diagnosis, and its use, again, as a mode of treatment; but inasmuch as the two processes may very often be combined, it is better to take a different division, and to deal with the medical and surgical uses of aspiration. As far as the medical uses are concerned, perhaps the most important relate to abscess and other fluid accumulations in the liver, to pleuritic effusions, to the rarer forms of excessive pericardial effusion, to ascites, to excessive tympanites of the stomach or alimentary canal, and more doubtfully to hydrocephalus and general anasarca.

As regards the liver, there can be no question of the immense value of aspiration both in abscess and hydatids, and even more so as regards the former than as regards the latter; for in the case of a hydatid cyst it has been shown that simple puncture with a fine trocar or even needle is sometimes enough to insure the death of the parasite. This apparently results from compression of the hydatids by virtue of the elasticity of their surroundings when a portion of fluid has escaped into the peritoneum, from which seemingly no evil results. But in the case of hepatic abscess things are far otherwise; and we do not know that anything can make this clearer than a very striking extract from an article on the subject by Professor Maclean, of Netley, in Reynolds's "System of Medicine." In the last volume of that work, which appeared in 1871, we find the following:—

"If it be true, as I believe it is, that the most favourable route an abscess of the liver can take is through the right lung, and the least favourable—the one giving the smallest number of recoveries—is through the abdominal walls, it appears to me unjustifiable to expose the patient, by a surgical operation, to the risk of admitting air, with its mischievous properties, into the cavity of an abscess tending to a comparatively safe point of discharge."

Next Dr. Maclean alludes to the use of Bowditch's syringe in one case, from which he augured well of it in future cases; but in the very next page is a note so telling that we again beg leave to reproduce it:—

"Since the above was in type, I have used this instrument again and again, and in some instances with the happiest results. In single abscesses tending to the surface I have no hesitation in saying that it affords the best hope of a happy issue."

Can anything be more striking than these two paragraphs?—and yet how brief a space had elapsed between the penning of the two! Surely, were this the only triumph of aspiration, it would be something for which to be proud as well as thankful.

Nor do we think the method less meritorious as regards disease of the pleura, especially in empyema. Who does not remember the wretched history of such cases? A poor patient would appear—emaciated, sweating, and with a hectic flush on the cheek, the side protuberant, the intercostal spaces bulging, and very likely with the fatal pointing about the fifth rib. What was to be done? If left alone, the patient would only die; if the side were perforated, and the pus removed, for a time he would improve, but only to fall back into a worse state than before. When the system of drainage-tubes was introduced, and the consequent ease of keeping the suppurating cavity sweet was made apparent, this was a great step, and in a pronounced case of empyema this probably still offers the best chance of safety; but by aspiration we ought to be able to prevent the formation of such purulent collections, save in such maladies as pyæmia, where they are only a local manifestation of a general condition, and where local treatment is useless. Take such a case as this: A healthy young man is exposed to violent heats in an ironmaker's works; and again, from the exigencies of his employment, is exposed to a pouring rain or heavy frost. He shivers, feels ill, gets a violent pain in his side, and applies for medical relief. In the olden time he would certainly have been bled; nowadays perhaps he has a blister. However, that stays the pleurisy, and again he returns to work, but only to fall back, and this time with a large effusion of fluid in his side. Now, what is to be done in such a case? Are we to leave him alone for a time, and then apply blisters, iodine, and the like to the affected side. True, with such treatment and a sound constitution the patient may get over the effects of his accident in six months—it may be less or more. But even if he does get over this, how is he left? With drooping shoulder and collapsed ribs, with adherent pleura and the risk of invaded lung,—not one of which is pleasant to contemplate. But with aspiration all this is different. You may resolve to tap, and you may remove what you think a moderate quantity of the fluid. All of which is quite possible as soon as the acute inflammatory symptoms have abated; but promptly in all cases after that you can operate—you can remove a given quantity of the fluid, and allow the lung to expand under the diminished pressure. Again you operate, and again allow the lung to expand, until the whole or as much of the fluid as can be with safety removed has been got rid of; and then you can leave the finishing touch to nature, exactly where it begins on the other plan. With such a mode of procedure we have seen patients who have been ill for months, in whom the fluid was getting turbid, and in whom before long we should have had an empyema, recover almost perfectly—not, perhaps, quite perfectly, for when there has been much effusion the lung is collapsed, and takes a long time even if it ever recovers its normal equilibrium; but in these cases it is quite certain never to do so without some extraneous aid. As we take it, a good sound rule for operation is to begin with a small tube, and to go on taking off fluid until the patient begins to cough—a sure sign that the collapsed lung is beginning to recover itself,—and then to leave matters for the time being. A day or two after, most likely, breathing sounds will be heard where previously all was silent; and with care this will go on, but as a rule it is bad policy to empty the pleura at once. It is, under such circumstances, much more likely to refill, especially if the lung has been long collapsed and is bound down, and there is much more risk of injuring the lung. Of this last accident M. Diculafoy makes light; but probably a more extensive acquaintance with the subject will lead him at all events to desire its avoidance.

Of pericarditis with effusion necessitating operation we shall not here speak; cases demanding such interference are rare, but when they do occur should be promptly met. Certainly we should never use an exploring needle for the purpose of emptying this cavity, even though cases are on record where needles have been removed with success from the substance of the heart. Again, as regards ascites, we think this method of aspiration has been far too much neglected; here, too, we think the plan of only withdrawing the peritoneal fluid by degrees is the best. Formerly the formidable character of the operation of paracentesis abdominis—one too often followed by fatal results, chiefly because not taken in hand in time—led to its general avoidance. For, surely enough, too often a day or two after such an operation the abdomen begins to enlarge from tympanites, the tongue to get dry, and the pulse to go up—signs which to one cognisant only of peritonitis in books mean little, but to one who has seen the disease only too often mean much. But, on the other hand, we have the full assurance of practical experience that the fine needles used in aspiration may be used in most states of the system without creating any particular disturbance. Now, here in his work Dieulafoy again errs, as it seems to us, and discredits most unjustly the merits of his invention. He talks of using the aspirator for emptying and cleansing the stomach of a child who had swallowed poison, but surely the ordinary stomach-pump is better suited for such a purpose; whilst, on the other hand, there are cases of cancer of the stomach where there is such enormous dilatation as to interfere with the action of the heart and to threaten a speedy dissolution. Under such circumstances we have seen the fine aspirating needles, introduced without a shadow of risk, bring back the patient from death's door to comparative comfort, and that too under conditions when even the attempt to pass the stomach-pump might have been fatal. So, too, have we seen the use of these fine needles with or without the aspirator bring back a tympanitic patient from agony to peace and rest, and that without any risk of peritonitis.

THE WAR ON THE GOLD COAST.

The overdue mail from the Gold Coast, which had been delayed through the breaking down of the mail steamer, had scarcely come to hand when the one which followed it also arrived. The intelligence received from the seat of the war by both of them contains very little worth recording. Sir Garnet Wolseley and the numerous staff which accompanied him had arrived, all well, on the Coast, but a sufficient time had not elapsed to enable him to form any plans for future operations, a grand palaver with the principal Fantee chiefs having taken place as a preliminary.

One satisfactory item which should not pass unnoticed is to be found in the fact that the general sickness appeared to be decreasing, so far as our own men and our allies were concerned. Amongst the invading horde of Ashantees, small-pox and dysentery, aggravated by starvation, were reported to be still making extensive ravages; and to these causes, aided no doubt by the salutary lesson inculcated by the first real encounter with our troops, may be attributed the want of activity which has characterised the movements of the enemy, although they are doubtless well aware of the slenderness of our garrisons both at Cape Coast Castle and Elmina.

Deputy Surgeon-General Home and the bulk of the medical staff now on the Coast are reported to be standing out bravely against the effects of the climate, and are labouring assiduously at their several posts; but we regret to hear that Surgeons Connellan and Horton are suffering from fever, the former severely. Surgeon-Major Rowe—one well experienced in Coast matters—has been specially appointed to take medical charge of the native force in course of organisation by Captain Glover for operations on the Volta. This contingent already numbers nearly 7000 men, and, as the enrolment of natives is proceeding rapidly in other places, we may be said to have lost no time in providing ourselves with a local corps to assist in the operations to be undertaken. The drilling of these blacks is being rapidly pushed on, but the opinion expressed by those who should be in a position to know is decidedly adverse to undertaking any advance without a strong nucleus of European troops. The native auxiliaries may supplement the efforts of our own regiments, and be made to do much work which will spare our men, but at best, with only two months' drill, they will form little more than an armed rabble, liable at all times to panics of the most demoralising kind.

Dr. Gouldsbury, who is stationed at Axim, appears to have had a very narrow escape; he started with a few native police in a boat to chase some Ashantees who had been discovered in a canoe hovering about the station, and in capturing the canoe his own boat upset, the whole of the rifles belonging to the police going to the bottom. In this defenceless position they were fired at from the shore, and were in great peril until rescued by a party from the fort.

The *Times* correspondent, in a long and interesting letter from the Gold Coast, reiterates the warning which we have already given, that the operations against Coomassie should be commenced not later than December; he states that although previously of opinion that the climate would certainly devastate our troops—the Bush being supposed to be a lair of pestilence and an abode of death,—personal experience has taught him that an inactive life in the jungle is less dangerous than active life on the Coast itself. The experience of all Anglo-Africans with whom he conversed on the subject pointed to the fact that European troops would suffer little if they were marched into the interior immediately on their arrival, kept upon the march until the work in hand was successfully and completely terminated, and then speedily reshipped for this country. We need scarcely remind such of our readers as have followed our remarks since the outbreak of the war that this opinion coincides entirely with what we have always expressed; and knowing the care and forethought which have been bestowed on all the medical arrangements for the expedition, we shall be disappointed if the result fail to establish the correctness of the views we have advanced. An ample supply of medical stores and medical comforts is already on the spot; nearly all the medicines, etc., which went down in the wreck of the mail-steamer *Nigritia* have been recovered, and have been forwarded on to Cape Coast Castle, none the worse for the immersion to which they were subjected, and a further stock is in course of preparation for transit.

The forthcoming campaign bids fair to be one of the most novel which has ever been undertaken by this country: it will be, in fact, a race against time. Once embarked in it, we *must* realise certain results before a given date, or consequences the most disastrous may be expected to follow; but, as everyone at head-quarters is thoroughly imbued with the importance of speed, it only remains to receive a list of Sir Garnet Wolseley's requirements to have them executed with all possible dispatch, and to rest in confidence for the successful result which every unprejudiced person may fairly anticipate.

THE WEEK.

TOPICS OF THE DAY.

The General Medical Council is yet without a home. The building now occupied by the Provident Institution at the corner of St. Martin's-place, which was believed to have been granted by the present Government to the Council, is now offered to that body at the rent of £600 a year, or, if they want a part of it, at £40 a room per annum. We hope Mr.

Lowe will not forget to quote this admirable piece of economy in his next after-dinner speech in defence of the Ministry, and that when Mr. Disraeli writes his next letter he will not omit to compliment the Cabinet on their having added to the functions of the advisers of her Majesty that of letting apartments to public bodies. We are glad to say that at the meeting of the Executive Committee of the Council on October 23 it was resolved to refuse the munificent offer of the Government. The Council therefore must look elsewhere for a home; and the time is short. They will have to leave their present somewhat disreputable surroundings at Christmas, for the premises are let to the "Hospital for Diseases of the Heart"—an institution incompatible under the same roof with the General Medical Council. In the meanwhile, the Treasurer and Registrars are empowered by the Executive Committee of the Council to make such arrangements as they shall find most desirable. With a balance of some £25,000 or £30,000, and a clear income of £5000 a year, we think there cannot be much difficulty in finding the Council a home.

The following members have been re-elected:—Dr. Andrew Wood, by the College of Surgeons of Edinburgh; Dr. Storrar, by the University of London; Dr. Aquilla Smith, by the King and Queen's College of Physicians of Ireland; Dr. Apjohn, by the University of Dublin. Of the re-election of the four Crown nominees—Sir Robert Christison, Dr. Stokes, Dr. Parker, and Dr. Quain—nothing has yet been heard, although it is rumoured that Sir Robert Christison will not desire re-election. The time of service of Dr. Leet, the representative of the Apothecaries' Hall of Dublin, and of Dr. Macrobin, the representative of the Universities of Edinburgh and St. Andrews, has expired, but we believe the official announcement of their re-election has not yet been made public.

We have received from Messrs. Barraud and Jerrard, of Gloucester-place, Portman-square, an admirable photographic portrait of the late Sir Henry Holland. It is one of the portraits contained in the March, 1873, number of their serial, "The Medical Profession in all Countries."

The *Times* of Thursday contains a letter signed "Indicus," appealing to the subscribers to the Royal School for Daughters of Officers in the Army to give their votes in December to Miss Edith Comberbatch Brydon, whose father, Surgeon W. Brydon, served in India for twenty-five years, was severely wounded in the retreat from Cabul in 1842, and was the only survivor of the Cabul army, and brought the news of its destruction into Jellalabad. He served under Sir Robert Sale at Jellalabad, and returned to Cabul with Sir George Pollock's army. In the Indian Mutiny he was shut up in Lucknow, and during the siege received a wound which accelerated his death. Such public services we should have thought should have at least been rewarded by competence for the hero's family.

The man Tuckfield, who brought an action against the Metropolitan Railway Company for injuries received in a collision at the Bishop's-road Station, has been found guilty of perjury at the Central Criminal Court.

The deplorable death of the wife of a medical officer of the Indian army from morphia, which has been made the matter of a coroner's inquiry, seems utterly inexplicable from the evidence that has been adduced. The administration of a grain of morphia (the quantity said to have been given) every half-hour for the purpose of procuring sleep is certainly the act not of a physician but of a madman. As we have said, judgment must be suspended until further evidence is forthcoming.

THE "JOHN MURRAY" MEMORIAL.

The following gentlemen have agreed to act as a committee for the purpose of raising funds to place a bust and memorial tablet of the lamented Dr. John Murray in the scene of his labours, Middlesex Hospital:—Dr. J. Ford Anderson; Dr. Joseph Bell, Edinburgh; G. W. Callender Esq., F.R.S.; Dr. W. Cayley; Campbell de Morgan, Esq., F.R.S.; Dr. Dyce Duckworth; Dr. Arthur W. Edis; Sir William Fergusson, Bart., F.R.S.; Professor W. T. Gairdner, Glasgow; Sir William W. Gull, Bart., F.R.S.; Ernest A. Hart, Esq.; D. Hepburn, Esq.; Dr. George Johnson, F.R.S.; Dr. Robert King; Dr. Robert Liveing; R. H. Lucas, Esq.; Dr. Morell-Mackenzie; Henry Morris, Esq., M.A.; Dr. Charles Murchison, F.R.S.; Dr. Richard Quain, F.R.S.; Professor W. R. Sanders, Edinburgh; Dr. Alexander Silver; George Southam, Esq., Manchester; Dr. A. P. Stewart; Dr. William Stokes, jun., Dublin; Lawson Tait, Esq., Birmingham. Campbell de Morgan, Esq., F.R.S., Treasurer. Arthur W. Edis, M.D., 23, Sackville-street, W., and Henry Morris, F.R.C.S., 19, Bedford-square, W.C., Hon. Secretaries. Any gentlemen desiring to contribute are requested to forward their subscriptions to the honorary treasurer, or either of the honorary secretaries.

THE ROYAL COLLEGE OF PHYSICIANS.

At the Comitia, held on Thursday, October 30, at the College, Dr. Robert Druitt was elected a Fellow of the College. The President announced that the Harveian Oration in the ensuing year would be delivered by Dr. Charles West. The Gulstonian Lectures will be delivered by Dr. J. F. Payne; the Croonian Lectures by Dr. Murchison; the Lumleian by Dr. Sibson.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

The half-yearly general meeting of the Society was held on Wednesday, October 22, in the library of the Royal Medical and Chirurgical Society, Berners-street. The chair was taken at half-past eight o'clock by the President, Dr. Burrows. It is much to be regretted members do not evince more interest in the affairs of the Society. At the hour appointed for the general meeting there were only eight members present, not sufficient to form a quorum; business was in consequence postponed for some time. The minutes of the courts of directors held since last general meeting were read. Mr. Edward Tegart was elected a vice-president, Dr. Quain one of the treasurers, and Dr. Fuller and Sir John Fisher directors. From the half-yearly statement of accounts it appeared that fifty-six widows had received £1053, divided in accordance with the urgency of the wants of the applicants; thirty-four children had received £176, including grants to three from the Copeland Fund. The total grants for the half-year had been £1229. The expenses for the same period amounted to £107. A legacy of £500 had been received from the executors of the late Mrs. Jane Lyon. A special grant of £30 was made to a widow of a deceased member, whose case did not come within the description specified by the laws for ordinary grants. A vote of thanks to the chair closed the meeting.

PROTECTION OF INFANT LIFE.

Some correspondence has lately taken place between the Metropolitan Board of Works and the Home Secretary on protection of infant life. The Home Secretary is of opinion that there would be great risk if, in order to prevent occasional crime, the houses of the poor were subjected to any serious amount of intrusion, and that such a result would be fatal to the permanence of any legislation on the subject; that he was not prepared to raise the standard of infancy from one year to seven years; and further, that he did not propose any alteration in the law on the subject, which has not yet been a year in force. It remains to be seen whether the Act at present in force will be sufficient to protect infant life. Great difference of opinion exists on the subject, but we believe that it is generally considered some further legislation may be necessary.

INQUESTS AT ST. PANCRAS WORKHOUSE.

A DISCUSSION arose at the last meeting of the St. Pancras Guardians on a return prepared by Mr. Hill, medical officer of the workhouse, of the number of inquests held at that place during the year and eight months ending September 30 last. This return was ordered at a previous meeting of the guardians, at the instigation of the Rev. W. R. Arrowsmith, who on that occasion strongly objected to an inquest which had recently been held on the body of a woman who died from the effects of a very severe fall in one of the wards. We agree with Mr. Seaton, who remarked at the time that there appeared to be a "dead set" made against the medical officer for merely doing his duty. The return showed that the total deaths were 453; that in sixty-seven of these the coroner had been called upon to make an inquiry, and that the great majority of them had occurred from preventable causes, only eighteen having been due to natural causes. The Rev. W. R. Arrowsmith, remarking upon the return, said the proportion of inquests to the number of deaths had been greater in St. Pancras than in any other parish in the metropolis with the exception of Bethnal-green. He thought Mr. Hill favoured the holding of inquests to an extent which called for the disapprobation of the Board, and he moved a resolution to that effect. The motion was, after some discussion, withdrawn, and an amendment adopted, declaring that the Board "regrets the number of inquests held by Mr. Hill on persons dying in the workhouse, and trusts that he will do his best to reduce the number in future." We trust that Mr. Hill will continue to do his duty. Under the Coroners Act he is bound to give notice to the coroner of any death occurring in the workhouse under circumstances which *primâ facie* appear to call for inquiry. This is a most wholesome regulation, and is at once a protection to the poor and to some extent a preventive to misconduct, if such prevails on the part of the officials. The guardians of St. Pancras must be sadly in want of a subject for discussion when they can find no better one than an attempt to limit a useful inquiry. Usually the discussions in this parish have had reference to parochial expenditure. In this case, however, as the cost of inquests falls upon the county, there is no such excuse for the opposition displayed. For the protection of prisoners, an inquest is held upon every one of them that dies. This system has been found to work beneficially, and we do not remember any instance in which it has been complained of. Surely the proportion of deaths occurring in St. Pancras Workhouse which were due to preventable causes is a sufficient vindication of Mr. Hill's conduct, and a complete answer to the adverse resolution respecting him.

PRESERVED AUSTRALIAN MEAT.

A DIFFERENCE of opinion has, it appears, arisen between the Manchester magistrates and the Home Secretary on Australian preserved meat and fresh meat. The preserved Australian meat has been adopted in the dietary of the City Prison, and a considerable saving has been the consequence. Mr. Powell, Inspector of Prisons, in his report to the Home Office on the subject, states that at least a sixth additional weight ought to be issued with each ration in order to render the preserved meat equal in nutrition to the freshly-killed meat. But the surgeon of the City Gaol appears to be of opinion that Australian meat is preferable to the meat formerly in use, both as to nutrition and economy. The result, however, of the correspondence on the matter is, that the recommendation of the Inspector has been endorsed by the Home Secretary, who withholds his sanction to the use of Australian meat in the prison unless the addition of one-sixth in weight is made to the rations. We think the recommendation of the Inspector was properly adopted by the Home Secretary, as there can be no doubt that the nutritive qualities of the Australian meat as at present preserved are inferior to fresh meat.

DISEASE-DESTROYING TREE.

M. GIMBERT, who has been long engaged in collecting evidence concerning the Australian tree *Eucalyptus globulus*, the growth of which is surprisingly rapid, attaining besides gigantic dimensions, has addressed an interesting communication to the Academy of Sciences. This plant, it now appears, possesses an extraordinary power of destroying miasmatic influence in fever-stricken districts. It has the singular property of absorbing ten times its weight of water from the soil, and of emitting antiseptic camphorous effluvia. When sown in marshy ground it will dry it up in a very short time. The English were the first to try it at the Cape, and within two or three years they completely changed the climatic condition of the unhealthy parts of the colony. A few years later its plantation was undertaken on a large scale in various parts of Algeria. At Pardock, twenty miles from Algiers, a farm situated on the banks of the Hamyze was noted for its extremely pestilential air. In the spring of 1867 about 13,000 of the eucalyptus were planted there. In July of the same year—the time when the fever season used to set in—not a single case occurred; yet the trees were not more than nine feet high. Since then complete immunity from fever has been maintained. In the neighbourhood of Constantine the farm of Ben Machydlin was equally in bad repute. It was covered with marshes both in winter and summer. In five years the whole ground was dried up by 14,000 of these trees, and farmers and children enjoy excellent health. At the factory of the Gue de Constantine, in three years a plantation of eucalyptus has transformed twelve acres of marshy soil into a magnificent park, whence fever has completely disappeared. In the island of Cuba this and all other paludal diseases are fast disappearing from all the unhealthy districts where this tree has been introduced. A station-house at one of the ends of a railway-viaduct in the Department of the Var was so pestilential that the officials could not be kept there longer than a year. Forty of these trees were planted, and it is now as healthy as any other place on the line. We have no information as to whether this beneficent tree will grow in other than hot climates. We hope that experiments will be made to determine this point. It would be a good thing to introduce it on the West Coast of Africa.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A PUBLIC meeting was held last week at the Mansion-house, presided over by the Lord Mayor, for the purpose of settling the preliminary arrangements for appointing a Hospital Sunday for the forthcoming year, and for electing the council and committee of distribution for appropriating the funds realised. The immediate supporters of the movement included gentlemen representing many different forms of religion, and a very unanimous feeling was expressed as to the desirability of perpetuating a movement which had been so auspiciously commenced. The Bishop of London, in proposing the first resolution, took occasion to remark that the present year's result was not nearly what might fairly be anticipated upon future anniversaries; in his own diocese alone, out of 500 churches collections were made in only 270, and although he was not in a position to promise that next year every church or chapel would have a collection, he had no doubt that the number willing to assist such a charitable object would be largely increased. The Lord Mayor elect (Alderman Lusk, M.P.) then proposed, and Bishop Claughton seconded, a resolution that June 14, 1874, be appointed the next Hospital Sunday for the metropolis, which was put and carried unanimously, as was the resolution which followed—namely, that the ministers of all denominations be again invited to co-operate. Some discussion afterwards took place upon the method of distributing the money collected—an adverse opinion being expressed as to the amounts recently presented to dispensaries—

in the course of which the Rev. Canon Miller proposed, and Dr. Glover seconded, a resolution suggesting that a committee be formed to consider and confer with the council as to the relative claims of hospitals and dispensaries on the sympathies of the public, the members to be chosen from representatives of both classes of institutions. A numerous council, with the Lord Mayor elect at their head as president and treasurer, and Sir Sydney Waterlow as chairman, was then elected, Messrs. E. H. Currie and R. B. Martin being reappointed honorary secretaries. The last resolution proposed was to the effect that the system of the next distribution be based upon the last three years' expenditure of each institution admitted to participate, after deducting the income derived by each from endowments, realised property, and legacies exceeding the sum of £100; and that no institution be allowed to receive a grant if it be found that the cost of its management exceeds a reasonable percentage of the whole current expenditure; also that the committee of distribution include at least one member of the medical profession who is not directly connected with the management of any hospital.

A MUNIFICENT SURGEON.

The late Mr. Joseph Taylor Winnard, for many years a surgeon practising in Wigan, has (says the *Manchester Guardian*) by his will bequeathed the residue of his property to the Mayor of Wigan for the time being, for the purpose of purchasing books for the proposed free library. The amount has not yet been stated, but report says it will be £20,000, and may be £30,000.

CHOLERA IN HOLLAND.

Our correspondent at Rotterdam writes:—"The cholera is slowly increasing in our country. A probable cause of infection, especially at Dordrecht, was the barque *Freia*, which came from the East Sea. On board of this ship there occurred three cases of cholera, of which two died in the hospital. The *Staats Courant* states that the mortality from cholera was thus:—From September 21 to 27, three cases; from September 28 to October 4, three; from October 5 to 11, nine; from October 12 to 18, twenty-one; and from October 19 to 25, twenty-four cases, of which five were in Rotterdam. Till now (October 28) there occurred here seventeen cases, of which ten have died."

CHOLERA IN NAPLES.

A correspondent of the *Times*, writing from Naples on the 19th ult. on the outbreak of cholera in that city, says—"Cholera has its duties to perform, and its voice should not be stifled. Every epidemic that visits this city reveals two facts—the existence in the streets and under the streets and in many of the private dwellings of all the elements for the generation and propagation of the disease. It reveals, too, another fact, and it is that the local authorities have in past times from '*incuria*,' and in later times from the spirit of partisanship which takes possession of them, been grossly neglectful of their duties. The bulletin of to-day gives eleven cases and ten deaths from cholera."

FROM ABROAD.—PROFESSOR FORDYCE BARKER ON SORE NIPPLES AND MAMMARY ABSCESS—INJECTIONS INTO THE VEINS IN CHOLERA.

The following is an abstract of an interesting clinical lecture on "Sore Nipples and Mammary Abscess," delivered by Professor Fordyce Barker at Bellevue Hospital Medical College, and reported in the *New York Medical Record* of September 15.

Professor Barker observes that in our text-books there is a great deficiency in the description of the various forms of these affections, and of the appropriate treatment for each of them: various substances are recommended as curative, without any definite rules being given as to the circumstances under which they are applicable.

He recognises three forms of *sore nipple*—1. Inflammation, which generally occurs in those cases in which the nipple is naturally contracted, or in others, which are not at all infrequent, where the nipple is almost absent. The child has great difficulty in getting hold of it, especially when it is still farther contracted through distension of the breast. The irritation produced by the child's efforts leads to inflammation of the nipple, and the propagation of this through the lacteal ducts may give rise to mammary abscess. 2. Fissure or erosion of the nipple, which may exist in two forms, one being the consequence of inflammation. But another form exists at the base of the nipple, causing the most intense pain and suffering at the time of suckling. 3. This is ulceration, as exhibited in the case which gave rise to the delivery of the lecture. The surface of the nipple is red and denuded of cuticle; it is also much retracted; and in this case there was a fissure at the top. The pain caused is very intense. The areolar tissue also around the nipple becomes inflamed, and perhaps a half or two-thirds of its substance may be destroyed during the process. These three forms may be distinctly and easily recognised.

In treating these cases, the first question is as to "drawing the nipple out." Dr. Barker does not approve of the practice of applying the child to the breast immediately after delivery, with a view of securing uterine contraction. He adopted it himself for some years, but has entirely abandoned it. He now believes that the woman should be completely restored after the fatigue of delivery before the child is applied—effectual uterine contraction being easily secured by other procedures. The first stage after parturition is one of exhaustion, owing to the great efforts that have had to be made; and so complete is it that it is very commonly manifested by nervous chills. If the woman is permitted to get a few hours' sleep her exhausted nerve-power is restored, and this is the time when the child should be applied. The breast is not yet distended, and the nipple is drawn out more easily than later. The traction, too, excites the more rapid secretion of the breast, and the first secretions act beneficially on the child. The nipple is now more easily grasped; and if we wait until the secretion of milk has actually taken place before applying the child, the distension of the breast becomes an obstacle to the free flow of the milk through the ducts, and thus a source of irritation. There are cases in which the nipple congenitally is so short that, the child not being able to get hold of it, it requires to be drawn out by mechanical means. Most of the breast-pumps used for this purpose are constructed on principles utterly devoid of common sense, having so small an opening in the part applied to the breast that the nipple is constricted, and the milk is unable to flow after the first two or three exhaustions of the instrument. This is prevented by having a pump with a large bell-shaped extremity; and Mattson's breast-pump is an instrument which fulfils this indication very completely, and is an excellent one.

With regard to the treatment of sore nipples, when the nipple is inflamed a poultice should be applied until this is subdued, after which a solution of nitrate of lead in glycerine (gr. x. ad ℥j.) is to be used. This is also the most complete prophylactic that Dr. Barker knows of. It should be applied immediately after suckling, first washing the nipple perfectly clean, and washing it off again before the child sucks. When properly used it is almost a specific against excoriations and ulcerations. If there is great tendency to sore nipples, the strength may be increased to fifteen or even twenty grains, but as a rule the ten-grain solution suffices. Next, where the cuticle is denuded, leaving a raw surface, or where it becomes so irritated as to threaten abrasion, an artificial

cuticle should be formed which will entirely protect the parts and allow the milk to pass. For this purpose collodion has been extensively used, the objections to which are, that, contracting as it dries, it becomes itself a source of irritation and discomfort, and does not readily permit the flow of milk. The compound tincture of benzoin is a most satisfactory application, four or five coats being applied with a pencil, having wiped the nipple dry after suckling. Under this coating cicatrisation takes place, and the patient is relieved. When there is a fissure at the base of the nipple, very small though it may be, it causes most agonising pain, and its most satisfactory treatment consists in touching it with a fine point of nitrate of silver, and applying the benzoin over this as before. When the inflammation and ulceration have gone on so as to destroy the surface of the nipple, and there is danger of the inflammation extending back to the mammary gland, the patient should not be tortured by the application of the child, which should be at once removed, emptying the breasts by the pump or rubbing. After this, Dr. Barker uses an ointment composed of rose ointment ℥j., carb. magnes. ℈j., calomel gr. xxx. The ingredients, freshly prepared every twenty-four or thirty-six hours, should be rubbed together very carefully. If the child is allowed to suckle at all, it should do so exclusively through a shield; and for this the cow's teat is to be preferred to the indiarubber, which emits an offensive odour and is very apt to render the child's mouth sore. If, however, it becomes necessary to use any of the shields ordinarily on sale, the one with a broad base, termed the L-shaped shield, should be selected. The ordinary shields are simply abominable.

Mammary abscess is a very troublesome complaint. The woman who formed the subject of the lecture had been confined nearly a month before she began to complain of her breast, and in three days suppuration had taken place. This is an important point often overlooked in books. The whole surface of the gland about the nipple was inflamed, and the patient had had chills, fever, etc. The case was probably one of those resulting from the presence of the peculiar poison which developes puerperal fever in some cases, peritonitis in others, and mammary abscess in others.

"There are three forms of mammary abscess—1. Inflammation of the cellular tissue surrounding the nipple, and external to the breast; 2. Inflammation of the substance of the gland itself; and 3. Inflammation of the areolar tissue between the gland and the thorax. The first form may result from irritation, and is nothing more than a purely simple phlegmon; it usually terminates rapidly, is not attended with the constitutional shock which accompanies glandular inflammation, and is to be treated as such inflammation elsewhere. As soon as fluctuation is detected, the question may arise whether the escape of pus should be permitted to take place spontaneously, or whether the breast should be opened by the surgeon. The amount of constitutional disturbance is to decide that; and if it is decided upon to open it, the incision should not be made within the areola, because the retraction which is incident to cicatrisation will spoil the nipple for future use. The sooner the discharge takes place, the sooner the healing process will be completed and the breast be restored to a healthy condition.

"In case the gland itself becomes inflamed, it is attended with more constitutional disturbance. There are headache, chills, fever, full pulse, and high temperature, with even yet greater disturbance if there is a tendency to the formation of multiple abscesses. If these cases are seen at a very early period of their formation, when there is great tenderness, with high temperature, fever, etc., pulse 108—perhaps 120,—it may be well to try to abort the inflammation. For this purpose I give ten grains of Dover's powder, with an alkali, and paint over the surface of the gland with tincture of iodine, covering it with a warm poultice or cotton padding and oil-silk. Empty the breast with a pump, and in most cases you will arrest the whole thing at once. The trouble is that the woman does not see the physician until this period has passed, and then suppuration should be favoured by poultices. Internally, the patient must be ordered as full doses of quinine as she will tolerate. As soon as fluctuation is detected, open the breast at the lowest point, because otherwise pus will burrow between the tissues of the gland, become a source of irritation, and produce another inflammation.

"The third form is called the 'sub-glandular,' and is attended with great constitutional disturbance. It has none of the external redness present in the other forms, being situated between the gland and the thorax. The gland sometimes becomes very prominent. The inflammation is attended with intense pain, rigors, and chills, while on the external surface there may be no special intimation of its existence. The most significant symptoms are that the patient complains of difficulty of breathing on account of the pain produced, and, when present, the prominence of the gland. These cases are generally exceedingly tedious, and sometimes dangerous, because the inflammation is so deep-seated that the pus between the gland and the thorax burrows about, forming sinuses and extensive fistulous tracts, which may be exceedingly troublesome and exhausting from the profuse discharge and constitutional irritation which are produced."

Professor Barker intends resuming the subject in a future lecture.

At a recent meeting of the Paris Hospital Medical Society, Dr. Dujardin-Beaumetz read a paper upon "Injections of Water and Saline Solutions into the Veins in the Algid and Ultimate Period of Cholera." In this he relates three cases from his own practice at the Beaujon, in which, although they all proved fatal, the injection was attended by temporary improvement. This of course has been the result which has attended the experience of most of his predecessors; but he does not think that the practice should be abandoned, but that we should seek to improve upon it. To this end he furnishes a summary of the particulars of eighteen cases of successful injection which he has found on record. We transcribe some of his general observations:—

"The condition of only employing these injections in the gravest cases, when there is a state of complete algidity, should continue to be observed. It is not to be doubted for a moment that much more advantageous results would be obtained were the injections practised at a less advanced stage of the disease, when the patient still retained some of his strength. But, in order to act thus, we ought to be in the possession of a liquid which may offer a complete substitute for the serum of the blood, and such a liquid has yet to be found. We should therefore avail ourselves of all other modes of treatment until the patient would seem to have but this one chance left. But this chance should not be lost to him, and we ought the less to hesitate to perform this small operation, inasmuch as it is always attended with amelioration, fugitive as this may be. . . . It would be very difficult to supply any exact statistics with respect to the results of these injections, and that for several reasons: first, many observers have not published their failures, while others have only signalised their successes; secondly, only desperate cases have been operated on; and thirdly, the injections have only been employed to combat an epiphenomenon of the disease, algidity. We all know that it does not suffice to remove the chill and cyanosis to effect a cure; for how often do we see individuals who, after a more or less complete reaction, succumb none the less after a variable lapse of time with comatose and typhoid symptoms. And if I may be allowed the comparison, it seems to me that injection into the veins has acted in cholera very much like tracheotomy does in croup—it does not cure the disease, but it prolongs the life of the patient. In fact, in all the cases of injection we find that a very notable amelioration is produced. The expiring patient is recalled to life: he recovers consciousness and speech, and recognises those about him; his circulation is re-established; his temperature is raised; the secretions are again, as is absorption, in operation. He feels great relief and a notable amount of comfort; and nothing can be more curious, more striking, I will even say more astonishing, than his resurrection. The amelioration, it is true, is generally temporary; but short though it be, it ought to stimulate us to seek for the means of perfecting this mode of treatment."

THE yellow fever is abating at Memphis, but the city is in a desolate condition.

EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, NAVAL, AND INDIAN MEDICAL SERVICES.

THE following were the questions in Anatomy and Physiology, Surgery, Medicine, Zoology, Botany, Physics, etc; given at the examinations of candidates for her Majesty's Army, Naval, and Indian Medical Services:—

Anatomy and Physiology.—Monday, August 11.

1. Give the origin, course, relations, and distribution of the glosso-pharyngeal nerve, and describe the dissection required to expose it in its course below the base of the skull.

2. Describe the cartilages and intrinsic muscles of the larynx, and state the nerves by which the latter are supplied, and their actions.

3. Give an account of what is known respecting the structure, nature, and properties of the *red* and of the white corpuscles of the blood.

4. Give the dissection required to expose the posterior interosseous artery of the forearm in the whole of its course; mentioning, in the order in which they occur, the parts that must be removed in order to expose it.

5. State the organs to which the pneumogastric nerves are distributed, and give their special function in each organ.

6. Describe the minute structure of the cornea and of the iris, and state the mode in which it may be best displayed.

Surgery.—Monday, August 11.

1. Describe the local and constitutional symptoms, and causes of acute periostitis; at what period of life it usually occurs; what treatment should be adopted; and what are the usual results on the bone affected.

2. A heavy cart-wheel passed over the middle of the thigh of a man. There being no external wound, by what symptoms would rupture of the femoral artery be diagnosed? and what should be the treatment?

3. Describe the symptoms which would be present if a small foreign body had slipped into the trachea. In what situation would it most probably lodge? and what treatment should be adopted for its removal?

4. Describe the progress of a case of syphilitic iritis, from its commencement, if allowed to continue without treatment; and what should be the treatment of a case in its various stages.

5. By what symptoms may an ovarian cyst be distinguished from ascites dependent on diseased liver, or from a fibrous tumour of the uterus?

6. Describe the symptoms by which cancer of the bladder may be detected, and for what conditions it might be occasionally mistaken.

Medicine.—Tuesday, August 12.

1. What are the views now entertained regarding phthisis and tubercle? Give the physical signs of a case of chronic phthisis, passing through all its stages, and ending in perforation into the pleural cavity.

2. What are the chief causes of anasarca? Describe the symptoms connected with the kidney and heart diseases of the two chief forms.

3. What are the principal causes of severe pain in the loins; and give the distinguishing symptoms of the conditions you enumerate?

4. What are the symptoms of cancer of the liver? Give carefully the after-death appearances.

5. Give an account of the stages of a simple labour, and state what conditions might render it dangerous, and how you would meet them

6. What is the composition of opium? and what is the action and use in medicine of its several ingredients?

Zoology.—Tuesday, August 12.

1. Give the characters and distribution of the principal races of man.

2. What are the principal differences between plants and animals?

3. Describe the structure of the heart in the different classes of vertebrata.

4. Give the principal characters of the class *Aves* and of its orders.

5. What are the chief modifications of the mouth of insects?

Botany.—Tuesday, August 12.

6. Describe the different modes of dehiscence of capsules, giving examples of each.

7. Explain the mode in which pollen is formed, and describe the structure of pollen grains.

8. What part in the vegetable economy is played by carbonic acid?

9. Describe the phenomena of conjugation in algæ and fungi.

10. Give the most important characters of the natural order Cruciferæ, and describe the various modifications of the fruit in that order.

Physics, etc.—Tuesday, August 12.

11. What is the nature of the transit of Venus, and with what object is it to be observed next year?

12. What is an artesian well?

13. Explain the term specific gravity, and describe the mode in which it is determined.

14. What are the physical causes of the circulation of the sap in plants?

15. Describe the structure of a compound achromatic microscope.

REVIEWS.

SOME MODERN WORKS ON CHEMISTRY.

A Manual of Elementary Chemistry, Theoretical and Practical. By GEORGE FOWNES, F.R.S. Eleventh edition, revised and corrected by HENRY WATTS, B.A., F.R.S. Pp. 1026. London. 1873.

Manual of Chemical Analysis, as applied to the Examination of Medical Chemicals. For the use of Pharmaceutists, Physicians, Druggists, and Manufacturing Chemists, and of Pharmaceutical and Medical Students. By FREDERICK HOFFMANN, Ph.D., Pharmaceutist, of New York. Pp. 393. New York. 1873.

A Course of Qualitative Chemical Analysis. By W. G. VALENTIN, F.C.S., Principal Demonstrator of Practical Chemistry in the Royal School of Mines and Science Training Schools, South Kensington. With nineteen engravings on wood. Pp. 226. London. 1873.

Quantitative Chemical Analysis. By T. E. THORPE, Ph.D., F.R.S.E., Professor of Chemistry, Andersonian University, Glasgow. Pp. 387. London. 1873.

THE books which have just appeared under the above titles may be fairly taken as representative of the present condition of the science and practice of chemistry in the present day. The first, although modestly styled "A Manual of Elementary Chemistry," enters pretty deeply into the theory as well as the practical details of this extensive subject; the second, which is strictly medical in its objects, is intended to guide medical men and pharmaceutists in their inquiries as to the quality, identity, and purity of drugs; the third has a wider scope, and treats of the methods adopted for conducting the qualitative analysis, or, in other words, for *testing* inorganic and organic bodies; and the fourth pursues the investigation in another way, and shows how the exact composition of each substance in nature, both by weight and by volume, may be determined.

As "Fownes's Chemistry" embraces, although in a comparatively small compass, the whole range of the science, it necessarily claims the first consideration; but as the general scope and contents of the volume are well known to chemists, it would be an unnecessary task to analyse them at length, and it is sufficient to state in what respects the present edition differs from its predecessors. It may be interesting, therefore, to mention that the third edition was nearly completed by the original author, Dr. Fownes, a short time before his death, in 1849, and was published in the following year under the editorship of the late Dr. H. Bence Jones, whose recent loss the profession has had occasion to deplore. The six following editions were carried through the press by Dr. Bence Jones and Dr. Hofmann, the latter of whom lived for several years in this country, until he was promoted to a professorship in Germany; and during their joint-editorship it was found necessary, in consequence of the rapid advance of the science and the great changes which had taken place in the entire system of chemical philosophy, to make considerable alterations and additions in almost every part of the work. Among other

changes, the chapter on the General Principles of Chemical Philosophy was rewritten, as also the greater part of the Organic Chemistry; the section on Animal Chemistry was entirely revised by Dr. Bence Jones, and the new Atomic Weights were introduced, and the Notation was altered in accordance with them.

In the present edition still further changes have been made. A considerable quantity of new matter has been added, chiefly relating to Organic Chemistry; but in order to avoid increasing the size of the book some parts of the section on Physics in the former volumes have been omitted. The plan adopted by Dr. Fownes in arranging the subjects connected with the non-metallic elements and their compounds has been retained—with, however, some alterations and additions; and in the section on Organic Chemistry, or the chemistry of the carbon-compounds, the same general arrangement is followed as in the last edition, except that these compounds are now divided into two great groups, called *fatty* and *aromatic*—which, however, are names we cannot approve, inasmuch as in many cases they are either erroneous or inapplicable. Surely tartaric acid, and oxalic acid, and acetic acid are not fatty bodies, and, except on purely theoretical grounds, neither are starch, or sugar, or alcohol, or ether; while, although the aromatic group has certainly a greater claim to that designation, it is difficult to perceive why tannic and gallic acids, for instance, should be included in the category.

The section on Animal Chemistry, which was under the supervision of the late Dr. Bence Jones, remains nearly as in the last edition; but it will be found that the weights and measures used are those of the French decimal system, which, although unquestionably more philosophic than that used in Great Britain, will be found a stumbling-block to many English readers; and temperatures are expressed generally on the Centigrade scale.

Dr. Frederick Hoffmann's "Manual of Chemical Analysis" is intended to supply a want which must frequently be felt by dispensing practitioners of medicine, as well as by the druggist and the manufacturing chemist, when engaged in testing the characters of the medicinal chemicals with which they have to deal. Dr. Hoffmann observes that the knowledge they seek to acquire on such matters is widely scattered through chemical, pharmaceutical, and medical manuals and journals, and his object is to furnish a special guide for ready reference in the application of chemical analysis to the subjects of the examinations in question. His book is divided into two parts, the first and shorter being devoted to a brief general description of chemical operations and reagents, and of a few important general tests, together with a very good summary of the principles and practical applications of volumetric analysis; while the second contains a description of the physical and chemical properties and relations of the medicinal chemicals and their preparations, and of the methods employed for establishing their characters and ascertaining their quality and purity. Dr. Hoffmann states that this latter portion has been compiled with special reference to the fifth decennial edition of the United States Pharmacopœia, to the latest British Pharmacopœia, and to the Pharmacopœia Germanica of 1872. The difficulties of chemical notation, now in a transition stage from the new to the old, have been avoided by omitting it altogether —"for want of unanimity," says Dr. Hoffmann, "and absolute certainty in this particular point of chemical philosophy."

Mr. Valentin's "Course of Qualitative Chemical Analysis" is in its nature entirely practical, being prefaced by a few brief remarks, which are illustrated with some well-executed wood engravings, on qualitative analysis in general, and on the usual apparatus by which it is conducted, and on group-reagents and special reagents. The reactions of the different metals and non-metallic bodies and their compounds are then successively described, and a chapter is devoted to the reactions of the organic acids. Some practical exercises are presented for the use of the young analyst towards the end of the volume, which concludes with a series of tables for the qualitative analysis of simple and compound substances both in the dry and wet way, together with some appendices giving lists of reagents, a table of the solubility of salts in water and in acids, and schemes for recording analytical results.

Dr. T. E. Thorpe's "Quantitative Chemical Analysis" is divided into five distinct parts. The first gives a description of that indispensable piece of apparatus in this kind of analysis, namely, the balance,—the mechanical principles involved in its construction, and the mode of using it, together with an account of the operations generally occurring in practical processes, such as filtration, the incineration of filters, etc.; the second consists of a graduated series of examples in simple gravimetric analysis; the third part treats of volumetric analysis, and describes the more important volumetric processes; the fourth contains an account of the methods—gravimetric and volumetric—employed in the analysis or valuation of ores, minerals, and some of the more important industrial products, and the subject of water-analysis is fully considered; and the fifth part treats of the general processes of organic analysis. The decimal system of weights is adopted in this work, and also the new notation, and the temperatures are reckoned on the Centigrade scale; and there is a plentiful supply of well-executed engravings in illustration of the text.

Chemistry—which to many medical readers appeared at one time only a kind of accessory study to medicine, and as such formed one of the subjects taught at the Medical Schools—has now attained to such gigantic dimensions that instead of being compressed into a six months' course of lectures, it might well occupy the thought and labour of a lifetime, which is still too short to comprehend all its applications and ramifications. As a science, it is little more than a hundred years old, if, indeed, the early discovery of the gases by Black, Priestley, and Lavoisier can be said to constitute a science at all. It is probably only since the discovery of potassium and sodium by Sir Humphry Davy, at the very commencement of the present century, together with the ingenious development of the atomic theory by Dalton, and the still more recent researches made by the aid of electro-chemistry by Faraday, that chemistry can be really said to have attained to the dignity of a special and separate science; but as to its claims to that distinction at the present moment there can be no doubt whatever. Its connexion with medicine being in a twofold aspect—as teaching the mode of preparing and analysing therapeutic agents, and as constituting an integral and essential portion of the domain of physiology—renders an acquaintance with its laws and its practical details imperative in the case of all students and practitioners of the healing art; and while we fully and entirely admit this necessity, we cannot but regret that the enormous extension and development which its domain has undergone renders a due amount of attention to all its branches almost impracticable to the average medical reader or learner, who has at the same time many other subjects to claim his allegiance. To say nothing of the encyclopædias of chemistry published in the present day, and the treatises upon it, extending to a score or so of bulky volumes, it will be sufficient to cast our eyes on the contents of one of the books now under notice—namely, "Fownes's Chemistry," to appreciate the labour which the student must undertake who endeavours—especially if he have had no previous training—to master its contents. The difficulty, too, will appear even greater when we compare one of the former editions (as, for instance, the fourth, which is also now lying before us) with the present one; for it almost appears by this comparison that the chemistry of 1852 is entirely a different matter from that of 1873, and thus the conscientious student who may have thought that he had overcome his difficulties in acquiring a knowledge of chemistry twenty years ago, finds that he is still a tyro in the pursuit, and the uncomfortable feeling may steal over him that twenty years hence the chemistry of the future will be equally obscure to the diligent student of the present day.

During the period which has intervened between the first appearance of "Fownes's Chemistry" and the present edition several discoveries have indeed been made; and the researches made by means of spectrum analysis, in particular, have revealed the existence of several elementary bodies previously unknown, while they have proved the presence of many known bodies in greater quantity in nature than was before suspected. But after all it must, we think, be admitted that the discoveries of new *facts* have been by no means so numerous as the development of new *theories* and *hypotheses*, and that the real difficulty of the student of the present day is to unravel the intricacies of the latter two rather than to make himself adequately acquainted with the former. The *facts* of the composition of water, of atmospheric air, of ammonia, etc., are precisely the same now as they were in the time of Lavoisier and Priestley, but the theory of the constitution of many bodies has undergone very considerable changes. Water, the primary ground on which the determination of the atomic or combining weights of substances is established, still consists, as Lavoisier proved, of eight parts by weight of oxygen and one part by weight of hydrogen, and of one volume of oxygen and two volumes

of hydrogen; but the familiar numbers of 8 and 1, making up 9, are now superseded by 16 and 2, making up 18, which is precisely the same proportion, although the numbers are different. As the number 8 of oxygen has been doubled, it became necessary to double some of the other atomic numbers, and accordingly carbon, which was formerly 6, is now 12, sulphur from 16 has become 32, and in like manner calcium, iron, and zinc and others have doubled their former equivalents. We by no means intend to assert, or even to insinuate, that these changes have been arbitrarily made; on the contrary, they are the result of profound investigations, of a theoretical nature, which have at present received the general assent of chemists, and we refer to them only to show the difficulties which the modern student of chemistry is called upon to encounter, the more especially when he reflects that the theories of to-day are totally different from the theories of former years, and that the present theories may be superseded by others as time advances. The atomic theory of Dalton, however, remains essentially the same as in the time of its illustrious discoverer, although, as we have just remarked, the numbers assigned to the elements have in some instances been changed; but the theory of the *molecular* constitution of bodies, as contradistinguished from the *atomic*, is new, and although supported by learned and ingenious reasoning, must be very difficult of comprehension to the beginner; for chemistry partakes of the nature both of a practical art and an abstract science, and an acquaintance with the former is absolutely necessary in order to comprehend the reasonings involved in the latter. Hence it is obviously useless, in any book on chemistry intended for beginners, to commence the volume by an exposition of the theoretical laws which regulate the combinations or separations of atoms or molecules, and it is better to begin it by a general description of the properties of bodies, leaving the reasonings to a somewhat more advanced period. The late Professor Turner, one of the best lecturers on chemistry in his time, and under whom Dr. Fownes held the position of Professor of Practical Chemistry, taught the science in the manner we have just indicated, commencing his course of lectures by a series of striking but familiar experiments, and by explanations of the leading facts connected with the elementary bodies—as hydrogen, oxygen, nitrogen, and the like,—and after the attention of the student was thus gained by the appeal made to his eyes and ears, the theoretical parts of the course were introduced to explain and account for the phenomena exhibited.

In Dr. Fownes's manual the same plan is substantially adopted, and the present very able editor, Mr. Watts, has done well, we think, to adhere to it; and thus after some introductory observations on specific gravity, heat, light, electricity, etc., the reader is introduced *in medias res*, and becomes acquainted with the characters of the non-metallic elementary bodies and the mode of preparing them, his understanding being assisted, through the sense of sight, by well-executed illustrations of different chemical processes. Then, at the end of the section relating to these bodies, and before the description of the metals, the general principles of chemical philosophy are discussed at length, and the knotty questions involved in the mutual relations of atoms and molecules are fully set forth. It would be quite beside the truth, however, to state that the problems thus introduced are all adequately solved; and this unsatisfactory result arises from no fault of any of the distinguished editors of the book, but from the intrinsic difficulty and intricacy of the subject. In short, the *theory* of chemistry, as distinguished from the *facts*, is still in a transition state, and the shifting phases of conjecture and hypothesis, more especially those relating to organic compounds, resemble the ever-changing and brilliant colours and shapes exhibited by a kaleidoscope, where the primary forms are few and constant in their nature, but the varieties in which they combine together or separate from one another are apparently infinite.

Mr. E. M. Grace has been chosen Mayor of Thornbury for the ensuing year.

Lithotomy Instruments.—Mr. Gutteridge, one of the most successful lithotomists of the day, having cut 188 patients with a loss of only eight, will give a demonstration of his instruments and practice at St. Peter's Hospital on Monday next, the 3rd inst., at 3 p.m., when it is expected he will perform the operation of lithotomy also. Members of the profession are invited to attend.

GENERAL CORRESPONDENCE.

THE RECOGNITION OF THE PROVINCIAL SCHOOLS BY EDINBURGH UNIVERSITY.

[To the Editor of the Medical Times and Gazette.]

Sir,—I learn from your pages that there is a considerable development of the provincial medical schools of England, not only as regards numbers of students, but also as to teaching power. I equally learn from your "Students' Number" how small is the recognition of these schools by Edinburgh University. Seeing that many of these provincial students might wish to graduate there if proper facilities were given, is it not a reasonable request that the regulations as to students from these schools should now be reconsidered?

In passing through Edinburgh lately, I was surprised to learn what laxity existed as regards the recognition of extra-academical lecturers there, as compared with the strictness shown towards those of our provincial schools. One lecturer on the Practice of Medicine had been giving a *qualifying* course of lectures to a few ladies in his dining-room. This gentleman, having had only two students to constitute his class when giving his course at the College of Surgeons (or Physicians), had resigned his chair—if chair it may be called. Another lecturer on Surgery in the extra-academical school, having precisely a similar number of students in his class, it was a joke last session to say, when two students entered a surgical ward together, "Here comes Dr. ——'s class!" In truth, so numerous are these lecturers (all recognised by the University), that it is impossible they can have even a moderate class. On reference to your journal of September 13 it will be seen that there are four private lecturers on Surgery, two on Clinical Surgery, three on Practice of Physic, three on Midwifery and Diseases of Women and Children. Now, if small classes held—if the lecturers see fit—in their dining-rooms be recognised by the Edinburgh University authorities, why, in the name of common sense, cannot they recognise like lecturers at Leeds, Liverpool, Manchester, Birmingham, Bristol?

I write this in no hostile spirit towards Edinburgh, but the contrary. It is doubtless needful to take care that teachers be recognised out of the University; but it is just as needful that care be taken that those who are recognised are competent for their duty and have the fitting means and appliances for teaching their respective subjects—otherwise, certificates of courses of lectures are worse than useless.

October 25. I am, &c., M.D.

THE LATE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

[To the Editor of the Medical Times and Gazette.]

Sir,—I find the following in a leading article of the *British Medical Journal* of Saturday last (October 25, page 492):—"It is not quite the fact that all the acknowledged metropolitan leaders of the profession thought it right to make sacrifices to further the success of the meeting [of the British Medical Association in London]. Many did so; they made, indeed, every kind of sacrifice most cheerfully, generously, and even ostentatiously. Their efforts will always be gratefully remembered. There are others who did not think it worth while to postpone their ordinary holiday for a few days to take part in this great professional festival, or even to express regret at being prevented from doing so; and this is much to be regretted, *and will also not easily be forgotten.*"

As a "provincial," I have no idea against whom this spiteful threat (for such it reads to me) is uttered; but no matter who it may be, the utterance is intolerably insolent and presumptuous. It may be that the "acknowledged leaders" referred to experienced no regret; nevertheless, they must utter a lie on penalty of their conduct not being easily forgotten, and say they did. So also because they did "not think it right to make sacrifices of health and strength and time and (least of all) money, neither will that neglect be easily forgotten. I have thrice done my best to entertain the members of the British Medical Association in annual meeting assembled, and can testify that I never performed a more thankless duty. I do not believe that half-a-dozen members have more than a slight remembrance of the "sacrifices" I made. But who

cares for thanks? I was happy to see those I entertained, and that was my sufficient reward. It is alarming, however, to find that if circumstances prevent me enjoying this pleasure, the neglect to avail myself of the pleasant opportunity should be a matter of accusation and punishment, without even the opportunity being afforded one of explanation. Who is responsible for this outrage on propriety—the editor, Mr. E. Hart, a committee, or the Council? I am, &c.,

A Provincial Member of the British
October 27. Medical Association.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, October 21.

Sir W. Jenner, Bart., M.D., F.R.S., President, in the Chair.

Mr. McCarthy showed a specimen of Traumatic Separation of the Great Trochanter. Such an accident was very rare, and, though often recorded, was generally compound, not simple. A child came in and died of pyæmia following a sacral abscess. At the examination this portion of the bone was found separated. Ten days previously the child had fallen, and began to have swelling of the hip. It was able to walk to the hospital, but soon died, when the condition was discovered. A case in the practice of Mr. Aston Key was somewhat similar. In both instances the child could walk to the hospital.

Mr. Goodhart asked if the separation or the ostitis came first. He had seen a case of acute ostitis ending in separation of the small trochanter.

Mr. McCarthy said the inflammation of bone was secondary. The child died ten days after the accident.

This gentleman also showed a recent Fracture of the Odontoid and Atlas. A man fell into the hold of a ship, and was brought in with no power in his lower extremities. The breathing was diaphragmatic. In twenty-four hours there were signs of returning sensation, but in sixty hours the man died. It was then found that the atlas was in four pieces, and that the odontoid was broken, but kept in position by the ligament. Curiously, in this case there was no interference with the function of the phrenic.

Dr. Dowse exhibited a specimen showing a Foreign Body in the Crico-thyroid Pouch. He thought it a portion of necrosed bone. The patient was a female, the subject of tertiary syphilis, who suffered from spasmodic attacks of dyspnœa. Not much was to be seen with the laryngoscope. Afterwards she suffered from epileptiform convulsions without loss of consciousness. She died in an attack of dyspnœa.

Dr. George Harley suggested the possibility of its being a foreign body swallowed. He had seen something of the kind in a female patient supposed to have phthisis, bringing up large quantities of matter, till one day she spat up a fishbone. Then she remembered having swallowed one long before. The symptoms cleared off.

Mr. L. Brown suggested that it was a portion of one of the arytenoid cartilages.

Dr. Dowse did not think so, but the question was referred to Dr. G. Harley and Dr. Powell.

Dr. Dowse exhibited the Spinal Cord from a man the subject of Paraplegia induced by a fall from a scaffold twelve months before. Not even reflex movements could be induced in the limbs. He died gradually exhausted by sloughing sores. He had had fair respiratory power. The cord was found softened. The whole nervous structures were gone below the neck, where there was red softening. (Referred to Dr. L. Clarke and Mr. Kesteven.)

Dr. Peacock exhibited a specimen of Aneurism of the Aorta, forming a large tumour in the left dorsal region. The preparation was removed from the body of a man 52 years of age, who had served for some years in the navy, and had since followed the occupation of a labourer. About fifteen months before his death he fell on the pavement upon his back, and then was much shaken, and had pain in the left shoulder-blade after. The pain increased, and he had also dyspnœa, and about three months after he felt pulsation in the seat of pain, and after a tumour was noticed there. He continued at his work till two weeks before his admission into St. Thomas's Hospital on February 11. There was then a large pulsating tumour extending from the top of the shoulder to the lower angle of the scapula, and from near the spinous processes of the vertebræ to the anterior fold of the axilla. He experienced great pain in the tumour, and after his admission it steadily increased in size and prominence. Latterly the skin was covered with patches of redness, and these became dark-coloured and threatened to slough, and that result was only prevented by covering the surface with soap-plaster spread on soft wash-leather. The pain was relieved by the hypodermic injection of morphia. There were no signs of cardiac disease. The patient was throughout his residence in the Hospital peculiarly pallid and anæmic-looking, and he died exhausted. On examination the aneurism was found to originate from the posterior side of the descending portion of the arch, at about an inch and a half below the origin of the left subclavian artery. It was biloculate, one portion extending across the bodies of the vertebræ to form a tumour about the size of a large orange on the right side of the spine; the other, and much larger portion, protruding on the left side, and causing the large tumour in the dorsal region. The bodies of the fourth, fifth, sixth, and seventh vertebræ were extensively eroded, and a considerable length of the second, third, fourth, fifth, and sixth ribs were destroyed, so that the aneurism lay immediately beneath the serratus magnus muscle. It contained only fluid blood. The aorta and its branches were not enlarged or apparently diseased, and the heart appeared natural. The tumour had not exercised any permanent pressure on the œsophagus, bronchi, or nerves, and had only somewhat compressed the left lung.

Mr. De Morgan showed a specimen of Hernia of the Vermiform Appendix. The patient had suffered for forty years from a hernia, which he kept up with a truss. It came down every night, and was replaced in the morning; but a fortnight before admission he failed to return a portion. This was left behind, and was hard and doughy, the size of an orange. The neck of the sac was large, and the bowels were regular. There had been no vomiting or sickness. He imagined the tumour omental, but next day the patient was looking more collapsed, and there was more tympanites. He operated, and came down to a thick structure containing matter. This was opened, and he came on a small opening leading into a tract embedded in the dense structure. Congestion of the lungs came on, and the man sank. They then found the opening leading up behind the bowel. It turned out to be the appendix vermiformis, which had come down with the cæcum, forming a hernia behind the peritoneum. It must have been there long, but for some reason pus had been produced, and this had been mistaken for the hernia of the bowel.

Dr. Silver showed a specimen of Obstructed Common Bile-duct giving rise to jaundice and enlargement of the liver. The patient, J. B., a labourer, aged 53, a man of good family history, and enjoying good health up to the time of his fatal illness, came under treatment at Charing-cross Hospital on December 30, 1872. About six months previous to that date his fellow-labourers pointed out to him that he was jaundiced. He continued to work for some weeks, but, becoming too weak, he applied for relief at St. Bartholomew's Hospital, where he was admitted, and remained for three months without benefit. When seen he was of a dirty yellow hue all over, deeper in the face than elsewhere; his urine deeply bile-stained, and his fæces clay-coloured. On examination his liver was found uniformly enlarged, but not to any great extent. There was no indication of any epigastric tumour. He went on sometimes improving, sometimes falling back, exceedingly dull and apathetic, till February 17, when he died somewhat suddenly during the night. Latterly he had become ascitic. After death his liver was found to be large, weighing eighty-seven and a half ounces, the bile-ducts strongly marked on its surface, and seemingly varicose; its substance discoloured from bile. On removal, together with the duodenum, the opening of the common bile-duct was somewhat prominent, and filled with mucus. On tracing it upward it was found normal, but with no stain of bile till near the junction of the cystic and hepatic ducts, where there was a soft, villous-looking mass attached to the wall of the common duct, and thence extending both into the cystic and hepatic ducts. Immediately beyond this the hepatic duct was enormously dilated, even to the size of the duodenum, and containing great quantities of altered bile, which welled out when the protuberant bile-ducts on the surface of the liver were wounded. The cystic duct was slightly dilated, and the gall-bladder filled with a gelatinous mass of mucus stained with the remains of altered bile. This soft,

semi-gelatinous new growth was sharply defined above and below, and there were no adhesions to any surrounding organs nor any apparent tendency on its part to spread. After hardening, this new growth was examined microscopically, and was found to consist of cells of various sizes, tending to group themselves in isolated masses, with indistinctly fibrillated connective tissue between—a structure which could be called nothing but cancer. (Referred to Committee.)

In reply to Dr. Gibbon, Dr. Silver said the obstruction was entirely within the duct.

Dr. Legg said he had come across one other such case in reading. Was the matter retained in the bile-ducts tested for bile acids?

Dr. G. Harley thought the case unique. In long-standing cases the whole of the coloured contents of the gall-bladder might be absorbed, and only a colourless mucus remain.

Dr. Silver said the contents of the gall-bladder did not give the ordinary colour reactions, showing that they were in process of undergoing the change described by Dr. G. Harley. Pettenkofer's test was not tried.

Dr. Silver also showed a specimen of Diseased Liver whose chief interest lay in the difficulty which would attach to the diagnosis of such a case. The patient, a man aged 49, came under treatment at Charing-cross Hospital on February 28, 1873. It was elicited that he had been already a patient under one of the out-patient physicians, but that then he complained of vomiting and pain after food, bringing up also dark grumous matters. When admitted as an in-patient, however, his main complaint was ascites. Deeming it impossible to do any good by the ordinary means for relieving such accumulations, the man was tapped on March 1 by Mr. Hird, and fifteen pints fourteen ounces of fluid removed. From the effects of the operation he speedily recovered, but began to suffer a good deal from flatus, and the vomiting and pain at his stomach were troublesome. About the middle of March he began to swell again, and ultimately died quite suddenly on the 20th. After death there were found signs of recent peritonitis and much fluid in the abdomen. The liver weighed thirteen pounds, and had its right lobe converted into one enormous hydatid cyst, containing hydatids in all stages densely packed and with no fluid between them. The left lobe was large, hard, and in a decidedly cirrhotic condition; it contained no hydatids. The stomach was nearly converted into a cancerous mass, which passed round from side to side and obstructed the passage of digested food. This was ulcerated internally and adherent externally. Behind was a softened mass extending into the interior of the pancreas, which was there adherent to the wall of the viscus.

A third specimen exhibited by Dr. Silver consisted of a Small Aneurism of the Pulmonary from a patient who had died of hæmoptysis. The patient, a male aged 32, a labourer, was admitted on October 9. He stated that about six months ago he began to spit blood, having been troubled with cough and spitting some time before. After that he improved, but just when he was about to return to his work he had another attack of hæmoptysis, since which time he has been permanently invalided. When admitted he had all the signs of phthisis. On October 15 he had another very severe hæmoptysis, and his temperature went up to 102°, whilst his dyspnœa became worse. Again he rallied somewhat, but on the morning of the 20th he suddenly brought up a large quantity of blood, and died. Having had signs of a long-standing cavity in the left apex, and having regard to the nature of the hæmorrhage, which always came in great gushes, it was judged probable that there was some aneurism of the pulmonary in the walls of the cavity, and on tracing the vessel to the margin of the cavity, such an one was discovered, about the size of a pea, and in close proximity to several large vessels which had been obliterated. From it, in all probability, had come the fatal hæmorrhage.

Mr. Wagstaffe showed a portion of a Large Tumour of the Parotid. It had grown slowly till it attained the size of two fists, projecting backwards and upwards, and pressing on the nerves. He removed it without great trouble. It weighed sixteen ounces, and had a honey-combed structure, consisting of cysts, partly degenerated dense connective tissue, with glandular tissue intermixed.

Mr. Godlee exhibited a specimen of Mycloid Disease of the Femur from a patient of Mr. B. Hill. Eighteen months ago this was seen, and supposed to be a white swelling, but it was seen to be entirely in the upper part of the joint. Last year pain was felt, and the swelling rapidly increased. Slight movement was, however, possible. There was only slight pain, and little or no tenderness. Several enlarged glands began to show in the groin, and amputation was resolved on. The cartilage was soft, and the outer condyle was gelatinous, but there was no actual involution of the joint. The shaft of the bone was inflamed, and the parts discoloured with blood. The character of the soft mass was typically myeloid.

Dr. Cayley showed for Mr. Nutt the photograph of a Vesical Calculus, apparently mulberry. No history was given.

OBITUARY.

SIR HENRY HOLLAND, BART., M.D., F.R.S., D.C.L.

On the eighty-sixth anniversary of his birth, died, at his house in Brook-street, this distinguished physician. In this journal in the early part of last year—February 3 and March 30—was given a long and exhaustive review of his work, "Recollections of a Life." It will be unnecessary for us now to give more than a brief sketch of his career. He was born at Knutsford, October 27, 1787, on the very verge of the French Revolution. He was for a year or two at school in that town, and subsequently became a pupil of the Rev. Mr. Turner, Newcastle-on-Tyne. In 1803 he left Newcastle for a year, and was at the school of Dr. Estlin, near Bristol. He there became the head boy, succeeding Sir J. C. Hobhouse, afterwards Lord Broughton; and contracted an intimate friendship with Dr. J. Bright, for many years one of the physicians of Westminster Hospital. At the Christmas vacation he came to London, and passed some time with the celebrated Dr. Aiken, who resided at Stoke Newington. At sixteen years of age he was articled to a Liverpool merchant. He had no liking for mercantile pursuits, and determined to enter the medical profession. He passed two sessions at the Glasgow University, and there became acquainted with the celebrated Sir W. Hamilton. Subsequently he entered at the University of Edinburgh, and there formed acquaintance with most of the leading men who were then connected with that renowned seat of learning. Amongst these were Brougham, Sidney Smith, Walter Scott, Dugald Stewart, Jeffery, Henry Erskine, and others. He became identified with the leading Whigs and the *Edinburgh Review*. To his connexion with the Whig party may be traced the success of his future career. Soon after his graduation he was appointed to accompany the Princess of Wales on her Continental tour. This unfortunate lady was afterwards Queen Caroline, and on the memorable trial against her for "pains and penalties," Holland rendered most important service in her defence by the straightforward and manly evidence which he gave in her favour. It is not too much to say that this evidence had a remarkable influence in obtaining her acquittal. We have gone into the subject at considerable length in the first notice of his "Recollections." In 1816 he established himself in practice in Mount-street, Grosvenor-square, and four years afterwards removed to the house in Brook-street, in which he died. From the first he was a successful practitioner, and his income soon reached £5000 a year. His connexion with the Whigs—though he himself never took any active part in politics—was of great service to him. He numbered even at this early period among his patients most of the distinguished members of the party with which in early life he had been associated. He attended Prime Ministers, Lord Chancellors, judges, and men of eminence in the literary world. He gives in his "Recollections" striking portraits of these men; and we cannot do better than refer our readers to the remarkable volume in question. His chief contribution to medical literature was his "Medical Notes and Reflections"—a book that gave evidence of his highly cultivated and philosophical mind. Sir Henry Holland was so much occupied with his attention to "great personages" that he seldom found the opportunity of attending the gatherings of the members of his own profession. We never recollect seeing him in any medical society during his long life. But as President of the Royal Institution he was seldom or never absent from his post. In person Sir Henry was of the middle height, and of a spare and active figure. To the last he maintained his physical and mental activity and freshness. Within a few months of his death we met him in Grosvenor-square, walking—or almost running—with his accustomed agility. To the question of how he felt, the answer returned was "Never better in my life!" His appearance and manner justified the truth of this rejoinder. His face was not indicative of great power, but it denoted

sagacity and perfect self-possession. As a practitioner he was of the old school, and had less faith in medicines than those who had to administer them. Greater physicians than Sir Henry have flourished in his day, but no one can be named superior to him as combining literature and medicine. If he did nothing to raise the political influence of our profession, he did much by his personal character to elevate it in the eyes of the public. J. F. C.

ROBERT WILLIAM SMITH, M.D., Vice-President R.C.S. Irel.

With deep regret we have to record the death of this most distinguished surgeon and pathologist. The melancholy event occurred on Wednesday, October 28, and was caused by an illness which, though of old standing, assumed formidable proportions only at the close of last July. We have already referred to it in our columns. Dr. Smith's fame as a surgical pathologist has scarcely ever been equalled, certainly has never been surpassed. But not alone in this branch of the profession did he hold a foremost place, although its superior charms led him to a great extent to forego the advantages and emoluments of private practice, and to devote himself almost wholly to the theory and science of surgery. His worth was early recognised, and for very many years he was Surgeon to the Richmond Hospital, an institution with the history of which his name will ever be inseparably united. To his untiring industry the splendid museum of that Hospital owes its existence; and strangers from all countries, when visiting Dublin, have always made it a point to see perhaps the finest collection of drawings, casts, and preparations illustrative of surgical pathology which it has ever fallen to the lot of one man to accumulate.

In 1849 Dr. Smith was appointed first Professor of Surgery to Trinity College, Dublin, and he held this important chair until his death. His professorial lectures were unique for the clear and brilliant style of their delivery, and for the inimitable manner in which their subject-matter was dealt with. Many generations of students have hung on the words which fell from his lips from year to year, and they were not slow to recognise the intrinsic value of his lectures. The writer of this notice has often and often listened with pleasure to the wonderful "word-painting" of surgical lesion or disease which was so characteristic a feature in Professor Smith's discourses. There never was a better-read man or a more learned member of the profession. He seemed to know the works of the first surgeons of France and Germany almost literally off by heart, and how great he was on authorities (to use a student phrase) was but too well known to many a candidate Master in Surgery. As a classical writer, also, Dr. Smith will always be remembered. His "Treatise on Fractures and Dislocations," which first saw the light in 1847, has won a world-wide reputation, and the same may be said of his magnificent work on "Neuroma," which appeared some two years later.

One more sphere of usefulness in which he shone must be mentioned. In 1838 the Dublin Pathological Society was instituted, mainly owing to the earnest efforts of Dr. Smith and some of his most intimate friends. He was appointed secretary, and for the thirty-five years during which the Society has existed he held this annual office. What further proof is needed of the care and ability with which he watched over the interests of the Society?

So far we have spoken of Dr. Smith as a surgeon; it remains but to say that as a man he was thoroughly upright. He never truckled to any sect or party, but throughout his career he was ever ready to defend right against wrong, to vindicate the principle of impartiality, and to oppose to the utmost of his power whatever appeared to him to savour of injustice or of error.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, October 23:—

Clunn, Thomas Robert Hood, Mauntile, Pembroke.
Denton, Thomas John, Bridlington, Yorkshire.
Ransford, Thomas Davis, Guy's Hospital.
Rigley, James Arthur, Preston, Lancashire.
Twort, William Henry, Tunbridge Wells.

The following gentleman also on the same day passed his Primary Professional Examination:—

Hopgood, William Charles, University College.

The Apothecaries' Hall, Dublin.—At the Professional Examinations held in October, 1873, the following gentlemen received the licence to practise Medicine and Pharmacy:—

Fisher, John Baptist.
Foy, George Mahood.
Lyon, Richard N.
O'Sullivan, John Joseph.
Spence, Robert.

The following candidates passed the Preliminary Examination in Arts:—

Donaldson, Ebenezer.
Fryer, William Francis.
Greany, Hugh Joseph.
Hallowell, Joseph James.
Helihoy, David J. Daniel.
Kidd, Thomas.
Maguire, James.
Myles, Zachary George.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Gray, John H., M.B., M.R.C.S. Eng.—House-Surgeon to the Hospital for Sick Children, Bristol, *vice* Dr. Eliza Walker, resigned.

James, Wm. Dale, M.R.C.S. Eng.—House-Surgeon to the Royal Cornwall Infirmary, Truro, *vice* Mr. Salmon, resigned.

Yeld, Henry John, M.D., M.R.C.S. Eng., L.S.A.—Medical Officer of Health for the Borough and Port of Sunderland.

MILITARY APPOINTMENTS.

War Office.—Medical Department.—Surgeon-Major William Ferguson retires upon temporary half-pay. Surgeon-Major Joseph Richard Kehoe retires upon temporary half-pay. Surgeon John Montgomery Fiddes, M.B., to be Surgeon-Major, *vice* Ralph Robert Scott, retired upon temporary half-pay. Surgeon Charles Frederick Richards, M.B., from half-pay, to be Surgeon, *vice* George Scott Davie, M.D., promoted.

Army Hospital Corps.—Apothecary to the Forces Frederick Philpot to be Captain of Orderlies.

Brevet.—Honorary Surgeon J. R. Deane, Civil Medical Officer, Bhawlapore State, to have the local and honorary rank of Surgeon-Major.

BIRTHS.

Annesley.—On October 23, at Cheltenham, the wife of Surgeon-Major J. C. Annesley, Bengal Army, of a daughter.

Gogarty.—On October 19, at Winchester, the wife of H. A. Gogarty, M.B., L.R.C.S.I., Rifle Brigade, of a daughter.

Sutton.—On October 22, at the Norwich Borough Asylum, the wife of Frederick Sutton, M.R.C.S. Eng., L.S.A., Resident Medical Superintendent, of a son.

Ward.—On October 16, at Montagu-place, Russell-square, the wife of J. Ward, M.R.C.S. Eng., of a daughter.

MARRIAGES.

Edwards—Laing.—On September 18, at St. John's, Hackney, Thomas Edwards, Esq., to Susanna, widow of John Laing, M.A., M.D.

Leslie—Elder.—On October 22, at Trinity Episcopal Church, Deanbridge, Edinburgh, Louis Gordon Leslie, M.R.C.S., L.R.C.P., Arundel, Sussex, to Janie, only surviving daughter of the late John Elder, Esq., Writer to the Signet, Edinburgh.

Miall—Collings.—On October 22, at the Church of Our Lady and St. Joseph, Hanwell, Eugene Henry Miall, L.R.C.P. Edin., L.R.C.S., to Charlotte Matilda Alice, youngest daughter of the late Thomas Collings, Esq., of Hampton Wick.

DEATHS.

Fawcus, Annette, widow of the late James Fawcus, M.D., of the Bengal Medical Service, at Anerley, on October 20, aged 43.

Dalby, William, T.M.D., M.R.C.S. Eng., L.S.A., J.P. for the county of Surrey, of 169, Kennington-park-road, suddenly, at Shrewsbury House, Plashet, the residence of G. Gregory, Esq., on October 26, aged 60.

Garthon, James Slapp, M.R.C.S., late of Norwich, on October 20, after a lingering illness, aged 74.

Harrison, Amelia Eckford, wife of the late John Harrison, M.D., of Highgate, at Hampstead-lane, on October 16.

Holland, Sir Henry, Bart., M.D., F.R.C.P., F.R.S., D.C.L., L.L.D., on October 27, his 86th birthday.

Lewis, D. E., L.S.A., formerly of Liverpool and Bath, at Plumstead, on October 18, aged 77.

Macdonald, Patricia, youngest daughter of the late Alexander Macdonald, M.D., of Inverness, at 2, Ardross-street, Inverness, on October 22.

Mathew, Margaret, widow of the late P. Mathew, M.D., H.E.I.C.S., at 13, Marshall-place, Perth, on October 27, aged 90.

Torrie, James, M.D., at 19, Union-place, Aberdeen, on October 26, in the 83rd year of his age.

Vallance, Mary Ann, widow of James Thomas Vallance, M.D., F.R.C.S., late of The Grove, Stratford, Essex, and Villette, Broadstairs, Kent, at Cambria House, Primrose-hill-road, N.W., on October 25, aged 64.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Candidates must be Members of one of the Colleges of Surgeons of Great Britain or Ireland. Applications, with testimonials, to the Chairman of the Committee, on or before November 15.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CHERTSEY, EPSOM, REIGATE, AND DORKING.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to Mr. Francis H. Beaumont, Buckland Lodge, Reigate, on or before November 1.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Assistant-Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before November 12.

HOUSE OF CORRECTION, WANDSWORTH-COMMON, SURREY.—Surgeon. Candidates must be duly qualified. Personal applications to the Governor between November 8 and 11, between 11 a.m. and 2 p.m.

LEEDS PUBLIC DISPENSARY.—Senior Resident Medical Officer. Candidates must be duly registered. Applications, with testimonials, to Mr. John Horsfall, 31, Albion-street, Leeds, on or before November 6.

METROPOLITAN DISPENSARY AND CHARITABLE FUND.—Physician. Candidates must possess a Diploma from a British University, and also be Fellows or Members of the Royal College of Physicians, London, or undertake to become so within six months after election. Applications, with testimonials, to the Secretary, before November 15.

RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY.—Resident Medical Officer. Candidates must be doubly qualified and registered. Applications, with testimonials, to the Secretary, 13, Cavendish-street, Ramsgate, on or before November 9.

ROYAL FREE HOSPITAL.—Junior House-Surgeon. Candidates must possess a medical or surgical qualification from one of the Examining Boards of the United Kingdom and be registered under the Medical Act. Applications, with testimonials, to the Secretary, on or before November 4.

SWANSEA UNION.—Medical Officer of Health for the Rural Parishes in the Union. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to G. B. Haynes, Clerk, 5, Fisher-street, Swansea, on or before November 1.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WESTMINSTER HOSPITAL.—Assistant-Surgeon. Candidates must be F.R.C.S. Eng., and must attend at the Hospital with their testimonials on November 11, at 1 o'clock p.m.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Clifton Union.—Mr. D. E. Barnard has resigned the Workhouse; salary £130 per annum.

Dursley Union.—The Second District is vacant; area 10,120; population 5755; salary £90 per annum.

Rothbury Union.—Mr. James M. Pringle has resigned the Whittingham District; area 25,697; population 1451; salary £10 per annum.

APPOINTMENTS.

Andover Union.—Wm. J. H. Lush, M.R.C.S. Eng., L.R.C.P. Edin., to the Fifth District.

Metropolitan Asylum District.—Wm. G. Balfour, L.R.C.P. Edin., L.R.C.S. Edin., as Superintendent of the Asylum at Hampstead.

Pontypridd Union.—Rees Hopkins, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Workhouse and Pontypridd District.

DR. R. FOWLER, of Bishopsgate-street, has been appointed Medical Officer of the C division of the Fire Brigade in the place of Dr. Woodforde, resigned. There were eighteen candidates.

HOSPITAL SUNDAY FUND in Manchester this year amounted to £8666, against £6971 in 1872.

THE Lambeth Vestry has very properly decided that in future the inspectors under the Adulteration Act shall be under the control and direction of the Medical Officer.

WE regret to state that Dr. Anderson, aged 50 years, who formerly held a good position professionally, was found drowned on the 24th ult. in the Temple Locks of the Forth and Clyde Canal.

THE German Imperial Chancellory have issued an official return of the cases of cholera which occurred in the eight eastern provinces of Prussia between May 22 and the 7th ult., which shows the number to be 38,624, and of these 19,655 were fatal.

AN outbreak of typhoid fever is reported in the neighbourhood of Wellington. Thirty cases have been traced to impure water. Dr. Sandford describes the contamination by sewage as "something fearful to contemplate." It appears the district is almost without drainage.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS IN IRELAND.—On Friday, October 24, 1873, J. Emerson Reynolds, M.D., Professor of Chemistry, and Keeper of the Minerals, Royal Dublin Society, was elected Professor of Chemistry in the School, in room of the late William Barker, M.D.

GOING WITH THE TIMES.—An advance to 3½d. a quart has been announced by the milk dealers of Bradford, and, in the event of a public analyst being appointed, it is their intention to charge 4d. a quart.

ON this day (Saturday, November 1) the Board of Trinity College, Dublin, will appoint examiners in Arts (Classics, Mathematics, and English), who shall be members of the Conjoint Examining Board for Ireland under the Medical Act, 1858.

MR. THOS. HARPER WHITAKER, surgeon, Kirkby Lonsdale, took the oath and qualified as a magistrate for the county of Westmoreland, at the last quarter sessions held at Kendal.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Henry Marais, Honfleur.—1. We know none such. 2. The abbreviations stand for Doctor of Medicine and Fellow of the Royal College of Physicians.

S. B.—Pitman's—from any bookseller.

A Provincial Teacher.—Dr. Ogle has not yet received the returns respecting the provincial schools, in consequence of the delay of the Birmingham authorities, who for some years past have omitted to send the returns in time. The other schools have complied with the regulations.

M.B.—The treatment is not new; it was recommended by the late Mr. Skey. It is, however, a valuable mode of managing the disease.

G. B., Wales.—A new note on Magnetism, by M. J. M. Gaujain, was read at the *séance* of the Académie des Sciences on September 29 last.

Charity.—Hospital Sunday Fund in London has been fixed for June 14 next year.

A. B. E.—The Excise duty on medicine vendors was last year £7285 15s. This is in addition to the stamp duty on patent medicines.

Inquisitive.—Dr. Lankester's account for inquests held in Middlesex from August 7 to the 3rd ult.—251 inquests—amounted to £649 1s. 6d.

Arts Examinations.—The list of successful candidates was published exclusively in this journal. Your letter should be addressed to the publishers, 11, New Burlington-street.

Observer.—We gladly reproduce the following from the *Army and Navy Gazette*:—"The medical authorities at Whitehall-yard have been untiring in their exertions to render the sanitary and medical success of the Ashantee expedition certain. All that science and experience can suggest is being freely made use of. The heads of the sanitary and medical branches deserve the highest praise for the way they have acted for the health and comfort of the troops."

A Metropolitan Teacher.—The session 1860 was the *annus mirabilis* for new entries of students, both in the metropolitan and provincial schools, caused by the desire to escape the preliminary examination in arts, etc., about to be required by the regulations of the Royal College of Surgeons of all students commencing the study of the profession. In this year the entries at the metropolitan schools amounted to 1228, and at the provincial schools to 333, making a total of 1561.

L.S.A., Fowey, Cornwall.—The Apothecaries Act received the Royal assent on July 12, 1815. In the case of the Company against Mr. Roby, it was held that, although the party had been in practice before and upon July 12, 1815, he was not entitled to resume his practice after August 1 if he had discontinued it before that day. Your neighbour (deceased) on the opposite side of the river could not, from his age, have been "in practice prior to 1815."

Mr. Edward Forbes Lankester has been the successful competitor for the exhibition of £120 a year given at St. Paul's School to the first scholar for the year after competition. He has also obtained, after examination, a scholarship worth £80 a year at Lincoln College, Oxford, where he is now pursuing his studies. Mr. E. F. Lankester is the son of the Coroner for Middlesex, and brother of Mr. E. Ray Lankester, Fellow of Exeter College, and Deputy of the Linacre Professor of Physiology, Oxford.

F.R.C.S. (exam.), Southampton.—After a careful examination of the last published Calendar of the College of Surgeons, we find that the following gentlemen passed for Fellowship and Membership on the same day—viz., Messrs. William Mitchell Banks, Liverpool, December 9, 1869; Timothy Holmes, Cumberland-place, Hyde-park, May 12, 1853; Thomas K. Hornidge, Charles-street, Westbourne-terrace, May 11, 1854; Athol A. W. Johnstone, Brighton, August 12, 1847; Joseph Lister, F.R.S., Edinburgh, December 9, 1852; George May, jun., Reading, December 11, 1851; Edwin Rickards, Birmingham, June 9, 1870; and Wm. Frederic Teevan, Portman-square, June 10, 1858.

Specs.—"Human Longevity, its Facts and its Fictions, &c.," by William S. Thoms, F.S.A. (London, Murray, Albemarle-street).

Psychologist.—The quotation to which you allude is by Milton, viz.—

"The mind is its own place, and in itself
Can make a heaven of hell, and hell of heaven."

Homo.—The costs of the recent action brought by the women students against the University of Edinburgh amount, we understand, to upwards of £850.

COMMUNICATIONS have been received from—

Mr. J. H. Gray; Dr. Vinen; Mr. Borchert; Mr. Sellars; S. B.; Mr. A. Harvey; Mr. L. Kidd; Dr. Farre; Dr. G. B. Halford; Mr. Blackett; Mr. W. W. Reeves; Mr. Searson; Mr. G. Eastes; Mr. T. H. Whitaker; Mr. N. Alcock; M.B.; Mr. A. Haviland; Dr. Phillips; Mr. A. L. Mease; Mr. T. M. Stone; Dr. George Scott; Mr. F. A. Mahomed; Dr. Fayrer: Mr. Lawson Tait; Professor Erichsen; Mr. J. Chatto; Mr. Balmanno Squire; Mr. W. D. James; Mr. Kershaw.

BOOKS RECEIVED—

James's Introductory Lecture on "The Progress of Medicine," delivered at the London Hospital—Sellars's "Chemistianity"—Blanc's Cholera, How to Avoid and Treat it—Die Anfänge der Lehensweisheit, von Dr. F. A. v. Hartsen—Statistical Report on the Health of the Navy for the year 1871—Nachrichten über die Gesundheitszustände in verschiedenen Hafenplätzen, von Dr. Max Leudesdorf—Lawson's Diseases and Injuries of the Eye, second edition.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Lancet—British Medical Journal—Allgemeine Wiener Medizinische Zeitung—Derbyshire Advertiser—Gazette Hebdomadaire—Pharmaceutical Journal—Le Progrès Médical—The Students' Journal and Hospital Gazette—Le Mouvement Médical—The Grocer—La Tribune Médicale—Gazette des Hôpitaux—La France Médicale—The New York Druggist—Philadelphia Medical Journal, October 4 and 11—Exeter and Plymouth Gazette—Manchester Daily Examiner and Times—Medical Press and Circular—London Medical Record.

APPOINTMENTS FOR THE WEEK.

November 1. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

3. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. General Meeting. Dr. Routh, "A Case of Stone impacted in the Kidney." Dr. Purcell, "A Specimen of Calculus in the Pelvis of Kidney." Dr. E. Symes Thompson, "A Case of Scrofulous Kidney." Dr. Berkart, "On the Nature of so-called Bronchial Asthma."

Royal Institution, 2 p.m. General Monthly Meeting.

4. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Pathological Society, 8 p.m. Dr. Greenhow—Large Hydatid Cyst of Liver. Dr. W. Legg—Gall-stones, with Abscess of the Liver, perforating the Pericardium and Pleura. Dr. Goodhart—Mediastinal Tumour in Exophthalmic Goître. Mr. Nunn—Pistol-shot Fracture of the Skull. Dr. Liveing—Human Hearts showing the Moderator Band. Dr. Henry Green—Fibroid Induration of the Heart. Mr. Potts—Osseous Deposit within the Arachnoid. Mr. H. Arnott—Sarcoma of the Omentum in a Child. Dr. Cayley—Psammoma of the Cerebral Dura Mater.

5. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Obstetrical Society, 8 p.m. Dr. Wiltshire, "On the Common Skin Diseases of Children." Mr. Tapson, "Note on the Removal of Intra-uterine Tumours." Dr. McCallum, "A Case of Extra-uterine Fœtation." And other Communications.

Royal Microscopical Society, 8 p.m. Mr. S. J. McIntire, "Notes on Acarellus." Rev. W. H. Dollinger and Dr. Drysdale, "Further Researches into the Life-History of the Monads."

6. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Harveian Society, 8 p.m. Mr. Cripps Lawrence, "A Case of Congenital Umbilical Hernia." Dr. Hughlings-Jackson, "On a Case of Apoplexy."

7. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

Medical Society of London, 8 p.m. Meeting of Council.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 25.

BIRTHS.

Births of Boys, 1101; Girls, 1075; Total, 2176.
Average of 10 corresponding years 1863-72, 2140·4.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	694	710	1404
Average of the ten years 1863-72	691·6	671·7	1363·3

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·39 in. The highest was 30·06 in. on Sunday, the 19th inst., at noon, and the lowest 28·76 in. on Thursday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

ON METHOD IN SURGICAL DIAGNOSIS.

A Lecture delivered at University College Hospital.

By PROFESSOR ERICHSEN,

Senior Surgeon to the Hospital, and Holme Professor of Clinical Surgery in the College.

(*Concluded from page* 427.)

The symptoms presented by the patient are, as I have already said, subjective—they must be described by the patient himself; and here the surgeon gets upon totally different ground, and has to exercise a considerable amount of caution in effecting his diagnosis, because patients will very frequently do one of three things. They may unconsciously exaggerate their symptoms—that is a condition that is extremely common in nervous and hysterical people; they exaggerate not only the actual existence of any symptom, but its relative importance to others. One symptom has chiefly attracted their attention, and on that they dwell. They employ exaggerated language in describing it; they will tell you that they have got an "agonising" pain, a "distracting" pain; they will use the strongest expletives in that way in connexion with their symptoms, often unconsciously exaggerating the importance of one particular symptom. Then, again, they will sometimes, and for various reasons, consciously and designedly either exaggerate or conceal symptoms. They will do both; and it is very important for the surgeon not to be misled in these respects, and to use his utmost powers of cross-examination and of searching inquiry in order to elicit whether symptoms in reality exist which are pretended, or whether symptoms which in reality do exist are designedly kept in the background. Here the difficulties of diagnosis become great, but fortunately it is but rarely that the surgeon has to deal with cases in which the phenomena presented to him are purely subjective, and in which the subjective phenomena cannot be supplemented or corrected by those objective phenomena to which I have already directed attention as being so infinitely more important.

Now let me say a few words about the method of effecting the diagnosis itself. You will find that by adopting a definite given method you will be able to arrive much more quickly, with far greater simplicity, with much less trouble to yourself and to the patient, and with infinitely more certainty, at the true nature of his condition, than you can by not following a definite rule.

In the first place, if you have to do with an injury, always ascertain the way in which that injury has been occasioned. That of itself will often throw great light upon the injury itself. For instance, an old person is walking across the room, the foot is caught in the rug, he falls to the ground and is unable to get up again. That condition of itself will almost explain to the surgeon what has happened,—an intra-captural fracture of the neck of the femur. The same accident would not happen from that cause at an early period of life. A person falls from a height, alights upon his vertex, and is bleeding from the ear. The bleeding from the ear, coupled with the fall from the height, will infallibly lead you to the true conclusion that he has a fracture of the base of the skull, with a fissure through the petrous portion of the temporal bone. Always therefore ascertain the cause that has led to the accident, and that will often throw great light on the very nature of the injury sustained.

When you have to do with a surgical disease, try to learn something about the constitutional condition of the patient, both as to his previous condition of disease and his acquired or hereditary diseases. You will see at once whether he is strumous, whether he is cachectic, or whether he is healthy. You will ascertain by inquiry whether he has had syphilis, or—so far as you can ascertain—whether there is an hereditary tendency to cancer, to gout perhaps, or to consumption. But do not attach undue importance to hereditary tendencies. An hereditary tendency only involves the presumption of the existence of a given disease. It renders the chances greater of the development of disease in the offspring of a similar nature to that which is known to have existed in the progenitor. It proves nothing. But let me warn you with regard to this point of hereditariness. There is an immense fallacy often connected with the determination of the hereditary tendency of disease. By far the greater number of people with whom one has to do surgically, know no other members of their ancestry than their fathers and their mothers, and many do not even know them. In some parts of this country—so far as we can rely on statistics—it would appear that in one case out of every ten only one parent can be absolutely determined. But whether a patient knows anything about one or both of his parents, he very commonly knows very little or nothing about their diseases; and when you go a step further back in his genealogy, and recollect that every individual has four grandparents, from any one of whom he may acquire an hereditary disposition or tendency to disease, how little does he know of the condition of the health of any one of his grandparents beyond the disease possibly of which he died,—and still less of the whole number. If we go one step further back—to the third line of ancestry only—and reflect that there are eight great-grandparents to every individual, we get into a haze of ignorance and confusion with regard to hereditariness out of which it is perfectly impossible to extricate oneself. But yet there can be little doubt that many hereditary tendencies are transmitted from grandparents and even great-grandparents nearly as readily as from the parents themselves. Go into any great family picture-gallery, and you see the same nose, the same form of countenance, the same expression of the eye, transmitted to and recognisable in the present generation, from an ancestor who lived, perhaps, one or two centuries ago. From a comparatively remote ancestry in this way you will find the same physical lineaments transmitted. The same physical constitution and tendencies necessarily follow the transmission of those physical characteristics, and yet how little do we know, in the greater number of cases, of this not very remote transmitter of those features and those tendencies. Hence that question of hereditariness, as a rule, is utterly valueless in estimating the probability even of the nature of any given disease.

And now let us see how the diagnosis is at last to be effected. There are three distinct methods by which you may make a diagnosis, and by attention to these methods you will be able to make your diagnosis absolutely and certainly with very little trouble to yourselves. It is the employment of these methods, often unconsciously, the result of long habit, that gives a surgeon what is called experience. Experience, in point of fact, is nothing more than prolonged observation, the results of which have been analysed, stored up, and are daily utilised by the possessor. Experience is not gained by merely seeing a large number of things, but by observing what is seen accurately and well—observing them minutely, and reasoning upon the phenomena presented by them. You will see in social and domestic life how many individuals go through the world without gaining the slightest real experience of it.

As I have already said, there are three methods that you may employ. The first and simplest method—and, happily, in surgery we have very simple methods of diagnosis—is by finding one pathognomonic sign. By "pathognomonic" is meant a thing which of itself indicates the nature of a condition. For instance, a person complains of dimness of vision. You look into his eye, and you see an opacity of the lens. That of itself determines at once the nature of his disease—cataract. You need not ask him a single question or go a step further. Again, a person complains of trouble about the bladder. You introduce a sound, and you feel a calculus and hear it struck. Thus at once a single sign—and that sign a pathognomonic one—is determinative in itself and by itself, not only of the existence of a malady, but of the very nature of that malady. You determine by that single sign, not only the existence, but the very nature of the malady that exists. Well, in surgery always seek for the pathognomonic sign, and endeavour to determine, if you possibly can, at once and by a single sign, what the patient's lesion may be.

Now, the second method in surgery consists in getting what may be termed a "pathognomonic group" of signs—that is to say, a set of signs which singly and individually are not indicative of any one given disease or injury, but which, taken collectively as a group, indicate incontestably the nature of some given injury or disease. Take, for instance, the case to which I have already alluded—of an elderly person being tripped up upon the floor and being unable to rise. You look at the limb and find that it is somewhat shortened, that it is everted, that the patient is unable to raise it off the ground, that he complains of considerable pain, and that you feel crepitus about the region of the hip. Now, any one of these signs—

shortening of the limb, eversion of it, inability to move it, and crepitus—any one of these signs is common to a variety of different injuries and diseases of the lower extremity; but the group, taking them collectively, is indicative of only one single condition, and that condition is fracture of the neck of the femur. Hence, although the individual signs may be untrue in themselves so far as the determination of any given injury is concerned, they are absolutely true, and incontestably so when grouped together, in determining the nature of a particular injury. That is the second method, then, of effecting a surgical diagnosis, by getting a pathognomonic group of signs or symptoms, for it will do for either.

The third method is a very important one, and it is the method that was greatly employed in the French school of surgery, and the employment of which undoubtedly led to the high position that it occupied, and does occupy, as a diagnostic school. It is what may be termed the negative method, or what is termed by French surgeons the "method by exclusion." By this method you first of all ascertain what a thing is not, and then by excluding everything that is not, you arrive at last at what it is. It seems a roundabout way of arriving at the truth, but in point of practice it is an exceedingly simple way. Let me give you an illustration. A patient comes to you with a tumour in the scrotum. You are in doubt as to what it is. You examine it first of all by transmitted light. You find that it is not translucent; therefore it is not a hydrocele. You examine the upper part; you find there is no impulse on coughing, and that the cord is not covered; therefore it is not a hernia. You find that the cord itself is not enlarged, is not tortuous, and vermiform in its feel; therefore it is not a varicocele. Having removed hydrocele, hernia, varicocele from any possible tumour of the scrotum, what have you left? Why, two conditions—hæmatocele and sarcocele. You find that it has not followed a blow, that it is not globular and uniform, that the scrotum is not discoloured; therefore it is not a hæmatocele—*ergo*, it must be the last of these conditions, and that is a tumour of the testicle: a sarcocele. In that way, by determining what a thing is not, you speedily arrive at what it is; and this determination in the hand and in the mind of a practised surgeon is so rapid as to be almost instantaneous. The whole process is gone through in his mind with such rapidity that as he lays his hand upon the part he feels for everything, and he finds that four out of five conditions are absent; and his diagnosis is made almost instantaneously, although it is made by that process of negation or exclusion, and though the steps that lead to it are apparently complicated.

Those, then, gentlemen, are the three methods by which surgical diagnosis may be effected; and you will find that by the employment of any one of these methods, sometimes varying them according to the different cases, you will be able to arrive easily and satisfactorily, and usually with certainty, at a correct knowledge of the nature of the case before you.

ON THE RIGHT USE OF DISINFECTANTS.(a)

By H. LETHEBY, M.B., M.A., etc.,

Professor of Chemistry in the College of the London Hospital; Medical Officer of Health and Public Analyst for the City of London; and President of the Society of Medical Officers of Health.

(*Concluded from page* 489.)

8. Charcoal and other Porous Substances are powerful oxidising agents, and they owe their action to their property which they possess of condensing upon their surface and within their pores large quantities of vaporous and gaseous matter, which by the very force of condensation they bring into contact with atmospheric oxygen, and thus by a process of slow combustion burn up organic miasms almost as thoroughly as if they were passed through the ignited coals of a furnace. In the case of wood charcoal it will absorb about nine times its volume of oxygen, and ninety times its volume of ammonia.

This property of absorbing offensive effluvia was described by Löwitz, a German chemist, at the close of the last century, and in 1805 Giraud proposed to use it as a means of disinfecting night-soil. In 1814 the subject was further investigated by Theodore de Saussure, who ascertained the exact volumes of different gases and vapours which wood charcoal would absorb. Since then the question has been further explored by Figuier, Bussy, Thenard, Allen, and Pepys, Count Morozzo, and others; but it was not until the year 1853 that the facts of the inquiry began to acquire practical importance. In that year Dr. Stenhouse, pursuing an experiment of Mr. John Turnbull, of Glasgow, found that putrid organic matters, when covered with a layer of charcoal, were free from offensive smell, notwithstanding that they putrified and decayed with more than usual activity.

Let me give you some experimental illustrations of this.

Now, the sole condition which is necessary to this is the free access of atmospheric air, which the charcoal uses in oxidising the putrid miasms. It is useless therefore to expect a beneficial action of the charcoal unless it can obtain oxygen; but getting this it will carry on its *eremacausing* power for an indefinite time. The applications which have been made of this power are numerous:—1. There is the respirator of Dr. Stenhouse, which arrests putrid miasms, and enables us, as I know from experience, to work comfortably in the most filthy atmospheres. 2. There is the air-filter, which I shall presently describe as applicable to the purification of the air of sewers, etc. 3. There is the charcoal water-filter, which, with water containing oxygen or worked intermittently, will purify water from the foulest matters. Other applications of it will occur to us presently, but I beg of you to remember that as the action is entirely dependent on the free access of oxygen, it is folly to expect that charcoal will act as a deodoriser or disinfector when this agent is shut out. It has therefore failed to disinfect sewage when used continuously as a filter for that purpose.

Again, everyone is familiar with the purifying power of common earth; the graveyards, indeed, of every large city, testify to the enormous quantity of organic matter which may be disposed of through its agency; and looking at the magnitude of the subsoil filth of this city, it is surprising how little it has affected the virgin gravel a few feet below the surface. All this is referable to the catalytic action of the porous soil, whereby the countless tons of decomposing matters have been oxidised and converted into harmless nitrates, which abound in the city wells, and which might, in case of an invasion, furnish our volunteers with abundance of "villanous saltpetre."

9. Air and Water are likewise powerful agents of destruction, and show their beneficial action in the one case in the effect of good ventilation, and in the other in the disintegration of organic substances as they flow along in our polluted rivers—thus giving them the means of rapid self-purification. A heavy storm of rain, too, is a great purifier of the air, and is often the turning-point in the progress of an epidemic; but besides this, water, by reason of its endosmic action, is inimical to the corpuscular structures of many specific contagia, and, by bursting their cell-like envelopes, destroys their vitality.

10. Disinfection by Heat.—The power of fire as a disinfectant is well-known, and has been recognised from the remotest time. The sacrificial altars of early nations were the rude methods by which this agent was employed; and so fully did the ancients believe in its salutary effects, that in time of pestilence it was often resorted to as the only effective means of purifying the air. Caius, in his "Boke of Counseill against the Disease commonly called the Sweate or Sweating Sickness," in 1552, advises the use of "fyres either in houses or chambers, or on that side the cities, townes, and houses that lieth toward the infection and wynde commyng together, chefely in mornynges and eueninges, either by burnyng the stubble in the felde or windfallynges in the woodes, or other wyse at pleasure. By which pollicie," he says, "skilful *Aeron* deliuered Athens in *Gretia*, and diuine *Hippocrates abdera in Thratia* frō ye pestilēce, and preserued frō the same other the cities in *Greece*, at diverse times eōying with the wynde frō *Ethiopia*, *Illyria*, and *Pœonia*, by puttyng to the fyres wel smelling garlādes, floures, and odoures, as *Galene* and *Soranus* write. Of the like pollicie for purgyng the aier were the bonfyres made (as I suppose), frō long time hetherto vsed in ye middes of summer, and not onely for vigiles." In the popular mind there has always been a notion that the plague of London was exterminated by the Great Fire.

The temperature at which infectious matter is rendered inert has lately been a subject of keen controversy, chiefly in relation to the temperature at which the vitality of living germs and minute infusorial creatures is destroyed. The late Dr. Henry, of Manchester, demonstrated experimentally that the vitality of vaccine matter is destroyed at a temperature of

(a) Read at the meeting of the Society of Medical Officers of Health on Saturday, October 18, 1873.

140° Fahr., and that the virus of scarlet fever is inert after being exposed to a heat of 204° Fahr.; but some of the lower organisms appear to be more tenacious of life, for, according to Dr. Crace Calvert, the common vibrio will bear a temperature of nearly 300°, and his black vibrio, which appears to be a very salamander of animalcules, is not killed by a heat of less than 400° Fahr. After a long investigation, however, before the Académie des Sciences of Paris, it was unanimously agreed by all parties to the controversy of spontaneous genesis that none of the lower organisms or their germs would resist in air a temperature of 130° C. (= 266° Fahr.), and in liquid a temperature of 110° C. (= 230° Fahr.). This, indeed, was the temperature fixed by Pasteur himself, although many of the members thought that 100° C. (= 212° Fahr.) was sufficiently high to destroy all vitality. In most cases, in fact, a temperature of 180° Fahr. is sufficient to destroy infusorial life, for that will coagulate albumen, of which they are made. Assuming, however, that it is desirable to use as high a temperature as possible for disinfection, it is important to know what is the effect of heat on textile fabrics. Up to a temperature of 250° Fahr. most of these fabrics are unchanged, unless the exposure is maintained for many hours, when they become discoloured and slightly brittle. Above this temperature the change is more marked, and with a dry heat of 300° Fahr. cotton fabrics are slightly charred, and therefore spoilt. At 400° they become dark brown, and crumble into powder when rubbed. At 500° gaseous hydrocarbons are produced, and at 600° all vegetable and animal tissues are converted into charcoal, with the evolution of empyreumatic oil and gas. It would seem therefore that for practical purposes a heat of 250°, aided by a jet of steam, for the purpose of diffusing the temperature and helping its action, may be safely applied to textile fabrics.

In the case of noxious vapours, however, as the fetid effluvia from tallow-melting, bone-boiling, soap-making, etc., the organic miasms must be destroyed by actual combustion, and to this end they must be conveyed into and through a large body of fire. In many cases it is necessary to remove aqueous vapour from the miasms by means of a scrubber or condenser before they pass to the fire, and in all cases the products of their combustion should be conveyed into a tall chimney-shaft, in order that a good draught may be secured for their delivery to the fire.

The employment of heat for disinfecting purposes should be taken advantage of on all possible occasions. Foul linen from the sick-chamber should be immediately boiled in water or steeped in boiling water. Milk, whether tainted or not, should always be boiled before using; and in cases of suspicion as to the contamination of drinking-water, it should be boiled and filtered through animal charcoal, for there is no reliable evidence that any of the common agents of infection will resist a temperature of 212° Fahr. applied for a few minutes. Lastly, meat should be thoroughly cooked, so as to destroy parasitic and other infection.

And now, having broadly examined the several powers and modes of action of the leading disinfectants, we will briefly consider the way in which they may be most advantageously applied, taking as examples the common cases which present themselves in actual sanitary practice.

First and foremost of these cases is *the disinfection of the sick-chamber and of the articles contained therein.* This is avowedly a difficult matter, for the presence of the sick person and his attendants prevents the use of volatile or aërial disinfectants in such quantity as to be of undoubted service; chlorine, for example, or hypochlorous acid, or sulphurous acid, or carbolic acid vapour, must be present in the atmosphere in the proportion of at least one part per 1000 to be effective, and in this proportion they are so irritating as to be irrespirable. While, therefore, the room is occupied by the living, we must rely on other means of disinfection and the immediate destruction of tainted articles. Matters discharged from the body should be received in a vessel containing active disinfectants, as about half a pint of either of the following solutions, namely:—A solution of two pounds sulphate of iron (green copperas) in a gallon of water (= 20 per cent., specific gravity 1096); or a solution of one quart of chloride of zinc (Sir William Burnett's fluid) to three quarts of water (= about 8 per cent. solid chloride, specific gravity 1077); or a solution of four fluid ounces of carbolic acid (Calvert's No. 5) to a gallon of water (= 2·5 per cent.). All articles of clothing, bedding, etc., should be boiled in water or plunged into boiling water before they are taken from the room, and in addition to this they should be steeped in a solution of carbolic acid of the above-mentioned strength. Special agents of infection—as the desquamated cuticle in scarlet fever, and the phagedenic discharges of ulcers and foul wounds or sores—should be the subjects of constant attention; pomades and other matters being freely employed to the surface of the body in the former case, and antiseptics and disinfectants in the latter. Besides this, all superfluous articles of furniture, as carpets, curtains, etc., should be removed from the room early in the case, and free ventilation and the utmost cleanliness should be always practised—everything like soiled rags, dressing, etc., being immediately burnt. As regards the use of aërial disinfectants, I am inclined to think that acid vapours are the most effective—as chlorine, or chloride of lime, or acetic acid,—for these only are capable of destroying the vitality of vaccine lymph, and therefore, by inference, of other contagia; besides which, they sweeten the atmosphere, and render it more pleasant for respiration.

When, however, the room is vacated, disinfection of it may be practised with the most perfect success. In the first place, all the articles contained in it should be spread out, so as to receive freely the sulphurous acid fumes which are to be generated therein; and, having closed the windows and stopped up as completely as possible every aperture and outlet from the room, measures should be taken for producing the needful quantity of sulphurous acid. This should not be less than 1 per cent. of the air of the apartment. Now, as a cubic foot of sulphurous acid is produced from 603 grains of burning sulphur, it is evident that every 100 cubic feet of space will require at least this quantity of sulphur for disinfection. To be certain of the results, however, it is advisable to use the sulphur in slight excess—say an ounce and a half for every 100 cubic feet of space. The sulphur may be safely burnt in a shallow pipkin or coarse earthenware saucer containing some live coals or a little bisulphide of carbon; in fact, this latter compound, if accessible, is the best form in which the combustion of sulphur can be effected, for it contains about 84 per cent. of sulphur, and is very combustible. The pipkin or saucer should be supported upon a pair of tongs laid across a pail of water, so that in case of accident the burning sulphur may fall into the water and do no injury. After a period of six or eight hours the room may be opened for ventilation and the several articles be spread out for an airing, or taken to the disinfecting chambers for still greater safety. The floor and painted parts of the room should be then thoroughly cleansed and the ceiling treated with limewash.

2. *Infected Clothing and Bedding* should be subjected to a further process of disinfection in the chambers provided by the local authorities for that purpose. These are a room or chamber for exposure to the concentrated fumes of burning sulphur (from 4 to 5 per cent. of them in the air); and next a chamber for disinfecting and for killing parasites by heat. This should be so constructed as that its temperature can be well regulated and maintained (as from 240° to 250° Fahr.) for four or five hours. It should be self-regulating and self-registering in this respect, and, therefore, be easily managed. The apparatus in use in the City of London for this purpose was constructed by Mr. Leoni, and it is very effective in its action, for during the last two years we have disinfected 2583 articles of clothing, bedding, etc., with the most perfect success. In fact, during the recent epidemic of small-pox, nearly 2000 articles were thus treated, and I am not aware of a single case in which it was not successful. This accords with the experience at the several small-pox and fever hospitals of London, and shows that, whatever may be the effect of such treatment with Dr. Crace Calvert's black vibrio, it is abundantly efficacious in the case of common contagia, be the virus what it may.

3. *Treatment of Dead Bodies.*—This is a matter which frequently demands attention, as when bodies are kept in rooms occupied by the poor, or are brought to the mortuary for safe custody. I have already told you that carbolic acid has been most successfully employed by Dr. Devergie at the Morgue in Paris for the preservation of the dead. As little as one part of the acid in 2000 of water, freely applied to the corpse, will prevent putrefaction. A sheet, therefore, saturated with a solution of one per 1000 of the acid and applied to the body will preserve it. So also will a couple of pounds of good carbolate powder, containing 15 per cent. of carbolic acid, placed in the bottom of the coffin. Metallic salts also will preserve the dead, and in some cases they are preferable to carbolic acid, as they are without odour; thus

sawdust, nearly saturated with a solution of chloride or sulphate of zinc (specific gravity 1077), may be placed around and over the corpse when in the coffin, and in this manner decomposition will be arrested.

I might here mention that the diseased and putrid meat seized in the City, amounting to nearly two tons per week, is disinfected with crude carbolic acid before it is sent away from the markets; and this not only prevents decomposition, but it also prevents the use of the meat for improper purposes.

In the case of old burial-grounds which are offensive, as well as church vaults, the best means of disinfection is the covering of the ground with fresh earth to the depth of several inches, and the planting of trees and sowing of grass. In this way we have dealt successfully with the city grave-yards, twenty-six in number, and covering a superficial area of about 48,000 square yards, in which, according to a moderate computation, there are at least 48,000 tons of human remains. Church vaults should be disinfected by first opening the vaults, exposing them freely to the external air, and throwing into them a quantity of quicklime. The coffins should then be rearranged crosswise like bricks in a building, and filled in with dry earth or mason's rubbish, with which about 5 or 10 per cent. of vegetable charcoal has been mixed. Ventilation should then be brought into connexion with the vaults by means of an upcast and downcast shaft of the size of a rain-water pipe, and the whole closed in. In this manner in 1860 the late Mr. Grainger and myself proceeded to disinfect all the vaults, amounting to 250 in number, of the seventy-one City churches. These vaults contained the coffins and remains of many thousand dead bodies—at least 11,000—in a very offensive condition; and the effect of it has been most successful. When bodies are removed from the vaults to other places of burial they should be enclosed, coffins and all, in cases containing carbolate of lime powder in good quantity.

4. *Sewage and Sewer Gases.*—The best disinfectants of sewage are the mineral salts, as the salts of iron and alumina in conjunction with lime. Ordinary sewage subjected to the action of from one to two parts of each of these agents per 7000 of sewage is immediately disinfected, the flocculent matters being rapidly precipitated, leaving a clear supernatant water which may be safely distributed upon land, or allowed to flow into a running stream of moderate volume—as from ten to twelve times that of the defæcated sewage. So effective is this operation that it ought to be universally applied to the sewage of towns when it is not discharged into the sea. The matters of cess-pools and privies require the application of large quantities of metallic salts—the best being sulphate of iron (green copperas) or chloride of zinc—either of which should be used of the specific gravity of about 1100.

Sewer gases are easily disinfected by vegetable charcoal in the manner already explained—the charcoal being placed upon trays in boxes which are situated in the course of the ventilating shafts from the sewers or drains. Many years ago I advised the adoption of this plan in the City of London, and there is a large district, eastward of Bishopsgate-street, where all the sewer ventilators are fitted with charcoal air-filters. The district is in the filthiest quarter of the City; it contains 1700 houses, occupied by about 14,000 inhabitants, and the total length of the sewers of the district is about 25,587 feet. Along these there are 104 air-shafts fitted with these ventilators, 265 trapped gullies, fifteen flushing tanks, and twenty-six side entrances. The air-filters consist of an iron box eighteen inches deep and fourteen inches square, containing a movable frame of six trays or sieves, upon each of which there is a layer of wood charcoal, in pieces as large as filberts, about two inches deep. Our experiments were commenced in 1860, and they have been maintained with perfect success until the present time, for they are still in action. I have repeatedly submitted the charcoal from the ventilators to chemical examination, and have always found that it contains abundance of nitrate, together with a peculiar alkaline salt of a nitrogenous nature with associated hydrocarbon. These ventilators are best fixed where they are protected from actual wet, as against the sides of houses, or in the course of a shaft or pipe carried up from the soil-pipe of the closet. In such situations their action is continuous for many years, and they should always be thus used where foul gases escape from the soil-pipe, the drain, or the closet of a house. Air-filters of this description have been adopted and applied with more or less success by Mr. Rawlinson, Mr. Baldwin Latham, and Mr. Bazalgette.

5. *The Offensive Gases and Infected Air* of noxious and unwholesome trades are easily destroyed by fire—there being contrivances for conveying the foul gases first through scrubbers or condensers and then into the back part of the ash-pit of the furnace fire. In this way moisture and other condensable matters are removed, and the residual gases and vapours are consumed by the glowing fire through which they must pass before they reach the chimney-shaft. By carrying the vapours to the back of the ash-pit of the furnace we insure their combustion, for when the ash-pit door is closed (as it ought to be) the draught is so powerful that it draws the vapours from the chambers or boilers in which they are generated, and forces them through the furnace fire.

In some cases the air becomes so loaded with minute particles of dust, etc., as to be extremely irritating. This is so in cotton mills, and with flock workers, feather cleaners, stone and steel grinders, chloride of lime makers, millers, firemen, etc. The remedy for this is easy, for a pocket-handkerchief over the face or a respirator packed with cotton-wool will shut out all noxious solid particles—in fact, the power of cotton-wool is so great in arresting the minute particles of matter, germs and others, which float in the atmosphere, that, according to Professor Tyndall, it is capable of producing an atmosphere absolutely free from dust, which will bear the severe test of his electric beam. Schroeder and Pasteur say that air filtered through cotton-wool is deprived of the power of producing infusorial life. Here is an experiment which is very striking in this particular: In these flasks I have a super-saturated solution of sulphate of soda, which, while in a state of active ebullition, was closed with a plug of cotton-wool, and in this state it has been allowed to cool. Atmospheric air, of course, has entered the flasks to take the place of the condensed steam, but in so doing it has been strained by the wool, and the solution has failed to crystallise. When, however, I remove the plug of cotton-wool, you will remark that the liquid instantly becomes solid, in consequence of the rapid formation of a mass of crystals. This is no doubt due to the falling in of a few particles of atmospheric dust, which were floating by at the time of withdrawing the cotton plug, and which immediately became nuclei for the growth of the crystals.

A still better respirator than cotton-wool is that of Dr. Stenhouse, which consists, as I have said, of a layer of granulated charcoal. Here is one of them, which I have used successfully on many occasions when conducting analyses of putrid matters in cases of suspected poisoning. Attempts have been made to keep down the dust of the public thoroughfares by means of deliquescent salts put into the water-carts; but such contrivances are exceedingly dangerous to tradesmen's goods, when in certain states of the atmosphere they become dry, and are blown with the dust into the shops, and settle upon the goods, for, at the outset of damp weather, they absorb moisture from the air, and spoil the goods. Cooper's patent in this country, and Marcus's in America, are illustrations of this. They are solutions of common salt and chloride of calcium in water, the gravity being from 1040 to 1085. They have been tried in America and on the Continent, but have failed.

6. *Shambles, Slaughter-houses, Cattle-layers, etc.*, should be kept sweet and wholesome by strict attention to cleanliness, and by the frequent use of cream of lime, with a little chloride of lime as whitewash.

7. *Breweries, Brewing Utensils, and Distillers' Vats* are easily and effectively cleansed and disinfected by means of sulphurous acid or a strong solution of bisulphite of lime, aided in the case of fungoid casks by a jet of steam.

Lastly, the purification of *Water* is insured by a few drops of permanganate of potash solution (Condy's fluid) or of chlorozone—leaving them to act for a few hours, and taking care that the pink colour is distinctly maintained to the very end of the process. Boiling the water for several minutes, and, after allowing it to cool, filtering it through animal charcoal, is also a safe method of disinfection. The filters of the London and General Water Purifying Company are admirably adapted for this purpose, as they contain a large volume of charcoal, which can be aërated by intermittent filtration. I find, indeed, that water thus filtered is absolutely free from organic taint, looking blue like distilled water when examined in large volume, as in a glass tube two feet in length; and the action of the filter is so enduring that it is maintained in the case of ordinary water for more than a year.

And now, gentlemen, in leaving the subject and inviting you to a discussion of it, I have only to say that I have care-

fully avoided a controversial treatment of it, not merely in respect of the possible or even probable causes of contagion, but also in respect of the many kinds of disinfectants which are daily advertised for public use. It is true that most if not all of these have come under my observation, and have been the subjects of experiment; but I have not dwelt on this, for my principal object has been to show you what, in my individual experience, I have found to be the most effective means of dealing with the several kinds of infection which almost daily occur in our sanitary practice.

ORIGINAL COMMUNICATIONS.

GLEANINGS IN WAR SANITATION

FROM N. PIROGOFF'S "BESICHTIGUNG DER MILITAIR-SANITÄTS-ANSTALTEN IN DEUTSCHLAND, LOTHRINGEN, UND ELSASS."

By NATHANIEL ALCOCK, L.K.Q.C.P., A.M.D.

(*Concluded from page* 432.)

To the honour of modern surgery must it be added that very few amputations of the upper extremity were performed, this operation being superseded by the conservative method. At the same time it appeared strange that disarticulation of the shoulder should have been so seldom practised, since this was one of the commonest operations within Sebastopol, and at the beginning of the siege yielded good results. Yet in the late war but three or four such patients were seen, and it was said that of eight operated on in Strasburg only one recovered. This disparity may, however, be in part explained by the fact that in the Crimea most wounds were caused by large shot, leaving no alternative but amputation, whereas with the Germans most wounds were produced by bullets.

Of amputation at a point between the anatomical and surgical necks of the humerus, Dr. Pirogoff found but one instance; yet from his own experience in the Caucasus he has been led to prefer this to disarticulation at the shoulder-joint. Of ten so treated by him all recovered, whereas of nine disarticulations four died, and of ten amputations in the middle third of the bone two were lost.

Disarticulation of the forearm was not done, having been probably replaced by resection. Amputations of the upper extremity had in general not bad results, and the conservative method was equally successful in the same part. On the other hand, amputation of the lower extremity increased in danger with every succeeding inch from the leg upwards.

As regards the mode of operation in thigh amputations, no one plan seemed less fatal than another. Professor von Langenbeck was most satisfied with the results of a large anterior skin-flap; but Dr. Pirogoff had previously practised the large anterior flap, including the muscles with the skin, in ten cases at Sebastopol without achieving a single recovery.

Of the leg amputations noticed, in one-half the ridge of the tibia protruded through the ulcerated skin, and this arose from the oblique direction of the incision to which the German surgeons so obstinately adhere, whereas by the vertical cut the formation of abscesses, the perforation of the skin, and the protracted cicatrisation of the wound could be avoided.

In conclusion, Dr. Pirogoff alludes to the cases of his own osteo-plastic operation on the foot, of which he counted eight. Of these three were in a satisfactory condition except that the under flap containing the piece of the os calcis was not brought sufficiently forward; and this was caused by its shortness, by too little of the bone having been removed, and by the neglecting to apply a permanent bandage after the operation. With regard to the five other cases—in one the flap became gangrenous, necessitating leg amputation; in another the bone necrosed; and in the third death occurred from some unrecognised cause; the remaining two were convalescent. Thus, of eight cases five had a successful issue.

Of the diseases which usually attend external injuries and operations, pyæmia showed itself most frequently, bringing in its train hæmorrhage—since, doubtless, all secondary bleedings after amputation are due more or less to pyæmic taint; and this opinion is testified by the fact that the majority of hæmorrhages, notwithstanding repeated ligature of the vessels, terminated in death. The autopsies in the Karlsrühe hospitals on pyæmic subjects showed the presence of thrombi either in the neighbourhood of the wound or in distant vessels, thus, in the latter case, opposing the "mechanical theory" of the disease; for if the vessels adjoining the wound be free and permeable, whence arise the outlying thrombi? Is it not more feasible to attribute their formation to the intrinsic action of the pus-infected blood? And if their independent production be thus conceded, must not their existence in the internal organs—the lungs, liver, etc.—be similarly explained?

One circumstance, however, in favour of the mechanical theory is that the form of pyæmia characterised by metastatic abscesses occurs almost exclusively among wounded, and seldom arises among those affected with internal suppuration from organic causes.

The mechanical theory asserts that wounds are invariably followed by the development of clots in the injured vessels, especially the veins, that therefore the possibility exists of a detached fragment being at any moment carried by the circulation into the capillaries of the lung or liver, and there becoming the nucleus of an abscess. Dr. Pirogoff formerly upheld this doctrine, but, while still admitting that many cases of traumatic pyæmia may owe their origin to thrombi, he is now further convinced that these thrombi are not the main source of the disease, but only the bases which the ferments prepare for subsequent pus-fermentation in the body; that only those clots originated under the influence of pus and other ferments contribute to the production of metastatic abscesses and pyæmia, since these abscesses never make their appearance until suppuration has been established in the wound; that pyæmia is induced above all things by the congregation of suppurating wounds in an enclosed space; that it not unfrequently presents itself in the form of external depôts of pus without any evidence of thrombi; that the pus sometimes collects in the liver to an extent out of all proportion to the extent of the thrombosis; and finally, that pyæmia with enormous liver abscesses now and then follows a most insignificant surface-abrasion without any evidence of thrombosis round the wound.

With great interest Dr. Pirogoff sought for instances of suddenly arising and rapidly increasing tumefaction of stumps accompanied by burning pain, and followed by speedy death, such as he had observed after the second bombardment of Sebastopol, and has described under the name of "local sclerosis of stumps," and which were in his opinion due to septicæmia; but none had been noted in the last war, although sometimes after thigh amputation early death from unknown cause was recorded.

Hospital gangrene assumed the diphtheritic character, never presenting the hæmorrhagic or fungous form as seen in the Crimea. Hospital erysipelas appeared periodically, attacking at once many wounds on the introduction of one erysipelas patient into a hospital. In this disease some of the Leipzig surgeons used with success Dr. Pirogoff's mode of treatment by camphor. Acute purulent infiltration of wounded limbs, which produced such horrible results in the hospitals at Sebastopol, was unknown among the Germans. Tetanus, however, was more frequent than in the Crimea, and seemed to invade the hospitals periodically, since while weeks would elapse without a case, suddenly many would come on together. The disease evinced a like fickleness with regard to the effects of treatment, being at times amenable and again intractable, although all were dealt with in the same manner. The duration of some cases for weeks, and their subsequent cure, was not a little surprising, but whether the malady was chronic from the beginning, or became so after treatment, was difficult to decide. The remedies most extolled were vapour-baths, opium, and chloral; and two instances of recovery from chronic tetanus under the use of one-drachm doses of chloral were seen. Obstinate traumatic neuralgia was best relieved by alternate subcutaneous injections of strong atropine and morphia solutions. Chronic diarrhœa of the wounded was not infrequent in the hospitals about Metz, and prevailed especially in districts subject to epidemic influences, thus rendering it difficult to determine how far it depended on the protracted and unwholesome suppuration of wounds, and how far it possessed an epidemic character. Occasionally it ran into dysentery, and this was most usually coincident with the arrival of a dysenteric patient in the hospital. Yet, notwithstanding the many forms of bowel complaints that prevailed, no instances of true cholera ever occurred. Scurvy, too, was remarkable by its absence. With regard to the effects of syphilis on the healing of wounds, no accurate observations have been made, and Dr. Pirogoff would earnestly commend the investigation of this subject as worthy of universal attention to all his colleagues, foreign and domestic.

In reviewing the foregoing experiences, Dr. Pirogoff considers that the most serious consideration for the future is to establish means for the quickest possible removal of the wounded from under fire and from off the battle-field. To accomplish this the organisation of sanitary detachments must be rendered much more complete. Omitting the claims of humanity, the actual interests of the fighting power has to be given up for the formation of a sanitary force, yet this will be even numerically more than compensated by the number of recovered combatants returned to the ranks, by the diminution of mortality, and above all by the maintenance of a high *morale* from the fixed conviction that through the provisions of Government immediate succour awaits the sufferer.

It has been previously shown that 400 trained stretcher-bearers are required for 1000 helpless men. Supposing, then, the rate of such casualties be at 10 per cent., 4000 would be needed for an army of 100,000 strong. But this apparently large demand upon the fighting element could be materially lessened by the formation, in conjunction with the private-help societies, of a mixed carrying corps, the military members of which would bear the wounded to the outskirts of the battle, from whence the civilians could remove them to the nearest ambulance; and by this means the inconvenience of undisciplined volunteers mingling with the troops in action could be avoided.

As a further step towards prompt assistance to the wounded, not only the sanitary detachments, but also the rank and file, should be instructed how to control bleeding by pressure, and how to apply the first simple bandages.

Another rule bearing most weightily on the prospects of the wounded is, that all crowding at the bandage-places near the battle-field should be strenuously guarded against; but this cannot be fulfilled without a complete reform in the relations of the War Administration and the Medical Department. The latter must be made much more independent, and at the same time entirely responsible for the suitable disposition of its members.

The most important measure would doubtless be that military surgeons should not accompany the troops under fire, but be assembled in readiness at the nearest bandage-places and movable hospitals. Again, when the order of battle had been arranged by the military chiefs, the selection, distribution, and equipment of the bandage-places should be in the uncontrolled power of the Medical Department, and the most experienced surgeons of all should be told off to the sorting of the wounded into the classes before enumerated. This above everything expedites the first disposal of them, avoids overcrowding, and prevents the chaos and confusion which must otherwise inevitably ensue.

The first line of bandage-places must not be confounded with the ambulances, which have movable, or even temporary, hospitals. In these bandage-places those beyond hope must not be allowed to accumulate. Those needing immediate help must be attended to (amputations, however, being undertaken only in cases of complete destruction of limbs from large shot), and such minor operations as sawing off the projecting bones, etc., being alone carried out. Those capable of transport must be furnished with immovable bandages, and all spare time should be assiduously devoted to filling up the diagnosis tickets, which will obviate further handling. Such rules of duty at the first depôts are no doubt contrary to the received opinions of immediate help in war; but anyone who has realised even once in a lifetime a methodless attempt to deal with a hundred wounded, while many hundred more are awaiting assistance, can testify that in the first line of bandage-places the diagnosis, the classification, and the distribution of the wounded are the most important duties.

With regard to the proportion of military surgeons to be enrolled, however considerable their number may be, it can never be held sufficient but that at some time the unforeseen accidents of war may paralyse even the very best allotment of professional services, in anticipation of which the Government should put itself in communication with the private-help societies on the one hand, and should on the other, as the Germans did, invite the leading professors of the medical universities and faculties to act as consultants at the bandage-places and hospitals, entrusting to them the final diagnosis, the classification of the wounded, the deciding on operations, and the carrying out of the most difficult, with, at the same time, a voice in the Military Medical Council at each head-quarters.

Yet it must be remarked that, notwithstanding the great good done by the German professors, still, by forgetting their position as consultants, and journeying from place to place as operators merely, they not only lessened their own usefulness, but caused bitter murmurings among the younger surgeons, who were thereby deprived of the opportunity of performing even the most common-place operations.

Persons deserving of such authority ought to act more as administrators, and to be able, by their influence, to strengthen the working of the whole ambulance system, as well as to assume the position of mediators between the private help and the Government staff, where the proposals of the former have to be carried out by the latter. As regards the young surgeons, praiseworthy though their efforts are, still they could be made much more serviceable under the direction of experienced teachers, and for this purpose the professors would be of infinitely more value than the military surgeons of long service. It is not advisable for the juniors to hurry to the ambulances, for, even though under guidance their hands may be useful, there is little for their heads to do. To them the ambulance is a kind of kaleidoscope into which they gaze to weariness, but from which they carry away nothing save a vague and confused impression of the things seen; whereas at the hospitals, at the bedside of the sick, they gain an accurate and fruitful experience.

Alluding briefly to the various adaptations of railway-vans for the conveyance of wounded, Dr. Pirogoff gives the preference to the American System. Particular stress is, however, laid on the necessity of adopting the Prussian device of Evacuation Commissions, which, consisting of a commandant, three surgeons, a transport company of sixty to eighty men with their officer, and some students, were charged with the fulfilment of all duties towards the sick from the time when they were despatched by train from the seat of war till they had been located in the various distant hospitals in which vacancies could be provided for them.

Passing, in conclusion, to the subject of international philanthrophy, Dr. Pirogoff recalls the obstacles which the difficulties of neutrality oppose to its success, and, earnestly exhorting his fellow-countrymen to the fullest development of their own national private help, forcibly adds that, "without possessing power, without concentrating this power on the establishment of national help, and thus learning to assist themselves, they cannot think of a participation in the international aid."

A constant penny collection throughout the country, under the advocacy of able and zealous delegates who would interest and educate the people in the nature of the undertaking, is the means proposed for attracting subscriptions; while railway accidents, manufactory accidents, and epidemics are suggested as occasions for displaying the vitality of the society in time of peace by supplying gratuitous aid to the sufferers.

For this purpose a staff could be enrolled, its members taught and exercised in the various regimental hospitals, and at the same time money might be advantageously spent in accumulating imperishable articles, while a surplus was reserved for the immediate provision of the less durable articles when required; and *apropos* of these is mentioned the removal from the list of the Russian Commissariat of Liebig's extract, which, from its deficiency in sugar, starch, and fat, is held to be not a complete nutriment, but, by reason of its creatin and other meat extracts, to be an adjunct merely to digestion, assisting in the assimilation of albumen and the other elements of nutrition.

Again, with his closing words, Dr. Pirogoff entreats his country not, at first, to devote its attention to international help, but to strain every nerve in the foundation of a solid national aid society, equipped with every requirement that patriotism and money can procure, and ready at any moment for the sudden emergency of war.

GUINEA-PIGS AS ARTICLES OF FOOD.—This little animal, so clean and plump, should be made an object of alimentation. Many persons feel a repugnance at this because they wrongly believe it to belong to the rat kind. This is a mistake, which should be at once rectified. Nor is it of a porcine nature. It is timid, incapable of mischief, and lives on vegetable substances. Its flesh is delicate and nutritive. As it can be reared without much difficulty, is very fertile and economical to feed, living as it does on cabbages, grapes, or pickings, it ought to find a ready reception in our markets.—*Union Méd.*, October 11.

OUTLINE OF OBSERVATIONS AND INVESTIGATIONS ON YELLOW FEVER.

By JOSEPH JONES, M.D.,
Professor of Chemistry and Clinical Medicine, Medical Department, University of Louisiana;
Visiting Physician of Charity Hospital, New Orleans.

No. I.—Notes upon the Early History of Yellow Fever.

The first question of importance which presents itself in this inquiry, is whether yellow fever had ever prevailed amongst the aboriginal inhabitants of North and South America and of the West Indies, previous to the discovery of America by Columbus and the explorations and conquests of the Spanish adventurers, and the establishment of the Spanish, French, and English Colonies?

The West India Islands, and certain limited portions of North and South America, as Mexico, Central America and Peru, appear to have been at the time of their discovery by Europeans covered with a sufficiently dense population for the establishment of those conditions upon which the origin and spread of certain diseases are supposed to depend. The medical historian, however, has only imperfect and doubtful data upon which to found any opinion as to the nature of the epidemic and contagious diseases which afflicted the aborigines previous to the discovery of the Western Hemisphere. That the more populous nations of America were not exempt from diseases of an epidemic and pestilential nature has been well established.

The pestilence called by the Mexicans "Matlazahuatl" desolated the cities of the Toltecs in the eleventh century, and forced them to abandon Mexico, and to continue their migrations southward, and to the west and north-west; it invaded the populous cities of Central America, and a similar disease committed great ravages amongst the Indian tribes which occupied the country between the mountains and the Atlantic coast a few years before the landing of the Pilgrim Fathers.

The Matlazahuatl, a disease closely resembling yellow fever, but which is said to be peculiar to the Indian race of America, has seldom appeared more than once in a century; it raged in the eleventh century amongst the Toltics, it made great ravages amongst the Mexicans in 1545, 1576, 1736, 1737, 1761, and 1763, and amongst the Indians of the Atlantic coast in 1618 and 1619.

According to Alexander Humboldt, the Matlazahuatl, although pestilential in its nature, and attended with hæmorrhage from the nose and stomach, was distinct from the Vomito Prieto, and was peculiar to the aborigines of America. The Spanish authors call this disease a plague. The following passage from Humboldt's "Political Essay on New Spain" appears to embody all that is known with reference to the nature of the Matlazahuatl of the Mexicans:—

"The Matlazahuatl, a disease peculiar to the Indian race, seldom appears more than once in a century. It raged in a particular manner in 1545, 1576, and 1736. It is called a plague by the Spanish authors. As the latest epidemic took place at a time when medicine was not considered as a science, even in the capital, we have no exact data as to the Matlazahuatl. It bears certainly some analogy to the yellow fever or black vomiting; but it never attacks white people, whether Europeans or descendants from the natives. The individuals of the race of Caucasus do not appear subject to this mortal typhus, while, on the other hand, the yellow fever or black vomiting very seldom attacks the Mexican Indians. The principal site of the Vomito Prieto is the maritime region, of which the climate is excessively warm and humid; but the Matlazahuatl carries terror and destruction into the very interior of the country, to the central table-land, and the coldest and the most arid regions of the kingdom.

"Father Forribio, a Franciscan, better known by his Mexican name of Motolina, asserts that the small-pox at its introduction in 1520, by a negro slave of Narvaez, carried off half the inhabitants of Mexico. Torquemada advances the hazardous opinion that in the two Matlazahuatl epidemics of 1545 and 1576, 800,000 Indians died in the former, and 2,000,000 in the latter. But when we reflect on the difficulty with which we can at this day estimate in the eastern parts of Europe the number of those who fall victims to the plague, we shall very reasonably be inclined to doubt if the Viceroys Mendoza and Almanza, governors of a recently conquered country, were able to procure an enumeration of the Indians cut off by the Matlazahuatl. I do not accuse the two monkish historians of want of veracity, but there is very little probability that their calculation is founded on exact data.

"A very interesting problem remains to be resolved. Was the pest which is said to have desolated from time to time the Atlantic regions of the United States before the arrival of the Europeans, and which the celebrated Rush and his followers look upon as the principle of the yellow fever, identical with the Matlazahuatl of the Mexican Indians? We may hope that this last disease, should it ever reappear in New Spain, will be hereafter carefully observed by the physicians."—"Political Essay on the Kingdom of New Spain," vol. i., pp. 117, 118.

"Long before the arrival of Cortez there has almost periodically prevailed in New Spain an epidemical disease called by the natives Matlazahuatl, which several authors have confounded with the Vomito or yellow fever. This plague is probably the same as that which in the eleventh century forced the Toltecs to continue their emigrations southwards. It made great ravages amongst the Mexicans in 1545, 1576, 1736, 1737, 1761, and 1763; but as we have already observed, it differs essentially from the Vomito of Vera Cruz. It attacked few except the Indians or copper-coloured race, and raged in the interior of the country on the central table-land, at twelve or thirteen hundred toises above the level of the sea. It is true, no doubt, that the Indians of the valley of Mexico who perished by thousands in 1761 of the Matlazahuatl, vomited blood at the nose and mouth; but these hæmatemeses frequently occur under the tropics, accompanying bilious ataxical (*ataxiques*) fevers; and they were also observed in the epidemical disease which in 1759 prevailed over all South America, from Potosi and Oraso to Quito and Popazan, and which, from the incomplete description of Ulloa, was a typhus peculiar to the elevated regions of the Cordilleras. The physicians of the United States who adopt the opinion that yellow fever originated in the country itself, think they discover the disease in the pests which prevailed in 1535 and 1612 among the red men of Canada and New England. From the little which we know of the Matlazahuatl of the Mexicans, we might be inclined to believe that in both Americas, from the remotest periods, the copper-coloured race has been subject to a disease which in its complications resembles in several respects the yellow fever of Vera Cruz and Philadelphia, but which differs essentially from it by the facility with which it is propagated in a cold zone, where the thermometer during the day remains at ten or twelve Centigrade degrees (50° and 58° Fahrenheit)."—"Political Essay on the Kingdom of New Spain," vol. iv., pp. 135-137.

During the four centuries in which the monarchy of the Toltics lasted, they multiplied considerably, extending their population in every direction and founding numerous and large cities, and building those great pyramids and monuments which required the united efforts of multitudes for their completion; but the calamities which happened to them in the first years of the reign of Topillzia—A.D. 1131-52—gave a fatal shock to their prosperity and power. For several years their country was afflicted with such a severe drought that their fields failed to yield them their necessary fruits; the air, infected with mortal contagion, filled their graves with the dead, and the minds of the survivors with consternation: a great part of the nation died by famine and sickness, and the wretched remains of the nation, in order to save themselves from the common calamity and from utter destruction, deserted Mexico, and sought relief from their misfortunes in other countries. There was therefore in this desolating plague of the Toltecs the usual association of famine and pestilence; and it is probable, that as in the history of many other nations, the former was the cause of the latter, and that the disease probably partook of the nature of the typhus and typhoid fevers of the present day. Humboldt, however, does not appear to be fully sustained in resting his opinion as to the absolute difference between the Matlazahuatl of the Mexicans and yellow fever (*vomito prieto*), upon the fact that the former prevailed at high latitudes and elevations.

The stereotyped expressions of systematic writers as to the limitation of yellow fever to certain elevations, must in the light of certain facts be abandoned. It has been supposed that yellow fever was confined to the sea-shore, either because persons who bring that disease disembark there, and goods supposed to be impregnated with deleterious miasms are there accumulated, or because on the seaside gaseous emanations of a peculiar nature are formed. It is certain, however, that yellow fever has prevailed in the elevated table-land of Caracas,

3000 feet above the level of the sea, upon more than one occasion. In 1696, a bishop of Venezuela, Diego de Banos, dedicated a church to Santa Rosalia of Palermo, for having delivered the capital from the scourge of the black vomit (*vomito nigro*), which is said to have raged for the space of sixteen months. A mass celebrated every year in the Cathedral, in the beginning of September, perpetuates the remembrance of this epidemic. The year 1696 was very remarkable for the yellow fever which raged with violence in all the West India Islands, where it had begun to gain an ascendency in 1688. This disease also carried off in Caracas a great number of European soldiers in 1802.

In the remarkable epidemic of yellow fever which prevailed in Peru in 1855 and 1856, the disease passed even the barrier of the Andes, committing fearful ravages in Andine and Transandine regions, at elevations of 14,000 feet above the level of the sea. Even the ancient capital of the Peruvian empire, Cuzco, at the elevation of 11,378 feet above the level of the sea, was not exempt from the ravages of yellow fever. No authentic records exist, from which may be gathered any facts illustrating the nature of the pestilence which, according to the "Gentleman of Elvas," desolated certain Indian nations a short time before the invasion of De Sorto; it is supposed, however to have been similar to the Matlazahuatl of the Mexicans.

The terrible pestilence which wasted the American Indians in 1618 and 1619, a short time before the Pilgrim Fathers landed in Massachusetts, has been supposed by Noah Webster and others to have been yellow fever. This supposition cannot be maintained because, the disease prevailed with the greatest severity during the winter and in extremely cold weather. We are not justified in adopting the conclusion of Webster simply because there was a general yellowness of the skin attended with hæmorrhages from the nose.

About 1750, a malignant epidemic disease prevailed amongst the Indians of the Atlantic coast, but did not afflict the whites, and which, in like manner, Webster considered as the "infectious yellow fever." The patients were said to have first complained of a severe pain in the head and back, which was followed by fever; in three or four days the skin turned yellow as gold, a vomiting of black matter took place, and generally a bleeding at the nose and mouth, which continued until the patient died. These symptoms resemble to a certain extent those of the disease known to the Mexicans as Matlazahuatl; and also those which characterise the malarial hæmaturia, which, since the recent war for the establishment of the independence of the Southern States, has prevailed to a considerable extent, and has been attended with a high rate of mortality.

The American Indians, in common with the whites, were subject to the various forms of malarial fever (intermittent, remittent, and congestive or pernicious, and malarial hæmaturia), and it is well-known that in the first settlements of both North and South America, the Spanish, French, and English colonists suffered terribly from these diseases. Many of the most flourishing and populous settlements were in a few years almost depopulated by these fevers, which committed the greatest ravages in those towns and colonies which were located near the mouths of large rivers in low marshy regions. Entire armies were destroyed by these fevers; and the pioneers who cleared the forests and drained the low lands, were either suddenly cut off by these "high grades" of bilious fever, which were often attended with a yellowness of the skin (jaundice), incessant vomiting of bilious matter, which was sometimes mixed with blood (black vomit), or were slowly poisoned by the malaria of the swamps and marshes, and dragged out a miserable existence, rendered almost intolerable by enlargements of the spleen and liver, derangements of the blood and nervous system, neuralgias, and dropsies.

In that form of paroxysmal malarial fever characterised by complete jaundice, intense vomiting, nausea, and hæmorrhage from the kidneys, which has received different names at different times and in different countries, and which is no "new disease," even in the United States of America, the hæmorrhage from the kidneys is preceded by capillary congestion of these organs and is attended by desquamation of the excretory cells and tubuli uriniferi.

Malarial hæmaturia (*hæmogastric malarial fever*), as a general rule, occurs only in those who have suffered from repeated attacks of intermittent fever, or who have been enfeebled by a prolonged attack of remittent fever, or whose constitutions have been impaired by bad diet, excessive labour, and frequent exposure to cold and wet and the exhalations of swamps and marshes. And whilst some of the symptoms—as the nausea, incessant vomiting (and in extreme cases black vomit), deep jaundice, and the impeded capillary circulation—resemble those of yellow fever, yet there are marked differences between this disease and yellow fever. The presence of albumen in the urine of this so-called malarial hæmaturia is attended also with the presence of coloured blood-corpuscles, excretory cells of the kidney and of the tubuli uriniferi. The excretory tubes of the kidney appearing in the urine are often impacted with coloured blood-corpuscles, and deeply stained by the colouring matters of the blood. As a general rule in yellow fever, the tubuli uriniferi are loaded with yellow, granular, albuminoid, and fibroid matter. In some cases immense quantities of green biliary fluid, or liquid tinged with bile, were vomited, and the patients died in a state of collapse, with blue mottled and purplish extremities, and sunken, pinched features. As a general rule, suppression of the functions of the kidneys was a fatal sign, and, as in yellow fever, was sometimes attended with convulsions, coma, and delirium. Careful examination of the blood revealed a marked decrease in the fibrin and coloured blood-corpuscles; in fact, this change in the blood was characteristic of all cases of this disease which have come under my observation. The pathological changes which I have observed after death from malarial hæmaturia are characteristic of paroxysmal malarial fever, and not of yellow fever—viz., enlarged slate-and-bronze-coloured liver, loaded with dark pigment granules, deposited in greatest numbers in the portal capillary network; gall-bladder distended with thick, ropy bile, presenting, when seen *en masse*, a greenish-black colour, and in thin layers a deep yellow. As much as 1000 grains of bile of high specific gravity has been obtained from the gall-bladder, whilst in yellow fever not more than 120 grains of bile are, as a general rule, contained in the gall-bladder.

As it is well established that malarial hæmaturia, and the severe and most fatal forms of malarial fever, prevail only in certain years, and appear to be dependent to a large extent upon the degree of heat and moisture, as well as upon the amount of organic matter in the soil, and as these epidemics in the tropical and temperate regions of America are often of the widest extent and severest character, and as the Indians suffered from these diseases to an almost equal degree with the whites, and as they were in North America without the most important remedies—bark and quinine,—it is not unreasonable to suppose that at certain seasons large numbers perished by these diseases. And were it not for the free use of quinine in the treatment of paroxysmal fevers, many of the cities of the Southern States, surrounded with swamps and marshes, would have been depopulated; and even in the more elevated regions of the country, as in the rich valleys of the Cumberland and Allegheny mountains, and along the rivers flowing into the Atlantic and Gulf of Mexico, the mortality from paroxysmal malarial fever would in certain seasons be very great but for the free use and powerful antiperiodic virtues of quinine.

(*To be continued.*)

London Anthropological Society.—At a meeting of this Society held at 37, Arundel-street, Strand, Dr. Charnock, F.S.A., in the chair, the election of several new Fellows was announced, and the following papers were read:—1. "Report of Meeting of British Association at Bradford," by Dr. John Beddoe, F.R.S., President of the Department of Anthropology at Bradford. 2. "On the Pretended Identification of the English Nation with the Lost House of Israel," by A. L. Lewis, Hon. Sec., L.A.S., showing the absurdities involved in this theory, which has of late been extensively propagated. 3. "On Primitive Marriage," by C. Staniland Wake, V.P.L.A.S. The paper showed that there is no direct evidence of the former existence of a general condition of promiscuous intercourse between the sexes, and that the indirect evidence arising from the practice of polyandry and exogamy, and the use of the classificatory system of relationship is insufficient to establish such a custom, the existence of which is inconsistent with the habit among primitive peoples of tracing descent from a common ancestor. Drs. Kaines and Carter Blake, Mr. Staniland Wake, Mr. J. G. Tipper, Mr. Buckley, Mr. Carpenter, Mr. Tomkins, and the President joined in the discussion which ensued. It was intimated that the first number of *Anthropologia*, containing the proceedings of the Society, may now be had.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. PETER'S HOSPITAL.

STONE IN THE BLADDER—LITHOTRITY—CURE.

(Under the care of Mr. TEEVAN.)

E. B., AGED 20, single, barber, was admitted into the Hospital on April 2, 1873, having been put under Mr. Teevan's care by Mr. G. F. White, of Kingston-upon-Thames.

History.—The patient states that so long as he can remember he has suffered from pain in the back, affecting chiefly the right loin. Every now and then the pain was very severe, and attended with difficult micturition. Has noticed for a long time past that his urine has been very red, and that there was often a brickdust-looking sediment in his *pôt-de-chambre*. Last winter commenced to suffer from frequent desire to urinate, with much pain at the end of the penis at the conclusion of the act. During the past month a few drops of blood have generally trickled from the urethra just before he had finished making water. A fortnight ago the increase in the severity of his symptoms obliged him to apply for relief. No history of stone in family. Patient was born in London, his father in Woolwich, and mother somewhere in Kent. Has never suffered from gout or rheumatism, and has no recollection that his parents ever had those complaints.

Present Condition.—Patient is a small man, of pale aspect, fairly nourished, but with a very depressed and anxious-looking countenance. When quiet he is quite comfortable, but if he attempts to walk only a few yards he is seized with an urgent desire to urinate, and can only accomplish the act by going on his hands and knees. The urine is slightly bloody, and only passes with pain. There is some albumen in his water, but probably not more than could be accounted for by the blood and mucus.

Mr. Teevan examined the patient with a lithotrite, and, finding the stone to be little more than one inch in diameter, he determined to crush it.

April 7.—To-day Mr. Teevan introduced a lithotrite-scoop, and broke the stone. Very little *débris* passed after the operation.

14th.—Three pieces of the calculus were crushed to-day, and a considerable amount of *débris* came away the next day.

19th.—Two small fragments were pulverised with a smaller lithotrite than used on the former occasion. Two days afterwards patient's right testicle began to swell, with much pain and tenderness. His tongue was foul, pulse quick, urine cloudy, and skin hot and moist. The testicle continued to enlarge for three more days. Ice was applied externally, and henbane and potash internally, the bowels being kept well open.

25th.—Six leeches were applied to the external abdominal ring, as the testicle was no better. Much relief, attended with diminution of swelling, followed their application.

30th.—The constitutional disturbance having all gone, the testicle was strapped, but in the course of a few hours the plaster had to be removed, as the patient could not bear the pain of the pressure. The iodide of lead ointment was ordered to be rubbed into the testicle, and the iodide of potash to be taken internally.

June 5.—As the testicle had but slightly improved, and as the patient was complaining of much pain at the end of the penis when making water, Mr. Teevan came to the conclusion that the irritation caused by the presence of the fragments of stone was keeping up the orchitis, and he accordingly passed a small olivary elastic bougie to ascertain the state of the parts. No increase of inflammation attended the introduction of the instrument, though its passage was painful, and on June 11 and 13 Mr. Teevan again passed the bougie, in order to lessen the sensibility of the urethra, and prepare it for the lithotrite.

16th.—To-day a delicate lithotrite was used to crush two fragments. Much *débris* came away for two days afterwards, and the patient was greatly relieved by the operation, which was repeated on June 23, and again on the 30th, when there was a slight rigor the same evening.

July 7.—Another crushing took place, and the patient was attacked with rigors the same evening. Three days later the bladder appeared to be freed of all stone.

14th.—A small fragment was found to-day and crushed.

18th.—The patient, who says he is now quite well, was ordered to take a long ride in an omnibus. Not the slightest annoyance followed the jolting, and on July 25 the patient left the Hospital cured.

October 6.—To-day the patient called at the Hospital to say he remained well. The urine was acid and contained no albumen; specific gravity 1015.

Remarks.—Mr. Teevan observed that there were two points of interest in the case. In the first place, the treatment had been interrupted by an attack of orchitis; and, secondly, the patient suffered from rigors on two occasions. Now orchitis, during a well-conducted course of lithotrity, was extremely rare. He had operated on twenty-three patients by lithotrity, and in one other case only was the testicle affected. In the present instance it would appear that the inflammation had been caused by the irritation of the fragments of the calculus rather than by the lithotrite, for the attack came on after the use of a slender instrument, and amelioration followed the re-employment of the lithotrite. Rigors also were unusual, and, when they occurred, generally made their appearance very early in the treatment of the case. In all probability the constitutional disturbance caused by the orchitis, aided by the character of the calculus, which was of oxalate of lime, predisposed to their occurrence. Notwithstanding the drawbacks experienced in the course of the treatment, the result was all that could be desired, and the patient remains perfectly well.

ROYAL PORTSMOUTH HOSPITAL.

STONE IN THE BLADDER — RETENTION OF URINE FROM VESICAL ATONY—LITHOTOMY—RECOVERY.

(Under the care of J. WARD COUSINS, M.D. Lond., F.R.C.S.)

J. C., AGED 9 years, had suffered more or less for three years with symptoms of calculus. He was admitted in February, 1872. His mother stated that the vesical distress had increased during the last few months. The patient was much emaciated, his countenance expressed protracted suffering, and he was constantly straining and crying with severe pain. The urine was ammoniacal, and contained a little blood with much muco-purulent matter. On examining the abdomen the bladder was found enormously distended, even reaching to the epigastric region. The constitutional symptoms were severe. He frequently vomited; pulse very small and feeble; tongue coated and dry down the centre. The bladder was at once emptied with the catheter, and a stone readily detected. He was ordered fluid nourishment and wine, and a draught containing nitro-muriatic acid with belladonna every four hours. In a few days the constitutional symptoms improved, and, as the vesical trouble urgently demanded relief, the lateral operation was performed on the 24th. The stone weighed eighty grains, and its external surface presented a phosphatic coating. The patient rapidly recovered, and three weeks after the operation left the Hospital.

STONE IN THE BLADDER—LITHOTOMY—RECOVERY.

(Under the care of J. WARD COUSINS, M.D. Lond., F.R.C.S.)

J. D., aged 8 years, was admitted in January, 1873, labouring under calculus. He was brought to the Hospital by his grandmother, who stated that his parents were both dead, and that, when only a few months old, he had suffered from pain and difficulty in passing water. For the last three years his sufferings had been constant and intense; lately his urine had dribbled away from him night and day. The lateral operation was performed a week after his admission, and he recovered without a bad symptom. At the time of the operation some difficulty was experienced in passing the sound in consequence of a false passage which existed between the bladder and the rectum—the result of former explorations. Still more difficulty, however, was found in extracting the stone, from the high and contracted condition of the bladder, which did not contain a drop of urine. The stone was composed of lithic acid, and it weighed seventy grains.

STONE IN THE BLADDER, ELEVEN OUNCES IN WEIGHT—ABSCESS OF KIDNEY—DEATH—AUTOPSY.

(Under the care of J. WARD COUSINS, M.D. Lond., F.R.C.S.)

E. W., aged 55, was admitted on May 3, 1873. There was no history of gout or rheumatism. He stated that for twenty

years he had suffered a great deal from gravel and stricture, and that his distress had much increased during the last three or four weeks. He looked pale and haggard, and his countenance clearly expressed prolonged suffering. Recently he had lost flesh, and his urine had occasionally contained blood. He appeared often in extreme pain, and made frequent efforts to pass water, which constantly dribbled away, and was collected with great difficulty for examination. The urine was alkaline, fetid, and full of muco-pus. On exploring the bladder it was found literally filled with a large calculus. The prostate gland and urethra were quite healthy. The patient had no idea that he was suffering from stone, and at once expressed his willingness to submit to an operation. A few days, however, after his admission he refused his food, and complained of tenderness over the abdomen. Delirium supervened, and he sank into a typhoid condition, and died on the 31st.

Autopsy.—The lateral operation was performed after death, but the stone could not be extracted even with a very free division of the prostate. It was readily removed by the supra-pubic method. The calculus completely filled the bladder. It was oblong and regular in form, and weighed eleven ounces. The long diameter measured three inches and a half, the short diameter three inches, and the circumference corresponding to the long diameter ten inches. On opening the abdomen the peritoneum presented many recent adhesions, and its surfaces were smeared with purulent secretion. The right kidney was wholly disorganised, and converted into an abscess; the left was large and flabby. The ureters were dilated. The bladder was much thickened in every part, the average thickness of the wall being about one-third of an inch. The mucous membrane was superficially ulcerated and covered with phosphatic deposit. About an inch behind the orifice of either ureter the internal surface of the bladder was marked with a rounded opening leading into a large sacculus. These sacculi were equal in size, and were each capable of holding three or four ounces of fluid. Their structure was thin, and they appeared to be simple protrusions of the mucous and serous coats of the bladder.

Remarks.—The retention which occurred in the first case was caused by vesical atony. The bladder had lost its expulsive power, but the paralysis was only temporary, and probably it was caused by accidental distension of the organ. The patient suffered much in the act of passing water, and very probably he voluntarily retained his urine to avoid pain. On the other hand, the retention may have been caused by the accidental position of the calculus. Atony of the bladder is, in my experience, a condition rarely seen in children. It, however, often happens to old people associated with disease of the prostate and chronic cystitis. In children the presence of a stone generally excites great irritability of the bladder, and causes frequent micturition. In the second case the difficulty of the operation arose from the high and contracted condition of the bladder. If that viscus had been previously injected with a few ounces of water, it would have greatly facilitated the discovery and extraction of the stone. The third case is a remarkable one. The patient had been the subject of calculus for many years, but at the time of his admission he had no idea of the nature of his disorder. Here the severity of the symptoms was certainly not in proportion to the size of the calculus. On looking at the case it appears marvellous that the patient could have endured for so long a time the pain and irritation produced by such a concretion, but the bladder seems in these chronic cases to get accustomed to the presence of a foreign body. The stone, moreover, was fixed within that organ, and occupied the whole of its cavity, and this absence of mobility must have considerably lessened the urgency of the symptoms. The stone could not have been extracted with safety by any perineal operation. If the patient had applied earlier for assistance, the supra-pubic operation would have given him the best chance of relief. Such extreme calculi are fortunately very rare. The urine had dribbled away for years, the function of the bladder was completely destroyed, and the sacculi situated beneath it, together with the dilated ureters, were the only receptacles for the urine. The patient in all probability had laboured under secondary disease of the kidney for a considerable period, and at his advanced age this complication would have rendered any surgical operation particularly dangerous.

THE salary of the Surgeon of the Birmingham Prison has just been increased to £200 a year.

Medical Times and Gazette.

SATURDAY, NOVEMBER 8, 1873.

THE ARMY MEDICAL WARRANT OF MARCH, 1873.

IT will be a matter of general satisfaction to the medical officers of the army to learn that the pressure brought to bear upon the authorities in connexion with the new Army Medical Warrant has not been without result, in proof of which we quote the following extract from a circular dated November 1, 1873:—

"Our will and pleasure is that from the date of our said Warrant (March 1, 1873) the following rule shall govern the pay of Surgeons after fifteen years' service, and that the provisions of Article 6 of our said Warrant shall not be applicable to officers who before March 1, 1873, were entitled to forage in virtue of their several ranks.

1. The pay of Surgeons after fifteen years' service in that rank shall be seventeen shillings and sixpence per diem.

2. Officers of the Army Medical Department who, prior to March 1, 1873, were in receipt of forage or forage allowance in virtue of their several ranks, shall continue to receive forage or forage allowance for the number of horses to which they were entitled before that date in accordance with the regulations then in force."

It will thus be seen that at least two of the grievances complained of have been removed, and the unanimity on the subject which prevailed all through the service, and, indeed, all through the profession,—as evidenced by the opinions expressed in the leading medical journals—has not been without its effect upon her Majesty's advisers. It will be remembered that the new Warrant made no provision for increase of pay to Surgeons after a period of more than ten years' service, whereas the Warrant it superseded provided for a further increase after fifteen years. The argument by which this innovation was sought to be justified referred to the fact that under the new scheme it was hoped that promotion would in every case take place before fifteen years' service was reached, and had this argument been irrefutable there would have been no cause for complaint; but experience pointed to a far different result, and it was urged with some justice that if the War Office authorities had had so much faith in an increased rate of promotion, there was but little necessity to have done

away with the maximum rate of pay allotted to Surgeons, when so few would ever remain in that rank to claim it.

The question of the forage allowance, again, was one on which we have constantly expressed a very strong opinion. Even given the most parsimonious Government, we failed to see how any arrangement could be looked upon as equitable which sought to deprive medical officers of many years' standing of advantages which had been enjoyed by them from the date of their entering the service: and without speculating on the wisdom of the course hereafter to be adopted to the medical branch of the service in the matter of forage, we heartily concur in the amendment we now publish, which makes the new law prospective instead of retrospective.

If we are to consider the concessions now made as a first step towards emendating the clauses in the Warrant of March last most obnoxious to the Army Medical Service, we may fairly assume that the Warrant itself, though received with so much coldness and dissatisfaction in the outset, will eventually become popular amongst all ranks. There are, as we before observed, many good points in it; and so long as the Secretary of State for War (as in the present instance) consents to be guided by the advice of the heads of the Medical Department, medical officers may rest assured that their interests will be carefully studied, and all reasonable grievances placed in course of removal.

We published some few weeks since a letter from an Army Medical Officer serving in India, complaining that the Government of that country had declined to ratify the conditions of the new Warrant, and stating that he and several other officers, though gazetted Surgeons-Major in the large batch of promotions which took place in April last, had been refused the increase of pay attaching to their superior rank. We have every reason to believe that the difficulties on the subject which arose between the home authorities and those in India have now been removed; and we have no doubt that by this time the gentleman in question and all others concerned have found themselves on a similar footing, as regards rank and pay, with medical officers of the same grade doing duty at home.

Whether the anticipations will be realised that promotion under the operation of the new Warrant must be more rapid, time alone will show. We cannot leave this portion of the subject without again expressing a belief that one of the best methods of preventing stagnation would be to give the right of retirement after twenty years' full-pay service, instead of after twenty-five. If it were not considered expedient to grant this boon generally, it might be conceded in the case of those medical officers who could show a proportion of say ten years' foreign service, and who should thereby acquire the right of retirement upon £1 per diem. Many officers would doubtless be inclined to accept such conditions, and the small extra expense thereby accruing to the country would be amply repaid by the increased popularity which would be conferred on the medical service of the army.

ASPIRATION.

III.

The surgical uses of aspiration are equally important with the applications of the same appliance in medicine. Thus, in retention of urine from enlarged prostate, where that organ acts as a valve to the urethra, and where there is less chance of getting an instrument passed with a full bladder than an empty one, the plan offers great hope of success, and experience shows that it may be without detriment performed again and again. As to the rectal operation, surgeons differ greatly in their estimate of its value; and it is precisely where, under any circumstances, puncturing the bladder in this way is most difficult, that aspiration is best adapted for the case. On the whole, most surgeons would say that if the retention depended on an impermeable stricture it were better to deal with that at once, but with enlarged prostate such procedure is not so easy. However, the operation being resolved on, we must see that the needle is long enough to reach the interior of the bladder, making due allowance for its contraction as emptied. The needle should be about four and a half or five inches in length, fine, and its permeability should be tested previous to use; otherwise the bladder may be reached and no urine flow. The vacuum should then be made before introducing the needle, and that should be thrust in just over the pubes in the median line, and thence pushed very slowly downwards towards the bladder; the urine rising in the aspirator shows that the organ has been reached. Still it should be pushed a little farther than this, for the reason above mentioned, and then the distended bladder should be carefully and cautiously emptied, no manipulation whatever being allowed; after which the needle should be quickly withdrawn. The alteration in the condition of the patient is marvellous, but it is quite true that this is no step in the way of cure. In one case occurring under M. Guyon's care the bladder was so punctured twenty-three times.

Again, in certain accumulations of fluid in joints, particularly the knee, aspiration offers great hopes of success; but, like any other method, it is liable to abuses. The cases for its application should be as carefully selected as for any other method of treatment, and the measure should not be condemned because in its indiscriminate application a certain proportion of cases have been failures. It has been proved by clinical experience that in the greater number of instances fluids of any kind may be thus withdrawn; but it seems to us that it is best suited for those chronic collections of fluid which have resisted ordinary remedies. We are too well accustomed to see small collections of fluid in joints clear off speedily to be anxious to aspirate all that come under our care; but for many of the sub-acute forms of hydrarthrosis the process seems to us invaluable, for it is exactly in these we have been accustomed to see remedy after remedy applied, and yet the condition remain unchanged. Here, as before, the rule is to use a fine needle, to see that it is not choked with rust, and to permit of no kind of manipulation other than aspiration. Should the fluid reaccumulate, as it is apt to do, it must be again withdrawn with like precautions.

In another group of cases aspiration has been surgically employed, but of these we can say little of our own knowledge—that is, in strangulated hernia. The practice is founded on the belief that in a majority of cases the hernia cannot be returned on account of accumulations of fluid and gas in the loop of intestine. Of course such a procedure is not in the slightest degree adapted to an omental hernia, nor to a hernia of the cæcum behind the peritoneum, nor to one or two other kinds we could mention. Nevertheless, it has been tried and has succeeded, and is therefore well worth bearing in mind. It is true it may be insufficient, but it does no harm, and the ordinary operation may be equally well, or even better, undertaken after it than before.

There is still another application of the method which promises to be very successful. Anyone who has had to deal with a case of hydrorachis from spina bifida must have felt how unsatisfactory were the resources of his art. True, you may puncture the swelling and withdraw the fluid, but then the patient dies; sometimes we hear of a success, but failure is the general experience. Now here aspiration, especially if the integuments are not thinned, holds out hope of cure if cautiously pursued and assisted by other means. Then, too, injections of iodine may or may not be employed; successes in both ways are reported. By the way, we should remind our readers that iodine and other injections should never be made with the aspirator. In the instrument as now made that is impossible; but with the older instrument (and that which we prefer) it is

quite possible, but should be avoided, as such a practice speedily destroys the air-tight valves.

Of other applications of aspiration—to hydrocephalus, to ovarian cysts, to serous cysts, to hydrocele, and to various forms of abscess—we shall not here speak. In some of these its value is clear, in others much more doubtful; but we may expect still greater developments of the method than even these amount to. In one case where we had some hopes of its success, it proved in our hands a failure. More than once the introduction of tubes into anasarcous limbs has been followed by a copious discharge of fluid, and we had hoped that by applying to such tubes a permanent vacuum we might facilitate the flow of fluid and increase the quantity discharged. The patient we selected for the trial seemed in every way suitable, and a fair-sized trocar was introduced into the loose tissue of the popliteal space, but only a small quantity of fluid—not more than a few drops—appeared, and the experiment had to be abandoned, though it is quite possible that the plan may succeed better in other cases. In conclusion we may say that Dr. Dieulafoy's book(a) might have been written in better English, but its contents amply compensate for the mode in which they are set forth.

THE FEMALE MEDICAL STUDENT QUESTION AT EDINBURGH.

At the statutory half-yearly meeting of the General Medical Council of the University of Edinburgh, held on Friday last, a short debate occurred on matters relating to the medical education of women. The tone of the debate was such as to justify the remark that it strongly resembled a funeral service over the remains of the female medical agitation in Edinburgh. The discussion arose upon the submission to the Council of a measure taken by the University Court consequent on the recent decision of the Court of Session determining finally that the admission of women to degrees in medicine was beyond the powers of the University of Edinburgh. The Secretary read the following extract from the minutes of the University Court:—

"The University Court, having considered the action at the instance of Miss Jex-Blake and others against the Senatus Academicus and the Chancellor of the University, and the judgment of the Court of Session thereon, resolve—'That it is expedient that the regulations of the University Court for the education of women in medicine in the University of Edinburgh, contained in their minute of November 10, 1869, and approved of by the Chancellor of the University on November 12, 1869, should be suspended *in hoc statu*; and with the view of carrying out the necessary procedure for having such regulations suspended, the Court, in terms of the Universities (Scotland) Act, sec. xii., 2, direct the Secretary to communicate this resolution of the Senatus Academicus of the University for consideration.'"

It appeared from statements made during the debate that the University Court had come to the determination to suspend the regulations for the education of women in medicine, and that, further, the Senatus had taken action upon that resolution that in the present state of affairs it was undesirable to admit women to the medical preliminary examinations in arts. At the Council meeting the supporters of the ladies were unwilling to admit of this summary suppression of their favourite agitation, and endeavoured to raise a discussion on the merits of the procedure adopted by the University Court and the Senatus. One gentleman, who, if we are not mistaken, acted as demonstrator of anatomy to the ladies when their presence in the anatomical class-room gave rise to a disgraceful disturbance, appeared as the censor of the University Court and Senatus, and hurled a series of denunciations at the higher authorities of the University. With the assistance of the Principal he controlled his feelings sufficiently to permit him to bring his speech to a close by proposing a motion, the measured terms and heroic spirit of which must have sent a pleasant thrill through the ranks of his supporters. Beyond, this, however, the motion seems to have led to no particular result.

Subsequently a Free Church theological professor proposed that the Council should acknowledge receipt of the communication from the University Court, and regard it as unnecessary to express at that time any opinion upon the step taken by that Court. This motion he propounded with expressions of dissatisfaction, and a threat to bring up the matter at a subsequent meeting.

It was clearly shown that the Council had no voice in the matter at all, and that the Court had only acted in a spirit of official politeness in acquainting the Council with what it had done. In all cases it is necessary that proposed changes should be submitted to the Council for their consideration; but in this special instance it was demonstrated that the suspension of the regulations for female medical education was not a proposed change, but a step rendered imperatively necessary by the decision of the Court of Session. We hope that the supporters of female medical education will take this view of the case, and permit the bones of this distasteful contention to rest in peace after this burial service in Queen-street Hall. By adopting this suggestion they will remove a cause of social and domestic dissension, which for several years has been to Edinburgh society as active an excitant of discord as the Tichborne trial has been to the people of the English metropolis.

THE WEEK.

TOPICS OF THE DAY.

Dr. Sieveking has received the appointment of Physician Extraordinary to the Queen. We congratulate Dr. Sieveking on a distinction which rewards a long course of honourable and useful professional work.

We are informed that the authorities of the University of London have selected Dr. Richard Quain, F.R.S., and Mr. Cooper Forster to represent the University on the Committee appointed by the Royal Colleges of Physicians and Surgeons and the Universities of Oxford, Cambridge, and Durham, to complete the scheme for a Conjoint Board of Examination in England. Last Monday there was to have been a meeting of the Committee at the Royal College of Physicians, but there was not a sufficient number of members present to form a quorum.

A correspondence has recently been published between the Secretary of the Society of Arts and the Secretary of the Prime Minister, on the subject of National Museums and Galleries. The Society of Arts sent Mr. Gladstone a letter requesting him to receive a deputation, who would present a memorial signed by 250 Peers, Members of Parliament, and men of eminence in science and art, praying that Parliament would grant greater public aid for the establishing of museums, libraries, and galleries in the great centres of population. Mr. Gladstone refused to receive the deputation, on the ground that the matter was within the province of the Privy Council. The Society of Arts replied to the effect that the matter was of such national interest that they declined to submit it to a mere department of the Government. Thereupon Mr. Gladstone wrote back asking for a statement in writing of their views, which he would lay before his colleagues. The wish of the Society of Arts and of those associated with them in the matter is to obtain larger Parliamentary grants for national and local museums, galleries,

(a) "A Treatise on the Pneumatic Aspiration of Morbid Fluids: a Medico-Chirurgical Method of Diagnosis and Treatment of Cysts and Abscesses of the Liver, Strangulated Hernia, Retention of Urine, Pericarditis, Pleurisy, Hydrarthrosis, etc." By Dr. Georges Dieulafoy, Gold Medallist of the Hospitals of Paris. London: Smith, Elder, and Co. Pp. 394.

and libraries, and to place them under the authority of a Minister of the Crown—a member of the Cabinet with direct responsibility to Parliament,—and thereby to get rid of all unpaid and irresponsible trustees, except trustees under bequests or deeds. Their plan includes all museums and galleries supported or subsidised by Parliament, and their aim is to render them all subservient to national education. We think such a movement will enlist in its favour the support of all scientific men. The matter will no doubt occupy the attention of the Royal Commission on Science.

A letter from Boma, in Western Africa, dated August 12, 1873, contains a statement that Livingstone was a prisoner in a town twenty miles distant, without means to pay his ransom. Assistance, however, had been sent to him, and he would probably be at Boma in a month.

Dr. McLeod, a Surgeon-Major of the Madras Army, has been committed by the Carlisle magistrates on a charge of manslaughter. He is charged with killing his wife by administering a large quantity of morphia. The evidence given before the magistrate showed that Dr. McLeod had acknowledged giving Mrs. McLeod a grain of morphia which he weighed; he afterwards administered an unweighed quantity, probably about two grains, every half hour, until symptoms of poisoning showed themselves, and Dr. Robert Walker was sent for. It is supposed that about seven grains of morphia were administered. When Mrs. McLeod was seen by Dr. Walker, she was lying on the hearth-rug in her drawing-room, insensible, livid, breathing with difficulty, and the pupils of the eyes contracted. Dr. McLeod rendered active assistance in endeavouring to restore his wife, and seems to have been under the impression that it was right to administer morphia in increasing doses "until an effect was produced." The account of his conduct seems hardly to be reconcilable with his sanity. He was admitted to bail.

A chemist, named M'Dermott, residing at 155, Abbey-street, Bermondsey, has been fined £10 and costs by the Southwark magistrates under the Adulteration Act for selling an admixture of citric acid, tartaric acid, carbonate of soda, and sugar as citrate of magnesia. Query: What is the composition of the substance sold as granulated citrate of magnesia in most chemists' shops? According to Squire's "Companion to the British Pharmacopœia," it is an "effervescent citro-tartrate of soda," prepared from seventeen parts of bicarbonate of soda, eight of tartaric acid in powder, and six of citric acid. This preparation is known in France as "Limonade sèche, ou citrate de magnésie"; in England as "effervescent citrate of magnesia." If this be so, we cannot but think the chemist was hardly dealt with. The name is no doubt wrongly given; but if the purchase had been made from the best-known chemist's firm in London, would not the same article have been sold?

UNDERPAID NURSES.

It is to be regretted, although from the cause assigned we are not surprised, that the St. George's, Hanover-square, guardians are constantly losing the nurses to their infirmary. It appears the latter are paid lower wages at St. George's than at Shoreditch and other parishes. This inadequate remuneration, we are informed, is the cause of these frequent changes. There can be no doubt the frequent changing of nurses is troublesome and perplexing to the medical officer having under his care the treatment of the sick poor. A well-trained and efficient nurse ought to be fairly remunerated. It is questionable economy to underpay her. The nurse has duties to fulfil which require experience and skill. Surely the guardians of St. George's, Hanover-square, should blush to find that the poor district of Shoreditch pay their nurses better than one of the richest parishes in London.

PROVINCIAL MEDICAL SCHOOLS.

In the return of students registered at the Royal College of Surgeons, and published in the *Medical Times and Gazette* of the 18th ult., as pursuing their professional studies in the eleven recognised metropolitan hospitals during the present session, a considerable increase over the number of the preceding year was observed. The additions since allowed by the President have augmented the total (inclusive also of those studying for the licence of Dental Surgery) to the unprecedentedly large number of 1650. In the return just completed for Dr. Ogle, the Government Inspector of Provincial Anatomical Schools, there also appears a considerable increase over the number of last year, as will be seen below. Taking them in numerical order, there appear at the—

	No. of Students.
Manchester Royal School of Medicine and Surgery	138
Liverpool Infirmary School of Medicine	84
Birmingham Royal School of Medicine	79
Leeds School of Medicine	46
Cambridge University School	40
Newcastle-upon-Tyne College of Medicine	34
Bristol Old Park Medical School	24
Sheffield Medical Institution	10
Hull and East Riding School of Medicine	(closed)
Total	455

In addition to the above there are of course a great number of students attending only the medical and surgical practice of the above and other provincial hospitals to which no schools are at present attached, although recognised for this particular subject.

The following comparative table will no doubt be read with considerable interest, not only by the metropolitan and provincial teachers, but by the profession generally. It has been compiled with great care, and may be relied on as a fairly correct statement of the past decade.

	Metropolitan Schools.	Provincial Schools.	Total.
1864	995 students	247 students	1242
1865	1013 „	249 „	1262
1866	1027 „	258 „	1285
1867	1125 „	257 „	1382
1868	1194 „	284 „	1478
1869	1241 „	330 „	1571
1870	1298 „	357 „	1655
1871	1475 „	368 „	1843
1872	1496 „	402 „	1898
1873	1650 „	455 „	2105

It will therefore be seen that at our eleven recognised metropolitan hospitals there is an increase of 154 students over the number of last year. At the provincial schools the addition to the classes is also remarkable, as the gross number now pursuing their studies amounts to 455, being an excess of 55 over those of last session, notwithstanding the disappearance of one school as shown above. It is stated that there is also an increase in the number of gentlemen pursuing their studies in the Scotch and Irish schools.

THE ASSAULT CASE AT THE ROTUNDA HOSPITAL, DUBLIN.

Mr. (commonly called "Dr.") Mulvany, perpetrator of the gross assault on Dr. Johnston, the Master of the Rotunda Lying-in Hospital, to which attention was drawn in our Dublin correspondent's letter of the 13th ult. (page 450), was on Thursday week, the 30th ult., sentenced to six months' imprisonment. The prisoner had been recommended to mercy by the jury, acting under the advice of the Court, and consequently penal servitude was omitted. Since this sentence was passed, Dr. William E. Steele, Registrar to the Branch Medical Council for Ireland, has written to the newspapers to say that Mr. Mulvany's name does not appear in the list of medical men registered in accordance with the Medical Act of 1858.

THE ASHANTEE WAR.

If the news brought by the mail recently arrived from the Gold Coast be correct, that the Ashantees were preparing to deliver an attack in force on Cape Coast Castle itself, we may calculate that but a short space will elapse before the requirements of Sir Garnet Wolseley are made known to the authorities in this country—always supposing that the Ashantee threat of driving all the whites into the sea be not carried out. The intelligence is certainly rather grave, and such must have been the opinion of Captain Glover, or he would not have paid a large sum of money to the commander of the mail steamer *Soudan* to put in (out of her course) at Cape Coast Castle for the purpose of warning Sir Garnet Wolseley of the projected attack.

At home the medical preparations for the expedition may be said to be almost complete. The hospital ship, *Victor Emmanuel*, after a narrow escape of being blown up and burnt, through the carelessness of someone who had failed to discover that the powder magazine had not been properly cleansed when the vessel was last put out of commission, is progressing satisfactorily, twelve hundred men being employed upon her to hasten the execution of the necessary alterations. She will, it is expected, take out with her a staff of about forty military medical officers, and over a hundred men of the Army Hospital Corps to wait upon the sick in the capacity of nurses, compounders, cooks, etc., for which purpose the men composing this latter corps undergo a preliminary training at the Royal Victoria Hospital, Netley.

The troops selected to proceed to the seat of operations have been carefully inspected, man by man, by experienced medical officers, with a view of allowing none to embark but those whose state of health is such as to permit their undertaking the fatigues and dangers likely to be encountered in a campaign of this description.

Surgeon-Major Gore, late of the 34th Regiment, has been appointed Sanitary Medical Officer to the expedition, and has already arrived at Cape Coast Castle to commence the onerous duties of such a post. Upon this officer some of the most important work of the campaign will necessarily devolve: to his experience must be confided the choice of the best spots for halting and camping, the testing of water for drinking purposes, and a general vigilance over every detail likely to affect adversely the health of the troops. It is by no means improbable that as the force advances to the neighbourhood of Coomassie some of the wells will be found to have been poisoned, and great care will have to be taken to ascertain the safety of using the water before the men are allowed to partake of it.

The new uniform for the regiments expected to embark has been already prepared at the Royal Army Clothing Depôt, at Pimlico, and is reported to be both light and comfortable, and well adapted for service in the tropics. We trust that, if possible, the issue of new boots will be avoided, as no part of the soldier's equipment is so likely to produce fatigue and straggling; and some long marches may fairly be anticipated if an advance upon the capital of Coomassie is definitely determined on.

The present suspense cannot, at any rate, be expected to last much longer; Sir Garnet Wolseley is not likely, with the stern necessity of speed before his eyes, to delay unnecessarily in making his final arrangements; and any day now may bring to hand the despatches which will set in motion all the resources of the country for hurrying off the little army to re-assert the superiority of our dominion on the Gold Coast.

IMPORTANT DECISION UNDER THE PUBLIC HEALTH ACT.

A case of some importance was last week heard before Sheriff Russell, at Wick, Aberdeen, under the Public Health Act and Privy Council Orders. Dr. Banks, medical officer of the local authority, sued Captain Reid, of Portgordon, for his fee for examining his vessel on her arrival at Wick from Dantzic Captain Reid's liability was denied. It was held that the Privy Council Order committed the examination of vessels to the officers of Customs. On Dr. Banks' behalf it was urged that the duty of inspection was entrusted to the officials of the local authority under section 7 of the Privy Council Order. The Sheriff's decision was that the spirit of the Privy Council Orders was evidently to entrust the duty of inspection to local authorities, so as to secure the protection of their localities. He could not see how it could be made out that the inspection in the first place was entrusted to the officers of Customs. In this case Dr. Banks had been sent by the local authority, and having done the work of inspection, he was entitled to be paid his fee by the defendant. He therefore gave decree with costs.

ROYAL INSTITUTION OF GREAT BRITAIN.

At the general monthly meeting, held on Monday, November 3, George Busk, Esq., F.R.S., Treasurer, in the chair, the Secretary announced the decease of Sir Henry Holland, the President, on October 27. Henry Adolphus Focking, Esq., and Major John Andover Wood were elected members of the Royal Institution. The special thanks of the members were given to Charles Woodward, Esq., F.R.S., for his present of his work on the "Polarisation of Light," and of much valuable apparatus illustrating the subject; and also to William Salmon, Esq., M.R.I., for his donation of £10 for the promotion of scientific research in the Royal Institution.

SANITARY PROCEEDINGS AT RICHMOND.

For some years the drainage of Richmond has been under the consideration of the Vestry, but at length the Vestry have adopted the "tunnel" scheme for the drainage of the town. A vestryman has, however, since given notice that he will convene a meeting to set aside the resolution on the subject. It is simply disgraceful that one of the most beautiful towns in the neighbourhood of the metropolis should be rendered unhealthy by preventable causes. Of course the amendment of which the "vestryman" has given notice will be defeated.

A HEALTHY VILLAGE.

Mr. John Saville, the registrar of Howden, in the East Riding of Yorkshire, which has a population of 2300 persons, states that no death has occurred there since August 17, to present date October 25—more than nine weeks. Only thirty-one deaths were registered during the past twelve months ending September 30, or at the rate of 13·47 per 1000. Eleven of the deceased persons attained upwards of seventy years.

ADMINISTRATION OF SANITARY LAWS IN WALES.

The *Cambrian News and Aberystwith Times* says—"Our readers will probably be astonished to hear that at Aberystwith the offence of selling meat unfit for human food is only punished by a fine of 10s. inclusive of costs. At Aberystwith the offence of spreading disease is considered to be of so trivial a nature that a merely nominal fine is quite sufficient. The sooner more magistrates are appointed, the better it will be for the people."

RESIGNATION OF DR. STRANGE.

On the resignation of Dr. Strange, Physician to the Worcester Dispensary, the Committee unanimously resolved—"That this Committee receives the resignation of Dr. Strange with regret, and directs the secretary to convey to him their high appreciation of the long and valuable services which he has rendered to the institution."

BREAD AND MILK IN PADDINGTON.

Dr. Hardwicke, the Medical Officer of Health for Paddington, in his quarterly report presented to the Vestry on Tuesday last, states, *inter alia*, that of seventeen samples of bread he found ten to contain alum, and in three cases in excessive quantity. The practice, he stated, of using alum appeared still very common, and indicates an inferior quality of flour used for bread. This, he had no hesitation in saying, was dangerous to health, especially to old people. The milk supply of the parish had been vastly improved since the previous examination; but although all the milk-sellers charged 5d. per quart, some of the milk was inferior, and Dr. Hardwicke recommended that it should be tested as brought up by the Great Western Railway before delivery to the retail dealer.

SPURIOUS TEA.

The City of London Commissioners of Sewers on Tuesday adopted the recommendation of the Sanitary Committee on the subject of spurious tea, to apply to the Government to introduce a Bill into Parliament early in the next session to empower all local authorities throughout the kingdom to enter on shipboard and in all bonded warehouses and other places within their respective districts, to examine, and, if necessary, to seize such teas as, in the judgment of the duly authorised officer appointed for such purposes, were adulterated or unfit for human food, and to destroy such as should be legally condemned.

ANTI-VACCINATION PROCEEDINGS.

Several members of the Anti-Vaccination Society were last week fined by the Marylebone magistrate 15s. each and costs for neglecting to have their children vaccinated. All the fines were paid by an agent of the Society, who attended for the purpose. This proceeding shows that the Act must be carried out with the utmost vigour, in order to defeat the organisation which has been formed against it. In the end the law must prevail.

DWELLINGS OF THE POOR.

At the weekly meeting of the Council, on Monday, of the Charity Organisation Society, the report of the special committee on the dwellings of the poor was presented, which recommended that extensive and effectual powers of purchase, demolition, and direct or delegated reconstruction should be vested in the chief existing municipal authorities of London—the Corporation and the Metropolitan Board of Works; and that the Corporation and the Metropolitan Board should be urged to use those powers, when obtained, in a bold and comprehensive manner.

THE EPIDEMIOLOGICAL SOCIETY.

The Epidemiological Society holds its first meeting for the coming session on Wednesday next, the 12th inst. Inspector-General Lawson retires from the presidency, and will be succeeded by Inspector-General Smart, M.D., C.B., R.N., who will open the session by an address. Dr. Corfield also retires from the secretaryship, and he is succeeded by Dr. W. Squire, of 6, Orchard-street, Portman-square.

TESTIMONIAL TO DR. BOND.

A testimonial in appreciation of his valuable services as Principal of the Hartley Institution, during eleven years, has been presented by friends at Southampton to Dr. Bond, who was lately appointed Sanitary Medical Officer for the County of Gloucester. The testimonial consisted of a large compound binocular microscope, together with an ebonised pillar-table cabinet complete.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The following gentlemen were duly admitted Fellows of the College on October 30:—Dr. William Coverdale Beaty Eatwell; Dr. Thomas Beath Christie, of the Royal India Asylum, Ealing; Dr. Henry Moon, of Brighton.

MR. GUTTERIDGE'S OPERATION FOR LITHOTOMY.

On Monday last Mr. Gutteridge operated for stone on a boy in St. Peter's Hospital. In some points this operation differs from that usually performed. We reserve our account of it until next week.

FROM ABROAD.—SMALL-POX IN BOSTON—JONAH AND THE WHALE IN THE BELGIAN ACADEMY.

Dr. M. E. Webb read before the Massachusetts Medical Society a paper on the "Small-pox Epidemic in Boston in 1872-73" (reported in the *Boston Journal*), the chief facts of which we transcribe. He laments the great additional loss of life that was incurred owing to the utterly inefficient sanitary provisions of the civic authorities: and when these were reformed, through the pressure of public opinion, amendment soon followed. For the same reason he is unable to give any details of the cases treated out of hospitals, the number seized and dying being all that has been recorded.

The epidemic commenced January, 1872, and terminated at the end of April, 1873. The number of cases reported amounted to 3722, and the deaths to 1026, a percentage of 27·56, exceeding that of Philadelphia or New York. The great virulence of the disease was further proved by the number of *hæmorrhagic cases*. Of 1232 cases in the hospitals, 97 (or 7·58 per cent.) were of this form, all proving fatal. Supposing the same fatality to have attended the cases not removed to hospitals (but which was in reality greater), there would be 282 deaths from this form. It occurred most frequently in vitiated constitutions, syphilitics, drunkards, prostitutes, etc.,—males and females suffering equally. Extreme prostration came on rapidly, followed by a lobster-red erythema over the whole body. The conjunctivæ were injected with blood, and here and there papules or vesicles were filled with bloody serum. Usually on the second day there occurred hæmorrhages from the mucous surface of the mouth, fauces, bladder, and rectum, and in females invariably from the uterus. It was attended by a peculiar odour, but was not so contagious as the milder forms of the disease. Its early diagnosis was sometimes difficult, resembling as it did other exanthemata, while its characteristic appearances were only seen when the patient was dying or dead, and sometimes only after diligent search.

A further proof of the intensity of the epidemic was seen in the unprecedented number of *recurrent cases*, Dr. Webb having personally witnessed thirty-eight cases with scars from former recoveries, three of these having had the disease twice within three months. He has also seen three instances of a third attack, there being in two of these marks of vaccination performed before either attack.

With respect to the effects of *vaccination*, it is stated that while of 113 non-vaccinated 55 (or 48·76 per cent.) died, only 130 out of 690 (19·55) vaccinated died, and of 84 revaccinated 15 (17·85) died. The number of deaths was considerably less in those who had more than one scar than in those who only had one. Various facts occurring during the epidemic, however, have shown Dr. Webb that vaccination may yet give efficient protection when there is no external mark whatever. He refers also to a paper by Dr. Cotting in the *Boston Journal*, April 25, 1872, giving an account of a hypodermic injection of vaccine virus, so performed as to produce no external scar. He prefers "animal" to "humanised" virus, both because there is no danger of introducing syphilis (a danger undoubtedly existing, though not so frequent as supposed), and because it is more protective. Among thousands thus vacci-

nated, he is not aware of a single case of variola having occurred.

Besides the ordinary *complications* of the disease, he has observed two conditions not noticed by writers on the disease:

"1. In females, if the disease had been in any way severe, they have invariably menstruated during the primary fever. In girls, the first period came on, and in women near the climacteric the catamenia reappeared, when perhaps menstruation had been delayed for a year. So common has this been, that a diagnosis has been made from this fact alone that there was a flow of blood from the uterus occurring out of its regular time. In some way the poison seems to affect the uterus, and to exert a special action upon its functions. 2. In several cases, and always where the disease has been mild, and had passed regularly into the desquamative stage, suddenly, without warning or perceptible cause, patients would have convulsions—inflammation of the brain or cord—followed by paralysis either complete or partial, and death in twenty-four or forty-eight hours. In three instances paralysis commenced in one leg; then the arm of the same side was affected; then the other leg and arm; then complete paralysis—the mind of the patient remaining clear to the last. There were two cases that had paralysis without the first symptoms of inflammation, and both died. The urine in these cases was heavily loaded with albumen. All the cases (some eight in number) that we have seen proved fatal."

Dr. Webb's account of the treatment pursued during the epidemic, which seems to have been highly judicious, does not call for notice.

The *Révue Scientifique* relates an incident which has just occurred in the Belgian Academy of Sciences.

M. Edouard van Beneden, Professor of the University of Liège, read at the Academy an account of a zoological voyage which he has recently made to Brazil, where he collected many interesting facts. Among other things he observed that he had great difficulty in obtaining a dolphin, owing to the superstitious respect entertained by the Brazilian fishermen for this animal. "An ancient belief, also spread throughout Europe, attributes to dolphins the habit of bringing to shore human bodies, which their instincts have led them to discover. The fable of Jonas is a reproduction of this popular belief." M. Henry, Professor of Chemistry, and M. Gilbert, Professor of Mathematics in the Catholic University of Louvain, immediately took umbrage at this passage, and addressed to the President of the Academy a violent protest, declaring that to characterise the story of Jonas and the whale as a "fable" was an attack upon the religious convictions of the Catholic members, and demanding that the Academy should censure the author of the expression, in order to prevent a repetition of such a scandal. It is to be observed that M. E. van Beneden made use of the expression with no critical or jocular intention; and so far from any disposition of this kind being congenial to him, he was appointed himself to his present post of Professor of Zoology at Liège by the Catholic ministry now in power, and his father is the well-known Professor of Zoology in the Catholic University of Louvain. M. Quetelet, the venerable Secretary of the Academy, whose moderation is so well known, believing the writers of the protest had made a mistake which they would one day wish to be forgotten, passed over the letter in silence. Professor Gilbert, however, one of the writers, insisted on its being read. M. E. van Beneden at once rose to explain, but M. Quetelet stopped him, saying that the Academicians were quite at liberty, under their own responsibility, to express their opinions upon any subject, and that it was an absurdity to attribute to M. van Beneden any intention to annoy others, who in fact had no right to feel hurt at an opinion or statement merely because they did not agree with it. It was a primary duty of the Academy to protect the intellectual liberty of its members, and for it to accede to the pretensions now made would be to excite the ridicule of entire Europe. The Academy at once passed to the order of the day, and the two Catholic professors, in imitation of Bishop Dupanloup, who refused to sit by the side of M. Littré at the Institute, sent in their resignations of membership.

CONSTIPATION IN PNEUMONIA.

By PROFESSOR SKODA.

Under the above title the *Allg. Wiener Med. Zeitung* of September 30 publishes an interesting clinical lecture by Professor Skoda, of which the following is an abstract:—

In cases of pneumonia (he observes) the practitioner not infrequently meets with obstinate constipation, which lasts for a long time; and the question arises, whether, for the relief of this, he should or should not resort to active measures. Before replying to this, however, the point may be first considered of within what limits of time defæcation may occur normally during a state of health, in order to judge how far constipation arising in disease is a disadvantage. And we find at once that great differences exist in this respect among persons in an entirely normal condition; for while in the great majority of men a daily stool takes place, in a not inconsiderable number this happens only every second or third day, and in some even more than three days elapse. On the other hand, there are other individuals whose normal condition it is to have more than one stool a day—a circumstance not to be overlooked in delivering a prognosis in such subjects when they become the subjects of diarrhœa. Again, there are persons, chiefly females, in which constipation lasts, not only for days, but even for weeks. While such prolonged constipation continues, the subject of it is still able to eat with a good appetite, no especial or remarkable effects being produced by the food taken. This, of course, is not considerable in quantity, yet it remains inexplicable how during the continuance of such a constipation anything can be eaten. The question arises, whether such constipation does not lead to alterations in the person's state of health. Upon this point it is to be observed that the fæces discharged by such persons are not different to those of individuals who have a daily stool. And there is good evidence to show that the fæcal residua of nutrients may long remain within the canal without any corresponding damage being done to the economy, the fæces undergoing no change during a prolonged retention which can injuriously influence it; so that the differences in the production of stools are attended with no corresponding differences in health of the individuals concerned. This position, which experience has rendered irrefragable, is unfortunately continually sinned against in practice; and Professor Skoda warmly protests against the unwarrantable manner in which purgatives are sometimes resorted to, running risks which might be easily avoided by bearing the above considerations in mind.

With respect to the gases which are developed within the intestinal canal, they are retained as well as the fæces; but in long-continued constipation, if this be not caused by a strictured condition of the canal, in the majority of cases no gases are present. It is well known that the presence of gases in the intestinal canal is essential for procuring the expulsion of its contents, and that they facilitate this by preventing the friction of the fæcal masses against the walls of the intestine. Another important office which they fulfil is that they facilitate the movements of the diaphragm, following or receding before these; and if they were not present, the movements of the abdominal parietes consequent upon those of the diaphragm must be much more considerable. That the gases developed within the canal do exert a great influence upon its evacuation, may be inferred also from the fact that in all cases where they are not present such evacuation is attended with very great difficulty. Of this influence of the gases we

have further proof in the fact that, in individuals in whom the evacuation of fæces is very difficult, this is rendered much easier by the employment of articles of diet which favour the generation of these gases. To this end the use of brown bread is especially to be recommended. Leguminous vegetables do this to a still greater extent, but their employment is not suitable for all persons, as in many they give rise to a troublesome amount of flatulence. But in order to render the evacuation of fæces easy, not only is it necessary that gases should be present in the canal, but liquids also. We should therefore endeavour to supply these by ordering such as will not be completely absorbed in the canal. Ordinary soup is not suited for this purpose, as it is too rapidly absorbed. Acid substances should be preferred, for most acids cannot be at once absorbed in the canal, because they require first to become combined with alkalies—a process that requires some time for its accomplishment. Meanwhile they produce an irritating effect upon the canal, and contribute essentially to its easier evacuation. When constipation has lasted for weeks, and is dependent upon diseased conditions, such means are of no avail. The peristaltic movements are entirely arrested, and for such a state of things different measures must be adopted. While increasing the quantity of gases and liquids in the canal, we must attempt to reproduce the peristaltic movements, the cessation of which is sometimes dependent on the spinal cord. Quinine should be given, while friction of the abdominal parietes with aromatic oils and the use of electricity should be resorted to. In many such cases faradisation of the abdominal parietes has proved of marked utility. In obstinate cases hydropathic treatment may be of service, as also may warm baths; and Oppolzer used to apply cold applications to the abdomen with frequent success.

Applying the foregoing observations to the case in question, it is therefore to be observed that the mere occurrence of constipation in pneumonia should cause no anxiety; and Professor Skoda has frequently insisted that while it is requisite to keep the patient in a state of quietude, we should avoid administering purgatives merely because constipation is present. Of course the accumulation of fæces may be such as to become troublesome, or the gases and fluids may be in such quantity as to impede respiration, so that, when the abdomen becomes distended, interference is not only justified but imperative. And in those cases where there are constant and irritating attempts at passing stools without any evacuation taking place, the practitioner must also intervene in order to obtain actual evacuations. But Professor Skoda insists strongly that if constipation has persisted for several days, and is unaccompanied by distension of the abdomen, it is not to be regarded as a disadvantageous circumstance, but, on the contrary, is a far more favourable symptom than a frequent passing of stools would be. Further, he declares that it is entirely an error to suppose that the pneumonia is favourably influenced by exciting a diarrhœa; in fact, it is only to add a new ailment in the shape of an abdominal catarrh, increasing the patient's sufferings, and rendering his condition worse than it was. In no case where diarrhœa has occurred during pneumonia has this afforded any relief to the respiration. If, for the reasons already given, it becomes necessary for the practitioner to interfere during the pneumonia, he should do so by means of enemata. The internal use of purgatives is almost always attended by a certain amount of irritation, even when there is no pain produced in the abdomen; and this additional irritation is not a matter of indifference in a patient already suffering from a serious disease. It is the same with the action of purgatives as with that of emetics, as set forth by Oppolzer. There does not result from their use, as is so generally supposed, any real improvement or relief in the condition of the patient, whose original malady is much oftener rendered worse in consequence. It is only when the aggravation which they have caused has subsided, and the patient has reverted to his original condition, that he feels himself apparently better. Such apparent improvement is not to be ascribed to the action of the purgatives or emetics that have been administered, but to the ease which is felt at the cessation of the irritation which they give rise to, although this may leave the patient in the same state in which he was before these irritants were prescribed.

ST. VINCENT'S HOSPITAL, STEPHEN'S-GREEN, DUBLIN.

The medical session was opened by the inaugural address, which was delivered in the theatre of the Hospital by Professor Quinlan, M.D., Physician to the Hospital, in the presence of a large number of the friends and of the medical students of the Hospital.

After some preliminary remarks, he said: In his immortal treatise on "The Orator," Cicero proved that perfect oratory is shown in the application to the purposes of eloquence of every branch of classical learning. So, in like manner, we may affirm that scientific medicine consists in the application to the investigation or relief of human suffering and disease of almost every branch of natural and experimental science. Chemistry and Botany are the ancient handmaids of Medicine; but in latter days the sciences of electricity, of optics, of heat, of sound, of fluids, and of practical mechanics, have taken their share either in physiological investigations or else in the examination or treatment of diseased conditions. All these departments of science have, within the lifetime of the present generation, made immense strides; and have, in fact, like astronomy, become departments of applied mathematics—foremost among them electricity, which is now so exact a science that the electrician is able to point out, in an Atlantic cable, the exact position of a flaw which is situated hundreds of miles from the shore and hundreds of fathoms beneath the sea! The other sciences are worthily keeping pace; but when we come to medicine, we find that her scientific progress is not equal, and that, although a splendid and carefully cultivated art, she has not yet attained the degree of an exact science. And yet medicine has, within the last quarter of a century, accomplished some great discoveries which will stand the test of time and experience, and which are worthy of being placed upon the same pedestal as those of the circulation of the blood or of vaccination. Foremost among those I would place the introduction of the method of producing insensibility to pain in surgical operations, which it would not be too much to say has completely revolutionised operative practice. Formerly the great aim of the surgeon was to accomplish his awful but necessary duty to his agonised patient as rapidly as possible, and a clinical clerk, with a watch, always stood by to note the time so occupied. Mr. Herbert Mayo performed amputation at the hip-joint in ninety seconds. Mr. Edward Hutton, whose resident pupil I had the honour of being, amputated at the middle of the thigh in seventy-eight seconds; and I have heard M. Jobert de Lamballe pronounce not very slowly the words *un, deux, trois* while he with lightning speed removed an arm at the shoulder. We have changed all this. We operate, like the sculptor, upon an insensible mass; we go carefully through our work; and, although accomplishing it as quickly as we can, we do not count the seconds. A new class of operations, under the title of conservative surgery, has, to the great benefit of humanity, sprung up, in which we endeavour to carefully remove the precise site of disease or injury, and to leave for future use the surrounding structures—for instance, in incurable disease of the knee, instead of amputating the thigh, the surgeon now removes the actual diseased joint, and leaves the sufferer with a whole limb, stiff at the knee, but as good for walking as ever. This operation, like the old revolving pistol of the time of Henry VIII. contained in the Tower Museum, is an example of a discovery made long since, but abandoned because it could not be put into practice. It was first performed in Liverpool towards the end of the last century by Mr. Parkes under the following circumstances:—A sailor presented himself with an incurable knee, and Mr. Parkes proposed, according to the practice of the time, to amputate the thigh. This the sailor refused, saying that the loss of his limb would consign him to pauperism, and that he would

sooner die; adding, however, that he would submit to any operation, however painful, which would leave him the limb. Mr. Parkes conceived the great idea, and successfully carried it out. The man recovered, and afterwards went many voyages to the West Indies, mounting the rigging, and doing with facility all the duties of his craft. Although well known and imitated successfully in Paris the following year, this operation fell into disuse for nearly half a century, for the simple reason that it was too slow and painful, and that ordinary human endurance could not bear it. Its successful performance is now a matter of the most ordinary routine practice; and no surgeon thinks of amputation in such a case unless in military practice, where the necessary after-treatment cannot be accomplished. In the late Franco-Prussian War, however, even this difficulty was overcome. This resection of the knee, as it is called, is but the type of a host of operations which anæsthetic practice has introduced, in which, the element of pain being eliminated, and that of shock to the system much diminished, we proceed to our work with the calmness and accuracy of an anatomical dissection. I speak of this subject with peculiar pleasure, for in it the Dublin School of Medicine has worthily held its own. Both in chloroform and ether Dublin practice has been distinguished for efficacy, and, above all, for safety beyond many neighbouring capitals; and our ratio of fatal cases has been amazingly low. This has been solely attributed to the complete knowledge on the part of the Dublin faculty of the conditions of safety in anæsthetics and to their care and caution in using them. Notwithstanding our favourable experience of chloroform, it has occurred to Dublin surgeons that perhaps the original though disused agent—ether—might prove the safer of the two. On this question being ventilated a committee was appointed in our College of Surgeons to consider it; and I refer to that committee with pride, because in this matter medicine will assume the attitude of an exact science. All the hospitals of Dublin are associated together in the great work. Every case of ether or of chloroform occurring in them is carefully tabulated on a fixed uniform schedule. All the facts will thus be ranged into a focus, and by a process of scientific induction a really correct result will be obtained.

REVIEWS.

A New Operation for Anchylosis of the Elbow-Joint resulting from Fracture, and Rigidity the Result of Unreduced Dislocation. By Patrick Heron Watson, M.D., F.R.S., F.R.C.S., Lecturer on Surgery and Clinical Surgery, Senior Surgeon Royal Infirmary; Surgeon to the Chalmers Hospital for Sick and Hurt, Edinburgh. Edinburgh: Printed by Oliver and Boyd, Tweeddale-court. 1873.

Excision of the elbow-joint for anchylosis, partial or complete, the result of injury, has long been recognised as sound surgical treatment. In Dr. Watson's experience, however, the resulting limb has not been so satisfactory as in those cases in which the operation has been done for disease; in some cases too great a degree, in others too small a degree of mobility has resulted. The first modification attempted of the simple operation of resection of the articular surfaces of the humerus, radius, and ulna, was to save the insertion of the triceps muscle. The method now proposed is one which, while it preserves muscular attachments, at the same time effects the removal of as much of the osseous textures as is necessary. The operation is thus described by the author:—"1. A linear incision to be made over the ulnar nerve to the inner side of the olecranon process, rather longer than that usually employed in the ordinary excision of the elbow by linear excision. 2. The ulnar nerve to be turned over the inner condyle by careful dissection. 3. A probe-pointed bistoury to be introduced into the elbow-joint in front of the humerus, and then behind that bone, and carried upwards, so as to divide the upper capsular attachments in front and behind. 4. A pair of bone-forceps to be next employed to cut off the entire inner condyle and trochlea of the humerus, and then introduced in the opposite diagonal direction, so as to detach the external condyle and capitulum of the humerus from the shaft. 5. The truncated and angular end of the humerus to be cleared, turned out through the incision, and smoothed across at right angles to the line of the shaft by means of the saw, whereby (6) room might be afforded so that partly by twisting, partly by dissection, the external condyle and capitulum might be removed without any division of the cutaneous tissues on the outer side of the arm."

Dr. Watson had practised this operation in six cases, with satisfactory results in all. It is claimed by the author—and fairly, we think—for this method that it is original; its merits are that the attachments of the triceps and brachialis muscles are left undisturbed, that the area of operation is limited almost exclusively to within the capsular ligament of the elbow-joint, and that a more ready access is gained to the ulnar nerve than by any other method. In cases of complete anchylosis or where any obstacles are found to prevent the execution of the more limited resection, this operation may always be converted into a complete excision of the joint. The plan appears to us so good that we shall unhesitatingly put it upon its further trial at the first opportunity.

Die Ohrenheilkunde der letzten 50 Jahre. Vom Dr. W. Kramer. Berlin. 1873.

Aural Surgery during the last Fifty Years. By Dr. W. Kramer. Our old friend Dr. Kramer, having completed the fiftieth year of his practice as an aurist, and noticing that his contemporary practitioners in that branch made no sign of duly celebrating the great event, has thought proper to erect a monument to himself and to present us and posterity with the above-named publication as a memento of his supreme merits as an aurist. Without the least desire to deal harshly with the aged doctor, we are compelled out of regard for the truth to state that the pamphlet under notice is to a considerable extent a *réchauffé* of his treatise "Aural Diseases and Aural Surgeons in England and Germany, 1865,"(a) and of his other works.

Age does not seem to have weakened his pugilistic tendencies nor chastened his style. His hand and pen are still against every man who ventures within his domain. There is but one standard of aural science—and Kramer is its prophet. This is the main gist of the pamphlet.

We should have been glad to welcome a fairly written synopsis of the progress of aural surgery during the current century, but the treatise in question is merely a polemical campaign against the more eminent living and dead writers on aural diseases, who, with scarcely an exception, are described as ignoramuses, and not a few as charlatans. In justice to our aural Don Quixote, it must be stated that in one respect he is impartial—for he strikes right and left, demolishing the quacks of his imagination, be they English, French, Germans, or Russians: they all share alike, and are mowed down without the least scruple. Our German *confrères* will no doubt take care of themselves if they think it worth while.

For reasons already stated this pamphlet does not admit of serious review, but we cannot refrain from culling a few flowers from the choice vocabulary of Kramer when treating of otiatrics in England. Troeltsch, it seems, stated in his work on "Diseases of the Ear" that the scientific development of aural surgery was mainly due to the English aurists, Wilde and Toynbee. This greatly excited the wrath of Kramer, who considers that he, and he alone, has laid the foundation of aural surgery as a science. Kramer repeats in this production his former attacks on English aurists, and especially on Toynbee as the head of them, in the most harsh, not to say vulgar, terms. Thus (page 26) he writes—"Toynbee's superficial knowledge and complete lack of real medical attainments, as manifested in his pretended diagnosis of acute and chronic affections of the middle ear, is only exceeded by the senseless audacity with which he tries to introduce the *rigidity* of the tympanic membrane as a morbid entity into the system of aural diseases, for which his own dissections do not furnish any support whatever." And again (page 27), "When we consider Toynbee's thoughtless diagnosis and treatment of the membranous ligaments in the tympanum, of the anchylosis of the stapes to the fenestra ovalis, and the apocryphal *rigidity* of the membrana tympani, we must confess that by this alone he proves himself a *charlatan* of the first water." But when we sum up all his own contributions to aural surgery, as well as those of Wilde, every impartial man will at once admit that Troeltsch has made himself supremely ridiculous by ascribing to Wilde and Toynbee an essential influence upon the scientific development of otiatrics, and by calling Toynbee 'the great reformer of aural surgery.'"

Kramer then reiterates his charges that Toynbee did not see nor examine during their lifetime the patients from whom

(a) "Ohrenkrankheiten und Ohrenärtzte in England und Deutschland."

the specimens were collected. This assertion having been proved a deliberate misstatement, Kramer now qualifies it in the following tame manner:—"My exposure of Toynbee's procedures, which have been published in English journals many years ago, may have induced Toynbee to publish some cases which he asserted to have examined during lifetime—*i.e.*, by the miserable light of a taper, and by the aid of the equally miserable Valsalva experiment."

The hypothesis of Helmholtz in relation to Corti's fibres is rejected by Kramer as an idle fancy.(b) Troeltsch, Gruber, Schwartze, Moss, Voltolini, Wreden, Wendt, Politzer, etc., are summarily and ignominiously dismissed. Thus, of Troeltsch and Gruber he says—"I think the procedures and the conduct of *these public teachers of otiatrics* can only be called *charlatanism.*"(c) He is equally complimentary to Hinton, whom he terms "Toynbee's hodman."

With regard to tinnitus, Kramer observes (page 61)—"The perfectly incorrect conception of tinnitus by Troeltsch is on a par with his crude empirical treatment of the same. He recommends fomentations, injections into the tubes, glycerine, tepid water, narcotics, chloroform, perforation of the tympanic membrane, and finally, if nothing will do, the great helper in need 'dear electricity.'" All this is mixed up pell-mell as in a marine-store, no rational indication being given; the only hope being that "a blind pigeon may, peradventure, find a pea." Kramer continues—"In opposition to this, a characteristic treatment of tinnitus, I will, in an appendix, give my own experience on the nature and treatment of tinnitus," which accordingly he does, and with the conclusions of which on many weighty points we find ourselves unable to agree.

"In conclusion," observes our author, "modern aurists have not discovered one single physiological fact which will stand a strictly critical and experimental examination. My observations on the conduction of vibrations through the air in the tympanum to the fenestra ovalis, experimentally verified, are probably the first step in this direction." Hence Kramer concludes that otiatrics have, as a science, made no progress since 1862; but that, on the contrary, aural sugery has retrograded both scientifically and practically. This retrogression, he maintains, is chiefly due to the false conception of the problems of pathological anatomy, the defective knowledge of the real wants of aural surgery, and also to the conceited self-estimation of Troeltsch as the leader and standard-bearer of modern aurists.

We have already stated that it goes against our grain to deal harshly with a practitioner of fifty years' standing, especially when we bear in mind that Dr. Kramer has done good service to aural surgery at a time when that branch of medical science was but little cultivated; but the overweening vanity of this author, and his utter disregard of professional amenity, left us no option in the matter. We now take leave of Dr. Kramer in perfect good humour, and are extremely glad to learn from his pamphlet that he is in excellent health, and we heartily wish that he may enjoy his green old age *cum dignitate*. That he will henceforth abstain from his undignified controversy with the younger generation of aurists is more than we can venture to hope for.

VIENNA, October 13.

PROFESSOR HYRTL ON THE SCIENCE OF ANATOMY.

THE celebrated anatomist, Professor Hyrtl, intends to close his brilliant career after the lapse of this semester, and announced his intention to-day, in his introductory lecture, to a crowded audience. During an anatomical career of now forty years (the much-esteemed teacher began), the days were sacred to him when, at the beginning of each season, he used to enter the lecture-room, meeting an assembly of young men full of desire for knowledge, to receive the master's first greetings and welcome, and to be introduced into the beautiful dominion of a science which has been to him a true partner through life, and shall now become a worthy object for the student's aspiration, an affluent source for the education of their minds, an invaluable bequest of truth for their future career as physicians. It is no exaggeration (Hyrtl continued) to adorn with such attributes the science which I have served my life long, and which you are about to imbibe. And thus, with a kind of devotion, for the last time I commence my lectures, and will preface the serious work by a few serious observations on the nature of anatomy and its twofold signification as a subordinate branch of medicine, and as independent science.

He who gains some new acquaintance in life asks himself how he becomes impressed by it, whether he remains indifferent or becomes confident, whether it pleases his feelings and proves useful towards his ends. You, gentlemen, have the same right to similar questions, since you are about to make the acquaintance of a science which at present is entirely unknown to you, of the dimensions of which you are still ignorant, and the significance of which, with respect to the medical avocation, you cannot understand, but forebode.

The first question to which I have to reply is—What is Anatomy? It is a thing half science, half art; a thing that by work of hands has paved its way into the realm of mind. One may call it a handicraft, but with the golden basis of a science. Its task—"Non fingere et excogitare, sed invenire quid natura faciat atque ferat"—is the most becoming and most beautiful given to the aspirations of our mind. The classical ages having the γνῶθι σεαυτον as the device of their investigation, had a mere presentiment of the reason of that task, attempting the performance of it in the sphere of reason. Philosophy was the result, but it was reserved to anatomy to raise the veil from the material part of this existence. The aim to investigate the human body is pursued in a threefold manner, for to gain a knowledge of an organised body three things must be known—its external shape, its internal structure, and the manner of its action. The three questions which with respect to man are put to science are responded to by three subdivisions—namely, by physical anthropology, in so far as it concerns the external form; by anatomy in the strict sense of the word, revealing the marvels of the internal structure by dissection; and by physiology, teaching the phenomena and laws of life. Anthropology, as conception of the external properties of man, as knowledge of shape and its variations, consequent upon descendency, mode of life, clime, age, food, etc., must entirely be left to the zoologists, who have to close their scientific system with beast; and however man's ability of mind and haughty consciousness of his mental superiority may struggle against the relationship, he will still remain the brother of animal. The young science of authropology has already gained great significance, having radically reformed our notions on the origin of man, and it will not fail to gain still greater influence on our social life. In certain circles of society it is, therefore, considered a dangerous science, and for that reason no chair has yet been founded for its teachings at our university. Anatomy, however, and physiology are looked upon as necessities for medical men, and for these sciences rather too much is done by Government than too little.

Concerning the relation between anatomy and medicine, it would be a misconception to consider the former a mere preliminary study for the latter. Anatomy forms the basis of medicine, and it is more than arrogance to attempt to cure a patient without a knowledge of the healthy human organism. The dissecting-room, therefore, forms the Propylæ of medicine, and there are no words impressing with greater reverence the minds of those about to enter than the ones over the door of the dissecting-room of Paris—"Hic locus est, ubi mors gaudet succurrere vitæ." Now, if such an intimate connexion exists between anatomy and medicine, when the former is the starting-point of the latter, when it is impossible to walk with propriety on the toilsome path of a medical man without it, it is quite superfluous for me to impress your minds with the courage and power, with the endurance and persistence you will be obliged to employ in the investigation and acquirement of that knowledge as the representative of which I am now addressing you.

What awaits you here certainly is not the charm of grace—the dominion of death with its abhorrent attributes has no æsthetical aspect; the welcome it offers you is cold and earnest as is the corpse.

(b) Some little time back we came to the knowledge of the fact that more than one hundred years ago an acute French physician had anticipated the discovery of the fibres of Corti; it remained for Corti to demonstrate them. Neither Corti, Helmholtz, nor Tyndall mention this physician, and as most probably his writings on the subject are not known to them, we shall shortly accord to these foreshadowings a brief space.

(c) The *italics* are in the original.

The Viennese physicians stuck always to the sentence—"Homo quantum scit, tantum potest," which has been translated by an Austrian Minister of State as "Knowledge is power." All acquirements of modern industry are emanations of applied science, and the inquisitive and thinking observer of the International Exhibition in the whole palace will find not one object contradicting this principle. The International Exhibition itself is a Pantheon of knowledge, a temple in which the conquests of mental combats are deposited. After having considered the methods to be pursued in anatomical teaching, Professor Hyrtl winds up thus—"I am convinced that you will not consider the place from whence I am addressing you as that of a crammer with the title of professor, drawling in monotonous, tedious, pedantic words—the old fashion. So you may receive my hearty greetings, expressing at the same time a hope that also in this semester, which is to be my last as a teacher of anatomy, our meetings may become satisfactory to both of us. You must, however, accustom yourselves not only to *learn* anatomy, but also to *conceive* it. For that purpose there exists *one* means, which I name to you at the conclusion—viz., honesty, exertion, and unceasing labour."

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, October 28.

The Introductory Lectures.

Once more has the busiest week in the medical year—that of the "Introductories"—come round, and a few notes of some of the addresses will doubtless be of interest to many of your readers.

The Royal College of Surgeons generally takes the lead in point of time in commencing the session, and this year proved no exception to the rule. On Monday, October 27, Dr. Mapother, Professor of Physiology in the School of Surgery, lectured before a large gathering of the profession and of students on the interesting subject of "Lessons from the Lives of Irish Surgeons." Naturally, the Professor's remarks were addressed more especially to the student portion of his auditory. He commenced as follows:—

"Examples are better than precepts, and therefore it struck me that you would be glad to learn the ways in which our great surgeons, whose names will occur daily to you in the course of your studies, attained their eminence. You will be reminded of many of them as you walk through these halls, for since the foundation of this College—ninety years ago—she has always desired to perpetuate, by marble or canvas, the fame of her most distinguished members. Success among the public is not always a true test of skill or knowledge, but those who have been raised to our high places, or whose memories are here cherished, have, without exception, deserved such honours.

"If the saying of Dr. Gregory be true of the surgeon—namely, that 'the only judges of his merit are those who have an interest in concealing it,'—it must be allowed that the Fellows of our College have always acted most disinterestedly. I have arranged in chronological order the names of some of those whose lives and labours offer useful lessons for reflection, commencing with two or three who flourished at the end of the seventeenth century, and ending with some whose loss is still fresh in our memories. If dates and details about some of the earlier surgeons appear dry, I trust you will bear with me—for, believe me, the more you learn of your profession, the more pride you will feel in these countrymen of ours who have done so much without any of the aids for study which are now possessed by all of us."

The lecturer then proceeded to give a brief biographical sketch of most of the great fathers of surgery in Ireland during the past 200 years. Into his narration he interwove anecdote and history; and in tracing the origin of the College of Surgeons, mentioned "The Guild of Barbers of St. Mary Magdalene," chartered in 1446 by Henry VI., that unhappy king, for "the Promotion and Exercise of the Art of Chirurgerie," and which consisted of men and *women*. Clinical teaching is generally supposed to have originated during the present century in Dublin; but Dr. Mapother showed that so far back as 1785 four wards in Mercer's Hospital were set apart for the reception of cases for the lectures of the College of Physicians. He added, too, that clinical teaching was even older than this, having been pursued eighteen centuries ago, although in no very pleasant way for patients, as appears from the following lines translated from Martial:—

> "I'm out of sorts, but Symmachus is here,
> His hundred pupils following in the rear;
> All feel my pulse with hands as cold as snow,
> I had not fever then—I have it now."

Within the narrow limits of a letter it would be impossible to do full justice to Dr. Mapother's address, but I may be permitted to give at length its closing sentences:—

"And now, gentlemen, several considerations suggest that I should bring these commentaries to a close—firstly, the desire to respect your patience; and secondly, that others whom I would wish to notice are too lately taken from us to receive dispassionate treatment at my hands.

"On some future day justice will be done to the memories—too early lost to surgery—of William Henry Porter, most eloquent of lecturers and most elegant of surgical writers; of John Hatch Power, my revered master; of O'Bryen Bellingham, the most earnest friend of the Surgical Society; of Robert Williams, the sturdy advocate of the College rights; and of the benevolent Kingsley—all of whom are commemorated by bust or portrait. Still to the catalogue of great Irish surgeons must be added the names of Peile and Wilmot, and O'Ferrall and O'Beirne, Hutton and Ellis, Harrison and Ledwich, Smyly and Banon (lost to us whilst Presidents-elect); and from the lives of any one of them fruitful and good lessons may be deduced. None of those whose career we have studied to-day gained any position through nepotism. Of those who depend on such influence alone, it has been said by Sir D. Corrigan, in an address last July at St. Mary's Hospital:—'I have occasionally—nay, often—seen men raised by the influence of connexion or extraneous circumstances into temporary eminence—but if they went up like a rocket, they came down like the stick.'

"A universally regretted death and two resignations have changed our professional staff during the year. Charles Benson and William Hargrave—than whom the College never had more tried or trusted servants—have sought well-earned repose. William Barker, who, although not a surgeon, was a teacher and well-loved friend of a thousand, has passed away. Younger but no less earnest men fill their chairs.

"Let me end this lengthy lecture by reminding you that the leaders of our College for several generations owed their positions to honour and industry, as well as to genius, and verified the words of William Hunter—'A young man cannot cultivate a more important truth than this: that, apart from future recompense, merit is sure of its reward in this world.'"

To-morrow (Wednesday) Dr. Quinlan is to deliver an inaugural address at St. Vincent's Hospital; on Saturday, November 1, the session at the Ledwich School of Medicine is to be opened by Dr. A. Wynne Foot, Lecturer on Medicine; and on Tuesday, November 4, Dr. Lyons will lecture in the Catholic University School of Medicine. Of these and other addresses I hope to send you some account in due time.

GENERAL CORRESPONDENCE.

DIPSOMANIA.

Letter from Mr. J. Dixon.

[To the Editor of the Medical Times and Gazette.]

Sir,—Is it too late to substitute a better word for Dipsomania? I believe it was invented by Hufeland, and certainly a worse compounded word could hardly be found. Etymologically, it means "madness from thirst," whereas it is intended to imply either madness from drunkenness or an insane craving after strong drink. To the ordinary British citizen, untroubled by Greek derivatives, no doubt the word commends itself—it is so like *tipsy-mania*. Kuehn noticed the faulty composition of the word, and suggested an excellent substitute, *Methomania*; μεθη, meaning intoxicating drink. I get my information concerning Hufeland and Kuehn from Krans's "Med. Lexikon."

October 31. I am, &c., J. Dixon.

The report presented to the Committee having the management of the Hospital Sunday Fund in Liverpool, at their annual meeting last week, showed that the receipts were, by various collections, £8124 18s. 9d.; Hospital Saturday boxes, £1696 11s. 1d.; which, with other contributions, made a total of £10,018 12s. 2d.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, October 28.

Dr. C. J. B. Williams, F.R.S., President, in the Chair.

Mr. William Miller Ord communicated notes of a case of Duchenne's Pseudo-hypertrophic Muscular Paralysis, which, with the discussion thereon, we shall publish next week.

Subsequently the President (Dr. C. J. B. Williams) read a paper "On the Acoustic Principles and Construction of Stethoscopes and Ear-Trumpets." After noticing the invention of the stethoscope by Laennec, its modification by Piorry, and the introduction of the trumpet-end instrument by the author thirty years ago, he enunciates the principle of the stethoscope to be to conduct the sounds from the chest to the ear, both through its solid fibres and through its enclosed column of air. He then considers the *material* and the *form* best suited for this office. Wood, as a conductor of sound, is the best material, especially deal, and such woods as are rigid in longitudinal fibre, and yet light; the same reason makes them fit for sounding-boards of musical instruments. The only objection to wood is its fragility, especially when reduced to the shape best suited for stethoscopes. Metals are good conductors; but their coldness when first applied to the chest and ear, and their weight, are objectionable. Horn, *papier maché*, or guttapercha, would answer better; but a more suitable material is found in a preparation of india-rubber called ebonite, being easily formed into any shape, being also light, durable, and a good conductor of sound. With regard to the form of the instrument, after long and varied trials of stethoscopes of different shapes, the author is convinced by reason as well as experience that the trumpet-end instrument is the best. Conducting the sounds by its enclosed column of air as well as through its solid walls, this trumpet end brings both its solid and its contained air into closer contact with the chest-walls, from which the vibrations proceed, than can be done with a conical end, or any other: and there is neither too much hollow, which causes a confusing reverberation, nor superfluous weight of solid, which checks the weaker vibrations of sound. This form is also more comfortable to the patient, and easier and more steady for the observer; because its application is by a flatter contact and a firmer base than that of conical instruments, the edges of which often give pain. After discussing the subject of the transmission of sound through flexible tubes, the author admits their power, but concludes that the sounds are more or less modified by reverberation in them, especially when long or with large hollows. Dr. Williams concludes the subject of stethoscopes by a description of two forms made in ebonite—one for the hat, another for the pocket—and of some of their uses. The acoustic principle of the ear-trumpet is quite distinct from that of the stethoscope. The latter simply conducts pectoral sounds through its solid and its enclosed column of air. The ear-trumpet, on the other hand, acts solely as a reflector to receive the waves of sound from the open air, and to direct them into the ear as a focus. The best materials for reflecting aërial sounds are those hard and dense, such as metals, glass, porcelain, etc., but the weight of some of these, the fragility of others, and the intrinsic tinkling note of all, form objections to their use as ear-trumpets. Still the best instruments in common use are made of silver, plated metal, or japanned iron. The lightness of aluminium would render it more eligible. Polished ebonite also forms a good reflecting surface, and, although inferior to metal, has advantages over it in lightness and freedom from intrinsic sounds. The form of the ear-trumpet requires careful consideration. The simplest and most efficient reflector is a hollow cone with a wide base open to catch as large a body of sound as possible, and to reflect it in the simplest and most direct way through the apex into the ear. All repeated or secondary reflections of sound, as in parabolic and spheroidal cavities, are to be avoided; because, being retarded, they confuse the sound by an echo following, instead of adding to its distinctness. Such instruments may increase the noise, but they impair the clearness of articulate sounds, which ear-trumpets ought to convey pure, and unmixed with extraneous notes. But in point of fact these confusing sounds are met with in all ordinary ear-trumpets, causing the conch-like roar, like that of the sea heard in large shells. This noise is a reverberating echo of sounds from without, and takes its tone from the note proper to the size of the cavity or tube in which transverse or longitudinal vibrations are excited, responding to every noise or impulse. These noises are confusing, and often painful to sensitive ears, and should be avoided. They are much lessened by widening the open base of the cone; but they may be further diminished by several other expedients, as exemplified by the instruments exhibited, the most convenient of which is obliquely truncating the cone, leaving open half or more of its length. In so doing the instrument has an obvious resemblance to the ears of many quadrupeds, and probably this form is wisely designed to aid their hearing without the confusing noise of mere tubes and cavities. Perhaps, too, the hair with which the ears are fringed may subserve a like purpose, from which a hint may be taken if required.

After the reading of the paper, Dr. Williams exhibited and explained various forms of stethoscopes and ear-trumpets. Acoustics had been studied more in relation to musical notes than to common sounds, which could be understood much better by bearing in mind the definition which he had formerly given of sound, as *motion of a certain force resisted by a certain force*. The moving and resisting forces, acting alternately in opposite directions, constitute the vibrations of sound. These are best produced and conducted in hard, rigid bodies; but the conduction of sound is favoured also by similarity in density: thus a solid transmits its vibrations most powerfully through a rigid solid of the same density, and much less freely through air. The sounds of air but feebly affect dense solids, such as metals; in fact, they are reflected by them—turned away. But a solid of less density and great rigidity, such as wood, transfers vibrations more freely from metal to air and from air to metal, as exemplified by the tuning-fork on a sounding-board; and this property renders wood the best material for stethoscopes, which have to transfer sounds from the chest, generated both in air and in solids, to the solid structures of the ear. But it transfers the aërial chest-sounds still more perfectly through the column of air contained in the stethoscope, which thus becomes a sounding-board conductor, which, through the rigidity of its walls and the lightness of its mass, is sensitive to receive and faithful to transmit the weakest vibrations. To exemplify these remarks the following stethoscopes were shown, with comments:—Solid perforated cylinders, introduced by Laennec (one actually made and used by him): too heavy and clumsy, and not well fitting the ear or the chest. Unperforated cylinders: inferior in conducting power for breath- and voice-sounds. Piorry's slender stethoscope, with ivory cap and pleximeter: too small at pectoral end, and ivory screws troublesome and impair conducting power. Modification of the last, made all of wood, with a larger conical end, with cap and stopper to fit without screws: a good instrument. A similar one, with a hole in its side to show that opening the column of air impairs the conducting power, closing the hole restores it. Another instrument of this shape had a drum of thin indiarubber at its pectoral end; this, by preserving air-tight the enclosed column of air, enabled it to conduct sounds well, without complete contact, as on the ribs of very thin patients. The thin indiarubber water sac of Dr. Scott Alison is useful for a similar purpose with any stethoscope, by increasing the contact and conducting power for thin subjects, or even when applied outside the garments. Trumpet-end stethoscopes in wood and ebonite, either made in one piece (which may be carried in the hat), or with the ear end to take off and fit into the chest end, making it thus strong and portable for the pocket (supplied by the Indiarubber, Guttapercha, and Telegraph Works Company at Silvertown). These are the last devised, and recommended by Dr. Williams. A binaural stethoscope constructed by Dr. Williams thirty years ago was also shown, made of wood with metal tubes to each ear; it was found to convey the sounds from the chest with exaggerated loudness, but, being quite inflexible, it was awkward for application. The double stethoscope of Dr. Leared, shown at the International Exhibition of 1851, was a great improvement in being flexible, and fitting to the ears with a spring. The binaural and differential stethoscopes of Dr. Marsh and Dr. Scott Alison seemed to promise still further advantages to those whose hearing is equally good in both ears—a capacity which a great many do not possess. But of all these instruments, and of most long flexible stethoscopes, it may be said that although some sounds are exaggerated, others are impaired, and there is not that clearness and simplicity

which we hear in the sounds transmitted through the short wooden or ebonite instruments. With respect to ear-trumpets, Dr. Williams requested the members to try some of those in common use, of which several good specimens were before them, kindly lent by Messrs. Coxeter and Messrs. Weiss. The long flexible ear-tube answered perfectly well for a *tête-a-tête* conversation with a deaf person; but the ear-trumpets to be used in society or in public assemblies all had more or less of the roar of reverberation, drowning and confusing articulate sounds. Of the wide conical ear-trumpets, in which Dr. Williams had attempted to obviate this, one was made of japanned tin-plate, with eight or ten small holes in its sides to give vent to the transverse vibrations. This expedient was partially successful, the roar being slight and the magnifying power about ten times—that is, the ticking of a clock would be heard at ten times the distance at which it would be heard with the unaided ear. A longer cone of stiff paper, terminating in a short ear-piece of metal, was still more free from roar, and magnified the sound twelve times. This was the most successful of all the ear-trumpets. A third and smaller cone, of gutterpercha, had two diaphragms of stiff paper crossing in the centre and running in the axis of the cone, also to stop the transverse vibrations, which they did in great measure, the magnifying power being eight times. Lastly, a cone of ebonite, twelve inches long, truncated obliquely to half its length, magnified ten times, with only a slight roar excited by loud sounds. This last Dr. Williams considers likely to be the most practically useful instrument, and it may be improved by opening still further the cone to two-thirds of its length, which would make it still more like the ears of animals. Taking these for models, and avoiding as much as possible tubes and cavities, which are the cause of the confusing reverberation, we may hope to get means to aid the failing hearing in some measure as we do the failing sight. In reply to Dr. Leared, Dr. Williams said that he thought that the power of double stethoscopes to increase the sound more than single ones was of the same kind as that of binocular telescopes and microscopes, by impressing a larger surface of sensation.

CLINICAL SOCIETY.

FRIDAY, OCTOBER 24.

PRESCOTT HEWETT, F.R.C.S., President, in the Chair.

BEFORE commencing the business of the meeting, Sir W. GULL took occasion to give expression of his regret at the lamented death of Dr. John Murray. In this the President amply concurred, and expressed a desire that the sympathy of the meeting should be conveyed to Dr. Murray's friends.

Dr. THEODORE WILLIAMS introduced Dr. Guinier, of Montpellier, who wished to demonstrate on his own person to the Society a new and effective method of Gargling. Dr. Williams stated that the chief features in which this method differed from the ordinary one were—1st. That the head, instead of being thrown far back, is only slightly inclined. 2ndly. That respiration is impossible during the operation, and that all that can be effected is a single expiration. 3rdly. That deglutition is almost absolutely controlled. 4thly. That the soft palate is drawn high up, and that the liquid used for a gargle, passing the epiglottis, enters the larynx, penetrating as low as the vocal cords.

Dr. GUINIER then, by the aid of the laryngoscope, demonstrated his method of gargling, and showed the water lying in the upper portion of the larynx and the white vocal cords shining through it. He also displayed in a beautiful manner the various acts of vocalisation, and gave explanations as to the plan by which he had educated his throat to these movements, the great point being the articulation of certain vowels, such as "oe," before gargling. He thanked the Society much for the kind attention they had given him, and hoped that in a future year he should be able to make a further demonstration.

Dr. LIVEING said he had often pointed out to his pupils that the uvula was less sensitive than the neighbouring mucous membranes.

Mr. PUGIN THORNTON asked what gargles had been found useful. An experiment had been made to demonstrate the fact that in ordinary gargling the fluid reached the surface of the larynx. It was this: First of all a gargle containing tannin was used, and afterwards iron applied by a brush, when it was seen that the larynx was blackened.

Dr. B. YEO doubted if the noise produced was due to the cause described. It was rather due to the passing of air through the fluid. Early training was most important in learning how to raise the soft palate.

Dr. THEODORE WILLIAMS, in replying for Dr. Guinier, said his method of gargling needed considerable practice to acquire, but that at Cauterets, where Dr. Guinier was physician, it was carried on on a large scale, and that young women, and even children, could manage it after a time. The liquid generally used was the water of the sulphurous springs.

Sir WILLIAM GULL read a paper on Anorexia Hysterica (Apepsia Hysterica). He introduced the subject by stating that in the Address on Medicine delivered at the meeting of the British Medical Association at Oxford in August, 1868, and published at the time in the medical journals, he had referred to a form of disease occurring mostly in young women between the ages of fifteen and twenty-three, and characterised by extreme emaciation, and often supposed to be due to latent tubercle, mesenteric disease, or so-called atrophy. This state he purposed at the time to call *apepsia hysterica*, and added in a note appended to that address—"I have ventured to apply this term to the state indicated, in the hope of directing more attention to it." In the paper now brought forward the word *anorexia* had been preferred to that of *apepsia*, as more fairly expressing the facts, since what food is taken, except in the extreme stages of the disease, is well digested. Dr. Laségue, of La Pitié Hospital, Paris, in April last published remarks on this state (translated into the *Medical Times and Gazette* of September last), which he also called *anorexia hysterica*. Dr. Laségue seems not to have known of the reference to this morbid condition which was made by the author of the paper at the time named; therefore Dr. Laségue's observations are the more confirmatory, having been made from an independent point of view. The author believed that the want of appetite was due to a morbid mental state. He had not observed in the special cases in question any gastric disorder to which the want of appetite could be referred. He believed that the origin was central, not peripheral. It was notorious that certain mental states were apt to destroy the appetite, and it would be admitted that young women of the ages named were specially obnoxious to mental perversity. We might call the state hysterical without committing ourselves to the strict etymological value of the word, or maintaining that the subjects of anorexia hysterica had any of the common symptoms of hysteria proper. The author then gave details of two well-marked cases of this malady, with photographs of the patients in the stage of extreme atrophy, and after they had recovered their weight and strength. In the starvation stage, when the patients were for the most part brought for advice, all the functions were found to be below the normal standard, but otherwise normal. Temperature half a degree to a degree below normal; respirations 12; pulse 56 to 60. An examination of the viscera of the chest and abdomen discovered nothing texturally abnormal. In fact the clinical characteristics were those of starvation only, without any signs of visceral disease. It was remarkable how long this condition often continued, and with how little change in the vital functions, the pulsation and respirations remaining at the low standard named for a year or two or more. Such patients, though extremely wasted, complained of no pain, nor indeed of any *malaise*, but often were singularly restless and wayward, if the prostration had not reached its extremest point. In one case only had a fatal issue occurred, though sometimes the exhaustion was so great as to make possible recovery seem very doubtful. In this fatal case, thrombosis took place in the femoral veins, the patient became feverish and died. Death followed from the thrombosis and the starvation only. The post-mortem examination discovered no tubercular nor other lesion. The author insisted that the diagnosis of these cases was to be made from the slowness of the pulse and breathing, from the slightly depressed temperature, and the absence of any sign of visceral disease in the chest and abdomen, whilst the emaciation was explicable by the fact of chronic starvation. In reference to treatment he contended that the patients require meral control, and that, if possible, a change in the domestic relations should be made. That from the beginning food should be given at short intervals, and that patients should not be left to their own inclinations in the matter. If the exhaustion had reached an extreme

point, then it might be necessary to apply external heat to the body, as well as to administer food; as Chossat had long ago shown that starved animals, when the inanition was extreme, could not digest food without the aid of external heat. One of the best ways of applying heat in such cases was that suggested by Dr. Newington, of Ticehurst, by an indiarubber tube, having a diameter of two inches and a half, and a length of about four feet. This tube, filled with hot water, and placed in the bed along the spine of the patient, is often of of great value. The author had not observed much advantage from the administration of drugs, whether tonics or alteratives. Believing the disease to be due to a want of mental equilibrium, he would rather trust to moral influences and to feeding than to medicines, though these might still be amongst the *adjuvantia*.

Sir William Gull further read some remarks on a Cretinoid State supervening in adult life in Women. The observations on this morbid state were made on five cases. In two of them they had extended over several years. He had not seen the disease in men. In four of the cases the changes named had begun between the ages of forty and fifty, in the fifth the history was not conclusive as to how far it might not have existed to some extent in childhood. In one if not in two the malady began after the cessation of the catamenial period, and in two the catamenia still continued and were rather profuse. The morbid condition to which the author wished to call attention was a general and gradual increase of bulk throughout the frame; but especially the outline of the face was changed from oval to round, or became somewhat oval transversely, like the refracted disc of the moon at rising. The complexion was soft and fair; the skin presented a peculiarly smooth and fine texture, which had a porcellanous aspect; the cheeks were tinted of a delicate light rose-purple. The cellular tissue under the eyes became loose and folded, and that of the neck and under the jaws thickened; the lips were large and thick, and of a rose purple; alæ nasi thick. The distance between the eyes appeared disproportionately wide, and the root of the nose depressed; this change gave the face a flattened, broadened character, which was quite peculiar, the whole expression being at the same time gentle and placid. The tongue grew broad and thick, the voice was guttural, and the pronunciation clumsy, as if the tongue were too large for the mouth. The hands had undergone a characteristic change, and became broad, thick, and spade-like, from thickening or infiltration of tissue. With this change in the face, tongue, lips, and hands, there was gradually increasing languor and disinclination to exertion; and the mind, from being active and inquisitive, assumed a placid and lazy indifference, with a liability to occasional outbreaks of temper. The intellect remained unimpaired. The integuments of the chest, abdomen, and upper and lower extremities were loaded with subcutaneous fat. A cursory aspect of one of these cases without any previous experience of its peculiarity would have led to the suspicion of some disease of the heart causing venous obstruction, or of a morbid state of the kidneys favouring œdema. Neither of these conditions was present in the cases under consideration. All the viscera were healthy. Although a large deposit of subcutaneous fat accompanied the changes named, the author contended that the mere condition of corpulency, obesity, or fatness would not explain the pathology of these cases. Common observation showed that in ordinary polysarcia there were no attendant changes which could be regarded as cretinoid. The author stated that his remarks on this state were rather tentative than dogmatical, but he believed that anyone who should observe the malady in question would regard it as substantive and definite, and as having special characters. That it was allied to the cretinoid state would appear from the facial expression, the changes in the tongue and hands, and the coincident change in the locomotive powers and in the mental activity. The author referred to Dr. Fagge's paper on "Sporadic Cretinism occurring in England." Dr. Fagge had cited a case beginning as late as the eighth year in a subject previously healthy and well-developed, and had speculated upon the possible supervention of the disease in the course of adult life. Rösch had recorded two instances of this disease beginning respectively at the ages of five years and between seventeen and eighteen. In the cretinoid condition in adults which the author had seen, the thyroid body was not enlarged in four cases, but from the general fulness of the cutaneous tissues in the neck he was not able to say whether the thyroid was wasted or not, as Dr. Fagge had found it to be in cases of sporadic congenital cretinism; nor was the author able to determine the presence of the supra-clavicular masses of fat outside the sterno-cleido-mastoid muscles first described by Mr. Curling, and specially noticed by Dr. Fagge as occurring in congenital sporadic cases. The author added that such masses of supra-clavicular fat in the lower triangular space of the neck were not infrequent in the adult, without any associated morbid state whatever. When the change which the author had described as occurring in adults had begun, so far as his limited experience went, it continued. Some advantage seemed to be derived from baths and frictions, fresh air and change of place—from such means, in fine, as stimulated the nervous system and quickened the peripheral venous circulation; but the results were very limited. This was specially shown by comparing two clinical reports made of the same case at an interval of seven years. The details singularly coincided, showing how little change had occurred in that time.

Dr. Quain said he had long been familiar with the form of disease described by Sir William Gull, and he had seen several like cases. He doubted the propriety of regarding them as hysterical. He related a very remarkable and typical case—that of a young lady, in whom there gradually came on such a distaste for food that it ultimately became an absolute loathing. She was quite willing to do all she could for her benefit, but food she would not take. At last she became so exhausted that she was more or less unconscious, and she could scarcely move her limbs. She then more resembled a dried mummy than a living being. Life was maintained by essence of meat disguised as medicine, and brandy mixture. She finally recovered, and was now in good health. Dr. Quain could not help thinking that there was some morbid state of the gastro-intestinal mucous membrane which led to this distaste for food. He mentioned a case in which the phenomena closely resembled those in the case already described. In the latter case, the reluctance to take food ceased after a spontaneous and copious attack of vomiting and diarrhœa. This patient passed through a tedious convalescence, but recovered, and is now alive and well.

Dr. Greenhow insisted on the importance of altering the surroundings in such cases. In one instance he caused the patient to be moved to another house, and she speedily improved. Her relations were of unsound mind. In another case, where the patient's mother was of unsound mind, and who fell into such a state, he caused the residence to be changed, and she soon began to improve. This, he was sure, was the real treatment.

Mr. B. Carter said that twenty years ago such cases were sent to Mr. Mackenzie, whose practice he had seen, and whose principles he had set forth in a little book many years ago. In some instances the patients desired to raise sympathetic feelings, and occasionally, to make the idea of food horrible to them, raised some disgusting image to the mind. In one instance the image so conjured up was putrid cat pudding.

Dr. Poore asked if there were any symptoms proper to starvation in Sir William Gull's case. Thus the Welsh fasting girl became restless and sleepless; the pulse and temperature rose as soon as she could get no food.

Dr. Symes Thompson said it was difficult to draw the line between such cases and real insanity. He remembered one such case where there was some doubt as to sending the patient to an asylum; however, she was sent and improved greatly, but was unfortunately removed and in no long time starved herself to death.

Dr. Greenhow explained that in both his cases there was restlessness at night, but no mental disturbance.

Dr. Williams asked, inasmuch as the mental rather than the bodily condition seemed at fault, would not forcible feeding do good?

Mr. Smith referred to a case in which signs of insanity began by a great repulsion to the Bible; when this passed away the same kind of feeling came on as regards food: when food was left in her way the patient destroyed it.

Dr. Edis said that when he was at Ticehurst a young lady came under treatment who had suffered the loss of a very dear relative. She refused her food, and no amount of coaxing could get her to take it. They used beef-tea enemata for a time, and in a short time she began to improve and left quite well.

Sir W. Gull, in reply, referring to the question of hysteria, said there was perhaps no great amount of hysteria, but it could hardly be called insanity. In one case the patient afterwards suffered from hysterical pain in the hip. We could not always send these patients from home. He doubted if the

mischief was peripheral, he rather thought it central. As to the Welsh fasting girl, she died of urinæmia, seeing she got no water, and not of starvation.

OBITUARY.

JOHN BUTTERWORTH WALKER, M.R.C.S.

Mr. J. B. Walker, aged 58, died at his residence, in Clifton-gardens, Maida-hill, on Saturday last, November 1, from acute pneumonia, after only a week's illness, during which he was attended by his friends Dr. Sieveking and Mr. Bullock (of Great Cumberland-place). Mr. Walker was the son and only child of Mr. John Walker, a gentlemen of good fortune, who resided for many years at Sydenham, and latterly in Stamford-street, Blackfriars-road. He pursued his medical studies at King's College, and also at St. Thomas's Hospital, where he became a dresser under the late Joseph Henry Green. At the Hospital he was always attentive to his duties, and, by his kindness to the patients and general amiability, became a favourite both with his master and fellow-students. He commenced practice at Iver, in Buckinghamshire, and married Miss Robinson, the step-daughter of Mr. Pennington, surgeon, of Needham Market, Suffolk. She died five years ago, leaving him with a family of ten children. Mr. Walker removed from Iver to London about twenty years ago, and for the last fifteen years resided in Clifton-gardens. In this wealthy district of London he had a good practice, and a large circle of friends, including many leading members of the profession. His genial character, kindness of heart, and amiability endeared him equally to all his friends and patients, and his gentlemanly bearing and high sense of honour added greatly to his social character and position. His eldest son, Mr. Robert Walker, pursued his medical studies and distinguished himself at St. Mary's Hospital, and was amongst those selected to join the surgical staff in the late Franco-German war. The honorary distinction of the Cross, for merit, from each country he recently received. He has for some time been engaged in assisting his father in his practice, to a large share of which he will in all probability succeed.

F. CRACE CALVERT, M.D., F.R.S.,

Died on the 24th ult. at his residence, Clayton-vale, Newton-heath, Manchester. He was seized with typhoid fever during a visit to the Vienna Exhibition last July, and his condition was aggravated by ulceration of the lungs, which was the cause of death. He was Professor of Chemistry at the Manchester Royal Institution. As an analytical chemist, Dr. Calvert has long had a more immediate professional connexion with Manchester, but his research has made him known to scientific men throughout the world. His doctor's degree was sent him by the late Baron Liebig. He was a Fellow of the Royal Society of England, a Fellow of the Chemical Society, and an Honorary Fellow of the Chemical Society of Paris. He was also a member of the Royal Academy of Turin, and of the Imperial Academy of St. Petersburg. He went to Manchester from France in 1846. He then received the appointment of Honorary Professor at the Institution in Morley-street. Dr. Calvert was a favourite pupil of Chevroul at Paris, and had previously studied chemistry under Girardin, at Rouen. Dr. Calvert was born in London. He was the son of Colonel Crace, a gentleman of fortune, who took his wife's name on his marriage. Hence the compound name borne by their son—Frederick Crace Calvert—who has died at the early age of fifty-four. He was married to a French lady, and they had one child (a son), who died in early youth.

JOHN ELDON YOUNG, M.D., Surgeon-Major of the 18th Foot,

Died on the 26th ult. at Gosport, in his 44th year. He entered the service October, 1853, became Surgeon in May, 1863, and Surgeon-Major. Served at the siege and fall of Sebastopol in 1854-55—medal with clasp, and Turkish medal.

Royal College of Surgeons, Ireland.—We understand that the dignity of President of the College for the ensuing year will be conferred upon Mr. Joliffe Tufnell, Surgeon to the City of Dublin Hospital; and that the Vice-Presidency will probably be offered to Mr. H. G. Croly, of the same Hospital.

MEDICAL NEWS.

Royal College of Physicians of London.—The following gentleman, having passed the required examinations, was admitted a Member on October 30:—

Morris, Beverley Robinson, M.D. Dublin, Nottingham.

The following gentlemen were admitted Licentiates of the College:—

Dawes, Richard St. Mark, 19, Lanark-villas, W.
Head, Robert Turner, East Grinstead.
Hills, Thomas Hyde, Maidstone.
Lattey, Walter, Southam, Warwickshire.
Mackinlay, James Egan Harrison, 7, Earl's-terrace, W.
Nunn, Philip William Gowlett, 14, Vale-place, W.
Ranford, Thomas Davis, Guy's Hospital, S.E.
Sherwood, Arthur Paul, 25, Edwardes-square, W.
Warden, Charles James Hislop, 21, Westmoreland-place, W.

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on obtaining a qualification in Surgery recognised by this College:—

Nunez, San José de, Costa Rica.
Parakh, Dhanjioha Navroji, 201, Euston-road, N.W.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, October 30:—

Bailey, James Johnson, Stockport.
Lyddon, John Henry, Chatham.
Robbins, Henry John, Aldeburgh, Suffolk.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Buchan, Charles Forbes, M.B., M.S.—Medical Officer f No. 2 of Bridgwater Union.

Burman, J. Wilkie, M.D.—Medical Superintendent of the Wilts County Asylum, Devizes, *vice* the late Dr. Thurnam.

Grier, Charles, L.R.C.P., L.R.C.S.I., L.A.H.—Honorary Medical Officer to the Bristol Hospital for Sick Children.

Johnson, Sydney, M.B., M.C., of Dalton—Medical Officer of Health for Dalton-in-Furness.

Orwin, Arthur Wigelsworth, M.R.C.S. Eng., L.R.C.P., and L.M. Edin.—Resident Medical Officer to the Guest Hospital, Dudley, *vice* Llewelyn Thomas, resigned.

Pigeon, Henry, L.R.C.P., M.R.C.S. Eng., L.M.—Honorary Medical Officer to the British Hospital for Sick Children.

Tichborne, Charles R.C., F.C.S., M.R.I.A.—Lecturer on Chemistry at the Carmichael School of Medicine, Dublin.

NAVAL APPOINTMENTS.

Admiralty.—Dr. John H. Pemberthy, Surgeon to the *Zephyr;* Dr. George Robertson, Surgeon to the *Excellent;* Thomas H. Atkinson, Surgeon to the *Hibernia;* Francis J. A. Waring, Surgeon to the *Boscawen;* Edmund A. Lucas, Surgeon to the *Lord Warden*, additional, for disposal; William C. Sandys and Alfred N. Kelly, Surgeons to the *Iron Duke*, additional for disposal.

BIRTHS.

Brown.—On October 23, at 1, Bartholomew-road, Kentish Town, the wife of Andrew Brown, L.R.C.P. Edin., L.R.C.S., of a daughter.

Dalzel.—On October 30, at 40, Kensington-park-gardens, the wife of Surgeon-Major W. F. B. Dalzel, M.D., late Bengal Army, of a daughter.

Kavanagh.—On November 2, at Ierne House, Wickham-road, Lewisham-road, S.E., the wife of P. Kavanagh, M.D., L.R.C.S.I., L.S.A., of a daughter.

Littlejohn.—On November 2, at 24, Royal-circus, Edinburgh, the wife of H. D. Littlejohn, M.D., L.R.C.S., of a daughter.

Slade.—On October 28, at Puddletown, Dorchester, the wife of R. Slade, M.R.C.S. Eng., L.S.A., of a son.

MARRIAGES.

Hunter—Norton.—On October 30, at St. Mark's, Surbiton, Alexander Hunter, Captain 101st Royal Bengal Fusiliers, eldest son of the late James Hunter, M.D., of Bryansford, co. Down, to Lorina Emily, youngest daughter of the late Edmund Norton, Esq., of Lowestoft, Suffolk.

Milne—Garstang.—On October 30, at Holy Trinity Church, Dobeross, Manchester, John Milne, Esq., of Liverpool, to Marian, only daughter of Walter Garstang, M.D., M.R.C.S. Eng., L.S.A., of Dobeross.

Powell—Bennett.—On October 30, at Mountfield, R. Douglas Powell, M.D., F.R.C.P., of Henrietta-street, Cavendish-square, eldest surviving son of the late Captain Scott Powell, formerly 23rd Royal Welsh Fusiliers, to Juliet, younger daughter of Sir John Bennett, of The Banks, Mountfield, Sussex.

Pullan—Wright.—On September 20, at St. Mary's Church, Poona, Captain Ayrton Pullan, Bengal Staff Corps, to Janet Frances, daughter of Alexander Wright, Esq., Surgeon-General Indian Medical Department.

Sankey—Thorne.—On November 4, at the parish church, Kensington, Julius O. Sankey, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., the Turl, Oxford, youngest son of the late Rev. R. Sankey, rector of Witney, to Agnes Emma, youngest daughter of T. H. Thorne, Esq., of Leamington.

DEATHS.

BLAND, CORNELIUS, L.S.A., at Winchester-street, Pimlico, on October 29, aged 63.

CUTCLIFFE, HENRY CHARLES, F.R.C.S., Acting Professor of Surgery Medical College, Calcutta, at Calcutta, on October 21, aged 41.

HUNT, MARIA HARRIETT, wife of Henry Hunt, F.R.C.P. Lond., of 3, Brook-street, Hanover-square, and Shermanbury Place, Sussex, on October 29.

LOVE, GILBERT, M.R.C.S. Eng., at Wimbledon, on October 29, aged 53.

MILBURN, JOHN T., M.R.C.S. Eng., Surgeon half-pay, late 10th Hussars, at Crawcrook, Ryton-on-Tyne, on October 28.

SMITH, ROBERT W., M.D., F.R.C.S.I., M.R.I.A., Professor of Surgery in Trinity College, Dublin, and Vice-President of the Royal College of Surgeons, Ireland, at Eccles-street, Dublin, on October 28.

SQUIRES, CATHERINE JANE, wife of Wm. W. Squires, M.D., M.R.C.S., at Hardy-street, Nelson, New Zealand, on August 20, aged 24.

YOUNG, JOHN ELDON, M.D., L.R.C.S.I., L.A.H., Surgeon-Major H.M. 18th (the Royal Irish) Regiment, aged 44.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Candidates must be Members of one of the Colleges of Surgeons of Great Britain or Ireland. Applications, with testimonials, to the Chairman of the Committee, on or before November 15.

BRISTOL ROYAL INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before November 20.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Assistant-Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before November 12.

HOUSE OF CORRECTION, WANDSWORTH-COMMON, SURREY.—Surgeon. Candidates must be duly qualified. Personal applications to the Governor between November 8 and 11, between 11 a.m. and 2 p.m.

METROPOLITAN DISPENSARY AND CHARITABLE FUND.—Physician. Candidates must possess a Diploma from a British University, and also be Fellows or Members of the Royal College of Physicians, London, or undertake to become so within six months after election. Applications, with testimonials, to the Secretary, before November 15.

RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY.—Resident Medical Officer. Candidates must be doubly qualified and registered. Applications, with testimonials, to the Secretary, 13, Cavendish-street, Ramsgate, on or before November 9.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, of whom particulars may be obtained.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WESTMINSTER HOSPITAL.—Assistant-Surgeon. Candidates must be F.R.C.S. Eng., and must attend at the Hospital with their testimonials on November 11, at 1 o'clock p.m.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Chippenham Union.—Dr. Kitchener has resigned the Pewsham District; area 3566; population 1679; salary £18 3s. 4d. per annum;—and the Workhouse, salary £50 per annum.

Drayton Union.—Mr. Thos. Roberts has resigned the Fifth District; area 11,201; population 2480; salary £21 per annum.

West Derby Union.—Mr. J. W. Warburton has resigned the Township of West Derby; salary £125 per annum.

APPOINTMENTS.

Bideford Union.—John Thompson, M.D. St. And., F.R.C.S. Eng., L.S.A., to the Bideford District.

Boston Union.—Wm. H. Radley, M.R.C.S. Eng., L.S.A., to the Boston District and the Workhouse.

Great Ouseburn Union.—Tertius D'Oyley Pain, L.S.A., to the Tollerton District.

Narberth Union.—Hugh P. J. Price, M.R.C.S. Eng., L.S.A., to the Third District.

North Bierley Union.—Philip E. Cogan, M.D. and M.C. Queen's Univ. Dub., to the Ninth District; Wm. R. Maekley, M.R.C.S. Eng., L.S.A., to the Thirteenth District.

PROFESSOR FLOWER, F.R.S.—This gentleman, whose illness we have already noticed, left England on Thursday last for an extended sojourn in the East, carrying with him the sincere wishes of his numerous friends for a return in perfect health.

MUNICIPAL HONOURS.—Mr. John Frankerd, F.R.C.S., has just been elected mayor of the ancient borough of Langport, Somerset, for the fourth time.

THE Liverpool Town Council have resolved to take measures for the compulsory purchase of a site at Bromborough for a cholera hospital.

DR. JOHN M. COLEMAN, of Wolverhampton, has been presented with a very handsome timepiece by the members of the Queen Adelaide Lodge of the Loyal Order of Odd Fellows, to which he is medical officer.

SMALL-POX has broken out near Cape Town, but the precautions taken lead to the hope that the disease will not become epidemical.

THE hospital erected at Dingwall, Inverness, as a memorial to the late Dr. Ross, of Dunglust, was formally opened on the 25th ult.

ASSISTANT-SURGEON HARRY LEACH, 1st Brigade Kent Artillery Volunteers, passed the requisite examination prescribed by the Army Regulations for the Reserve Forces on October 22 last, and received a certificate of proficiency.

ROYAL COLLEGE OF SURGEONS.—The primary (or anatomical and physiological) examinations for the diploma of Membership for the present session commence this day. At present the number is rather below the average. The "pass," or surgical, pathological, and medical, will commence on Friday next; and the primary Fellowship examination on Saturday, the 22nd, and the "pass" on Thursday, the 27th instant.

PRESENTATION.—On Thursday last Dr. Fitzgerald, of Folkestone, was presented by his patients with a very handsome and gratifying testimonial, which, in deference to his well-known musical tastes, most appropriately took the form of a magnificent walnut-wood grand piano, by Collard and Collard. It was accompanied by a beautifully illuminated address (the work of one of his patients), containing the names of the subscribers, and stating that the instrument was presented to him by a few of his patients and friends, as a mark of their high esteem and regard.

CLINICAL SOCIETY OF LONDON.—On Friday, the 14th inst., at 8.30 p.m., the following papers will be read:—Dr. G. Johnson, "On Cases of Poisoning by Homœopathic Concentrated Solution of Camphor;" also, "On Cases of Temporary Albuminuria, the result of Cold Bathing." Dr. Anstie, "A Remarkable Case of Death from Meningeal Congestion without any Inflammation." Mr. Henry Arnott, "On a Case illustrating Esmarch's Method of Controlling Hæmorrhage in Operations by Elastic Bandaging."

YELLOW FEVER IN AMERICA.—"A gratifying decrease," says a correspondent of the *Times*, writing from Philadelphia on the 21st ult., "in the number of cases of yellow fever, in consequence of the cold weather, is reported from Memphis. The daily death-rate is down to twenty to twenty-three, and the streets are said to present a more animated appearance than for a month, there being many signs of a revival of business activity. Over 1500 deaths have occurred since the fever began its ravages. At Montgomery, Alabama, the deaths from yellow fever average three daily; at Columbus, Texas, five daily."

UNIVERSITY OF DUBLIN.—On Saturday, the 1st inst., the Board of Trinity College, pursuant to advertisement, elected three examiners in arts, who will be members of the Conjoint Examining Board for Ireland, under the Medical Act of 1858. The examiners appointed were the following:—In Mathematics: Robert Stawell Ball, LL.D., Professor of Applied Mathematics, Royal College of Science, Dublin. In Classics: John William Moore, M.D., F.K.Q.C.P.I., ex-Scholar of Trinity College, Dublin. In English: Edward Dowden, M.A., Professor of Oratory and English Literature in the University. The Professorship of Surgery, vacant by the death of Robert W. Smith, M.D., will be filled up on this day (Saturday, November 8).

DEATH OF AN OLD COLONIST.—The Wellington (New Zealand) *Post* of August 6 says:—"Another old settler (Dr. Knox) died in the hospital at the age of 82 years. Dr. Knox arrived in this colony some thirty-two years ago, and after various changes at last settled down in the Porirua district, where he practised his profession and acted as coroner, until failing health a few weeks ago compelled him to seek refuge in the hospital in order to obtain proper medical attendance and nursing. In early life Dr. Knox was demonstrator of anatomy to his brother, the celebrated Professor Knox, whose name became so familiar in connexion with the Burke and Hare cases. During his residence in this colony Dr. Knox pursued his scientific studies with unwearied diligence, and to his knowledge of anatomy the Colonial Museum is greatly indebted for many interesting exhibits. The *Transactions of the New Zealand Institute* have also been enriched by many valuable contributions from his pen. He was an especial authority on all questions regarding the Cetacea family, and his residence at Porirua afforded him many opportunities for pursuing this branch of scientific inquiry."

THE Quarterly Return of Deaths by the Registrar-General, ending September 30 last, states that in the third or summer quarter of this year 114,343 deaths were registered. The annual death-rate was so low as 19·4 per 1000, and 2 per 1000 lower than the average rate in the corresponding quarters of the ten years 1863-72. The death-rate last quarter was lower than in the corresponding period of any year since the remarkably cold and wet summer of 1862, when the deaths were equal to but 18 per 1000 annually of the population. Had the death-rate last quarter been equal to the average rate in the ten last summers, nearly 12,000 more persons would have died than those whose deaths were actually recorded. A very large proportion of this decrease in the number of deaths was due to the continuance of a marked decline in the fatality of the principal zymotic diseases. The 114,343 deaths registered in the whole of England and Wales included 35,252 or 30·8 per cent. of infants under one year of age, and 24,524 or 21·4 per cent. of persons aged sixty years and upwards. During the three months ending September last 277 deaths were reported from small-pox, 1180 from measles, 2593 from scarlet fever, 502 from diphtheria, 1666 from hooping-cough, 3053 from different forms of fever, and 13,925 from diarrhœa; in all 23,196 deaths resulted from these seven principal zymotic diseases, against 33,963, 31,388, and 27,428 in the corresponding quarters of the three years 1870-71-72.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN OCTOBER, 1873.—The following are the returns (by Dr. Letheby) of the Society of Medical Officers of Health:

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	—	—	—	—	—	—
West Middlesex	17·11	0·018	0·083	0·001	13·8	3·3
Southwark & Vauxhall	17·97	0·053	0·086	0·002	14·0	3·3
Chelsea	18·00	0·058	0·088	0·001	14·2	3·3
Lambeth	18·10	0·044	0·091	0·002	14·3	3·3
Other Companies.						
Kent	28·69	0·013	0·249	0·000	21·8	5·9
New River	17·61	0·027	0·110	0·001	14·0	3·3
East London	18·67	0·040	0·125	0·001	14·8	4·0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was very slightly turbid—namely, in those of the Southwark and Vauxhall, the Chelsea, and the Lambeth Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 118,874,212 gallons; and the number of houses supplied was 505,295. This is at the rate of 35·4 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 24·9 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

The returns of the Grand Junction Company have not been received.

OPIUM SMOKING.—Daily observation in hospital and dispensary practice during the past eight years, as well as attentive scrutiny of the health of opium smokers in all classes of society, abundantly proves to my mind the deleterious influence of opium smoking on health, and the serious effect it has on longevity. Its effects on the constitution, as I have observed them, appear to be—in the earlier stages, sluggish liver, obstinate constipation, irritable stomach, loss of appetite, and, generally speaking, impaired nutrition; later on, when the quantity of opium smoked is large, there is an enervated condition of the whole system, constant epigastric uneasiness, total loss of appetite, great attenuation, and general debility. The effects of the drug are modified by the circumstances of the individuals. It is amongst the poor labouring class of people that its most pernicious results are found. A working man who smokes opium has frequently to stint himself of the common necessaries of life; the consequence is, rapid deterioration of health and loss of muscular power. He becomes unfit for the usual amount of work, and the little he earns is spent on opium. Very soon he gets into a state of utter destitution. It is somewhat different in the case of those in comfortable circumstances who do not require to undergo manual labour. The deterioration of health in their case is more gradual, although none the less certain. For the first few years, when the consumption is small, they only experience the minor discomforts of disturbance of the digestive organs and loss of tone; but later, when the quantity consumed is large, the victim becomes enervated and emasculated, and suffers from general atrophy. The testimony of intelligent smokers as to the influence of the drug on the sexual appetite, is, that in the earlier stages, when very little is smoked, it excites desire; later on, when the system becomes enfeebled from excessive use of opium, impotence results. Women, too, who become confirmed opium smokers, are, as a rule, barren. I cannot speak with certainty as to the alleged influence of opium smoking in preventing disease, but judging from the large number of opium smokers amongst the patients in hospital and dispensary practice, I am rather inclined to believe that instead of giving immunity from disease, it rather predisposes to it. However that may be, there can be no doubt as to the influence it has in weakening the natural powers of the constitution in resisting disease. This is especially manifest in such diseases as dysentery, fever, hæmorrhage, and shock after surgical operations, in all of which the mortality among opium smokers is very great.—*Report of the Chinese Hospital at Shanghai, by Dr. James Johnson*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

P. O. S.—The session of the Royal Society will open on the 20th inst.

G. N. N. W.—Under consideration.

M.D., Adelaide, S.A.—Thanks for your favourable opinion; your letter has been handed to the publishers, by whom the back numbers will be sent next mail.

A Navy Surgeon.—The total invested funds of the Royal Naval Benevolent Society, according to the last report, was £44,502 8s. 7d.

Vincent F.—Yes; the late Sir Henry Holland compiled one of the series of County Reports then in course of production under the Board of Agriculture. It was published in 1807, and related to his native county—Cheshire. Sir Henry was but eighteen years of age, and he received £200 for it.

Ashantee, Southampton.—Messrs. Bell, of Oxford-street, have introduced a most useful and compact little pouch, not larger than a pair of stockings rolled up, and yet it contains two bandages each six yards long, water-proof lawn, lint, neat little box containing a roll of adhesive plaster, corium (lamb-skin), and envelopes containing indiarubber court plaster and gold-beater's skin. You will find it an admirable travelling companion. Take also one of Atkins' pocket filters, notwithstanding the large number already supplied by order of Government for the troops.

Corrigendum.—In the Paris letter which appeared in the *Medical Times and Gazette* of October 18, page 449, second column, thirty-second line, *for* "pathological dross" *read* "pathological drop."

ECONOMIC SCIENCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Medical Times and Gazette* of October 18 occurs the sentence "Medicine no longer gives riches." If this be true, medical men should economise. Perhaps the result of an experiment I lately made with coals might prove of interest to some members (especially the young married ones) of our profession. Of a respectable neighbouring coal merchant I bought a quantity of the highest-priced and lowest-priced coals, the latter being denominated "nuts," the price of the one being (about a month since) 39s., and the "nuts" 28s. per ton. I measured and burned a given proportion of each coal on two consecutive days, each day being calm with little wind; thermometer standing at 57°, which was suspended from the ceiling, hanging five feet from the grate and four feet from the ground, the mercury turned away from the direct rays of the fire. The following was the result (fire lighted at 9 a.m.):—

Coals at 39s.	Thermom.	Coals at 28s.	Thermom.
10 a.m.	62 degrees.	10 a.m.	60 degrees.
11 „	66 „	11 „	64 „
12 noon	66 „	12 noon	67 „
1 p.m.	68 „	1 p.m.	71 „
2 „	68 „	2 „	74 „
3 „	68 „	3 „	68 „
4 „	65 „	4 „	67 „
5 „	62 „	5 „	67 „

"Nuts" are supposed to be the *small* coal of the better sort, and should contain no dust. The goodness of household coal depends on—1st, its heat-giving power; 2nd, durability; 3rd, cleanliness in burning. The "nuts" fulfilled the two first conditions, for when burning the thermometer went up 6° higher than when the other sort was burning, and the fire lasted an hour longer. On the other hand, the "nuts" gave a reddish-brown dust not found in the dearer coals. The dust was, however, heavy, and did not fly about the room. This extra dirt is the drawback, but when the hearth is, as it should be, swept three or four times a day, the affair is of small importance, compared with the advantage of getting coals 11s. per ton cheaper. The cheap coals I bought might have been exceptionally good—I do not know. All coals ought to be inspected before purchasing. They should be bought in summer after dry weather, when they are light. They should present a glistening appearance and be of convenient size (remembering the labour required to break large lumps), and should have

no dirt or slack. The slack of many coals burns well, as that of Whitehaven, but the buyer, if no judge, is better without it. If anyone choose to try "nuts," he must ascertain that they are the small pieces of a *superior* coal, and not dust and rubbish; and they must not be so small as to run through the bars of the grate. The present price of the coals I bought are respectively 42s. and 32s. per ton. I am, &c., A Bayswater M.D.

Mr. Balmanno Squire's Photographs of Skin Diseases.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I have long been so thoroughly imbued with the sentiments expressed in your advice to me in your notice of the "Photographic Clinique of the British Hospital for Diseases of the Skin" that I am desirous of explaining my apparent disregard of them in my choice of the cases represented in that publication. In my earlier student-days I was in the habit of deprecating the ardour of my fellow-tyros in giving, as they generally gave, special or even almost exclusive attention to "either very unusual or very intractable forms of disease." I was, and still am, in that respect, a follower of Bacon, and think that what is of the greatest practical use to the greatest number is the *summum bonum*. The "Photographic Clinique," I admit, does not wholly aim, in its limited sphere, at such a mark; but an attempt of the kind you advise had already been made in my "Coloured Photographs of Skin Diseases" some years since; and the sale of that work has sufficiently proved the justice of your remarks. The "Photographic Clinique," unlike its predecessor, is published for private circulation only, and those who were invited to subscribe were at the same time duly advised that any cases represented in that publication would be solely such as were "either very unusual or very intractable forms of disease." Your judgment is justified by the result, since the circulation of the "Photographic Clinique" has not equalled that of the "Coloured Photographs"; and this notwithstanding that they are, so far as I am able to judge, far superior to the illustrations presented in the "Coloured Photographs." Your flattering commendation of them is, however, ample amends for that; but I was already aware, from the circumstance I have referred to, that one must not stray too far from everyday life if the object in view be general utility. I am, &c., Balmanno Squire.

9, Weymouth-street, Portland-place, W., October 29.

A Doctor's Log.—No. VII.

(*Concluded from page* 456.)

February 17.—Preparing for the end of the voyage. Note that the strength has been 999 men, 60 officers, 141 women, 167 children; one birth, one death, one epileptic left at Malta. The hospital will be closed to-morrow. No sick, we trust, will be left in Bombay. Thirty-four men, twenty-two women, and sixteen children have either been in hospital or received extras, in addition to a number of men, women, and children attending. Sea-sickness, a heavy gale, rapid changes of climate, the heat of the Red Sea, must be taken into consideration. The baggage brought out of the hold, tons and tons of strong-boxes, barrels, and packing-cases, which have been piled one over another, have stood the rough usage, the rolling of the vessel; and now the old proverb of the weak going to the wall in the shape of smashes, splitting across, chipping off corners, or the crushing of contents. Many casualties, specially affecting bath-tubs and thin, uncorded, unplated boxes. Early in the morning we pass lightships and lighthouses, and, entering the magnificent harbour of Bombay, notice a peculiar medicinal smell in the air and very dirty water. On the left is a pretty spit of land, with trees, houses, barracks and church-steeple, indicating Colaba. On the right apparently are a number of islands, and in the distant foreground, beyond the men-of-war, steamers, ironclads, trading-vessels, and fishing-boats innumerable, are more mountains. One woman promptly has a bad fall; another is suddenly taken ill and must be left behind. The baggage is taken off on lighters to the railway-station pier—about two miles,—whilst the passengers, now accustomed to boatmen without any clothes, go to another pier to see the city. Large open spaces, splendid detached buildings, palatial hotels, good shops in dirty back streets corresponding to a London mews, a burnt-up common with a band-stand, a poor cathedral with good monuments, a fair race-course, all hurriedly noticed. Everything terribly dear—two shillings here, two shillings there, a bag of rupees soon gone. Try a buggy in the evening, to be reminded of the "Arabian Nights" or *L'Africaine* at Covent-garden. Myriads of people in turbans and dresses of every colour—the most lively shades of violet, purple, crimson, green, and gold—drive superciliously along. Excepting on foot no women seen, but two or three Parsees with bloated cheeks and tremendous corporations loll back in one carriage, a pompous looking black man in a brougham, dandies with lively turbans in mail phætons, occasionally barouches, the coachmen and footmen looking civil, whilst the noble men inside are scowling; any number of broken-down buggies, also postmen in red, policemen in yellow, soldiers—and all fit into the kaleidoscope noticed on the mall and about the park, varied with fat cricketers in crimson—white teeth and dark faces everywhere. From the guide-book, the local Bradshaw, learn that in addition to medical college and hospitals there is a kind of Brown institute for diseased and decrepid animals; that hotel living averages fourteen shillings a day; one-horse buggy ten shillings a day; house-rent at Malabar-hill, the fashionable quarter, ranges from £20 a month to £100, and considerably more. A bachelor can live at a club for £35 a month. Excepting the head-dress, Europeans dress as in London; the ladies as if at a genteel English watering-place—some in splendid carriages; and in a brougham, in a black suit, a black hat, the usual basket containing stethoscope, *Medical Times and Gazette*, and papers in front, spot the professional face—careworn, anxious, up all night, with a fine practice, but a large family and an expensive establishment. Notice gas-lamps, water-pipes, good roads, omnibuses, pillar post-offices, and princely houses occupied by merchants. The crowds in the native town laughing, wrangling, bargaining—the women with bracelets and anklets, cowed and subdued, trudging about, some with heavy weights on their heads, others attending to the stolid, stupid-looking bullocks, etc.

In the evening go off from the railway-station previously alluded to—a forlorn place where the men had food, and officers a dinner at the rate of a first-class London hotel: soup, muttony-chop, beef-steak suggestive of indiarubber—uncomfortable carriages, the men closely packed, the jolting terrible—miserable work. In the moonlight notice dry plains, lofty mountains, rivers, swamps, graceful palm-trees. Tired, restless, suffering agonies from facial neuralgia; still the beauty of these palm-trees, generally solitary, spreading out like ostrich-feathers, of the hills dotted with rich jungle, the deep valleys and ravines, relieved by waterfalls,—all attract attention. It was too dark to observe the engineering triumph in the Tal Ghat, an elevation of 1912 feet, which the railway, by a zig-zag system of reversion down one hill, up another, next the locomotive shrieking through tunnels in the hard rock, somehow traverses. Then at the railway-station, breakfast, a wash or even a bath can be procured. At a short distance further on we reach Deolalee, our first halt, about 112 miles from Bombay, consisting of a small native village; a large encampment made up of huts and tents sufficient to accommodate 2000 invalids (they say); also officers' quarters, and a mess. A battery of horse artillery is allowed two blocks of building, their wives and children another, with a certain amount of furniture, blankets, and carpet-rugs. The rations, tea, bread, meat (generally boiled), provided; a sergeant receives 1s., and a gunner 6d. a day; the rest of the pay judiciously stopped just now, liquor unfortunately being procurable. In the cases of married men with children more will be allowed according to requirements, and if the husband be unsteady, his pay will be given to the wife. Every man, woman, and child will be visited daily, and every portion of the barracks. The native sweepers are responsible for the cleanliness of the lavatories and latrines, the individual occupants for their rooms. The natives do the cooking for fourpence a head; also bring water from some distance, all filtered before drinking; and the entire absence of drainage involves constant supervision. There are hospitals both for men, women, and children much the same as in England. The country about consists of beautiful blue hills, the summits either peaked or fantastically shaped, the more distant wreathed with clouds; and close to the camp on one hill is a ruined temple. The time expired; men and invalids frequently noticed to be slack, occasionally unsteady. Allotted a stone hut (one of a terrace) of fair proportions excepting the height—simply tremendous,—stone floor, one table, one chair, one cane-bottomed couch; a kind of back kitchen attached, called a bath-room, contains a tub, washing-stand, commode, and a frame holding three filtering vessels each above the other, containing water which trickles eventually on to the floor. Medical officers are advised never to travel without bedding, and if here a few days, to unpack luggage, which may all be kept in the room. My boots are mildewed, some splendid saddles, although packed in tin, are all but destroyed through damp, or else the dew whilst out in the open last night. One man, through a careless servant, has lost baggage; another finds a carefully packed mirror smashed; whilst a third broods over the ruins of his chest of drawers; and an old stager suggests that all packages should be raised on stones, for the white ants here are lively. The weather is that of Dover in hot summer; our food the old muttony-chop and beef-steak, cutlets *à la* country captain, lean and tough; the beer, claret, and ice very good, but terribly expensive; tea very good, bread also, and the curry fit for the gods. Breakfast at nine, good eggs; lunch (I prefer the English words) at one; dinner at 7.30; no wine drank after, but somehow brandy and soda fit in later; gin and tonic also popular. Nights very cold on the cane-bottomed couch, and the total darkness very bewildering; you feel your way from the mess, and tumble into a ditch unless provided with a lantern.

February 21.—Gradually settling down. Engage on the chance one native servant—worth ten Europeans as regards obedience, activity, intelligence, and method. It is something marvellous to note how rapidly wants are anticipated—nothing forgotten; and although he speaks but little English, and I no Hindustani, it is all a matter of pantomime. Then he drives away the barbers, beggars, tailors, snake-charmers, conjurers, dealers in shawls, sandal-wood, and precious stones, who implore the "great prince," "the illustrious chieftain"—meaning me—to patronise them. My European servant has also his satellite, who "great princes" him too; and to-day, as a procession carried in the baggage, a young lady, whose scanty attire would shock the Lord Chamberlain, carrying on her head a large box full of medical books, heavy in every sense; an aged patriarch, with a white beard; one or two boys, also with chests of drawers on their heads—the European servant marched behind, gently persuading them, with a big stick significantly flourished. On the head, about the shins, or the stern, you can hit with impunity; but about the chest and abdomen frequently fatal, through rupture of the spleen. Time, doubtless, will answer the question—why hit them at all? Men all healthy; women and children of the Battery suffering from diarrhœa somewhat seriously. One woman, who had been under treatment during the voyage, confined last night unexpectedly, and to my surprise attended by native apothecary—a very intelligent man, with all the importance of a lord mayor. The woman remains here a month to get strong, then with her husband proceeds direct to final destination. Find that India is a fearful place for documents, returns, statistics—apparently as long as these are correct and voluminous other matters are secondary. Time will explain this, and the reason why the rules, regulations, and circulars of one presidency differ from another. Read in the chronicles of Bombay that Gabriel Boughton, in 1636, surgeon, cured an Emperor's daughter; next a favourite "mistress" of a native Prince; and in consideration of such skill, was allowed permission to trade throughout India, besides securing important privileges for the English nation in the country. There is always a doctor in every story. Note the mortality of Bombay is represented as twenty-eight per thousand—Dr. Semple kindly lending "Report of Sanitary Commissioners for Bombay." Note the percentage of total abstainers—in the artillery 3, cavalry 1·3, infantry 1·9. The artillery show a high ratio of sick in 1869 of ague, fever, and diarrhœa at Deolalee—something associated with bedding and serge clothing issue. Deolalee may be described as a rest-camp for a few troops going up country, and for the numerous invalids and time-expired men about to proceed to England, and at the present considered healthy. In 1869, the analysis of water showed only one objectionable point—viz., a relatively large amount of ammonia, nitrates and nitrites; otherwise considered excellent—after careful filtration, I presume. Since the report, many improvements have been carried out.

February 23.—Diarrhœa amongst the men—their own fault; treated by compound colocynth and ipecacuanha, rest, abstinence from food (cold tea excepted). Tender feet and tight boots, the leather shrunk. Men go out shooting doves, partridges, and plovers. Curious to notice the kites, vultures, and other scavenger birds so tame. Find that excreta, removed by natives, is buried about two miles off. The soil is very porous, the water-tanks large and deep, the wind like a blast-furnace. Thermometer 92° Fahr. Men's rations good; see that each soldier has his belt and flannel shirt; explain that resting-camps are the resort of thieves; see that the filters are clean, and their use understood; encourage the drinking of tea, which is very good, the coffee not so. Examine the men daily, and in common-sense language explain to them their prospect of good health if careful and temperate in all things. We cannot fight against the blazing sun like the thick-skulled native, who goes about with his head shaved, with cholera, sunstroke, malaria, and dysentry ever lurking about him. "Sauve qui peut" is our motto. We have conquered India, but as to climate, health, the preservation of children, more anon, my intention being to record all things which appear curious and of interest to the

Griffin.

Typhoid and Constipation.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The paper by Dr. Nelson on "Constipation simulating Diarrhœa," published in the numbers of the *Medical Times and Gazette* for August 23 and 30, leads up to an opinion I have long entertained of the *origin* of typhoid fever. He says—"Seeing that from the undue retention of such offensive and effete matters [fæces in the intestines] there must be reabsorption and the determination of disagreeable molecules and odours to the skin, lungs, and elsewhere," etc.,—by which the blood becomes poisoned, and typhoid fever originated. That undue retention of fæces in the intestines is an invariable accompaniment of typhoid fever I am certain; had I kept notes of cases I could clearly have proved that fact, and I think have established the opinion I have ventured to express.

Sussex, November. I am, &c., W. E. P.

COMMUNICATIONS have been received from—

Mr. G. F. Yeo, Dublin; Dr. O'Donovan, St. Lucia; Dr. W. Alfred Johnson, London; The Secretary of the Apothecaries' Hall; Mr. Page; Mr. A. Borgen, London; Dr. West, London; Dr. Hawkins, Dorchester; Dr. Althaus, London; Dr. Quinlan, Dublin; The Secretary of the Anthropological Society; Mr. H. A. Davis, Durham; Mr. T. M. Stone, London; Dr. Quain, London; Mr. Teevan, London; Mr. J. Chatto, London; Dr. Semple, London; Dr. Bruce, London; Mr. N. Alcock, Aldershot; Dr. Calman; Mr. A. Orwin, Barnsley; Dr. Letheby, London; Mr. H. W. Green, London; W. E. P.; Mr. B. Vincent, London; Kaltenbach and Schmitz, London; Mrs. E. S. Gibbs, London; Dr. Wilkie Burman, Devizes; Mr. Poole, London.

BOOKS RECEIVED—

Morgan on Sewage, Sewage Produce, and Health—Walker's Egypt as a Health Resort, with Medical and other Hints for Travellers in Syria—De Valcourt's Sketch of Cannes and its Climate—Calvert on Carbolic or Phenic Acid and its Properties—Clarke's Surgery—Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1872—Althaus' Electricity, third edition—Man and Apes, by St. George Mivart.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—American Journal of Medical Sciences, October—Manchester Examiner and Times—Inverness Courier—Bulletin Général de Thérapeutique—Pharmaceutical Journal—Science Gossip—The Obstetrical Journal of Great Britain and Ireland, November—Lancet—British Medical Journal—Le Mouvement Médical—Gazette Médicale—La Tribune Médical—La France Médicale—Liverpool Daily Courier—Le Progrès Médical—Gazette Hebdomadaire—Carlisle Express and Examiner—Revista de Portugal e Brazil—Edinburgh Medical Journal—The Southampton Times, and Winchester, Portsmouth, Isle of Wight, and Hampshire Express—Melbourne Age, August 23 and September 5—Sydney Morning Herald—The Nelson (New Zealand) Daily Examiner—The Allahabad Pioneer—American Journal of Insanity, October—Indian Medical Gazette—Edinburgh Daily Review—The Scotsman—Birmingham Gazette—Monthly Microscopical Journal—Practitioner.

APPOINTMENTS FOR THE WEEK.

November 8. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

10. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Mr. Thomas Bryant, "A Case of Intestinal Obstruction and Gastrotomy." Mr. A. E. Durham, "A Case of Foreign Body in the Pleura accidentally introduced through Opening made for Empyema, and successfully treated." Dr. Purcell, "A Specimen of Calculus in Pelvis of Kidney." Dr. Symes Thompson, "A Case of Scrofulous Kidney."

11. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Anthropological Institute, 8 p.m. Meeting.

Royal Medical and Chirurgical Society, 8½ p.m. Mr. Jonathan Hutchinson, "On Abdominal Section and other Treatment for Intussusception." Dr. Gee, "Case of Renal Calculi."

12. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Epidemiological Society, 8 p.m. Introductory Address, by the President (Dr. W. R. E. Smart, C.B.).

13. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Hunterian Society (London Institution), 8 p.m. Dr. Peacock, "On the Advantages of Sea Voyages in the Treatment of Disease."

14. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

Clinical Society, 8½ p.m. Dr. George Johnson, "Two Cases of Poisoning by Homœopathic Solution of Camphor." Dr. Anstie, "A Remarkable Case of Death from Meningeal Congestion without any Inflammation."

VITAL STATISTICS OF LONDON.

Week ending Saturday, November 1.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·79 in. The highest was 30·34 in. on Tuesday morning, and the lowest 28·95 in. on Saturday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

LECTURES ON THE DIAGNOSIS OF TUMOURS OF THE BRAIN.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,
Physician to the London Hospital, and to the Hospital for the Epileptic and Paralysed.

Lecture III(a).

Gentlemen,—Omitting for the present any further reference to the important fact that destruction of much of the cerebrum or cerebellum may exist without any striking mental or physical symptoms, I now speak of the symptoms of tumour and other adventitious intracranial products in detail.

Class (1).—*The Symptoms which show that there is an Adventitious Product in the Head, but which do* not *show its particular Nature nor its Position.* These symptoms are often the sole ones at first. We take them separately—

a. Double Optic Neuritis.—I must say very little of this, since I have already spoken at length on it (*Medical Times and Gazette*, 1871, August 26, September 16, etc.), but I will again urge three things—(1) That double optic neuritis may exist when vision is apparently perfect; (2) that optic neuritis, without affection of sight, is as good evidence towards the diagnosis of organic disease as is optic neuritis in which vision is lost; (3) another matter scarcely less important is as to recovery from neuritis. I am certain that the most striking appearances of double optic neuritis may pass away (after large doses of iodide of potassium in my cases), leaving sight good; or, to speak with great caution, they will pass away so far as to render it impossible for a careful observer, seeing the patient for the first time when recovered, to be able to declare that the peculiarities discoverable about the optic nerve are pathological.

b. Headache.—We can only attach importance to headache for the diagnosis of an adventitious product within the cranium when it is severe. We can attach little importance to simple transitory headaches, as many people suffer from these occasionally who keep well in other respects. First of all, you must make sure that what the patient calls headache is real pain. A patient often calls a feeling of "confusion," of "swimming," etc., *headache*. I do not allude to these feelings, nor to what we so often hear described as "a weight at the top(b) of the head," feeling of "pressure," etc. These are common in women about the change of life, and in what is called (or mis-called) nervous debility, and in many other cases. You should always ask the patient what kind of headache it is, and his reply will give you a notion of the real character of his head-misery. You will find that it is often not a pain—not an ache: I speak of *severe aching*. I do not mean to imply that the headache in cases of intracranial tumour is always severe. It may be, and usually is, little marked at the very beginning of the illness. This is well exemplified in the case of a boy eight years of age who came under my care April 8, and who died May 26, 1867, of hydatid cyst in the left cerebral hemisphere (in effect a tumour, "foreign body"). I give an extract from the report of his case (*London Hospital Reports*, vol. iv., p. 391):—"He had been ill about eight or nine months, complaining of pains in his head now and then. His mother said—'*I used to think it was a sick headache, because it came on now and then.*' He would complain when he came in from play, and would lie on the sofa, and then it went off." Then he had no pain for several weeks; but after that it was so bad that he was "almost raving mad," and it "used to bring on a sickness." About 3 or 4 a.m. he would begin to complain of pain in his head, and "there was no more peace until about 10 a.m.," and then he retched and brought up stuff "like yolk of egg." If, however, the pain be not severe, we cannot attach much importance to it for the diagnosis of an adventitious product. Had we been consulted for the earliest of the boy's attacks, we perhaps should have thought as his mother did—that they were sick-headaches (*migraine*). Of course I can give you no exact measure of the intensity of the pain, but you may judge by the patient's expressions and by his manner. He may say, "It is not a *common* headache." He uses very strong, and sometimes strange, expressions, such as—"I thought I should go mad with pain." One patient whom I saw for cerebral symptoms, dependent on softening of the right lobe of the cerebellum with a lump of tubercle the size of a hazel-nut, said, "It seemed as if his brain were crushed"; and again, "as if his head were squeezed betwixt two boards."(c) The patient's friends may tell us that he sits down, lays his head on his hands, and remains moaning for hours, or that he stamps about the room, or that he "raves with pain," and sometimes —I take it this is hyperbolical—that he knocks his head against the wall.(d) As to its *continuance*, if it be recent it might indicate meningitis. We dare not attach importance to severe pain in the diagnosis of an adventitious product, unless it be of several weeks' duration, or unless there be well-marked double optic neuritis.

The pain in intracranial tumour may be in any part of the head. It is very often at the back of the head, shooting forwards to the temples or eyes. We must not infer from this that the tumour is in the cerebellum or under the tentorium. In the case of tubercle of the cerebellum just mentioned, there was no pain at the back of the head. Niemeyer (vol. ii., p. 238) says:—"We must be very careful about localising the tumour from the seat of the pain." And observe how cautiously he speaks when he adds (I italicise some words)—"Only pain confined to the back of the head permits us to conclude that very *probably* the tentorium is stretched, and that the tumour is *probably* situated in the posterior fossa." The pain in intracranial tumour is rarely at the vertex. It is generally diffused. It does not follow the tracks of nerve trunks, and is usually bilateral. It does not extend into the face. There is, of course, the obvious exception to the last statement that intracranial tumours squeezing the trunk of the fifth nerve may cause pain in the face. Again, when the adventitious product is an abscess from disease of the ear, there may be pain in all or most branches of the fifth nerve on the side of the ear disease; but this is from the ear disease, and not from the abscess. It is only when the pain is *persistently* of one side of the head, not extending to the face, that we can attach importance to it in localisation. In these cases the membranes (dura mater especially) are usually involved. As, however, in most such cases there is syphilis, the local pain may be due to changes in the periosteum. G——'s pain was in the left temple and left side of the forehead.(e)

Percussing the head is considered by some to be a useful means of ascertaining the position of a tumour, it being supposed that, when the pain is brought on or made worse when a part of the head is percussed, the tumour is of the brain in the region underneath that part of the head. I have not yet used this method of investigation in many cases.

It is to be observed that in the severest cases the pain occasionally passes off altogether. Thus the patient may be sleepless at nights from pain, and yet be well enough to go to his duties in the morning, and perform them somehow. You go to a patient one day and find him curled up in bed, suffering intense pain, and hear that he has been vomiting urgently. Next time you go to see him you may find him sitting by the fire, reading the newspaper, and apparently quite well. This is a matter of very great practical importance. Do not be deceived by these pseudo-recoveries. Occasionally a patient with cerebral tumour who is "doing well" dies suddenly. I have had several cases sadly illustrating this mode of death from adventitious products within the cranium. In my last lecture I spoke to you of rapid death by hæmorrhage from cerebral tumour, but patients will die in a few minutes or half an hour from (or at any rate with) intracranial tumour, there being no acute or recent change *discoverable* post-mortem.

(a) Lecture I. appeared August 9; Lecture II., August 23.

(b) "The brain is liable to suffer from the poisoned blood on which it must feed, in chronic kidney disease; and we find headache, frontal, occipital, or vertical, very common. Vertical headache is a symptom of very great importance in this condition, and is regarded as almost pathognomonic; indeed, frequent and recurring vertical headache is a diagnostic symptom of the greatest moment."—Fothergill "On the Heart," page 295, chapter "On Heart and Kidney."

(c) The case was under the care of Dr. Shann and Dr. Daniel H. Tuke, of York. I recorded it in the *Medical Times and Gazette*, August 30, 1862, page 222.

(d) I once saw a speechless child (not a deaf mute), whose mother told me that he had a habit of knocking his head against the floor. There was no hyperbole here, for when put down I saw the child strike its head and also its face against the floor strongly; the horrible squashy sound made by the contact of the nose and the ground showing that the force was considerable.

(e) As will be seen in the report of her case, *Medical Times and Gazette*, November 16, 1872, there was only complaint on one occasion of pain at the back of the head, although the tumour was of the cerebellum.

The case of G—— illustrates these remarks (*see* November 16, 1862).

I do not remember, however, any case in which there were such striking and repeated intermissions of symptoms as in G——'s case. Sometimes when we saw her she seemed so absolutely well that to those who had not gone into the case the diagnosis of intracranial tumour must have seemed preposterous. Those who do not keep in mind that there may be no obvious symptoms whatever from an adventitious product in the encephalon would necessarily think so.

The patient's headache is often brought on by disturbance, especially by moving about. This is important, because the effects of your remedies for the relief of pain will vary according as the patient is kept still or not. I had under my care a man(f) who used to go to bed simply to apply the ice-bag. I think it very likely that the rest necessary to adjust the ice-bag was really the cause of the relief.(g)

In some cases, but in very few indeed, of intracranial tumour there is no severe headache. Thus, in a case I recorded (*Medical Times and Gazette*, June 17, 1865), there was neither headache nor vomiting, though I found post-mortem a tumour the size of a large walnut, which, growing from one lobe of the cerebellum, had flattened the same side of the pons, the crus cerebelli, etc. In another case (see the *Medical Times and Gazette*, Case 8, July 12, 1873), of tubercle the weight of about eleven ounces in the left cerebral hemisphere, there had been little pain; there was double optic neuritis, etc. In a case I saw with Dr. Soutter of glioma of the superior (uppermost) frontal convolution, there had been no pain throughout.(h) Further, it must not be forgotten that a patient may have severe pain for weeks, and then get rid of it. Pain is, of course, not a symptom of tumour, but of changes excited by tumour in the brain—probably in the brain near it.

c. Vomiting.—This is not always present. The more rapid the progress, and the younger the patient, the more likely is there to be vomiting—attacks of vomiting. Its striking character is that it is "purposeless." It will come on not only after taking food, but when the stomach contains no food. There is usually not a sudden emptying, but a continuous retching; the patient says he strains much, and often the result is that only mucus or thin greenish fluid is brought up. The patient may tell us that he only gets up a little "phlegm," or that he vomits bile. It usually comes on at the time when the headache is unusually severe. The presence of bile in the vomit, I suppose, leads to the diagnosis of biliousness, or of "bilious or gastric" fever in the early part of the course of some cases of cerebral tumour. It is not at all uncommon for children blind from optic neuritis to be said to have become so "from bilious fever." I suppose that if any one vomits long, and strains much, he will bring up bile, whatever may be the cause of his vomiting. The tongue, however, is usually clean, and the appetite may be quite good in the intervals of the attack, as G——'s was. Besides, the patient in the early stage may look quite well, and may never have had any dyspepsia before the cerebral illness.

I have heard in cases of cerebral affection the diagnosis of some disease affecting the medulla oblongata or pneumogastric nerve when the patient vomited much. I have seen one case of tumour of the brain in which vomiting was excessive. There was found a small tumour on one side of the pons near its junction with the medulla oblongata; and this may have "irritated" the pneumogastric (see report of case in *Royal London Ophthalmic Hospital Reports*, vol. iv., pt. 4, p. 420). There was also a tumour at the sella turcica, and also of the left cerebral hemisphere. In another case of syphilitic disease, involving among other cranial nerves the pneumogastric, vomiting was a marked symptom (*London Hospital Reports*, vol. iv., p. 318). But in another case in which this nerve was similarly diseased (*London Hospital Reports*, vol. iv., p. 314) this had not been a marked symptom. On the whole, I can attach no importance to vomiting as a *localising* symptom: it may occur with tumour in any part of the brain. Let me enforce one thing: do not from the mere fact that there is headache and vomiting of bile make the diagnosis of disease of the liver. The diagnosis of disease of the liver coming on in a young and healthy-looking man is at any rate as difficult as the diagnosis of disease of the brain—provided, of course, there is no ascites and no jaundice and no organic lesion of the liver discoverable by palpation. The diagnosis of disease of the liver is often confidently made when all these signs are absent. If you use the ophthalmoscope in these cases of severe headache and vomiting, you will often see a pathological condition of the end of one cerebral nerve, and unless you hold that disease of the liver leads to optic neuritis, you can be sure that the patient's illness is not owing to disease of that much-blamed viscus. It is now agreed on I suppose universally, that the so-called "sick-headache" (migraine) is really a nervous affection (Anstie, Latham, Liveing). There is, indeed, in many cases of cerebral tumour, what may be called an artificial migraine.

d. Alterations of Pulse, Respiration, and Temperature ("*Cerebral Fever.*")—So far we have spoken of the chief symptoms of Class 1 separately, but there are other symptoms of the same order—other non-localising symptoms—viz., alterations of pulse,(i) respiration, and temperature. The symptoms, instead of being spread out over many weeks or even months, are, so to speak, run up into a few days or weeks. To give a severe case in illustration. The patient, after days or weeks of headache, which may not keep him from work, takes to his bed from increase of pain and from urgent vomiting. He *rapidly emaciates*, becomes profoundly apathetic, taking no notice of anything said to him, and perhaps often cries out, "Oh, my head!" His pulse may become slow—*e.g.*, 60—and may be irregular; his belly retracts, and his epigastrium sinks in during inspiration; his temperature is lowered. This is a marked case. We have all degrees of spreading out and running up of the symptoms.

Do not suppose that the patient, who is partly insensible, who has convulsive seizures, irregular pulse, and, to put it briefly, symptoms very like those of tubercular meningitis, will necessarily die. He occasionally recovers, but usually with loss or great defect of sight or with a liability to convulsive seizures. I mean that he gets into very good general health, and occasionally becomes too fat, probably because (his appetite remaining good) he leads a life of enforced idleness from the affection of sight.

Observe, emaciation is not a sign of cerebral *tumour* only, nor of any *one* kind of adventitious product. It attends the acute illness to which any adventitious product may give rise.

Such a severe condition is often called meningitis; and it is not easy to say it is not, especially if the patient be an adult. Tubercular meningitis in the adult is one of the most difficult of all cerebral diseases. There is from tubercular meningitis or from the "irritation" of tumour (or adventitious product of any kind) what Trousseau called "cerebral fever." (From sudden hæmorrhages of the brain we may have a very rapid development of the symptoms enumerated above.) In all these cases there is, I think, an essentially similar condition. Hence difficulties in diagnosis. I do not mind admitting that I find the diagnosis of the particular cause of this "cerebral fever" most difficult in some cases. I shall shortly relate one case in which I was in doubt whether a boy, twelve years of age, was suffering from tubercular meningitis or from tumour of the pons Varolii. After a few days' hesitation betwixt the two I decided for meningitis, but at the autopsy tumour of the pons was found. I saw another case in which a girl, twelve years of age, had symptoms which I supposed with others to be due to tubercular meningitis. She got quite rid of all cerebral symptoms, except paralysis of the left sixth nerve; but this recovery, whilst it might practically negative meningitis, did not negative the continued existence of grave cerebral

(f) Case mentioned at end of remarks, November 23, 1872, p. 569; he died somewhat suddenly in January; syphilitic tumour of middle lobe of cerebellum.

(g) I have now a patient who has from intracranial disease, probably tumour, severe headache, and double optic neuritis, who had severe pain after one examination. I wished to try the continuous current for the relief of this "artificial migraine," but by rest (half an hour) it passed off before I could apply the current. My clinical clerk, Mr. Sincox, has applied it several times since, and has thereby, he believes, cut short attacks of severe pain.

(h) This case is, perhaps, the most important case of cerebral tumour I have ever seen. It illustrates the recent brilliant experiments of Professor Ferrier, and having been mentioned by me (*British Medical Journal*, May 10), is referred to by him, in his paper in vol. iii. of Crichton Browne's "West Riding Asylum Reports," as bearing on localisation of movements in the convolution referred to in the text. I mention the case here because I wish to say that I did not make a correct diagnosis of the exact position of the tumour in the strict sense of the word diagnosis. I inferred the position of the growth in this case simply because I had seen a previous case like it. From Ferrier's researches we shall learn to diagnose the seat of disease in various convulsive seizures from rational evidence.

(i) The fact that alterations of pulse, respiration, and temperature occur in cases of disease of the "organ of mind," is one of very great importance. In cases of *discharge* of the very highest sensori-motor processes we have that most "mental" symptom, loss of consciousness, along with that most "physical" one, pallor of the face (cases of *petit mal*). For a physiological study of mind (notably for that of emotional manifestations) the "vital" symptoms resulting from disease of the cerebrum must be very carefully borne in mind.

lesion. The sequel showed that it did not. She had subsequently an entirely different set of symptoms from necrosis of the right fibula, and died by hæmorrhage. At the autopsy three cerebral abscesses were found, presumably pyæmic.

If the patient's symptoms—headache, vomiting, and neuritis—began when he was in good flesh, it might be said that his illness was most likely not tubercular meningitis, but tumour. However, this I think is not really of much value, as in some cases of tubercular meningitis the patient is well nourished. At the post-mortem in one case recently examined the patient was a fat young woman. The absence of previous pulmonary symptoms, or of previous ill-health of any kind, does not negative the diagnosis of tubercular meningitis. If the patient have had any epileptiform seizure some *weeks* before the meningitis-like condition came on, it is probably tumour. Then as to traumatic meningitis, we have usually the history of a recent blow. If the blow occurs months before, it is probably an adventitious product (abscess or new growth, syphilitic especially). The occurrence of specially nervous symptoms does not help you very much, as they may come on in tubercular or traumatic meningitis. In tubercular meningitis there is occasionally very distinct hemiplegia, and this, strange as it may seem, can occur early in the case, when the patient is not unconscious. I remember well a case in which a patient *was admitted for hemiplegia*. He was so well in general health that I took a clear history from him. He died of tubercular meningitis, and had "scrofulous disease" of both supra-renal capsules. I suppose the hemiplegia in such cases depends on thrombosis of the Sylvian artery, the Sylvian fissure being the one most "clogged up" by lymph, etc. Nevertheless, in spite of this one case, if a patient had had any specially nervous symptoms (palsy of any cranial nerve, hemiplegia, or convulsion) *before* the meningitis-like condition set in, I should exclude meningitis; and I should exclude it if double optic neuritis, or any very marked alteration of the discs, was found very early—in the first week, let us say. I should exclude it in favour of some local "coarse" disease.

But when recovery follows, what are we to say of these cases—I mean recovery to good general health? I still think them to be cases of cerebral tumour. For, as I have insisted, the absence of paralysis or mental defect—and, indeed, the absence of all symptoms—does not negative the existence of an adventitious product. We rarely have the chance of deciding this point. We have occasionally. In the *Royal London Ophthalmic Hospital Reports*, vol. iv., pts. 4 and 5, I recorded a case of a boy, eight years of age, who seemed to have entirely recovered from severe symptoms believed to be the result of cerebral tumour. He had double optic neuritis, and yet, when recovered, his friends supposed his sight to be good; but I found he could only read with the left eye. He was afterwards taken to an ophthalmic hospital for his defect of sight. A relapse occurred, and at the autopsy, by Dr. Swyer and myself, we found tumour of the middle fossa of the skull and of the middle cerebral lobe. The disease had caused perforation into the mouth.

ORIGINAL COMMUNICATIONS.

HISTORY OF THE EPIDEMIC OF DENGUE IN MADRAS IN 1872.

By MOODEEN SHERIFF,
Surgeon to the Triplicane Hospital, Madras.

The dengue has occurred for about fifty years in all quarters of the world. It has prevailed epidemically in America, Asia, and Africa, and sporadically in Europe. It is not new to India, for its prevalence was noticed and recorded at Calcutta about twenty years ago; but it is new to Madras.

Origin and History.—It seems to have originated in the British West India Islands, where it was known as "dandy fever," "from the stiffness and constraint which it gave to the limbs and body." It was named dengue by the Spaniards of the neighbouring islands, and this word, according to the new "Nomenclature of Diseases," is now adopted in French, German, Italian, and English.

The first epidemic of dengue noticed in medical works is that of 1824 in America, where it continued to prevail more or less epidemically under the title of "break-bone fever" until 1828, and then disappeared completely for about eighteen or nineteen years. It broke out in the same country in 1847 and 1850, and again in 1861. In 1853-54 the disease was very prevalent at Rangoon, Calcutta, and several other parts in the Bengal Presidency. As far as my knowledge extends, the Bombay Presidency seems not to have been visited by dengue until the year 1871, and the Madras Presidency till 1872.

Prevalence of Dengue in Arabia.—In 1870, when I was at Mecca, there were no cases of dengue, but I heard of its occurrence on two or three occasions during the few previous years. It was known there under the name of "Aburuka-bah" or "Aburukab," which means literally "the father of the knee," and is given because of the great pains and stiffness which it often produces in the knee-joints. It seems to have visited Arabia again in 1871, and was prevalent at Mecca, Medina, Tanyef, and Jedda in some part of that year as well as in the first quarter of 1872. I have obtained this information from persons who have been on a pilgrimage to Mecca from Madras during the last two years, some of whom remained there for fifteen or sixteen months. Almost the whole of the pilgrims from Madras have laboured under the attacks of "Aburuka-bah," and therefore know what this disease is by personal experience. The symptoms they describe are identical with those of dengue; and a few of them are still not free from pains in the joints, though it is nearly one year since they suffered from Aburuka-bah at Mecca. In June, 1871, the dengue broke out epidemically at Aden. Dr. Read, of the Rifle Brigade at that place, made a report on this epidemic, which is published in the *Proceedings of the Sanitary Commissioner of Madras*. According to this report, the disease was raging at Zanzibar and other parts of the African coast in the early part of the above year (1871), whence it was introduced into Aden by native trading-vessels.

Importation of Dengue from Arabia into India.—It lasted at Aden as an epidemic for a few months, and then continued for a few more sporadically. The free communication which exists between Aden and Bombay, Cannanore, Calicut, and some other sea-ports on the Malabar coast, was the means of importing the disease into the latter places during the above period. The troop-steamers *Jumna* and *Dalhousie* are supposed to have been the chief vessels which conveyed dengue from Aden to Bombay and Cannanore in the latter part of December, 1871; and with sufficient reasons. About the beginning of 1872 the disease made its appearance in Bombay, Poona, and Cannanore, and from the two first-named places it was carried all over India by means of railways. During the last year the dengue has been prevalent in many stations, towns, and villages in each presidency of India, and its visits have also been heard of in China, Burmah, Nepaul, and some other places. In some places it hardly left one inhabitant unattacked, and ceased to prevail only when there were no fresh subjects. It is still more or less prevalent in Madras and some other parts of India.

Synonymes of Dengue.—Dengue is known by many names which we should be acquainted with to recognise the disease if it prevails in other countries. In addition to those I have already mentioned—viz., dandy fever, dengue, denguis, break-bone fever, Aden ague, and Aburuka-bah—the following are the other most common names:—Scarlatina rheumatica, eruptive rheumatic fever, eruptive articular fever, eruptive epidemic fever of India, Mudak-Máriáta. Of all the above synonymes, eruptive rheumatic or eruptive articular fever is a more suitable term for the disease; but, as the word dengue is applied to it in the new "Nomenclature of Diseases," as already remarked, it will of course supersede the use of all other names, at least in all the countries under the British rule. The last name in the above list (Mudak-Máriáta) is a Tamil one, derived from two words—*mudak*, contraction or stiffness, and *Máriáta*, the name of an idol or Hindoo deity; it is very frequently used for this disease by the natives of Southern India.

Prevalence of Dengue in the Madras Presidency and in the Fourth District of Madras.—I first heard of this disease in Madras from Dr. Chipperfield's paper, published in the *Madras Monthly Journal of Medical Science*, No. xxviii., April, 1872. It will be observed from this paper that the first case in this city occurred on February 8, 1872. I did not see any case until July, but from this month till the end of 1872 the number which came under my observation was about 600.

During the above periods, especially in August, September,

and October, the prevalence of dengue was much greater than that of any other disease ever witnessed during my experience of twenty-five years. It scarcely left a house unvisited in the Fourth District, and in every house it visited it generally spared no inmate. No age, sex, or rank has been exempted from its ravages. The oldest patient suffering from the disease was about eighty years of age, and the youngest about two months. The female patients were quite as numerous as the male, but, as usual, the number of the former applying for relief at the Dispensary was comparatively very small. The disease made no difference between the rich and poor, high and low—his Highness the Prince of Arcot having been amongst its sufferers, as well as many of the beggars going about the streets. Not one quarter can have escaped. The epidemic was at its height in September, and somewhat less extensive in October, and there is no doubt that it would have continued till the whole population had been exhausted were it not for the sudden check on October 13 and 14, when there was very heavy and continuous rain, which produced a great change in the weather, and with this the disease became at once very mild and sporadical. It continued in this form till the end of 1872.

Symptoms.—The essential symptoms observed in the last epidemic were—pyrexia; pains in the joints, muscles, and bones; eruption; and headache.

1. *Pyrexia.*—This was of a continued type, and of very short duration, lasting generally from twelve to seventy-two hours. In some cases, however, it was prolonged to seven or eight days, and in a few to fifteen or more. In many of the cases in which the pyrexia continued more than a week, it was characterised in the latter part of its course by remissions or intermissions.

The fever came on either suddenly or was preceded by pains in the body, particularly the back and spine, for a period varying from some hours to three or more days. During the first half of the epidemic its attacks were almost invariably sudden, while in the second the preliminary pains were very frequently observed.

The fever was generally very strong, with burning hot skin; very frequent (120 to 140) and strong pulse; frequent (28 to 36) respiration; white or brown and furred tongue; thirst; and scanty and high-coloured urine. It was very frequently accompanied by convulsions and insensibility in children, and often by headache and delirium in adults.

2. *Pains.*—Next to pyrexia, the pains were the most constant and characteristic symptom. In severe cases they were not only felt in all the joints, but also in the muscles and in the bones; and they were described by the patients as of a gnawing and breaking character, with more or less stiffness in the parts affected. The large and small joints were affected alike, and the pains were seldom confined to less than six or eight joints, in well-marked cases. In the order of frequency, the wrist, ankle, and knee-joints, and the spine and fingers were first; the toes, elbows, and shoulder-joints the second; and the hip-joints the last. The affected joints were always more or less stiff, and frequently swollen, tense, red, and tender to the touch, as if congested or inflamed. At the termination or relief of pyrexia the pains generally abated, but in some cases they increased instead of decreasing. In either case, the pains which remained after the attack did not leave the patients entirely for some days, weeks, or months, and in some rare cases even for a year.

3. *Eruption.*—Though not invariable, the eruption is a very frequent symptom. It was generally transient and very variable in its character. For the most part it was like that of measles, scarlatina, erythema, or roscola; but in some instances it bore a resemblance to urticaria or lichen, or to a mixture of two or more of the above eruptions. In some patients the rash consisted of a mere blush or slight redness, which was discernible in Europeans, but not in natives; and in the former, again, the palms of the hands and soles of the feet were often entirely of a peculiar crimson colour. When the rash on the face was not far from the eyes, the conjunctivæ became frequently implicated in redness, and occasionally with lachrymation.

The rash was generally very partial and scanty, not being in many cases more than a few patches, and it was very seldom so copious as to occupy the whole or greater part of the body. The face, neck, chest, hands, and arms were most frequently the seat of the eruption, and it was also pretty frequently observed on the feet and legs. The duration of it was generally about the same as that of pyrexia—viz., from twelve to seventy-two hours. Among all kinds of eruption, the crimson or peculiar discoloration of the palms and soles of the feet was very obstinate in some cases, and in a few European patients it did not disappear completely for weeks—not even after a severe desquamation.

The rash may occur with the fever simultaneously or on any day afterwards, and in the latter case it generally makes its appearance on the third or fifth day. In some instances it is delayed till the eleventh or thirteenth day, while in a few others it does not occur at all in the original attack, but breaks out very distinctly on the relapse of the disease after twenty or thirty days. The occurrence of the rash was generally noticed on the odd days, as the third, fifth, seventh, etc. In many cases the rash has been observed to occur two or three times in the course of the disease, and it may therefore be divided into primary and secondary. The secondary is nothing but the recurrence or relapse of the primary, and occurs two or three times with a variable interval. For example, in a very severe case in my own family an efflorescence made its appearance together with the fever on the first day, and disappeared on the second; it reappeared on the fifth, to subside again on the following day; and at last broke out very copiously for the third time on the thirteenth day, when it remained for two or three days before it began to decline. The secondary rash was generally more distinct than the primary.

The rash, whether primary or secondary, was almost always followed by a desquamation, which was occasionally copious and lasted for weeks or months. I am aware of a few Europeans and natives who were not free from desquamation of their palms and soles of the feet for more than one or two months after the attack of the disease. It was generally of thin scales, like that in measles; but in some instances the cuticle of the palms and soles of the feet separated copiously, as in small-pox.

4. *Headache.*—Frontal headache, as a very frequent and peculiar symptom, was rare, particularly among the natives. I did not see more than six or seven cases in which this symptom was very prominent or peculiar. In two of these cases a dull pain in the eyeballs was also much complained of by patients. True, headache was present in many cases, but it was not peculiar or more severe than it is often experienced in the simple continued fever.

Sequelæ.—Convulsions; permanent pain, stiffness, and swelling in the joints; pericarditis; paralysis; diarrhœa and dysentery; debility; conjunctivitis; derangement of the brain; abortion.

a. Convulsions.—Dengue was very commonly accompanied by, or terminated in, convulsions among children; so much so, that every child attacked with it was expected to suffer from them. They generally occurred in the early part of the disease, and were accompanied by more or less insensibility. They were certainly the most dangerous of all the symptoms or sequelæ, and I have heard of many deaths from them. Some children under my own care were very nearly losing their lives from this symptom, but fortunately recovered.

They were generally clonic, but occasionally tonic or tetanic. The latter were more fatal than the former, probably from implicating the muscles of respiration.

The adults did not enjoy a complete immunity from convulsions, for I heard of some cases and saw a few myself in which they were present. In one of the cases which came under my own observation the convulsions were severe, distinctly tetanic, and chiefly confined to the respiratory muscles, which became repeatedly rigid after an interval of two or three minutes. During the rigidity, which lasted for about a minute on each occasion, the respiration was at a standstill, and thus the patient was threatened with suffocation.

b. Permanent Pain, Stiffness, and Swelling in the Joints.—After the cessation of fever, the pains and stiffness in the joints were almost invariably left behind for days to weeks or months. Among the sufferers of the last epidemic there are several who are not yet quite free from them, and some are still partially crippled, not being able to walk about or use the arms freely. A few, again, are still labouring under pains occasionally, though it is about a year since they have suffered from dengue at Mecca. In some cases the swelling of the joints was also a very obstinate accompaniment of the pain, but was generally slight, and of shorter duration than the latter.

c. Pericarditis.—In several cases with severe articular pains pericarditis was rather severe. One of the subjects of this

complication was very near dying, and the pains in this case were extremely intense, and he is still lingering on with them. Among the fatal cases of dengue I have heard of, some patients are said to have died after complaining of pain in the chest, and, if it is so, it is not improbable that the immediate cause of their death was pericarditis.

d. Paralysis.—One case terminated in general paralysis, including the optic nerve (amaurosis) and bladder. He was admitted under the head of paralysis, became bedridden, and died in the Hospital. I am informed by a medical friend that he knows two patients at Black Town who became suddenly amaurotic after an attack of dengue.

e. Diarrhœa and Dysentery.—In four or five cases the fever was accompanied by diarrhœa, and in one or two by dysentery. Two of the cases of diarrhœa were rather obstinate, but after all yielded to medicines.

f. Debility.—In some cases the general debility and prostration were much greater than could be expected from the suffering of so short a period as that of the attack of dengue. This was particularly the case with old persons, among whom I have seen a fatal case from debility alone.

g. Conjunctivitis.—In one or two instances there was actual conjunctivitis, requiring to be treated.

h. Derangement of the Brain.—A few children were deranged in their mind after the attack of dengue, and remained so for a long time. One of them is still in the same condition. This child is a daughter of a very respectable man in Royapettah. She was attacked twice within two months, and suffered from convulsions and partial insensibility in the first attack. The second attack or relapse was milder, and was not attended with convulsions, but accompanied by distinct eruption. The derangement of mind is the result of the original attack. She is now very dull and stupid; she neither asks for anything nor is inclined to play, and there is much deficiency in the power of articulation.

i. Abortion.—In September, when the disease was at its acme, two cases of abortion have been heard of as the result of dengue.

Relapses.—In addition to intermissions and remissions, the disease was found to recur occasionally after a complete apyretic interval, varying from one or two weeks to as many months. Its return after so long an interval must be considered, I think, as a relapse. This is doubted by Aitken. Out of many cases of relapse I have seen, I shall detail two by way of illustration:—1. A female child, Zynab Bee, aged 4 years, suffered severely from dengue about the beginning of October. The attack was accompanied by convulsions and insensibility. The child recovered gradually from the attack, but was slightly and permanently deranged in mind. On December 14 it was attacked with the fever again, and on the following day, when I saw it, the face, scalp, ears, and neck were covered with red patches like those of erythema. The fever subsided on the third day, and the rash on the fifth. There were no convulsions on this occasion, but the child appeared more deranged in mind than after the first attack. 2. The second case was that of a police-constable, Mahomed Cossim, who was admitted as an in-patient from dengue on the 3rd, and discharged on the 20th October. He was admitted again from the same disease as an out-patient, on December 23, and discharged on the 6th of the following month. There was no rash in the original attack, but the relapse was accompanied by it.

There were several cases of two relapses, and a few of three, most of them among children and youths. For the most part the fever in relapse was milder, and the rash more frequent and distinct than in the original attack.

Whenever the fever occurred after an apyretical interval of hours or days within a week, I have considered it a paroxysm, but after a week a relapse.

Period of Incubation.—I am aware of some persons who came to Madras, when dengue was prevalent, from villages and outstations where it was not in existence. They suffered from the disease here, and generally on the fourth or fifth day after arrival. A friend of mine also came from Bangalore to Madras, where he remained only two days, and on the third he went to Vellore and was seized with dengue on the railway before he reached the latter place. There was no dengue at Bangalore or Vellore at that time. From the above facts it would appear that the period of incubation is from three to five days.

Pathology.—Dengue is apparently a compound of two diseases, or, in other words, depends upon two kinds of *materies morbi*, one of which is like that of an eruptive fever, and the other the same as that in rheumatism or gout. The urine is generally acid in reaction, of high specific gravity, and contains an excess of uric acid.

The disease is highly infectious and contagious, in which respect, according to the experience of the last epidemic, it excels small-pox, measles, and all other eruptive diseases in this country. The contagion of the malady is stronger and more active amongst Europeans than in natives.

Causes.—As the disease attacked almost the whole population, under all circumstances, and without any difference of sex, age, nation, or locality, it was difficult to find out what its predisposing causes were. Its prevalence, however, was most extensive when the weather was very hot and oppressive, and received a sudden check when it became very cool, after the very heavy showers of rain we had on the 12th and 13th October last.

The exciting cause is a specific contagion, propagated by human intercourse.

Diagnosis.—In every place in which it made its first appearance it seems to have been confounded with several other diseases. If the rash was present, according to its nature it was mistaken for the measles, scarlatina, roseola, erythema, or urticaria. In the absence of rash, dengue was generally confounded with rheumatism, and sometimes with gout. Whatever the nature of the eruption may be, the dengue is distinguished from all other eruptive diseases by the presence of severe and obstinate pains in the joints; by the rash being generally very scarce, occurring more than once in an attack, and at irregular periods (either at the commencement or at any indefinite time during the course of the disease); and by the remissions, intermissions, and relapses. In addition to these, it is distinguished from measles by the absence of catarrhal symptoms, and from scarlatina by the absence of the severe affection of the throat and of the peculiar appearance of the tongue. The distinction between dengue and rheumatism and gout, and between it and ephemeral, simple continued, or intermittent and remittent fevers, is clear, from the combination of the contagion, rash, and severe articular pains.

Prognosis.—Dengue seldom proves fatal to adults, and even this indirectly by pericarditis, paralysis, etc. It is, however, dangerous to children, in whom it often proves fatal by convulsions. I have seen only two fatal cases, which I have described under the head of sequelæ, and in both these instances the patients came under treatment in a hopeless condition. The numerous deaths which have been heard of during the prevalence of the disease were all among the patients who were not subjected to treatment.

Treatment.—Although deaths from dengue were frequently heard of during the last epidemic, yet the natives of this country generally displayed a great disinclination in using medicines for this disease. The Hindoos, who were foremost in this respect, had a religious prejudice against the use of medicines in Mudak-Máriáta, and thought that it was not a disease, but an expression of anger of their deity, Máriáta, which must be assuaged by religious acts, as poojahs, etc., and not interfered with by medicines. The Mahomedans were advised by their hakeems not to take any medicine in Aburukabah, for it was supposed by them to be the result of natural and salutary efforts of the system in throwing out the vitiated and over-heated bile.

The epidemic, however, being very extensive and severe, a sufficient number of patients (about 600) did receive medical treatment, and I thus had ample opportunity of comparing the result of these cases with those that were left without medicines. My experience is greatly in favour of the former plan. I have not seen any fatal case among the patients who have submitted themselves to medical treatment, except the two who, as already mentioned, were in a most hopeless condition when relief was sought; while several deaths were heard of daily during the epidemic among those that did not take any medicine. Besides, there were many cases under my own care which were in great danger from convulsions, pericarditis, etc., and there is no doubt that some of them would have terminated fatally if left without treatment.

I may mention another circumstance to show that treatment is indispensable even in mild and simple cases. As I explained before, the pains, stiffness, and swelling of the joints were generally left behind for some days, weeks, or even months after the relief of pyrexia. These after-symptoms were often severe out of all proportion to the attack in their duration and intensity. In many a slight case they were very severe and obstinate, and *vice versâ*; and they have been most frequently

observed in those persons who have not submitted themselves to any treatment.

Whether severe or slight, dengue was generally very amenable to treatment. The attacks were readily cut short by medicine, and removed finally by quinine. A dose of purgative or emetic was the first medicine used in most cases, and was followed immediately after its action by a saline or diaphoretic mixture, or by James's powder. The diaphoresis ensuing from the above medicines generally relieved the attack, or produced an abatement, in six, eight, or twelve hours, and sometimes, in severe cases, in twenty-four or thirty-six hours. Occasionally the medicines were not successful in producing the desired effect until they were assisted by the use of warm or foot baths. As soon as the fever subsided, quinine was administered in four- or five-grain doses every three or four hours, which either checked the fever at once, or converted it into remittent or intermittent. In case of conversion, quinine and diaphoretic medicines were used alternately for a few days longer, or until the attacks were finally cured.

The headache was relieved generally by foot-baths, and sometimes by cold application to the forehead; the articular and muscular pains by fomentations, liniments, and warm baths; and convulsions by warm baths, ice or cold lotion to the head, leeches to the temples, blister over the neck, and mercurial purgatives. Among the patients suffering from articular pains after the attack of dengue there were some very severe and obstinate cases, requiring active treatment of rheumatism, including leeches, blisters, and alkalines.

Though not a malarious disease, dengue is greatly influenced by quinine, and I may cite my own case in illustration of this fact. In the middle of September, while engaged in attending upon a great many cases of this disease, I began to feel occasional pains and stiffness in my joints and back, from which I thought I might get an attack. A few days afterwards the pains were suddenly increased on one morning, with a slight fever and headache, and continued to get worse, till they were very severe in about six hours. Being now certain that I was labouring under dengue, I took five grains of James's powder with warm tea, and repeated it every second hour till three doses were taken. The third dose made me very sick at the stomach, and produced one broad motion. About this time I felt some sweat about the neck and forehead, to increase which, and to relieve the headache, I put my feet in hot water and covered myself up with shawls. In about half an hour afterwards I was in perspiration, which almost relieved the attack. Immediately after this I began to take quinine every third hour, in four-grain doses. Next morning I was able to do my duty as usual, and felt no inconvenience, except a little stiffness in the back, fingers, and toes. In the early part of October, about a fortnight after the first attack, I again felt a severe pain and stiffness in the back, which extended in two hours to several joints. I took eight grains of quinine at once, and repeated it in four-grain doses every third hour. In about eight or ten hours I was almost free from the above symptoms. About a week after there was a second relapse (third attack) of the pain and stiffness, which disappeared again under the use of the same medicine. After this relapse I continued the use of quinine in a small quantity for some days, and suffered no more from the symptoms of dengue.

Prophylaxis.—Isolation is the best measure that can be adopted for preventing the prevalence of dengue. Isolation, however, cannot be effected after the disease begins to prevail in a large village or town, particularly in a city like Madras; and it should, therefore, be carried out before it finds its way into the midst of any population. The best and easiest way of carrying this measure into effect would be to establish a quarantine in every village or town whenever the disease is expected to be introduced from any place.

When the prevalence of dengue was most extensive, in the month of September, the people in the Fourth District were much alarmed, and some of them requested me to give medicines to protect them from the attacks of the disease. Knowing quinine to have great influence over dengue, I thought it might also be useful as a prophylactic, and advised them to take it in a small quantity two or three times a day. They accordingly bought a very large number of quinine pills, each containing from two to four grains. Although I have no notes upon these cases, yet I am sure that with a few exceptions they have all been exempted from the disease.

Statistics.—As I have before mentioned, the number of cases from dengue which I have seen during the last year was 600. This number is not at all in proportion to the very extensive and fearful epidemic we had in the Fourth District, and the chief cause of this, as explained elsewhere, was a disinclination on the part of the whole native community to use any medicine in dengue. The number of cases from this disease would have been still smaller were it not for its greater portion consisting of public servants, who sought for admission chiefly to account for their absence from duty during their illness.

No death has occurred in the above 600 cases, and the two cases which have proved fatal from the sequelæ of the disease have been recorded under the head of other diseases for the reasons already explained.

Out of the 600 cases, 412 were treated as out- and 130 as in-patients, and fifty-eight were private cases attended upon by me in their own residence.

As this report is intended for out-patients, I shall for the sake of brevity show in figures a few of the chief statistical points connected, as follows:—

Race.	
Europeans and East Indians	57
Mahomedans	235
Hindoos	120
Total	412
Occupation.

ON DIPHTHERIA: WITH ESPECIAL REFERENCE TO A RECENT EPIDEMIC IN ITALY.

By ROBERT HUNTER SEMPLE, M.D., M.R.C.P.L.,
Physician to the Bloomsbury Dispensary.

Diphtheria has probably been known since the earliest period of history, but owing to the obscurity of its early symptoms, the occasional rapidity of its course and termination, and the capricious nature of its visitations, it has sometimes been unnoticed altogether; sometimes it has attracted an unusual degree of attention; and sometimes (and indeed very often) its true nature has been altogether misunderstood. It has appeared as a fearful epidemic, sweeping off thousands of the population, at different periods—in Spain (1611), in Naples (1618), in Sicily (1625), in France (1757), in Sweden (1762), in New York (1771), and at several other times; but in point of fact it has been always present, although sometimes in so mild a form or in such isolated instances that its real character has been mistaken.

At the commencement of the present century—namely, about 1816—it appeared as a destructive epidemic in and about the town of Tours in France, where it attracted the attention of Bretonneau, who, though practising in that town, admits that the disease in the form in which it then presented itself was new to him. But, as is now well known, he devoted himself

most energetically to develope and describe the whole history and nature of the epidemic; and with the assistance of Velpeau, then his pupil, he was able to prepare and to publish the masterly researches which have for ever connected his name with that of diphtherite or diphtheria, both of which names were proposed by himself. It is equally well known that after raging as an epidemic, not only in the neighbourhood of Tours, but in many other parts of France, the malady at length reached the north-western frontiers of that country; and after attacking and carrying off several English patients in Boulogne-sur-Mer, it crossed the Channel, and appeared as an epidemic in Great Britain, where it raged most extensively in the years 1856, 1857, 1858, 1859, and 1860.

There is no doubt whatever that the British epidemic of those years was the same disease as that described by Bretonneau, and afterwards by his pupil Trousseau, and by Guersant, Bouchut, Empis, and others; but the question raised at the time, and perhaps not yet definitively settled in all people's minds, was whether it was a new disease, or one which had long been prevalent on the surface of the globe. I believe that it is not a new disease, and that, although it is no longer at present prevailing in England as a virulent epidemic, and never did occur here as an epidemic before 1855 or 1856, yet it has always existed in this and other countries in the sporadic form under the name of pseudo-membranous croup, and under that title it still occurs, though happily somewhat unfrequently, at the present day, in the British Islands.

I myself saw several cases of the epidemic at the period to which I refer as the epoch of the British visitation, and I happened about the same time to be engaged in editing and translating the French memoirs then in existence on the subject. Ever since that time I have carefully noted all the facts and writings relating to the disease, whether of a theoretical or practical nature, as far as they came within my reach, and I have seen several additional cases, taking care in the fatal ones to verify the facts observed during life by post-mortem examinations. I have come to the conclusion that Diphtheria is a disease always present upon the globe, but exhibiting two distinct forms—namely, the epidemic and the sporadic.

The first form is the disease described in excellent monographs by Nola (1620), Ghisi (1747), Cortesius (1625), Marteau de Granvilliers (1768), Bard (1771), Wileke (1764), and Bretonneau. The second is that which is only occasionally seen but is generally fatal, and is, or usually has been, denominated croup. I by no means assert that Diphtheria is Croup; but I maintain that the so-called croup with pseudo-membranous exudation is the same disease as tracheal (or laryngo-tracheal) diphtheria. This is the view now entertained by some of the most distinguished members of the profession, and most especially by that Nestor of our calling, Sir Thomas Watson; but I hope that I shall not be considered egotistic if I remark that my opinions on this subject were formed and published long before the appearance of the last edition of Sir Thomas Watson's excellent Lectures, in which the view I now advocate, and have always advocated, first appeared.

These preliminary remarks are necessary in order to introduce the subject which I now venture to bring under notice—namely, the recent outbreak of an epidemic of Diphtheria in Florence, in the vicinity of that city, and in other parts of Italy. The course of the disease, the victims it selects, its dreadful mortality, its capricious visitations, its intractability to therapeutic measures, are all features which are parallel and analogous to those observed in former epidemics, but with this difference—that it has now found the physicians prepared, by historical and pathological researches, for combating its approaches, and qualified to give lucid and careful descriptions of all its leading characters. I have been deeply impressed by the elaborate history given of the disease by the Italian physicians, and their thoughtful commentaries on its nature, pathology, progress, and treatment; and I think it very desirable that some of the particulars, which are at present inaccessible to many readers, from their being written in a foreign language and scattered through the pages of Italian medical journals and in monographs, should be presented to the medical profession in this country.

The sources from which, among others, I have derived my information as to the recent Italian epidemic are—the medical journal published in Florence, *Lo Sperimentale*, *Giornale Critico di Medicina e Chirurgia*, which contains a series of original memoirs on the subject, entitled "Istoria Clinica della Difterite osservata nella città di Firenze e Contorni nel Decennio dal 1862 al 1872"; a monograph by Dr. Oscar Giacchi, of Poppi (a small Italian town), entitled "Natura e Terapia dell' Angina Difterica"; a Report by Dr. G. Faralli, entitled "Studi sulla Difterite," which comprises a history of the whole subject, prepared for the *Sezione di Medicina Teorico-Pratica* of the Medico-Physical Society of Florence; and a small monograph by the same writer on the *Ciclo Termico* (Thermic Cycle) of Diphtheria.

It appears, in the first place, that the recent Italian epidemic—like that observed by Bretonneau, at Tours—shows itself independent of climatic or local influences, and that it attacks indifferently high and low, rich and poor, the dwellers in the city, and the inhabitants of the country, the cottager in the plain, and the peasant who breathes the pure air of the mountain. Children, however, as has been observed in all other epidemics, are the chief victims, although adults are by no means exempt, and often take the disease from the children. Dr. Nesti, who contributes a paper to *Lo Sperimentale*, entitled "Della Difterite nella città e contorni di Firenze dal 1863 al 1872," states that although the malady has furnished most victims in the northern, north-eastern, and south-western parts of Florence, yet it has propagated itself centrifugally to neighbouring parts, attacking localities altogether different in their geological conditions, the land being sometimes sandy, sometimes calcareous and clayey; and different also in their local position, for the epidemic has been equally fatal in the low-lying and fertile plains, as in the dry, elevated, and mountainous and pleasant regions of Fiesole, Ruballa, Mugello, and the like. Social conditions are alike disregarded by the epidemic, for (the same writer continues) it has attacked with equal virulence the uncared-for child of the peasant in the squalid cottage, and that of the noble and rich proprietor in his splendid palace. Dr. Giacchi, who practises in the country, gives evidence to the same effect, stating that in the lovely hilly regions, bathed by the waters of the Arno, and where the pure air is scented only by the emanations from the pine and the beech trees, the diphtheric epidemic is quite as destructive as in the corrupted atmosphere of great cities and amidst the mephitic exhalations of marshes.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

MEDULLARY SARCOMA OF THE FEMUR—DEATH—POST-MORTEM EXAMINATION.

(Under the care of Mr. BERKELEY HILL).

[Reported by Mr. ARTHUR KEMPE.]

THOMAS J., aged 34, confectioner, was admitted on July 28. The patient states that about two years ago he was kicked on the leg by a man, from the effects of which he was lame for about two days. The leg was bandaged, and he then for the first time felt pain in the left hip; but after using a little embrocation, the pain left him. From time to time the hip pained him, but never became swollen till April, 1873. He then went to a doctor, who treated him for sciatica. After having been treated for two months, he went to Buxton, in Derbyshire, to take the baths, during which time the hip seemed to swell more. The swelling went on increasing rapidly, and a fortnight ago he was confined to his bed. He then rubbed it with iodine, but no improvement taking place, he came here July 28. He says he has had small-pox about fourteen years ago; is married. Family history good. Never suffered from rheumatic fever, cough, or spitting of blood; never had pleurisy. Whole leg ached after standing, but pain went away on resting. Perspires much at night, when pain is worse. Is losing flesh; appetite bad for three months; gets little sleep. No pain on defæcation; motions good size—never any pus in them. He has noticed for some time that his water has been of a smoky colour, and he does not pass it so often as he used. In February his leg was so well that he danced all night, feeling only a little stiffness; dancing did not make it worse. First felt pain behind the great trochanter, the pain also going down the outer side of the leg. No pain in the calf or inner side of the thigh; no pain around body, or in iliac fossa. The left hip is very much swollen indeed, œdema spreading as far down as the knee, and over the iliac region. No tenderness anywhere along the spine, or over iliac bone or sacro-

iliae joint. Attempting movement of iliac bone gives him no pain, nor does percussion of the femur. Deep pressure on left iliac fossa causes pricking feeling. On examining the left groin, a distinct hard mass can be felt in the iliae fossa, and the edge of the psoas muscle is very hard. The chief swelling is in the gluteal region, where it commenced; but it extends forwards to the inner side of the thigh, filling the groin, half-way down the thigh, and upwards along the back to the angle of the scapula. The swelling in the left inguinal region lies in the iliac fossa, is hard, smooth, elongated, extending about three inches above Poupart's ligament from the middle line to the anterior iliac spine. Skin over tumour in gluteal region and outer side of thigh is mottled-purplish, elsewhere simply pale and œdematous. On examination per rectum, left ischio-rectal fossa is found to be filled with a hard, firm swelling, accurately limited to left half of the perineum; does not seem to pit on pressure. Measurements:—Calf: Left—13½ in.; right—13¼ in. Thigh: Left—lower part 14¾ in., middle 23 in., upper 27¼ in.; right—lower part 14½ in., middle 17½ in., upper 19¼ in. From lowest piece of sacrum to left spine of ilium antero-superior—left 17½ in., right 14 in.

August 1.—Mr. Hill introduced an aspirator trocar behind the great trochanter deeply into the swelling, but no fluid came away or even filled the needle. Only one puncture made.

From this date till the date of his death the patient continued unable to get up. He suffered severely from time to time; occasionally had a severe cough; was frequently sick and unable to take food; lost flesh rapidly; and some œdema of the right leg supervened.

Post-mortem, fourteen hours after Death.—Abdomen opened by the usual incision; transverse one was then made between the crest of the ilium and the ribs, and then one longitudinally down the thigh. The flap thus formed was thrown outwards, and thus the sartorius was disclosed stretched over a large and very elastic tumour, which bulged forwards into Scarpa's triangle and outwards between the extensors and the glutei. In doing this the glands of the groin were found to be infiltrated with the growth, large, irregular, and white. It was found impossible to remove the tumour entire, and so sections were made into it. Its substance was for the most part perfectly white or slightly pink, and dark reddish-brown from extravasation of blood, and very large patches of a light yellow colour, evidently cheesy. It extended from the middle of the femur through the whole of the upper part of the thigh and towards the middle line. It just involved the symphysis pubis, and filled up a greater part of the cavity of the true pelvis, where it infiltrated the obturator internus, but apparently did not affect the bone. Above this, all the glands by the side of the aorta were matted together by the growth, presenting a similar appearance to strumous mediastinal glands. In the thigh the tumour involved the soft parts rather than the bone; its exact point of origin could not be discovered. It did not appear to infiltrate the bone, but the femur just below the trochanters, as well as the internal part of the pubes, was entirely broken across and crumbled. Small spicula of bone also existed throughout the tumour. The femoral artery and vein passed through the centre of the growth; neither was occluded, but the growth sprouted at various points into the vein. On the right side the femoral vein was plugged, probably the result of pressure from growth of the glands. The cartilage over the head of the bone was perfect, but the inner wall of the acetabulum was almost destroyed, and the ligaments and tendons quite softened. In the walls of the heart there were several small deposits of similar appearance to that of the large tumour; some of these were found immediately below the pericardium, and several existed inside the heart in the columnæ carneæ, etc. Under the pleura of both lungs there were similar deposits to those under the pericardium, but none in the substance of the lungs. Lungs apparently healthy; congested at bases. Liver of normal appearance; no deposits. Kidneys large; no deposits. Spleen, no deposits. On examining microscopically a portion of the tumour, it was found to consist of pretty uniform round cells, larger than lymph corpuscles, and each situated in an alveolar space formed by a faint fibrillar structure.

MR. GUTTERIDGE'S OPERATION FOR STONE IN THE BLADDER.

As we stated in last week's number of the *Medical Times and Gazette*, Mr. Gutteridge performed his operation for vesical calculus on Monday, November 3, at St. Peter's Hospital for Stone. Mr. Gutteridge, as we think, very wisely gave hospital surgeons in London a chance of witnessing him perform lithotomy after his own method, and of thus judging for themselves of its value. Did he practise in London he perhaps would not have thought it necessary to have given public announcement in the medical press, or a prolonged intimation on the Hospital notice-board, of the date on which he would operate. As, however, he came up from Birmingham, and was only a few days in town, he sent cards of invitation to the surgeons at the metropolitan hospitals. It was in this way we learnt of the opportunity of seeing him execute what, in more ways than one, must be acknowledged an extraordinary and successful operation.

Mr. Gutteridge's scheme consists of two parts, viz.—to use his own words,—"of a due combination of incisions of parts ascertained by extended experience to be capable of being safely severed; and of implements with which the successive stages may be most surely and with least danger accomplished." The patient was a boy sixteen years of age, a native of the Black Country, and was submitted to operation without being anæstheticised, as Mr. Gutteridge has a strong objection to chloroform or ether in lithotomy. Kneeling before the patient when in the lithotomy position, and with his eye thus in a line with the perineum, the operator first passed the staff, which he handed to his assistant; he then made very firm pressure with the fingers of his left hand upon the anus, thus dragging the skin of the left side of the perineum, with the lower extremity of the gut, well over towards the right tuber ischii. He next rapidly plunged the scalpel into the groove of the staff at a point a little to the left of the raphe, and on a level with the anterior extremity of the tuber ischii, and then, without running the scalpel along the groove, he made it cut its way through the soft tissues. Next he passed the beak of the cystotome into the roughened groove, and, with the cutting edge directed a little upwards from the horizontal direction, he passed it onwards through the prostate and then turned the edge downwards and brought it out at the lower extremity of the skin-wound. This done, he passed his left index-finger into the bladder, felt the stone, then withdrew the staff, and passed in along the finger a grooved conductor, much like a narrow blunt gorget, and along this, after withdrawing the finger, he guided the forceps, only one blade of which was *in* the groove of the conductor. The stone was seized and at once withdrawn, and the operation thus completed.

It will be understood from this account that the method differs from that adopted by other surgeons in that—(1) no anæsthetic is administered; (2) that in dividing the structures in the ischio-rectal fossa the scalpel is thrust by one plunge into the groove of the staff at the point of the anterior extremity of the wound, and that owing to the traction made on the anus, the incision through the skin, when the parts are relaxed, is seen to extend over the tuber ischii; (3) that the incision whereby the bladder is opened is semilunar in shape, and describes a curve constituting an arc (as Mr. Gutteridge states it) of 100 degrees of a circle; (4) that the forceps are guided into the bladder along a grooved director instead of along the left index-finger. Mr. Gutteridge spares, if possible, the membranous portion of the urethra, and lays open only the prostatic part. His aim is to make his knife enter the canal at the apex of the prostate gland.

For these modifications in the procedure special instruments are provided. These were recently shown to members of the British Medical Association, at the forty-first annual meeting, in August last, a description of which Mr. Gutteridge has himself given as follows:—"A table constituted of a fixed frame, on which is a sliding top, whereby the patient may be firmly fixed and kept symmetrically in all respects, and yet through which, by means of a simple screw action, the position of *tight-up trussing* may be speedily relaxed, and the pressure on the respiratory and venous systems lightened, so that in a protracted operation rest may be given and renewed efforts made, by intervals, at the operator's pleasure—a resource in the aged and the fat of the very first importance as respects the sustaining the patient's power of endurance without fatal congestion. The manual instruments consist, first, of a staff, with handle capable of being used by the operator and the assistant at the same instant of time, and with a furrow for the knife to traverse, coiling slightly, and ruffed so that the holder of the knife may have a positive assurance of the knife and staff being in real contact throughout the course of the knife, until it is entered

into the bladder. Secondly, an implement consisting of a handle shaped for the finger and thumb, with scalpel mounted at one end; and at the other a beaked knife—properly a cystotome—fixed at a right angle to the scalpel on the axis of the haft, so that one instrument may effect, by a move of the finger and thumb, the two distinct incisions, the external one and that of the prostate. Thirdly, a conductor for the forceps conformable in respect of size to the operator's left forefinger. Fourthly, forceps with supplementary handles by which the stone may be compressed with hair-light pressure while increased force is brought to bear on the main arms of the forceps; admitting of the separation of the process of compression and traction; as well as relaxation of the hold of the stone, for the purpose of adjustment of the forceps to the stone, or gentleness of pinch, in case of the stone being of friable material."

The operation for stone performed with these instruments and in this way Mr. Gutteridge would desire to have known as "lithotomy made speedy and safe." Certainly in his own hands, when performed as we saw it, it is rightly so styled. It was done in a remarkably short time—less than half a minute,—and every step in the operation was executed with rapidity and precision. The boy has gone on perfectly well since the operation, and within forty-eight hours afterwards the urine was all voided by the natural passage. This, as is well known, is an unusually short time between the operation and the safety of the patient, which is secured by the flow of urine along the urethra. Yesterday, the eleventh day after the operation, the patient returned to his home in Staffordshire, perfectly cured. We sincerely hope we shall have other opportunities of seeing Mr. Gutteridge cut for stone.

SATURDAY, NOVEMBER 15, 1873.

THE GUINEA FEE.

In a recent number (October 18, 1873) we took occasion to discuss briefly the subject of professional fees. We showed that, owing to the marked depreciation in the value of gold in recent times, the traditional guinea fee represents at present only a fraction of the real value which it possessed during earlier historical periods. We assumed that the existence of a general augmentation of personal and domestic expenditure would be universally admitted, and expressed our belief that the guinea of the time of William and Mary was equal to at least three of our sovereigns in exchangeable value for the leading commodities of life. From these considerations we drew the conclusion that though nominally our leading physicians and surgeons receive the same fee as their predecessors of the eighteenth and latter part of the seventeenth centuries, yet in reality the present is equal to only one-third of the original guinea fee. The contrast has already awakened a considerable amount of attention, which, if the profession is alive to its own interests, and desirous of maintaining its position of honourable independence, will not abate till the effort to restore to medicine its equitable emolument and consequent social position has been crowned with success.

We have heard, however, in various quarters this statement discredited, and it is on this account we have thought it worth while to adduce in our present article indisputable evidence of the prices paid for the necessaries of life at a time when Radcliffe consoled himself at the loss of five thousand guineas by saying it would be repaired by going up an equal number of pairs of stairs, and when Radcliffe's neighbour, Dr. Gibbons, received £1000 a year from the overflow of patients who were not able to gain admission to the great physician of the day.

The guinea fee then was prevalent during the reign of Queen Anne, and there is every reason to believe that it dates from a still earlier period. This has an important bearing on the case, because during the last years of the seventeenth century, immediately before the commencement of the reign of Queen Anne, there was a marked increase(a) in the price of all commodities and a reduction in the value of labour. If the guinea fee dates its origin from the seventeenth century, when, owing to the worthless state of the silver coinage resulting from age and constant use, one guinea was commonly exchanged for 30s. in silver,(b) when beef was 1s. 6d. per eight pounds, and(c) artisans' wages were 6d. a day, instead of from the eighteenth century, when beef had reached the price of 3s.(d) for eight pounds, and artisans' wages had risen to 1s. 4d. to 1s. 6d. a day,(e) the only inference is that even in the eighteenth century the guinea fee should have been substituted by a fee proportionate to the altered rates of living and remuneration. But, even granting that we are to estimate the value of a guinea fee by the amount of provisions and other necessary commodities purchasable by it during the reign of Queen Anne, or even during the first half of the eighteenth century, we think we shall be able to prove that our original statement regarding the value of a guinea fee is more than justified by historical evidence.

The relative price of butchers' meat in the eighteenth century and now affords a fair index of the price of other marketable materials. During the first half of the last century bullocks were valued at an average of about £3 a head. In 1712 we have "four oxen £18," and in 1723 "four bullocks £8,"(f) and many similar entries. Though these oxen were certainly not, either in weight or quality,(g) equal to our

(g) Professor Rogers points out that in the sixteenth and seventeenth centuries meat must have been very lean and poor in quality, as suet was four times as dear as meat itself.

present cattle bringing from £20 to £30 a head; yet a certain allowance has also to be made to their credit. Compared with other commodities, oxen in the early part of the eighteenth century were dear.(h) This arose from the fact that they were marketable not only for butchering purposes, but as beasts of traction and burden. In fact, notwithstanding their very low price, they were actually dearer than horses; so that on this and various other considerations, which we cannot at present adduce, we are justified in stating that in 1700-15 beef was little, if anything, more than one-tenth of its present price.

Then with regard to mutton. In 1707 sheep were worth 4s. a head; in 1724 they had risen to 5s., and in 1751 to 6s. 6d. a head.(i) At present two guineas would not, we imagine, be considered too high an average. In fact, in a Scotch paper taken up at random we find them quoted as high as 52s. 6d. Here, again, we may safely affirm that mutton in the early half of the eighteenth century was valued at one-tenth of its present price. It is a remarkable circumstance that during the eighteenth century the average price of wheat was almost the same as during the seventeenth.(k) Since then, however, wheat has advanced 33 per cent.(l) Poultry, during the first half of the last century, was almost ridiculously cheap. About the year 1700 two geese and a gander were sold for 4s. the lot; a cock and four hens went for 2s.; while eight ducks cost the small sum of 2s. 8d. In 1712 two geese and a gander were sold for 3s., and even as late as 1749 five ducks and a drake were knocked down at 2s. the lot.(m) This information throws some significance into the phrase to "make ducks and drakes" of a thing, for these bipeds appear to have been looked upon as the lowest edible form of animal existence. It is unnecessary to compare these with present prices. At that time a one-guinea fee would have purchased the stock of a complete poultry-yard.

Coals, shortly before the commencement of the reign of Queen Anne, cost 9s. a load—presumably about a ton.(n) As already mentioned, horses were in 1702 cheaper than oxen. They averaged £2 a piece, and subsequently rose, till in 1750 they were worth £4. From various items regarding "trotting" horses we can infer that a serviceable animal to drive would cost about £10.(o) In the year 1700 hay was 6s. 8d. a load, and in 1750 had risen to 15s.(p)

Any comparison of prices current in the early part of the eighteenth century with the present prices would be incomplete without a reference to the relative value of wearing apparel. Now, it fortunately happens that an honest Yorkshireman by the name of Hopkinson has had a very complete copy of his tailor's bill(q) transmitted to posterity. Mr. Hopkinson's liabilities were contracted about the year 1700. For one coat and waistcoat he paid, or rather it was intended that he should pay, 1s. 6d.; a pair of "britches" were put down at 6d.; and for a lot embracing two hats, a pair of stockings, and a pair of shoes, the purchaser was asked to pay the modest sum of 2s. 6d.(r) Mr. Hopkinson was a Yorkshireman, and *à priori* purchased his clothing on the most advantageous terms. Moreover, the clothes purchased may not have been of a very high class, either in material or in construction; but there is external evidence to show that his bill represents pretty closely the value of wearing apparel at that time.(s)

In 1708 bloodletting cost 6d., but by whom the operation was performed is not mentioned. With regard to the price of drugs, it is recorded that in the same year an employer of labour paid "for brimston and jollup for Jane, 8d." The services of the country practitioner do not seem to have had a very high money value, if one can judge by an entry—"To ye surgeon for cuering a bile, 6d."(t)

To complete the comparison of the value of articles of diet in the early part of the eighteenth century and now, it is necessary to add that the ordinary price of ale was 9d. a gallon,(u) and claret, as near as we can discover, had reached the still moderate price of £6 6s. a hogshead. Previously to 1735, when a duty of 20s. a gallon was imposed by Walpole on spirituous liquors, English brandy was 4s. a gallon, sherry was 3s. a gallon, while port was 5s. 4d.;(v) and there is reason to think that at this time the higher-priced drinks were not in great demand.

After this statement of facts, it is unnecessary to contrast formally prices current during the reign of Queen Anne and the first two Georges with prices prevalent in our own time. If our quotations are approximately correct, our statement that living is now three times as dear as when the guinea fee system was established, instead of exceeding the truth, falls considerably short of it. And though at that time prices varied in different places and at different dates more than now, we believe that our statements represent average quotations during the different dates specified.

During the latter half of the eighteenth century there was a marked advance in the list of prices. So much was this the case, that, as far as the mere price of commodities is concerned, the year 1799 was a much dearer year than 1869. In 1779 the market value of about fifty leading articles of commerce was, compared with prices in 1869, in the ratio of 202 to 119.(w) But, as we shall have occasion to show, other considerations than the mere advanced prices of leading commodities must be entertained before we can reach correct conclusions regarding the variations in the value of money. From 1750 to 1770 beef was sold at 1½d., 3d., and 4½d. per lb., according to quality; mutton fetched 2¼d., 3½d., and 4d.; fowls were sold at 2¾d., 3½d., and 8d. each, geese at 1s., turkeys at 2s. to 2s. 6d., and hares at 1s.; ducks had established their reputation to the extent of being valued at from 4d. to 9d. each as articles of diet; butter was sold at 4½d., 6d., and 11½d. per lb. of eighteen ounces; cream fetched 3d., 4d., and 5d. a pint; lobsters were valued at 1½d., 2d., and 4d. each; and oysters could be bought at 8d. per 100.(x) A turbot cost 6d., and a pair of soles could be bought for 4½d. Ale was 1s. a gallon; but spirituous liquors appear to have fetched a high price.(y)

At these rates a very substantial dinner with fish, fowls, joint, pudding, cheese, beer, etc., could be provided for eight persons at a cost of 4s. in all. At the same period coals cost 7½d., 10d., and 11d. per Cornish bushel, which was equal to three Winchester bushels. Hay was 2s. 6d. a cwt.(z) Wearing apparel was almost twice as dear as in the early part of the century. Labour was better paid than previously, but

(r) It appears that Hopkinson was a weaver, but also, if one may judge by the nature of his transactions, a small employer of labour. The same merchant charges against him "4 loomes with all the other working tooles belonging to his traid, £6." The apparel recorded in the text very probably consisted of working clothes. The "britches" were probably made of leather, as these are frequently entered at about the price paid by Hopkinson. "Two coats more, 10s." is an entry which, as indicating the value of Hopkinson's holiday or Sunday clothing, may afford a nearer indication of the value of respectable attire. The same merchant appears to have settled Hopkinson's funeral expenses, which, including "Crowner's fees," were £1 12s. 6d.
(s) Thus, in 1697, gloves are entered at 4s. a dozen; in 1708, a hat, 1s. 10d.; in 1732, two wigs, 2s.; in 1708, a yard of Scotch cloth and making, 1s. 7d.; one dozen stockings, 2s.; three dozen women's ditto, 18s.

still wages appear to have been very low. A gardener received 1s. 6d. a day; a tailor received 8d.; artisans 1s. 4d., and women engaged in outdoor labour 3d. a day.(a) The wages of a maid-servant were £2 10s. per annum, and of a man-servant £4 5s.(b) Wheat retained the same average, but began to rise soon after this period.(c) Such horses as had been sold in 1750 for £4 were in 1783 worth from £6 to £8.(d) During the last two decades of the eighteenth century there commenced a general rise in prices, which continued till the year 1815. Between 1790 and 1800, butchers' meat was doubled in price, and wheat more than doubled.(e) In taking a more general view we find that during the last decade of the eighteenth and the first decade of the nineteenth century the price of the fifty leading commodities of life advanced almost 100 per cent.(f)

From 1815 to 1849 the tendency of prices was to fall, but, owing to the influence of the discoveries in Australia and California, the value of gold was so much depreciated, that since 1849 the cost of articles necessary for the maintenance of life has been gradually rising.(g) Professor Jevons affirms that between 1849 and 1865 prices had risen 21 per cent., and that beef and mutton had advanced to the extent of about 1s. per eight lbs.(h) Compare the prices of 1840 to 1849 with the present prices; the market price of the carcase of beef, "sinking the offal," was 5d. per lb.,(i) as compared with 9d., the present price. During the same decade the market price of mutton was 6¼d. per lb., as compared with 9¾d., the present price. At the same time milk was supplied to St. Thomas's Hospital from Romford in Essex at a price varying from 9d. to 1s. per gallon; eggs were sold at twenty for 1s., and good butter was retailed at 10d. per lb.(k) Thus, only twenty years ago beef was little more than one-half, and mutton two-thirds its present price;(l) milk cost little more than half that 5d. per quart which contemporary milkmen claim as the value of the pure fluid; while eggs and butter were less than half their present price. At the same time colliers' weekly wages varied throughout the decade from 19s. 10d. to 16s. 3d.,(m) which at present is little more than their daily pay. Masons, blacksmiths, and carpenters earned from 12s. 7d. to 14s. 9d. per week—only about one-third of their present earnings.(n)

Though the prices of food and the remuneration of all classes, whether artisans, tradesmen, or members of all learned professions, except the medical, had greatly increased at the period at which we have now arrived, the guinea fee—established when all personal and domestic expenses were almost as nothing compared with those of 1840-50—continued to be regarded as the proper remuneration for the advice of our leading physicians and surgeons. And now that prices are so much higher than in 1840-50, and men of all classes enjoy incomes greatly in advance of those of their predecessors of the last generation, the guinea fee still holds its position in our system.

The only argument which can be adduced in opposition to our statement relative to the increased expense of living is that in the beginning of the present century the fifty leading articles of food were very much dearer than now. But we hold that it is fallacious to judge the matter exclusively by that circumstance. In the earlier years of the century, physicians and surgeons had to live in the same quarter with tradesmen and professional men with incomes much smaller than the same classes now enjoy. Under these circumstances they could easily maintain their proper social position even when provisions were dearer than now. But under the present circumstances the members of a profession, whose usefulness depends to a certain extent upon the maintenance of its social position, cannot fail to be prejudicially affected unless its higher ranks be remunerated in proportion to the requirements of the time and the current value of skilled and unskilled labour.(o) The investigation of the history of prices shows that a moderate surplus income is necessary for the promotion of social and moral integrity and intellectual culture. The man whose income barely covers his outlay will be much more likely to adopt questionable methods of procuring money than one whose income is more than equal to his requirements. In the medical profession especially it is necessary to remember this, as no other profession so essentially requires a strict adherence to the principles of honour to prevent it degenerating not only into a trade, but into a very questionable trade.

During the course of the present century another agency has been at work in inducing a combination of conditions such as renders it imperative that people in respectable grades of society should have proportionate incomes. The progress of invention and manufacture has greatly increased the number of articles of taste and luxury; and though that may appear at first sight to be a small outlet for the spending of money, yet it is one of those small outlets whose constant stream leads to a leakage of no inconsiderable magnitude.

Independent of the many considerations which we have adduced in support of our own claim for an increase of the consulting fee, there are others on which we cannot enter. For instance, there are increased house-rent,(p) increased value of higher education, increased expenses of individual members of families, and many similar and self-evident conditions. We would refer such of our readers as are desirous of further information to independent sources of investigation. They will certainly find that, with an intermission due to exceptional agencies, the cost of living has gradually increased throughout the course of modern history, and that since 1849 there has been a steady advance in prices associated with conditions directly necessitating a still further advance.(q) Up to thirty

(a) "It is probable that some of these prices included board, which was valued at 10s. a week in case of ploughmen, as in other places men-tailors are said to have earned 13s., and women-tailors 7s. a week."—P. 217.

(b) This was in a gentleman's family. In the year 1839 (which was a cheap year), domestic wages had in the same district reached double these sums and were steadily increasing.

(l) "Results of the Trade of the United Kingdom during the year 1860, with Statements and Observations relative to the Course of Prices since the year 1814." By William Newmarch, Editor of the *Journal of the Statistical Society*. At Newgate Market the highest quotations for beef were—in 1851, 32d. and 36d. per eight lbs.; in 1861, 50d. and 52d. The Metropolitan Market prices in the *Times* for Tuesday, November 11, 1873, taken at random, are 74d. to 78d. Mutton was, at Newgate, in 1851, 44d. to 46d.; in 1861, 56d. to 60d.; and in Metropolitan Meat Market of 11th inst., 78d. to 82d. per eight lbs. Previous to this date (11th inst.) prices have been for some time rather lower than usual, even though it is understood that Government has been purchasing for the Ashantee expedition.

(m) Porter's "Comparative Statement of Prices and Wages."

(n) In Lancashire, wages between 1839 and 1859 increased to an extent varying in different trades from 10 to 45 per cent. Between 1851 and 1861 wages in the building trade had increased 10 per cent., and since then a constant advance has been going on.—See "The Increase of Material Prosperity, etc.," by J. H. Elliott, *Statistical Journal*, vol. xxxi., p. 365.

(o) "While statisticians are disputing, society has practically accepted the fact of a rise. The pay of the army is increased; the whole of the Civil Service and the staff of the Bank of England receive larger salaries; and, could the information be obtained, I believe the same change might be shown to have occurred in most private establishments."—Jevons, in *Economist*.

(p) There is a difficulty in determining advances in house-rents, as differences of accommodation cannot in comparisons always be taken into account. Professor Rogers found, however, that during the course of the sixteenth and seventeenth centuries rents had been doubled twice in 170 years. It is fair to surmise that during the eighteenth and nineteenth centuries there has been at least a proportionate advance. Also, Tooke's "History of Prices," vol. i., p. 313.

(q) "Since then—1849, the first year of the gold discoveries in Australia and California—the course of prices seems to have been entirely altered, and a permanent rise has been established"—Professor Jevons. Jevons' calculations are based on the price-lists of the *Economist* and the tables in Tooke's "History of Prices."

years ago Ireland alone used to supply us with the meat we required beyond our own native produce; but at present, while we import the full surplus food of every country in Europe and of America,(r) Australian produce has recently been introduced in the attempt to meet a demand which, notwithstanding high prices, continues to increase.

Under such circumstances involving present high prices and threatening future advances, the medical profession ought rightfully to claim a modification of fees, so that our leading physicians and surgeons may receive for their services a fee equivalent—not in name, but in reality—to that prevalent in comparatively recent periods, when one guinea was equal to at least three of our sovereigns; and members of the profession not in consulting practice may then also obtain a proportionate payment for their services.

THE PHYSIOLOGY OF VISION.

I.—The Identity of Light and Heat with other varieties of Force.

When we were at school we used to be taught that light, heat, and electricity were imponderable bodies—matter, that is, over which gravitation had no power, and which consequently could not be weighed. This corpuscular or material theory of light had its origin with Newton, whose genius did much to commend it to the minds of men, and was held up to the last even by such men as Sir David Brewster. But even before the days of Newton, that wonderful man Hooke had in his enunciated views shadowed forth a different idea, and had in some degree anticipated the grandest of modern generalisations—the unity and indestructibility of force. He is thus quoted by Tyndall: (a)—"First," he says, "that all kinds of fiery, burning bodies have their parts in motion, I think will be very easily granted to me; that the spark struck from a flint and steel is in rapid agitation, I have elsewhere made probable; that heat argues a motion of the internal parts is (as I said before) generally granted; and that in all extremely hot shining bodies there is a very quick motion that causes light, as well as a more robust that causes heat, may be argued from the celerity wherewith the bodies are dissolved. Next, it must be a vibrative motion." Here we have plainly enough shadowed forth the great modern doctrine of the identity of light and heat, or rather their common origin in vibratory motion. All this, however, was forgotten and eclipsed by the grand discoveries by Sir Isaac Newton of the nature and character of gravitation and of the complexity of white light. Nor did even the true nature of light occur to anyone subsequently, till the whole thing was worked out in a masterly manner by Dr. Thomas Young, who first and finally established the true nature of light, as wave-motion or vibration in an ether otherwise imperceptible to us.

About the year 1840, working in two opposite directions, a German country doctor and a Manchester manufacturer nearly simultaneously came to a momentous conclusion—viz., that the amount of force available in nature does not vary; it may change its mode of manifestation, and so seem to cease to exist, but in reality is indestructible. True, the doctrine did not assume a perfect form all at once; but once announced by Dr. Mayer and Joule, some thirty years ago, it has not ceased to rivet the attention of the later investigators, from whose hands it has issued even mathematically correct, and "Joule's unit," as it is called, is now universally used in engineering science as the basis for calculating how much work can be done by a given quantity of heat. For the due understanding of the transformation of force, we must first aim at elucidating the simplest modes of force. We all know that heavy bodies are attracted by the earth to a degree which admits of being measured, and which we call their weight, and that this tendency may be utilised and converted into work—say in raising another body to a given height; and it is this which, in a certain way, is taken as the basis or unit already spoken of. A pound weight falling one foot generates a force which, could it be applied undiminished for the purpose, would suffice to raise a pound weight of any substance through the space of one foot. This is the unit of work; it is called the foot-pound. Now, Joule's researches aimed at measuring exactly the amount of heat which could be generated by the fall of a given weight through a given distance; and by means of appropriate apparatus he was able to prove that the weight of one pound falling through a height of 772 feet was able to raise a given weight of water 1° Fahrenheit. The heat was in this case produced by the old familiar process of friction. Thus it was shown that work might be made to appear as heat; and the converse process of converting work into heat is familiarly illustrated to us by the steam-engine. But in the last case another mode of force is visible. The heat used is generated by combustion; and combustion is essentially a chemical process in this case, consisting of the oxidation of carbon. Here, however, another fact had to be determined—viz., whether the heat developed by the oxidation of carbon is always the same in the end whether the oxidation goes on quickly or slowly. About this there is now no reasonable doubt. But is it possible to again render the carbonic acid produced by this combustion a source of active force? for if not, then this force is permanently locked up—in fact, destroyed. In reality we see the converse process going on around us day by day in vegetable life, where carbonic acid is constantly being absorbed, the carbon fixed as wood, and so again rendered a potential source of energy. This can be still more clearly demonstrated in the case of hydrogen, which, when oxidised, produces great heat, the new compound being water; but water may be decomposed, and hydrogen and oxygen set free in a condition capable of again yielding the mode of force called heat by their chemical union. This is done by the mode of force called galvanism or electricity, which, in its turn, is generated by the chemical action of sulphuric acid on zinc, or some similar decomposition essentially chemical in its nature; so that we have here the chemical force converted into electricity, and the electric force acting so upon water as to render its components once more chemically active.

The cycle is complete. Work can be made to give rise to heat, and heat to work; chemical force may give rise to heat or to electricity; whilst this last may appear as chemical force, as heat, and as light. We have said little of the assumed identity of heat and light, because they are so intimately connected that it is harder to conceive of them apart than to conceive them of common origin. The rays of the sun are at once light- and heat-giving; all our artificial means of lighting also generate heat, and, if we concentrate the sun's light-giving rays, we do so with what is emphatically called a burning-glass. It is only when we call to mind that objects may give out heat before they are heated red-hot that we realise the fact that they are in some respects dissimilar. Nevertheless, they are in essence the same: both consist of vibrations or waves, both are contained in the solar rays—the only difference being that the waves which give rise to the sensation of heat are longer than those that give rise to the sensation of light; and whereas the long heat-waves can be appreciated by any sentient surface of the body, the shorter light-waves require a special organ for their due appreciation, which is the sentient surface we call the retina. But besides these—the long heat-waves and the medium light-waves—there are still others too short to

(r) Messrs. Edmund Phillips and Son's "Report on the Provision Trade," 1859.

(a) "Six Lectures on Light, delivered in America in 1872-73, by John Tyndall, LL.D., F.R.S., Professor of Natural Philosophy in the Royal Institution." London: Longmans. Pp. 277.

produce any effect on the retina, though they can manifest themselves by their chemical effects. These are the so-called chemical or actinic rays, to which the effects of photography are due, but which are not appreciable by our unaided senses. Thus we have light, heat, and chemical action generated by rays identical in kind, origin, and substance, differing only in their wave-lengths, and to which alone is due the difference in their physical effects.

THE WEEK.

TOPICS OF THE DAY.

It was announced in the *Gazette* of Friday last that "the Queen has been pleased to appoint George Burrows, M.D., F.R.S., and Physician-Extraordinary to her Majesty, to be one of the Physicians-in-Ordinary to her Majesty, in the room of Sir Henry Holland, Bart., M.D., F.R.S., deceased. The Queen has also been pleased to appoint Edward Henry Sieveking, M.D., to be one of her Majesty's Physicians-Extraordinary." The whole profession will be gratified by the new honour conferred on the much-esteemed President of the Royal College of Physicians. There is no member of our common profession who possesses more thoroughly and more deservedly the confidence of his brethren than does Dr. Burrows. Of Dr. Sieveking's appointment we spoke last week. The Court medical appointments of the present reign reflect the highest credit on the advisers of the Sovereign in these matters.

We regret to hear that Mr. Quain contemplates retirement from the representation of the Royal College of Surgeons in the General Medical Council. We believe that the resignation of Mr. Quain will prove a loss to the General Medical Council and to the College of Surgeons that will not be easily repaired. No member of that body has had more thoroughly at heart the interests both of the medical profession and of the College which he has most worthily represented.

From some expressions which fell from Mr. Bradford, the representative of the Society of Apothecaries in the General Medical Council, in his speech at the annual dinner on Lord Mayor's-day at Apothecaries' Hall, we gather that it is the intention of the Society to obtain from Parliament, as soon as possible, the necessary powers to join in the Conjoint Examination for England and Wales. We believe that the assent of the Government has already been asked and obtained, and that an enabling Bill is prepared, and will be passed through Parliament in the next session. This being done, the only question will be as to the course which will be pursued in Scotland and Ireland. If the profession in the sister countries will agree to establish conjoint boards similar as regards fee, requirements, and standard of examination to that which will be established in England, there can be no doubt the whole profession and the public will be benefited. But we fail to see that any benefit will accrue from partial and imperfect combinations, and we should look with dismay at the erection of one portal in England, whilst two remain open in Ireland, and at least eight continue to compete for the "siller" of the medical student in Scotland.

The following document is in course of signature, and has already been signed by many of the leading medical and other inhabitants of the district supplied by the Dairy Reform Company:—

"To Charles Murchison, M.D., F.R.S., LL.D.—We, the undersigned, late customers of the Dairy Reform Company, and others interested in public health and pure milk supply, desire publicly to express to you our sense of the skill and perseverance with which you traced and established the cause of the late alarming and fatal epidemic of typhoid fever. We owe to you the vigorous proceedings which forced an inquiry and arrested the epidemic. We wish to express our sympathy with you for the serious illness of several members of your family, and our indignation at the manner in which you have been publicly attacked by the manager and secretary of the Dairy Reform Company."

From Scotland there is another story of the reappearance of the sea-serpent. The supposed marine saurian has been seen on three different occasions—by two ladies from Dunrobin, by Dr. Soutar, and by the Rev. J. M. Jonas, of Golspie, a gentleman who has some reputation as a naturalist. Dr. Soutar describes it as apparently about forty or fifty feet long, "rushing about near the shore and raising a neck about four feet above water." A drawing made of this frisky apparition represents its back composed of a series of concentric rings, with a long neck and a pair of ears similar to a horse's. Mr. Jonas supposes it to be a plesiosaurus or some allied form. Mr. Frank Buckland suggests the more probable explanation of a long line of porpoises or seals, supposing the apparition to have been living; if dead, of a mast encased with seaweed.

Mr. Richard Davy has been appointed Surgeon to the Westminster Hospital, in the place of Mr. E. Legge Pearse, resigned.

Mr. Francis Mason has been appointed Consulting Surgeon to the St. Pancras and Northern Dispensary, in the place of the late Mr. Bishop. Mr. Mason was Surgeon to the Dispensary some years ago.

We this week have the pleasure of publishing a very valuable paper on the late epidemic of "dengue" in Madras, from the pen of Moodeen Sheriff, a Mahomedan gentleman, and Surgeon to the Triplicane Hospital, who has himself performed the journey to Mecca. The importation of the dengue from Arabia to India will constitute an interesting page in a future history of epidemics.

THE WAR ON THE GOLD COAST.

There seems to be little doubt that all the details of the Ashantee War were deliberated on at the Cabinet Council on Monday last; and, from the anticipatory preparations which have since been quietly going on, it would appear as though the Government were fully prepared to act at once upon the requisitions which it is fully believed the West African mail, due on the 15th inst., will convey.

The troop-ships *Himalaya* and *Tamar* will leave Plymouth on the 15th inst. for Queenstown, where it is expected they will embark the 2nd Battalion of the 23rd Regiment and the 2nd Battalion of the Rifle Brigade. These regiments have called in all their detachments, have received their medical equipment, and are kept in readiness to go on board at extremely short notice. It is rumoured that each of these corps will have five medical officers attached to it, so as to insure a thorough medical supervision.

Surgeon-Major T. Basset Reid, has sailed in the mail steamer of the 5th inst., to reinforce the medical staff at present doing duty at Cape Coast Castle, and a large number of army medical officers have been warned to hold themselves in readiness to embark for the same destination. Probably no expeditionary force ever yet left this country with so strong a contingent of medical men attached to it as will be the case in the present instance, should the contemplated arrangements be duly carried out.

We hear that several of the officers upon Sir Garnet Wolseley's staff provided themselves before starting with the prescription for bilious remittent fever so strongly recommended by Dr. Livingstone. It will perhaps be remembered that in his interesting volume on the Zambesi expedition the Doctor published the ingredients of a pill which was found to be of the greatest service to everyone accompanying him. The formula includes resin of jalap, powdered rhubarb, quinine, and calomel, and was always administered previous to the employment of quinine.

Hypodermic injection will no doubt be largely resorted to in the treatment of the sick on the Coast. In many cases the stomach rejects quinine almost as soon as taken, and, as its exhibition by the enema is very unsatisfactory, the only other method of employing it is by hypodermic injection. Ample supplies of quinine must be forwarded, if not already provided, as it is being generally administered, prophylactically, to all Europeans who have arrived on the Coast.

Whatever may be the result of the campaign, the Government would appear to be perfectly unanimous as to the means adopted for prosecuting it, and tolerably easy as regards a satisfactory termination; for it is semi-officially announced that, though Ministers will remain in town, there will probably be no more Cabinet Councils held for some time after the end of the present month. This confidence should be a good augury for the ultimate success of our arms.

UNIVERSITY OF DUBLIN.

On Saturday, November 8, the Board of Trinity College appointed Edward Halloran Bennett, M.D., University Anatomist, Professor of Surgery in the room of Robert William Smith, M.D., deceased. This appointment has given general satisfaction, more especially in the School of Physic in Ireland, which has been the scene of Dr. Bennett's labours for many years. The post of University Anatomist, thus rendered vacant, has, we believe, been offered to Dr. Thomas Evelyn Little, one of the Demonstrators of Anatomy in the School of Physic, and a very distinguished graduate of the University.

THE EDINBURGH UNIVERSITY CLUB.

On Wednesday evening the members of this Club assembled at St. James's Hall, Piccadilly, according to custom, to dine together for the fourth time during the present year. Between forty and fifty gentlemen were present, including some visitors of distinction, among whom were Mr. Savory, Professor Wanklyn, and the Rev. Dr. Gordon. Dr. Wilbraham Falconer, of Bath, occupied the chair. The toast of "Prosperity to our Alma Mater" was proposed by Dr. George Harley. In the course of his remarks Dr. Harley alluded to a statement recently published by the authorities of the Dublin University, to the effect that that University was the first to introduce clinical medicine as a systematic course of instruction for students at the bedside, when a class of this sort was instituted at the University towards the close of the last century. Dr. Harley had taken the trouble to refute this statement by referring to certain documents to show that Professor Cullen conducted a class of Clinical Medicine about the year 1780; and Dr. Sharpey had proved that a chair of Clinical Medicine in the University of Edinburgh was founded about the year 1748. Dr. Lyon Playfair, C.B., M.P., referred to the representation of the University *àpropos* of the coming election. For all he knew, before the Club met again he would have to seek for a renewal of their confidence as their representative member in the House of Commons. The constituency when he was elected numbered 5000 members on the Council of the University. He had recently revised these numbers, and found that while there had been considerable changes and additions the constituency remained numerically the same. Dr. Playfair referred to the growth and development of the universities in Scotland, and the ever-increasing numbers of English students availing themselves of the Scotch degrees. The authorities of St. Andrews University, having watched the rapid increase of the neighbouring town of Dundee, had resolved to establish an affiliated college in this important centre of commerce for the East of Scotland. The Town Council of Glasgow were now erecting a magnificent building, which would stand comparison with, and in many respects surpass, any of the university buildings in the United Kingdom. Dr. Playfair alluded with pride to the confidence hitherto placed in him, and to the marked absence of party, political, or religious bias in a mixed constituency whose object it was to return a man who would best promote the interests of the University in Parliament. Dr. Playfair concluded by saying that some reforms in the charter of the University, which had been long contemplated, had made such progress that they had now only to go through certain forms before they would become law. The dinner was served in the usual Scotch style, interspersed with some lively Scotch songs.

THE MIDDLESEX HOSPITAL MEDICAL SOCIETY.

The opening meeting of the 100th session of this Society was held in the Board-room of the Hospital on Thursday evening, November 5. Mr. Andrew Clark, the President, occupied the chair, and Mr. Smith, the House-Surgeon, read a paper on "Erysipelas" to a large meeting, consisting of over sixty students, most of the resident officers, and some few of the staff of the Hospital. Before the paper of the evening was read the President addressed some remarks to the meeting bearing upon the advantages which societies of the kind offered to students, more especially when—as is the case at the Middlesex Hospital Society—some of the lecturers and members of the staff took an active and personal interest in the proceedings. He then stated that during the past session there had been many very excellent papers read and discussed, numerous and instructive pathological specimens had been exhibited, and the meetings had been well attended throughout. He was glad to state, too, that the treasurer had a satisfactory report to make. After throwing out some hints as to subjects upon which papers might be written and with advantage brought under the notice of the Society, he called on Mr. Hammond Smith to read his paper on "Erysipelas." Mr. Smith dwelt more particularly upon the etiology of erysipelas, and referred to the outbreaks which occurred in the military hospitals during the late Franco-Prussian war, also to the repeated occurrence of the disease in one particular bed in the Middlesex Hospital. He brought some evidence to support the view that there is a close relationship, if not an actual identity of nature, between erysipelas and puerperal fever, and he concluded his essay by laying stress on the importance, in the treatment of the disease of paying attention to general rules of hygiene rather than to the particular drug that should be administered internally, or the styptic that should be applied externally. We understand that this Society intends to celebrate the centenary of its existence by a *soirée* in January.

MEMORIAL FROM INDIAN MEDICAL OFFICERS.

A memorial (which appeared in this journal on October 25) praying for the redress of certain grievances has just been presented to the Secretary of State for War by the Surgeons-Major and Surgeons of the Army Medical Department serving in India, signed by 213 out of 306 members of that body in active service. The principal grievances detailed in the memorial are the following:—That the Army Medical Warrant of March, 1873, has inflicted material injury upon the Surgeons-Major and Surgeons by withdrawing many rights and privileges; that a large number of the memorialists have been suddenly deprived of appointments in regiments, to their positive loss of income; that the relative rank of medical officers is lower than it should be; that selection for promotion is the rule and not the exception, at the expense of merit and long service; that selection is placed in the hands of the Commander-in-Chief, instead of being vested, as it should be, in the head of the memorialists' own profession; that retiring allowances are calculated upon too low a scale, considering the increased cost of the necessaries of life; that administrative appointments are indefinitely prolonged; that the term of

leave granted is not sufficient; that the position of the memorialists at mess is false and unworthy; that military men are appointed governors of general hospitals, whereas such posts might with advantage be conferred on medical officers; and that there is no allowance to medical officers in charge of regiments and batteries of artillery.

THE LAST ILLNESS OF THE LATE EMPEROR NAPOLEON.

At a supper in connexion with the Midland Medical Association at Birmingham, on Saturday last, Sir Henry Thompson referred to Mr. Gamgee's allusion to one subject (the death of the Emperor Napoleon), which, he said, was the only one upon which he (Sir Henry) must not utter a word. He imagined they all valued, as one of the highest qualities of members of their profession, the utter impossibility of anyone being able to get out of them that which had been committed to their care. It was utterly impossible for him to reply to the inuendoes which one found in journals and abroad. With regard to the case to which Mr. Gamgee had referred, if it had been the case of Smith, Brown, or Jones, they knew he should not speak about it for the world; and how could he about that case? But the time would come—and he should demand that time—for those charged with making known what was to be known about the case, to do so. After all, it was a plain, straightforward case, such as they and he saw in the hospital every month or two; but the position of the personage made it so much more interesting. When the time did come—and it would come one of these days,—he should insist that all the particulars of the case should be made known, and he should not flinch from any verdict which his professional brethren might give. He was ready to rest any reputation he might have upon everything he did in that case; and he might venture to say, in connexion therewith, that he did not look back with regret upon anything he counselled or did, and that he should be able to prove when the time came. It is to be regretted that any further delay should occur with reference to the publication of the details of the illness to which the late Emperor Napoleon succumbed. Taking for granted, as we do, and as Sir Henry Thompson says, that "it was a plain, straightforward case," we are at a loss to understand why the particulars have been so long withheld from the public. It is due to all parties concerned, but more particularly to Sir Henry Thompson himself, that an immediate stop should be put to rumours, however unfounded, which are, nevertheless, regarded by many as having some foundation in fact.

ANTI-VACCINATION IN MARYLEBONE VESTRY.

We should scarcely have thought that any, much less a metropolitan parochial body, nowadays could so far have supported the anti-vaccination theory as to refer the subject for serious inquiry to a parochial Sanitary Committee. Yet such a proposal has just been adopted by fourteen against twelve votes. The overwhelming evidence which has been from time to time produced in establishing the beneficial results of vaccination; the Act of Parliament legalising its compulsory enforcement after a most exhaustive inquiry by the Legislature, are to be subjects of an inquiry by the collective wisdom of a Marylebone Sanitary Committee. The following discussion took place on this subject at the Marylebone Vestry meeting, last week, on the return from the board of Guardians of the number of persons vaccinated during the past year being read:—Mr. Emery stated that he held in his hands an extract from medical journals showing that the most loathsome diseases were promulgated by vaccination, and he moved that the subject be discussed at the next meeting. Mr. Hiscox seconded the motion. Professor Marks said that discussing the question would lead to no practical result, and moved the next business. The motion was seconded and negatived. Mr. Taverner held that the subject was essentially a medical one, and ought to be considered by practical men capable of giving an opinion thereon; he would therefore ask Mr. Emery to refer it to the Sanitary Committee or a special committee. The Rev. C. J. P. Eyre (the rector) maintained that the question was one with which the Vestry had nothing whatever to do. An Act of Parliament had been passed, and the Vestry were bound to obey it. If any alterations were required, the parties complaining should endeavour to obtain a repeal of the Act. After some further discussion the motion was adopted on a division by fourteen to twelve.

ASSUMPTION OF MEDICAL TITLES.

A case of some interest, with reference to the assumption of titles by a registered practitioner, was decided last week at the Southwark Police-court. The prosecution was evidently a vindictive one, but, leaving out all extraneous matter, may be summed up in a few words. Dr. Archer Farr, of the Waterloo-road, is a L.R.C.P. Edin., Licentiate of the Faculty of Physicians and Surgeons Glasgow, and L.S.A., and it appears has been in the habit of signing certificates and styling himself "Physician and Surgeon." It was contended by the prosecution that he acted illegally in assuming these titles. It was eventually decided by Mr. Partridge, the presiding magistrate, that the defendant had not infringed the provisions of the Medical Act, and the case was very properly dismissed, with five guineas costs. We are glad to observe that Mr. Partridge took a common-sense view of the question, free from all nonsensical and technical points.

ANALYTICAL TESTS.

A deputation of master bakers waited on the Shoreditch Vestry last week to inform the Board that to their personal knowledge they knew instances where alum had been mixed with the flour in baking, which on analysation had been certified as being pure, while in other cases the bread which had been made purposely to test the analysis was stated to contain a quantity of alum that would be injurious to human health. These (as it would appear) contradictory certificates had not been obtained from the parochial analyst, but from Dr. Letheby and Professor Gardner, of the Royal Polytechnic Institution. The statement of these facts has induced the Vestry to refer the whole question to a special committee for consideration. It was further resolved to invite parochial analysts and others to attend the committee meetings, and assist them in their investigation of the matter. We shall reserve our judgment until the report of the committee is published.

DUBLIN SANITARY ASSOCIATION.

We are glad to see that the labours of this thoroughly useful and voluntary body are at last bearing good fruit. In the Dublin papers of Monday last is contained a full description of the new floating hospital for the port of Dublin, named on the 8th inst. the *Prudence*, but not yet launched, owing to the sinking of a tug-steamer close to the slips on which the hospital was built. In the same papers an advertisement appears relative to the undertaking of domestic scavenging by the Corporation of Dublin. Thus two sanitary measures, suggested many months ago by the Association, have been carried into effect. Such is the influence for good of a practical public opinion.

TESTIMONIAL TO DR. LLOYD, MELBOURNE.

A meeting, consisting chiefly of members of the medical profession, was held on September 2 last, in Melbourne, to present Dr. Lloyd with a silver tea and coffee service, in recognition of the services rendered by him as treasurer of the Medical Association of Victoria, and editor of the *Medical*

Gazette. Dr. Lloyd, in returning thanks for the testimonial, referred to the important services rendered to the profession by the Medical Association at a time when the provisions of the Medical Practitioners Statute were being overridden and systematically evaded, to the serious injury of various members of the profession, by the metropolitan and other coroners. The service bore the following inscription:—"Presented to Frederick Lloyd, Esq., M.D., by a few medical friends, in appreciation of his services as Treasurer of the Medical Association of Victoria, and Editor of the *Medical Gazette*—August, 1873."

CONVALESCENT COMBATANTS.

Two men of the 16th Lancers (states the *Bombay Gazette*) have been entertaining the depôt at Wellington with a prize-fight. The combatants, however, after the fifth round found themselves prisoners, and were called upon for an explanation of their conduct. The Wellington depôt is a home for convalescent soldiers, and if the energy now displayed fairly illustrates the bracing effects of its climate, great credit is due to the officer who first selected it as a sanitarium.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The paragraph regarding this body last week was erroneous, for we are now informed that Mr. Tuffnell was elected Vice-President in room of Professor R. W. Smith on last Thursday, and that Professor Mapother, Mr. E. Hamilton, and Dr. Tabuteau will seek the votes of the Fellows when Mr. Tuffnell's term of office expires next June.

BRITISH PHARMACEUTICAL CONFERENCE.

The following circular is being issued to the presidents and officers of the Medical Corporations and Schools and to other leading members of the medical profession:—

"Sir,—At the tenth annual meeting of the members of the British Pharmaceutical Conference, held at Bradford during the third week of September, 1873, the important subject of unusual doses in prescriptions, and the position which pharmacists should occupy in relation thereto, was carefully and patiently discussed in its pharmaceutical bearings by members from all parts of the country. By an 'unusual dose' was understood a large quantity of potent medicine designedly prescribed in rare cases, but which, as a rule, would not be dispensed by the pharmacist without hesitation. The result of the debate was the unanimous adoption of a series of resolutions embracing what was believed to be the essentials of safe practice in the matter. Further, the President of the Conference was requested to bring the resolutions under the notice of the presidents of the Medical Colleges and Corporations, and other leading medical authorities, and the medical journals, in the hope that the action taken would be approved and supported by physicians and medical practitioners generally. The proposal is that the prescriber should call attention to an unusual dose by adding, on the same line, his bracketed initials, thus (F. W.). A similar plan is already adopted on the Continent, and, indeed, in some countries is enforced by law. Appended is a copy of the resolutions. I trust that they will meet with your individual approval, and that you will contribute your influence in giving them wide publicity amongst the members of the medical profession.—I am, Sir, yours faithfully, Thomas B. Groves, President."

The following are the resolutions above referred to:—

"That this Conference, having considered various proposals for the use of special signs to mark unusual doses on prescriptions, and the great advantages to be derived from such signs, considers that the bracketed initial letters of the prescriber's signature, written immediately after the unusual dose, is the best suited for the purpose. This Conference also respectfully urges upon medical men the importance of the prescriber's full name and address being written on *all* prescriptions, to facilitate communication between the prescriber and dispenser. This Conference likewise considers it desirable for the dispenser to retain all prescriptions in which initialled unusual doses are prescribed."

FROM ABROAD.—NÆVUS TREATED BY CROTON OIL—DR. SCHWEIGGER ON ETHER IN PLACE OF CHLOROFORM.

Dr. De Smet communicates to the *Presse Médicale Belge* (November 2) an account of a case of nævus which he has successfully treated by means of croton oil. He observes that when the nævus is visible, vaccination is objectionable on account of the cicatrices which are left; and moreover, as in his own case, the child has frequently been already vaccinated. In this case the girl, five years of age, had a small nævus, which was situated immediately below the lower eyelid. Numerous small superficial vessels also converged towards it, the nævus, including these vessels, being a little larger in size than a half-franc piece, and having a slightly projecting centre. After perchloride of iron had been tried without avail, the croton oil was resorted to. Fifteen sewing-needles were passed through a cork so as to allow their points to project for about two millimetres, and the points were so disposed as to represent as nearly as possible the form of the nævus and the direction of its chief vessels. The cork was then dipped in croton oil, and, having been applied exactly over the nævus, the points of the needles were quickly forced into the part. Painful at the moment, this inoculation only left after it a slight sense of heat and pricking. A little wadding constituted all the dressing. Next day there was some swelling and a little vesication, but no pain. On two occasions, at intervals of two or three days, the part was slightly painted with the croton oil. The success was complete, the nævus completely disappearing, and the vessels becoming obliterated, so that no trace of the malady remains.

The advantages of the plan of treatment consist in the entire absence of cicatrix, its easy application, the little pain caused, and the rapid effect produced, the patient in this case being cured in a week. Of course it would not be applicable when the nævus is deep-seated and its vessels are voluminous, but it is well suited for cases where the nævus and vessels are superficial, and especially when the child has been vaccinated. Probably in some cases repeated frictions with the oil might suffice, but when the vessels have attained a certain magnitude their obliteration requires the punctures.

At a meeting of the Berlin Medical Society (reported in the *Wochenschrift* of October 13) Dr. Schweigger read a paper on "Ether-Narcosis," wishing to draw attention to a subject that has excited more attention in England and France than in Germany. In reference to operations upon the eye, with which he has most to do, he said he was of opinion that anæsthetics should be employed; for in operations in which a millimetre more or less may decide the fate of a man we cannot be too careful in our technical procedures; and that such operations are more easily executed under narcosis is undeniable. But to attain this end we must narcotise very deeply. It does not suffice to render the patient merely unconscious; and no operation should be begun until the cornea has been rendered so insensible as to allow of the contact of the finger or the introduction of the fixator without the excitement of reflex action in the eyelids and muscles. This is one of the disadvantages of anæsthetics, as in some individuals they have to be employed for a full hour before this end can be attained. In some cases, and especially in *abusus spirituosorum*, we can hasten on the narcosis by a preliminary injection of morphia; but even this, although seldom, fails, and there are individuals who cannot be narcotised. Another disadvantage is the occurrence of vomiting, which, however, may usually be avoided by narcotising on an empty stomach. Its danger is the greatest disadvantage of chloroform; and although Dr. Schweigger has never met with a fatal case, yet he has not infrequently witnessed appearances that indicated the greatest danger to life. A circumstance which should always be carefully attended to is the state of the pupil. A

moderate dilatation of this warns us to be careful, while a suddenly occurring and wide dilatation is always a sign of impending asphyxia. The moment this is observed, or when the respiratory movements are insufficient or arrested, the tongue should be drawn out of the month by means of a hook-forceps. The respiratory movements, which had been arrested by the falling back of the root of the tongue on the epiglottis, then are resumed. And to this, the most simple and the longest known procedure, Dr. Schweigger attributes his having been able to restore several patients who were in a most dangerous condition. Wishing to avoid, if possible, these terrible contingencies, he has of late resorted to ether, and has been so well satisfied with the results that he has not recurred to the use of chloroform. The ether narcotises as deeply and as rapidly as chloroform, while, after the inhaling apparatus has been removed, consciousness is sooner restored. In the light of his recent experience, he can only wonder how it came to pass that the employment of chloroform so rapidly superseded that of ether, and can only attribute this to the fact of ether being at that time badly administered. Nothing can be simpler than the apparatus now employed. A napkin is folded into the shape of a funnel, at the bottom of which is placed a piece of sponge of suitable size, and the whole is placed within a similar funnel, formed of impermeable material. Not less than twenty-five grammes of ether are poured upon the sponge, and the funnel is so applied as to include both month and nostrils. Used in this way, the ether exhibits no disadvantage as compared with chloroform, while it possesses the very great advantage of being much less dangerous. The circumstances which led Dr. Schweigger to abandon the use of chloroform have never been witnessed by him during the use of ether. Dr. Bardeleben observed that the superiority of chloroform to ether became so rapidly admitted because, in fact, the bulk of operations were not those on the eye. The fugitiveness of the effects of ether were just those which rendered it of little use to the surgeon; and its use is by no means free from danger, as death has resulted from it. If ether be preferred for operations on the eye, chloroform will continue to be employed in other operations. Dr. Liebreich observed that in operations on the eye rapid narcosis is desirable, and, as this can be accomplished by several narcotics, the least dangerous should be chosen. Chloroform and ether are both dangerous, death resulting suddenly from paralysis of the heart, and when the symptoms of this appear all means are useless. The bichloride series, such as the bichloride of methylene, which is much employed in England, are of safer employment. In them the narcosis commences in the head, the other parts of the body becoming narcotised only after some time. When dilatation of the pupils is observed during the use of chloroform, it is probable that it is not pure, but mingled with some of the bichloride series, which always induce such dilatation. Ethylidenchlorid produces a narcosis than which none can be better for operations on the head. Anæsthesia of the head is produced while muscular tone still continues, and rapid recovery from its effect takes place. These bodies possess the advantage of not producing paralysis of the heart, as may easily be seen by experiments on animals. In reply to Dr. Bardeleben, Dr. Schweigger observed that the shortness of the duration of the narcosis from ether was no objection to its use, as this may easily be prolonged by additional ether. Its danger is infinitely less than is that of chloroform. Dr. Lewin wished to call attention to a mode in which death is sometimes caused during narcosis. Some time since he produced a normal degree of narcosis by means of chloroform, when the patient made a deep and stridulous inspiration, and the various symptoms of impending death appeared. Passing the finger down to the larynx, it was found to be quite closed, the free end of the epiglottis having passed deeply into it, so as to seem fixed in the rima, completely blocking up the entrance of the larynx. On drawing out the epiglottis, respiration became re-established, and the threatening suffocation was averted. It may be supposed that in some of the cases of death from chloroform a similar condition of things has prevailed, the epiglottis having fallen backwards, its free end becoming fixed within the rima during inspiration.

NOTES ON FOREIGN HOSPITALS AND SCHOOLS OF MEDICINE.

I.—Denmark.

Denmark possesses but one university and medical school—the University of Copenhagen. Nine years ago the Danes could boast of a second University—at Kiel,—but this they lost when Schleswig-Holstein was ceded to Germany after the war of 1864. It is to the capital of the country, therefore, that the stranger must go who wishes to acquaint himself with the state of medical education in Denmark.

University education in Denmark is under the administration of the State, and so, with public resources virtually at their command, a few influential and energetic men have been able to accomplish great results in the departments of science and medicine. There is no miserable competition here of divided or opposed private interests, such as works so banefully in London; but the country being small and the University without a rival, there is complete unity of purpose in the plans which are being adopted for sound medical training. The results have been equally successful. In many departments of medical education, and probably on the whole, Denmark is setting England an example which she will do well to follow, both as regards her system of scientific and clinical training and the provisions for carrying this out with success. She is well forward in the great reformation in medical education which for the last fifteen years or more has been breaking over the face of Europe. The arrangements are, however, by no means definitely completed. While England is anxiously remodelling her entire system of medical education and examinations, and Germany daily increasing the number of laboratories and hospitals from north to south, one could hardly expect to be informed that the medical faculty at Copenhagen has established a perfect system of training, that natural science in Denmark is housed in perfect laboratories, and the practical physician taught in hospitals which are beyond improvement. We do not wish to make such a statement, for we shall have occasion presently to describe how extensive are the reforms which are still being planned and carried out. But this we confidently say—that, what with the recent and projected additions to the buildings for experimental science, especially in the way of laboratories and museums, and the possession of one of the finest general hospitals in the world, as well as of a special clinical hospital, the Danes have much less to do before they rest satisfied with their work than almost any of their neighbours.

The curriculum of medical study at the University of Copenhagen occupies six years, the first two of which are devoted to what might be called purely preliminary or scientific subjects. As in our own country, there are two sessions in each year of study, but they are peculiar in Denmark in being spring and autumn, instead of winter and summer sessions. The spring or first session commences on February 1, and ends in the first week of June; the autumn or second session commences on August 23, and ends on December 22. The English visitor who is anxious to see the Danish system of medical education in actual working will do well to bear this arrangement in mind.

The first year of the student's curriculum—he can hardly be called a student of medicine until the first two years of preliminary scientific education are past—is devoted to philosophy, including logic, psychology, and the history of philosophy. At the end of the second session an examination is held on these subjects.

The second year is devoted to natural science. Physics, chemistry, botany, and zoology are taught theoretically and practically, and the student works in the chemical laboratory. At the end of this year an examination must be passed on the subjects of the two preceding sessions, and this having been

done the preliminary education is finished, and the study of the purely professional departments begins.

The student now commences his attendance on systematic lectures upon anatomy and physiology (under different professors), and works at practical physiological chemistry in the laboratory of the Physiological Institute, which he can do with much benefit from his previous acquaintance with chemical facts and methods of a more elementary kind. He does not dissect during the first year. As a rule many of the students now go to the Clinical Hospital and attend the surgical practice; but this arrangement is neither enjoined nor recommended.

Anatomical dissections are commenced by the student in his fourth year, and continued during four successive sessions. At the same time and for the same period he attends lectures on medicine and surgery; so that for two whole years he is making himself familiar with three subjects which are probably the most important of the whole curriculum. During this period, also, the student attends to several other departments. In the fourth year, for example, he is instructed in the principles of general pathology and in pharmacology; while fourteen days in each session of the fourth and fifth years are devoted to what are called "medical practice" and "surgical practice," but which really consist in little more than writing prescriptions under the direction of an assistant-physician. Of infinitely greater advantage to the student are the surgical and medical clinics, which he now attends regularly, as will be described when we come to consider the Danish hospitals.

The first professional examination comes on at the end of the fifth year, and comprises anatomy, practical anatomy, physiology, and pharmacology. This over, the sixth and last year of study is entered upon. Systematic lectures are delivered to the men of this year on therapeutics, forensic medicine, and midwifery; pathological anatomy is fully studied; and, in addition to the ordinary clinics, those especially devoted to diseases of children and syphilis are attended. In the second session of this, their last year, the students go by the name of "examinatores," and when it is completed the second professional examination comes on. At this examination the candidate has to give evidence of a satisfactory knowledge of the following subjects:—1. Medicine, theoretical and practical, and a thesis. 2. Surgery, theoretical, practical, and operative, and a thesis. 3. Pathological anatomy. 4. Forensic medicine. 5. Midwifery.

Having passed through this ordeal, the licentiate has still to study midwifery practically before receiving the degree of doctor of medicine; this occupies only six weeks.

The average number of medical students at the University of Copenhagen at the present time is about 300—that is, about one-fifth of the men attending the various faculties. The Danish as a class resemble Scotch rather than English students. Denmark is a flat agricultural country from one end to the other, and the farms of Zealand and Jütland are apparently the homes of the majority of the Copenhagen students of medicine. It would be out of place in this report to comment on the intelligence and culture of the medical profession in Denmark in general; but it is our duty to acknowledge thus publicly the extreme cordiality with which we were received amongst the professors in Copenhagen, and the very obliging manner in which they showed us all that was to be seen and answered our numerous inquiries.

The English physician who visits the University of Copenhagen will be somewhat surprised—unless he is familiar with Germany—to find the medical department located in buildings at a distance of about half a mile from the University proper. While the latter is situated in the extreme west of the old town, the buildings where anatomy, physiology, and pathology are taught, as well as the Clinical Hospital and the Lying-in Institution, will be found in the north-east or fashionable quarter of the city. Here they form a large block lying between the Norges or Bred Gade (*Street*) and the Amalie Gade, in the neighbourhood of the Amalienborg Palace and other public buildings, and but a short distance from the harbour-side. It is this block of medical buildings, much more than the University proper, that is interesting professionally, and we will at once proceed to describe the various departments which it contains. The Clinical Hospital, however, will be described more conveniently along with the other hospitals of Copenhagen, and these we propose to reserve for a future occasion.

The remaining portion of the building, which is devoted to the teaching of science, takes the shape of a large, plain house, fronting the Norges Gade and flanked by two wings which extend towards the back. The house is in great part old, but the physiological portion (occupying one of the wings) has been only recently rebuilt, and important additions will be immediately made to the other wing for the purpose of extending the pathological museum. The central point of the building is a large auditorium or lecture-room, which is common to several of the professors. The anatomical museum, dissecting-room, etc., are situated on either side of the auditorium; the pathological collection is arranged on the upper floor; and the Physiological Institute occupies the whole of the south wing. The rest of the house is fitted up as residences for the professors of anatomy and physiology—an arrangement which at first somewhat surprises the English visitor.

The anatomical department is under the superintendence of Professor Schmidt. This gentleman, though still young, has acquired considerable reputation as an anatomist. He has made several important original researches on the development of the heart and brain, and he was the first to discover and describe the adenoid tissue of the pharynx. The suite of anatomical rooms consists of a museum, a dissecting-room, a room for histology, several working-rooms for mounting preparations, and vaults for storing the subjects. The anatomical museum at Copenhagen is a single large room, containing numerous specimens arranged in cases. Some of the preparations are of great value; and we would especially notice here the wonderful injections by the "corrosion" process, a fine example of permanent left vena cava superior, dissections of the anatomy of the ear, and numerous stages of the development of the brain. The dissecting-room is of moderate dimensions, and well lighted from the west. The floor is waxed, and the walls and roof covered with glazed tiles. The dissecting-room is open from November 1 until March 31, and about ninety bodies are dissected annually. The students hurry through the abundant material, and a subject is never more than two or three weeks on the table. No special text-book is used in the dissecting-room, which is superintended by the professor and a prosector. The student attends the systematic anatomical lectures during his third year, as has been already described. Professor Schmidt lectures during the spring and autumn sessions five times a week, from twelve to one o'clock in the afternoon, and holds an examination on topographical anatomy on the sixth day for an hour and a half. The room for practical histology is but small, and is supplemented by a large room in the Physiological Institute, to be presently described. The course of elementary histology is a voluntary one, and is held at an hour arranged at the commencement of the session. Hartnack's microscope is in general use at Copenhagen.

The Physiological Institute has been recently rebuilt and arranged under the personal superintendence of Professor Panum. This eminent physiologist, who was formerly professor at Kiel, is one of the leading promoters of scientific education in Denmark, and the medical school at Copenhagen as a whole—and not merely the department of physiology, although it especially—owes much of its present prosperity to Panum's influence and zeal. As we have already recorded, physiology is taught at Copenhagen in the same year as anatomy—that is, in the third year, or first professional year of the student's curriculum. The following arrangements are at present followed:—The Professor lectures publicly four days a week during the spring and autumn sessions from eleven till twelve, chiefly to junior students. Weekly demonstrations are held for an hour in the forenoon, and twice a week colloquial examinations are made by the Professor on the subjects of the lectures and demonstrations. During the same time the students work at practical physiological chemistry in the chemical laboratory of the Institute, which we will presently describe. Elementary histology, as we have already seen, is taught by the professor of anatomy. Advanced students are instructed privately in the laboratory free of charge; and twice a week, for two hours in the afternoon, the professor and his assistant hold a course of medical chemistry in the laboratory. Senior students alone perform experiments on animals.

The Institute is a large plain building of several storeys. On the highest floor is located a select anatomical museum of human and comparative specimens arranged according to the various systems—for example, the human and comparative anatomy of the organs of hearing in one case, the same of the organs of touch in a second case, and so on. Professor Panum holds the opinion very strongly that anatomy and physiology must go hand in hand; that structure is too frequently forgotten in the study of function; and that a well-chosen collection of

illustrative anatomical specimens is indispensable for the successful teaching of physiology. In this interesting museum some of the dissections of the ear, and of the viscera of the whale, and a very extensive series of malformations and monstrosities, deserve special mention. The physiology lecture-room is seated for 100 students, and is specially fitted up for class demonstrations. The room for practical histology accommodates twenty working students at a time, their tables being arranged at the windows and in the centre of the room. There is also provision for working by artificial light by means of gas-lamps with conical shades suspended from the roof. The laboratory for physiological chemistry is equally complete in its way, being fitted up with work-places, which are abundantly furnished with reagents, gas, water-taps, and so on. The room for physiological experiments on animals is comparatively smaller, and, of course, reserved for more advanced workers. On the same floor is a small room which serves as a pharmacological museum. The collection of physiological instruments is very large and fine; the room in which they are arranged opens into the private chamber of the professor. The underground floor of the Physiological Institute is occupied with cellars used as kennels, a rough analysis chamber, and a gas analysis room. The amount of space occupied by dog-kennels, rabbit-hutches, frog-tanks, etc., is somewhat surprising to an English eye. The windows here, and, indeed, in all other parts of the Physiological Institute, are triple, to prevent the cries of the animals from proving a nuisance to non-professional neighbours.

The Professor of Pathology at Copenhagen, Dr. Reisz, who has occupied the chair for the last ten years, is also pathologist at the Clinical or Frederiks-Hospital in the neighbourhood. The valuable products of the necropsies have been preserved, and the result is an excellent pathological collection in the opposite wing of the building to that occupied by the Physiological Institute. The museum is arranged in two rooms, flanked by one or more preparing-chambers, and is already too large for the available space, so that extensive enlargements are much required and will be at once begun. The pathological collection at Copenhagen well deserves careful inspection. Diseases of bones are abundantly represented. In a large collection of diseased hearts we were shown two very instructive specimens of ulcerative endocarditis, a disease of which no fewer than five cases have now been observed at Copenhagen since the year 1858. There is also a large collection of morbid growths. Professor Reisz lectures on general pathology in the common auditorium already referred to, twice a week during both sessions, from one to two p.m. These lectures are attended, as we have already explained, by students of the fourth year. Special pathology is included under the head of Medicine and Surgery. Pathological anatomy, on the other hand, is included among the subjects of the sixth or last year. Professor Reisz lectures systematically on this subject twice a week from one to two p.m., and gives other lectures and holds examinations in the course of the week at ten in the morning. Once a week, from two to four, there is a demonstration of diseased organs; and once a week, from one to three, there is a histological demonstration of the same.

This completes the description of the building in the Norges Gade and the scientific subjects to which it is devoted. We will now pass on to notice as briefly as we can the other departments of natural science which are chiefly to be found at the University.

The University of Copenhagen is an unpretending building in the Frue Plads, which was founded some 400 years ago, but has been more than once rebuilt. Although well towards the west of the city, and so removed from the mouth of the harbour, the University was one of the places which suffered most in the bombardment of Copenhagen by the English in 1807. The entrance-hall, staircase, and *Fest-sal* are magnificently and very artistically decorated with painted roofs, frescoed walls, and wood carvings. The north side of the buildings is occupied by the library, while the new zoological museum is situated in the rear. The handsome new library does not call for description in a professional report such as this, but we may mention that among the 300,000 volumes which it contains there is a very large collection of medical works in all languages. It will also interest some of our readers to know that the 4000 manuscripts in this library include Arne Magnaus' unique and invaluable collection of manuscripts from Iceland, chiefly upon Icelandic and Danish law and necromancy.

The Zoological Museum at the University was erected six years ago, and is one of the most handsome buildings of the kind in Europe. It contains a central quadrangular court, under a glass roof, and surrounded by open corridors in three storeys, off which the various rooms open. The court, which is decorated in a splendid but artistic and appropriate style, contains the skeletons of the larger mammalia, and this arrangement has a very pleasing effect. The collection in this museum might be described under two heads—first, as it represents zoology in general; and secondly, as an exhibition of the natural history of Denmark, Scandinavia, and the Baltic. Altogether a very large collection, arranged and kept with scrupulous care under the superintendence of Dr. Lütken, the Zoological Museum at Copenhagen ranks next to those of Vienna and Berlin. It may interest the naturalist to know that he will find in it several almost unique specimens, such as a skull of the Dodo; a stuffed specimen of *Alca impennis*—a very rare northern sea-bird without wings; and another of *Didunculus strigirostris*—a rare tropical pigeon, once considered to be allied to the Dodo. Here also is Lund's celebrated collection of tertiary fossils from Brazil, presented by that gentleman to his native country. Norwegian corals are abundantly represented, and there are numerous examples of Gorgoniadæ from Norway and the East Indies, with the Gorgons *in situ*. The Zoological Museum is open for study every Wednesday and Saturday from twelve to two o'clock. A second museum, containing whales only—a very famous collection—is located in another part of the University buildings. The Professor of Zoology is Dr. Steenstrup, who, along with two extraordinary professors, gives demonstrations in the museum. We have already seen that zoology is studied during the second year of medical education.

The Chemical Institute of the University is in the Newester Gade, and here lectures and demonstrations are given by Professors Thomson and Joergensen, the former of whom is also superintendent of the laboratory. Professor Thomson lectures four days a week during the whole session, and for the first part of the session every day. On the first four days of the week, from twelve to three in the afternoon, the same professor gives demonstrations in the laboratory. This laboratory has been built some fifteen years, and contains working-places for fifteen to eighteen students. Professor Joergensen lectures twice a week on the chemistry of the metals in the second part of the session, twice a week on inorganic quantitative analysis, and twice a week on organic qualitative analysis. There is a second chemical laboratory in Copenhagen connected with the Polytechnic School. The same two professors lecture there as at the University, and the laboratory is under the superintendence of Joergensen. Separate courses of physiological and pharmaceutical chemistry are given by the professors of the respective subjects.

On another occasion we will pass on to describe the clinical teaching at Copenhagen and the hospitals of the city.

Appended is a concise statement of the course of medical study in Denmark. The subjects of study are the same during both sessions of each year. The examinations take place at the end of the year in which they are recorded:—*First year:* Psychology; Logic; and History of Philosophy. (Examination on Philosophy.) *Second year:* Physics; Botany; Zoology; Chemistry; and Practical Chemistry. (Examination on the same subjects.) *Third year:* Anatomy; Physiology; Practical Physiological Chemistry. Surgical Practice. *Fourth year:* Anatomical Dissections; General Pathology; Medicine; Surgery; Pharmacology; Medical and Surgical Clinics. *Fifth year:* Anatomical Dissections; Medicine; Surgery; Clinics. (Examination in Anatomy, Physiology, Practical Anatomy, and Pharmacology.) *Sixth year:* Therapeutics; Forensic Medicine; Midwifery; Pathological Anatomy; Clinics (including Syphilis and Diseases of Children). (Examination on Medicine, Surgery, Pathological Anatomy, Forensic Medicine, and Midwifery.) Six weeks' Practical Midwifery.

THE HUNTERIAN COLLECTION.—At a meeting of the trustees of the Museum of the Royal College of Surgeons on Saturday last, Mr. George Busk, F.R.S., a member of the Council of the College, was unanimously elected a member of the Board, in the vacancy occasioned by the decease of the Bishop of Winchester; and Mr. Alban Henry Griffiths Doran, M.R.C.S., L.S.A., of St. Bartholomew's Hospital, has been appointed Second Assistant in the Museum, in the vacancy occasioned by the resignation of Mr. Jas. Lidderdale, M.R.C.S.

REVIEWS.

Du Traitement des Plaies en général, et en particulier d'un Mode nouveau de Pansement Antiseptique, par le Coal-tar et le Charbon; suivi d'un Aperçu sur la Pourriture d'Hôpital et son Traitement. Par le Dr. Louis Beau, de Toulon, Médecin-en-Chef de la Marine; Professeur de Clinique et de Pathologie Chirurgicales à l'Ecole de Médecine Navale de Toulon. Paris: J. B. Baillière et Fils. Pp. 134.

Assuredly antiseptic surgery is in no fear of languishing at present, whatever may be the value of the theory upon which the "antiseptic" dressings are employed. Only a few months ago we reviewed in these columns a volume entitled "Earth as a Topical Application in Surgery," in which it was explained that earth, rich in yellow ferruginous clay, free from grit and foreign matter, and well dried and sifted, is an alleviator of pain, a deodoriser, and the possessor of the power (1) of arresting and sometimes of preventing inflammation, (2) of exciting wounds to heal with rapidity, and (3) of preventing putrefaction.

Now we have before us a description of the treatment of wounds by a new kind of dressing, styled by the author of the treatise, and the originator of the dressing, "*l'emulsion au coal-tar saponiné.*" This emulsion of coal-tar is asserted to possess antiseptic properties without any irritating ones, and to have power in checking congestion, inflammation, and pain.

The search after some more efficient disinfectant for offensive wounds and ulcers than was at the time known, led Dr. Hewson to employ earth: the desire to find a dressing which is at the same time antiseptic, emollient, anti-infectious, and anti-inflammatory, has led Dr. Beau to the employment of "*coal-tar saponiné.*" The greater number of disinfectants, as he says, are also irritants, but this (the only one amongst antiseptic dressings of undoubted efficacy) is an exception to the rule. It is made by mixing rather less than two and a half parts of an alcoholic tincture of saponine (obtained from *Quillaya saponaria*) with one part of coal-tar, and after digesting the mixture in a sand-bath for eight hours, it is then filtered. This mixed with water in the proportion of one-fifth part constitutes the mother-emulsion, which can be diluted according to requirements with two, three, or four parts of water, or with fifteen or twenty times the quantity; or the water of the emulsion may be replaced by glycerine. As an application to wounds this mixture is spoken of by its introducer in terms of the highest praise; so also is the employment of animal charcoal and coal-tar, with charpie steeped in coal-tar. The dressings, though in some cases they must be frequently removed, require for the most part few changes; and the dressings first applied can in other cases be left on the wounds during the whole process of healing. Then they may be reckoned in the category of the dressings which provide a permanent moisture, such as Percy, Lombard, and Larrey advocated in France, and which, under the name of "water-dressings," Macarthy and Liston in England made popular. They are, too, at once antiseptic and disinfectant and isolating dressings. The same remarks, however, which we made in noticing Dr. Hewson's treatise we are led to adopt in referring to Dr. Beau's—viz., that however efficacious the dressings may be found, we cannot hope they will obtain any great popularity, owing to the cumbrous character and the uninviting nature of the materials themselves. Dr. Beau, however, does not confine himself to an account of coal-tar for wounds, for he devotes the first forty-one pages to a description of the treatment of wounds in general. This includes some general considerations as to wounds, and as to the etiology of the complications of wounds. Then comes a rational exposition of the principal kinds of antiseptic dressings hitherto employed: —(1) *Dressings on the Principle of Occlusion* (including some remarks on subcutaneous operations), viz.—the "pneumatique occlusion" of M. J. Guerin, and the continued aspiration of Maisonneuve; as well as the isolating dressing with cotton-wool introduced into the Hôpital Saint Louis in April, 1871, by M. Alph. Guérin, and founded upon the discoveries of Pasteur and the ideas of Tyndall, but which, for reasons stated in the text, is very often useless, if not positively objectionable. (2) *Disinfectant Dressings*, including charcoal; the dust of tan, Peruvian bark, and other substances of the same kind, which act at once as coagulating and absorbing agents; resins; camphor; essential oils, and a host of other materials.

The third part consists of a short sketch of hospital gangrene and its treatment, extending from page 118 to the end of the book. It is divided into three chapters: the first is on the nosogenic element of hospital gangrene, which Dr. Beau says is of a cryptogamic nature; the second, on the treatment, preventive and curative, of the disease; and the third contains a few concluding remarks, in which the author tells us that he was incited to write upon the subject by the destructive epidemic of gangrene which distressed the Seamen's Hospital at Brest during the late war. In this epidemic the charpie steeped in coal-tar acted satisfactorily as an absorbent agent for putrid gases; and the emulsion of *coal-tar saponiné* kept up around the diseased surface a sufficiently preservative and parasite-destroying atmosphere.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

Edinburgh, November 4.

Meeting of the University Council—Opening of the Session—Address by the Principal.

The opening of the session 1873-74 of the Edinburgh Medical School has taken place without any of the turmoil which has accompanied the commencement of recent sessions.

The last blast, let us hope, of the trumpet of the retreating female medical party was blown at the meeting of the General Council of the University held on Friday last. The following extract from minutes of a meeting of the University Court of date July 17 was read:—"The University Court having considered the action at the instance of Miss Jex-Blake and others against the Senatus Academicus and the Chancellor of the University, and the judgment of the Court of Sessions thereon, resolve—'That it is expedient that the regulations of the University Court for the education of women in medicine in the University of Edinburgh, contained in their minute of November 10, 1869, and approved of by the Chancellor of the University on November 12, 1869, should be suspended *in hoc statu*; and with the view of carrying out the necessary procedure for having such regulations suspended, the Court, in terms of the Universities (Scotland) Act, sec. xii., 2, direct the secretary to communicate this resolution of the Senatus Academicus of the University for consideration.'"

After some remarks by Professor Macgregor, Mr. Hoggan (who, it will be remembered, at one time aspired to become, in a somewhat irregular way, a lecturer to the lady students) expressed his surprise that the University Court should have made such a resolution without having first consulted the General Council. He considered that if they had power to do so it was a mere farce to come and ask the Council for its consent. He had hitherto considered that the Council was one of the governing bodies of the University, and that its consent was necessary to steps taken in confirming or rescinding all new regulations made; but he found that these new regulations had been really rescinded by the Senatus before the consent of the Council had been asked. He objected to any further action in this matter being taken until their position and rights had been both defined and vindicated. He referred particularly to the applications made some time ago by certain ladies to be allowed to go through their preliminary examination in arts; this matter was referred to the Senatus, who, on October '27, resolved as follows:—"The Senatus consider it undesirable *in hoc statu* to admit ladies to the medical preliminary examination in arts, and resolve accordingly." He asked if the Senatus had any power to make such a resolution without the consent of the Council having been asked and obtained to the rescinding of the former resolutions. If the consent of the Council was not necessary, there was no use in asking it. But if it was necessary, then the Senatus had taken up a position at once illegal and insulting to the members of the Council. Mr. Hoggan concluded by moving that—"In view of the illegal position assumed by the Senatus towards the Council on the question before it, the Council refuses to take further action until its rights and position have been defined and vindicated."

Sir Robert Christison thought it was important that the Council should know its own rights, and also evident that Mr. Hoggan was not aware of them. In regard to this question, the right of the Council was this—that when the University Court passed a certain resolution such should not go definitely forth as a law of the University until it was submitted, in the

first instance, both to the Senatus Academicus and the Council, who might or might not give an opinion on the matter. While the University Court was called upon to communicate with the Council and Senatus, it was not bound by the opinion of either.

Mr. Hoggan's motion not being seconded, fell to the ground, and the following motion by Professor Macgregor was ultimately adopted unanimously:—"That the Council instruct their secretary to acknowledge receipt of the communication from the University Court, and consider it unnecessary in the meantime to express any opinion regarding it."

The present session of the University of Edinburgh was formally opened yesterday by an address from the Principal, delivered in the Queen-street Hall. There was a large attendance of students.

Sir Alexander Grant commenced by pointing out the large increase in the number of students during recent years. Last year 1906 students matriculated, being the largest total number on the rolls since the year 1826. The increase on the previous session was fifty-two. This increase was, he said, owing entirely to the numerous fresh accessions to the medical faculty. This faculty during last session numbered 782, no less than 180 of whom obtained degrees in medicine. "We have thus," he said, "within the University of Edinburgh by far the largest and most important medical school in the United Kingdom." While congratulating the Edinburgh Medical School on its prosperity, he went on to say—

"Prosperity is never a thing to be boasted of or relied on, and it may well raise a thought whether, as the old Greek mother-cities used often to be outvied and endangered by their colonies, it may not come to pass that the medical school of the University of Edinburgh will some day be eclipsed and reduced to a second rank by institutions which are at present quite juvenile, and which are a sort of offshoot from ours. Such reflections are suggested by reading of the opening of the splendid new buildings of the Owens College at Manchester—an institution which boasts not only Edinburgh names among its teachers, but also what Edinburgh is as yet far from being able to boast, the best chemical laboratory and theatre in Europe. The question of proper buildings for medical teaching is now assuming an acknowledged importance in all civilised countries. Germany has set the example. Within the last few years the University of Leipsic has been furnished with a complete accommodation for scientific teaching in its latest forms; and during the same period, from various causes, the number of students in the University has risen from about 500 to about 2500. That University of Berlin, besides other buildings, has received the most costly theatre for chemistry that has ever been erected. The University of Bonn only last year saw the completion of a new and splendid anatomical theatre; and quite recently it has been announced that the University of Prague has received a grant from the State funds to the amount of £42,000, for the erection of theatres and laboratories for chemistry, anatomy, and physics. Looking nearer home, I need hardly remind you of the favoured sister University of Glasgow, which, like Tyre of old, seems to live delicately, and to lack nothing that ships and wealth can bring, among which may be reckoned educational architecture and stately palaces for science. It is not only when compared with these brilliant instances that the medical school of Edinburgh appears as a Cinderella. There is a real daily-felt inconvenience and disadvantage in its present arrangements. The class-rooms of the University were devised half a century ago, and were amply sufficient for the requirements of those days. But since that time a great and important change has passed over the character of medical teaching. Mere listening to lectures (however good in themselves) forms a far less exclusive part of the training of the medical student than used to be the case. Practical work—actual dissecting or experimenting for several hours each day—is now thought to be the indispensable condition of a thorough medical education. Anyone can perceive how sound must be this view of the preparation of the student for the duties of a profession so essentially practical as that of medicine or surgery. It stands to reason that even the theoretic part of these professions—the discovery of new laws and new methods—is likely to be better encouraged by a system which calls on the student to exercise his own powers, than by the older method, which left him comparatively passive, and merely required him to imbibe the theories of his teachers. But for all the modern requirements of medical teaching, both in respect of giving the students ample convenience for their manipulations, and in respect of giving the teacher concentrated space and clear light for demonstrating before numerous audiences, the class-rooms of the College of Edinburgh are sadly deficient. There is, however, some prospect of having these deficiencies supplied at no very distant date."

The learned Principal went on to say that the site lying to the east of the new Royal Infirmary, between that building and the University, has been purchased for the purpose of building theatres, class-rooms, and laboratories. Through the munificent liberality of Sir David Baxter (who bequeathed £20,000 towards this object) and others, the University authorities have now either received or been promised sums amounting in all to about £36,000 for this purpose. Looking to the assistance which might fairly be expected from Government towards a clearly proved necessity of the University, Sir Alexander Grant thought he might say they had already got half-way towards the attainment of the object.

The Edinburgh Extramural School of Medicine was opened yesterday forenoon. Dr. George W. Balfour delivered the introductory lecture in the hall of the Royal College of Surgeons. Dr. Balfour endeavoured to picture the astonishment which would be experienced by one of the skin-clad savages who inhabited the shores of the Firth of Forth or the site of this city 2000 years ago, could he now be introduced to the changed scene. But his awe-struck amazement would be as nothing compared with the admiring astonishment with which Hippocrates, the father of our art, could we rouse him from his long slumber, would regard the present state of medicine. He pictured him scornfully surveying our paltry architecture as he passed along our streets to the Royal Infirmary, where, after ascending the main staircase, he is conducted into one of the side rooms, and courteously received by the attending physician and his clinical clerks, who—mindful of Mr. Syme's first axiom, never to look surprised at anything—are politely blind to the scanty raiment of their strange visitor. Warmed by the genial atmosphere around him, feeling himself as it were at home amid the sick and their surroundings, conscious of his own personal reputation and of the esteem in which his views and his works were held for many hundred years, the venerable gentleman essays to impart a little clinical instruction in return for the kindness with which he has been received. Attracted by the appearance of some fluid collected in glass jars which he thinks he recognises, he proceeds to descant on the prognostics to be derived from the appearance of urine. He points out that clouds in the urine are favourable in proportion to the lightness of their colour, but that however light may be that colour, the prognosis becomes more unfavourable if the cloud should rise instead of fall, and absolutely unfavourable—a fatal sign—if there is a general turbidity of the urine without any sediment, while a sediment, smooth, white, and consistent indicates freedom from danger and a short illness; but if the urine be occasionally clear the disease will be protracted. Yellow thin urine indicates an unconcocted disease, and a danger lest the patient may not be able to hold out till the disease becomes concocted; while a dark-coloured urine is always bad, and the darker the urine the worse the prognosis, especially if it be accompanied by a farinaceous sediment; and if bubbles settle on the urine the kidneys are affected, and the complaint is sure to be protracted. Thus pleasantly discoursing on the results of his experience obtained in his own infirmary—the Asclepion of Cos—and delighted at the ease with which his clear and incisive if somewhat dogmatic sentences have flowed from lips silent for so many hundred years, Hippocrates glances complacently round upon his audience, and finds that while he has been speaking one of the young men has by boiling some of the urine in a test-tube obtained an opaque, milky-looking fluid, and another a copious brick-red deposit. A little aghast at these peculiar and unexpected results, he wisely says nothing, and when suddenly asked as to what he thought of the comparative merits of picric and nitric acids as tests for albumen, he feigns a little deafness. But the look of helpless imbecility which begins to steal over his face is not lessened when another inquires whether he prefers Moore's, Trommer's, or Boc Hoher's test for sugar in the urine, or whether he pronounces any other less fallacious; and what he thinks of a milk diet as a curative agent. The words "milk diet" recall the fast-fading colour faintly to his cheek, and with one timid glance at the microscope beneath which one of the clerks has a preparation the nature of which he is anxious to know, poor Hippocrates passes out into the ward discoursing pleasantly of the virtues

of ass's and of cow's milk, of their hurtfulness in fevers, and of their curative virtues in gout and in phthisis. The physician ignoring his peculiar ideas as to the use of milk in fever, courteously inquires his views as to tubercle, what he thinks of its relation to inflammation generally and to catarrhal pneumonia in particular; and without waiting for his answer shows him a fine specimen of the "cracked pot" sound, and then hands him a stethoscope that he may listen to a peculiarly good example of bronchophony. The word has a Greek ring about it, and thinking he may understand it better with the instrument in his hand, Hippocrates takes it, and uncertain what to do with it, looks first at it, and then through it, considers whether he should listen to it as to the moaning of the sea in a shell, or whether the sound is to be produced by blowing through it as a trumpet; and utterly bewildered by all he has heard and seen, suddenly recollects an important engagement in Thessaly, and with many thanks returns the wonderful but unknown instrument, and departs a sadder if not a wiser man, fully conscious that if called upon to pass a clinical examination of to-day, he—the greatest clinicist of antiquity—would infallibly be found wanting. Dr. Balfour went on to say that the first lesson to be learned from this little episode of Hippocrates was the very great advance in scientific accuracy which medicine has made since his day. The second lesson—and a very important one it was—was that the most thorough knowledge of ancient medical lore, and the most perfect acquaintance with the purest Ionic Greek, were of no practical value to the medical student of the present day. He urged the study of natural philosophy, and natural history, more especially of vegetable physiology. He considered chemistry most important, and believed that medicine would assuredly halt until we had a practical chemist attached to all our infirmaries. He then urged upon the students how they should approach and carry out their study of medicine. He concluded a very interesting and amusing address by referring to the changes that had taken place in the teachers of the School since they last met. Dr. Arthur Gamgee had been appointed Professor of Practical Physiology in Manchester, and Dr. Bell Pettigrew, whose researches into the anatomy of the heart, the mechanics of flight and of animal movement generally, and the physiology of the circulation, had already made him an European name, would now lecture on physiology. Dr. Grainger Stewart would commence a course of systematic medicine; and they had on the most important subject of insanity and psychological medicine two new names to enrol—Dr. Clouston (successor in Morningside Asylum of their old and much-esteemed friend Dr. Skae), whose inquiries had extended mainly in the direction of the therapeutics of insanity; and Dr. Batty Tuke, whose name was well known as a most able investigator into the physical causes of insanity.

BIRMINGHAM.

November 11.

Sir Henry Thompson at the Midland Medical Society—Mr. Gutteridge and St. Peter's Hospital—Clinical Study at the General Hospital, also Cases therein—Queen's Hospital: Opening of New Wards—Hospital Sunday—Zymotic Diseases Prevalent—Gaol Appointment—Sewage Question and the Town Council.

The annual meeting of the members of the Midland Medical Society, held on the 9th inst., was graced by the presence of Sir Henry Thompson, who had been invited by the Council to deliver the opening address. This was an additional attraction, and brought together a large assembly of the members of the profession and their friends. Sir Henry took for the subject of his discourse, "The Future of Operative Surgery in relation to Stone in the Bladder," and he handled it in a very able and edifying manner, prophesying for stone extermination in like manner to "plague" and other diseases, which had and might be extinguished by a judicious and enlightened policy. On the conclusion of the address, a vote of thanks was unanimously accorded him on the motion of Mr. Gamgee, proposed in his usually eloquent manner.

In reference to the presence of Mr. Gutteridge, of this town, at St. Peter's Hospital on Monday last, he informed us that the boy upon whom he operated has already recovered, and gone home to the Black Country. The operation occupied only twenty seconds; the stone was of moderate size; and the wound healed by the first intention—this being about the fourth time in which so satisfactory a result has occurred in this gentleman's experience. We hear with satisfaction that Mr. Gutteridge intends ere long to give the profession the benefit of his vast experience in the shape of a pamphlet on "Lithotomy."

The medical staff of the General Hospital has furnished a capital electrical room, and some highly interesting results have followed the use of the continuous current. A Daniel Murshead battery (100 cells) is the one used. Under the care of Dr. B. Foster there is a very interesting case of locomotor ataxy, which has been greatly relieved by an ascending current to the spine; and a case of facial paralysis is improving by the continuous current after faradisation had proved useless. In the same physician's care was a case in the last stage of pseudo-hypertrophic paralysis. The boy has been under observation since 1869, and his wasted limbs present a striking contrast to their former huge size four years ago, as is shown by his photograph. Under the new arrangements at this Hospital, all the clinical teaching is carried on very actively, and, as far as possible, the systems of the General and Queen's Hospitals have been assimilated. The students of Birmingham now have the doors of both hospitals open to them, and, consequently, the opportunities for clinical study are unsurpassed. It is noteworthy that a committee which has been sitting at the General Hospital for the revision of the laws of the institution has specially discussed the question of the advisability of having the medical officers on the Board of Management; and it is gratifying to the profession to learn that it was determined, by nine to two, "That it was desirable and expedient that the honorary medical officers should have a voice in the Council of Management." This decision is at once honourable to the committee and an evidence of the *entente cordiale* which exists between all the officers of the General Hospital. Last Saturday was quite a field-day for the working-classes here. It was the opening day of the new buildings of the Queen's Hospital, for which they had obtained so much money. The Mayor and *élite* of the neighbourhood, with a large body of friends and supporters of the institution, took part in the ceremony, which passed off with perfect *éclat*. Still, when the debt of £6000, which is yet owing, is wiped off, there will be a more unbounded satisfaction at the completion of the work. In connexion with the rearing of this additional structure the name of Mr. Gamgee stands conspicuous, and he has also the proud satisfaction of being the author of "Hospital Saturday."

"Hospital Sunday" this year was for the amalgamated charities, when the collections amounted to £5000 and upwards—none too large a sum when we consider that it has to be divided amongst twelve charities.

Cases of typhoid and scarlet fever abound in the town, many of them of a severe character; there have been numerous deaths from both diseases. The scarlet fever has assumed in many instances a malignant type, with sloughing ulceration of the fauces and low fever. In some of the cases of typhoid we have been enabled to trace the cause to the water-supply, which we found to be contaminated by sewage matter, which had found its way into the wells from too closely adjoining privies. No outcry has as yet been raised against our milk-cans; the only interference with the milk-dealers has been in the shape of fines imposed on them by the magistrates for a too reckless use of "Simpson."

The profession will be glad to know that the magistrates have gained the victory in the case of the salary of the Surgeoncy of the Gaol, and that the stipend will be £200 a year instead of £100 as was desired by the economists, so that now there will be no difficulty in getting candidates to apply for the appointment—in fact, we hear that there are several in the field.

As showing the importance of the "sewage question," and how it occupies the public mind, we may mention that at our recent municipal elections it became quite a party-cry, and was one of the principal topics discussed in the electioneering speeches, and a test of the merits of the different candidates—amongst the successful of which stand the names of Mr. Barrett and Mr. Cox, both members of our profession.

Cholera has (according to the *Bombay Gazette* of the 20th ult.) been very prevalent amongst the European population at Jubbulpore, and the public offices have been removed as a precautionary measure.

GENERAL CORRESPONDENCE.

IN WHAT BRITISH MEDICAL SCHOOL DID SYSTEMATIC CLINICAL TEACHING ORIGINATE?

LETTER FROM DR. GEORGE HARLEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the abstract of Dr. Mapother's introductory address at the Royal College of Surgeons, Ireland, which appeared in the pages of your journal of November 8, it is stated that "clinical teaching is generally supposed to have originated during the present century in Dublin"; but Dr. Mapother showed that as far back as 1785 four wards in Mercer's Hospital were set apart for the reception of cases for the lectures of the College of Physicians.

If by this it is implied that systematic clinical teaching in the United Kingdom originated in Dublin, I venture to call Dr. Mapother's attention to the fact that clinical lectures were given as a systematic course within the walls of the Edinburgh Infirmary by at least three successive generations of teachers during the last century—to wit: Drs. Andrew Duncan, Francis Home, and the renowned Cullen. And not only were the lectures delivered, but some were actually printed and published, as is proved by an octavo volume of no less than 332 pages now lying on the table before me. The title of this volume is—"Clinical Lectures, delivered in the years 1765 and 1766, by William Cullen, M.D., etc. Taken in shorthand by a gentleman who attended." This work was published in London in 1798, eight years after Dr. Cullen's death; and from the preface we learn that Dr. Cullen at least, if not others before him, was in the habit of delivering regular courses of clinical lectures in Edinburgh at that very early date; for the concluding words of the preface express a regret that there is no "*complete copy of all Dr. Cullen's clinical lectures.*(a) We fear (adds the preface) such a thing does not exist; but a diamond is not to be thrown away because we do not possess the whole mine."

I had written thus far when Professor Sharpey referred me to Thomson's "Life of Cullen," vol. i., p. 101, where I find the following passage:—"In this country the merit of first proposing to explain in clinical lectures the nature and treatment of the cases of patients admitted into a public hospital belongs to Dr. John Rutherford, Professor of the Practice of Physic, to whom this privilege was granted by the managers of the Royal Infirmary of Edinburgh in the year 1748. In the following year the same privilege was extended to the other professors."

I am, &c.,

GEORGE HARLEY, M.D., F.R.S.

Harley-street, Cavendish-square, November 11.

BLOODLESS OPERATIONS.

LETTER FROM DR. FAYRER.

[To the Editor of the Medical Times and Gazette.]

SIR,—The mode of controlling hæmorrhage during surgical operations ascribed to Esmarch is no doubt most excellent and ingenious, but it is not new. The Indian medical officers for many years have been practising the same principle in the removal of scrotal tumours. The growth is raised, compressed with a bandage to squeeze out the blood, and a cord applied round its neck to prevent the ingress of more; amputation follows, and with a very trifling loss of blood compared with that of former operations. Whilst denying any novelty in the principle, I readily admit the great advantage of the new method of its application. The elastic bandage and cord are improvements on the cloth bandage and cord, soaped and running through a ring, used in Calcutta, and I hope my friends in India will lose no time in adopting this improvement. If you will refer to the *Medical Times and Gazette* of 1862 and 1863, you will find previous communications on this subject.

Another useful application of the elastic cords to surround and constrict the limb, and of the elastic bandage—if applied from above downwards instead of the reverse,—would be in the case of snake-bite: the cord to prevent entry of poison into the circulation, the bandage to press out that already inoculated, and prevent its diffusion in the arcolar tissue. A small incision through each puncture would favour the exit of blood and poison; and a sucking instrument like an artificial leech would still further do so.

I am, &c., J. FAYRER.

(a) The italics are in the original, and not introduced by me.—G. H.

DELIQUESCENT CHLORIDES IN STREET-WATERING.

LETTER FROM MR. W. J. COOPER.

[To the Editor of the Medical Times and Gazette.]

SIR,—The report of Dr. Letheby's paper "On the Right Use of Disinfectants," which appeared in your last week's number, contains an extraordinary *addition*, having reference to the application of deliquescent chlorides in street-watering. Dr. Letheby did not allude to the subject of deliquescent chlorides or to street-watering. If he had done so in the terms stated in your report I should have taken the opportunity in discussion of contradicting such statements, which could only have been put forward in complete ignorance of the success attending the use of deliquescent salts in laying dust, saving road material, and preserving tradesmen's goods from injury, of which benefits abundant proofs are extant. But as my object in writing this letter is to obtain correction of an error and explanation of a singular discrepancy, I will not further trespass on your space, except for the purpose of stating that I was present from the beginning to the end of the reading of the paper, and the discussion which followed.

I am, &c.,

Royal Hotel, Norwich, November 11. W. J. COOPER.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 28.

Dr. C. J. B. WILLIAMS, F.R.S., President, in the Chair.

(*Continued from page* 534.)

MR. WILLIAM MILLER ORD communicated notes of a case of Duchenne's Pseudo-hypertrophic Muscular Paralysis, with special reference to the temperature of the overgrown limbs, and with general remarks. The patient, a child aged seven, had suffered for two years from progressive weakness of the back and lower limbs, of which no exciting cause was known. There was no impairment of the mental faculties, but the child constantly fell while walking, and could not get up again without seizing some firm support by the hands. The sacro-spinal muscles and the muscles of the thigh were thin and poor, but the calves were distinctly overgrown. The observation to which attention was specially directed was, that the calves were distinctly warmer than the thighs by from 1·9° to 3·9° Fahr. The fibres of the muscles, being removed by an *emporte-pièce*, showed no material deviation from a healthy structure, certainly no degeneration; but there appeared to be an increase of the white fibrous element between the primitive fasciculi. It was suggested by these facts that the disease was in a very early stage, and that vaso-motor derangement, probably paralytic, played a great part in its production. The diseases called "progressive muscular atrophy of childhood" and "infantile paralysis" were compared with the pseudo-hypertrophic paralysis. It was noted that, whereas in the former of these a definite wasting of certain parts of the cord had been demonstrated by Dr. Lockhart Clarke and Dr. Bastian, no morbid appearances had been detected in the brain or spinal cord characteristic of the pseudo-hypertrophic paralysis. It was inferred from these and other considerations that the origin of the disease must be looked for in the sympathetic or ganglionic nervous system. No affection of sensation was detected in this case; and the one morbid condition was the gradual weakening of the muscular power in the lower half of the body generally, associated with the hypertrophy of the calves. This was regarded, not as a true hypertrophy of muscle due to excessive use, but as an overgrowth of interstitial connective tissue due to hyperæmia.

DR. ALTHAUS said Dr. Ord had made out a new point when he found an increase of temperature in the parts concerned. He thought it must throw light on the subject, and seemed to point to the trophic system of nerves being at fault. The

case was not a pronounced one, but seemed only commencing. There was no doubt about its nature; still it was not very marked in the calves, and the microscopic appearances were slight. Griesinger and Billroth had also described the pale condition of the muscle. In other cases there had also been noted true hypertrophy of the muscular fibres, so that in this disease there seemed to be two stages—one of hypertrophy, one of wasting. Eulenburg and Cohnheim's case was remarkable for the changes in the nerve-centres, there being considerable development of fat about the cord, and wasting of the lateral columns; the sciatic was also covered with fat. Duchenne believed the mischief to be cerebral; he had seen marked alteration of sensibility, but that was not noted here. Cohnheim's case pointed to the spinal cord as the seat of lesion. The mischief was also symmetrical in most cases. As faradic sensibility was diminished, that too pointed to a cerebral origin.

Dr. Langdon Down thought it neither vaso-motor nor spinal, but rather cerebral, for in nine cases he had noted want of intellectual power. Sometimes, as in one of his cases, there was no loss of sensibility, for the process of removing portions of muscle was very painful.

Mr. W. Adams said Dr. Meryon's cases were not referred to. He had seen a good many cases. Often the resulting deformity was supposed to be due to a contraction of the parts. Often, too, the muscles of the forearm and leg were large, whilst the arm and thigh seemed wasted. Dr. Meryon thought arsenic did good.

Dr. George Harley asked if the muscular hypertrophy was fibrous or fibrillar. Fibres might vary in size even in the same muscle, but the fibrillæ did not vary. The author seemed to think the rise of temperature due to hyperæmia; in reality both hypertrophy and increase of temperature were due to the same cause. He thought the condition depended on paralysis of the vaso-motor system of nerves.

Dr. Ord, in reply, agreed that this was an early case. The structures seemed paler than usual. Dr. Althaus and he must surely be referring to different cases by Eulenburg and Cohnheim. Sensation in his case was normal and the intellect fairly good, except that the memory seemed short. The elder brother of the patient was an idiot. Dr. Meryon's cases were disputed, therefore he did not refer to them. His views quite agreed with those expressed by Dr. George Harley. He did not measure the fibrillæ.

THE PATHOLOGICAL SOCIETY.

Tuesday, November 8.

Sir W. Jenner, Bart., M.D., F.R.S., President, in the Chair.

Dr. Dowse showed a specimen of Medullary Disease of the Kidney. The patient had long suffered from pain in the back, and had passed albuminous and bloody urine. When seen he was cacheetic, the abdominal veins enlarged, and in the left side a large tumour. About a month before death he suddenly became collapsed, and vomited a quantity of dark matter, but improved somewhat thereafter. He died rather suddenly. A portion of his brain was softened, his liver was cirrhosed, and the left kidney was enlarged and cancerous; masses of cancer were also found round the duodenum and colon. (Referred).

Dr. Fagge showed a specimen of Suppurating Lymphatics and a Large Spleen from a female who had been wasting for nearly two years, ever since her marriage. First a mass formed in the left groin, which opened and discharged; after that the leg opened and discharged serous-looking fluid. After death all the lymphatics seemed enlarged, beginning with those round the Fallopian tube and ovary on the left side, where there was a quantity of pus. The glands all up the side to the neck were enlarged and suppurating, so were they in the porta and round the bronchi. The liver was large, but apparently healthy. The spleen was also large, with masses the size of walnuts in it, something like syphilitic disease; but of this there was no other sign. It was not Hodgkins' disease.

Dr. King said he had seen something like this condition of spleen in fenny Lincolnshire, where it was attributed to malaria.

Dr. Greenhow exhibited a specimen of Hydatid Disease of the Liver from a female, whom he first saw in 1867. She then presented manifest signs of hydatid disease, and was tapped, much fluid being removed. There were also some signs of lung complication. She was better till 1869, when she began again to increase in bulk, and when last seen she was very large. Again she was tapped and some fluid removed, but she did not this time diminish in size. Shortly after this she began to shiver, and pus formed. The cavity was regularly washed out with Condy's fluid, but she gradually sank. The hydatid sac was found to involve most of the thorax on that side, and the ribs were thinned. There was hardly any pleural cavity left, and the lung was greatly condensed. Another and smaller cavity was found in the liver; he supposed it the one formerly tapped.

In reply to Sir W. Jenner, Dr. Greenhow said he thought the smaller was the one formerly punctured, as it corresponded to the seat of the puncture.

Dr. Legg showed a specimen of Obstruction of the Common Bile-duct by a Gall-stone, with consequent enlargement of the biliary-ducts. An abscess formed round one of these large ducts, and opened into the peritoneum. Subsequently an opening was made into the pericardium and pleura. The patient was a Jewess, aged 23, who five months before admission complained of pain in the right side, vomiting, and jaundice. She was not, however, jaundiced in the hospital. The stools, too, were brown, yet the gall-stone was tightly wedged in the duct. Below the duct was pale grey; above it was full of bile. The cystic duct was free, and the gall-bladder was not enlarged. A case something like it was recorded in Frerichs.

In reply to Sir W. Jenner, Dr. Legg said he accounted for the brown stools by other sources of colour besides the bile, as from medicines, hæmorrhage, etc.

Dr. Cayley having elicited that the ducts were only dilated on the left side, suggested that the duct on that side only had been compressed and obstructed up to shortly before death, when the stone had moved to the situation where it was discovered.

Mr. Nunn showed the parts concerned in a Shot-wound of the Skull. The subject committed suicide by putting a pistol to his ear, where was a large lacerated wound. The ball pierced the brain, and impinged against the skull on the other side, producing a fracture, but not piercing the bone. The outer table was fractured much more extensively than the inner—the reverse of what happens if the fracturing force impinges against the outer table first.

Dr. Liveing showed two Hearts with Moderator Bands, attention to which had been drawn by Dr. Rolleston in his Harveian Oration. One, the larger, was on the right side, the other, and smaller, on the left. Their function was probably to check the dilatation of the heart to any undue extent.

Sir W. Jenner said they were fully described in Dr. Wilkinson King's paper in the *Guy's Hospital Reports*. He thought they were not uncommon on the right side and quite as large as this; on the left they were rarer. In some animals, as the hare, they were well marked.

Dr. Green exhibited a specimen of Fibroid Induration of the Heart, from a man, aged 52, who was brought into Charing-cross Hospital dead, and no history was attainable. The heart was large, especially on the left side. The pericardium was healthy; the endocardium was thickened, opaque, and white, especially towards the apex; the ventricle was dense, and tough on cutting, and was fibroid to the naked eye, especially near the endocardium; the fibroid structure was more abundant in certain situations; the right ventricle was dilated, but not very thick; the outside of the organ was fatty, and its valves healthy. The kidneys were hard, but not particularly so; the connective-tissue in the walls was partly corpuscular, partly fibrillar, similar to its condition in cirrhosis of the liver. There seemed to be four kinds of fibroid change in the heart—one from old pericarditis, another from endocarditis, a third affecting the right side in emphysema, and a fourth in syphilis.

Dr. Fagge had seen a specimen something similar last week, but he could not add much to what had been said. An old man, aged 70, felt very faint in the City and fell down. He was taken to Guy's Hospital, where, when seen, his pulse was slow and his temperature low. He died, when the only change found was a fibroid left heart. There was not much change in the endocardium. In another case he had seen, the mischief did not seem to spread outwards; there was most change in the middle of the heart's wall. There was no history of syphilis, and there was no small cell-growth.

Mr. Greenfield asked if the kidneys had been examined microscopically. He had seen a specimen at St. Thomas's,

where were vegetations on the valves, and the kidneys were large and hard. The heart was as in Dr. Green's case, but in the kidneys round the vessels was a nuclear growth. The urine had been albuminous.

Dr. Green said the vessels of the brain were in his case fatty and atheromatous.

Mr. Nunn thought there was no reason to limit this change to syphilis.

Mr. Potts exhibited a specimen of Osseous Deposit in the Arachnoid, from a female patient aged 44. She had been under delusions, mainly of a religious kind, and was sent to an asylum. She complained of pain in the head, and ultimately died comatose. A deposit of bone was found on each side of the longitudinal sinus.

Dr. Ralfe exhibited a specimen of Aneurism of the Aorta in the Sinuses of Valsalva, from a young Chinaman who had been exposed to great hardships in the Eastern seas. He had a double bruit at the base of the heart. He gradually grew worse until he died, when the left ventricle was found dilated. The valves were healthy, but incompetent, owing to the aneurism and dilatation. The aorta was atheromatous.

Mr. Clark brought forward a specimen of Ruptured Heart from an old woman who was run over in the street. There was no mark externally, but the ribs and sternum were fractured. The pericardium was filled with blood, and in the right apex was a small orifice, through which a stilette passed into the ventricle; otherwise the heart was healthy. The spleen was ruptured. There was no clear account of the time of her death.

OBITUARY.

GWYNNE HARRIES, M.D.

At the age of thirty-three, and at the outset of a career of great promise, Dr. Gwynne Harries, one of the Inspectors of the Medical Department of the Local Government Board, has just died. His death affords another proof of the dangers to which all members of our profession are exposed, but which attach themselves in a special manner to posts such as that which Dr. Gwynne Harries so well filled. Naturally a man of considerable physical vigour, and having his heart thoroughly in his work, he never thought but how he could best perform his duty. Just prior to his death he had been investigating outbreaks of typhus and scarlet fever in one of the northern counties, and in the performance of his official duties he contracted the latter disease. Up to midday on Wednesday of last week he was still at his duties, but, feeling ill, he was compelled to leave his work unfinished, and he reached town on Thursday morning. Severe throat symptoms and other indications of scarlet fever having set in, he was removed to the London Fever Hospital. But the unremitting attentions which all connected with that establishment so gladly bestowed upon him were of no avail—he rapidly sank, and died soon after noon on Saturday. Before removal to the Fever Hospital he was under the care of Dr. Robt. Liveing; after removal, Dr. Broadbent and Mr. Mahomed, the Resident Medical Officer, took charge of the case. He was there also seen by Dr. Murchison and Mr. Simon. The latter spent some time at his bedside, and Dr. Broadbent's and Mr. Mahomed's attention was unremitting. One could not help being most deeply impressed during the progress of the case with the enormous advantage of the reserved rooms at the Fever Hospital for cases like that of Dr. Harries, which must else have been treated under the disadvantages of a crowded hotel or a lodging-house. Dr. Harries had been a successful student and a prizeman at King's College; he was a graduate of the London University; and it was in recognition of abilities of a high order that two years and a half ago he was appointed to the post in which he has died. His death is keenly felt by his chief and his colleagues, by whom he was looked upon as an able and genial fellow-worker and a hearty friend. On Monday his remains were taken to Paddington for removal to his home at Haverfordwest, in South Wales, and Mr. Simon, accompanied by Mr. Netten Radcliffe, Dr. Thorne Thorne, and Dr. Ballard, the only members of his staff who were in town, attended at the station on the occasion. On Wednesday the funeral took place, Dr. Buchanan being present on behalf of the medical officer and inspectors of the Local Government Board. Dr. Harries leaves a widow, but no family.

The following characteristic letter, honourable alike to the memory of its lamented subject and to the writer, has been addressed by Mr. Simon to the editor of the *Times*:—

"In Memoriam.

"Sir,—In respect of the office I hold, I beg you will allow me to add a few words to the announcement which your advertising column contains of the death at the age of 33, of Dr. Gwynne Harries, one of the Inspectors in the Medical Department of the Local Government Board.

"From the time, about two and a half years ago, when Dr. Harries entered this branch of the public service, he had identified himself, heart and soul, with our work. Having brought into it attainments and moral qualities of a very high order, which would have won him success and honour in any career of life, he had given them with enthusiasm to his duties, and he had been prized among us as he so highly deserved.

"On Thursday last he returned to London from the North of England mortally stricken with fever, which he had caught in the performance of his duties. In one of the reserved rooms of the London Fever Hospital, the value of which for emergencies of this sort can hardly be over-estimated, he had every possible skill exerted for him, and with every possible kindness and sympathy: but it was in vain, and on Saturday his disease ended in death.

"For the officers of the Department from which Dr. Harries has been taken I may simply and truly say that we are all in sorrow for our colleague, that we shall ever remember him with sincere esteem, that we shall miss him as a brother in our work.

"To Dr. Harries' family—to those who have to deplore an irreparable private loss in this early close of a life which abounded in vigour and promise, and seemed destined for a long career of happy usefulness—it will doubtless, even now, be some consolation to reflect that he died in obedience to the claims of the public service, doing his professional duty in work which is full of hope for others. Like many who have wept for the fallen of far different battle-fields, they have lost their dearest in the service of their country; but of the Civil servant, as of the soldier, no better memory can remain than that his loyalty, even unto death, has been true to the standard under which he served.

"I am, Sir, your obedient servant,

"3, Parliament-street, November 11. John Simon."

JEAN JACQUES CYPRIEN COSTE.

Although we have already furnished an obituary notice of this distinguished *savant*, our readers will be interested on perusing the following particulars of his life, contributed to the *Revue Scientifique* by M. Léon Souberain.

"Coste was born at Castries (Hérault) on May 10, 1807, and pursued his medical studies at Montpellier, where he became *chef de clinique* of Delpech. While giving the greater part of his time to the fulfilment of the duties of his post, he also commenced, with that eminent surgeon, researches in embryogeny—a study, indeed, which was to form the constant occupation of his life; and in 1831 he presented, under the conjoined names of master and pupil, to the Academy of Sciences a memoir, 'Sur le Développement de l'Embryon des Oiseaux,' which soon afterwards obtained for him the prize in physiology. About this time he accompanied Delpech on a mission to Scotland and Ireland for the purpose of studying the outbreaks of cholera, and took an important part in the work published by Delpech on his return. Coste also published conjointly with his master the 'Recherches sur la Génération des Mammifères et sur la Formation des Embryons, 1834-38'—a work which caused him to be chosen as substitute for De Blainville in the chair of comparative anatomy of the Muséum d'Histoire Naturelle. His lectures, published in 1837 by MM. Gerbe and Meunier under the title of 'Cours d'Embryogénie Comparée,' enabled him to expound his ideas and to make known his work on development in the different degrees of the animal series. Next year he was sent by the Government into Germany, in order to examine the various museums and to collect all documents relating to embryogeny — a portion of science pursued there at that time with much success. In 1838 he published his 'Ovologie du Kanguroo,' in reply to the researches of the great English naturalist, Richard Owen, and also a memoir on 'Le Nidification de l'Epinoche,' which excited much attention.

"In 1838 the chair of Comparative Embryology was founded at the Collége de France, and Coste became its occupier,

having already delivered lectures in that establishment, in which he communicated the results of his important researches. Finally, in 1847 he published the body of the doctrine resulting from his experiments in his 'Histoire du Développement des Corps Organisés et de la Gestation chez l'Espèce Humaine.' Elected a member of the Académie des Sciences in 1851, Coste became its president in 1871, after having fulfilled the office of secretary for two years in place of Flourens. An *éloge* on Dutrochet which he read during his period was much remarked.

"Coste's researches on embryogeny are highly appreciated by *savants*, but works of this serious character excite but little attention beyond the learned world; and it is as the promoter of pisciculture, the art destined to replenish the waters, that his name has become so popular. Other persons have taken an important part in the application of this art but it is to Coste that is due the glory of having given it its true value. The influence that he has exerted on the progress of pisciculture cannot be better exhibited than in the words of M. Quatrefages:—'Having an enlightened and unlimited confidence in the future of aquiculture, and one of the first at the work in common, M. Coste has done, and especially caused to be done, much. Strong in the high authority conferred upon him by his scientific position, and also fortified by the administrative support and high patronage which he has known how to conciliate, he has shown an ardour quite unequalled in encouraging this rising industry, in defending it against unjust mistrust, in stimulating new applications, in proclaiming the results already acquired, and in foreseeing new and yet greater ones.'

"In 1852 Coste obtained the foundation of the establishment at Huningue, a true *atélier* of pisciculture, which served as a model for those which were organised at a later period in England, Belgium, Holland, Russia, etc. This model establishment at the present time remains with Alsace and Lorraine in the hands of the Germans, and has not yet been replaced in any other part of France. But if we no longer possess Huningue, happily we have the fish-pond laboratories at Concarneau, which Coste established for continuing his researches, organising a miniature sea-world in a transparent abode, where nothing escapes investigation. The Concarneau laboratory has since been imitated in various places, in consequence of the services which it renders to science; and numerous observers to whom Coste always gave free access to his laboratories have borne witness to the immense utility of these arrangements.

"Inspector of the river and coast fisheries since 1861, Coste never ceased contributing to the progress of aquiculture; and the successes obtained in the Bay of Forêt, in the Karnak river, and most of all in the Bay of Arcachon, testify loudly to the importance of what he accomplished. Arcachon, which had dwindled down to insignificance, now possesses a bay peopled by numerous parks of oysters, and finds all its past splendour revived. . . . Coste died poor, but leaves a memory dear to all who knew him. Let us hope that the important collection which he had formed by preserving all the demonstrative preparations of his scientific experiments, and which are of capital importance for the history of embryogeny, will be preserved in the establishment where these different materials have been amassed; and that it will remain at the disposition of *savants*, perpetuating among them the name of the excellent man whose loss we now deplore."

GILBERT LOVE, M.R.C.S.

Mr. Gilbert Love, of Wimbledon, whose death took place on October 29, was born in Tyrone, Ireland, in 1820. He was educated at Trinity College, Dublin, and was about twenty years of age when he came to England. His first professional engagement was at the St. Marylebone Infirmary, where, according to the testimony of Dr. Robert Boyd, the then resident physician, he was particularly attentive to the sick poor. In 1841 he went to Wimbledon, and assisted Dr. James Bright, then in practice there, for about three years. In 1844 Dr. Bright left Wimbledon, and Mr. Love, having obtained his diploma from the Royal College of Surgeons, set up in general practice for himself, and eventually took Mr. Finch (one of his contemporaries at the Marylebone Infirmary) and Mr. Pocklington into partnership. Wimbledon was the scene of his labours for thirty-three years; and during his long residence there he had nearly identified himself with the charitable and social institutions of the place. He was one of the originators of the Cottage Hospital—if, indeed, it does not owe its existence to his conception. But of the high regard and esteem in which he was held at Wimbledon no more striking evidence can be required than the following letter, addressed to him in his last illness:—

"50, Albemarle-street, W., Oct. 28th, 1873.

"Dear Mr. Love,—We think it may give you pleasure to know that the project of a testimonial to you from your friends and neighbours has been welcomed with unanimous approbation. No sooner was it known that you, who had been for so many years the alleviator of their pain and the sympathiser in their sufferings, were yourself bowed down by an illness so painful and dangerous as to compel you to resign your profession, than all classes, high and low, pressed forward to testify their sorrow, sympathy, and esteem. The sum which has been collected as an offering to you, and of which, on the part of our friends and neighbours, we have now to beg your acceptance, is of comparatively small value, apart from the evidences—written and spoken—of regard which have been received from all the contributors. It cannot be regarded but as a demonstration of the number of friends you have among us, by whom your constant kindness and consideration will never be forgotten.—We remain, dear Mr. Love, your sincere and grateful friends, John Murray, William Williams, Horace Watson, Alfred Markby, Chas. J. Wynne.—We enclose a cheque for £800."

HENRY CHARLES CUTLIFFE, Surgeon of the Bengal Army,

Died on the 24th ult., aged 41. He entered the service May, 1858, and became Surgeon May, 1870. He was Fellow of the Royal College of Surgeons, and acting Professor of Surgery at the Medical Hospital, Calcutta.

MEDICAL NEWS.

University of London.—The second M.B. Examination commenced on November 3, and was completed on Monday, November 10. Out of twenty-seven candidates who presented themselves, seventeen passed in the first division and five in the second. The names are as follows:—

First Division.

Addy, Boughton, St. Thomas's Hospital.
Barlow, Thomas, B.Sc., University College.
Benham, Henry James, University College.
Bird, Cuthbert Hilton Golding, B.A., Guy's Hospital.
Bomford, Gerald, King's College.
Cockburn, John Alexander, King's College.
Colgate, Henry, University College.
Coupland, Sidney, University College and Middlesex Hospital.
Dodson, Andrew, Birmingham and Guy's Hospital.
Dyson, William, B.A., University College.
Firth, Charles, St. Bartholomew's Hospital.
Harvey, Charles William, University College.
Petch, Richard, King's College.
Pope, Harry Campbell, Liverpool Royal Infirmary and University College.
Railton, Thomas Carleton, Manchester, and St. Bartholomew's Hospital.
Rayne, Charles Alfred, University College.
Skerritt, Edward Markham, B.A.

Second Division.

Appleyard, John, University College.
Baber, Edward Cresswell, St. George's Hospital.
Bindley, Philip Henry, University College.
Cornelius, Walter Bernard, University College.

Horncastle Union.—Thomas Hobbes Cresswell, M.R.C.S.E., L.S.A., of the Wragby District.

Oswestry Incorporation.—Robert de la Poer Beresford, M.D. Glasg., L.R.C.P. Edin., L.R.C.S., L.R.C.P., to the Whittington District.
Peterborough Union.—Fergus Malcolm Brown, L.R.C.P., L.F.P.S.Q., to the Castor District.

ANALYST.

Reading Borough.—Mr. John Shea, M.D., as Analyst.

THE Kensington Vestry have appointed Dr. Dudfield their public analyst.

DR. TRIPE has been voted by the Sanitary Committee of Hackney £75 for his services as analyst for the year.

THE new regulations as to examinations in the Royal College of Surgeons, Ireland, have now been published. They have been already indicated in our number for September 20, in connexion with a letter from Dr. Jacob.

THE Cockermouth Rural Sanitary Authority has been appointed the Port Sanitary Authority for the harbour of Workington, until September, 1874.

MR. MUNDELLA, M.P., in answer to a deputation of the Sheffield Grocers' Association, on Monday,—who waited upon him to urge the Government to undertake the analysis of teas in bond, to prevent impure teas passing into consumption through the Custom-house—undertook to bring the matter under the notice of the proper authorities.

A MEETING of the Society of Medical Officers of Health will be held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Saturday, the 15th inst., when Dr. G. Ross will read a paper on "The Ventilation of Hospitals, Schools, and Public Buildings."

NEW SOUTH WALES COMMISSION OF THE PEACE.—His Excellency the Governor, with the advice of the Executive Council, has been pleased to appoint Dr. John James Hill, of Lambton, one of the magistrates of the territory.

ST. PANCRAS NORTHERN DISPENSARY.—Mr. Francis Mason, F.R.C.S., Assistant-Surgeon to, and Lecturer on Anatomy at, St. Thomas's Hospital, has been unanimously elected Consulting Surgeon to the above Dispensary, in the vacancy occasioned by the decease of Mr. John Bishop, F.R.S.

EXAMINATIONS. — The following were the questions submitted to the candidates at the Primary (or Anatomical and Physiological) Examination for the diploma of Member of the Royal College of Surgeons on Saturday last, viz :— 1. Give the anatomy of the prostate gland, describing its size, form, situation, connexions, and structure. 2. Describe the changes which occur, both in the position and the internal conditions of the eyeballs, during near and distant vision, mentioning the parts concerned in effecting those changes. 3. Describe the form, structure, and attachments of the valves in the heart and great arteries; and explain in what manner the valves perform their offices. 4. Describe the first, seventh, and twelfth ribs, mentioning their peculiarities. 5. Describe the astragalus, mentioning the bones with which it articulates, and the ligaments connecting them. 6. Describe the diaphragm, and its functions.

NEURALGIC ULCER OF THE LEG.—M. Terillon recently related to the Société de Chirurgie two cases of ulcer of the calf of the leg, attended by excessive pains, which yielded to no means employed, until an excision of a portion of the sciatic nerve had been performed. He refers to a case of M. Verneuil's, occurring in a young girl, and in which the pains were so incessant and had so exhausted the patient's powers, that amputation was had recourse to. The ulcer reappeared in the stump, and the pains recurred. Excision of a portion of the sciatic nerve caused the pains to disappear as by enchantment, and the ulcer rapidly cicatrised. These facts have led M. Terillon to conclude that the primary source of the ulcer was an altered condition of the sciatic nerve. M. Ledentu, reporting on the paper, observed that he could not adopt this conclusion absolutely, for he had himself lately met with a case of neuralgic ulcer of the leg, in which the pain yielded to hypodermic injections. M. Verneuil, too observed that conclusions from his case would be premature as the patient is now suffering from another relapse.—*Union Méd.*, November 4.

A MULTITUDE OF COUNSELLORS.—M. Faucon, of Amiens, having a very complicated case of multiple anchylosis which had not yielded to mechanical and other treatment, brought his patient to the Paris Society of Surgery, in order to ask its opinion whether he should persevere with the treatment, or what better could be suggested. The Amiens surgeon certainly cannot complain of any penury of advice, for this he had of every description. "I should not hesitate," M. Tillaux declared, "to try and re-establish motion by a sharp and sudden rectification." "Take care what you are about!" cried out MM. Marjolin and Paulet. "You will expose your patient to frightful accidents, and perhaps kill her. Proceed very slowly, and do not lose courage over the case." "The child is rheumatic," remarked M. Forget; "*noli tangere.*" "She is scrofulous," said M. Perrin; "modify her general constitution." "Give her sulphur-baths," exclaimed several members. "Send her to the seaside," said M. Trélat. M. Faucon retired with his patient, returning to Amiens rich in counsels, having only an *embarras du choix.*—*Union Méd.*, November 4.

NOTES, QUERIES, AND REPLIES.

He that questionth much shall learn much.—*Bacon.*

Nichol B.—The Orthopædic Hospital at Birmingham was established in 1817.

A Foreigner.—A paper by Dr. Von Jhering, "Zur Reform der Craniometrie," is in the last number of Bastian and Hartmann's *Zeitschrift für Ethnologie.*

MEMORIAL TO THE LATE DR. JOHN MURRAY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is proposed to place a bust and tablet in Middlesex Hospital as a memorial of the late Dr. John Murray. A small committee has been formed for this purpose, consisting of—Dr. J. Ford Anderson, Dr. Joseph Bell (Edinburgh), G. W. Callender, Esq., F.R.S., Dr. W. Cayley, Campbell de Morgan, Esq., F.R.S., Dr. Dyce Duckworth, Dr. Arthur W. Edis, Sir William Fergusson, Bart., F.R.S., Professor W. T. Gairdner (Glasgow), Sir William W. Gull, Bart., F.R.S., Ernest A. Hart, Esq., D. Hepburn, Esq., Dr. George Johnson, F.R.S., Dr. Robert King, Dr. Robert Liveing, R. H. Lucas, Esq., Dr. Morell-Mackenzie, Henry Morris, Esq., M.A., Dr. Charles Murchison, F.R.S., Dr. Richard Quain, F.R.S., Professor W. R. Sanders (Edinburgh), Dr. Alexander Silver, George Southam, Esq. (Manchester), Dr. A. P. Stewart, Dr. W. Stokes, jun. (Dublin), Lawson Tait, Esq. (Birmingham). Subscriptions will be received by Campbell de Morgan, Esq., F.R.S., Treasurer; or by Arthur W. Edis, M.D., 23, Sackville-street, W., and Henry Morris, F.R.C.S., 19, Bedford-square, W.C., Honorary Secretaries. The following subscriptions have been received and promised :—

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·36 in. The highest was 29·82 in. at the end of the week, and the lowest 29·07 in. on Thursday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

LECTURE ON HOSPITAL PATIENTS, DOCTORS, AND NURSES.

By Dr. LIONEL BEALE, F.R.S.

(INTRODUCTORY TO HIS CLINICAL LECTURES AT KING'S COLLEGE HOSPITAL.)

GENTLEMEN,—In the first lecture of a session we are permitted, by custom, to introduce topics which could not be conveniently referred to in our ordinary lectures. This year, as on former occasions, I propose to say a few words upon our work here, and I shall refer to one or two other matters upon which, perhaps, some persons in authority may think I have no right to speak; but, as twenty years have passed since I became a teacher in this school, I think I may, without impropriety, claim the liberty to say what I think upon any matters that may be of interest to those who follow the medical profession; and, though my remarks may not be popular, I have no desire to say anything in a way that may offend those who differ from me.

Now, as regards the notions that have been put forward concerning the *nature of man*, the doctrines entertained *on the nature of disease*, the *management of the sick*, the *internal administration of our hospitals*, the *rights and duties of nurses, doctors, and students*—there has been, there is, and there will be, much difference of opinion. Your teachers, like yourselves, differ in the views they have formed upon many subjects. Men hold sacred very different principles, and think and work in different ways. Perhaps it would have been better if there had been no differences of opinion; but, there being differences, it is better that they should be acknowledged and known than that they should be simply hidden under a cloak of insincerity. I do not believe that any form of humbug is more evil in its results than the humbug of appearing to agree with principles which you do not believe to be true, or by silence sanctioning a policy which you deem to be wrong, and think likely to be disastrous if carried out.

Now, with reference to the poor patients under our care. How many ways are there of regarding them at this time? Some look upon a patient as a force-transforming apparatus more or less damaged, or as a force-conditioning machine which conditions irregularly or improperly, or as a molecular mechanism the equilibration of which has been disturbed. A sick man might be called a kynetic apparatus whose peripatetic property had been temporarily modified. Patients seem to have been looked upon by some as organisms, a part of whose natural history it is desirable should be carefully studied; by others as wicked beings suffering well-merited punishment for sins committed; by others again as the degraded consequences of a wilful pauper-producing middle class. But doctors and nurses possibly regard patients as sick and suffering persons requiring temporary care and help while they are ill and unable to work and earn wages. We know that patients are made like ourselves, and many of us feel very glad to be able to freely give them the benefit of all that we have been able to learn by study and gain by experience. We look upon sick people as being something more than mere matter. We know that they have organs, mental and bodily, which are not in the slightest degree like any machines of which we have knowledge or experience, or can form any conception.

With regard to the origin and nature of man we have for some years been inundated with a great deal of a new sort of cant,—and I believe the cant of people who pretend to be able to account for everything by *law*, when they can explain next to nothing concerning the simplest changes characteristic of a living being, to be the most pernicious of all kinds of cant. There are people who affirm that it has been demonstrated by science that miracles are impossible, that prayer is an absurd and useless formality, that there is no Personal God, and that honest and upright men must confess that they are no longer Christians. People who support these notions support philosophical cant. Every one of these assertions rests upon pure fiction; not one of them is in any sense true, or in the slightest degree approaches truth. Those who believe them are simply believers in philosophical and scientific blunders, or something worse.

Remember, gentlemen, that up to this day no one has explained how the particles of a blade of grass are piled one upon another during its growth, but yet there are many teachers who pretend to be able to account for the most subtle phenomena of our existence, and venture to assert in so many words that we have been formed by the sun, and that we think and feel and hope and work by reason of the properties possessed by the material particles of our bodies. Probably few who come face to face with sick people will be much influenced by such notions. If, however, they are absurd, it is time that they should be given up.

I am sorry to find the *Students' Journal and Hospital Gazette* dissenting from the practical and sensible views advanced by my colleague Professor Curnow, and quoting with approbation some of the extravagant remarks of one of the "soundest thinkers" and "most advanced" men of the day—"That man, I think, has had a liberal education, who has been so well trained in youth that his body is the ready servant of his will, and does with ease and pleasure all the work that, as a mechanism, it is capable of; whose intellect is a clear, cold logic-engine, with all its parts of equal strength, and in smooth working order; ready, like a steam-engine, to be turned to any kind of work, and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of nature and of the laws of her operations."

But what is there that is sound, or thoughtful, or advanced in comparing us with steam-engines? "The human body is a machine"; "Thought is as much a function of matter as motion is"; "We shall arrive at a mechanical equivalent of consciousness, just as we have arrived at a mechanical equivalent of heat"; "All things living are machines"; "It is because the body is a machine that education (the formation of habits) is possible,"—are texts from the same "advanced" syllabus, and I could give you more were it worth while to do so. Every one of the above propositions is unproved and unprovable. Their actual truth is, however, it is said, to be certainly demonstrated when we are all dead by some "clear, cold logic-engine" about to be. But if you desire to form a conception of the consequences to which all this miserable speculative dogma must surely lead, read the autobiography of Mr. J. S. Mill. In that interesting book you will find the confessions of a "clear, cold logic-engine"—if ever there was one,—and sufficiently unsatisfactory and melancholy you will find them to be.

In a review in the *Times* of November 10 it is well said with reference to the crisis in Mr. Mill's mental history, which occurred when he was about twenty, that "he sought comforters and found none. His father, he felt, would be the last to help him. In none of his friends had he the confidence of a thorough sympathy. Father and friends had all been working for the general happiness, not for a ease of individual misery. Continual analysis, he felt, had exhausted his affections, and the fountains of vanity and ambition had been dried up within him as completely as those of benevolence. Work was now mechanical." The same writer further remarks that "few readers of this autobiography will fail to see that John Stuart Mill was at fifty what he was at twenty, at twenty what he was at ten, and at ten just what his father—however fearfully and wonderfully—had fashioned and made him." (*Times*, November 10.) Is there an English father who would repeat upon his own son the experiment performed by Mr. James Mill? Is there an English son who does not feel thankful that he was not brought up like John Stuart Mill?

But now let us go to our wards; let us speak with the sick people, not as if they were machines, which we know they are not, but as they are—men who think and feel, and hope and despair, who suffer and ask for relief, though in language not exactly that of the logic-engine or the calculating-machine. Study them like sensible men. Picture to yourselves while at the bedside of the sick the phenomena that you know to be going on in a perfectly healthy organism, and try to make out what organs of the sick man are disturbed in their action and what are really changed in structure by disease, and the nature of the morbid changes which have given rise to the result. Above all, record the facts elucidated by your investigations. Take cases—whether they be "interesting" or "uninteresting," whether they be important or unimportant, slight or severe.

The medical attendants of the sick are, indeed, bound to

their helpless patients by no ordinary ties. The relationship has not been exactly defined by legal authority or precisely estimated by political economists. The duties and responsibilities alluded to are altogether different from, and cannot properly be compared either with, those which the merchant and the manufacturer are in honour bound to exercise in their dealings with their customers who confide in them, or with the contract entered into by workmen with their masters. The duties of lawyers to their clients, of teachers to their pupils, of the clergy to the members of their flock, are very serious, and it is very important that they should be conscientiously undertaken and faithfully discharged. But our duties differ from all of these, and in a greater degree than any one differs from any other. Nor is it easy to point to clearer evidence of the exercise of true courage than is afforded by the conduct of the clergy, doctors, and nurses during the prevalence of a serious outbreak of contagious fever in discharging the arduous work of attending the sick-poor, unless it be the conduct of medical officers on the battle-field.

"To my mind there is nothing so impressive, even amid the varied and startling scenes of the battle-field, as the group which is found round a wounded combatant. There lingers the friend, forgetful for a moment of glory; and there, with the bullets whistling round him, kneels an unarmed man, examining and dressing the wound, with clear head and steady hand, as if he were in the peaceful hospital."—(*Times* Special Correspondent, Cape Coast Castle—*Times*, November 18, 1873.)

I have known some who take, or profess to take, or have persuaded themselves that in order to be logical, and cool, and calculating, and unsentimental, and practical, and business-like, they ought to try to make us believe that they do take a purely business view of all matters connected with the poor and sick. Some appear to have made up their minds that they will not allow themselves to be influenced by what has been termed a sentimental consideration. But if sentimentality enables people to go and nurse and doctor the sick and suffering, in close dirty rooms in a fever-stricken town where several are dying day by day, there is surely not much to deplore if, looking from a purely business point of view, it should be found that such conduct might be characterised as "sentimental" in the highest degree. Whether it is utilitarian may be open to doubt, but that it is useful will be admitted, not only by the sufferers, but by all who are interested in them. Perhaps very many of the people of England who have not as yet undergone conversion into logic-engines and thinking-machines, may have sense and feeling enough left to perceive that medical work—especially amongst the poor—is not the sort of work that can be executed by a machine, or the sort of work that can be paid for by weight or measurement. But strange theories have been entertained concerning the duties and remuneration of those engaged in the service of the sick, though not, perhaps, more extravagant or more curious than many of the so-called *new* notions that have been advanced concerning the relationship of person to person,—some contending that we ought not to allow a human being to die if his life can be saved; others, less prejudiced, and perhaps less sentimental, considering that if an organism cannot provide for itself, or if it is distinctly useless, it may be considered unfit to survive, and be left to its fate. So far, however, there can be little doubt that we doctors and nurses do feel it to be our simple duty to save and protect life, and to prolong life to the utmost possible extent, if we cannot restore its possessor to health. And though it might be clearly proved by the very coldest and most engine-like logic that a given life was utterly worthless or even injurious to the material particles under its dominion, as well as to society; and although it might be scientifically demonstrated that the members of any particular class of human beings were utterly unfitted to survive, and had never been intended to live as long as they actually had lived, and had interfered with others more fit to live than themselves, it would, nevertheless, be our duty, as doctors, to preserve life to the utmost of our powers.

Considering the odd ultra-philosophical speculations that have been very fashionable of late, some of us do not feel astonished that the idea of euthanasia, among many other extravagant notions, should have been revived, and have excited considerable attention in purely intellectual circles. It must, however, be confessed that some little confusion of ideas seems to have existed with regard to the precise nature of an act to which the term "murder" has been applied by jurists, and there has also been some difference of opinion as to what constituted suicidal intention or tendency; while, on the other hand, the new arguments did not render it philosophically certain that it would be to the advantage of general society if what has been called murder, and has been regarded as a crime, was transformed into a virtue, legalised, and, under certain wholesome restrictions deemed perfectly safe, actually performed. The new laws that would become necessary have not, however, yet been drafted, and for the present medical practitioners must be contented to act as their predecessors have acted, and must save life and prolong life to the latest moment by every means at their disposal.

It is often most difficult to judge whether a patient will recover or not, and when you become practitioners you will be astonished every now and then to find a patient get quite well whose case you had considered almost hopeless. And be assured that you ought not to give up any case of acute disease as long as the slightest chance of improvement remains. I have known instances of fever patients, said to have been "given up" by the doctor, recover under the influence of beef-tea and brandy administered by non-professional advisers. You cannot be too careful to avoid committing yourselves too hastily to a gloomy prognosis in any case, but if you do so in acute diseases, especially in children, you will be often wrong. You have admirable opportunities of studying prognosis in our wards here, and you will find it very instructive to write down what you think will be the course of a given case, the time you deem it probable that the patient will live, and what you consider will most likely be the mode of death—of course taking care that the poor patient is kept in ignorance of your speculations. At the same time keep accurate notes of the actual facts as they are developed.

Case-taking must be conducted with intelligence, and everyone must prepare himself for the work. No one can take a case well until he has acquired much knowledge besides that which he is able to pick up in the wards of a hospital, or by carefully observing cases of sickness. You must bring to the assistance of the sick a mind well trained in scientific studies, for it is only after a preliminary scientific education that the mind becomes fitted for prosecuting practical medical work.

The scientific work of the early days of professional life is entirely unpaid, and too often underrated or unnoticed. It is of no value in the commercial market; nobody wants it; and, as a necessary consequence, it is treated with contempt by many self-satisfied arrogant persons, who have the will, but, happily, not the power in England, to crush out and extinguish every kind of work and thought which differs from what they can alone esteem—*business that pays*. Unhappily, scientific medical work and thought have had to encounter the determined opposition of some members of the profession itself, and in this way purely scientific men and unprofessional people, who know nothing whatever about the matter, have been prejudiced against doctors who prosecute any branch of science. Some Englishmen find it difficult to tolerate individuality, and detest intellectual independence; and such are often led to oppose self-denying workers whom, if they could but understand, they would certainly support.

I offer no apology for speaking thus. I have myself for more than twenty years worked at science in connexion with medicine, and at first under great difficulties. We who thus work are all occasionally snubbed by people who are for ever challenging every effort made by those who desire to work for the advancement of knowledge that will not pay, and which is therefore considered unpractical and useless. The unsympathetic inquiry of "What's the good of it?" is always being made. Those who propound it never wait for the answer, and would not listen to an answer, but go on and on in their own self-satisfied successful way, never thinking of the difficulties they would experience were the same sort of question proposed to them as regards their work from our point of view. But for a poor investigator even to think of questioning in this way would be universally condemned as a piece of gross impertinence, which would have to be put down by the united strong hand of a number of people empowered to act as a body, and able to do many things which not one would incur the responsibility of doing in an individual capacity. There are many who work very very hard in these days without enjoying either the advantages of pay, independence, or the power supposed to be associated with work; and if we are to be divided into two classes—those who are obliged to work in order that they may live, and those who can live without the necessity of working at all—the first class will include many who do not enjoy the privileges belonging to the working classes, but who work harder than any of them, and the second class will

comprise many who work harder for nothing than others do for pay.

It has been the lot of many in the medical profession to have performed a very large amount of unremunerative work, and everyone amongst us who hopes to add to existing knowledge must be content to do so. It seems but fair, since the work done may be of general advantage, that at least a place in which work can be conducted should be provided for those who are ready to give up their time to researches in connexion with medicine. For many years I had a laboratory and work-rooms of my own close to our hospital, where I was occupied in chemical and microscopical work that should have been performed in the hospital and on a larger scale. More than twenty years since, in the time of Dr. Todd, before our present building was commenced, many of us ventured to hope that the necessary work-rooms would be provided in the new institution. In every hospital there ought to be a good laboratory and a good microscope-room. The committee of this hospital a year or more ago purchased for us an excellent microscope, which has done good service; but there is at present no room warm and well lighted and otherwise well adapted for careful microscopical work. We have begged for this year by year. It has never been distinctly refused, but it has not yet been provided. Rooms exist in this building that might be applied to the purpose, but objections—trivial objections—have been raised. It has been hinted that the supporters of hospitals give their money for the relief of the sick poor only, and not for the examination of their secretions; but this idea is not the real source of the opposition in our case—it is much nearer home.

I have yet to learn that the subscribers to our public hospitals desire that the means required by the medical officers for the proper investigation of disease should not be supplied to them. My belief is that a very large majority are thoroughly disposed that we should have everything that is requisite—not only what is absolutely necessary, but that which is desirable and convenient. It is ridiculous to suppose that any sensible person giving money to a charity should stipulate that not a fraction of it should be devoted to the purchase of microscopical or chemical apparatus required by the physician. It is not reasonable to suggest that they would object to this any more than they would object to the purchase of surgical instruments. Less than the one-hundredth part of our annual expenditure in this hospital would provide all that we want. It seems a small thing to ask for; but we have asked, and for years in vain. So far from our condition having improved, it is worse than it was when I was a student in the days of the old hospital. Even urinometers cannot in these days always be obtained for our use, and objections are raised to furnishing the necessary supply of thermometers. It has even been hinted that some very influential persons, whose duty it is to see that the funds are carefully administered, are not convinced that the thermometer is of any practical use or required for the proper discharge of our duties to the sick. However, one thing is certain—that we must have thermometers; and if they cannot be provided for us, we must raise a subscription, and purchase these and other things for ourselves. What is the custom in other public hospitals I do not know, but it seems to me that very liberal provision ought to be cheerfully made for the requirements of medical officers who freely give their services for the benefit of the poor.

(To be continued.)

Municipal Honour.—Mr. Kirk, M.R.C.S., L.S.A., has been chosen Mayor of the ancient borough of Hedon, the second time in three years.

Health of Scotland.—During the month of October there were registered in the eight principal towns of Scotland the deaths of 2379 persons, of whom 1230 were males and 1149 females. Allowing for increase of population, this number is 54 under the average for October during the last ten years. A comparison of the deaths recorded in the eight towns shows that during October the annual rate of mortality was 20 deaths per 1000 persons in Edinburgh, 21 in Dundee and in Perth, 23 in Leith, 25 in Aberdeen, 26 in Glasgow, 35 in Paisley, and 45 in Greenock. Of the 2379 deaths, 995, or 42 per cent., were of children under five years of age. In Perth, 23 per cent. of the persons who died were under five years of age; in Edinburgh, 35; in Paisley, 40; in Dundee, 42; in Glasgow, 43; in Aberdeen, 44; in Greenock, 47; and in Leith 53 per cent.

ORIGINAL COMMUNICATIONS.

ACUTE ATAXY.

By THOMAS STRETCH DOWSE, M.D., F.R.C.P.E.,
Medical Superintendent, Central London Sick Asylum.

The following case is of especial interest, inasmuch as it represents by signs and symptoms exceptional conditions of actual morbid change, both in the brain and spinal cord, which changes are evidenced by alterations of function in mind and ganglionic centres. For instance: there was impairment of perceptive and intellectual power, there was the rigid and prolonged opisthotonos of tetanus, inco-ordinate and jactatory movements of the upper extremities, sometimes resembling chorea, the inability to stand unaided, and the absolute inability to co-ordinate the movements of the lower limbs in progression, with other conditions peculiarly analogous to posterior spinal sclerosis. These symptoms led me to consider it as an absolute lesion of the posterior columns and grey matter of the cord, not primarily of an inflammatory nature, but rather due to capillary emboli in the grey matter itself. I have therefore given to it the name of acute ataxy, as I have never seen anything comparable to it, and it certainly differs from any recognised form of nerve lesion which has found a place in the nomenclature of diseases of the nervous system.

C. S., aged 54, admitted into Central London Sick Asylum May 9, 1873; discharged November 7. Her history was as follows:—She was the mother of eleven children, five of whom are living. Menstruation had ceased at the age of forty-nine. Her health for years past had been good, but when fourteen years of age she was frightened into an attack of chorea, which lasted eighteen months. At the age of thirty she had acute rheumatism, which left no lesion of the valves of the heart. After this time her health continued good until she heard of the loss of the vessel in which her son was sailing, the effect of which news was to cause (as she called it) a heavy shock to her nerves, resulting in a succession of fainting fits, between which she would sit for hours gazing vacantly, and taking no heed of surrounding objects. Persons passing and repassing, or even speaking to her, would not excite her attention, but when touched she would suddenly start, and every part of her body appeared to be in violent agitation. After this her reason became affected, and she would wander for miles without eating, drinking, or speaking to anyone. In this state she continued for three or four days. She then resumed her employment, but at times suffered greatly from vertigo, and for a second or two she would lose consciousness, always having a tendency to fall forward during these attacks. Now comes the history of the present illness. It appears that she went to bed on the night of May 2 tolerably well in health, but suffering from great mental depression, on account of the loss of her son; and when she awoke in the morning found that she was totally unable to control her movements. She could lie perfectly still in bed, but when she attempted to exercise voluntary power the muscular actions were not only not under the direction of her will, but were subject to a series of movements not unlike those of chorea.

Upon admission into this Asylum, the condition just described was not manifest, and there was simply inco-ordination of voluntary movement both in the upper and lower extremities. This inco-ordination only resulted when the will was brought to bear upon and direct movement. She complained of having a sense of "pins and needles" all over the body, from the roots of the hairs of the head to the ends of the nails of both extremities. A few days after this she was seized during the night with intense pain along the whole course of the spine, producing tonic spasm with persistent opisthotonos, which was greatly relieved by the administration of chloroform. This was the first time she complained of spinal pain. On the following day grave constitutional symptoms set in; her temperature rose to 102°; there were acute lancinating pains darting from the occiput to the sacrum, with occasional tonic spasms of groups of muscles distorting the general conformity of the body; retention of urine; vomiting; and reflex spasms, confined especially to the upper extremities. The tongue was dry and brown; pulse 130; and the respiration weak and jerky. This condition continued for two or three days, and then passed off by degrees, when the following notes were made:—Memory very imperfect;

sight at times diploptic. She is quite unable to stand, and when she attempts to walk throws the legs about in all directions. Has a tendency to lie in a semi-dreamy condition, and when any part of the body is touched starts violently. Still complains of occasional shooting pains throughout the whole course of the spine, as well as the feeling of "pins and needles" all over the body. (It might be here remarked that the estranged muscular sense was in no way assisted by vision.) There is failure of grasping power of both upper extremities, equal in degree. She says the arms feel heavy, like lead, and the power of muscular co-ordination is completely lost in them. She can drag the limbs up in bed, abduct or adduct them co-ordinately, but these actions are performed with great slowness and apparent difficulty. There is no power to raise the extended legs from the heel. She is continually holding imaginary conversations with unseen people. At this time her temperature was 104°, pulse 105. A week after this it was observed that there was some improvement in the degree of co-ordinating power, yet she is unable to feed herself, and, instead of carrying the food to her mouth, holds it still, and moves the head forward to catch it. The feelings of prickings and shooting and cutaneous formication have passed away. She can now fasten her dress or pin her shawl without difficulty, but she is unable to stand without support, and even when thus assisted she has to be propped, so to speak, behind to keep her from falling on her back. The body is rigidly fixed, and the spine and head arched backwards. When she attempts to walk the legs are jerked upward, and the feet fall heavily down upon the heel. She says that the extremities feel like lumps of lead. So marked is this impression in her mind that, when lying down with her arms upon her body, she says that their weight is more than she can bear. There was no marked cutaneous anæsthesia, yet the muscular sense was undoubtedly deficient, producing a degree of numbness. There was no especial tenderness when the spines were gently percussed, but forcible pressure upon the dorso-spinal muscles caused great suffering.

From this time she gradually and progressively improved in health. The ataxy in the upper limbs had completely subsided in about six weeks after the commencement of the attack, and the same condition in the lower extremities became less evident day by day, so that at the time of her discharge she possessed scarcely a trace of the disease from which she had been suffering. When discharged the only points exhibited by her, and referable to the spinal lesion, were the inability to walk a straight line, for, when desired to walk a given distance of twenty yards, she invariably diverged to the right, always at about the same angle of thirty degrees. Also it was by an effort of enforced will that she was enabled to stand erect with the eyes closed; and during progression the feet were always kept some distance apart and the heel implanted on the ground prior to the sole of the foot.

Highgate.

OUTLINE OF OBSERVATIONS AND INVESTIGATIONS ON YELLOW FEVER.

By JOSEPH JONES, M.D.,
Professor of Chemistry and Clinical Medicine, Medical Department, University of Louisiana;
Visiting Physician of Charity Hospital, New Orleans.

No. I.—Notes upon the Early History of Yellow Fever.

(*Continued from page* 520.)

It is evident, therefore, that the origin of the American plague or typhus (*vomito prieto*, *fièvre jaune*, yellow fever) is involved in doubt, on account of the prevalence in the tropical and sub-tropical regions and temperate zones, both amongst the natives and foreigners, of some forms of malarial fever, often attended with jaundice, passive hæmorrhages, and black vomit. If it could be determined at what time this terrible disease was clearly recognised by the medical profession and historical writers as distinct from paroxysmal malarial fever, and as dependent upon a specific cause or upon a combination of causes peculiar to itself, a firm ground for the discussion of its origin and of its relations to the native population, as well as to the foreign elements, would be established. But it is well known that many of the descriptions given by various authors will apply as well to the severe forms of paroxysmal malarial fever as to yellow fever, and also that the distinction of the one from the other has been the result of comparatively recent labours; and even at the present time there are not a few physicians who hold to the identity of both diseases in their origin and essential nature.

The opinions in regard to the causes of yellow fever have been arranged by systematic writers under three heads:—1. That it is a disease induced solely and essentially by contagion. 2. That it is essentially of endemic origin. 3. That, being of endemic origin, it afterwards becomes contagious. The doctrine that not only intermittent, remittent, and congestive or pernicious paroxysmal malarial fever, but also yellow fever, assume more or less, according to circumstances, the type of one another, has been extensively entertained by the medical profession. Believing them to arise from essentially the same causes, variously modified, which assail the system through the same avenues, these fevers are regarded by this class of reasoners as essentially the same, modified by the intensity of the cause and by the prevailing constitution. And it has strangely been sought to maintain this position by the fact that the natives of southern cities, in which yellow fever is of such frequent occurrence as to be pronounced endemical, possess in a great measure an exemption from this malady, and suffer only from mild intermittent and remittent, whilst those lately arrived from northern latitudes so often fall victims to yellow fever that it has in some cities received the name of *strangers' fever*.

To sustain the opinion that yellow fever arises from miasmatic effluvia, the following facts have been frequently cited:—1. Yellow fever always appears simultaneously with bilious remittent. 2. A high range of atmospheric temperature is essential to the generation of its cause. 3. Its first appearance is almost always in the lowest and most filthy parts of towns, and in localities favourable to the production of miasmata. 4. The supervention of storms, heavy rains, or cold weather puts an immediate check to its progress.

It has been asserted that whilst at New Orleans, Charleston, Savannah, and Gibraltar the same individual is seldom twice attacked by yellow fever, in the West Indies and on the Coast of Africa it is said to secure no subsequent immunity. With some writers it is still even a disputed question whether certain fevers which have, or are supposed to have, their source in vegetable miasms or in effluvia from marshes, or from infusoria or fungi developed and propagated under certain combinations of heat, moisture, and putrefying vegetable and animal matters, are subsequently spread by contagion; whilst some writers contend that within the tropics yellow fever may at any time, under certain conditions of moisture and temperature, arise *de novo* in the impure atmosphere of the crowded and filthy ship or city. Others, again, as strenuously uphold the doctrine that it is a specific contagious pestilential disease, which, like small-pox or measles, may be transported and communicated from one ship or city to others, thus following the great avenues of commerce. Whilst a third class adopt and advocate a doctrine which embraces the main features of both propositions. Some who hold that yellow fever may be engendered *de novo* in the hold or atmosphere of ships navigating in the warm, moist tropical regions, have coupled with this view the doctrine that if this poisoned atmosphere be allowed to escape at the wharves of cities situated beyond the yellow fever zone, those only who come within the sphere of its influence will be affected; and its subsequent spread will depend upon conditions of filth and crowding of such localities, the disease never spreading endemically, and falling harmless among the inhabitants of a salubrious locality.

According to this view, the development of this malignant fever requires the conjoint operation of both local and general causes, constituting an endemico-epidemic, which is unsusceptible of propagation by specific contagion; and in the summer atmosphere of a city lying beyond the yellow fever zone there must exist some peculiar combination of circumstances, or some peculiar agency favourable to its development. In these cases it is affirmed that there is generally found an infected district, which slowly and regularly extends its boundaries, rendering all who come within its limits subject to this form of fever. It has been said that the experience of several centuries teaches us that the cause of this fever is perennially present in the tropical and sub-tropical cities of America; that it is indissolubly connected with climate; that it maintains the same relation towards the human system as the other malarious emanations of swamps and lowlands; and that it is liable to be developed at any time in different degrees of intensity by the combined operation of heat and other agents.

Amongst the most striking circumstances in the etiology of yellow fever are the marked geographical boundaries within which it is confined and the circumscribed localities in which it prevails, the disease being rarely met with south of the 35th or north of the 40th degree of latitude, and even between these limits being more frequent in the Western than in the Eastern Hemisphere; its almost universal limitation to commercial sea-ports elevated but a few feet above the level of the sea, although it occasionally spreads to towns and cities in the neighbourhood of the latter, situated in the interior country or on the banks of navigable rivers; and the fact that it is very frequently circumscribed within certain limited and well-defined portions of the locality or city in which it prevails. The shores of the Western Archipelago, and of the Gulf of Mexico and the Caribbean Sea, constitute the prolific hot-bed in which has been generated and propagated the mysterious poison of this disease, which has desolated cities, armies, and fleets, and destroyed the successive swarms of adventurers and invaders from Europe and the colonies of North America.

If it were possible to determine with accuracy the nature of the severe and fatal forms of fever which afflicted the first explorers and colonists of the tropical and sub-tropical regions of America, and even the very companions of Columbus, the question of the origin of yellow fever would be relieved of much uncertainty and doubt. If we are to credit the accounts of some authors, the first trace of yellow fever was observed at the end of the fifteenth and beginning of the sixteenth century at San Domingo and Porto Rico, in the continent of South America, and in the Gulf of Darien, at which latter place it is said to have prevented the Spaniards from settling. In November, 1493, Columbus landed at San Domingo with 1500 Spaniards, in order to found the city of Isabella. A severe and fatal fever carried off the greater part of them within a year after their arrival, and the disease is described as being "yellow as saffron or gold." From 1544 to 1568 there is no record of the disease having prevailed as an epidemic until 1635, when it appeared in Guadaloupe, and thenceforward it occurred at irregular intervals. In the seventeenth century it spread along the continent of South America to latitude 8° south, and in North America to latitude 42°, but only on the eastern coast of both. The first appearance of the disease in the United States was at Boston in 1693, and in Charleston and Philadelphia in 1699. It is said first to have appeared in the Gulf of Mexico, at Biloxi Bay in 1702, and Mobile in 1705; but Humboldt held that it had prevailed from the very foundation of Vera Cruz, and was indigenous to this city. It prevailed at Pensacola and Mobile in 1765.

In the eighteenth century it appeared on the west coast of South America in latitude 2° south. On the North American continent it spread to latitude 42° north; it extended even to Europe, and reached the Pacific and Madagascar. At the beginning of the nineteenth century it penetrated deeper into the North American continent than formerly, reaching as high as latitude 47° north, and in Europe it extended to latitude 48°, and prevailed in the Canary Islands and Leghorn.

Ever since yellow fever attracted attention it was recognised as a distinct disease from the remittent autumnal fevers of the temperate zone. It has prevailed as an endemic at Havana, raging epidemically from April to December, and occurring sporadically during the rest of the year. From time immemorial it has been endemic at Vera Cruz, in the Gulf of Mexico, where its chief victims are strangers who come from cold regions during the hot season, as well as Europeans and those natives who exchange the more elevated and cool regions of Mexico for the coast.

At the time when Spain possessed by far the best and largest portion of the American continent, extending from the north of California to the Straits of Magellan—a space of between 6000 and 7000 miles,—a system of commerce was established which appeared to be eminently favourable to the origin and spread of yellow fever. The Spanish galleons were, in fact, very large men-of-war, built in such a manner as to afford ample room for the stowage of merchandise, with which they were commonly so encumbered as to be rendered incapable of defence. The fleet of galleons consisted of eight such men-of-war, and generally convoyed from twelve to sixteen merchantmen. During times of peace the galleons sailed once a year regularly, though at no set time, but according to the pleasure of the King of Spain and the convenience of the merchants. They sailed from Cadiz to the Canaries, thence for the Antilles, and after reaching this longitude they bore away for Carthagena. As soon as they came in sight before the mouth of Rio de la Hacha, after having doubled Cape de la Vela, advice of their arrival was sent to all parts, that everything might be prepared for their reception. They remained a month in the harbour of Carthagena, and landed there whatever was designed for *terra firma*. They then sailed to Puerto Velo, where having stayed during the fair, which lasted five or six weeks, they landed the merchandise intended for Peru, and received the treasures and commodities sent from thence. The galleons then sailed back to Carthagena, and remained there till their return to Spain, which usually happened within the space of two years. When orders for returning home arrived, they sailed first to the Havana, and having joined the flota, and what other ships were bound to Europe, they steered northward as far as Carolina, and then, taking the westerly winds, they shaped their course to the Azores, when, having watered and victualled afresh at Terceira, they thence continued their voyage to Cadiz.

The Spanish flota consisted, like the galleons, of a certain number of men-of-war and merchant ships; there were seldom more than three of the former and sixteen of the latter in this fleet. They sailed from the coast of Spain some time in the month of August, in order to obtain the winds that blow in November for the more easy pursuing their voyage to Vera Cruz. They called at Puerto Rico on their way to refresh, passed in sight of Hispaniola, Jamaica, and Cuba, and, according to the winds and season, sailed either to the coast of Yucatan, or higher through the Gulf to Vera Cruz. The Spanish flotilla being intended to furnish not only Mexico, but the Philippine Islands also, with the goods of Europe, was obliged to remain in Vera Cruz for a considerable time, and sometimes found it necessary to winter in that port. This fleet usually sailed from Vera Cruz in the month of May, but was sometimes detained as late as August; it then made for Havana, and returned to Spain in company with the galleons.

The Spanish towns were generally built in low, unhealthy localities, surrounded by marshes and swamps, with narrow streets and high walls or fortifications, which not only compressed the towns within certain limits, and induced crowding and favoured the accumulation of filth, but also prevented to a certain extent the free circulation of air.

(*To be continued.*)

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, etc., etc.

(*Continued from page* 463.)

Case 7.—Stephen M., aged 9 years, was bitten on the left foot by a tiger snake (hoplocephalus curtus) at 2 p.m., January 28, 1869. He at once ran home to his mother, who put some salt into the bitten part. Noticing the boy getting giddy, she carried him to a neighbour, who scarified the place and burnt some gunpowder upon it. He then carried him on horseback to Mr. Henshall, chemist, who treated the boy with brandy and ammonia and Underwood's antidote (a decoction of fern applied locally). By 7 p.m., the boy getting worse, he was taken to Mr. Stillman, chemist, who immediately applied a pledget of lint saturated with strong liquid ammonia to the wound, and administered brandy, ammonia, and hot coffee internally. At 9 p.m. the boy was evidently sinking, and Mr. Stillman having been joined by Mr. Henshall, they decided upon using the injection as recommended by Professor Halford. A half-ounce glass syringe having been carefully charged with diluted ammonia, in the proportion of two parts of strong ammonia to ten of water, Mr. Stillman opened a vein at the bend of the elbow, from which dark, thick blood oozed slowly. Mr. Henshall inserted the nozzle of the syringe, and slowly injected upwards towards the shoulder about half the contents of the syringe. On the syringe being removed, the thumb was kept pressed over the orifice till a pledget of lint saturated with cold water was bound on the arm. The effect was instantaneous: the boy, who had been in a state of stupor, at once rallied, and the wound in the foot bled afresh, the blood being brighter in colour and less thick. Afterwards friction was applied to the icy cold extremities, and hot coffee given *ad libitum*. At 2 a.m. the boy was so far recovered as to sit before a fire and play with a kitten. It was remarked that whereas the ammonia and brandy that were given by the mouth were almost instantly rejected, he retained the hot coffee very well.

We were first made acquainted with this case by Mr. Sturt, police magistrate, of Melbourne. Another police magistrate, Captain Panton, had seen the boy when overpowered by the poison, and afterwards when so rapidly recovered. I was anxious to be certain that Messrs. Henshall and Stillman had really injected the ammonia into a vein. The following letter will, I think, satisfactorily set this at rest:—

"Seymour, February 26, 1869.

"Dear Sir,—You can rely that the vein of the arm was opened, and the nozzle of the syringe was inserted into the vein; also that the ammonia was injected into the cavity of the vein and passed upwards through the channel of the vein. My reasons for certainty are, not only having deliberately injected it myself, but the trace of swelling or inflammation which was distinctly to be seen by the red appearance assumed along the whole line of the vein from the orifice to the shoulder. The boy had pain along the vein when touched for the space of three days afterwards. There can be no doubt in our minds of the perfect efficacy of your discovery, and also that this was a real case of snake-bite pushed to the last extremity. The boy is now perfectly recovered, and does not suffer the least inconvenience. I shall be most happy to send any further information required in my power.

"Your obedient servant, S. H. Henshall, M.P.S.
"(Countersigned) A. Stillman."

The points in this case which pleased so much at the time were the successful manner in which the little operation had been performed by these two gentlemen, the fact of so young a boy being so instantaneously relieved, and the wound in the foot recommencing bleeding, showing the relief to the peripheral circulation, to which I have before alluded.

Case 8.—A boy, aged 9 years, putting his hand into a hole to get a rabbit, was bitten (as he said) by an opossum. It was no doubt by a snake; but it was twenty-seven hours after the accident that he was brought to the Kyneton Hospital. Five minims of liq. ammoniæ fortior, with twenty-five minims of water, were injected into the basilic vein. Before the injection the pulse was intermitting, the extremities cold, and the pupils dilated and insensible to light; there was also lockjaw. Four hours afterwards a similar dose was again injected. No apparent effect followed the use of the remedy, and the child died, remaining perfectly sensible to the last.

There are points about this case which it will be useful to touch upon. The first unfavourable thing to mention is the great length of time between the bite and the use of the injection; the second is the age of the patient. We might ask whether the dose was not too small for so severe and prolonged a case. But we shall find further on other cases presenting the singular symptoms of perfect consciousness with dilated and fixed pupils, with more or less of tetanic symptoms, from which it would appear that these are symptoms that should cause greater anxiety than the most profound coma. It is true that consciousness accompanied by dilated pupils need not excite too much anxiety, but when to these are added pains about the neck, and trismus, then I think the case should be looked upon as very grave. The fixed, dilated pupil necessarily, by loss of accommodating power, interferes with vision, but in addition there may be also affection of the internal seats of sensation, and the following interesting facts show that they are occasionally joined to affections of the seats of general or common sensibility. This would not surprise us if we are to regard the optic thalami as actually those seats, and the corpora quadrigemina as those of vision, seeing that being so closely connected they might be similarly affected.

Mr. Clement Hodgkinson, Deputy Commissioner of Lands in Victoria, furnishes the following facts:—

"In 1841, when employed on Government surveys in the northern part of New South Wales, I was bitten by a large black snake. The venom of this reptile did not, however, produce any unconsciousness or mental confusion, and I was therefore able to note all the symptoms displayed, which were as follow:—1. Slight numbness in the part punctured by the fangs, but no local pain or swelling. 2. General feeling of lassitude, and weakness of the muscles of the neck. 3. Insensibility to the effect of pungent salts when held to the nostrils, and to pinches inflicted on me by some of the on-lookers, who desired thereby to prevent me from falling into a comatose state. 4. Deprivation of sight. About two hours after I was bitten this symptom attained its greatest intensity, and I was then scarcely able to distinguish the features of the persons near me. The treatment under which I recovered in about three or four hours after I was bitten consisted in the suction of the punctures by some aborigines (who successively took spells in performing this friendly office), and in making through the punctures a cut, to which was applied some nitric acid."

These are most interesting facts, and show the very general benumbing influence of the poison, and the value of quick and repeated suction in mitigating the symptoms. At the same time the case stands almost in contradiction to what I have just said relative to similar symptoms when attended with stiffness of the neck and trismus; but yet it was not tetanic symptoms Mr. Hodgkinson relates, but weakness in the muscles of the neck and general lassitude. In this seems to be the difference between the cases. My object is not so much to be right as to record all worthy facts on so perplexing a subject.

Case 9.—This case I take from a letter of Dr. William Rae, of Bacchus Marsh:—"About noon on July 17, 1869, a robust man, aged 23, while stooping on his hands and knees to drink from a water-hole, felt a sharp stinging pain on the inside of the palm of the right hand, which he at the time supposed was caused by a thistle. On getting up, however, he saw a snake, about eighteen inches long, getting into the water immediately under him. The man at once ran to an adjoining hut, where the bitten part of his hand was freely excised with a razor. The wound bled profusely. He then rode to my residence (a distance of six miles), where I saw him. Suction was employed, and the wound cauterised. As there was no appearance of general systemic disturbance, he was sent home, with instructions to send to me at once should drowsiness or any other untoward symptom appear. I did not again see him until five o'clock in the afternoon. In the interim he had kept pretty constantly on the move, but about three o'clock numbness of the right arm, oppression about the chest, impairment of vision, and drowsiness set in. No vehicle was at hand, and he set out on horseback to see me again, accompanied by two friends. On the way the disposition to sleep became so great that one of his friends had to support him on the horse, while the other kept up pretty severe flagellation with a stick. When I saw him he could scarcely be roused. Shouting and shaking only elicited from him an occasional monosyllable. The pulse was feeble and intermittent, and the pupils dilated and fixed. I ascertained that, with the exception of one glass of brandy, which he had been induced to take about three o'clock, and before the symptoms had become very urgent, he had had no stimulants or other medicine. The case seemed a favourable one for testing the value of Professor Halford's method, and accordingly the median cephalic vein of the right arm was exposed, and twelve minims of liq. ammon. fort., in a drachm of warm water, carefully injected into the blood-current by means of a hypodermic syringe. Within a minute indications of returning consciousness were apparent, and in about ten minutes he had sufficiently recovered to walk out in the open air unassisted. He was kept under notice for a few hours, when he went home, no unpleasant symptoms having occurred in consequence of the treatment adopted. The man called upon me on the following day, when he was quite well. The notable features in the case are—first, that of the injection of the ammonia alone having been relied on; and, secondly, the permanence of the good effect obtained by a single application of the remedy."

This case shows how little we can depend upon the so-called excision of the bitten part by anyone but a surgeon; it is usually little more than scarifying that is done. This is not to be wondered at, and it is only necessary to draw attention to it, since in many of the recorded cases the same thing is said to have been done, and it is as well to know its value.

Shortly after this case occurred, Dr. Rae was good enough to call upon me and give me the fullest particulars, and I have only to add to his account his great astonishment at the immediate result of his treatment. He assured me that riding home in the evening, and seeing so great a crowd surrounding his house, he could not guess its meaning, when, to his surprise, he saw the man, who had been bitten in the morning, now apparently dying. He had the man carried under the verandah of an hotel opposite, and there, surrounded by the excited crowd, injected him, with the result stated above. Dr. Rae assured me that I should hear of many similar cases if only people would now believe as he did. His words have come true.

Something must be said, also, about the unusual time of

year—viz., winter—for snake-bite to occur. It so happened that about this time there had been many warm and sunny days, that on which the accident happened having been one of the most delightful. At such times one might possibly meet a snake near a water-hole, and it is a habit, I believe, with bushmen to look carefully about such places before they stoop down to drink. Mr. Knefft, a great authority on the habits of snakes, says—"The general habits of snakes will be found much alike in similar climates, whether north or south of the line. Where frost occurs, all the reptiles retiro underground into the burrows of various animals; but in the more genial regions, where the thermometer seldom or never ranges below freezing-point, they select sunny hill-sides abounding in flat stones, through which the rays of the sun easily penetrate, and beneath them make their winter quarters. They do not fall into a dormant state, since bright warm days will bring them out a few yards at least from their hiding-places."

Case 10.—A boy, aged 17, was bitten on the foot by a small whip snake (hoplocephalus flagellum, or H. coronoidis), about eighteen inches long; he was freely dosed with brandy and ammonia. On arrival at the Creswick Hospital he was very drunk, but not insensible; the pulse was rapid, but not weak. To be on the safe side, Dr. Hyde Starke injected twenty minims of liq. ammon. fort. mixed with forty of water into the median cephalic vein. Within half a minute he complained of great pain in the eyes and head. On being put to bed he recovered most unusually quickly from the drunkenness, and continued well.

In this case Dr. Starke could find no symptoms of snake-poisoning, and the case is only recorded as an instance of the relief of symptoms of drunkenness by a double dose (twenty minims) of liq. ammon. fort.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

CASES UNDER THE CARE OF DR. OGLE.

Cerebral Affection, apparently of Syphilitic Origin.

Rachel G., aged 52, a married woman with eight children, and who had also had a miscarriage, had been suffering for three months with pains in the head and limbs and loss of appetite, and two months before admission into the Hospital (under Dr. Fuller's care at that time) had had some kind of fits. Over the left side of the forehead and also over the right clavicle were encrusted ulcers, and there was slight dropping of the upper eyelid of the left eye and slight internal squint of the same eye, the pupils being equal. It seemed that of late the patient had greatly lost her hair. She was placed on iodide of potassium. It was very soon found that there was some loss of power over the sphincters, and that she had occasionally difficulty in expressing herself correctly. Under treatment she became quite rational; the pain in the head greatly diminished; and after being five weeks in the Hospital she left, and returned home. Six weeks later she came again to the Hospital under the charge of Dr. Ogle. At this time she was constantly dozing and was dull and stupid, complaining at the same time of great pain in the head. The pulse was quick and the breath fetid, as if she had been salivated. The dark-crusted sore on the forehead existed as on her former visit, and was evidently connected with diseased bone. Dr. Ogle gave her fifteen grains of the bromide of potassium three times a day, and obtained from Mr. B. Carter an ophthalmoscopic examination, by which it was found that both discs were obscured in outline (neuritis descendens), and the right retina was studded with small hæmorrhages. The stupor became greatly aggravated, and after a time she lay in almost a comatose state for some days, apparently about to die, unable to speak, and passing urine and evacuations unconsciously. She was then put under the influence of ten-grain doses of the iodide of potassium three times a day (which was not given earlier owing to the apparent salivation), and she soon improved, so that in nine days she was quite sensible and easily roused to talk, though still inclined to sleep. The patient was seen by Mr. H. Lee, with a view of ascertaining whether anything could be done to the diseased frontal bone; but he did not think it desirable to interfere with it. She greatly improved under the continued use of the iodide of potassium, and no longer was drowsy, though some pain in the head remained; and she went home, able to attend to work, at her own request. The condition of the eye and eyelid remained unaltered. Dr. Ogle considered that this case showed well the benefit arising from the iodide of potassium in the disease, and believed that the drowsiness and semi-coma were owing to serous effusion which was absorbed under the influence of the drug. It was to be regretted that the patient could not remain in the Hospital, so as to have continued its use.

Excessive Epistaxis in a Girl, aged six years—Anæmic Bruit at the Apex of the Heart.

The girl, Rachel E., otherwise healthy and of healthy family, had had an attack of epistaxis one year before, and for two months previous to admission had been out of health, with loss of appetite. The present attack had existed four days, and after nausea and vomiting of blood she was brought to the Hospital exceedingly pale and anæmic, and complaining of great giddiness, but with no pain. The heart was beating forcibly and rapidly, and the pulse was 180 and almost inappreciable as to force. She was bleeding freely from the nose, which was at once plugged. On examination a loud systolic bruit at the apex of the heart was audible, and the jugulars of the neck were full and pulsating, but nothing wrong was found with any of the inner organs. Ice was applied to the forehead and given by the mouth, and small doses of tincture of digitalis every four hours, and milk, eggs, and beef-tea. The hæmorrhage had ceased on the plugging, and the patient's pulse and general condition improved, and the plug was removed. For a few days she went on well, but the epistaxis recurred, and again the patient was blanched and became almost lifeless in appearance, the pulse being hardly discernible. Brandy had to be given in addition to the use of ice, and the tincture of perchloride of iron was given every four hours. On one or two occasions blood was brought up by vomiting. The patient eventually quite recovered her looks, but the action of the heart remained irritable, and for some time the cardiac bruit remained very loud. Digitalis infusion was given, and a belladonna plaster applied over the heart. The bruit gradually became fainter, and was looked upon by Dr. Ogle as anæmic in character, but was somewhat audible even after the child had been to the Wimbledon Convalescent Hospital. Dr. Ogle considered it was interesting and somewhat unusual to have an anæmic bruit confined to the apex of the heart. As to the exact character of the bruit, Dr. Ogle found some difficulty in establishing whether it was mitral or tricuspid; but from the jugular pulsation, etc., he was inclined to look upon it as being tricuspid, bearing in mind the observations on so-called anæmic murmurs by Dr. Parrot in the *Archives Générales* for 1866, (a) who supposes them to result from inefficiency of this valve, owing to enlargement of the right side of the heart as a consequence of atony.

Pulmonary Phthisis, with High Temperature unaffected by Quinine.

The following was one of several cases in which observation was taken as regards the influence of remedies upon temperature in disease:—

The patient, Richard D., aged 18, was admitted on March 20 with physical signs of consolidation of the upper parts of both lungs, cough, increased action of the heart, and much redness of the tongue. Cod-liver oil with good diet, and wine with cascarilla and the compound tincture of camphor, were given. Subsequently the cough became more troublesome, as also the palpitation, and much small crepitation became audible at the apices of both lungs.

At this period (April 5) the temperature was 102° in the evening, being the next morning 103·4°, and the pulse 120. Iodide of potassium and salines were given, and afterwards squill and cinchona bark. This treatment was continued until the 15th, when the temperature was registered as follows:—15th: a.m., —; p.m., 101°. 16th: a.m., 100°; p.m., 100·2°. 17th: a.m., 100°. 18th: a.m.: 100°; p.m., 100°. 19th: a.m., 101·4°; p.m., 100°.

On the 20th sulphate of quinine was given in doses of six grains three times a day, and the temperature, as measured afterwards, was as follows:—20th: p.m., 102·4°. 21st: a.m., 102·2°; p.m., 101°.

(a) See vol. ii., p. 129.

On the 22nd the quinine was increased to ten grains each dose, and the temperature taken was as follows:—22nd: a.m., 102°; p.m., 101°. 23rd: a.m., 103·4°; p.m., 101°.

On the 24th some diarrhœa came on, and the quinine was omitted. The temperature continued as follows:—24th: a.m., 102°; p.m., 101·4°. 25th: 102°.

On the 27th the patient left the Hospital at his own request, as he felt so well that he said he must be going to work.

Dr. Ogle contrasted the above with several others showing that temperature in many cases of phthisis was lowered by the use of quinine.

BRITISH SEAMEN'S HOSPITAL, CONSTANTINOPLE.

SKIN GRAFTING.

(By JOHN PATERSON, M.D., Surgeon-Superintendent.)

Skin-grafting has been successfully practised for three years at this hospital in nearly all cases of chronic ulcers. The process is simple. A piece of skin is nipped up with the forceps, and snipped off with scissors. It is then spread out on the surface of the ulcer, and with the point of a knife pushed partially or wholly under the granulations. A piece of perforated linen wrung out in cold water is then applied over the part, and covered with oiled silk or gutta-percha tissue. Perfect rest and cleanliness are all that is afterwards required. At first the grafts were merely laid on the surface of the ulcer, and kept in position with isinglass plaster, but displacement of the pieces often occurred, even after they had adhered. Several grafts are inserted at a time, or at intervals of forty-eight hours. They are taken from the patient himself, or from any healthy subject willing to give them, and from any convenient part—generally, however, from the upper arm or inner part of the thigh. Grafts the size of a large millet-seed are found to answer best; the larger ones do not succeed so well, as the epidermis swells and then disintegrates, and often causes irritation, producing unhealthy looking little perforations. The nucleus of germinating tissue however remains, and takes on a healthy action after the *débris* has been washed off and the irritation has subsided. It would seem that the reproductive power of a graft is limited, for in no case have we seen a large ulcer heal with one or two grafts. Seldom does a graft increase beyond the size of a sixpenny-piece, and the progress of growth in each graft is slower when there are only a few, and placed at a greater distance from each other. Adhesion of the graft takes place, though slightly, in twenty-four hours, as observed when grafts were laid on the sore, and without dressings. In other respects the process observed closely corresponds with that described by M. Reverdin and Mr. Pollock. That a general stimulation of the sore is produced cannot be doubted; the edges soon begin to show a healthy action. In very callous ulcers, which have resisted other treatment, this is often well marked; exuberant granulations have been observed to arise forty-eight hours after the insertion of the grafts. The newly formed tissue from grafts is easily influenced by any disturbance of system. In one case intermittent fever occurred during the process: the growth of the grafts was suspended for several days, and a portion of the new formation was absorbed or disintegrated. In another case active diarrhœa supervened, with a like result.

In the case of a lad, aged 16, severely scalded, the system was much lowered by the excessive suppuration; several of the grafts grew to an unusually large size. As he improved in health and the nutritive powers became active, nearly all the pieces disappeared; they afterwards grew afresh, but did not again reach their former size. Black skin seems slower than white to take on the action, as observed in three cases where alternate rows of black and white grafts were inserted at different periods. In no case tried could a hair be grown when transplanted on the graft, nor did epithelium when freely sprinkled over several large ulcers produce any result. A piece of skin, half an inch square (cut from an amputated foot after it had lain an hour and a half in cold water), was applied to a large ulcer on the back. It slightly adhered in twenty-four hours; in forty-eight hours it was soft and swollen; the surface then began to wrinkle and contract; in four days it was disintegrated to half the original size; in seven days it was reduced to a morsel not much larger than the ordinary-sized millet-seed graft; it then grew as usual. Grafts applied to unhealthy ulcers do not always fail, but the process is much slower, and they often healthily stimulate the sore. A negro with a large chronic ulcer over the tibia had alternate rows of black and white skin engrafted. The white grafts grew quicker than the black. When cured, the cicatrix presented a mottled appearance—the black grafts produced dusky, and the white bright fawn-coloured tissues. Grafts from a negro inserted into an ulcer on a white gave a deep fawn-coloured cicatrix. About four months afterwards the colour of the cicatrix had become much lighter. In several cases the grafts, after progressing favourably for many days, entirely disappeared when no constitutional disturbance could be traced, though probably it did exist.

Medical Times and Gazette.

SATURDAY, NOVEMBER 22, 1873.

HOSPITAL MEDICAL OFFICERS AND HOSPITAL COMMITTEES.

The great increase in the number of the so-called medical charities during the last forty years has rendered the relation of the honorary medical staffs of those institutions to the institutions themselves and to their governing bodies a matter of the highest and most general professional interest. Unfortunately an idea has been allowed to gain strength in some quarters that the physicians and surgeons who constitute the professional staffs of the numerous hospitals and dispensaries, which have sprung up in London and in all country towns, are a set of persons who, although seemingly they give their services gratuitously, are really amply paid by the honour and glory and practice which they derive from their positions; and are, therefore, in some sense the remunerated servants not merely of the institutions, but of the president, vice-presidents, treasurers, committees—even, indeed, of the paid officers who manage the funds which a benevolent public places at their disposal. Moreover, recent events at a London hospital, to which we shall presently refer, serve to show that this idea has obtained the very startling embodiment of a requirement that the medical officer not merely should do his duty as physician or surgeon to the institution in which he holds a post, but that it is also his duty to place himself under the surveillance of the governing

body, who have the right to gag his mouth if he express an opinion out of doors which they may choose to regard as inimical to the interests of the institution, or rather to their management of those interests; and even to compel him to submit any anonymous articles which he may contribnte to the periodical press of the country to their censorship, and in case of his incurring their displeasnre to inflict on him the penalty of summary dismissal.

We need not say that any such view of the relations of medical officers to medical charities is almost too ridiculous for serious discussion. No medical practitioner, be he physician or surgeon, who possesses a spark of self-respect, or who is in the slightest degree alive to the honour of his calling, would consent to submit himself to the espionage of a hospital committee or to barter his right of free speech, free action, and of free writing (within, of course, the limits of morality and propriety) in public journals, for the reward of being allowed to exercise his profession by gratuitously treating the sick. Certainly no English surgeon or physician who is presumably a gentleman would accept a hospital appointment on such terms. But the following facts, to which our attention has been called by a non-medical contemporary—the *Pall-mall Gazette*,—prove that it is on terms like these that the medical officers of the Metropolitan Free Hospital are expected by the governing committee of that Hospital to hold their appointments. The simple fact, as we gather it from a letter in our contemporary, is that a physician on the staff of that Hospital—Dr. John Chapman, a gentleman distinguished in literature and science—has been summarily dismissed from his office by the Governing Committee of the Metropolitan Free Hospital because he was the author of some unsigned editorial articles in the *Pall-mall Gazette*, in which he exposed the abuses of the out-patient system in the London hospitals in general, and cited the Metropolitan Free Hospital as one of his examples. Now for the details of the process.

From the able and temperate letter published in the *Pall-mall Gazette* of the 13th inst., headed "The Metropolitan Free Hospital," and signed "T. J. P. Jodrell"—a gentleman well known as a munificent subscriber to various medical charities, including the Metropolitan Free Hospital itself,—we learn that several articles on the "Abuses of Medical Charity" were published in the *Pall-mall Gazette* during the last summer, and in one of them, adverting to the dispensaries and to the out-patient department of the hospitals of the metropolis, the writer said—"the out-patient waiting-rooms of the different institutions, unless exceptionally large and exceptionally well ventilated, are, as a rule, crowded to excess, and during the summer months almost to suffocation." This statement was supported by a description of the waiting-rooms of four hospitals—viz., St. Bartholomew's, the Children's Hospital in Great Ormond-street, the Royal Free, and the Metropolitan Free—a description known to be true by every professional man who visits them. The passage relating to the Metropolitan Free is as follows:—

"At the Metropolitan Free Hospital, during the early part of each week, not only is the waiting-room so densely packed with patients that anyone would find it a somewhat difficult task to force a passage through it, but the lobbies and staircases are equally crowded. At this Hospital the men are seen before the women, so that many of the latter often wait several hours before reaching the consulting-room."

Having described the waiting-rooms in question, the writer remarks—

"Considering the average length of time which patients have to wait before they are prescribed for, and the frequently crowded state as well as the insufficient ventilation of the rooms in which they are pent-up meanwhile, we cannot help thinking that many of them, besides losing their time (which in a large proportion of cases is equivalent to losing their wages for the day), experience more harm than good from their visit to the Hospital."

The statements we have quoted concerning the Metropolitan Free Hospital gave offence, it seems, to its managing committee, which summoned the medical staff to its presence, and instituted an inquiry concerning the authorship of the article. The physicians first interrogated declared themselves ignorant who had written it, but when it came to the turn of Dr. Chapman, one of the Assistant-Physicians, to be questioned, he, after protesting against the propriety of the question, and finding it useless, under the circumstances, to insist on his privilege, avowed that he was the author. Subsequently a meeting of the Medical Committee (which consists of the eleven members of the professional staff) was called, and five out of the eleven attended. These gentlemen passed a resolution "expressive of the deep regret of that Committee that an article calculated to do such serious injury to the Hospital in the opinion of the charitable public should have emanated from one of their colleagues, and their great surprise that he should deem it consistent with the feeling of honour to continue to hold the appointment of Assistant-Physician to a public charity which he deliberately and anonymously in the public press disparages." With this resolution in their hands, the General Committee requested Dr. Chapman to resign his appointment. Acting according to the advice of several gentlemen holding the very highest rank in the profession, he refused to do so, and was then summarily dismissed.

"With respect to the article in question," says Mr. Jodrell, "I am told that three of the most eminent men in the profession, whose names I only forbear to mention because I have not the honour of being personally acquainted with them, have expressed the opinion in which I cordially concur, that there is nothing in the article itself which a medical officer of any of the hospitals mentioned in it might not with propriety have written." We heartily agree with him and the "eminent men" he refers to; and further, we think the thanks of the profession are due to Dr. Chapman for his efforts in promoting a reform, which, at a meeting of a large number of metropolitan practitioners, presided over by Sir William Fergusson, was declared to be urgently needed, and especially for advocating that reform so effectually as he has done in a journal exercising an extensive influence over public opinion, and capable of reaching a considerable proportion of the subscribers to our hospitals and dispensaries, who are alone able to *enforce* a change for the better.

Viewing the matter as we do, we should not have been surprised if, when Dr. Chapman's colleagues heard of the unprecedented conduct of the Committee in first asking him to resign, and, on his refusal to do so, in dismissing him, they had all resigned together. But we confess to a feeling of utter amazement in learning that a certain number of them at once proceeded most unenviably to distinguish themselves by passing the resolution already quoted, and thus supplied a colourable but wholly unjustifiable pretext to the General Committee for dismissing Dr. Chapman because he had dared to call public attention to what he believed to be a glaring and undeniable mismanagement of the trust confided to the Hospital managers by the charity-giving public.

We confess we feel ourselves puzzled as to the intellectual and ethical standard accepted by those medical men who passed the resolution we have quoted, but we experience some slight relief in observing what Mr. Jodrell rightly designates a significant circumstance—viz., "that though the Medical Committee comprises the whole medical staff of eleven members, five only were present on this occasion, the three Surgeons and the two other Assistant-Physicians, one of whom only, with the three Surgeons, signed the resolution, and he (Dr. McNalty) a very young man, not yet admitted a Member of the College of Physicians. The three principal Physicians were conspicuously absent." Dr. Partridge did not sign the resolution.

We would willingly draw a veil over this part of the story. It is always our custom to try to be "a little blind" to the faults, failings, and follies of our professional brethren, but we confess we are at a loss to find an excuse for the action of the moiety of the Medical Committee in this matter. If the resolution was intended to obtain the favour of the General Committee or of any of its members, all we can say is that the procedure was simply pitiable.

Of the conduct of the General Council itself in this matter we have already intimated our opinion. We only hope that the subscribers to the Hospital will convene a meeting to express their opinion of this unprecedented piece of petty tyranny. It is either true that the out-patient rooms of the Metropolitan Free Hospital are unhealthily crowded in summer, or that they are not; of this Dr. Chapman is a far better judge than any one of the Hospital Committee. But supposing that he was mistaken, and that the odours of Paradise and the balmiest breezes refreshed the poor wretches huddled together in those waiting-rooms, the public press was as open to the Governing Committee to correct the statement as it was to Dr. Chapman. But instead of a dignified denial, and an invitation to the public to inspect their admirable arrangements, and to judge for themselves, the Committee avenge their righteous cause on Dr. Chapman by turning him out of the institution, where his only fault had been that he had used his talents in the most telling way in his power to convert it into a hospital for the cure, and not for the spread of disease.

This matter wears—as we at first intimated—a serious aspect for the whole medical profession. If honorary officers to medical charities are to be subjected to the treatment which Dr. Chapman has suffered, the public will certainly be the losers, for there will very soon be no medical charities. But we hold that the precedent is a most dangerous one, and should arouse the indignation of the whole profession. We certainly do not estimate highly the value of an appointment to the Metropolitan Free Hospital, but we do estimate in its full significance the fact that a Hospital Committee has dared to turn out of his appointment a physician for the sole act of contributing to a leading paper some anonymous criticisms upon hospital management in general, and that of the hospital with which he was best acquainted in particular. Such tyranny is probably without precedent in England in any society of gentlemen, and if we want to produce its analogue we must look for it amongst the outrages of trades-unionism.

THE PHYSIOLOGY OF VISION.

II.—The Propagation of Light.

Resting on our oars in a gently agitated sea, we note that with each successive wave the boat we are in rises and falls again from the crest to the trough of the sea; but, with all this, each succeeding wave finds us in exactly the same place as regards surrounding objects. The excursions of the boat have only been upwards and downwards; there has been no lateral motion; and so it has been with each particle of water composing the wave itself. The wave seems to travel in a given direction, but the motion of its component particles is always at right angles to this; and so it is of light. With sound this is not so: sound-waves are not waves of elevation and depression, but of condensation and rarefaction, so that the motion of the vibratory particles is to and fro in the direction pursued by the sound-wave, not at right angles to it, as in light. The waves of both light and sound tend, if not deflected, to travel in straight lines, and in every direction from their origin.

Falling upon any surface, even of the most transparent body, a beam of light is broken up. Some of its component rays pass on, but certain others are bent back or reflected, and it is only by these reflected rays that the object becomes visible. If all rays passed on through it, none could reach the eye, and so no picture or image of the object could be formed there. The laws of reflexion are well known; the angle which the incident wave forms with the perpendicular to the surface on which it falls is always equal to the angle at which it is again reflected—a principle which has been utilised in many optical instruments incidental to our calling, especially the laryngoscope and ophthalmoscope. But the light which passes on through the transparent body does not follow an even course; it is deflected—bent out of its track—or refracted, and this too in accordance with certain laws. If the transparent body has its surfaces parallel the one to the other, the deflection of the incident ray is exactly neutralised by the deflection of the emergent ray, and so no permanent deviation of the ray from its course is observable. But if these two surfaces are inclined to each other at an angle, as in the wedge-shaped piece of glass we call a prism, the effect of the one surface is not to neutralise, but to intensify the deflection caused by the other; so that the ray of light is bent permanently out of its path. If a double prism is employed, two rays of light originally pursuing divergent paths may be made to converge, and to meet in a point called a focus. An ordinary convex burning-glass is only a multitude of such inclined surfaces; it acts essentially in the same way as the double prism. In nature we know only of two kinds of rays—those pursuing a parallel course (as those from the sun) and those following a divergent course (as seen issuing from a candle-flame): but by the use of such a glass as we have mentioned both of these may be made to converge. An optical apparatus of this kind we encounter in the eye itself, and with its imperfections are associated some of the most important defects of vision.

If a ray of light (such as is allowed to pass through a pin-hole in a piece of paper) be made to fall upon a prismatic piece of glass, and its image examined beyond, we shall no longer see a bright white dot, but instead a streak disclosing the gorgeous array of colours seen in the rainbow. The white light is resolved into a series of rays, beginning with red, passing on through yellow to green, and from green through blue to violet. The same thing inevitably happens with all ordinary simple lenses, and such an influence must be exerted by the optical arrangement in our eyes, yet we are not at all aware of it. True, such an effect may be avoided, and is avoided nowadays in what are called achromatic object-glasses, used in microscopes where the lenses are not composed of one kind and piece of glass only, but are built up of plate and flint glass. No such arrangement exists in the eyes, yet to all intents and purposes our eyes are achromatic; not absolutely so (as will be seen hereafter), but achromatic to such an extent as to seem to be so.

The eye as an optical apparatus is well likened to a photographer's camera. The box which gives shape and rigidity to the whole is the sclerotic. In front lies the optical apparatus, which in the eye consists of the cornea and the lens. Behind, when the photographer is at work, is a plate of ground glass on which fall the rays of light, and on which, when the camera is properly adjusted as to distance, an image is formed; the glass plate being moved nearer to the lens or farther away from it till an exact and perfect picture is seen on the glass of the object to which the camera is directed. This picture is, however, evanescent; to render it permanent the place of the ground glass is taken by a properly prepared and sentient plate, whereon the light itself may paint a picture. This sentient plate in the human eye is represented by the retina. Only one thing seems deficient in the eye—that is, the means of focussing, as it is called; but that, too, exists, in the form of the ciliary muscle. To the structure and functions of these various parts we must next draw attention.

THE ASHANTEE WAR.

The suspense and uncertainty which have prevailed for the past few weeks as to the ultimate steps which would have to be taken for the subjection of the Ashantees, are gone at length, and before these lines are published the little expedition which has been restlessly waiting for orders to embark will be on its way to reinforce Sir Garnet Wolseley. The result of the preliminary skirmish, particulars of which reached us by the last mail, has been to show that, however useful our native allies may be as auxiliaries to take the heaviest duties—such as transport—off our European troops, to depend upon them when actual fighting begins would simply be to invite a repetition of the disasters which up to the present have invariably characterised any operations undertaken by us against the Ashantee power.

The satisfactory reports recently received as to the health of the settlement at Cape Coast Castle, are again more than confirmed. The fugitives who had thronged into the town during the rainy season having left, small-pox has almost entirely disappeared, and throughout all ranks there is very little sickness. Two or three slight cases of fever amongst the members of the staff which arrived with Sir Garnet Wolseley have been notified, but with this exception the new arrivals have not suffered. There is, however, reason to fear that the appointments to the African Commissariat Department have not been very judiciously bestowed, the last batch of officers sent out to this arm of the service consisting of very young men; and as the statistics of most tropical stations show that young and growing lads suffer far more severely from climatic influences than more matured men, it must not be considered surprising if a large percentage of sickness should occur in this branch.

The recent skirmish in the Bush has been of vast service to the heads of all the departments on the Coast; it may, in fact, be looked upon in the light of a rehearsal for the more important work which is to follow. Deputy Surgeon-General Home, V.C., although still in rather delicate health, elected to accompany Sir Garnet Wolseley as principal medical officer of the small army; this consisted of about 400 men in all, barely half being Europeans. Surgeons-Major Jackson and Moore were also attached to the troops, and by their exertions earned the hearty approbation of their chief. The *Times* correspondent, who was present throughout the day's proceedings, passes a very graceful eulogium on the conduct of all the medical staff present. He points out that not the least interesting sight to be seen during the operations was the conduct of the medical officers when any of the men chanced to be hit; the coolness and dexterity with which they manipulated the patient whilst a heavy and continuous fire was going on all round was especially deserving of praise. And it must not be forgotten that the present exceptional campaign will place the doctor on a much more level footing with the combatant officer than has ever been the case before. The whole column is compelled to proceed almost in single file through the Bush, and as it is next to impossible to say on what part of the line an ambuscade may at any moment fall, it results therefore that the medical officer is as much exposed to danger as every man in the whole force; and it is to be hoped that this fact will not be lost sight of when the rewards are distributed, at some distant day, for what we all hope will turn out to be successful operations against the enemy.

The result of the experience gained during this small *reconnaissance* is most satisfactory. Although the day was intensely hot, scarcely any of the men were compelled to fall out, and it must be borne in mind that few of the force had enjoyed much sleep during the previous night, whilst some of the Marines engaged, through an oversight were unprovided with their proper rations. Under the most difficult circumstances, with all the fighting thrown in, fourteen miles at least were accomplished by the main body, and some portion of the force covered about two-and-twenty. The Marines had been cooped up for three months on board ship, and could scarcely be said to have been in first-rate condition for undertaking such a distance under a tropical sun. The pathway was by no means adapted to continuous pedestrianism; in some places being so bad in the centre that the men had to walk with their legs straddled wide apart, whilst in others there was nothing for it but to wade through a noisome bog halfway up to the knee, the disturbance of the oozy slime causing a fearful stench to arise resembling sulphuretted hydrogen. Careful observation has forcibly demonstrated one most important fact: if an advance to Coomassie be definitely decided on, it will be essential to have a large number of staff officers of all kinds to accompany the troops. The peculiar nature of the country to be traversed renders it impossible to keep more than a handful of men in sight at one time. The ordinary contingent of officers therefore could not possibly hold their men under supervision during the march, and the services of the surgeon might very possibly be urgently required at a spot some distance from where he would at the moment be posted.

Taken as a whole, the accounts received of this affair from all quarters may be said to bear out the opinion which we have from time to time expressed as to the exaggerated nature of the difficulties to be encountered in an advance upon the Ashantee capital, always provided that the proper season be chosen. The casualties attendant upon this preliminary trial of arms are certainly not greater than what might be expected under similar circumstances in any tropical climate, and all accounts agree in representing the district for some miles from Cape Coast Castle as the most difficult to traverse in the whole one hundred and ninety miles to be covered before reaching Coomassie.

Some vigorous attempts are to be made to render Cape Coast Castle and its vicinity less deadly to Europeans. A sanitary staff has been appointed, who will ruthlessly combat native prejudices and filthy customs; and if by their endeavours the death-rate of this pestilent coast be only slightly reduced, the present difficulty will not have been without its advantages to that portion of the community who are compelled to brave the dangers of its much-dreaded climate.

At home the dispatches of Sir Garnet Wolseley have found the authorities thoroughly prepared; the *Tamar* and *Himalaya* have sailed to embark the troops who had been for some days awaiting the signal to go on board. Each of the vessels carries all the necessary fittings to receive sick and wounded men, after the landing of the troops they take out, at Cape Coast Castle. It appears to have been definitely determined that the sick and wounded shall not be kept for a longer period than is absolutely necessary on the Coast; hence every transport which has already left or will hereafter leave the country is to be made available for bringing home invalids. Preparations will be made for receiving some of these at Liverpool, whilst others will be landed at Gibraltar should it be found that the mild temperature of that place would be in any way instrumental to their recovery.

The principal hospital-ship for the station, the *Victor Emmanuel*, has been pushed on in all her arrangements with the greatest despatch. She has just been commissioned, and it is to be hoped that before many days are over she will be despatched to her destination. Doubtless a great deal of necessary work had to be got through to fit her for her new occupation, but as it is extremely improbable that Sir Garnet Wolseley will allow much time to be lost after the arrival of his reinforcements before taking the field, it is surely important that this vessel should be in a position to receive casualties, which may be expected to occur as soon as his forces have commenced operations; and it would have seemed to be more in the order of things if the departure of this vessel had been

identical with the sailing of the transports conveying the troops. Her arrangements for the sick are said to be of the most complete description, and medically she will be under the charge of Surgeon-Major Bleckley. The War-office authorities are about—with what object does not appear—to appoint a military officer to the chief command on board. As the ship is to be employed ostensibly as a hospital, it would surely have been sufficient to place her in the hands of the medical staff without increasing existing dissatisfaction by nominating a combatant officer to a post in which he can be of little real use. She has been fitted by Messrs. Savory and Moore, of London, with a surgery, in which are included all the most convenient facilities for dispensing; and from her great size this most necessary department is roomy and commodious (unlike the small cupboards usually set aside for this purpose on board ordinary ships), a very complete operating-table forming a portion of its equipment.

As we have before stated, the heads of the Medical Department at Whitehall have thoroughly accepted the grave responsibility which the requirements of the present war have thrust upon them; and if—as we have no reason to doubt—the results should be found to be commensurate with the activity and forethought displayed, the country will be able to congratulate itself that this most important portion of the arrangements has been well and satisfactorily carried out.

THE WEEK.

TOPICS OF THE DAY.

The acceptance of the Postmaster-Generalship by Dr. Lyon Playfair will create a vacancy in the seat for the Universities of Edinburgh and St. Andrews. Dr. Lyon Playfair has already issued an address to the electors. It remains to be seen whether he will be returned without opposition. Putting aside political differences, if the University of Edinburgh is determined to oppose the formation of a Conjoint Board of Examinations in Scotland, they cannot have a better or abler representative of their views than Dr. Lyon Playfair.

Mr. Disraeli's address before the University of Glasgow on the occasion of his installation as Lord Rector will, we think, add even to his reputation. The practical lesson given, that in order to success in life two things are necessary—a just knowledge of the extent and character of a man's own powers, and a knowledge of the spirit of the age in which a man lives,—have all the simplicity and force of truth. The first is an old lesson (how seldom soever learnt) in the mouth of a thousand teachers, but it has not often been taught with the second. The one is the key-note of philosophy, the other of utility. Mr. Disraeli, with the sagacity of a statesman, enforces them together. It would be out of place in a medical journal to reproduce the splendid generalisation on the spirit of equality —civil in England for centuries past, social in France, but now physical and material, which is rising and threatening society—which terminated his address. We can only commend it to those of our readers who have not yet read it.

The election to the Presidency of the Royal Society is creating some discussion. A large party of naturalists and others in the Society are in favour of conferring that honour on Dr. Hooker, of Kew Gardens. His appointment, however, is opposed, on the ground that being already in his position at Kew a public officer, his presidency would prevent the Government consulting the Council of the Society upon the reorganisation of the natural history collections at South Kensington.

The Rev. Mr. James M. Joass has written to the *Times* a letter giving an account of the supposed sea-serpent. Mr. Joass writes like a naturalist and a person who is well acquainted with marine sights and appearances. He corrects some misapprehensions in the former correspondence. The appendages, which were described as ears like those of a horse, he believes to have been diaphanous and nearly semi-circular flaps or valves overarching the nostrils, which were in front. The cavity of the eye seemed to be considerably further back, and a peculiar glimmer in it, together with the sudden disappearance of the creature under water, presented the only signs of vitality.

Mr. Charles Beke, writing in the *Times*, announces that Dr. Livingstone may be shortly expected in this country. The news brought by the last African mail was that Livingstone was reported to be about thirty or forty miles from St. Salvador, or about 200 miles from the West Coast.

Dr. Murchison, in acknowledging the vote of thanks given to him by the Vestry of Marylebone, in reference to his services in discovering the cause of the late epidemic of typhoid, has very honourably and gracefully remonstrated with the Vestry for omitting all public mention of the services of their own medical officer, Dr. Whitmore, on that occasion.

THE GUINEA FEE.

In a recent letter the London correspondent of the *Dundee Advertiser* comments on the demand for advanced professional remuneration. He says—"The rise of prices which prevails in so many trades is about to be extended to the learned professions. Both the lawyers and the doctors are moving, and it is indeed surprising that the former at least have not already seen fit to increase the charges on their unfortunate clients. The case for the doctors has been stated with great ability and force by the *Medical Times and Gazette*." After cordially admitting the justice of the claim which we have advanced for a modification of fees, the correspondent adds—"If the addition to the guinea fee were to be strictly proportioned to the rise in prices, I am afraid that it might at once ascend to five guineas. I hope, however, that our medical friends will be moderate in their demands, and that they will for the present be satisfied with doubling their fees. We can no more do without doctors than we can do without coals, and we are as much at their mercy as that of the colliery owners and the coal merchants. If they are satisfied with simply turning the guinea fee into two guineas, their considerate mercy will be duly appreciated by a benevolent public."

THE ROYAL SOCIETY MEDALS.

The Copley Medal and the two Royal Medals in the gift of the Royal Society have this year been awarded as follows:—The Copley Medal to Professor Helmholtz, the distinguished physiologist, physicist, and mathematician, of Berlin; a Royal Medal to H. E. Roscoe, F.R.S., Professor of Chemistry in Owens College, Manchester; and a Royal Medal to Dr. Allman, Professor of Biology in the University of Edinburgh.

LONDON ANTHROPOLOGICAL SOCIETY.

At a meeting of this Society, held at 37, Arundel-street, Strand, on the 18th inst., the President (Dr. R. S. Charnock, F.S.A.) in the chair, the following business was transacted:—1. Extracts from letters from foreign correspondents were read, one of which announced an alleged discovery of a Phœnician inscription of the fourth century B.C., near Rio de Janeiro; and one from Captain Burton, mentioning the discovery at Maeshowe, in Orkney, of Scandinavian inscriptions in Arabic letters. 2. "Personal Observations of the Sae-lies or Flathead Indians of North America," by J. Simms, M.D., of New York. The discourse treated of the manner of fashioning or deforming the head, the customs, dress, diet, disposition of the dead, etc. Dr. Simms also gave a brief description of the Quatsino Indians who inhabit the north-western coast of

Vancouver Island; the mode of fashioning their peculiar sugarloaf form of heads, their superstitions, food, etc. He also gave a very interesting account of the Digger Indians of California, their colour, form, dress, manner of living, general habits (including badges of mourning), food, etc. The Snakes, Utes, Piutes, Foxes, Siouxs, and other tribes were also briefly described. Dr. Carter Blake, Mr. A. L. Lewis, Dr. Kaines, and the President took part in the discussion.

AN IRISH VERDICT.

THE adjourned inquest on Ellen Sexton, who was murdered in Limerick, was concluded on Tuesday. The police did not produce the woman accused of the murder. The coroner having summed up the evidence tendered by the Crown, the jury returned the following verdict:—"We find that Ellen Sexton met her death by wilful murder on Sunday night, November 9, and that it was caused by some person or persons unknown. We also wish to express our dissent at the Crown having refused to give more evidence."

DR. ALFRED CARPENTER ON SANITARY LEGISLATION.

THE paper read at the Norwich Congress of the Social Science Association, last month, by Dr. Alfred Carpenter, on "Administrative Areas for Sanitary Purposes," is now before us in the form of a pamphlet. It is a clever disquisition upon the subject. It treats with considerable ability on the defects of previous, and the obvious requirements of future, sanitary legislation. We agree with the following practical observations of Dr. Carpenter, that he would not entirely repudiate the good which has resulted from the permissive plan of legislation which has been adopted, and which in recent years has marked the progress of sanitary knowledge.

"Whilst those who acted as pioneers of hitherto much-neglected sanitary work differed among themselves as to the best kind of practice, it was no wonder that our legislators were themselves at sea; and, as a natural sequence, they left local authorities to use their own judgment and act according to their light. This permissive plan is visible throughout the whole of the Public Health Act of 1848. The experience gained in those places which put that Act in force within their borders enabled Parliament to make much of that which was permissive in 1848 become compulsory in 1872. It is to be expected that much which remains permissive in the Act of 1872 will be compulsory in the next Public Health Bill. It is evident that there should be a commander-in-chief—a Minister of Public Health—as distinct from the destitution authority, and who should not be one with the destitution authority, but who should have official control over all matters connected with the public health, portions of which are now regulated by the Home Office, other portions at the Local Government Board. Next, there should be inspectors, having jurisdiction over one or more county areas, responsible to their chief. The county areas should be subdivided into such union or water-shed areas as may best meet the sanitary exigencies of the case. Over these the county authorities should appoint medical officers of health, who should in most instances give their whole time to the duties of their office, sending their reports to, and being obedient to, the instructions of those local authorities who exercise jurisdiction over the area supervised by them. The district supervised by the health officer should include the whole of a particular town, without reference to the borough or parish boundaries, taking, when convenient, the crests of the hills or sets of houses draining into one watershed or into one branch of a given stream. This arrangement can in most cases be easily carried out if the county is taken as the basis of elective authority. The area to be supervised must not be larger than one man can personally inspect at least twice in the year, and this independently of those special inspections which should always be made when there is evidence of disease which may spread. Efficiency requires this actual inspection, and it is a mistake to suppose that the work of the health officer should be guided by the health reports alone, and that there is no need of inspection unless disease has put in an actual appearance. There must be the regular as well as the irregular inspection. The frequency of the latter will be determined by the evidence afforded by the outbreak of disease. To obtain this evidence the health officer must be in intimate relationship with the union medical officer, who should have positive instructions—indeed, it ought to be to his interest—to communicate the required intelligence to the health officer as soon as it arises."

TAKING THE "BULL BY THE HORNS."

THE duty of a public analyst is no doubt sometimes unpleasant, and even invidious. There are some honest, conscientious tradesmen. The enforcement of the Adulteration Act on such for selling articles which have been found by the public analyst to be adulterated, but which they sold in the same condition as bought from the wholesale dealer, is clearly a hardship. This hardship has been recognised and felt, especially in the article of "tea." We are glad to observe that several chambers of commerce and other public bodies have already petitioned the Government to undertake the analysation of tea in bond before its sale and dispersion to the public. This seems to be a reasonable proposal. The Government enforces a duty of 6d. a lb. on it as "tea," and should therefore take the responsibility of ascertaining its condition. Such protective action on the part of the Government would save much bitterness and injustice, and relieve the public analyst, in many cases, of a very invidious position. We trust these efforts to remedy this critical position of the retail dealer will succeed. It has the further recommendation of striking at the root of the evil. We fail to perceive the difficulties that are said to surround the plan proposed. The milkdealers of London have taken "the bull by the horns," and have formed themselves into an association to protect them from being supplied with an adulterated article by the proprietors of dairy farms. Already they have obtained a conviction, which will operate as a warning to others. It seems an absurdity to analyse the water of a brook while we neglect to ascertain the purity of the spring from which it is supplied.

MORTALITY FROM OVERCROWDING.

DR. LANKESTER, in his last report to the St. James's Vestry, stated that the death-rate during the past twelve months in the Berwick-street district (occupied chiefly by the poorer classes residing in the parish) had been 25 per 1000, as compared with 14 per 1000 in the district of St. James's-square; and he added, "till the time comes when it shall be seen necessary to erect proper dwellings for the poor of London, overcrowding, with all its physical degradation and moral pollution, must be submitted to as a lesser evil than driving men, women, and children into the streets and to places far away from their work and the exercise of that industry by which alone they can be kept from destitution and pauperism." The comparison in the death-rate of two of the districts in this parish, which Dr. Lankester makes, is very striking. The vast number in this metropolis of similar poor districts to that of Berwick-street, St. James's,—the consequent waste of human life, and that too from preventable causes,—is, even after all recent sanitary reform, appalling. If the healthy condition of the poor is to attract attention proportionate to their numbers, the question of suitable dwellings for them will become a primary one, and more ample legislative powers must be given to deal effectively with a subject so vast and so important.

RECENT PRESENTS TO HARVARD COLLEGE.

DR. EDWARD WIGGLESWORTH, a lecturer in the medical school of Harvard College, has presented to the school a very valuable collection illustrative of diseases of the skin. Dr. C. Ellis, the Dean of the Medical Faculty, has given the microscopes

to the school, to be lent, under the direction of the Professor of Pathological Anatomy, to medical students who are too poor to buy such instruments for themselves—a very liberal arrangement, and such an one as might be imitated with great advantage in other medical colleges.

ARMY MEDICAL OFFICERS FOR THE GOLD COAST.

THE following list shows the names of the Army Medical Officers (as far as we have been able to collect them from various sources) who are now on their way or about to embark for service on the Gold Coast:—

Surgeons-Major.—Bleckley, Kelly, Turton, Elliott, T. B. Reid, Woolfreyes, Julius Wiles (attached to the 2nd Battalion, Rifle Brigade), Sydney Alder (attached to the 2nd Battalion, 23rd Regiment), D. Fraser, J. Fanght, and Finnemore.

Surgeons.—Smith (with Royal Artillery), Murphy (with Royal Engineers), Bolton, Macrobin, MacCrystal, Eagar, Purdon, Wilson, Brown, Low, Weir, O'Brien, Doig, Hannagan, Turner, Lowe, Beattie, Catherwood, Clarke, Heather, Brown, Hanrahan, Fleming, Hughes, Croker, Supple, Wade, Ward, Venour, Robertson, and Gray.

We believe that the majority of the foregoing gentlemen are volunteers, and the alacrity which has been shown to accept service in the present war augurs well for the execution of the important duties which it is generally expected will fall to the lot of the medical officers in the forthcoming campaign.

HONESTY IN THE NORTH OF LONDON.

TOUCHING the appointment of a public analyst for Hampstead—an appointment which it appears the Vestry has delayed in making up to the present time,—a chemist in the parish writes to the *Hampstead and Highgate Gazette* as follows:—He states that, "knowing as we do that we are all honest men in Hampstead, and that no single article of food or medicine is nor can be at commercial prices absolutely and chemically pure, ought we not to profit by others' experience, and show a little discretionary wisdom, taking time to consider what can and what cannot be done in this most difficult and vexations Act of Parliament before appointing a public *persecutor*, whose time is to be spent in worrying his neighbours to commercial death by fines and imprisonment for accidents of which they are perfectly innocent, and in which errors of analysis may quite possibly be the principal contributors."

WARMTH AS A PREVENTIVE OF DISEASE.

DR. WHITMORE, Medical Officer of Health for Marylebone, in his last report to the guardians refers to the high price of coals, and says—"The value of the means employed for preventing the diffusion of epidemic contagious diseases may be open to question, but there cannot be two opinions as to the efficacy of bodily warmth in resisting a class of diseases which unfortunately are but little thought of, and which as a rule are ten times more destructive of life than the most fatal epidemics." He recommends, as constituting the most urgent sanitary requirements of the poor at the present time, coals, blankets, and food.

THE CREAM OF A JOKE.

OUT of six samples of milk examined by the Public Analyst for Limehouse, one was found to be pure, whilst all the others were pronounced to contain an excessive quantity of cream! The Medical Officer reported to the district Board of Works that there could be no doubt but that the vendors of milk knew their customers when the samples were procured. The Committee resolved to leave in the hands of the analyst the best arrangements to be made for procuring genuine samples.

FROM ABROAD.—SANITARY CONDITION OF PARIS—POISONING BY COFFEE—ASPIRATION IN STRANGULATED HERNIA—CAPILLARY EMBOLI IN CHOLERA.

M. BESNIER, in his quarterly report on the health of Paris, states that this, which during July had been as favourable as during the preceding months of the year, in August and beginning of September underwent a sudden modification, as exhibited in the great increase of mortality from cholera and typhoid fever. This modification was very remarkable, not only for the rapidity with which it was produced, but for the universality and uniformity of its manifestations alike in the town and in the hospitals, and among the civil and military population. As in former reports, he gives detailed tabular views of the corresponding atmospherical conditions, but believes that it would be premature to draw any conclusions from their approximation. Notwithstanding these epidemic visitations, which sensibly raised the mortality during September, the sum total of deaths occurring in the Paris hospitals during this quarter has been lower than that of the corresponding quarter of any of the six preceding years. During the whole three months, however, *diphtheritic affections* remained extremely frequent, and did not undergo the diminution which they have usually manifested at this period of preceding years. The number of deaths were more than double the number of patients in that quarter of 1867. Of the *eruptive fevers*, measles alone acquired some intensity, while scarlatina prevailed very slightly, and small-pox continued, as in the former quarter, to be absent, not a single case occurring during the whole quarter. *Typhoid fever* underwent its usual seasonal exacerbation, which in this year coincided with the appearance of the earliest cases of cholera. The number of cases has not exceeded the mean of former years; but the circumstance which has characterised the epidemic of this year is the elevation of its mortality from 27 per cent., the mean of the corresponding quarter of former years, to 33 per cent. The cases of *cholera* have been reported to the Hospital Medical Society as they have occurred; and a general summary will be given in the last quarterly report for the year. *Diarrhœa* was less prevalent and more mild than usual during the month of July, and but little increased in August. It suddenly increased in September, the cases exceeding in number those of the same quarter of all preceding years. The mean mortality was returned as less, probably from most fatal cases being reported as deaths from cholera. The tables of the *puerperal affections* show that, as in former years, there is always a diminution of mortality during the summer months. The women who were delivered in the hospitals furnished a mortality of 3·30 per cent., those delivered at the homes of *sages-femmes* 1·26 per cent., and those delivered at home 0·35 per cent.

Dr. Curschmann, of Berlin, relates (*Deutsche Klinik*, No. 41) the following case of poisoning by coffee:—He was called, in the afternoon of August 10 last, to a tailor's wife, aged 27. It seems that, believing herself to be in a state of pregnancy, of which she had a great fear, she had two hours before drank a very strong decoction of coffee, in the hope of inducing abortion. This she had prepared by boiling 250 grammes of fresh roasted and finely ground coffee in about 500 grammes of water. The decoction was then forcibly pressed through a woollen filter, and the whole of it she drank off at once, without any addition being made to it. A quarter of an hour afterwards the symptoms began to appear, the great increase of which caused the reporter to be sent for. He found her sitting on a sofa, with a pale countenance expressive of the deepest mental anguish. She complained of want of air, and a sensation as if her chest were compressed, and clung convulsively to articles of furniture or the persons near her, moving constantly from place to place and trying to get up, but sinking down

again quite powerless. The limbs, and especially the hands, were affected by chorea-like movements, so that the patient was unable to hold either a glass or spoon. She recognised those about her, and was aware of the cause of her sufferings, but still her sensorium was evidently not quite clear; and next day she retained only a very obscure recollection of what had occurred. Plain or connected answers were not obtainable from her, and only after much effort and persuasion could her attention be engaged at all, she continuing to incessantly repeat the same phrases in the most dolorous tone. The pupils, somewhat enlarged, acted normally, and there was neither disturbance of vision, headache, or singing in the ears. The forehead was cold, and the temperature of the other parts of the body did not seem raised, but the excessive restlessness of the patient prevented the application of the thermometer. Corresponding with the patient's complaint of a feeling of suffocation and excessive breathlessness, the respiration was painful, short, and rapid, counting from 24 to 30. Auscultation indicated no abnormality. The patient complained also of distressing palpitation, and the excessive impulse seemed almost to raise the chest; but although the sounds were loud and penetrating, they were pure. The pulse was 112. An hour after taking the coffee severe diarrhœa commenced, which continued to recur about every half-hour for long afterwards. But more distressing to the patient than this was a frequent desire to pass urine, which came on every quarter of an hour. The urine, having a specific gravity of 1014, was considerably increased in quantity. The patient remained in the same state for several hours, becoming somewhat more quiet later in the evening, under the influence of morphia; yet, upon the whole, a very restless night was passed. In the course of two or three days she entirely recovered, the menstruation reappearing, the absence of which had led her to believe herself pregnant.

At the Société de Chirurgie, M. Dubreuil read a report on a paper by M. Dieulafoy on "The Treatment of Strangulated Hernia by Aspiration." In this he relates twenty-seven cases, showing the great utility of this procedure in many cases, and its innocuity in all. It is true that it implies that a diseased intestine may be returned, but the same remark applies to the taxis. M. Dubreuil cannot accept all the conclusions of the author. He does not admit that aspiratory puncture should be the first means resorted to, believing that moderate taxis, which is always inoffensive, should be first tried; but he does not hesitate to recognise that aspiration constitutes a real progress in the treatment of strangulated hernia. Both MM. Verneuil and Trélat also admit that in certain cases aspiration is very useful, as when the strangulated hernia is complicated by effusion into the sac, the withdrawal of this liquid by aspiration much facilitates exact diagnosis, and allows of a hernia being reduced which had previously resisted numerous efforts by the taxis. This can be brought to bear directly on the intestine, which is no longer masked by the presence of the liquid. Aspiration thus becomes at once explorative and curative. M. Trélat took the same view of the utility of aspiration; but M. Sée stated his opinion that all that is necessary may be effected by means of a trocar. M. Verneuil pointed out that the evacuation of the liquid by means of a fine trocar is a matter of difficulty, while this is easily accomplished by aspiration. M. Desprès, the irreconcilable adversary of aspiration, predicted for it a sinister future. In his opinion there is no other treatment for strangulated hernia than operating.

M. Bouchut read, at the Académie des Sciences, a second communication on "Capillary Emboli and Hæmorrhagic Infarctus observed in Cholera." He observes that in his former communication he pointed out a lesion which he has met with in cholera that has not hitherto been described; and additional observations upon the subject are the cause of the present communication.

In all cases of cholera which are severe enough to cause death there are formed capillary emboli characterised by hæmorrhagic infarctus variable in size and in number. They are met with in the subcutaneous capillaries, and in the small vessels of the endocardium, the pericardium, the lungs, the kidneys, and the intra-muscular conjunctive tissue. M. Bouchat has never met with them in the brain, although he believes that in some cases of sudden death after cholera they have existed. These emboli take on the form of apoplectic kernals, or sanguineous infarctus, varying in size from that of a small pin-head to that of a large pea. When beneath the skin, they are indicated by a violaceous livid-red spot, which does not concern the substance of the dermis. They are formed in the subcutaneous conjunctive tissue by a sanguineous effusion, the centre of which is of a deeper blackish colour. An injection of water propelled by the central artery of the limb, and returning by the veins, does not remove this hæmorrhagic deposit, nor does it traverse the obstructed vessels. These subcutaneous emboli have been met with eight times in eight autopsies. In the kidneys the infarctus, a centimetre in breadth, are found placed superficially under the fibrous envelope, penetrating to about three millimetres into the cortical substance. They consist of a blackish sanguineous infiltration of a very deep colour. These have been met with only once in eight autopsies. In the lungs the infarctus, which are hard, black, and superficial, assume a slightly conical appearance, having their base turned outwards. Injection of water by the pulmonary artery exerts no effect upon them. In the eight autopsies they have been met with twice. In the heart these infarctus are small, miliary, and placed in the interior of the organ under the endocardium, scarcely penetrating the muscular substance. They have also been met with on the walls and the columns, and on the large column giving attachment to the tendons of the mitral valve as many as eight have been counted. They have been met with three times in the eight autopsies. In one case they have also been met with at the exterior under the pericardium, being very small.

The heart itself always presents important alterations either in its internal membrane or its cavities, whether this be valvular endocarditis at the free edge of the valves or a more or less old cardiac thrombosis, characterised by whitish, adherent, fibrinous coagula mingled with yellowish, semi-transparent, gelatiniform coagula, and soft, black, cruoric clots of recent formation. The endocarditis may be absent, but the thrombosis is always present.

"It is probable that it is to this commencing valvular carditis, and especially to the cardiac thrombosis, that we should attribute the production of these capillary emboli and hæmorrhagic infarctus. This anatomo-pathological discovery seems to me to furnish the explanation of the mechanism of those secondary phlegmasiæ which are so grave during the stage of reaction of algid cholera. In fact, after the stage of cyanosis and of general vascular stasis, when reaction becomes re-established, the blood propels before it the thromboses which form obstructions here and there, and induce fatal meningites or pneumonias. The course of the blood cannot be re-established, obstructed as it is by the emboli proceeding from the heart, and hence result local congestions followed by more or less decided phlegmasiæ."

The Gray's Inn-road Workhouse, which is used as the hospital of the Holborn Union, is so full of patients that the Holborn Board have resolved that the board-room at the Workhouse be prepared for the reception of patients.

In Calcutta, in the week ending September 27, six deaths from cholera were returned. In Paris, two deaths from cholera were recorded in the week ending the 14th inst. One fatal case of cholera was registered in Brussels in the week ending the 8th inst., and in Vienna during the same week eight deaths from the same cause were returned.

CLINICAL REMINISCENCES.—No. IV.

By PEYTON BLAKISTON, M.A., M.D., F.R.C.P., F.R.S.

Auscultation.

At the time when I entered the profession as a dresser at Addenbrooke's Hospital, in 1820, but little was known about auscultation in this country, although Laennec's discoveries had been for some time past promulgated in France. The Professor of Medicine, it is true, exhibited a stethoscope in his lecture-room and talked about the theory of auscultation, but he knew very little of its practical application to the discovery of disease. So slow was the progress of its adoption into general use that fourteen years later the friction-sound occurring in cases of pericarditis was heard for the first time by a leading physician of one of our largest metropolitan hospitals, under whose notice it was brought by a gentleman recently arrived from Paris; and another physician of the same hospital, who had the reputation of being a skilful auscultator, failed to discover the existence of an aneurism of the aorta, the signs of which were pointed out to him by the same gentleman.

For some years some of the senior members of the profession failed to recognise its value in practice, and some tried to sneer it down; the juniors, in the meantime, endeavouring to make themselves acquainted with it in the best way they could, the most zealous of them who had the means going to Paris for that purpose. It was my good fortune to come under the notice, and subsequently obtain the friendship, of Baron Louis, at that time Physician of the Hôpital de la Pitié, and through his kindness to obtain the *entrée* of the Hospital at all times. I generally went there in the afternoon, when the wards were quiet, and, by the aid of a few kind words and an occasional small *douceur*, I found myself always well received by the patients, and was enabled to practise auscultation at my leisure in almost every form of disease to which it was applicable. By attending the physician in his rounds next morning, and by an occasional question addressed to him or to one of the *internes* (always kindly and satisfactorily answered), I was enabled to test the correctness of the conclusions I had drawn from my own observations.

In the course of time the value of auscultation was fully recognised in our own schools and hospitals, and those pupils who were disposed to make themselves acquainted with its practice had opportunities of doing so; so that at the present day the generality of practitioners have a knowledge of its principles, and are enabled to turn it to a good account in the discovery of disease.

In the intermediate time, however, before these students had got into practice, public opinion having pronounced in favour of auscultation, whilst some practitioners frankly confessed that, not having been educated in its use, they did not feel themselves competent to employ it in practice, others less conscientious, who held truth in less estimation, although ignorant of its use, made a pretence of practising it. This gave rise to a very dangerous state of things: the patients and their friends being led to suppose that they had been skilfully examined, when a mere farce had been performed, and a gross deception practised.

The observations of Laennec were so extensive and accurate, and his treatise was so exhaustive, that, to the best of my belief, no additions, with one exception, have been made to them having any important bearing on the practice of auscultation. As regards the theory, however, the matter is different. For instance, the causes of the natural and morbid sounds of the heart have been investigated by various persons, and have given rise to much discussion. Some persons are of opinion that the question relating to the cause of the first or systolic sound is still unsettled. Dr. Williams I believe still holds that it is caused by muscular contraction, and I formerly was of opinion that it entered into the formation of the systolic sound in conjunction with the unfolding and tightening of the auriculo-ventricular valves. Of late years, however, the additional experiments of Dr. Halford and Messrs. Chaveau and Moray have convinced me and many others that both sounds are caused by valvular tension, as held by Dr. Billing in the first instance.

The manner in which sound is produced by the air entering and leaving the lungs has also given rise to much investigation and discussion. This subject was treated at some length in my work on "Diseases of the Chest," where it was shown that Laennec's views respecting the manner in which bronchial to-and-fro sound was produced by a solidified portion of lung are untenable; and in a paper read before the British Association in 1839 some experiments were detailed which tended to explain how it is that the voice assumes a coarse buzzing character when heard through a solidified lung—the vibrations of the walls of the bronchial tubes being more freely conducted to the ear, and thereby made to combine in a larger proportion with the vibrations of the air with them. It would be out of place here to enter more fully into the various discussions which, since Laennec's time, have taken place in respect to the theory of auscultation.

The exception to which I referred as having occurred in respect to the practice of auscultation has reference to a discovery—made in the wards of La Pitié, by Dr. Jackson, of Philadelphia—of the prolongation of the expiratory sound when heard over a portion of solidified lung; but he too failed in detecting the true cause of this modification of the expiratory sound. This is a valuable sign, and often furnishes the earliest indication of tubercular deposit or congestion of the lungs.

It would fill a large volume were I to detail all the cases which have fallen under my observation, in which the want of a practical knowledge of auscultation has wrought misery and trouble—of persons taken out of a lucrative profession or business and sent to winter at Madeira or some other southern climate, for the alleviation of pulmonary phthisis, which after all proved to be chronic bronchitis, and in no way calculated to shorten their lives, providing they were prudent and careful. Of some, on the other hand, being treated for rheumatism, and advised to continue a laborious occupation when suffering all the time from an incurable aneurism or a malignant tumour—their end being thus hastened. Let us hope that this state of things has in a great measure passed away, but let our young members lay it to heart, and strive hard to qualify themselves to become skilful auscultators. Very great expertness and extraordinary quickness of perception and soundness of judgment in deducing an accurate diagnosis in cases of obscurity are of course rare; but in what pursuit is excellence easy of attainment? A few cases illustrative of the above remarks may possibly fix their attention, and assist in confirming their resolution to overcome the difficulties which they may encounter.

Some years ago I attended a lady in consultation during a very severe illness which terminated favourably. In consequence of this I was consulted by her when she was suffering from some distressing symptoms evidently connected with the state of the uterus. As on former and somewhat similar occasions she had been in the habit of consulting a very eminent physician-accoucheur in London, I advised her doing so again. He considered her symptoms were occasioned by congestion of the uterus, and recommended the internal application of leeches. On her return she requested me to take charge of her whilst she was undergoing this line of treatment. I advised her, however, to return to London, and place herself under the immediate care of her physician-accoucheur, or if she could not do so to wait some time longer before commencing the treatment he had recommended; because her case did not exactly fall within the line of my usual practice, and also because I could not help thinking her symptoms might be occasioned by pregnancy, and were not so urgent as to prevent her waiting; whereas if she proved to be pregnant the treatment might have induced abortion. She preferred to wait. Next time I saw her I suspected more strongly than ever that she was pregnant—if I remember right, from hearing the *bruit placentaire*. I sent her off to London again. Her physician held to his opinion, and sent down a special nurse to apply the leeches. She, however still hesitated, as I declined to sanction the treatment. In the meantime she increased in size, and I distinctly heard the sound of the fœtal heart. She again went to London, and her physician (who, by-the-by, was as deaf as a post) was wroth, and ridiculed the idea of her being pregnant. Upon this her husband took her to another gentleman, who at once confirmed my view of the case, and in due time delivered her of a child.

It will hardly be believed that at Birmingham within a period of eighteen months six cases came under my notice, in three of which tumours were supposed to exist, and in the other three pregnancy. The diagnosis in every case proved to be incorrect, the tumours turning out to be children, and the

supposed children tumours, the true state of things being in each case revealed by auscultation.

In some cases I have known auscultation fail to lead to the discovery of disease, not from any want of skill in its employment, but in consequence of its having been trusted to solely, without sufficient attention having been paid to other circumstances. Thus, in one case the patient, whether sitting, walking, or sleeping, invariably leaned forward, in consequence of his inability to remain a moment in the upright or recumbent position without being harassed by a fearful and incessant cough and a sense of suffocation. His chest had been examined by physicians of undoubted skill in Edinburgh, and nothing elicited which could enable them to diagnosticate the nature of his disease. I examined him myself in his usual position, and the one in which he had been examined in Edinburgh, with similar results; but having, with great difficulty, persuaded him to remain upright for a few seconds, the respiratory sound became coarse and whistling, and could be heard at some distance off, and on placing the ear on the chest there was found to be complete absence of respiratory sound over the upper third of the right side of the chest. It was clear, therefore, that there was a *movable* substance between the trachea and the anterior walls of the thorax, near the bifurcation, which gravitated on to and compressed the trachea and a bronchial tube leading to the upper third of the right lung when the patient was in an upright or recumbent position, and fell away from it when he was leaning forward. As a cancerous or strumous tumour would have been fixed, an aneurism with a narrow neck springing from the right of the arch of the aorta alone remained as the possible cause; and this was the diagnosis given, although not one of the usual signs of an aortic aneurism was present. A few weeks afterwards death took place during a violent fit of coughing, and a post-mortem examination confirmed the correctness of the diagnosis, the absence of the usual physical signs being accounted for by the fact of the pouch never having reached the surface of the chest.

A middle-aged gentleman, a member of a mercantile firm engaged in very extensive transactions, had been suffering for some time with flying pains in various parts of his body, but more particularly affecting his chest and arms. His medical attendant in the country, who was a first-rate surgeon, was doubtful about the nature of the case, and, as some very important matters were in the course of arrangement, on account of which it was very desirable to ascertain whether his complaint was one from which he was likely to recover or not, he proposed a consultation with a physician in a neighbouring large town, who had the reputation of being a skilful auscultator. He pronounced the chest to be free from disease, and considered the case to be one of chronic muscular rheumatism, recommending the patient to go for a time to the southern coast, as the weather at that time was very cold and raw. On visiting him the character of the pains in the chest and arms at once excited my attention, being described by him as radiating from the upper part of the sternum and from between the shoulders down both arms; so I requested him to remain in bed the following morning, with a view to a thorough exploration of the chest. On stripping him to the skin a curious appearance presented itself, the chest being covered with small veins, swollen almost to bursting, and in places resembling minute worms. It was evident, therefore, that there was an impediment to the return of the venous blood from the surface of the chest and upper extremities, and that it must exist at the vena cava superior. Auscultation failed to discover any decided signs of disease, but I thought I detected slight dulness on percussion and feebleness of the respiratory sound to the right of the upper portion of the sternum. The rheumatismal character of the disease was therefore at once dismissed, and its seat placed within the thorax. In a short time the signs of a mediastinal tumour became unequivocal, but whether aneurismal or malignant was doubtful. It increased rapidly in size, and another formed in the liver, both proving to be cancerous. When, however, the true and serious nature of the disease was discovered, it was too late to remedy the very great inconvenience that had arisen from it having been mistaken before the patient left home. I ascertained that he had not been stripped when examined previous to his coming to the seaside.

Failure in diagnosis has also not unfrequently occurred from a false interpretation of the sounds heard and the signs observed.

About twenty years ago a gentleman, aged 60, of powerful intellect and studious habits, placed himself under my care. His case was considered to be one of chronic pulmonary phthisis, and he had consequently been sent to Madeira during three consecutive winters. As his disease during this time seemed stationary, he determined to try a winter on the south coast of England. I found signs of chronic bronchitis and emphysema, but none of phthisis. I could only account for the misinterpretation of the physical signs by supposing that the unusually clear sound brought out by percussion over the emphysematous portions of lung had been mistaken for the normal resonance, and that consequently other portions of the lung comparatively dull were considered to be absolutely so, and to have been the result of solidification. I found, as often occurs in such cases, that the chest symptoms were much aggravated by dyspepsia, in its turn owing in a great measure to error in diet. Attention was therefore directed to this point, and after a time he regained a very fair amount of good health. He was enabled to complete a very important scientific work, which had been delayed for some time by his ill-health; and he lived nearly ten years longer, spending every winter at the south coast, and suffering more or less from the chronic bronchial affection, but still enjoying life.

A very unpleasant occurrence once took place in consequence of a misinterpretation of the physical signs and the want of caution in the medical attendant, and I give it as a warning:—I was called in to see a young lady in consultation with another physician and a general practitioner. They told me they had repeatedly examined her chest without discovering any marked signs of disease. Her face was puffy, her lips purple, and she was suffering from intense dyspnœa and a constant dry, hacking cough. Her pulse was very feeble, 130. She had rapidly lost flesh, and was restless, irritable, feverish, and very weak. All that could be discovered by auscultation was here and there a slight cooing sound and a trace of very fine crepitation, but no absolute dulness of one part as compared with another, and there were no morbid cardiac sounds. I pointed out to the medical attendants that the absence of physical signs of any ordinary disease of the lungs or heart, coupled with the existence of general signs of great pulmonary derangement, clearly pointed to the existence of some extraordinary disease, which could be none other than acute phthisis, the lungs being stuffed with innumerable unsoftened miliary tubercles and grey granulations, and that she had only a few days to live. After our consultation the brother of the patient came in, and asked me, amongst other questions, whether I considered his sister to be in any danger, to which I replied that I considered her to be in the greatest danger; and, turning to Dr. A., said, "That is our opinion, is it not?" Upon his replying in the affirmative, the brother turned round savagely upon him and said, "Good heavens! Dr. A., how could you tell me only this morning that there was no danger?" The scene that followed may be better imagined than described. It was no discredit to Dr. A. that he should have failed to discover the nature of the disease, which was one of such extreme rarity that in all probability he had never seen it; but it was very incautious of him to have stated there was no danger when the general signs indicated the existence of some serious and obscure affection.

I once saw justice very nearly miscarry in a similar case of acute phthisis.

About thirty years ago an insurance company whose chief medical adviser was a very old man, having been about forty years old when Laennec's discoveries were announced, disputed a policy of insurance on the ground that an important symptom of pulmonary consumption had been wilfully suppressed. I happened to be in court at the assizes where the cause was tried, the medical advisers on each side being pure surgeons! One of them, who was on the plaintiff's side, having caught sight of me soon after the trial commenced, and being nervous about the matter, advised the solicitor to retain me to assist in prompting counsel. A country practitioner was called to prove that in an illness of the person insured, previous to his policy being effected he had spat some blood. He gave his evidence very fairly, stating the attack to be one "of inflammatory cough," allowing that he had seen similar attacks with spitting of blood in persons in no way consumptive; that the patient completely recovered, and showed no symptoms of any chest affection afterwards. Another medical man deposed to attending him in his last illness of about six weeks' duration, and to opening the body afterwards. He said the lungs were stuffed full of small unsoftened tubercles; that as there was so much disease, in his opinion it must have been of long standing. In cross-examination he allowed that he had never

seen a similar case, nor heard it described as acute phthisis, and that he did not know the usual symptoms indicative of such a disease. Asked how the patient could have breathed for a long time past, when nearly all the air-space was occupied by solid tubercles, he completely lost his presence of mind, and owned that he had never thought of that. It also came out that the local medical referee of the company, a very skilful practitioner of high character, had auscultated the chest when the man had been referred to him for examination, and had reported him to be in sound health; he was not, however, called as a witness. The plaintiff's counsel was advised to impress strongly on the judge and jury that his client's case had been proved by the defendant's witnesses; that his last illness was acute phthisis, the duration of which hardly ever lasts more than six or seven weeks; that his previous illness was acute bronchitis, and in no way connected with phthisis; and to dwell strongly on the fact that the company had not called their own medical referee. The plaintiff, who had purchased the policy during the life of the insured, gained his cause; but without efficient medical prompting the facts elicited in cross-examination would never have come to light, and justice would have miscarried.

The medical adviser of the company, knowing nothing of auscultation or acute phthisis, doubtless told the directors that pulmonary consumption was slow in its course, and that blood-spitting was one of the most frequent signs of its existence, and altogether ignored the report of the local medical referee. The medical man who attended the insured in his last illness was equally ignorant respecting the form of consumption in this case, yet ventured to express an opinion in the witness-box as to the time it had existed—an opinion which he was forced to admit only showed his ignorance of the subject.

Now, however valuable auscultation may be in most diseases of the chest, yet there are some in which it fails to reveal to us the seat and nature of the affection—as, for instance, in thoracic aneurism within the pericardium, and sometimes in the commencement of the descending aorta; so also in the following case:—

A young lady suffered from severe fits of coughing, and lost flesh, appetite, and spirits. Auscultation, frequently practised, failed to elicit any abnormal sound. It was therefore supposed that some central irritation might exist, possibly seated in the bronchial glands or the interlobular pleura. No diagnosis, but an unfavourable prognosis was given. She went from home for change of air, and one day suddenly died, expectorating—and, in fact, suffocated by a large quantity of purulent matter. There was no post-mortem examination.

Another young lady has been suffering six or seven years with much the same symptoms, and I have always confessed my inability to discover the exact nature of her disease.

Again, it sometimes happens that auscultation fails to indicate the existence of disease in consequence of those who practise it not knowing exactly what to expect in certain cases. Thus, in an early stage of cardiac dropsy arising from the dilatation of the heart, the walls of which are in a state of fatty degeneration, some practitioners, misled by the writings of certain authors, would expect to hear a rasp or bellows sound, and to see venous pulsations in the neck if there were tricuspid regurgitation; and not meeting with one or the other, would conclude that the cause of the dropsy did not lie in the heart. But the fact is that tricuspid regurgitation scarcely ever gives rise to abnormal sounds, particularly when the walls are weakened by fatty degeneration, and little or no venous pulsations are rendered visible in the neck when the heart is in this state, a feeble current being met by an equally feeble regurgitation,—so that they would have been looking and listening for that which they had no reason to expect. What they probably would have found, had they looked for it, would have been an increase in the extent of præcordial dulness on percussion, and also an extension of the normal sounds produced on the left side of the heart quite to the back of the thorax.

I cannot close this subject without offering the same advice to students of the present day as I did to those of the last generation thirty years ago, because my experience has taught me that it is equally required now as then. I would, then, strongly recommend them, soon after commencing their professional studies, daily to auscult the chest of healthy persons of various ages for six months, thus making themselves thoroughly acquainted with its normal sounds; then to commence the study of abnormal sounds whenever an opportunity offers itself, but more especially in the wards of a hospital, when they are quiet, and where they will have opportunities of having the accuracy of the conclusions they have been inclined to draw from their own observation confirmed or corrected—employing not merely the stethoscope, but also the ear laid immediately on the chest, as I have been in the habit of doing myself for many years past. Percussion at first will appear to them very easy of performance; but they will find that this is far from being the case. In fact, a person well skilled in its practice can at his pleasure cause the chest to enact either a clear, resonant, or a dull heavy sound—in the former case striking lightly, and quickly withdrawing the finger with a spring; and in the other giving a heavy stroke and allowing the finger to rest on the one struck, thus deadening the vibrations of the walls of the chest. Thus it will be found that great practice is required in order to acquire the expertness necessary for the formation of a correct diagnosis.

I trust I may be pardoned if I add one word to teachers, which is, that they simplify as much as possible their nomenclature of sounds, in order not to confuse the young student, describing them chiefly by words in ordinary use—as splash, gurgling, rasp, bellows, creaking, rubbing, etc.,—and also that their clinical teaching take the form of examination on cases taken by the students themselves rather than that of lectures, by which means they will learn to educate themselves, and will be materially assisted and enabled more easily to retain that which they have thus practically learned.

INDIVIDUALISM.

AN INTRODUCTORY ADDRESS DELIVERED BEFORE THE MEDICAL SOCIETY OF KING'S COLLEGE, LONDON, ON OCTOBER 16, 1873.

By JOHN CURNOW, M.D. Lond., M.R.C.P.,
Professor of Anatomy in, and Hon. Fellow of, King's College.

Mr. President and Gentlemen,—I feel under a twofold disadvantage in having to read to you this year's introductory address. In the first place, I have been privileged to hear a larger number of these addresses than any other acting member of our Society. Of these, some dealt so exhaustively with the great medical or intellectual questions of the day, whilst others treated so fully of the history and objects of our Society, or were so replete with the special mental characteristics of their authors, that the remembrance of what I had heard almost deterred me from undertaking a similar task. Secondly, even while writing this, I was occupied with the anxieties attendant on the preparation of another introductory address, and the arrangement of the lectures for my first anatomical course. However, I determined not to fail in my duty as your senior Vice-President, knowing that under such circumstances I could depend on your favourable consideration.

I purpose to consider briefly one of the prominent features of our present age in its bearing on our general and technical education, and its more remote effect on our Society. For running counter to some ideas and theories at present widely prevalent, and for rebelling against some eminent orthodox opinions, I feel justified by the fable—

> "The mountain and the squirrel
> Had a quarrel;
> And the former called the latter 'Little prig;'
> Bun replied,
> 'You are doubtless very big;
> But all sorts of things and weather
> Must be taken in together,
> To make up a year
> And a sphere.
> And I think it no disgrace
> To occupy my place.
> If I'm not so large as you,
> You are not so small as I,
> And not half so spry.
> I'll not deny you make
> A very pretty squirrel track.
> Talents differ; all is well and wisely put:
> If I cannot carry forests on my back,
> Neither can you crack a nut.'"

This great characteristic, then, is the spirit of competition; competition for material wealth, in industrial enterprise, in every profession and occupation, and for every situation of honour or emolument. Undoubtedly the same motive has always actuated the human race, but organised competition

belongs especially to our own period, and it is only in the present generation that we have been asked to bow down and pay homage thereto. Formerly, for instance, scholarships and fellowships were founded to furnish men with the means of pursuing their studies mainly according to their individual bent; now, however, in a noteworthy speech delivered by the "apostle of competition," the present Secretary of State for the Home Department, on the presentation-day at the University of London in 1872,(a) we are told that students are almost to make scholarships and exhibitions their end, and that beneficent individuals are to found them, and so run no risk of their charitable intentions being altered by future Education Commissioners, inasmuch as such endowments could not possibly be abused.

As a logical outcome of this position, he proceeded to argue that the highest function of a university was not to teach, but to examine; and that professorships and fellowships should be disendowed, because the best and most successful teachers would get plenty of pupils, assuming that their chief object was "to cram" for examinations, and that the advancement of knowledge by originality of idea or experiment and by accuracy of research was of little importance. That competition in reading addresses and in rapidity of delivery is a fair test of the fitness of a telegraph or postal messenger for his situation is quite true, but whether every Government post of trust and responsibility should be filled on a system similar to that lately advocated by the Right Hon. Robert Lowe, before a select committee of the House of Commons, is, I think, open to question. I refer to this general topic because I find the same ideas making rapid strides in our own profession; and although up to a certain point competition is not only useful but necessary, we should carefully keep before us the special dangers attached thereto. The most recent example is afforded by the Council of the College of Surgeons in calculating, to two places of decimals, the claims of every medical school to public support. By this means they will probably succeed in "levelling-*up*" the teaching of the various professors and lecturers to the necessary standard for their membership. In addition they should work out to the same nicety the particular subjects in which candidates fail, and publish the results in the *Times* as well as in the medical journals, and then "cramming" would once more quickly take its due position in the education of the medical student.

But turning to our higher examinations, the competition that is engendered and encouraged has some great drawbacks, which, I fear, are not sufficiently considered. In the first place—and this is particularly true of our own profession—we can only test one side of a candidate: viz., his powers of acquisition and the facility with which he can reproduce the facts and theories stored up in his memory; whilst other qualities, such as accuracy of observation and readiness of action in emergencies, must be entirely overlooked. The acknowledgment of the element of chance in all our examinations at once shows this most conclusively, and a correct criterion of a man is frequently not obtained, although his future career is so largely dependent thereon.

Again, competition leads men in exactly the same groove, and renders them fac-similes, good or bad, of each other, or of their more immediate and successful teachers. This competition, in the case of the University of London, is spread over so long a part of that period of life when habits once formed are with great difficulty reformed, that many persist in the same line of acquiring the views of everybody else on every subject, without having any judgment of their own or the power of forming it. They are consequently at the mercy of every specious doctrine, and ready to hold any outrageous idea of disease and its treatment, or to doubt the efficacy of the most potent remedies in cases the most suitable for their administration. Books are read and lectures attended, not for their intrinsic merits, but for "what will pay," inasmuch as the practical benefits to be derived from the system of payment by results are as quickly appreciated by the student as by its older advocates. At a recent discussion by the Convocation of the University of London, on the substitution of German for Greek at the matriculation examination, after much bathos about the homogeneity, complexity, subtilty, richness, and power of the former language, the advocates of the change came to the great practical question, "Which will pay best?" And so a language that can be mastered by a residence of a few months in a neighbouring country is to be put on a footing of equality, as a means of higher education, with one which contains works that have done more to develope true culture (so essential in these days of exact science and mechanical detail) than all other writings since, those of Shakespeare, Dante, and Goethe alone perhaps excepted. Although "the University has no wish to discourage Greek," this will practically cause its removal from the curriculum of a large number of our schools; leading one almost involuntarily to apply to their subsequent scholars the touching words of Milton in reference to his blindness:

> "And Wisdom at one entrance quite shut out."

Too little insisted on, also, is the tendency of these severe competitions to foster men who are more ambitious of honours than their health or talents warrant, and who, instead of cultivating their powers of observation, and striving to obtain that technical knowledge which would make them of the greatest use as individual practitioners, fritter away their time in trying to learn theories which they cannot grasp, and to collects facts too numerous for their retentive powers. In this way much positive harm is done, and instances of this must flash across the minds of all the older members present; while it seems to me doubtful if the best men are improved, or even come scathless out of the ordeal. The mathematical honour lists at Cambridge show that the first men do not always turn out best in their future careers, and generally others who occupy a lower position come eventually to the front with fuller and more matured powers, and surpass those who, having so early exhausted their mental vigour, can do no more good work in the advancement of knowledge. I am afraid that, as in the domain of practical politics, so in that of intellectual thought, we are too rapidly following in the footsteps of our cousins across the Atlantic, who, since the War of Independence, having taught every child to read and write, have produced from amongst them one thinker only of acknowledged power and originality—Emerson.

I am particularly influenced in making these remarks at the present time by the fact that a man of so much authority as Professor Todhunter, in a recent work, entitled "The Conflict of Studies,"(b) awards the palm, among branches of general education, to the mathematical rather than to the experimental or the natural sciences, not solely on account of their mental effects, but he adds the monstrous reason, that attainments in the latter cannot be so readily tested by examination, forgetting that the aim of all education should be, not to communicate a result, but to impart a power. Moreover, as examinations cannot but be imperfect, education, whose proper object it is "to lead the mind to discern for itself, and not to rest on memory for rules to guide our art and practice,"(c) should be sedulously watched and guarded, and hold its due place as the primary factor in the production of the individual both as a man and as a medical practitioner. The obliteration of the individual in averages, and the sifting of competition, may be necessary ingredients in the great natural law of the "survival of the fittest," but the process is at best a very harsh one, and I am not satisfied that the result is as certainly beneficial as the well-known lines of the Poet Laureate would seem to imply,—

> "Knowledge comes, but Wisdom lingers, and I linger on the shore;
> And the individual withers, but the world is more and more."

On the contrary, I look on Individualism as the necessary, and indeed only, protest against the present all-pervading spirit of competition, with its "payment by results," and consequent copying of our teachers and successful fellow-students, for, as Dr. Paris says,—

"It is an instinct in our nature to follow the track pointed out by a few leaders; we are gregarious animals in an intellectual as well as in a physical sense, and we are addicted to routine, because it is always easier to follow the opinions of others than to reason and judge for ourselves; and thus do one-half of the world live as alms-folk on the opinions of the other half."(d)

To develope this Individualism, we should assiduously cultivate many of our attributes, which cannot be weighed scientifically, but which mark out and differentiate our particular intellectual character and mode of thought, and seem to depend on so many complex causes—such as hereditariness, temperament, early education, &c. In criticising a man's mental structure, we are much too apt to over-value the cold

impartiality of the intellectual or scientific reasoner, and to forget the great advantages of a certain amount of faith and enthusiasm in literature and in medicine, even if we are forced to make some allowances in weighing the conclusions. These qualities have been largely possessed by the greatest and most illustrious men in our profession, whereas the tendency of pure intellectualism has been to develope the general scepticism which has marked the medical teaching of late years. They have pre-eminently characterised those physicians who have achieved the most lasting reputations as teachers; and here I would especially refer to one of the founders of the medical school of this College, the late Dr. Todd, whose memory is so much venerated by the elder generation of King's men, who so freely acknowledge the great benefits derived by them from his teaching and example. As a corrective to the rigidity of the purely scientific mode of thought, the æsthetic side of art, literature, and science must not be lost sight of, as this is of vital importance in any attempt to reach the perfection of the individual character; for true culture, to quote the words of Mr. Matthew Arnold, "leads us to conceive of true human perfection as a harmonious perfection, developing all sides of our humanity;"(e) and though we shall never grasp the fulfilment of this ideal, we must strive to attain thereto, remembering that he who never despairs seldom completely fails.

As Individualism is of great importance in the formation and preservation of the highest intellectual thought, so it is also a primary influence in maintaining a high standard in medicine, which, as was so well expressed by my friend, Dr. Baxter, in a former introductory address, is "to us, not only an occupation but a life."(f) It has led the wisest and best men in our profession to think out for themselves the great problems of health and disease, and has prevented them from becoming mere physicists, chemists, or morbid pathologists, instead of true clinical physicians. The insistence on the observation of the phenomena of disease during the life of the patient is especially opportune and necessary just now, when on all sides we have inferences drawn concerning its nature, and suggestions made for its treatment, from laboratory experiments or post-mortem appearances only. These, of course, are extremely valuable as physiological or pathological studies, but, when forced into opposition to careful clinical observation, occupy a position which they are not warranted in assuming.

It is curious and interesting to watch the different phases of medical literature, and see how, with new means of investigation, and with more complete knowledge of each science, and of its peculiar methods, that science becomes the theoretic pivot on which our practice is made to turn. Thus in so short an experience as my own we have had four distinct schools claiming to govern our therapeutics—viz., the expectant, the statistical, the chemical, and now the physiological.

Of these the "expectant" has been of extreme value, by teaching us to examine the phenomena of disease as they occur, and without the introduction of disturbing elements. By it we have learnt the course, duration, and termination, or "natural history" of the more acute diseases, and the harm that is frequently done by interfering with their normal evolution. "Cutting fever short" is now hardly ever mentioned, even by the public. On the other hand, the practice was often allowed to run to an extreme, and to paralyse our treatment; for we must not forget that lives have undoubtedly been saved by using remedies judiciously and promptly, even in acute affections—*e.g.*, in pneumonia, erysipelas, diphtheria, etc. The expectant plan is but the revival of an ancient system, for the disciples of Ernst Stahl followed nature so implicitly that their practice was named, "a meditation upon death."

The "statistical" method has been pushed beyond all precedent by Hughes Bennett, to enforce his so-called restorative treatment of pneumonia,(g) as if all cases called by this name were exactly alike, and as if a few cases described minutely were not worth more than any number of incomplete observations heaped promiscuously together. The fallacies of this method, when thus applied, are so glaring, that one wonders at its ever being resorted to in the decision of individual therapeutic problems.

To the "chemical" school we are certainly indebted for the knowledge of the action of those remedies whose behaviour in the organism and in the laboratory is similar, and whose decompositions can be readily followed. Besides the chemical antidotes and escharotics, they are, however, limited to the groups of Antacids and Antilithics or Lithontryptics, and deal only with the secondary effects of the diseases in which they are employed, and so are apt to make us lose sight of the necessity of endeavouring to ascertain the conditions causing the ailments we are treating. This school, although temporarily obscured by other doctrines, has had a long period of supremacy, for its present disciples owe the fundamental ideas of their system to Basil Valentine, Paracelsus, Van Helmont, and their successors, whose extravagances should have been a warning against such unwarranted claims in its behalf as have recently been advanced.

I well remember how greatly I was charmed in my early student-days with the simplicity of disease and its treatment, as shadowed forth in a book, then at the height of its popularity. Writing in 1857, the late Dr. Bence Jones says, "that the theory and practice of medicine are in a transition state, and that the ground is being cleared for a new structure, based on the theory of the conservation of energy."(h) He divides diseases into mechanical and chemical, and the latter into diseases of suboxidation and peroxidation,—the latter class containing affections as remote as Bright's disease and hydrophobia. He assumes that he has satisfactorily explained by animal chemistry, hypertrophy, atrophy, and fatty degeneration, and looks forward sanguinely to the detection of the difference in chemical composition which he is sure must exist between an ordinary epithelial cell and an epithelial cancer-cell.(i) He includes the whole art of therapeutics in questions merely of diet and drugs acting chemically, and rest acting mechanically; and at the end of the work refers the reader to papers on twenty-two groups of substances, of which, to one's great surprise, only two or three have ever been used in medicine. The human body is literally looked on as a laboratory or a watch, and the necessity of the administration of food to postpone the fatal termination of a case of chronic gout is thus singularly pointed out:—

"Thus the original chemical disease of suboxidation of the urates may cause such an entire loss of mechanical power that not even a crumb of food can be raised to the mouth, or a fly can be driven away from the skin, and death would soon result from the debility of starvation, if external force was not made to compensate for that which cannot be produced within."(k)

I had thought that this school had altogether given way to the physiological one, now coming into prominence, but a curious link between them is to be found in some lectures delivered by Dr. Fraser before the Royal College of Physicians, Edinburgh, and published last year in the *British Medical Journal*, in which (following Blake and Rabuteau) he enunciates the following conclusions:—(l)

α. Salts of the same base have analogous actions. The exceptions to this law are so numerous, and depend on so many other conditions, that it is really not worth laying down—*e.g.*, compare ammonium carbonate with ammonium chloride, or sodium sulphate with sodium chloride.

β. Isomorphous substances produce similar effects; but chloride, fluoride, bromide, and iodide of potassium are isomorphous, so are the sulphates of zinc, iron, and magnesia, and also the phosphate and arseniate of soda.

γ. The metals are more active physiologically according as their atomic weights are more elevated. Passing over the puzzle as to how the activities of substances producing the most diverse physiological effects can be relatively compared, he illustrates this law by the examples of sodium, potassium, and thallium. "Sodium, with an atomic weight of 23, is inert; potassium, 39, is active in moderate doses; while thallium, 204, is a dangerous poison." He omits lithium—a more manifest member of the alkali group than thallium—which is so strongly recommended by Dr. Garrod for its activity and the smallness of its combining number, 7. Again, compare copper, 63·5, with lead, 207; mercury, 200, with bismuth, 210; or, even more striking still, arsenic, 75, with antimony, 122. Fourcroy in the last century expressed an idea of equal value when he said that the virtues of mercury were due to its specific gravity.

REVIEWS.

Essays on Diseases of Children. By Wm. Henry Day, M.D., etc. London: Churchill. 1873. Pp. 191.

This little book, the author tells us, is composed of papers which have already appeared in the pages of the *St. Andrews Graduates' Association Journal*, or in the columns of our weekly contemporaries, or which have been read before the Harveian Society of London. The first essay contains some general remarks on the study of children's diseases, which, if they cannot be characterised as novel, are nevertheless true and valuable. In the present age of refined diagnosis and of multiplied diagnostic instruments, it is well that the practitioner should occasionally be reminded that treatment directed to the constitutional state is that which is often most likely—in patients of all ages and both sexes—to control disease. Especially in children, in whom it is far less easy to determine the extent and degree of local mischief than in adults, is it not seldom better to rely upon the evidence derived from general condition than to trust to the uncertain knowledge to be obtained from doubtful local signs. Not that we should omit the endeavour to investigate the local affection, whatever that may be, with exactness; but he will be the most successful practitioner who, whilst he makes his differential diagnosis with all the care in his power, looks beyond the local malady to the general condition which has given rise to it, and on this founds both treatment and prognosis. The remarks on the general hygienic management of children in the essay are generally reasonable; the observations on medicines also would be endorsed by most practitioners.

The second essay is a short one on debility in children—a functional impairment of the vital processes, which may sooner or later pave the way to organic change. The two most common attendant symptoms, Dr. Day thinks, are headache and pain in the epigastrium—signs of debility in the brain and stomach. He gives a vivid sketch of a condition which is very common amongst the children of the poor in London.

The next essay is on infantile remittent fever, which he identifies with typhoid, and on the febrile state in general. He especially argues that the varying characters which typhoid, gastric, and remittent fevers assume afford no ground for assigning to them a diversity of causation.

Other chapters follow on an obscure case of cerebral disease, on headaches in children, and on laryngeal and tracheal irritation and croup. Perhaps the most valuable of these, as it is the longest, is the essay on headaches. Headaches in children the author classifies thus:—1. Cerebral headache, attributable to injury or to chronic or acute inflammation. 2. Gastric headache, from intestinal and hepatic derangement, known as bilious headache. 3. Epileptic headache. 4. Febrile headache. 5. Headache from anæmia, neuralgia, etc., constituting nervous headache. 6. Headache depending on some intricate change in the cerebral membranes or tissues of the brain. The cases of headache depending on obscure cerebral conditions which the author has recorded prove him to be an intelligent clinical observer. If Dr. Day's book does not give evidence of minute pathological research, or of the observation of disease on a widely extended scale, it at least affords proof of honest use of the materials within the reach of the London physician, and of independent thought and observation.

Egypt as a Health Resort; with Medical and other Hints for Travellers in Syria. By A. Dunbar Walker, M.D. London: J. and A. Churchill. 1873. Pp. 139.

Readers of the admirable letters of our well-known correspondent at Madras, and of the very clever sketches which we have published under the title of "A Doctor's Log," from the pen of an army medical officer, will already have learned something of the pleasures and annoyances, the benefits and disadvantages, of the voyage to the land of the Pharaohs. There can be no doubt that in the scale of health resorts Egypt has been for some years steadily rising, and it has certainly attractions—apart from its climate—which throw those of most other sanitoria into the shade. In the little book before us the author chiefly treats of the hygienic advantages to be derived from a sojourn in Egypt, and this rather in a general way, without much attempt at scientific comparison of Egypt and other localities supposed to be specially suited to the invalid. Neither does he give much local information that would be of use to the visitor in the land of Ham. The book will therefore neither supply the requirements of the physician who may wish special scientific information as to the climatic conditions of Egypt, nor those of the delicate traveller who may hope to find in it a Murray's guide with a medical adviser. Still it contains many hints which will be useful to patients, given in an easy, colloquial, unpretending style. The hints to travellers in Syria, which form the concluding section of the little book, are worth reading. Amongst other things, the author tells us that about two-thirds of the inhabitants of Syria are afflicted with intestinal worms, of which the most frequent is the round worm, *ascaris lumbricoïdes*. Boiling and filtering the drinking-water, santonin and scammony and calomel pills, are the prevention and cure. To reach Egypt, Dr. Walker recommends that most invalids should take the voyage from Southampton in preference to the land route. For sea-sickness he distrusts all remedies. He has no belief in ice to the spine, which, although it will not cure sea-sickness, will very probably produce lumbago. In a popular medical handbook we think an author's religious opinions are better left out: a section of readers at least would only be irritated by his remarks on Malta and his criticism on the course taken by "Protestant England" in allowing the religion of the inhabitants to be "rampant" there.

Lectures on the Clinical Uses of Electricity. Delivered in University College Hospital. By J. Russell Reynolds, M.D., F.R.S., etc. Second edition. London: J. and A. Churchill. 1873. Pp. 116.

We have so recently, in our articles on "The Medical Uses of Electricity," referred to Dr. Russell Reynolds's valuable writings on the subject, that we shall content ourselves with little more than an announcement that a second edition of the lectures has just appeared. Of all modern works on electricity in medicine these lectures seem to us second to none in practical value. They tell us what electricity can and what it cannot do, both as an aid to diagnosis and as a therapeutical agent, and this in clear and precise language. The present edition has been revised, and it contains some additional matter, but it does not differ in the main from its predecessor. A great charm of the lectures is the frank, unpretending, but thoroughly scientific style in which they are written. They convey the impression of being really intended for the instruction of the student—an aim which seems to us conspicuously wanting in not a few works on the same subject.

On Elephantiasis Græcorum, or True Leprosy. By Robert Liveing, M.D., etc., Physician to the Middlesex Hospital. Longmans. 1873.

The author, in his preface, tells us that the greater part of this little work constituted the Gulstonian Lectures for 1873. His object has been to collect from various sources a short account of the past and present history of leprosy, and to combine with this his conclusions regarding the causes, nature, and clinical features of the disease, drawn from the facts recorded, and from his own observation on several cases under his care. It needs but a perusal of the work to show that the author has succeeded in his object, and justified his opening remarks. The subject is one that has been of interest to mankind from time immemorial, and the frequent reference to it in Scripture history, together with the precise rules laid down for its diagnosis, proves how important it was considered to limit as far as possible this terrible scourge of humanity. Far from leprosy being a thing of the past, Dr. Liveing shows us that it is still prevalent, and that there is no disease that has a wider geographical distribution—"it is found both in the northern and southern hemispheres, and in almost every latitude from the poles to the equator." He discusses at length the several causes that combine to its production, and enters fully into the question of its hereditariness and contagiousness. The three different forms—the macular, the anæsthetic, and the tuberculated—are carefully differentiated, and illustrative cases given; allusion being also made to the allied diseases, morphœa, and white or Jewish leprosy. The subject is exhaustively treated, and reflects great credit on the author for the manner in which he has condensed into a most interesting work all that is known of the history, symptoms, and treatment of this dire disease.

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, November 11.

The Introductories (*continued.*) — Mater Misericordiæ Hospital—School of Physic, Trinity College—Catholic University—Ledwich School of Medicine.

The session at the Mater Misericordiæ Hospital was inaugurated on Monday, the 3rd inst., by an address from Dr. Valentine Brown, the recently appointed Assistant-Physician to the Hospital. The chair was occupied by the Right Hon. the Lord Mayor of Dublin; and a vote of thanks to the lecturer was proposed by Mr. P. J. Smyth, M.P. for the county Westmeath.

The first lecture in the School of Physic, Trinity College, was delivered on Saturday, November 1, by Dr. B. G. MacDowel, Professor of Anatomy. Several of the profession and a large number of students attended. Dr. MacDowel made a touching allusion to the great loss the School had sustained in the death of his colleague, Dr. R. W. Smith, Trinity College Professor of Surgery, who had been one of his oldest, best, and most trusted friends.

Dr. Robert D. Lyons, Professor of Medicine, delivered the opening address of the medical session, 1873-74, of the Catholic University, at the School of Medicine, Cecilia-street, on the afternoon of Tuesday, the 4th inst. The earlier part of his discourse was altogether devoted to the question of university education in Ireland. Having expressed regret at the collapse of the University Bill in the last session of Parliament, the lecturer explained to his auditory that the Catholic University was now undergoing a great reformation. Colleges and schools in all parts of the country were being affiliated to it; and with regard to the central university institution, he announced that the authorities had lately associated with them "the great body of Jesuits." This elicited mingled hisses and applause from the student portion of the audience. He further mentioned that he was authorised to contradict the statements of the *Times*, *Spectator*, and other papers, that the claim for a public grant to the University was now given up. The remainder of the lecture dealt with medical topics exclusively, and was admirably calculated to encourage and enlighten those entering upon their medical curriculum.

On Saturday, November 1, the sixty-fourth session of the Ledwich School of Medicine was inaugurated by an address from Dr. Arthur Wynne Foot, the Lecturer on Medicine in the School. Having acknowledged his sense of the dignity and responsibility of the position to which he had been recently elected in the School, Dr. Foot alluded to the removal within the past year of both his predecessors—one by death, the other to a different post of labour, each having gained a crown of laurel in the profession. Such addresses as he was then entering upon were frequently regarded as a kind of medico-theological or medico-political discourses—wearisome, meaningless, and listened to only as the lugubrious moaning wind when there was nothing else to listen to. That was because of the subjects treated of—these having, in the vast majority of cases, no interest for those who wanted to know the first principles of a profession in which they were but young disciples. He would not delay them in proving the already proved excellence of that School, nor introduce politics, nor call up whole legions of learning: he was a student himself, and preferred putting before them on that impressive occasion—the annual turning point, which gave each year an opportunity of repentance for past waste of time, and of renewal of energy for time to come—the fundamental ideas of industry, enthusiasm, and earnestness of purpose. He counselled them to work these golden threads into the web of their life as it issued from the loom of time, and to persevere in the task till they stood as shining lights in professional perfection. For any of them to do a thing rightly he should have three things—a wish to do the thing, a knowledge of how he ought to do it, and a will to make himself do it.

Having dwelt on the two former of these subjects, the lecturer alluded to the variability in the force of different persons' wills, to weak wills and strong wills, and to the differences between a wish and a will. He always thought that a great want in the education of medical students was the neglect to take means to make their wills active living forces, and for this neglect he in a large measure blamed those who had the supervision of them. But not wishing to discourage any, he proceeded to excite the interest of all by a brilliant picture of the duties and privileges of a medical life; and having shown that excellence in the profession would bring with it honour and gain, he dilated upon the reasons why they need not fear monopoly, nor be deterred by competition. He then addressed the various students according to their classes, pointing out that the application of the principles of industry, enthusiasm, and earnestness placed excellence within the grasp of men of moderate capacity, and within the reach even of those more heavily handicapped by extra sources of anxiety, as well as in the power of those who passed for the intellectual giants of a large and highly distinguished school. He warned them against being deterred from competition with "geniuses," men of fitful effort, who could do all things by turns, and nothing long. He recognised no definition of genius but "the transcendent capacity for taking trouble." (Applause). He urged on students to aim at success in the earliest beginning of their studies, by concentrating their force on all difficulties as they meet them. Little by little that goal must be attained.

Reviewing, in a most interesting manner, the causes of failure in students, he could find apologies for all shortcomings except the mildew of idleness. He would fearlessly proclaim from the outset the most uncompromising hostility against idlers, and would invite all true students to join him in the crusade. It was idlers who had made a byword of the name of medical students, and brought into disrepute a class of men braver, more generous, more tender, truer to all the truest instincts of human nature than were to be found among the students of any other profession. Thanks to idlers, and to them alone, the name of medical students had been traduced with systematic exaggeration by those who never knew the sentiments of the really representative men of the class. Having referred to the student's hospital life, his self-forgetfulness of danger in volunteering to carry in his arms with gentlest care the cholera, typhus, or small-pox patient, or to stand for hours daily in the very focus of pestilence, he said it was the foolish freaks of a few idlers, disclaimed by the majority, which had smirched their fair escutcheon and given to their enemies cause to blaspheme a name which was the embodiment of valour and disinterested virtue. He held out, however, hope of reformation, even to those who had slept far on into the morning of their lives—hopes of shaking off the nightmare of sloth which was threatening them with professional asphyxia. Even at the eleventh hour he would not withdraw the rainbow of hope, and would cast a rope to those who were about to sink, perhaps for the third time, in the seething flood of their own follies; let them catch it, and hold it, and be brought safe to land, and so be saved from suicide. He had always thought that a peculiar value in these periodic addresses at critical stages in their student-life was, that while the working and industrious men could be refreshed with encouragement and further stimulated by approbation, there was an opportunity, perhaps, of arresting the downward career of those who were sliding fast into the bottomless pit of idleness. Having touched on many other matters, all bearing on the students—their hopes, their fears, and their interests—the lecturer concluded with a brief recapitulation of the great principles he had advocated, and of the issues resulting therefrom.

GENERAL CORRESPONDENCE.

CLINICAL TEACHING AT EDINBURGH.

Letter from Professor Laycock.

[To the Editor of the Medical Times and Gazette.]

Sir,—I observe that our University Club has had its attention drawn to the early clinical teaching at Edinburgh, and it has occurred to me that the subjoined letter from a valued friend now dead would interest many Edinburgh graduates. The writer, Oswald Allen Moore, was a much esteemed practitioner in York, and Lecturer on Botany at the York Medical School. His grandfather, after whom Mr. Moore was named, and his father, were both surgeons. Dr. Withers was brother-in-law to his grandfather, Oswald Allen, of York. He graduated in 1772, and is best known by his treatise on "Asthma." There is a like MS. copy of Dr. John Rutherford's lectures in the library of the College of Physicians here, of date 1750; I understand copies were made for sale. I subjoin an extract

from the introductory lecture as an illustration of the style and method. Dr. Rutherford was appointed the seventh Professor of the Practice of Physic in 1726.

Edinburgh, November 17. I am, &c., T. Laycock.

"Dear Laycock,—In looking over some books formerly belonging to my great-uncle, Dr. Withers, of York, I found two MS. volumes of Clinical Lectures by the first (I believe) Professor of the Practice of Physic in the University of Edinburgh.

"You are aware that four Professorships of Medicine (in its various branches) were instituted in this University about the end of the first quarter of the eighteenth century, and that Dr. Rutherford was one of them: and as Professor of the Practice of Physic(a) he began in 1748 to deliver clinical lectures on the most remarkable cases in the Hospital, a practice previously adopted as respects surgical cases by Professor Monro.

"Although there is no title-page, I have other MSS. which prove the authorship, and also that the selection was made by some of the *alumni* of the University from lectures delivered between 1750-56. You will also see that I have been able to supply the date in many instances, and in one case even the name of a patient omitted in the report.

"If not too cumbersome, will you kindly allow them to act at least as lay-books to fill up a shelf or keep their companions tight.

"Accompanying my note I send an engraving of Professor Cullen. . . . . .

"I remain, my dear Professor, yours very sincerely,

Oswald A. Moore.

"15, Colliergate, York, October 10, 1855."

Extract from Professor John Rutherford's Introductory Clinical Lecture.

"But a true physician is acquainted with ye fundamental parts or principles of his art, who understands ye animal œconomy, and not only knows what health is, but can trace out ye causes of diseases and ye rise of ye symptoms. He likewise knows when and where nature makes an effort, supports her when weak, and co-operates with her in all her actions and operations as far as he can. He may be said to be her minister. He follows her as his guide, varying his practice as ye indications change. In short, he hits with reason in everything. Hippocrates desires us to follow Nature as our guide, and do nothing without her, tho' 'tis evident ye same diseases in different persons will produce different effects and symptoms, and require different methods of cure. From ye reasoning and practice he may be called a rational practitioner and physician. An empiric undertakes ye cure of diseases in a much easier manner. He despises all learning, and practices by wrote, and does not adapt ye remedies to ye nature of ye disorders. He takes all his intelligence from ye names, barely asking whether 'tis a fever, cholic, etc.; and without considering ye constitution of ye patient and other circumstances, he gives medicines which he only imagines to be good in such and such cases. Thus he goes on till ye patient either dies or recovers, paying no regard to ye different constitutions and diversity of shapes which disorders put on, whence arise so many indications and contraindications. This is a ready way to cure diseases by ye lump, and a much easier method than ye former.

"Ye method I propose to pursue is, to examine every patient before you, lest any circumstance should be overlooked. I'll conduct this by a plan which is ye most useful I know of:—1stly. I'll give you ye history of ye disease in general. 2ndly. I'll inquire into ye causes of it. 3rdly. I'll give you my opinions how ye disease is going to terminate; and 4thly. I'll lay down ye indications of cure. As I shall give you my mind freely, if you find me mistaken I hope you'll excuse me, as ye *ars medica* is not infallible."

CLINICAL TEACHING IN LONDON.

[To the Editor of the Medical Times and Gazette.]

Sir,—With regard to the question, "In what British medical school did systematic clinical teaching originate?" it might be interesting to your readers to know that Sir Benjamin Brodie considered himself to be the first clinical lecturer in London. In his autobiography, published in 1865, page 78, he says, speaking of his labours at St. George's Hospital in 1813—"I also began to deliver clinical lectures, and I believe that these were the first lectures of this kind which were ever delivered in a London hospital." Although this does not strictly answer the question mentioned, yet it decides it so far as London is concerned. I enclose my card.

November 15. I am, &c., St. Bartholomew's.

THE GENERATION OF TYPHOID.

Letter from Dr. C. G. Logie.

[To the Editor of the Medical Times and Gazette.]

Sir,—So much has been written regarding typhoid fever being generated by milk, and so strongly, too, have some urged upon us this theory, that they would almost lead us to call the disease the "dairyman's fever." But we know that typhoid may arise without the use of milk; and I know from inquiries last month, as in my student days in Edinburgh, and also while stationed afterwards in Portobello Barracks, that the families near those sewage meadows between Edinburgh and the barracks continue healthy on milk from the cows fed on those meadows. Again, it is a strange thing that if you give milk, pure from the cow, to many, they do not like it; mix it with water, and they appreciate it.

Now, I am not going to advocate allowing the dairyman to add the water from his probably contaminated sewage well (thanks to powerful legislation, this is put a stop to), any more than I should allow anyone to add water to my whisky; but I beg most particularly to call attention to the gross ignorance, or rather unintentional mistake, of our engineer department in the building of houses with regard to the pipes connected with cisterns, in so preventing us suiting our own tastes in this or any other respect with safety. Pray walk along by the backs of houses in streets and see for yourself. You can mark the soil-pipe, with its branches from every closet, on each flat, and in the cheaply built houses the scullery-pipes also connected with them. Now examine your cisterns indoors. You will discover what is called a waste-pipe sticking up in the corner. Where is the other end of this pipe? You will find it conveyed very neatly into the soil-pipe or nearest drain. As this waste-pipe is solely meant for the purpose of preventing an overflow (should anything go wrong in the ball-cock), it is, I may say, 364 days out of the year empty. It serves as a most excellent ventilator for all horrible gases from the soil-pipe or drain (most probably the main sewer in the street) to the surface of the water in your cistern, there to be greedily absorbed. Bath-rooms also suffer to a very great extent—baths being usually supplied with hot and cold water by the same orifice, from which it is emptied into the soil-pipe, the trap below the bath being, I think, not sufficient to check the foul air in the majority of cases from want of space.

The remedy for these glaring defects is very simple. Arrange so that you can see the other end of the waste-pipe alluded to; also of that of your bath. The latter can be so managed that the water from the bath may be utilised for garden purposes, whilst that from your cistern should be in the open air, and at some distance from any drain, fitted with a simple gutta-percha valve, preventing ingress of air, but allowing free outlet of water. While on the subject of valves, I beg most respectfully to call the attention of those connected with waterworks companies to the advisability of having valves (of a tricuspid shape) at certain parts of the various mains for the purpose of preventing regurgitation, and also for localising disease, so far as water may be concerned, if originated by other causes. I am, &c.,

Cosmo G. Logie, M.D., F.R.S.E.,
Surgeon-Major Royal Horseguards.

Regent's-park, N.W., November 14.

H. C. CUTCLIFFE, F.R.C.S., SURGEON-MAJOR BENGAL ARMY, OFFICIATING PROFESSOR OF SURGERY, CALCUTTA.

Letter from Dr. Fayrer.

[To the Editor of the Medical Times and Gazette.]

Sir,—The *Times* of a few days ago contained one of the brief and cruel telegrams such as those interested in India are and will be at times fated to hear. It ran thus:—"Dr. Cutcliffe is dead." This melancholy intelligence concerning one who was so recently in the prime of life and in the full exercise of

mental and physical powers of no ordinary character, unaccompanied as it was by details of any kind, whilst it caused the greatest anxiety and sorrow to his friends, yet left a shadow of hope that there *might* be some mistake. Alas! the mail of this morning has dispelled all uncertainty, for it brings the sad news that Henry Charles Cutcliffe died in Calcutta, of œdema of the larynx, at 2 a.m. of October 24 last.

A correspondent—a mutual friend and colleague, who was with him in his last moments and throughout his illness—writes—"I have only time for a few hurried lines to inform you that poor Cutcliffe died this morning, October 24, at 2 a.m. He was taken ill only on Monday last, the 20th, with a violently inflamed sore throat. I saw him first on Wednesday, and then there was a suspicious-looking patch on the right tonsil and the soft palate, looking something like a diphtheritic exudation. It never spread, however, and was not I think really diphtheritic, but a superficial slough, the result of an application of strong caustic solution on the Monday. From the commencement there was marked tendency to œdema, and this rapidly spread to the trachea and at last into the bronchial tubes, and ultimately caused death. Tracheotomy was performed, but gave little, if any, relief. You may imagine the shock to us all has been a terrible one." It has indeed! and to many more also in England who, beyond the immediate circle of his own family (to whom the loss must be irreparable), knew and appreciated his talents and his worth.

There are many who, having known him longer, could say more of the merits and promise of his early life than I can; none, I think, who more fully appreciated the realisation of that promise in his mature age. He was a skilful and scientific surgeon, a painstaking and impressive teacher, an officer well qualified to uphold the dignity of his service and profession, and to those who had the privilege of knowing him well a true and loyal friend. His place will not be easily filled, nor will his memory readily fade in the College where he taught so well.

More than one sad event of a similar nature has recently shocked our profession and the public in England. As it was, I believe, said of the eminent young physicians so early snatched away, that they had died like soldiers faithful to their trust, and at the post of duty,—so, indeed, has it been with Cutcliffe; for the disease of which he died was surely the result of exposure to evil influences when depressed by severe work in an exhausting climate—such influences, too, as he had himself long and ably laboured as a sanitarian to ameliorate or remove. He had worthily reached the post he most of all desired, and has lived, though the time has been so short, long enough to prove how admirably he could fill it, and how great a loss his premature death will cause to medical education, his service in India, and to a large number of sorrowing friends, in India and at home.

I feel, Sir, that I but imperfectly express the sentiments of all my colleagues in Calcutta in the few words in which I have communicated to you the sad details of Mr. Cutcliffe's death. I can only add that the deepest sympathy will be felt for his young widow and bereaved family. I am, &c.,

London, November 17. J. Fayrer, M.D., C.S.I.

HOW TO GROW *EUCALYPTUS GLOBULUS* IN ENGLAND.

Letter from V. F. Benett Stanford.

[To the Editor of the Medical Times and Gazette.]

Sir,—My attention has been drawn to an article of yours which was copied into the *Daily News* of November 8, in reference to the health-giving properties of the *Eucalyptus globulus*—or blue gum tree. As I have successfully reared from seed two dozen of these trees, and as they are now growing well out of doors, I think some of your readers would like to know how I succeeded. I obtained the seed five years ago from South Australia, and forced it in a hot-house; in one year it was four feet high, and now, in its fifth year, it is growing rapidly in a sheltered position in the park, having attained a height of thirty feet. The first three years the tree must be taken under cover every winter, and the fourth and fifth years should be protected for several feet up with wisps of hay or straw. When the trees are kept indoors in winter, it should be in an orangery or very high greenhouse, with plenty of light and little water. I have sent specimens of my five-years-old gum trees to Milton Abbey, in Dorsetshire, and to Donhead Rectory, in Wilts, where I believe they also flourish.

I am, &c., V. F. Benett Stanford.

Pyt House, Tisbury, November 18.

REPORTS OF SOCIETIES.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

Saturday, November 15.

Dr. Letheby, President, in the Chair.

Dr. George Ross read a paper "On the Ventilation of Schools, Hospitals, and Public Buildings," of which the following is an abstract:—"Good ventilation" is a comprehensive phrase; for it involves the consideration of the causes of noxious gases of all kinds, and of the best methods of dissipating and destroying them. My present object is more limited than this; for I do not intend to deal with the numerous sources of malaria, nor to advert to the various chemical means in use for purifying the atmosphere: I propose simply to consider the natural laws and methods by which air is distributed, and to point out the mechanical agencies by which the operation of these laws and methods may be assisted in our structural arrangements. Under the 132nd section of the Metropolis Local Management Act, by which medical officers of health are appointed, they are required "to point out the most efficient modes for the ventilation of churches, chapels, schools, lodging-houses, and other public edifices within the parish or district"; and I have thought that, in view of the proposed construction of a large number of new schools by the School Boards, this would be a suitable time to bring the subject of ventilation under the notice of this Society. The subject has, indeed, received a large amount of public attention, and many distinguished men have favoured us with their opinions upon it. Much practical good has, no doubt, been derived from their suggestions, but as yet general and even professional opinion is in a vague and hazy state upon the matter. In point of fact, the public are in despair as to the possibility of any successful method of ventilation, and there is a general disposition to fall back upon the open sash-window and open fireplace. With a view to ascertain which was the generally accepted system of warming and ventilation, I have visited a school-house, a workhouse, and a hospital—three institutions which have been recently erected, and which may be supposed therefore to represent the most advanced science in this respect. The school-house was one in my own neighbourhood, the workhouse was the new Lambeth Workhouse, and the hospital was St. Thomas's. For the sake of brevity I shall confine my observations to a single room, either occupied or intended for occupation, in each of these buildings. In the school-house the room for boys was at the top of the building. It measured 68 ft. long by 18½ ft. wide and 15½ ft. high, equal to 19,499 cubic feet, and, being intended for eighty children, provided a reasonable space. Fresh air was admitted directly from the outside by windows opening near the ceiling, and by the door when open. Foul air escaped by seven ventilators of perforated zinc in the ceiling, each about two feet square. The escape of the foul air was supposed to be assisted by five gas-lamps, each acting through the ventilators. There were three fireplaces. The fireplaces and the gas-lamps drew their supplies of air from the atmosphere of the room, and when lighted must of necessity deprive the children of the full supply intended for them, or otherwise must create a considerable draught from the windows, to the detriment of their comfort. As the gas-lamps would be rarely lighted, the advantage expected to be derived from their action must be considered as nugatory. The ventilation therefore practically amounted to this: that the fresh air, on favourable occasions, came in at the windows, and the foul air escaped by the same apertures. The ventilators in the ceiling could be of little use. When the external air was of a higher temperature than the air in the room, the descent of the fresh air and the ascent of the foul air, being left to the operation of natural forces, would be so trifling that a due ventilation could not take place; and even on September 15, when I visited the room, on a comparatively cool day, a distinct animal odour pervaded it. In the Lambeth Workhouse a day-room for males was 72 ft. long by

36 ft. wide and 12 ft. high. It was warmed by six fireplaces, all drawing their supplies from the room. The fresh air was introduced through revolving hit-aud-miss gratings in the middle of the floor, which admitted cold air from the outside. It could be also admitted, as a matter of course, by the windows. The foul air escaped by small perforated zinc openings in the ceiling, assisted by gas-burners, the vapour from which passed through the foul-air tubes. The gas-burners were supplied with air from the room. In principle and method, then, the ventilation of the workhouse was precisely the same as that of the school, but much more inefficient, inasmuch as the room was too low to afford sufficient capacity for the number of persons who will probably occupy it; and the hit-and-miss gratings for the admission of fresh air were so small as to be mere apologies for ventilation. It will be necessary to open the windows on most occasious, or the atmosphere will become offensive. With respect to St. Thomas's Hospital, I shall merely describe the arrangements of a single ward, thus giving the results of the method of warming and ventilatiou adopted in that building, and avoiding as much as possible controversial points. I went over this institution on September 16 at 4 p.m.—a fine temperate day, with a strong westerly breeze blowing. Fresh air was admitted into the ward by open windows, and as the wind was high outside it came into the ward in gusts, making cross-draughts and eddies iu all directions. Although numerous windows were open, I should not say from a rough calculation that there was more open space for the admission of air than was required for the health of the patients; but the air rushed in in a little gale instead of being admitted at a steady equal rate, as it ought to be under a good system of ventilation. I felt a draught about my ears and neck whilst I remained, and after I had left had a sense of coldness on the top of my head and a slight coryza, which troubled me on my way home. There were three large shafts passing through the ward, consisting of a smoke-flue surrounded by a hot-air shaft; and the ventilators by which the foul air escaped were iu the ceiling surrounding the shafts, the air being supposed to be assisted in its ascent by the heat from the shafts; but the shafts on the day I was there were not sufficiently warmed to effect this object. There were other small ventilators at the ends of the ward. There were three stoves and several gas-burners in the ward, all supplied when burning by the air in the room. All these well-intended arrangements were inoperative on September 16, for the iu- and out-passage of air was amply provided for by the open windows, which were the only real ventilators. The principle of this method of ventilation is the same as that of the other two institutions described; and whilst it falls far short of what I consider a good and sufficient principle, it nevertheless, as carried out in practice in St. Thomas's, gives too much air rather than too little. Iu point of fact, the principle is overridden for the purpose of getting a free supply of air; hence its insufficiency is practically admitted. In order to base a method of veutilatiou upon sound principles, it will be necessary, in the first place, to determine the quantity of pure air required for consumption by a single person within a given time; after that to ascertain the couditions and agencies for the supply of that quantity, so as to avoid draught, over-heating, and impurities. It is a well-ascertained fact that about thirty cubic inches of air are changed by an adult at each act of breathing. There are about fifteen inspirations in the minute, consequently 450 cubic inches are inhaled and exhaled each minute. Here, however, other facts come under consideration. The air at each inspiration is spoiled by losing 5 per cent. of its oxygen and gaining 5 per ceut. of carbonic acid. Air so deteriorated is poisonous. Conceding, as is generally allowed, that 1 per 1000 of carbonic acid might be breathed without being injuiious, theu each person would require about fifty times more air, or 22,500 cubic inches per minute, which is equivalent to thirteen cubic feet. As it is always prudent iu calculations of this nature to be on the safe side by allowing too much rather than too little, I would fix sixteen cubic feet as the due quantity for a single person per minute—960 cubic feet per hour, and 23,040 cubic feet per day. It is a maxim generally received that each person should be supplied with fresh air at the rate, at least, of 10 cubic feet per minute. The Royal Commissioners appointed to iuquire into the sanitary condition of barracks reported, in 1857, that the supply of air per minute for each man in his sleeping-room should not be less than 20 cubic feet. Our next point, then, is to consider what should be the size of the opening to admit thirty cubic inches of air, which is the quantity required for each respiration. These thirty cubic inches equal a body $3\times3\times3\frac{1}{3}$ inches, or a cross-section of 3×10 inches. An aperture, therefore, three inches wide and ten inches long would afford ingress to thirty iuches of air in one-inch cubes. This, however, does not entirely state the case. A human lung whilst respiring acts through a given period, and during that period the air travels about one foot, so that about twelve cubic inches would enter by the aperture instead of one. Hence the opening really necessary would be about one-twelfth of the size of that last stated—say half an inch wide and two inches long, or, to err again on the safe side, one inch wide and two inches long. In order to avoid draughts it is expedient that the velocity of the admitted air should be fixed at about two and a half feet per second, or teu feet each four seconds, that being the period of a respiration. Assuming that there are 100 persons or scholars in a room, each requiring 16 cubic feet per minute, the whole number would require 1600 cubic feet in that time, or about 107 cubic feet each four seconds; and inasmuch as these 107 cubic feet would enter at a velocity of ten feet in the four seconds, it follows that a cross-section of $3\times3\frac{1}{2}$ feet would give the required amount—that is to say, a room 80×30 feet would require an opening three-fifths of an inch wide all round. The 16 cubic feet of air admitted for each child each minute should be diffused through a sufficient volume of air to prevent draught and get warmed. Probably twenty times that quantity, or 320 cubic feet, would suffice for each child—altogether for 100 children 32,000 cubic feet, or equal to $80\times30\times14$ feet, which are about the dimensions already given above. A cross-section of $3\times3\frac{1}{2}$ feet is about the size of the upper sash of an ordinary window, and at first sight it might seem that this simple space, or any arrangement of spaces corresponding to it, would be insufficient to ventilate a large room for 100 children; but it must be remembered that the air is travelling at the rate of ten feet in four seconds—a velocity which is expected to be maintained by a furnace. By maintaining, at all seasons, a steady current of air, it would be found that the size of the aperture or apertures now recommeuded would be sufficient. The general result of these calculations may be thus compendiously stated in the form of a rule: that each person requires a continuous supply of about sixteen cubic feet of air per minute, moving at the rate of 150 feet in that time, and diffused through a space coutaining 320 cubic feet, the size of the opening for the admission of the air being about two square iuches. I have heard it gravely argued that, subject to the diffusion power of gases, the carbonic acid and sulphuretted hydrogen gases quickly disperse themselves through the air, and thus effect a sufficient ventilation. Commou experience convinces us that this notion is not correct. The weight of 100 cubic inches of air is 31 grains, and an equal measure of carbonic acid gas weighs 47·08 grains; air, therefore, is about one-third lighter than carbonic acid, yet if a jar of air be placed over one of carbonic acid, the latter will ascend, and after the lapse of a few minutes may be detected in the jar above. This is owing to the diffusion power of these gaseous bodies—that of air being 1, and that of carbonic acid in the ratio of 0·81. It is upon this property of gases, in fact, that the purity of our atmosphere depends. The diffusion power of carbonic acid is, however, much less than air, and so small that it cannot serve the purposes of ventilation. It cannot commonly be diffused as rapidly as it is generated, and its limited diffusion power therefore only increases the area of its poisouous activity. The same remark applies to sulphuretted hydrogen, which diffuses itself rapidly enough to be exceedingly disagreeable, but not to get rid of its noxiousness. It might appear reasonable to assume that by availing ourselves of this increased levity of heated air we should adopt the most natural and easy method of ventilating a room, but in practice it is found to fail. This failure is owing to several causes: first, because the watery vapour contained iu expired air condenses under the influence of cold draughts, and when condensed retaius its impurities; secondly, because the temperature of the air outside is frequently higher than that of the room, and the predicated action does not take place; thirdly, in a crowded room heat and impurity are so rapidly generated that they cannot be reduced without so copious a supply of cold air that an intolerable draught is created; fourthly, the foul air, which contains besides carbonic acid and water a quantity of putrescible animal matter, in rising is distributed through the apartment, and should there be persons sitting on a higher tier of benches—as in many public places, theatres, churches, courts

of law, etc.,—they are compelled to breathe the air vitiated by the persons beneath them; fifthly, as according to this method the fresh air comes either from near the floor, or from a door or window, great inequalities of temperature exist in the room, and various draughts are caused by the interchange of hot and cold air. It is necessary to utter a caution with reference to the phrase "the ascent of heated or foul air." Without pretending to question the repelling power of caloric, it is better for practical purposes to regard the phenomenon from another standpoint —that of the relative specific gravities of heated and cold air. By virtue of the attraction of gravitation, cold air must always descend, and in consequence of its descent the warmer air must either rise, being pushed up, as it were, to the higher place, or otherwise escape. Warm air cannot readily ascend against a superimposed mass of still warmer air, or air of less specific gravity; hence the assumption that heated air must always rise is incorrect, for it will ascend only when the air above it is of a lower temperature or greater density. The attempt, then, to ventilate a room by admitting cold air near the floor, as is often done, is unscientific. It is soon found that the heat and closeness are not abated until the warm air is let out, and the most ready escape for it is by the upper windows. After gasping caused by proximate suffocation, the upper sash is thrown open, and with the rush of warm air out, there is a rush of cold air in. This happens not only by the windows, but also by the ventilators near the floor, and numberless cross-draughts are the result. Even when the temperature outside is nearly the same as that within, which is probably the case on the majority of days in this country, the cold fresh air will not ascend from the ventilators near the floor, although of course there will be a gradual lowering of the temperature of the room. The only way to obtain fresh air will be by the windows. Should there be a fire in the room, it will draw air from every crevice above or below, and greatly exaggerate the evil. I need not suggest further reasons against this practice; the fact being that it is this method of which everybody complains, and which has necessitated the inquiry for a better system. Then it has been supposed that we might take advantage of the superior levity of heated air by providing a shaft up which it might ascend. This resource has been adopted upon the principle, no doubt, that the larger the quantity of heated air that can be collected in a mass, the more rapid its ascent—two cubic feet of heated air rising twice as fast as one cubic foot, and so for all proportions. The draught, moreover, is proportionate to the length of the shaft, and is measured by the difference between the weights of equal bulks of the ordinary air outside and the heated air in the shaft being multiplied by the height of the shaft. Thus, if the heated air were lighter than the external air by one ounce to the foot, and the shaft were fifty feet high, the heated air would ascend with a force of fifty ounces. These shafts have been provided in America, and in New York Dr. A. N. Bell(a) has conducted some investigations for the purpose of determining their efficiency. He found that the air in a close room provided with a ventilating shaft, when one of the windows was opened, yielded 17·2 parts of carbonic acid in 10,000. The window was then closed, and after the lapse of ten minutes, another examination gave 32·2 of carbonic acid, or an increase of 15·6 parts; thus showing the uselessness of a simple ventilating shaft. This failure is apparently owing to the temperature in a class-room rarely being sufficiently high to set up the necessary action in the shaft, and to the great specific gravity of carbonic acid which prevents its easy ascent. A ventilating shaft is, nevertheless, a *sine quâ non* for the perfect ventilation of a large room intended for occupation by numerous persons; but its action must be promoted by the use of a heating apparatus, for, under artificial conditions, natural laws must be subserved by artificial means. Now let us consider the best means for removing the foul air from a room and conducting it to the ventilating shaft. I maintain that in order to secure good ventilation the poisoned air should be carried out of the room as soon as it is breathed, so that the atmosphere of the room should be preserved in the utmost possible purity.(b) To do this the polluted air should be conducted away by means of apertures and tubes placed within a few feet of the flooring. For this purpose there should be a number of metal tubes (proportioned to the size of the room and the largest number of persons expected to occupy it) having hooded openings at about the level of the faces of the occupiers when seated—say three feet from the floor. These tubes might be ranged along the walls, or attached to any fixed furniture, as desks in a schoolroom, and should be carried under the flooring to a common duct or trunk. This common duct should be in connexion with a furnace in the ventilating-shaft, and the foul air conveyed by it might be either taken directly into the furnace and burnt, or it might be received into a chamber surrounding the furnace, and, becoming thus heated, carried away by a foul-air flue surrounding the smoke-shaft of the furnace. I prefer the first method, because it is simpler, and the foul air is effectually destroyed, and because I require the chamber for another purpose. In this way all the foul air would be drawn out of the room immediately it was expired, and would not contaminate the air introduced for respiration. The use of a stove would not entail much extra cost, as it would be required in winter to heat the room under any circumstances. In summer a ring of gas-jets in the shaft might answer the purpose of creating a draught. Suppose, then, that a single person, as already shown, deteriorates sixteen cubic feet per minute, one hundred persons would deteriorate 1600 cubic feet, which is equal to about twenty-six cubic feet per second; and as the velocity in the foul-air duct would be about six feet per second, it follows that a main duct with a cross-section of about four and a half square feet would suffice. The admission of pure air, for reasons already given, would be best done by the cornice or by the ceiling. Either part should be perforated with small apertures, whose aggregate cross-section should be rather in excess of that of the duct for carrying off the foul air. This method of ventilation is obviously opposed to those generally in use, inasmuch as it conducts away all the foul air by ducts near the floor, and admits fresh air by openings in or near the ceiling. Admitting the correctness of the principles upon which this system of ventilation is based, we feel bound to insist, in order that it should be practically successful, that it be not muddled and spoiled by introducing other oxygen-consuming and draught-causing agencies for which no provision is made in the calculations—to wit, there must be no free gas-lights nor blazing fires. By the proposed plan one stove in the basement would ventilate and warm every apartment in a house, and at a less cost than would be required to maintain a fire in several fireplaces. With an open fireplace there is an immense waste of caloric (consequently of fuel) and unavoidable draughts. If an open fireplace be considered indispensable, it, like the gas-lights, should have its separate supply of air from the outside. How important this is may be concluded from a consideration of the fact that one briskly burning fire will consume as much oxygen as forty or fifty persons, and would of course produce an equal demand upon the outer air for supplies to maintain its consumption.

(a) *Food, Water, and Air*, September, 1873.

(b) Mr. Martin, civil engineer of Boston, U.S., gave an excellent exposition of this method of carrying away the foul air, in a paper inserted about two years ago in a series of reports published by the Sanitary Board of New York. My argument follows his on this essential point.

OBITUARY.

JOHN GRANTHAM, F.R.C.S.

This esteemed member of the profession died on the 14th inst., at his residence, Crayford, Kent, in the seventy-third year of his age, after a long and painful illness, during which he received the unremitting attention of his old friends Professor Erasmus Williams and John Adams; latterly Mr. Henry Smith was associated with these gentlemen in consultation. Mr. Grantham, who received his professional education at the then united hospitals of Guy's and St. Thomas's, was admitted a Licentiate of the Society of Apothecaries and a Member of the Royal College of Surgeons on February 21, 1823, and an Honorary Fellow of the same institution on August 26, 1844. He was the author of a work entitled "Facts and Observations in Medicine and Surgery, with additional Memoirs." To the *Medical Times and Gazette* he contributed an interesting paper "On Ammonia as a Dermic Agent in Treatment of Disease." The deceased gentleman, who was a widower, leaves three daughters; his only son, a Member of the College of Surgeons, died a few years ago.

The deaths registered in the metropolis last week were 1636. During the last three weeks the mortality in London has exceeded by 30 per cent. the numbers returned in the three preceding weeks. This increase in the mortality was 28 per cent. in the West District, 24 in the North, 17 in the Central, 30 in the East, and 41 in the South groups of districts.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meetings, held on Tuesday, Wednesday, and Thursday, November 11, 12, and 13, the Licence to practise Medicine was granted to—

Clarke, Francis Edward. | Courtenay, John Hoysted.
Yeo, Gerald Francis.

The Diploma in Midwifery was granted to—

Clarke, Francis Edward. | Horne, Patrick.
Courtenay, John Hoysted. | Howard, William Wells.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma were admitted Members of the College at a meeting of the Court of Examiners on the 18th inst., viz. :—

Aspinall, Henry Moon, L.R.C.P. Edin., Fleetwood, Lancashire, student of the Edinburgh and Manchester Schools.
Benson, Percy Hugh, M.B. Aberd., Whitby, of St. Bartholomew's Hospital.
Brayn, Richard, Market Drayton, of King's College.
Chadwick, George James, L.R.C.P. Edin., Portland, Dorset, of Guy's Hospital.
Clunn, Thomas Robert Hood, L.S.A., Manor Bier, Pembrokeshire, of Guy's Hospital.
Conolly, Beaumont Rowley, Kilburn, of the Middlesex Hospital.
Dixon, Henry George, Dublin, of that school.
Elliott, Frederick Hawes, Andover, of University College Hospital.
Fenton, George Frederick, St. Remo, of King's College.
Firth, Charles, M.B. Lond., Norwich, of St. Bartholomew's Hospital.
Gould, Thomas, L.R.C.P. Edin., Halesowen, of the Birmingham School.
Hosking, William Henry, L.S.A., Ross, Westland, New Zealand, of the Charing-cross Hospital.
Hawton, James William Hambly, L.S.A., Devonport, of Guy's Hospital.
Houghton, Walter Benoni, Tottenham-court-road, of University College Hospital.
Hunt, Richard, Leeds, of that school.
Kesteven, Leighton, Holloway-road, of St. Bartholomew's Hospital.
Lechler, Henry Martin, M.B. Aberd., New Cross, of the Aberdeen School.
Lloyd, Morgan, Carmarthen, of Guy's Hospital.
Lowe, Charles Henry, Burton-on-Trent, of St. Bartholomew's Hospital.
O'Brien, James Octavius, L.S.A., Henfield, Sussex, of Guy's Hospital.
Parson, Henry, Clapham, of St. Thomas's Hospital.
Pilkington, William Binns, L.S.A., Crawshabooth, Lancashire, of University College Hospital.
Rigby, James Arthur, L.S.A., Preston, Lancashire, of Guy's Hospital.
Sheard, William, L.S.A., Croydon, of King's College.
Walmsley, Francis Henry, Manchester, of the Belfast School.
Watson, Percival Humble, Newcastle-on-Tyne, of that school.
Wilcox, Henry, M.B. Aberd., St. Neots, of St. Bartholomew's Hospital.

The following gentlemen were admitted Members on the 20th inst., viz. :—

Day, Edmund Overman, L.S.A., Hemel Hempstead, student of Guy's Hospital.
Douglas, Claude, Ilkley, Yorks, of St. George's Hospital.
Gibbings, Ashley, Chichester, of King's College.
Grant, John, M.D. Philad. and Toronto, of Newburgh, Ontario, Canada.
Greet, William Ambrose, L.S.A., Penton-place, W.C., of University College.
Keyworth, George Hawson, L.S.A., Wellingley, Yorks, of Guy's Hospital.
Lush, William Henry, West Lavington, of St. Thomas's Hospital.
Mason, Henry William, Cirencester, of St. Bartholomew's Hospital.
Philps, Vincent, Ongar, Essex, of King's College.
Pocock, Walter, Brixton-road, of St. Thomas's Hospital.
Pyburn, George Wilkinson, B.A. Cantab., Hull, of University College.
Vincent, Henry Bird, L.S.A., East Dereham, Norfolk, of St. Bartholomew's Hospital.
Whitington, Charles Edward, L.S.A., Tuxford, Notts, of Guy's Hospital.
Whittle, Edward George, Whitehaven, Cumberland, of University College.

Fourteen candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months. The half-yearly examination for the Fellowship of the College commences this day, and we understand that there is an unusually large number offering themselves.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 13 :—

Baskerville, John Dunbar, Kingstown, Ireland.
Findlay, A. C. T., Brooksby-street, Islington.
Gard, William John, Stoke Devonport.
Taylor, John William, Lewes, Sussex.

The following gentleman also on the same day passed his primary professional examination :—

Jones, Wm. Makeig, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BEEVOR, JOHN, M.D., F.R.C.P., M.R.C.S. Eng., L.S.A.—Medical Officer of Health for the Mansfield, Southwell, and Worksop Districts.

JACOB, EDWARD LONG, M.R.C.S. Eng., L.S.A., B.A. Lond.—Medical Officer of Health for Chertsey.

LEONARD, JOHN, M.R.C.S. Eng.—House-Surgeon to the Charing-cross Hospital, Strand, W.C.

RUSSELL, HENRY, B.A. Quebec, M.B., C.M.—Resident Surgeon to the Clinical Wards of the Royal Infirmary, Edinburgh.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—Astley Cooper, Staff Surgeon, second class, to the *Devastation*; Samuel Campbell, Staff Surgeon, second class, to the *Sylvia*: James Donovan, Surgeon to the *Newcastle*, additional for temporary service at Yarmouth Hospital; Charles J. Devonshire, Staff Surgeon, second class, to the *Eclipse*; William J. Volatti, Surgeon to the *Eclipse*; Frederick A. Nixon, Surgeon to the *Lord Warden*, additional.

WAR OFFICE.—MEDICAL DEPARTMENT.—Staff Surgeon Allen Bryson, M.D., from half-pay, to be Surgeon-Major, *vice* John Eldon Young, M.D., deceased.

BIRTHS.

BLACK.—On November 16, at 70, Marquess-road, Canonbury, the wife of Robert J. Black, M.D., of a daughter.

HARVEY.—On November 9, at 26, Rue Wissocq, Boulogne-sur-Mer, the wife of John S. S. Harvey, M.D., M.R.C.S., of a daughter.

PRESCOTT.—On November 14, at Woolwich, the wife of A. Knight Prescott, Staff Surgeon-Major, of a son.

WILL.—On October 17, at Trichinopoly, Madras Presidency, the wife of George Elmsly Will, Assistant-Surgeon Royal Artillery, of a son, still-born.

MARRIAGES.

EVES—COLLINS.—On November 12, at St. Philip's, Cheltenham, Charles T. Eves, Surgeon-Major H.M.'s Indian Army, son of the late Augustus Eves, M.D., of Cheltenham, to Caroline Agnes, youngest daughter of the late Henry Collins, Esq., of The Duffryn, Monmouthshire.

TOMES—COOK.—On November 12, at All Souls', Langham-place, W., Charles S. Tomes, B.A. Oxon., M.R.C.S. Eng., L.D.S., of 17, Albert-road, Regent's-park, to Lizzie Eno, daughter of Charles D. Cook, M.D., of Brooklyn, New York.

DEATHS.

BELL, Rev. WILLIAM, M.A., of Brasenose College, Oxford, eldest son of the late Thomas Bell, M.D., formerly of Cheltenham and Demerara, at St. Helier's, Jersey, on November 14, in his 47th year.

BURFORD, WILLIAM, M.R.C.S. Eng., L.M., late of Camden-road, at 1, Lancaster-terrace, Eastbourne, on November 17, aged 42.

COATES, MARGARET AMELIA, wife of Matthew Coates, F.R.C.S. Eng., Staff-Surgeon R.N., second-class, at 8, Stone-terrace, Devonport, on November 13.

CREAM, CHARLES A. H., eldest surviving son of R. Chevallier Cream, M.D., of Putney, Surrey, at Spring-gardens, Buff-bay, Jamaica, on October 10, in the 22nd year of his age.

DALTON, WILLIAM, M.R.C.P. Lond., F.R.C.S. Eng., L.S.A., late of Cheltenham, and formerly of Swansea, at Bournemouth, after a long and protracted illness, on November 12, in his 71st year.

GIBB, MARY CHARLOTTE, wife of Hugh Gibb, Surgeon-General Bombay Army, and only daughter of the late General Brackley Kennett, Bombay Army, at Glenyon, Central-hill, Upper Norwood, on November 10, in her 65th year.

GRANTHAM, JOHN, F.R.C.S., at Crayford, Kent, on November 14, aged 72.

PART, CAROLINE, wife of James Part, M.D., at 89, Camden-road, N.W., on November 8, in her 61st year.

TICEHURST, FRANCES ANN, beloved wife of W. D. T. Ticehurst, Surgeon 13th Regiment N.I., and eldest daughter of John Head, Esq., of Lewes, at Ahmednuggur, Bombay, on October 20, aged 32.

WATTS, ROBERT, M.R.C.S. Eng., L.S.A., late of Clifton, Bristol, at West Hackney, Middlesex, on November 14, aged 72.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BEDFORD GENERAL INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before December 10.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CONWAY UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Wm. Hughes, Clerk to the Guardians, on or before December 10.

DORSET COUNTY HOSPITAL.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman, on or before November 26.

HALIFAX INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. Candidates must possess at least one qualification. Applications, with testimonials, to the Chairman of the Medical Staff, on or before Nov. 25.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—House-Physician. Candidates must possess a recognised medical or surgical qualification. Applications, with testimonials, to the Secretary, on or before November 29.

KENT COUNTY LUNATIC ASYLUM, BARMING HEATH, MAIDSTONE.—Two Assistant Medical Officers. Applications, with testimonials, to Messrs. Beale and Hoar, Maidstone, before December 10.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, CITY, E.C.—Assistant House-Surgeon. Applications, with testimonials, immediately to George Croxton, Secretary.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, of whom particulars may be obtained.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, LOWER SEYMOUR-STREET, PORTMAN-SQUARE.—Surgeon to the Out Department. Candidates must be Fellows or Masters in Surgery, and registered. Applications, with testimonials, to the Secretary, on or before December 2.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

ST. GEORGE'S (HANOVER-SQUARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before November 24.

TEWKESBURY UNION, FORTHAMPTON DISTRICT.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to George Budham, Clerk to the Guardians, on or before December 16.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Droitwich Union.—Mr. John C. Gibson has resigned the Droitwich District; salary £100 per annum.

Wycombe Union.—Mr. J. J. Littlewood has resigned the Eighth District; area 3464; population 2409; salary £29 per annum.

APPOINTMENTS.

East Ashford Union.—Charles S. A. Atkinson, M.R.C.S. Eng., L.S.A., to the Workhouse; Joseph Manning, M.R.C.S. Eng., L.S.A., to the First District.

Epping Union.—Richard T. Grabb, L.R.C.P., M.R.C.S., to the Roydon and Great Parndon Districts.

Glendale Union.—George Smith, M.R.C.S. Eng., L.S.A., to the Ford District.

New Winchester Union.—Thomas Roberts, M.R.C.S. Eng., L.S.A., to the Twyford District.

Stockport Union.—Peter Downs, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Stockport District and the Workhouse.

Whitehaven Union.—Joseph Dixon, L.R.C.P. Edin., L.R.C.S. Edin., to the Harrington District; John Morrow, M.D., L.R.C.S. Edin., to the Lamplugh District.

UNIVERSITY OF DUBLIN.—SCHOOL OF PHYSIC IN IRELAND.—On Saturday last, November 15, the Board of Trinity College elected Thomas Evelyn Little, M.D., as University Anatomist, *vice* Dr. Edward H. Bennett, appointed Professor of Surgery. In his capacity of University Anatomist, Dr. Little becomes one of the Surgeons of Sir Patrick Dun's Hospital.

QUEEN'S UNIVERSITY IN IRELAND.—At a stated meeting of the Senate of the University, held at Dublin Castle on Friday week, the 14th inst., the following gentlemen were appointed examiners for the year 1874-75:—In *Medicine:* Henry Kennedy, M.B., Vice-President of the King and Queen's College of Physicians. In *Surgery:* James Valentine Browne, M.D., Professor of Surgery, Queen's College, Galway. In *Midwifery:* J. Rutherford Kirkpatrick, M.B. In *Materia Medica:* Walter George Smith, M.D., Censor of the King and Queen's College of Physicians. In *Medical Jurisprudence:* J. Emerson Reynolds, M.D., Professor of Chemistry in the School of Surgery, Royal College of Surgeons.

CITY OF DUBLIN HOSPITAL.—On Monday, the 10th inst., Mr. Arthur E. Barker, son of the late Professor of Chemistry in the School of the Royal College of Surgeons, Ireland, was elected Surgeon to the above institution in the room of Dr. William Thornley Stoker, recently appointed Surgeon to the Richmond Hospital.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE, JOHN-STREET, ADELPHI, LONDON, W.C.—The following arrangements have been made for the present year:—November 19—Opening Address by Major-General F. Eardley-Wilmot, R.A., F.R.S., Chairman of the Council. November 26—"On the Manufacture of Iron and Steel," by Sir Francis C. Knowles, Bart. December 3—"On Australian Vines and Wines," by J. T. Fallon, Esq. December 10—"On Mechanical Processes for producing Decorative Designs on Wood Surfaces," by Thomas Whitburn, Esq. December 17—"Whitby Jet and its Manufacture," by John A. Bower, F.C.S., Science Master, Whitby School. The chair is taken at eight o'clock.

AT the Clerkenwell Police-court, the other day, a milkman was fined £3 for selling adulterated milk. He quoted in defence our favourable report made some time ago as to the quality of the milk he sold. In our case, however, the milk was taken directly from the cow, the animal being milked directly into the vessel carried off. Had the dealer done so in the present instance he doubtless would have escaped a fine.

A CASE of true Asiatic cholera has been imported from Rotterdam, and landed in London, the patient dying in the London Hospital. The man was apparently well when he reached this country, and remained so for some time thereafter. This would lead us to believe that there must have been some source of infection on shipboard.

PROFESSIONAL EXAMINATIONS.—The following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the candidates for the diploma of Membership of the Royal College of Surgeons on the 14th inst., viz.:—1. State the local and general symptoms of a strangulated hernia in the inguinal canal, and describe the operation for its relief. 2. Describe the operation for placing a ligature on the radial artery in the upper third of its course. 3. Give the pathological anatomy, symptoms, and treatment of strumous ophthalmia (keratitis). 4. State the symptoms, diagnosis, and treatment of the various fractures of the upper end of the humerus. 5. What is necrosis? Describe its causes, the pathological changes which ensue, the bones most likely to be affected, and the surgical treatment. 6. What is talipes valgus? With what condition of foot is it commonly associated? Describe the treatment. The following were the questions on the Principles and Practice of Medicine, viz.:—1. Describe a typical case of enteric fever (typhoid), and in the absence of a rash distinguish it from acute tuberculosis, pyæmia, and meningitis. 2. You are called to a patient suffering from an acute affection of the chest after exposure to cold. State your reasons, according to the symptoms and physical signs, for believing that the patient has bronchitis, pneumonia, or pleurisy; or that he has a combination of these conditions. How would you treat him after your diagnosis has been made? 3. What do you understand by a nervine tonic? Give some examples from the Pharmacopœia, with doses of the medicines. Write one or two prescriptions for epilepsy.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Patterson, Constantinople.—We shall be glad to receive them.

Mr. W. Kirk.—Leslie's Pliable Plasters are to be obtained from Messrs. Mackey and Co., 2, Bouverie-street, Fleet-street, London, E.C.

Mr. Cooper.—Dr. Letheby's paper on "Disinfectants" was published *verbatim* as written. Portions, including that on street-watering, were omitted, as time would not permit the reading of the entire paper.

First Year.—The new edition of Wilson, edited by Dr. G. Buchanan, is a capital book, and if studied in the evening will well complement your day's work in the dissecting-room.

A. B.—The anecdote is as follows:—Douglas Jerrold at a party noticed a doctor in sober black waltzing with a young lady who was dressed in a silk of brilliant blue. "As I live!" exclaimed the wit, "there is a blue pill dancing with a black draught." It may not be out of place to relate the following:—Douglas Jerrold accompanied the late Mr. Wakley to witness some operations at the Royal Free Hospital. The first operation was amputation of the leg; the second was a minor one, for the removal of piles. Mr. Wakley told the wit the nature of the operation, and thought it was not worth his time to stay to observe it. "Oh!" said Jerrold, "I have seen the 'play,' and I would rather wait to see the 'after-piece.'" We believe this little episode with respect to Jerrold is now made public for the first time.

THE ARMY MEDICAL WARRANT OF NOVEMBER, 1873.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With regard to the Royal Warrant of November 1, 1873, I beg to point out that it perpetuates the injustice of depriving medical officers of the junior rank of the prospective claim to forage, stabling, etc., as a right, and as part of their emoluments on attaining the rank of field officer. I am one of those who have been serving for many years in the junior rank, and when nearly arrived at the top of the list of Surgeons I find that the most valuable privileges of the rank to which I aspire will, in virtue of the Royal Warrant of March, 1873, in all probability be taken from me. Having entered the service, and having served for many years under the conditions laid down in the Warrant of the year 1858, I feel that I am being treated with gross unfairness, and I hold that I am entitled to everything promised to me by the Royal Warrant under which I elected to serve. Perhaps those out of the service may not be aware of the value of the prospective claim which has been taken away from the junior medical officers of the army. To put it in a few words I estimate that the Surgeon-Major who is allowed forage will be able to keep his horse at the cost of about £6 a year, which is the sum given as wages to a soldier-groom. On the other hand, the Surgeon-Major deprived of the forage, stabling, and soldier-groom will keep his horse (often absolutely necessary on account of ill-health) at a cost of about £92 a year. In the cases given above, both officers may have entered the service under the same conditions,

and have served with the same expectations. The fortunate one being the senior by a month obtains his promotion before March 1, 1873, and gets all he bargained for; the other, by the unjust Warrant of March, 1873, is deprived of what he had every right to expect.

I am, &c., A. B.

COMMUNICATIONS have been received from—

Dr. Wood, Gloucester; Dr. Wilson, Cork; A. B.; Mr. Ingpen, London; Dr. Henry Russell, Edinburgh; Mr. G. Murray, Edinburgh; The Editor of "Nature"; Messrs. APPOINTMENTS FOR THE WEEK.

November 22. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 2½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

24. Monday.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Dr. Sansom. "A Case of Mitral Stenosis with Presystolic Murmur (with specimen)"; and "Cases of Exudation treated by the Aspirator." Mr. Jabez Hogg, "Cases of (1) Arrested Development of Left Eye; (2) Obliterated Lachrymal Duct in a Child of three years; (3) Multilocular Cyst in Neck of a Child of fourteen months, cured by Seton."

25. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Anthropological Institute, 8 p.m. Meeting.

Royal Medical and Chirurgical Society, 8½ p.m. Dr. Gee, "Case of Renal Calculi." Dr. Snow Beck, "Case of Fatty Degeneration of the Contractile Tissue of the Uterus; and on Cauliflower Excrescence of the Os Uteri."

26. Wednesday.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

27. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Hunterian Society (London Institution), 8 p.m. Dr. Phillips, "On Retro-uterine Hæmatocele." Mr. Rivington, "On Psoas Abscess."

28. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

Clinical Society, 8½ p.m. Dr. George Johnson, "On Cases of Temporary Albuminuria, the Result of Cold Bathing." Mr. Henry Arnott, "On a Case illustrating Professor Esmarch's Method of Preventing Loss of Blood during Surgical Operations by means of Elastic Bandaging." Dr. Cayley, "On a Case of Hæmoptysis."

Queekett Microscopical Club, 8 p.m. Dr. Braithwaite, "The Histology of Plants."

VITAL STATISTICS OF LONDON.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·93 in. The highest was 30·23 in. on Saturday, and the lowest 29·68 in. on Thursday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON UMBILICAL HERNIA.

By JOHN WOOD, F.R.S.,
Surgeon to King's College Hospital; Professor of Surgery in King's College, London.(a)

Gentlemen,—During the last few months we have had a good many cases of umbilical rupture, both in the infant and adult. The frequency of this complaint, and the importance of dealing with it properly and at an early stage, will speedily be recognised by each of you when charged with the responsibilities of practice. And this consideration has led me to choose this for the subject of my remarks to-day. Now, there are two varieties of hernia which usually come under the denomination of umbilical. The most common, and the most curable fortunately, is seen in very young infants and children. The other occurs in adults, most of whom have been subjected to distension of the abdominal cavity from corpulency or pregnancy, or both combined.

The *infantile* form is invariably more or less *congenital* in its formation, although it may not show itself to a noticeable extent until after the lapse of some months or even years after birth. Even in these latter instances a careful examination of the cicatrix which is left by the drying up and dropping off of the navel-string would reveal an imperfect closure of the fœtal opening, and perhaps a small protrusion at times when the infant cries. In order to understand its formation it is necessary for you to review the developmental changes which result in the formation of the placenta and umbilical cord and their differentiation from the fœtal portion of the ovum. At the beginning of the second month after conception the structure which ultimately becomes the umbilical cord is formed by the approximation and final connexion of the two vesicular processes, originally quite distinct—viz., the *umbilical vesicle* and the *allantois sac*. The former contains the yolk or early nutriment of the fœtus, and is connected by a canal—the *omphalo-enteric duct*—with the intestinal tube at the place where afterwards the ileo-colic valvular apparatus is found. The straighter part of the intestine below the point of connexion becomes afterwards the colon, with its vermiform appendix. The part nearer to the stomach becomes developed into the coils of the small intestine. These latter during the second month protrude into the substance of the cord for a considerable distance beyond the point where its highly elastic and gelatinous-looking substance becomes continuous with the abdominal wall of the fœtus. On the stomach side, or above these coils, the omphalo-mesenteric vessels pass from the umbilical vesicle to join the proper mesenteric vessels of the fœtus. Below them are the placental arteries accompanying that part of the allantoic duct which forms the urachus; above these, and, passing at this early stage almost directly backwards, is the umbilical vein on its way to the liver.

As development progresses, the coil of small intestines which is found at first in the interior of the umbilical cord becomes gradually withdrawn into the enlarging abdominal cavity, and the supplemental pouch of quasi-peritoneum formed within the hyaline substance of the cord becomes aborted, and finally obliterated. From this time the umbilical opening is occupied by the enlarging umbilical arteries and vein with the gradually dwindling urachus.

Thus the navel must be considered as a sort of double cicatrix, the upper portion of which is formed by the vessels of the umbilical vesicle, and the lower division, which becomes later on the chief constituent of the navel, is occupied by the placental vessels and urachus. Between these lies the pouch formed in the substance of the cord for the primary development of the folds of the small intestine. This arrangement you will find well demonstrated in a specimen of an ovum in the collection of Dr. Sharpey (published in Miller's "Physiology," Baly's translation, 1843, second edition, vol. ii., pl. iii. and iv.). If, however, the complete development of the infant is from any cause retarded or rendered irregular, this pouch of the navel-string may be to some extent persistent at the time of birth, just as the canal of Nuck may be in the groin.

In examining the bodies of prematurely stillborn infants, I have found this pouch extending into the navel-string to the extent of half an inch. By the first struggles of the child, or by the pressure made upon its abdomen in parturition, the bowel may at once appear as a protrusion within the cord, constituting the so-called *hernia of the umbilical cord*. In such cases that portion of the cord which covers the hernial sac does not shrivel like the rest, but assumes, in discharge of its continued functions, more or less of the appearance of the surrounding skin. In cases where the pouch remains, but no actual rupture is present, the portion of navel-string which invests it becomes enfolded in the cicatrix, which is wrinkled and inverted by the contraction of the umbilical vein and arteries, so as to form a larger, more puckered, and deeper depression than normal. This may afterwards become protruded and distended under the pressure of the abdominal viscera, and form that kind of umbilical hernia which appears directly or soon after birth. In all these cases the membrane which is technically called the peritoneal sac at this point is exceedingly attenuated, and in some instances hardly demonstrable. It is an imperfect formation, and for practical purposes may be esteemed non-existent. It is so adherent at the edges of the opening to the aponeurotic structures that it allows of no dragging or displacement of the surrounding portion of serous membrane, and the tension to which it is speedily subjected spreads it out into a very open mesh of tissue, having but slight resisting power in itself. I have seen several cases in which the tube of the urachus also remained pervious after birth, and exuded urine (sometimes in considerable quantities) in the exertion of crying or micturition.

Practical accoucheurs usually warn the student against tying the navel-string too close to the body of the child, for fear of including in its grasp a loop of intestine which might be present in a hernia of the umbilical cord. But it seems to me that the opposite habit of extreme caution in this respect leads to the application of the string at such a distance from the body that a portion of the root of the cord containing a tubular pouch may still remain, and leave a weakness at the part predisposing to a future protrusion. Thus it is not closed, as it might easily be at this time, by placing the ligature closer up to the abdominal wall. Of course care should be taken in doing this that any intestinal contents should be pressed out of the cord; and this is best done by pressure with the fingers, and then giving the cord a gentle twist on its own axis before applying the string.

The formation of so-called umbilical hernia later in life in adults who have a tendency to corpulency usually differs considerably in its pathology from that of the infant. A close examination will usually show that the opening into the abdominal cavity is placed in the linea alba above, below or to one side of the real navel. As the tumour increases in size, and the skin is distended over it, the navel becomes drawn over it so as to appear to form its point of departure. In the larger cases the bulk of the tumour is found to be below this point, and the part where the edge of the hernial opening presses most acutely and forcibly upon the contents, and most commonly strangulates them, is at the lower border. The weight of the protrusion itself increases this effect, and tends to bring the tumour lower on the abdomen as it increases in size.

The linea alba is perforated more or less regularly by branches of deep and superior epigastric vessels and twigs of nerve forming the terminal distribution of the intercostals. As the individual grows fatter, the adipose tissue is apt to form in masses extending along these vessels from the subperitoneal fat. The tendinous apertures lodging them are also under these circumstances frayed out by over-distension, and gradually become enlarged. If at this time, by illness or sudden alteration of habits, as after parturition in females, the fat is absorbed or the tension relaxed, a protrusion of omentum behind the peritoneum pushes forwards that attenuated membrane, and forms the sac of an incipient rupture, which may speedily increase under the effects of a bronchitic cough or the straining of constipation or defæcation. As a rule, while the umbilical rupture of children hardly ever contains omentum (which is at this age very scanty and imperfectly formed), but usually includes small intestine only, the rupture of adults almost always contains omentum, sometimes much thickened and hypertrophied, and may contain a portion of colon instead of, or in addition to, small intestine. In very large cases even a portion of the pylorus and duodenum may

(a) Delivered at King's College Hospital on October 10, 1873.

be involved, giving rise to distressing irritation of the stomach. I have seen many hernial protrusions, both in the child and in the adult, in the linea alba above the umbilicus, somewhat about midway between it and the xiphoid cartilage. At first, these are always formed of lobules of subperitoneal fat, sometimes constituting quite a fatty tumour, which has a distinct impulse on coughing, and can be pressed inwards to a certain extent, but never completely reduced. In after years these may certainly become developed into real herniæ, with a peritoneal sac containing bowel. Usually, with a little care in treatment, this may be prevented, since the opening is placed above the reach, as it were, of the small intestine, and is protected by the apposition of the liver and its round ligament.

The *diagnosis* of the umbilical herniæ of children is seldom difficult. Carcinomatous or other growths from the site of the navel-string may occasionally appear in early infancy, and receive a doubtful impulse in coughing. Their consistency, unyielding bulk, unvarying nature, and steady growth, will usually suffice to distinguish them. Chronic peritoneal abscesses may cause more difficulty. These make their way to the umbilicus, guided by the superior ligament of the bladder or round ligament of the liver, and in their earlier stages closely resemble umbilical rupture. They yield to pressure, and may be entirely pressed back into the abdominal cavity, and give a distinct cough-impulse. The previous history of abdominal inflammation or enlarged glands, the constitutional hectic, and afterwards a fluctuation felt in the tumour, will sufficiently distinguish them even before their final discharge of pus. An imperfectly closed urachus may also simulate umbilical rupture. Cases have been known in which small urinary calculi have been thus voided.

The herniæ of adults are most likely to be mistaken for subcutaneous fatty tumours; and, indeed, many of these supposed ruptures consist really of a fatty growth from the subperitoneal tissues protruding through the apertures before described. Though sometimes yielding a sort of impulse, and so simulating a real omental hernia, they are usually found destitute of a true cough-impulse, by reason of adhesions at the tendinous opening and other consolidating changes. *Hydatid cysts* may also be found in this situation.

The *treatment* of umbilical rupture in the child is fortunately very powerfully aided by the persistent tendency to a more perfect development which prevails after as before birth. If observed early and treated skilfully, these protrusions may usually be cured by the second or third year, and frequently in much less time. The protrusions of fatty lobules from the subperitoneal fat, however, are much more slow to disappear both in the child and adult. In these the chief care should be directed to prevent a rupture from succeeding them if the fat becomes absorbed, which may result from the intervention of some acute disease or anything causing the general removal of adipose tissue. Continued pressure will also accomplish this result, if carefully applied and maintained. In some cases I have removed these growths with the knife with success, and without the occurrence of peritoneal mischief. It should be borne in mind, in dealing with any kind of tumour about the linea alba, that it may be deeply and closely connected with the peritoneum, and may arise from pathological changes occurring in these fatty peritoneal outgrowths.

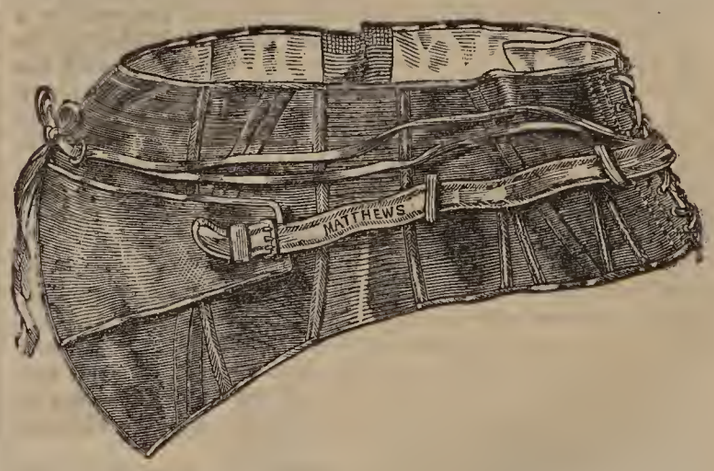
The readiest way of applying pressure to the umbilical ruptures of children is by means of common strapping placed over a flat piece of lead or pewter, or, what is usually more at hand, a penny-piece. This should be first enclosed in folds of strapping applied with the sticking side outermost, so as to adhere to the skin over the tumour. Over this broad straps of soap or adhesive plaster should be placed across the entire abdominal surface, and surmounted by a belt or bandage. This, though a valuable temporary expedient, can with difficulty be long maintained, on account of the constant trouble of changing, the liability to soreness and irritation of the skin, and a certain degree of skill which is demanded for its proper application. Very cheap and efficient appliances are now made by the surgical apparatus manufacturer, consisting of a broad belt of indiarubber, on the under surface of which is placed a pad for application to the protrusion. Some of these, however, I must warn you, are based on false principles, and, if they do anything at all, are apt to do injury instead of good. The difficulty experienced by the maker is to make the pad keep its place, and in order to effect this a convex or conical protuberance is placed within the hernial aperture like a cork in a bottle. Now, if this is effective in maintaining its position, its action necessarily is to accomplish a dilatation of the yielding borders of the ring, and thus to perpetuate and increase the rupture. If inefficient, it slips out of the aperture, and affords no resistance to the escape of the bowel; the only result being a dangerously false security.

Some years ago I devised a pad, consisting of an indiarubber ring adapted to the size and shape of the edges of the opening, which should press only on the edges, with the same tendency to close them as by pressure with the fingers in reducing the protrusion. The central aperture is covered over by a tense drum-like layer of indiarubber, which affords resistance to protrusion indeed, but produces no invaginating pressure. A figure of this umbilical pad is given in my work "On Rupture," and also in the last edition of "Druitt's Vade-Mecum." Latterly, Messrs. Matthews have modified this pad by an ingenious arrangement of air-pressure in the apparatus I show you. The ring pad itself is made into an indiarubber air-cushion, with a small aperture of communication into a globular air-chamber made of a thinner substance of the same material, and placed within the opening of the ring. Under ordinary pressure the projecting outline of the ring presses only upon the edges of the hernial opening, but under sudden succussion—as by a cough or laugh—some of the air is forced into the central globular cushion, and protrudes it, so as to meet the advancing rupture, and force

it back by an elastic rebound resulting from the same impulse which tends to force out the rupture. For certain cases this is decidedly an improvement. All this is aided by the elastic reaction, also, of the indiarubber belt which maintains the pad in its place. This should be broad enough to keep well in position, and may advantageously be fastened by loops to the dress of the child to prevent its shifting round, as it is apt to do in its fidgety movements. A free use of violet powder or starch will aid in preventing chafing.

In cases of fatty peritoneal growths a perfectly hard and flat pressure, as by a plate of metal or ivory, is the most likely to do good and cause the absorption of the tumour.

In umbilical rupture in the corpulent adult less hope can be entertained of a cure, but much comfort can be insured by a proper belt. This should be broad enough to cover the abdomen almost entirely, with elastic material at the sides, a lace up the



back, and kept from rucking up by whalebone ribs. Additional power may be obtained by a strap over the lower part of the protrusion, buckling at the side, and adapted to counteract the tendency to increase downwards and forwards in these cases. If the hernia be entirely reducible with comfort to the patient, an umbilical pad like those just described will be sufficient. But in many instances either a portion of the omentum or bowel remains permanently irreducible, or, if reduced, makes the patient feel so uneasy that it is impossible to maintain it in this situation. In such cases a concave or hollow pad is indispensable. It should have a raised, rounded rim or border of some soft and elastic material, as indiarubber, and should be

based on and supported by a shield of thin copper or other metal of the same shape to protect the protruding mass from accidental blows or injury from the clothing. In large cases, in corpulent people with pendulous bellies, the whole belt should be maintained in place by shoulder-straps, or even a perineal band or thigh-slop may be required.

The limits of this lecture, gentlemen, will not allow me to revert to operations which are sometimes required for the relief of umbilical ruptures, which I must accordingly reserve for some future opportunity.

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Resident Medical Officer of the London Fever Hospital.

No. XII.

(*For Photo-lithographic Plate, vide Medical Times and Gazette, November* 1, 1873.)

The Pulse in Typhoid Fever: the Respiratory Undulation—Typhoid with Hæmorrhage—Typhoid with Pneumonia—Acute Rheumatism with Pericarditis—Value of the Sphygmograph in Acute Disease.

Some examples of the pulse in typhus were discussed in the preceding paper, though the tracings reproduced in the plate do not convey any idea of the extremely bad form generally assumed by the pulse in this disease; for if the wild delirium of a severe case can be sufficiently soothed or restrained for a tracing to be obtained, yet later on the running, scarcely perceptible quiver, which frequently is all that occurs in the arteries of such a patient—the indication of the exhausted, fluttering heart,—cannot be traced by the sphygmograph, on account of the constant subsultus and restless involuntary movements which accompany the exhaustion that follows. Those tracings, therefore, which have been described, bad as they are, only represent the pulse in cases which have either been mild throughout, or else where death has ensued early in the disease from a heart previously feeble that has utterly broken down under the strain. The same conditions do not occur in enteric fever: in these cases from the beginning to the end a tracing can generally be obtained; the patient is more manageable, the fever much less intense. Indeed, in a mild case the disease will run its course without the pulse ever becoming *fully dierotie;* and in severe cases only does it become *hyperdierotic.* Those pulses which to the finger feel most dicrotic are merely *fully dierotie* pulses, with a large dicrotic wave, such as in Fig. 7, Pl. x. This pulse felt very dicrotic to the finger, although the so-called aortic notch does not dip below the line. In the most extreme forms of hyperdicrotism, such as in Fig. 7, Pl. ix., the double-beat cannot be distinguished by the finger. This form of pulse was probably described as a soft collapsing pulse by the older writers, and its true physiological meaning never appreciated. The finger, however, educated by the assistance of the sphygmograph, readily learns to distinguish it.

The form of pulse in enteric fever varies with the complications that may exist; it may become full, hard, and non-dicrotic when albuminuria coexists. This character will be considered hereafter. It may be undulating and hyperdicrotic from lung complication, or it may become extremely rapid and flickering after severe hæmorrhage. Deaths do not usually occur in this class of cases from failure of the heart, except in some instances where pneumonia has supervened and impressed its own characters on the disease.

The first case illustrated in Pl. x. is that of a lad, aged 16, a baker, who, like all of his trade when suffering from enteric fever, had an extremely severe attack, narrowly escaping death. He was admitted into the London Fever Hospital on July 25, 1873, having already kept his bed ten days. As he admits feeling ill for four days previous to this, he was at least in the third week of his fever, probably near the end of it. He had been much neglected, and when admitted was in a very exhausted condition, presenting typically what is known as the "typhoid state"—lying low in the bed, with a dusky, heavy countenance; he had to be roused before an answer could be obtained; he spoke with difficulty; his mouth was constantly open; teeth, gums, and lips covered with sordes; tongue dry, brown, and hard; breathing rapid and rather laboured; no cough or expectoration; abdomen full, soft, and tender, with much gurgling in right iliac fossa, and one or two rose-coloured spots. There was impaired resonance over both apices, before and behind, with coarse breathing, and occasional rhonchus; the urine was albuminous; his temperature was 105° Fahr. on the evening of admission, pulse 120, and respirations 36 per minute. All night he was very restless, with wandering delirium; he passed characteristic typhoid stools, but had not severe diarrhœa. His morning temperature was 104·5°, pulse 112, and respirations 32; while on the evening of the same day his temperature was 105·3°, pulse 120, and respirations 32. On this day the tracing reproduced in Fig. 1, Pl. x., was obtained; it is one from which the worst prognosis would be given, and recovery deemed impossible. It indicates an overtaxed heart: percussion has disappeared; the upstroke is short and rather sloping; the apex is perfectly rounded and very broad; the heart is contracting laboriously, the commencement being gradual instead of sudden; the systole is prolonged; and the tidal wave is consequently unduly sustained. The heart is not, however, actually feeble, for the pulse requires a pressure of four ounces to develope it to the extent seen in the plate. It is evidently labouring to overcome obstruction in front; the pressure in the vessels is comparatively high for fever—a condition that is always coincident with albuminuria, and also, though to a less extent, with pneumonia, both of which conditions are here present. This is probably the reason of the pulse being comparatively slow—viz., 112 per minute. The heart's contraction being thus slow and laboured, and the tension high, the dicrotic wave is correspondingly ill-developed. The degree of dicrotism also varies from one pulsation to another, sometimes being only *fully*, at others *hyper-dicrotic.* This is accounted for by the blood pressure varying with the movements of respiration. The same cause explains the different degrees of suddenness of the heart's contraction, some of the upstrokes being more abrupt and vertical than others, and the apices of these are not quite so round. When the tension is lowest, then the contraction is most sudden, and the dicrotism most marked. Einbrodt has proved experimentally that variations in the arterial tension are produced by the respiratory movements. He found the lowest tension to be coincident with a period immediately succeeding the commencement of inspiration; after that the tension gradually increases till expiration commences, when it continues to increase for a short time, and then during the remainder of expiration begins to fall, which it continues to do till after the commencement of inspiration, when the minimum tension is again reached. The increase of dicrotism coincidently with decrease of tension is best seen in Fig. 15, Pl. x., in which the respiratory undulation is particularly well marked. It is but imperfectly developed in the present instance.

Under the influence of free stimulation, good nourishment, and jacket poultices, the lad very rapidly improved. Two days afterwards his pulse had greatly regained power; his temperature had fallen a degree or more, being 103·5° in the morning, and 103·8° in the evening; his pneumonia also was relieved, the dulness at the apices being diminished and his respiratory murmur almost normal all over the chest. That rare eruption, the "*taches bleuâtres*" of French authors, appeared on this day. There were several patches of these blue spots on the abdomen, looking like small ecchymoses, or still more like half-wiped-off smears of ink. These spots are stated by Murchison and Trousseau to occur in mild cases. This, however, does not appear to be the opinion of all authorities; it certainly was not true in the present instance. The pulse had now the form represented in Fig. 2, Pl. x.: the percussion is good, the upstroke vertical and high, while, though hyperdicrotic, the dicrotism is not excessive; the blood-pressure was rather high, as the tidal wave is too much sustained, giving a tendency to a square summit; and the pressure employed was considerable —*i.e.*, four ounces.

On the following day (July 29) the pulse showed a diminution of power (*vide* Fig. 3, Pl. x.): the upstroke is a little shorter, the apex less pointed, and the pressure employed rather lighter. The dicrotic wave appears more developed, probably because the tension is less. The temperature was higher on this day; on the next it had risen still further, being 104·4° in the morning and 105·2° in the evening. His breathing was again difficult; coarse breathing and rhonchus on deep inspiration were audible all over the chest. There

was a crackling sensation imparted to the hand on palpation. His pulse was much worse; the tracing is reproduced in Fig. 4, Pl. x.—a great undulation in the respiratory line is visible, while the dicrotism is much increased. Fig. 5, Pl. x., was obtained on August 1, when the temperature had fallen to 102·8° in the morning and 104·2° in the evening, and his breathing was very much improved. He was, however, still very ill, having constant delirium and great restlessness. The tracing shows an over-taxed heart, the tops often losing their sharpness. Fig. 6, Pl. x., obtained on August 3, shows a great improvement, though his temperature, which had previously fallen, again suffered an exacerbation, reaching 103·4° in the morning and 104° in the evening. Some undulation in the respiratory line is again visible. Figs. 7 and 8, Pl. x., obtained on August 4 and 11 respectively, show the gradual return to the convalescent state; the albumen had disappeared from the urine when the last of them was taken. He still remained, however, in a condition of partial dementia till August 22. During the whole of this time his temperature kept up to about 99°, varying a little above and below this point from day to day. The pulse during the same period felt strikingly dicrotic to the finger. It was attempted to alter this character by digitalis, but without success. This series of tracings is characterised throughout by the high pressure required to develope the pulse. This would be sufficiently accounted for by the presence of albuminuria and pneumonia, were it not that when convalescence had commenced, as in Fig. 8, Pl. x., the albuminuria and pneumonia both having gone, the same high pressure was required—*i.e.*, four ounces.

The next four tracings were obtained from a case in which severe hæmorrhage from the bowel occurred.

C. M., aged 22, was admitted into Guy's Hospital, December 15, 1871. On that day he appeared to be doing well, and his fever to be of a mild form; his temperature in the evening was only 102·8°, pulse 94, and respirations 28. Fig. 9, Pl. x., represents his pulse on that day: it is but slightly dicrotic; the only noteworthy feature about it is the considerable pressure required to develope it—viz., five ounces. It is possible this character may have had some connexion with the hæmorrhage which subsequently occurred. On the following morning his condition appeared unchanged, his temperature being 102·3°, pulse 94, and respirations 28. The pulse-tracing on this day, Fig. 10, Pl. x., showed no change from the preceding one, save that it was a trifle larger. Before night, however, very profuse hæmorrhage from the bowel occurred, which left him blanched, unconscious, and apparently moribund; his pulse being barely perceptible to the finger, as a slight running movement which could not be counted. The sphygmograph gave the tracing reproduced in Fig. 11, Pl. x.—a feeble, small upstroke, with a comparatively large dicrotic wave. With every movement of inspiration a great diminution of tension or blood-pressure occurred, such as is seen in the middle of the tracing. The pressure now employed was even greater than before—viz., six ounces,—but the artery appeared contracted, and a considerable pressure was required to invade the contracted, and therefore thickened, wall sufficiently to obtain a tracing. Under the influence of brandy and opium he recovered considerably from this condition of exhaustion, and on the following morning the tracing obtained (Fig. 12, Pl. x.) had very greatly improved: the arterial contraction had relaxed, and it was now somewhat similar to that obtained before the hæmorrhage; the dicrotism, however, had increased, and the tension varied with the respiratory movements; the pressure, also, was diminished to three ounces. Unfortunately, with the relaxation of the arteries the hæmorrhage returned, and death ensued the same evening.

The next case illustrated in the plate is one of enteric fever complicated by double pneumonia: a case in which the pulse assumed its worst form—one from which there is no hope of recovery. J. H., a woman aged 25, was admitted into the London Fever Hospital on May 5, 1873. She had been a hard drinker, and had lived a dissolute life. On admission she had nearly completed the third week of her fever. She to be appeared extremely ill; her lips and gums were covered with sordes, cheeks flushed (especially the right one), with hot and dry skin; slight jaundice and parched tongue, with thin yellow fur. Her abdomen was full, soft, and tender, covered with a profuse eruption of rose spots. There was slight dulness, with small crepitation at the base of the right lung, and impaired resonance, with somewhat tubular breathing and increased vocal resonance at the apex of the same side. The sputa were rusty and tenacious; the temperature being 104° both in the morning and evening. With this general condition her pulse was extremely hyperdicrotic (Fig. 13, Pl. x.) and rather soft, only requiring one ounce and a half of pressure; percussion, however, was good. There was no undulation in the respiratory line; the breathing was not at this time distressed. On the following day she was much worse; laid low in the bed, with a dusky countenance and thick speech. Sordes were more profuse, tongue chapped, lips tremulous, unable to expectorate the tenacious pneumonic sputa. In the morning her temperature was 104·4°, pulse 176, respirations 44. Her breathing had now become rapid and difficult; moist sounds were audible all over both lungs, there was dulness at both bases, and diminished resonance over the whole chest. In the evening her temperature had fallen to 102·8°; her pulse was intermediate between the forms reproduced in Figs. 13 and 14. The dicrotism had diminished, but was more than is visible in Fig. 14, while the pressure required was still only one ounce and a half. The undulation in the respiratory line was now well marked. On the day succeeding this her condition was even worse: her breathing was terribly distressed, and she was unable to protrude her tongue; her temperature was falling rapidly. The pulse-tracing (Fig. 14, Pl. x.) has altered materially; it indicates obstruction to the circulation. The dicrotism is much diminished, while the pressure required has greatly increased, four ounces being now employed.(a) The respiratory undulation is well marked. On the following day she was moribund, being unconscious, speechless, and sleepless, with paralysis of the bladder, the heart having completely failed to overcome the increased strain thrown upon it. Her temperature had fallen to 98·2°. The tracing obtained on this day was of a hopeless character; it is reproduced in Fig. 15, Pl. x. The blood-tension is constantly varying with the respiratory movements, as does also the dicrotism; the upstrokes are sloping, and the heart evidently failing. In this tracing, as mentioned above, the coincidence of the greatest dicrotism with the lowest tension is well marked. She died on the evening of this day. An autopsy revealed the usual intestinal lesions accompanying enteric fever and general pneumonia of both lungs, with hepatisation of both bases and right apex.

In acute rheumatism the pulse assumes a variety of forms, but in each case it takes its character from the complication which exists, or from the form assumed by the fever. In a simple case of acute rheumatism, the pulse is most frequently non-dicrotic, and of the sthenic variety; but in a large number of cases where the fever either occurs in a delicate subject, is much prolonged, very intense, or complicated by bronchitis or pneumonia, the pulse may assume any degree of dicrotism. Indeed, this disease well deserves a plate devoted solely to it, but as it is inconvenient to do this, one form of pulse which is peculiar to it must be illustrated here—it is the pulse produced by pericarditis, of which the last series in the plate affords well-marked examples.

W. H., a lad aged 18, was admitted into the Highgate Infirmary on August 28, 1872, suffering from a slight attack of acute rheumatism; from this he became convalescent, but on September 18 he had a sudden and severe relapse. The swelling and pain in the joints became more general. There was profuse sweating, with severe pain over the sternum, and inability to take a deep breath. There was a loud to-and-fro pericardial rub over the heart, the action of which was rapid. The breathing was shallow, and the respiratory murmur coarse. In the evening, when the tracing was obtained, his temperature was 103·8°, pulse 160, and respirations 50 per minute. His pulse is represented in Fig. 16, Pl. x. It is the pulse always produced by pericarditis; its characters are very peculiar, the most so being the absence of dicrotism. The heart is acting in an extremely excited manner; the impulse is forcible and very sudden, as indicated by the well-developed percussion-wave. The length of systole appears prolonged, the tidal wave being sustained. Both of these features are accounted for by the excited action of the heart when its envelope is inflamed, but why the dicrotic wave should be absent it is not so easy to say: a rapid and forcible action of the heart is generally found to increase dicrotism, except under certain conditions of high pressure and sthenic inflammation, but even in these cases the dicrotic wave is still present, though but slightly developed; it retains, moreover,

(a) In the plate the pressure is erroneously marked as one ounce and a half; it should have been four ounces.

its usual position in the downstroke of the tracing; but in the pulse of pericarditis it is altogether absent, and the arteries during diastole appear empty. The tracing resembles more than anything that of aortic regurgitation, but there is no reason to think that the aortic valves act imperfectly in these cases; possibly the greatly prolonged systole may account for it.

To return to the case, however. On the day following that on which this tracing was obtained (*i.e.*, on September 19), effusion into the pericardium appears to have taken place. His lips and extremities were dusky, finger-nails blue; he complained of numbness and loss of power in the right arm; the veins generally were distended; he suffered from vertigo; the area of cardiac dulness was increased, extending to top of sternum; he had some cough, with scanty rusty sputa. His morning temperature was 104·6°, pulse 142, and respirations 36. His pulse-tracing (Fig. 17, Pl. x.) had improved; the impulse was less excited and forcible, the percussion-wave being greatly diminished. The artery, moreover, does not become so completely empty during diastole, though there is not a vestige of the dicrotic wave. On the following day (September 20) his pericarditis was subsiding, and his breathing easier, though the least movement caused him to become extremely blue and almost asphyxiated. The pericardial rub was diminished, while the area of cardiac dulness was still much increased. There was loud rhonchus, coarse breathing, and impaired resonance all over the chest; his temperature in the morning being 101·2°, pulse 130, and respirations 40. The pulse-tracing (Fig. 18, Pl. x.) had much improved, being smaller and less excited, while the dicrotic wave had reappeared. Three days afterwards, having steadily and rapidly improved, his pulse became normal (Fig. 19, Pl. x.), though his temperature still remained up, being 100·4° in the morning, with pulse of 120, and respirations 56. He still had a good deal of lung-trouble, but his pulse was of a sthenic nature.

The following day he again relapsed, suffering this time from pleurisy and pneumonia. His pulse did not return to the non-dicrotic pericardial form, but became extremely hyper-dicrotic; and later on his condition was almost hopeless, his breathing becoming as rapid as 92 per minute, and the respiratory undulation was strikingly developed in the pulse. He, however, eventually recovered from his fever, though a mitral systolic bruit remained permanent.

The value of the sphygmograph in fevers and other acute diseases may be enunciated thus:—As a means of scientific clinical observation and research it affords great assistance, and is full of interest. It gauges more accurately than can be done by any other means the power of the heart and the mode of its contraction; it warns us of its failure. It is the chief, if not the only, indication of the vascular conditions of high or low tension in the arteries. It distinguishes between the sthenic and asthenic forms of fever. It often affords valuable indications for treatment, especially in the administration of stimulants. Lastly, it is of some value in prognosis.

(*To be continued.*)

ON DIPHTHERIA: WITH ESPECIAL REFERENCE TO A RECENT EPIDEMIC IN ITALY.

By ROBERT HUNTER SEMPLE, M.D., M.R.C.P.L.,
Physician to the Bloomsbury Dispensary.

(*Continued from page* 547.)

BEFORE continuing my remarks on the late epidemic of diphtheria in Italy, it is necessary again to allude, although briefly, to the essential characters of that disease, and to the views which I entertain as to its nature. Diphtheria is essentially characterised by the presence of a skin or pellicle (διφθερα), not necessarily occupying the fauces or the air-passages, but very often found in those parts—in fact, it may appear in the nose, in the pharynx, in the Eustachian tube, in the vulva of females, on the conjunctiva, and even on other parts of the mucous membrane, or on the skin. In order to constitute the disease diphtheria, the pellicle must be also of a peculiar character, such as has been frequently described, and is now, or ought to be, well known.

When I am asked, therefore, whether diphtheria is the same disease as croup, I answer—Decidedly not, because, however vaguely the latter name may have been used, nobody pretends that diphtheria affecting the nose or the pharynx or the cutaneous surface of the body, is croup. It should also be mentioned that the work "croup" (which etymologically has no signification at all) has been employed to designate sometimes an ordinary inflammation of the larynx and trachea, sometimes a specific affection characterised by the presence of a distinct false membrane, and sometimes a spasmodic affection due to excentric causes; and, it may be added, it has also been used to denote the stridulous breathing which may be due to tumours in the larynx or trachea. It would, therefore, be equally absurd to describe croup, in this wide sense, as synonymous with diphtheria, which, as I have just remarked, is characteristically distinguished by the presence of a false membrane. But I have no hesitation in repeating my conviction that croup (so-called) with pseudo-membranous exudation is the same disease as diphtheria attacking the air-passages. In this sense, and in this alone, croup and diphtheria are synonymous terms, but I think it would be far better if the former word were removed altogether from scientific nomenclature.

As an epidemic malady diphtheria has not very lately prevailed in our own country, although sporadically it is occasionally, and indeed frequently, observed. In Italy, however, it has very recently appeared as a most destructive scourge, especially in Florence and the country round that city, and it is very interesting to observe that its features have been precisely similar to those of previous epidemics, the dates and localities of some of which I have specified in a former communication.(a)

It appears that in the year 1863 diphtheria, together with scarlatina and measles, prevailed amongst rich and poor patients alike in Florence and its vicinity, and more in the suburbs and the surrounding country than in the city itself. After that year the character of the disease was more mild, and its attacks became more infrequent, and its epidemic nature was dissipated by its taking a centrifugal course into districts more and more remote from Florence. But although all traces of the disease as an epidemic were lost, there remained in wounds, especially on the surface of the body, a certain disposition to assume the diphtheritic form, which resisted all attempts at cicatrisation: and sometimes the sores spread so much, both in surface and in depth, as to carry off the patient by the injury done to the tissues.

Matters thus went on until 1867, when, together with measles, hooping-cough, and a few cases of scarlatina, a new attack of diphtheria broke out in the country district to the east of the city, Varlungo being especially afflicted by the scourge.

With regard to the exciting causes of the disease, and the telluric influences which preceded or favoured its outbreak, no positive information could be gathered. It attained its maximum in the months between July and the succeeding December and January, but at the approach of spring its intensity diminished, and it gradually disappeared. It showed, as usual, a predilection for infants, and in some respects for the male sex, sometimes attacking young men from eighteen to twenty years old. It entered the hut of the beggar as well as the house of the opulent farmer, whether living in a low and dull situation, or in a high, airy, and open one.

The adynamic and insidious onset of the disease, so distinctly noted by Bretonneau and by all other accurate observers, was equally remarkable in the Italian epidemic, for it generally began, without any previous illness, with a feeling of uneasiness about the fauces, the pain being sometimes slight, and sometimes becoming severe as the disease advanced. At first the fever was not intense except in the very severe cases, in which the heat of the skin was much raised; the pulse became rapidly frequent and weak, and the patient appeared feeble and depressed, as if he had been suffering for several days from fever of an adynamic tendency.

Here I would pause for a moment to point out how characteristically different is the onset of this disease from that of the malady usually called croup, but which is generally nothing more nor less than an acute or chronic inflammation of the larynx and trachea, is successfully treated by ordinary depressing remedies, and in which, I will add, there is no false membrane. In this malady (laryngo-tracheitis) the early symptoms are very severe, but the danger is by no means proportionate, and, in fact, it may almost be said that the symptoms and the danger are in the inverse proportion to one another.

In diphtheria, on the contrary, the early symptoms are very slight in most cases, and, indeed, are sometimes so indistinct

(a) *See Medical Times and Gazette*, November 15, p. 546.

as almost to escape notice altogether; but as the disease advances, the respiration becomes embarrassed, the voice assumes a naso-guttural tone, and the tongue becomes covered with a whitish-yellow fur. The cervical glands soon become swollen, but without any reddening of the superposed skin. As in former epidemics, so it was observed in the Italian one, that the patients often became rapidly worse—they were cold and pale, with fluttering pulse, the mind sometimes remaining calm, and they generally died from sudden collapse from the sixth to the ninth day. Occasionally the disease was observed to spread to the bronchial tubes, and sometimes, though not very often, it was seen to invade the nostrils, without leading, however, from this circumstance alone, to a fatal result. It should be mentioned, in explanation, that Bretonneau and some of his followers regarded the extension of diphtheria to the nostrils as one of the fatal indications of the disease.

Local paralysis of the velum palati was not infrequently observed in the Italian epidemic, but more commonly, although at a later period, the lower extremities were paralysed, presenting a condition similar to what is called locomotor ataxy. This paralysis was not severe in proportion to the gravity of the original disease, but it sometimes supervened upon apparently slight attacks. In accordance, too, with former experience, it was found that the paralysis was almost always partial and was not fatal—for the most part disappearing spontaneously, and not lasting more than three months.

This epidemic of 1867 gradually disappeared; but, as in the former one of 1863, there remained a disposition in wounded surfaces to become covered with diphtheritic exudations, as above mentioned.

In 1869 diphtheria committed great ravages in the province of Vicenza, and some cases were seen in Florence, chiefly among children at the breast. In the following year a few isolated cases occurred of a sporadic character, but in 1871 the disease again assumed an epidemic form.

Dr. Leopoldo Nesti,(b) from whom much of the above information is derived, was unable to trace exactly the primary development of this most recent outbreak, owing to the want of sufficient documentary evidence; but he has collected as many particulars as possible from the returns of mortality presented to the Civil Government. From these documents it appears that in the last two months of 1870 four deaths from diphtheria were reported, one of them being the case of a youth of good family. Five cases were reported in January, 1871, four in February, and ten in March, some of the latter being proved to have been cases of transmission of the disease. From this period the reports of deaths from diphtheria went on continually augmenting; fourteen deaths occurred in the month of April, twenty-two in May, and thirty-two in June. Dr. Nesti ceases here to report the exact numbers of the cases returned, but he states generally that diphtheria subsequently diffused itself irregularly throughout the various medical districts into which the city of Florence is divided, attacking that of Piazza dell' Independenza, to pass with greater severity to those of Pellegrino and St. Salvi, in which last he observed and collected the numerous cases on which his narrative is founded.

Dr. Nesti goes on to remark that all the districts of the city, with few exceptions, either at early or later periods, have given a large tribute of innocent victims to this indomitable and ferocious disease (*questo male indomito e feroce*), which, he says, "daily saddens our families, and which, unless removed by Heaven, threatens to last with a similar tendency for a long time."

Before proceeding to notice some other particulars relating to the progress of the epidemic and its peculiar features as lately observed in Italy, I may mention that I have just received a letter from Dr. Wilson, who is attached to the British Legation at Florence, and who seems to indicate that the malady (of which he has himself seen many cases) is now again on the decline.

(*To be continued.*)

Physic and Beer.—It transpired in the hearing of a case in the Court of Exchequer on Saturday last, that large quantities of liquorice were manufactured in this country under the Spanish brands, and that amongst the purposes to which it was applied were those of making black draughts and colouring beer.

REPORTS OF HOSPITAL PRACTICE.

IN

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

OPERATION FOR REMOVAL OF THE FEMALE BREAST BY MEANS OF INDIARUBBER LIGATURES.

(By Sir HENRY THOMPSON.)

On Friday, November 21, Sir Henry Thompson performed an operation upon the female breast, which, so far as we are aware, is perfectly new to surgical practice in England. Previous to the entrance of the patient to the theatre, Sir Henry stated that the plan he was about to adopt had been brought recently under his notice during a visit to Vienna by Professor Dittel. An accident, as it were, suggested the treatment to Dittel, who now for some time has employed it in over 200 cases, such as of tumours of the breast, in removing the testes and even limbs, and in the cure of fistula in ano. Having been called upon to see a young girl dying from meningitis, the following account of the case was given him:—The patient, who had been constantly reproved by her step-mother on account of the untidy state of her hair, was advised some weeks before her death to get a tightly-fitting net for her head, and to wear it night and day. This she did till the last, when it was found that the elastic band of the net had cut its way through the scalp and cranium, and was resting on the meninges of the brain, fatal inflammation of which it had set up.

The immense power for effecting the solution not only of the soft tissues of the body, but even of bone, having, by the constantly contracting pressure of an elastic band, been thus so remarkably proved, Professor Dittel resolved to attempt in certain cases to substitute this power for the knife in surgical operations.

The application of the treatment to the mammary gland by Sir Henry Thompson we will now describe:—The patient, a woman of about fifty-three years of age, had for ten years been conscious of a tumour in the right mamma. When first noticed it was seated near the nipple, below and to its outer side, and was of the size of a walnut. As it was discovered about the time of her confinement with her last child, which died soon after its birth, she was led to regard the tumour as a "distended milk-duct." It has gone on increasing, however, though very slowly, and about eight weeks ago the skin covering the tumour commenced to ulcerate. At the time of the operation the histological characters of the tumour were doubtful. It was of the size of a large orange, ulcerated on the surface, somewhat pendulous, and freely movable upon the subjacent tissue. The patient was a robust and healthy-looking woman. Chloroform having been administered, Sir Henry drew the mamma forward from off the pectoral muscle, and then, with a very long, strong, and slightly curved Liston's needle, transfixed the submammary tissues. Through the eye, near the point of the needle, a long piece of very elastic indiarubber tubing, about the thickness of stout whipcord, together with a long silk ligature, was passed. The elastic ligature was then divided, and the needle withdrawn. Each half of the elastic ligature was tied very tightly, so as to embrace one-half the mamma, inclusive of the skin. In fastening the elastic ligature a piece of silk ligature was placed at right angles to the elastic between the skin and the knot, and while the single knot was tightly drawn, the silk was tied around it by an assistant to prevent it slipping. A double knot was then made, and this was secured by again tying the silk around the elastic.

The long silk ligature which had been passed with the elastic tubing through the submammary tissue was then removed. The purpose of passing this was precautionary, in order that another piece of elastic might be drawn along the same track in the event of either half of that which was first passed breaking. Another precaution very necessary to take is to hold the elastic firmly at the time of dividing it and while withdrawing the needle, otherwise the contractility of the tubing will cause its disappearance through the track made by the needle.

The time likely to ensue before the entire separation of the breast is eight or nine days. The pain excited during any

portion of this time is remarkably slight. Sometimes a little pain is suffered for a day or two. In the case of the patient now referred to, there was no pain after the first twenty minutes from the time of recovery from the chloroform, and the suffering during this brief period was not at all severe.

MIDDLESEX HOSPITAL.

LIGATION OF COMMON CAROTID FOR HÆMORRHAGE AFTER THE REMOVAL OF A CERVICAL TUMOUR BY ELASTIC LIGATURE.

(Under the care of Mr. HULKE.)

MICHAEL H., a labourer, aged 31, was taken into the Middlesex Hospital at 9 a.m. on August 30, 1870, bleeding profusely from a sinus in the neck at the anterior border of the left sterno-cleido-mastoid muscle. The blood welled up copiously in a continuous stream. Its flow stayed immediately on the application of a graduated compress. He had lost enough to drench his clothes to his feet, and to thoroughly blanch him and induce great faintness.

He related that in St. George's Hospital, several months previously, he had undergone an operation for the removal of a tumour from his neck by a new method (understood to consist in the strangulation of the tumour with indiarubber bands,—the skin having been previously reflected, and long pins passed behind the base of the tumour to serve as guides for the elastic constrictors). The removal of the entire tumour was found impracticable in this way, and about one month later, before the wound had closed, very copious bleeding took place, necessitating an operation (afterwards learned to have been deligation of the carotis communis above the homo-hyoideus muscle). When the thread had come away from the vessel, and the wound was nearly closed, he was transferred to the Convalescent Branch, from whence some weeks later he returned to work. A small part of the wound which had never healed continued to discharge a little matter. A few minutes before he was brought to the Middlesex Hospital, while wheeling a heavy barrow in a neighbouring street, he felt a sensation in his neck as if something gave way, and quickly found himself covered with blood, and become faint; he soon afterwards vomited. At 9.30 a.m., half an hour after his admission, his pulse beat 150 per minute, and the thermometer in the axilla marked 104·3° Fahr. On being questioned, he said he had had a severe shivering fit in the night.

August 31.—2 a.m.: Blood welled up profusely from the sinus, "as from a fountain." The sister applied a fresh compress moistened with perchloride of iron, by which the bleeding was stanched before the House-Surgeon could reach the ward. 10 a.m.: Pulse 96; temperature 98·2° Fahr. 10 p.m.: Pulse 128; temperature 102·2° Fahr. At 11 p.m. he vomited, and the compress shifting, the wound again bled; but the bleeding, though very free for a moment, was immediately arrested by digital pressure, afterwards replaced by a fresh compress.

September 1.—Wound sloughy; washed out with a solution of carbolic acid, and dressed, as previously, antiseptically.

2nd.—9 a.m.: Pulse 120; temperature 102°; stitch in side; tongue dry and brown. 2.30 p.m.: Pulse 120; temperature 103·6°; strong arterial pulsation at root of neck. 9.30 p.m.: Pulse 104; temperature 101·8°.

3rd.—In the night several rigors followed by copious sweats. At 9 a.m., pulse 105, temperature 100·2°; at 9 p.m., pulse 112, temperature 101·8°; a severe rigor at midnight.

4th.—At 3 a.m. another rigor, and a third at 10 a.m., followed by a profuse sweat, in which his pulse was 120, and temperature 97·8°. At 11 a.m. a slight rigor whilst still sweating. At 12.15, pulse 120, temperature 108°. At 9 p.m., pulse 118, temperature 101·2°. Has vomited several times in the course of the day and in the previous night, and has passed several loose stools. Says on the whole he is more comfortable.

5th.—9 a.m.: Pulse 100, temperature 101·2°; was sick several times in the night. The wound is cleaner, and the discharge is not fetid. At 12.30 p.m., profuse arterial hæmorrhage—the blood spouted in a stream as thick as a cedar pencil—instantly arrested by pressure.

The pyæmic condition of the patient—manifested in the repeated rigors and sweats, the instability and extreme variations of temperature, and the looseness of the bowels—and the probability of cerebral mischief, inferred from the vomiting unprovoked by ingesta, but occurring at any time—had been judged a sufficient bar to any surgical measures so long as the hæmorrhage was easily controlled by pressure; but it being now evident that another bleeding would be fatal, Mr. Hulke decided to anticipate any more loss of blood by laying open the sinus, and securing, if possible, the bleeding vessel. Anæsthesia was induced with chloroform, and the sinus was laid open; it ran in the direction of the great vessels, but though the tissues were roughly handled and scraped, no bleeding could be now provoked. The border of the sterno-mastoideus having been drawn out, and the omo-hyoideus and sterno-thyroideus muscles having been divided, the sinus was tracked in the sheath of the vessels down to the level of the collar-bone, and the carotis communis was tied at the lowest accessible point. The adhesion of the artery to its sheath, and of this latter to the surrounding parts, with the alterations in all the tissues produced by the long-continued suppuration, and the great distension of the internal jugular vein during expiration and several times when there was slight struggling, made it rather difficult to pass the aneurism needle. The pulsation of the artery was so feeble that it was difficult to realise the presence under the finger of so large an artery so near the heart. An hour afterwards he had a very severe rigor; he was delirious through the night, and he died at half-past seven o'clock on the following morning. No further bleeding had happened.

At the examination of the body several scars were noticed on the front and side of the neck—marks of the skin-flaps reflected in the original operation. Above the omo-hyoid the continuity of the carotis communis was interrupted at the spot where it had been tied in St. George's Hospital. The upper end was obliterated and lost in a mass of adenoma; the lower end, to the collar-bone, was imperfectly blocked by a disintegrated clot. The ligature which had been applied the day before was found around the vessel just where the clot ended below. The left cerebral hemisphere contained two abscesses, and the liver several.

SATURDAY, NOVEMBER 29, 1873.

INDIARUBBER LIGATURES AND THEIR USE IN SURGERY.

WE publish to-day, under the "Reports of Hospital Practice," the details of an operation for the removal of the breast, which we think we may describe, without fear of contradiction, as being entirely unprecedented in British surgery.

The operation was performed on Friday, November 21, in University College Hospital by Sir Henry Thompson. The

patient, a woman about fifty-three years of age, had for ten years been conscious of a slowly growing tumour in the right mamma, which had latterly gone on growing more rapidly, and within a few weeks had commenced to ulcerate. The tumour was not thought to be malignant, and it and the gland in which it was growing were freely movable upon the pectoral muscle. It was on this latter account no doubt admirably adapted for the process to which it was submitted.

As will be seen by referring to the description of the case, this process consists in the strangulation of the mamma by means of an elastic ligature passed beneath the breast through the submammary tissue, and the subsequent separation of the mamma from these subjacent structures by the ulceration provoked by the contractile and continuously constricting nature of the ligature.

Although, as applied to the mammary gland, this mode of removing a portion from the rest of the body is, as we believe, new to the surgical practice in this country, it is not so in Vienna. Here the treatment has for some time been employed by Professor Dittel, who has, so we learn from Sir Henry Thompson, removed a large number of breasts in this manner. He has, too, amputated limbs by the same means; and for the removal of diseased testicles and the cure of fistula in ano the elastic ligature has by this surgeon been found to answer well.

The accident which we are informed led Professor Dittel to attempt the removal of such large masses and parts of the body as breasts and limbs by a tightly applied indiarubber ligature is described elsewhere in these columns, and is sufficiently remarkable to excite amazement and wonder; though in comparison with the folly of fasting girls and hair and pin devourers, and the sufferings to which they put themselves, there is nothing incredible in the fact that a young girl who has been perpetually scolded for having an untidy head should tenaciously wear a head-dress which would save her hair from falling loose and her ears from harsh reproofs. Granting, however, the originality of the idea in Professor Dittel's mind of indiarubber tubing as a ligature, and the novelty of the application of elastic ligatures to large and important parts, as in the case now under Sir Henry Thompson; and granting, further, the soundness of the treatment in the cases to which it has been applied, two questions nevertheless arise, viz.:—(1) How far is the employment of elastic ligatures new to surgery in this country? and (2) In what does the advantage, if any, reside of elastic ligatures over inelastic ones, or over the removal of diseased parts by the knife? That elasticity in a constricting agent has been thought desirable by some surgeons for several years past, is evident from the fact that Mr. Henry Lee and those who have followed his practice have employed twisted indiarubber sutures or a piece of indiarubber stretched upon a pin in the treatment of varicose veins. Mr. Bryant has at different times since 1863 removed small pedunculated tumours from the limbs by means of small indiarubber bands and threads of elastic from spring-sided boots. Mr. Lee has, too, for four or five years used a fine, very elastic indiarubber ligature for the removal of hæmorrhoids; and in St. George's Hospital (and we believe, too, occasionally in University College) the same material is frequently applied to nævi. We publish this week, moreover, a case which came under Mr. Hulke's care in the Middlesex Hospital in 1870, of a man who had a short time before, in St. George's Hospital, undergone an operation for the removal of an adenoid tumour from his neck "by a new method," consisting in the strangulation of the tumour with indiarubber bands—"the skin having been previously reflected, and long pins passed behind the base of the tumour to serve as guides for the elastic constrictors." Again, at page 114 in vol. iv. of the *Clinical Society's Transactions* there is a paper, read by Mr. Henry Lee on March 10, 1871, describing the removal of a tongue for cancer by an elastic ligature passed around the base of the organ.

It is, then, only in so far as concerns the part strangulated, and not the mode of strangulation, that the operation on the breast we have described is new amongst us.

The advantage which an elastic ligature possesses over a silk or any inelastic one is evident when any but the smallest amount of tissue has to be constricted. An ordinary ligature, no matter how tightly it may be tied, must become loosened after a certain amount of the constricted tissues has been removed by ulceration; but an elastic ligature, as fast as it has caused ulceration of some parts, goes on contracting upon the remainder, and thus not only is a continuous pressure kept up, but the pressure is sufficient to prevent any intercommunication between the fluids of the necrosed and the living tissues. This latter most desirable object is not obtained by any but an elastic constrictor; for if any of the strangulated tissues happen to be not quite dead at the time of the loosening of the ordinary ligature, some return of circulation is likely to occur in them. Owing to the continuous pressure and contraction of the elastic upon the strangulated parts, there is, too, less risk of the entrance of any septic material into the general circulation. There may be a doubt, however, when a very large quantity of tissues is included in the ligature, how far the indiarubber, being constantly bathed in putrid discharges, retains its elasticity, and thus whether the contraction and pressure are continued until the whole of the ligated parts are quite separated.

The advantages over the knife which Professor Dittel supposes the elastic ligature to possess are—(1) That it does away with the necessity of a cutting operation, and all the horror and distress which the idea of such excites in the minds of many patients; and (2) it is attended by less risk of pyæmia. Without experience on this point of course it is impossible to express an opinion, and we may be sure that Professor Dittel has good foundation for his conclusion. But certainly there is reason for thinking that pyæmia is as prone to supervene upon a large ulcerated surface, with sphacelated tissues in its immediate neighbourhood, as upon an incised wound—even if the vessels are in a state more favourable to the admission of matter from without. The patient reported under Mr. Hulke's care died from pyæmia, brought on, it is true, only indirectly by the operation.

As applied to the limbs the treatment cannot be commended: we fail to see what advantages such a means can possess over ordinary amputation to compensate for its offensiveness and greater tediousness. For tumours of the breast, when there is a strong repugnance on the part of the patient to the use of the knife, when the disease does not infiltrate the submammary tissues or the axillary glands, and when the tumour and the breast are freely movable upon and can be drawn away from the pectoral muscle, it is undoubtedly applicable, especially as it has been proved to be so slightly painful; and in cases of a cancerous nature where it can be employed all chance of inoculating the surrounding tissues with the cells or fluid of cancer is thus avoided.

We may refer our readers for an account by Professor Dittel himself of this treatment to the *Allgemeine Wiener Medizinische Zeitung*, an abstract of which we intend publishing in an early number.

THE EDUCATION OF MIDWIVES.

We do not think that the deputation from the Obstetrical Society which waited on Mr. Stansfeld in order to enlist his aid in their project of educating, examining, and licensing midwives, had much cause to congratulate themselves upon the Ministerial utterances they elicited. The published report of the interview, which appeared in the *Times* of Saturday

last, shows that it ended in Mr. Stansfeld telling the obstetricians that they ought not to stop at creating a set of midwifery nurses only, but that they should allow women who have the qualifications and means to take a higher rank without undergoing a full medical examination. By this we suppose Mr. Stansfeld to mean that there should be created a class of female obstetricians, who, being trained to practise midwifery and in the diseases of women and children, are yet not to be physicians or surgeons in a complete sense, and are not to have a full professional education. The plan of the Obstetrical Society, on the other hand, is merely to train and license a set of midwives, or midwifery nurses, to work amongst the lower orders, who are to have just practical knowledge enough to enable them to manage a natural labour, and to send for a medical practitioner if any manual or instrumental interference be necessary. Allowing that the project of the Obstetrical Society might possibly supply a want in certain pauperised districts, we think that Mr. Stansfeld's improvement on it would introduce a dangerous set of practitioners—pure *accoucheuses*, with sufficient knowledge of their art to make them conceited, and sufficient ignorance of the science of medicine in its totality to make them dangerous.

The question, however, arises—whether the creation of a class of female obstetric practitioners be really a desirable one in the present day? The fact, which has been frequently insisted on in these columns—that obstetric practice, which was formerly in the hands of females, has everywhere passed into those of male practitioners—furnishes, at least, an argument that men are better fitted by nature, in body or in mind, or in both, to perform the office than are females. No important improvement in practical midwifery has ever been made by a female. Had midwifery remained the speciality of the female sex, is it likely that version would ever have been attempted, or the forceps have been invented? We doubt it. But, apart from these considerations, we confess we do not see any reason for disturbing the existing arrangements. Medical male practitioners are quite numerous enough to discharge the duties of obstetricians in all prosperous districts, and the recent advance of wages should tend to increase their remuneration. The project of the Obstetrical Society might indeed supply a class of midwives who would be acquisitions in a few very poor neighbourhoods; but we certainly do not believe they are needed throughout the country. The speakers in the deputation to Mr. Stansfeld—Dr. Tilt and Dr. Aveling—insisted upon the large number of deaths in parturition which occurred in the practice of midwives, and upon the burden which children made orphans by the loss of their mother in childbed imposed upon the ratepayers. We should like to examine the statistics by which these assertions are proved. That women do die through the ignorance and incompetency of male and female unqualified practitioners, we have no doubt, but we do not believe that they die in such numbers as materially to affect the rates. Neither do we believe that the crime of child-murder would be oftener perpetrated by uncertificated midwives than by certificated ones. Still, as we have allowed, the project of the Obstetrical Society might supply a want felt in workhouses, barracks, and amongst very pauperised communities. But we regard with aversion any movement which would tend to take the midwifery practice of the country out of the hands of the male medical profession properly so called. We are convinced that such a change could not be effected without increasing the mortality in childbed, arresting the progress of the obstetrical science and art, and without inflicting an unnecessary loss on the large mass of the profession. Fortunately, that part of the female sex which has any chance of requiring the obstetrician's aid seems pretty generally to share our opinions.

THE PHYSIOLOGY OF VISION.

III.—The Cornea, and its Pathological Teaching.

The first portion of the optical apparatus of the eyeball on which the rays of light impinge is the cornea, the structure of which is not only exceedingly interesting in itself, but is rendered still more so by the fact that on it have been made some of the most interesting experiments as to the process of inflammation. It is bounded in front by a stratified epithelium of the squamous kind. Behind this comes the true horny or fibrous tissue of the cornea; next a thin highly elastic and nearly structureless lamina; and finally a single layer of flattened endothelial cells, which separates it from the aqueous humour. Of these various structures the first and second are of most interest. As regards the external corneal epithelium, it is continuous with that covering the conjunctiva; but, as in most forms of stratified epithelium, it is only squamous on its surface, where the cells are broad, flat, and dentated. Deep down the cells assume the columnar form, with their long axes at right angles to the corneal tissue beneath; whilst the middle cells frequently exhibit processes or prickles which seem to be of great importance in regenerating epithelium. One of the most interesting facts, however, relating to the structure of the corneal epithelium is that the nerve-fibres, found abundantly in the proper substance of the cornea, may be clearly traced into the epithelium, where they form a fine meshwork surrounding and enclosing the corneal cells. These fibres are non-medullated, for the medullated nerve-fibres which enter the cornea soon lose their medullary sheath and form various plexuses, one of the most marked of them being situated immediately below the epithelial layer, whence are sent off the fine twigs which terminate in the epithelium, sometimes in somewhat swollen extremities, just beneath the most superficial layers of the epithelium. No direct communication between these terminal nerve-fibres and the epithelial cells can, however, be discovered.

The true substance of the cornea may be reckoned as composed of three layers, although only one is spoken of above. We may, however, include in it the layer lying immediately below the internal endothelium, commonly called Descemet's layer or membrane, though that is structureless, and another in many respects similar, which lies immediately beneath the external epithelium. Both might be spoken of, as regards the cells lying on their surface, as basement membranes. But the cornea proper is composed of fine fibrils, so arranged as to leave freely communicating interspaces, in which are contained the so-called corneal corpuscles. The fibrils of the corneal tissue are in many respects similar to those of ordinary fibrillar connective tissue, and are arranged in fine bands, which, decussating with each other, run for the most part nearly parallel to the surface of the cornea. By boiling, the corneal tissue yields a substance like gelatine, but allied to chondrin in many particulars.

But by far the most interesting corneal structures are the corpuscles. These are or may be of two kinds. One kind exists as minute masses of protoplasm, with distinct nuclei sending out in every direction rays or processes which through the interstices of the corneal tissue directly communicate with corresponding processes sent out by neighbouring corpuscles. In this way there is a completely connected and directly communicating plexus of protoplasmic bodies throughout the cornea. Looked at from the anterior surface of the cornea, these corpuscles appear flattened; looked at in profile, they seem elongated from side to side. Now, these corpuscles can be made to change their shape; especially they can be made to retract their processes, when they appear as small clumps of protoplasm, more or less amœba-like. This is best done by means of a shock of induced electricity; and it is after such a shock, and the consequent retraction of the protoplasmic processes, that the existence of actual canals, commonly called

serous canals, for the reception of these processes of the corneal corpuscles can best be demonstrated.

Still another kind of corneal corpuscles can be made out, especially in the frog and other amphibia. These bodies are to all intents and purposes similar to the lymph or colourless blood corpuscles of the same animals, and in the cornea they may be seen to undergo changes in shape similar to those observed in the same corpuscles in other parts of the animal under different conditions. These are the so-called wandering or migrating corpuscles, and their origin under normal conditions can hardly be doubtful—they come directly or indirectly from the bloodvessels of the animal.

Now, if by any means the cornea be irritated—say by the application of a sharp-pointed stick of nitrate of silver to any given spot on its surface,—this irritation is shortly followed by what is called a purulent infiltration. By this is really meant a congregation of leucocytes at the irritated point to such an extent as to give the cornea a cloudy appearance. But for long a fierce battle was waged as to the exact interpretation of the phenomenon. On the one hand, it was contended that this cloudiness invariably appeared first of all near the margin of the cornea; on the other, that it appeared wherever the irritation was most intense. The upholders of the former doctrine maintained that this cloudiness was due to the presence of leucocytes which had wandered out of the various bloodvessels surrounding the cornea. Those who held to the latter view pointed out that this could not be so, inasmuch as there was no apparent change between the irritated spot and the margin of the cornea. The latter therefore maintained that the active moving corpuscles could only have originated in the fixed corneal corpuscles already described, and they pointed to the fact that these could be made to alter their shape by various excitants, so as to become indistinguishable from ordinary amœboid corpuscles. Subsequent experiments demonstrated the truth of both views, and thus was established the validity of that important doctrine which teaches that inflammation is not only a local change in the tissues of the part, but is also in part dependent on the direct passage of white blood-corpuscles out of the vessels to the parts beyond, where they cease to be called white blood corpuscles, taking now the name of pus corpuscles. Moreover, these experiments show that by an increase of the normal elements of the cornea it may become completely opaque, whether these elements take the corpuscular or fibrillar form.

THE WEEK.

TOPICS OF THE DAY.

We are glad to announce that the report which had reached us, that Mr. Quain contemplated retirement from the representation of the Royal College of Surgeons in the General Medical Council, is unfounded. Mr. Quain has retired from the Committee of Reference embodied for the formation of a Conjoint Examining Board for England; but we are happy to state that he still retains his post in the General Medical Council, which could ill afford to lose a surgeon of his long experience and mature judgment in all matters relating to medical education.

The Queen has been pleased to reappoint Dr. Parkes, Dr. Quain, and Dr. Stokes as representatives of the Crown in the General Medical Council; and Dr. James Warburton Begbie, of Edinburgh, as a Crown representative, in place of Sir Robert Christison, who, we believe, declined to be again nominated. The appointments reflect great credit upon those who advise her Majesty in this matter. We are sorry, however, that the Council will lose Sir Robert Christison's sound practical good sense.

The Royal College of Physicians of Edinburgh has appointed Dr. Haldane as its representative in the General Medical Council, in place of Dr. Alexander Wood; and the University of Edinburgh has nominated Professor Turner, of that University, to represent the Universities of Aberdeen and Edinburgh, in place of Dr. John Macrobin.

It is announced that there will be no opposition to the re-election of Dr. Lyon Playfair as representative in Parliament of the Universities of Edinburgh and St. Andrews.

The subject of the prevalence of ophthalmia in pauper schools has lately been discussed in the columns of the *Times*. Mr. Brudenell Carter has published an opinion that this prevalence is mainly owing to the fact that pauper schools are not systematically visited by medical inspectors, and that consequently the hygienic condition of these schools contrasts badly with that of county lunatic asylums. We have no desire to defend the policy of the Local Government Board, and of the Poor-law Board which it replaced, in appointing non-medical persons to perform duties which clearly belong to the province of the sanitary medical inspector. We believe that the appointments to poor-law inspectorships have been made matters of political and personal jobbery, to the great detriment of the public service. But, on the other hand, the answer of Dr. Markham, who was himself a poor-law inspector for some years, published in the *Times* of Thursday last, pretty clearly shows that something more is required to get rid of ophthalmia from pauper schools than medical inspection and the enforcement of hygienic measures. From his experience of the mode of spread of ophthalmia by contagion, and of the persistence with which it recurs in children who have once suffered from it, he has been lead to the conclusion that the only way to eradicate the contagious ophthalmia of pauper schools is to separate once and always the sick from the healthy—to have separate hospitals and school attached to them, in which convalescents should be educated, and never allowed to return to the general schools.

In a recent trial about "nourishing stout," Vice-Chancellor Malins asked who Dr. Hassall was, a testimonial from that analyst having been mentioned in evidence. We thought it impossible that any householder who could read would have had occasion to ask that question. We do not know whether we ought not to congratulate Dr. Hassall.

THE WAR ON THE GOLD COAST.

The hospital-ship *Victor Emmanuel*, it is now stated, will positively leave for Cape Coast Castle to-day (Saturday). All the medical and surgical stores which she is to carry, and which will make her a kind of floating depôt, have been received on board. The detachment of the Army Hospital Corps appointed to her have joined, and as she has been duly commissioned we may hope that nothing further will occur to delay her departure at the date fixed. Since our last, the 42nd Highlanders have been put under orders for the expedition, and are expected to sail from Portsmouth about the 1st proximo. Although a kilted regiment, the 42nd will not be sent out in such an inappropriate costume for bush-fighting, but uniforms will be issued to officers and men similar to those already supplied to the 23rd Foot and the 2nd Battalion of the Rifle Brigade.

The despatches recently received from Sir Garnet Wolseley contain nothing of importance that was not previously known. Although the results of the encounters which up to the present time have taken place with the enemy may not be considered important from a military point of view, there is no doubt that the operations so far have been of great utility in demonstrating what can be done by European troops in marching and fighting in the Bush. The correspondent of the *Standard* has called attention to the great necessity which exists for frequent rests on the march. He states that Sir Garnet Wolseley has himself laid down a rule that troops upon the march should

halt five minutes in every hour—the first halt to be exactly one hour after starting. Now, in this exceptional climate such a rule is essentially necessary. Owing to the intense heat, the lungs have to work much faster; consequently the great strain both on heart and lungs is evinced by palpitation and shortness of breathing. Now, ten minutes' rest at the end of every fifty minutes' work would relieve the men, prevent falling out on the road, and send them off again refreshed for renewed exertion. These remarks appear so reasonable that commanding officers in the field would do well to weigh them carefully, more especially as the custom appears to have been adopted in the long march to Magdala during the Abyssinian campaign with signal advantage.

The question has been mooted as to the supply of beer to our troops on the Coast, and whatever may be the decision as regards the men actually in the field, there is no doubt that an ample supply should be forwarded for the hospital-ship. A medical officer long resident on the Coast once informed us that bitter ale was almost the only stimulant he took during his tours of service, and the experience of other officers confirms the wisdom of this. We trust, therefore, that the *Victor Emmanuel* will be amply supplied in this respect for the comfort of the sick and wounded.

It is satisfactory to note that, if the operations which have taken place up to the present time are to be taken as a guide, the percentage of killed, as compared with wounded, will only be small; nor will the ratio of severely wounded be very high. The weapons of the Ashantees are of the commonest kind, and several instances have already been noted in which no penetration followed the blow received from slugs fired by the enemy.

LIBERTY AND TYRANNY.

We deny the truth of the allegation made by Mr. Downes during the following discussion which occurred at the last meeting of the St. James's (Westminster) Vestry. We allude especially to the remark that there is among medical men a rising feeling to restrain the liberty of the subject. We are sure our professional brethren will repudiate with us such a charge. It is untrue and unjust. Dr. Lankester, the Medical Officer of Health, in discharging the duties of his office to inspect public buildings, reported that he had visited the "Criterion," and found the whole building well ventilated; in fact, he had never seen a public building so thoroughly ventilated. Mr. Downes asked the medical officer if it came within his duty to visit such buildings as that lately erected by Messrs. Spiers and Pond. Dr. Lankester replied that there was an express passage in his appointment to that effect. Mr. Downes said in that case he might go into any house he liked; it seemed to him that the more liberal the age was called, the less liberty they got. He believed the clause mentioned by Dr. Lankester applied only to certain places, such as workshops. Dr. Lankester said the state of the law allowed him to go into any house. It was for the purpose of preventing nuisances. A man had no right to keep his house dirty; one foul place might poison a whole neighbourhood. Mr. Downes did not like the practice; if they could go into houses like the "Criterion," they might go into any others, and he was sorry to see among medical men a rising feeling to restrain the liberty of the subject. Dr. Lankester said the medical men did not wish to restrain any one's liberty: they only interfered for the general safety. He had gone over Burlington House, and was about to have an interview with Mr. Barry, the architect, in regard to the ventilation. Mr. Spryng asked if the Government were likely to adopt any suggestion of Dr. Lankester's in reference to the ventilation, and if he could take any action in the event of their refusing. Dr. Lankester replied that he had the magistrates to appeal to. It was in his power to indict any person in the parish in such a matter. We have had occasion to speak of the praiseworthy and satisfactory manner in which the medical officers of health generally are fulfilling the duties pertaining to their important office. Hitherto, so far as we know, their powers have been exercised with discretion, and even leniently. It is idle and untrue for vestrymen to charge these gentlemen with a desire to "restrain the liberty of the subject."

THE ABUSE OF MEDICAL CHARITY.

An influential and largely attended conference was recently held at Birmingham, to consider the subject of hospital reform. Representatives from the hospitals and charitable institutions of the district attended. The following resolutions were unanimously passed:—"That inasmuch as the gratuitous relief afforded by the medical charities of the town is abused, it is desirable that a combined effort should be made by the medical charities to prevent such abuse in future." "That a committee be appointed to prepare and submit to a future meeting of this conference a scheme for the establishment of a central organisation for a systematic inquiry into the circumstances of all applicants for relief (except cases of urgency and accident), and also to prepare an estimate of the probable annual cost of such an organisation." A committee and honorary secretary were appointed, and the proceedings closed. The abuse of medical charity is, we are glad to observe, engaging not only the investigation and consideration of the public in the metropolis, but is being taken up with much earnestness in our large manufacturing and other towns generally. Although the subject is a difficult one, we trust some practical plan will be elicited, and that the abuse of medical charity will ere long be a reproach of the past.

HEALTHY KENSINGTON.

Dr. Dudfield, the Medical Officer of Health, in his last report to the Kensington Vestry, states that during the past month the deaths were equal to 16 per 1000 per annum, against an average in three years of 20·12 per 1000. The deaths in the metropolis were 24 per 1000, and the average in three years 21·66. The deaths from zymotic diseases were only 13, against an average of 39 at a corresponding period of three years. Thus in every respect this return is a singularly favourable one as regards Kensington parish, in which the death-rate was less by 4 per 1000 per annum than the average, while in the metropolis generally the rate was more than 2 per 1000 above the average. The report of Dr. Dudfield is very satisfactory, but it must be remembered that Kensington is a rich and prosperous parish. It has comparatively few poor inhabitants; there is little overcrowding; a fine gravelly soil, and pure air to make it a healthy locality. Dr. Dudfield has proved himself an energetic and discreet medical officer, and we always read his reports with satisfaction.

CHOLERA IN NAPLES.

The epidemic of cholera (writes the *Times* correspondent from Naples on the 10th inst.) during the last four days has maintained its usual character—sometimes increasing and then decreasing. "The cases in this interval have been 28, 9, 18, 30, and the deaths 15, 5, 11, 20, yesterday's report being the most unfavourable we have yet had. At some places in the neighbourhood, too, the malady has been very severe, but no statistics are published, and no reliance is placed on those which are so. As to the causes, or some of the causes, of this diffusion of cholera, I can only repeat what I have already said over and over again—they are to be found in the filthy habits of the people, and it is well that a stern and unrelenting censor has come to tell them that their health and their lives lie in their own hands." He adds—"The latest report of the epidemic is again bad—cases 30, deaths 21. It has broken out in Rome."

A GOOD EXAMPLE.

PROMPTITUDE of action on the part of officials under the Sanitary Act is of the utmost importance to its being carried out efficiently. Hitherto justice has been sometimes delayed, if not protracted, by the imperfections of the Act. We are glad to perceive that the Vestry of St. George's, Hanover-square, at their last meeting, on the motion of Dr. Schulhof, unanimously passed the following resolution, which will greatly facilitate the proper working of the Act:—"That in cases of proceedings to be taken by the inspector of nuisances before a magistrate under the Acts for the Prevention of the Adulteration of Food and Drink, and of Drugs, the authority appointed by the Vestry to carry out the Nuisances Removal Acts be empowered to call in the assistance of the parish solicitors whenever they may consider such a course desirable."

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

THE opening meeting of the present session was held in the College Hall, Kildare-street, on the evening of Wednesday, November 19. A large number of members and visitors were present. Dr. James Foulis Duncan, President of the Society, occupied the chair, and delivered an inaugural address. In it he discussed the questions of "epidemic influence," and of "change of type in disease," illustrating the latter in a novel manner by a reference to the infrequency of late years of acute mania, with its terrible train of mental symptoms. At the close of his address he made a graceful and touching allusion to the loss of three distinguished fellow-workers—Professors William Barker, R. W. Smith, and Robert Law; the last of whom, and "third in this galaxy of eminence, still lives, but his work is done." Subsequently Dr. A. W. Foot brought forward the details of a very singular case of blue chromidrosis, illustrating his remarks by a water-colour drawing of the patient, a young lady aged 17. The exudation of the pigment occurred on the forehead and temples; also beneath the eyes, on the side of the nose, on the chin, and over the back of one hand. It was consequent on a series of intense headaches, and its amount was increased by hyperæmia of the face, from stooping and so on. In six months the affection passed away—the happy result being due apparently rather to mental rest than to any therapeutical measures. Drs. Stokes and Grimshaw detailed somewhat similar cases. Amongst the visitors were Surgeon-General MacIlree, who is now in charge of the Army Medical Department in Ireland, and several of the surgeons-major and surgeons at present attached to the Dublin garrison, the President and many of the Council of the Royal College of Surgeons, and the Governor of the Apothecaries' Hall.

ROYAL COLLEGE OF SURGEONS, IRELAND.

ON Monday last, the 24th instant, Mr. John Hamilton was elected a member of the Council of this body, in the room of Mr. Tufnell, the recently chosen Vice-President of the College.

DUBLIN OBSTETRICAL SOCIETY.

THE first meeting of the thirty-sixth session of this Society took place at the College of Physicians, Kildare-street, on the evening of Saturday last, the 22nd inst. The large hall of the College was quite filled, and the assemblage included the Presidents and Vice-Presidents of the Colleges of Physicians and of Surgeons, the Governor of the Apothecaries' Hall, the Surgeon-General of the Army Medical Department in Ireland, and many other distinguished visitors. The following office-bearers were elected for the year 1873-74.—*President:* Evory Kennedy, M.D. *Vice-Presidents:* Lombe Atthill, M.D.; and Thomas Darby, F.R.C.S.I. *Committee:* Fleetwood Churchill, M.D.; John Denham, M.D.; George H. Kidd, M.D.; George Johnston, M.D.; Alfred H. McClintock, M.D. *Treasurer:* H. S. Halahan, L.K.Q.C.P.I. *Honorary Secretary:* J. R. Kirkpatrick, M.D. The President (Dr. Evory Kennedy) read an address introductory to the session. The Obstetrical Society now numbers 142 ordinary members, twelve honorary members, and ten associates; and its proceedings for the past two sessions have been published in handsome volumes for distribution among the members.

THE POPLAR MEDICAL OFFICERS.

THE duties of the District Medical Officers of the parish of Poplar have just been the subject of consideration by a special committee of the Guardians. The result of their inquiry appears to be that, as district dispensaries and the Poplar and Stepney Sick Asylum have been established in the district, the duties of the medical officers have been largely reduced: that in consequence a reduction should be made, either in their salaries or in their number. As to the mode by which either of these proposals can be legally carried into effect, the committee express some doubt; but the Guardians have adopted their commendation to apply to the Local Government Board for advice on the matter.

HONOURS TO A MEDICAL MAYOR.

A LARGE and highly respectable meeting took place on Tuesday, at the Devonport Town Hall, to do honour to Dr. May on the completion of his third successive year of office as mayor of the borough. Nearly £500, the result of a subscription, had been expended by a committee in a life-portrait of the ex-mayor for presentation to the town, and a service of plate to himself. Sir John St. Aubyn, M.P., made the presentation. Dr. May had rendered important services in bringing a second line of railway to Devonport. The grateful recognition of these services was the immediate occasion of the presentation.

A QUESTION OF RIGHT.

THE Local Government Board has declined to sanction the appointment of Mr. G. C. Smith as Medical Officer of Health for Newtown, on account of Mr. Smith being an assistant to a medical practitioner. If fully qualified, we are at a loss to understand the grounds upon which his appointment has been ignored. Objections of this kind are, to say the least of them, unsatisfactory, inasmuch as they may deprive a good and efficient man of an appointment to which he may be justly entitled.

PROPOSED TESTIMONIAL TO DR. SAUNDERS.

A COMMITTEE has been formed by members of the City Corporation and others, having for its object the recognition of the public services rendered by Dr. Saunders as chairman of the Library and Museum Building Committee. The Lord Mayor will receive subscriptions. Dr. Saunders has rendered most important services to the citizens of London, and his labours, particularly with respect to the library at the Guildhall, justly entitle him to some substantial mark of the approbation of the community.

LUNACY IN IRELAND.

THE official report on Lunatic Asylums of Ireland shows that the returns for 1872 indicated a decided increase in the number of registered lunatics, the figures being 10,958, as against 10,767. This increase is partly accounted for by the greater longevity arising from the improved treatment of mental diseases.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

THE second meeting of the above Society was held at the Royal Kent Dispensary, Greenwich-road, on Friday, November 7; Prior Purvis, M.D., in the chair. William F. Teevan, B.A.,

F.R.C.S., read a paper "On the Causes and Treatment of Retention of Urine. The next meeting will be held on Friday, December 5, at 8 p.m. precisely. Dr. C. J. Thorowgood will read a paper "On the Nature and Treatment of Asthma."

FROM ABROAD.—PROFESSOR BOUCHUT ON DIPHTHERITIC BUBO.

UNDER the title of "The Treatment of Diphtheritic Bubo," Professor Bouchut communicates an interesting paper to the *Bulletin d'Thérapeutique* of October 15. Although one of the important complications in diphtheria, croup, and scarlatina, it is not, he observes, much known, and is not to be confounded with the simple glandular enlargement often met with in diphtheritic anginas, and which is frequently regarded as a sign of diphtheritic poisoning. This bubo is a suppurating adenitis, having nothing specific or toxical in its nature, and which appears to be the result of irritation existing in the vicinity. It is, in fact, only another example of that law of glandular pathology according to which, wherever local irritation is present, there may be set up irritation, inflammation, or suppuration of the corresponding lymphatic glands. Thus, any irritation or wound of the foot or genital organs may induce swelling of the groin; that of the fingers, adenitis of the elbow or armpit; that of the scalp, occipital adenitis; that of the lungs or bronchi, mediastinal adenitis; and that of the mouth or tonsils, ganglionary inflammation of the neck under the angle of the jaw, or in the parotid region. The progress of any of these inflammations may vary much in different individuals, suppuration occurring rapidly in some cases and more slowly in others.

In the diphtheritic and scarlatinal angina, the progress of the bubo is not very acute. At first we find one or more glands swollen but scarcely painful, they seeming lost in the doughiness of the cellular tissue, which constitutes a tumefaction in the submaxillary region extending to near the ear. There is a deep-seated, peri-glandular phlegmon which cannot be arrested, and will go on to suppuration. The tumour becomes hard and painful, without any change in the colour of the skin and without feeling very hot to the hand. The movements of the neck are difficult or impossible; and if the febrile condition of the angina had abated, it is rekindled, the temperature rising to 38° or 39° and some tenths. By degrees the tumour becomes softer, and is the seat of a deep-placed and uncertain fluctuation, which may continue so for several days, only becoming subcutaneous very slowly. If not opened, it eventually discharges itself, but then there is a considerable collection of matter, and there is a deep detachment of the muscles of the neck, the connective tissue of which has disappeared; symptoms of putridity set in, and the child sinks.

The pus in these cases, at first disseminated, is slow in forming itself into an abscess, and when this has taken place there is already considerable detachment of the deep-seated parts. Here lies the danger of these cases, for when one has the courage to seek for the pus in good time, as soon as its formation has taken place, and before any detachments occur, these buboes heal readily enough. Of twenty-two cases of these abscesses met with in Professor Bouchut's wards, six having been opened in good time were cured, but all the other children died. The sole means, in fact, of preventing the fatal accidents which result from abscess of the neck caused by tonsillar diphtheritis or scarlatinal angina is opening it promptly, and, if necessary, inserting a drainage-tube.

The case which was the immediate cause of these reflections occurred in a child seven years old, who had been cured of a diphtheritis by means of injections of saponised coal-tar. There was only some albuminuria remaining, when the left submaxillary region became inflamed, and the temperature mounted up from 37·2° to 39·3°. Collodion was applied during three days without any result; and a deep-seated fluctuation was believed to be felt. As this is often a deceptive sensation in this region, M. Bouchut postponed interfering for another twenty-four hours. His doubts then continued the same; but, fearing that detachment of the deep-seated parts might occur, he ventured to pierce the supposed fluctuating point. A few drops of pus were seen on the blade of the bistoury, which had penetrated to four centimetres, and the opening was enlarged on a conductor. Two days afterwards the aperture had in part closed, pus was only imperfectly discharged, and the tumour was as large as at first—deep-seated fluctuation being perceptible. Having ascertained the size of the abscess by means of a probe, a counter-opening was made, and a drainage-tube inserted. The child did very well.

NOTES ON FOREIGN HOSPITALS AND SCHOOLS OF MEDICINE.

I.—DENMARK.

(*Continued from page* 559.)

In a former communication (*Medical Times and Gazette*, p. 558) we gave a short description of the plan of medical education adopted in Copenhagen, and, at the same time, entered somewhat more into detail on the subject of systematic lectures and the practical teaching of the sciences allied to medicine. Following the programme which was then proposed, we now pass on to consider the provisions for clinical instruction in Denmark, and to describe the hospitals where they are carried out. Copenhagen possesses, besides the Clinical Hospital proper, a very much larger general or Commune-Hospital, and this we wish to notice at some length as one of the finest institutions of the kind in Europe.

It was stated in the previous part of this report that the Danish student of medicine attends hospital practice during the last three—or sometimes even four—of the six years of his professional education. In the same place we mentioned, among the buildings belonging to the medical school, but at some distance from the University proper, the Frederiks- or Clinical Hospital, and the Lying-in Institution. It is in these two hospitals that clinical work is especially pursued, and these will be first described. How far the Commune-Hospital is also made available for clinical teaching will be discovered when it comes to be noticed towards the end of this report.

The Frederiks-Hospital.

This hospital is an extensive one-storeyed building in the shape of a quadrangle, the middle of which is occupied by a large garden. On entering the principal gateway, in the end of the quadrangle facing the Amalie Gade (Street), the visitor finds the half of the hospital which lies on his left, or towards the east and south, devoted to surgery, and that on his right to medicine. The dispositiou of the wards of this hospital will be most easily comprehended if we describe one of the four sides of the quadrangle. Confining our attention to the east side, we first find several open passages from the inside to the outside, intersecting it at regular distances, and cutting it into as many divisions of a nearly square shape. Each of these divisions is in its turn intersected lengthwise by a partition subdividing it into two wards, the one facing the garden and the other the outer yard. This longitudinal partition serves an important purpose in the ventilation of the hospital, for into the double wall, of which it is built, there open the escape-holes of the ward on either side. This is not the only means of ventilation in the hospital: there are also openings in the roofs of the wards, and we are able to say that without more provision for purity of atmosphere than this natural ventilation, the surgical wards in the Frederiks Hospital smell perfectly fresh and pure.

These wards on the east side of the building are devoted, as has been said, to surgery. They are of various sizes, some large and handsome, others smaller and with a more confined look,—all plain and destitute of anything in the shape of novelty of arrangement or furnishing, but at the same time scrupulously clean, very comfortable and pleasant, and, as has just been said, filled with fresh and pure air. At our visit to the hospital we had the pleasure of accompanying Dr.

Saxtorph, the Professor of Clinical Surgery, in his morning round. Saxtorph's name is a familiar one in this country, especially to the Edinburgh surgeons, whose practice he holds in the highest estimation. We found that the hospital contains altogether about 400 beds, and of these about 150 are surgical, under Saxtorph's care, the rest medical, belonging to the services of Professor With and Dr. Tahlerup.

The walls of the hospital wards are oil-painted, and the floors waxed. Some of the bedsteads are wooden, others of iron. Each bed is furnished with a mattress in three pieces, all hair, resting on a lower mattress of straw. The bedclothes are blankets and a thick coverlet. The ward furniture is plain and good, and in nowise peculiar. The nursing in Copenhagen is done by females only, who seem to know and do their work fairly well. There are no sisters in attendance.

The Professor of Clinical Surgery visits his patients every morning during the session from half-past seven to nine o'clock, accompanied by the students, to whom he briefly describes the most interesting cases. The regular clinical lectures and demonstrations are delivered in the "clinic" (as the operating theatre is commonly called on the Continent) four times a week for an hour, immediately after the completion of the visit. The students take their places on the benches, and the professor, introducing both in- and out-patients, lectures on the cases, and operates where it is necessary to do so. This constitutes the clinical instruction received by the Danish student of surgery, and the clinical instruction in medicine closely corresponds, except that it is given six times a week instead of four. The opportunity of forming a practical acquaintance with surgery and medicine is therefore very abundant, as far as instruction is concerned. For the purpose of applying this knowledge and making it thoroughly personal, the zealous student has the further opportunity afforded him of working in the Frederiks- and Commune-Hospitals during his fifth and sixth years of study. Some three to six men may, if they please, go to one of the clinics in the evening, examine for themselves the patients admitted during the day, and write the cases. Next morning the professor reads and criticises the written cases. This arrangement may be pursued for two months in each session; and the student may take medical cases for one or two sessions, surgical cases one session, and syphilitic and skin cases for one session each. As we have indicated, this practical clinical exercise is entirely voluntary; but according to the present prospective arrangements it will become compulsory after 1875, and a fifth department—ophthalmology—be added to medicine, surgery, dermatology, and syphilis. Everything considered, it must be confessed that the Danish student of medicine possesses rare opportunities of acquiring a really practical knowledge of his profession.

We believe it will interest our readers to learn something of the practice of one of the leading Danish surgeons, and we will therefore briefly record the system of treatment which we saw followed in the wards of Professor Saxtorph.

The antiseptic system of dressing is adopted in its most minute details, and that with the best results, according to Saxtorph. We saw cases of amputation, excision, compound fracture, abscess, etc., all treated antiseptically, and all looking well. Saxtorph says he has used carbolic acid ever since it was introduced by Lister, and sees no reason for discontinuing it. In one case of gunshot wound of the leg, admitted in a very bad state, with secondary abscess and septicæmic diarrhœa, carbolic acid was applied locally, given by the mouth, and administered in enemata. The limb was subsequently amputated, and the patient is now doing well. Erysipelas very rarely breaks out in the hospital, although cases are not uncommonly admitted. Saxtorph treats burns by wrapping up the part closely in cotton-wool, and leaving it as long as it does not stink. Simple fractures are, as a rule, put up in starch-bandages after the swelling has subsided. Hip-joint disease is generally treated by pulley-extension. Several cases of chronic scrofulous disease of other joints were fixed in a starch-bandage, while cod-liver oil was being given internally. Excision had been performed a month before in a case of chronic hip disease with fistulæ, but, in spite of the antiseptic treatment, purulent discharge had returned in abundance. It is worthy of note that of some ten cases of excision of the hip in Copenhagen, of which a record is kept, not one is now alive,—why it is difficult to say. A case of chronic effusion into the knee had been punctured, and the joint immediately put in a starch-bandage: the result promised to be good. Amputations, as far as we saw, are very successful in the hands of Professor Saxtorph, the stumps healing well and without the conical look and exposed bone so often visible in German surgical practice. Stone in the bladder is common in Denmark, and Saxtorph prefers operating for it by lithotomy. He adopts the lateral incision, and uses the blunt gorget in entering the bladder. Skin-grafting is regularly employed, and with good results. Poultices, such as are seen in the London hospitals, are not to be found in Saxtorph's wards, where warm-water fomentations and arnica "flowers" alone are used.

The surgical out-patients at the Clinical Hospital are attended to in the "clinic" or operating theatre. The number is very small.

Next door to the Clinical Hospital stands the Lying-in Hospital, which contains fifty beds. It is under the superintendence of Dr. Stadfeldt, the Professor of Midwifery. We believe the annual number of labours is now considerably less than it once was; but neither of this nor of the internal arrangements are we in a position to speak with certainty. We will therefore leave the Lying-in Hospital, and pass on to the description of the other general hospital at Copenhagen.

The Commune-Hospital.

This magnificent hospital is situated in the north-western outskirts of Copenhagen, on a large piece of garden-ground which was formerly covered by part of the city ramparts. Its situation is at once open and airy, and readily accessible, and as the new botanical gardens are being laid out in front, and the rest of the immediate neighbourhood is occupied by a public promenade, there is little fear of the building being ever robbed of its pleasant prospect and pure air.

It is by no means easy to describe in an intelligible manner the appearance and arrangements of this huge building. We are under deep obligations to Professor Rasmussen—a visiting medical officer, and one of the most distinguished members of the profession in Denmark—for the extremely obliging manner in which he personally conducted us over the Hospital, pointing out the general plan, and showing every place and arrangement which might be supposed to interest us as foreign visitors. Let the reader imagine a building in the form of a quadrangle, enclosing a garden, and with one of its sides fronting the approach to the hospital—this is the plan of the administrative portion of the institution. From each of the four angles of this building there runs out a single narrow block, in such a direction that two of them are continuous with its front, forming therewith the front of the hospital; and the other two continuous with its back, and parallel with the front, forming the back of the hospital. This is, roughly speaking, the arrangement of the place, and the four blocks last mentioned are those in which the public wards are contained. The plan of the hospital might be otherwise described as shaped like the letter H turned on its side, and furnished with a double cross-line, thus— ⊟ Most of the building is of three floors, exclusive of cellars. In the rear are two bath-houses (male and female), a large washing- and laundry-house, and an engine-house—together. Still farther back are placed two buildings—one on the west side for mental diseases, and the other on the east for infectious diseases. Farthest north of all are the stables. At a short distance from the hospital in the south-west corner of the garden is the dead-house, with the post-mortem room; and flanking the front approach to the hospital on either side are the houses of the senior surgeon and the superintendent respectively. All the buildings are of brick, and the style is modern and plain. There is no attempt whatever at ornamental display, yet the general effect is pleasing as well as imposing. The hospital was built but a few years ago at a cost of 1,500,000 dalers Danish, or nearly £170,000 sterling.

The annual number of in-patients is said to be about 10,000 to 12,000, and the number of beds is 800. The number of out-patients—surgical only—is very small. Patients are admitted and kept in the hospital free of charge, except such as desire private rooms, and are called private patients: these pay not over 1 daler (2s. 3d. English) a day, and some of them less.

Large though the building be, the arrangement of the wards and their adjuncts is not difficult to comprehend. As has been said, there are four symmetrical wings in the building, each containing three floors, and a description of one of these is a description of all. Selecting one of the floors, we enter it from the staircase at the nearest end, and find ourselves in a corridor running to the other extremity, along the whole length of the back of the block. The corridor is large and bright, and may be warmed by steam in winter. The doors of the

wards and nurses' rooms open from the corridor towards the front; while opening from it towards the back at frequent intervals are bath-rooms, water-closets, and small ward-kitchens, which have thus been built in behind the corridor by short wings being thrown out at the back. The various apartments will now be examined in succession.

The wards, as we have just indicated, are placed side by side along the front of the block, are separated from each other by the nurses' rooms, and open into a common corridor behind them. All the wards, with a few exceptions, are of the same size—large square-shaped rooms, with windows towards the front only, and furnished with four beds on either side. The walls are whitewashed, their coat being renewed every year. The floors are waxed. In the middle of each ward stands a handsome iron stove, by which alone the atmosphere is warmed. The beds are iron, and the bedding the same as in the Frederiks-Hospital. A locker beside each bed and a few chairs complete the furniture of the ward. Fitted into one corner of the room is a small sink with a water-tap—an arrangement which is considered objectionable by the physicians, from the liability to the return of sewage-gas into the ward.

The ventilation of this hospital, which is almost altogether artificial, is very perfect, and deserves to be fully described. The system is one of constant abstraction of the impure air by means of a powerful fan driven by steam, while the pure air readily finds its way into the ward by special openings in the wall. Entering under the windows, the pure air is conducted in a pipe to the ward-stove, around which it circulates until it makes its escape at the top. The air, thus warmed, forms the upper stratum of the atmosphere of the room, but soon loses this position, and, becoming impure as it descends, reaches the floor. In the walls, close to the floor on either side of the ward, are several small holes in direct communication with the common exit or foul-air tube, which is pumped at the further end by the fan. There is therefore a current of some strength at the escape-holes in the ward, and through these the foul air is constantly passing. The huge fan in the engine-room at the back of the hospital is itself a sight worth seeing.

The nurses' rooms—one between each couple of wards—do not require description here; there is an outer room which serves as a kind of store, and an inner or private room. The means of direct communication between the wards and nurse's room is a small window only—not a door, as in some hospitals. The attendants, as far as we saw, are all females; they are neatly dressed, with no special uniform. There is no sisterhood.

Directly opposite the door of each nurse's room, on the opposite side of the corridor, are three doors leading respectively into the water-closet, bath-room, and kitchen, which have been already mentioned. The kitchen—a small ward-kitchen only—contains a stove heated by steam, with a large copper for poultices, a second for hot water, and a third for keeping food, etc., warm. There are also utensils for plain cooking. The bath-room contains two large baths with douche, and hot and cold-water taps. The baths are mounted on wheels, and can be taken into the wards when required. The water-closet includes an urinal and an ordinary seat with water. Professor Rasmussen does not approve of this arrangement; he would have the stools at once disinfected and removed.

We have already had occasion to remark that private patients are admitted into the hospital at so much a day. Each of these patients is provided with a private room, a lofty, well-furnished chamber, situated in the upper floor of the north and south blocks of the administrative portion of the hospital. These rooms open off a lateral corridor, like the public wards, and demand no special description.

The central part of the front of the hospital is occupied by a small and very pretty chapel on the second floor, and on the first floor, immediately under the chapel, by an operating-theatre. The theatre is very well lighted from a large front window, and by artificial light when this is necessary. On either side of it are small operation-wards for use immediately after operations, and specially fitted with steam-pipes for raising the atmosphere to a high temperature. At the time of our visit several tracheotomy cases were lying here.

The practice or service in the Commune-Hospital at Copenhagen is a mixed one—an arrangement which seems less strange when thus expressed than it looks to the eye of the visitor. It means that medical and surgical cases are found side by side in one ward, and visited by the same medical attendant, who treats in succession typhoid fever, fracture of the femur, cancer of the stomach, and the stump of an amputated forearm. We wish to record some of the cases seen under the care of Professor Rasmussen, and his method of treatment. Dilatation of the stomach—a disease so seldom observed (or recognised?) in this country—was being treated very successfully by washing out the viscus with a syphon stomach-pump. Phthisis is treated with warm infusions of malt; Rasmussen questions the value of cod-liver oil. Emphysema and asthma in Copenhagen seem to be relieved by iodide of potassium. Typhoid fever is being treated by Rasmussen with sulphocarbolate of soda, with quinine in small doses in some cases, and with cold baths (16° to 18°) whenever the temperature exceeds 41°. The results of these various means are uncertain, for, as Rasmussen wisely remarks, no two epidemics of typhoid fever are alike. In his surgical practice it was interesting to find Rasmussen of a different opinion from his colleague, Saxtorph, in the Clinical Hospital, as regards the value of carbolic acid. The former professor now constantly uses a watery solution of sulphurous acid, and prefers this to all other dressings, carbolic acid included.

The hospital for mental diseases and the epidemic-house are two nearly symmetrical buildings well behind the hospital proper. The former furnishes accommodation for eighteen delirious or maniacal cases, is arranged on the same corridor system as the hospital, and is of course specially furnished for the class of patients that are treated in it.

The bath-houses are two symmetrical buildings—male and female. The bath-rooms are very extensive, and of every kind—Russian, vapour, ordinary, and so on.

The kitchen, washing-houses, laundry, etc., are all supplied with steam, and it is by steam that all the cooking, washing, drying, and dressing are done. Every patient on admission is stripped and sent to the bath. He is then sent to his ward and furnished with an entire change of clothes, both under-clothing and upper-clothing. Nothing whatever in the way of food or drink is allowed to be brought in for the patients. There are three scales of diet, which closely resemble those of London hospitals, namely—No. 1 (diet for severe cases), liquids only; No. 2 (diet for convalescents), soup, fish, etc.; and No. 3 (or ordinary diet), meat, fish, soup, etc. Wine is not included in the ordinary diet, but is very much used, especially clarets.

The pathological building has been mentioned before. It is of no great size, is built in the chapel style,. and contains a necropsy-room, a small mounting-room, and a dead-room. Post-mortem examinations are not compulsory in Denmark, but nearly all are obtained.

There are altogether five services at the Commune-Hospital—namely, those of Drs. Holmer, Rasmussen, Brunnicke, Aarstrup, and Engelstet. The first gentleman's service is purely surgical, and the last has charge of syphilitic and cutaneous cases. The department of dermatology and syphilis is an university clinic, attended once a week during the sixth year of medical study. Each of the services has connected with it three or more resident assistants, the chief of whom probably divides the work of the daily visit with the professor. A journal is kept of every case admitted into the hospital.

We may add a few notes of the practice of Professor Holmer, the surgeon in the Commune-Hospital. Holmer agrees with Saxtorph, and disagrees with Rasmussen, on the value of carbolic acid in the treatment of wounds. This surgeon adopts Lister's antiseptic system completely, and believes in its efficacy. Two instructive cases of tracheotomy for croup were seen under Holmer's care in boys of three and six years respectively. A special ward is employed for these tracheotomy cases, filled with warm, moist air by means of pipes. Holmer has operated on no fewer than fifty-one cases of "diphtheritic laryngitis," and has been blest with 50 per cent. of recoveries!

It has been already sufficiently indicated how the practice of the Commune-Hospital is open to the medical students of the University, and how far they avail themselves of the privilege.

Copenhagen contains at least one more hospital, the Hospital for Children and for Diseases peculiar to Women. We are not in a position to speak of this place. Dr. Hirschprung attends to pædiatrics, and Professor Horitz operates on the gynæcological cases.

ENTERING the hospital surgery during the late war, Dr.—— met Paddy Doyle, the orderly, and asked him which he considered the most dangerous of the many cases then in hospital. "That, sir," said Paddy, as he pointed to where, on a table, lay a case of surgical instruments.

INDIVIDUALISM.

AN INTRODUCTORY ADDRESS DELIVERED BEFORE THE MEDICAL SOCIETY OF KING'S COLLEGE, LONDON, ON OCTOBER 16, 1873.

By JOHN CURNOW, M.D. Lond., M.R.C.P.,
Professor of Anatomy in, and Hon. Fellow of, King's College.

(*Continued from page* 590.)

Now we hear on all sides the announcement of, and mutual congratulations on, the near approach of a scientific pharmacology, deduced from experiments on the lower animals, as the true starting-point for the future treatment of disease; and Claude Bernard, by his researches on curare, is hailed as the pioneer of the new science. Whilst believing that as in the chemical school, so there is also in this a certain amount of truth, still I fear for both the same danger—that their very exactitude will prove the weak point in their application to therapeutics. Experiments on lower animals, such as frogs, lead to definite and calculable results; but we all know that with different human beings the same doses of iodide of potassium, mercury, morphia, and other drugs act very differently. We dismiss the fact summarily by calling it idiosyncrasy, but this is a mere confession of our ignorance. Human beings, moreover, are not singular in this idiosyncrasy, for on referring to the report of the well-known experiments on the influence of mercury on the biliary secretion, by the Edinburgh Committee of the British Association, which was read at the Norwich meeting in 1868, we find that a young retriever (D. Table 1), under similar external conditions gave very different results to the other dogs operated on; and the author of a prize essay read before the Medical Society of Lyons has recently stated that chloral differs in its action on dogs, according to size, stature, and race—"old dogs being more readily influenced than young ones, and hounds and spaniels than bulldogs or terriers."(a) These researches tend to show that the higher in the scale is the animal experimented on, and the more complex are its vital phenomena, the farther removed is the result from the certainty attainable when lower animals or inorganic substances are the objects of our investigation. Again, with many of our most useful drugs, well-defined and characteristic effects are not produced on the healthy organism, and it is the presence of the disease which elucidates the action of the remedy. Thus, no one from its effects in health could have inferred the beneficial action of iron in anæmia, of bromide of potassium in epilepsy, or of quinine in ague. Our ignorance of the tissue-changes which constitute the first stage of most diseases is another barrier to this method; we know not the primary departure from health in such an every-day affection as gout, for when uric acid is detectable in the blood, and we combat its presence, the disease is far advanced. Hence we are unable to make use of the substances employed in exact physiological experiments, although their action is so definitely localised that one is stated to influence "the cardiac inhibitory ganglia, another the nerve-fibres intermediate between these ganglia and the ends of the vagi nerves, and another these endings themselves."(b) The conditions on which health and disease depend are still too complex and ill understood, and the differences in the same disease in different individuals are so inexplicable, that as yet only the roughest generalisations can be made, and the more mathematical and precise a science becomes, the more difficult it is to subject such varying and ill-defined phenomena to its dominion. To sum it up, Truth is against Life: Life is combative; Science non-combative. We are still reluctantly obliged to admit "the miracle of life which will not be expounded, but will remain a miracle."(c)

Under the physiological method we must return to the symptomatic treatment of disease, and use cold to lower increased temperature, atropia to dilate contracted pupils, nitrite of amyl to relax abnormally contracted small arteries, etc., quite overlooking the varying conditions on which these symptoms may be dependent. The present school of physiologists is so rapidly becoming purely physico-chemical, ignoring the subtler problems of nutrition, growth, and development, that its predominance in practical medicine will not be an unmixed benefit. The tendency to appear exact by disregarding the complexity of the factors is an old failing in our medical history, and when we read of non-lethal and minimum-lethal doses of disease, and see the minutely accurate numerical and graphic representation of those phenomena which can be thus shown, without the slightest reference to or regard for any others, I fear lest we revert to adjusting the doses of our drugs mathematically, according to the plan of Alkahendi, in the ninth century, who regulated them by the rules of geometrical proportion and of musical harmony; and so shall in some new guise reinstate the old therapeutic formula—"The doses are as the squares of the constitution." That this is scarcely an exaggeration of the extremes to which some mathematical enthusiasts ride their hobby is shown by Volkmann's formula for the influence of stature on the pulse; the ratio he deduces being "that of the ninth root of the fifth power of the height."(d)

The slow growth of medicine has often been urged against it by its detractors, but the more complicated the data with which any science has to deal, the more removed it is from being an exact or pure science, the less capable are its elements of being reduced to calculation, and the slower must its progress necessarily be. At present the constituent factors of the human constitution are so varying, so intricate, and so imperfectly known, while our medicinal agents are so numerous, and their real value in many cases so doubtful, that it is at all events premature to displace the old art of therapeutics by the new science of pharmacology (whose true position thereto is merely suggestive), and to substitute for the ancient empirical methods the modern physico-chemical ones. To prevent this from taking place, we must exercise our individual judgments, even if we are forced to oppose prevailing ideas, and to decline following the advocates of plausible, popular doctrines.

"Give me truths;
For I am weary of the surfaces
And die of inanition. If I knew
Only the herbs and simples of the wood,
Rue, cinquefoil, gill, vervain, and agrimony,
Blue-veteh, and trillium, hawkweed, sassafras,
Milkweeds, and murky brakes, quaint pipes and sundew,
And rare and virtuous roots, which in these woods
Draw untold juices from the common earth,
Untold, unknown, and I could surely smell
Their fragrance, and their chemistry apply
By sweet affinities to human flesh,
Driving the foe and 'stablishing the friend,—
O! that were much, and I could be a part
Of the round day, related to the sun
And planted world, and full executor
Of their imperfect functions."

I hope that I may not be misunderstood here. I value as highly as anyone every advance in science, and particularly in those sciences which are related to medicines, but I cannot look upon them as worthy of being called "allied" sciences; I regard them as preliminary and ancillary thereto, and I hold that the great aim of all of us should be not to become physiologists, anatomists, or chemists, but physicians; and that to attain to this end, the only workshop is the bedside, and the best guides are observation and experience. The final purpose of our profession is "to cure disease, to prevent disease, to alleviate pain, and to prolong life;"(e) we have therefore to acquire a practical art, and the perfecting of ourselves in its technicalities is the first essential. The limits in chemical, physical, and mechanical remedies are quickly reached; while the unwieldy mass of therapeutic agents used by us is so heterogeneous and chaotic as to render any scientific classification thereof impossible. The absurd doctrines based on such attempts in the past history of physic should be enough to frighten us from further essays in this direction. Each system in turn started from some fragmentary truth, but being forced beyond its legitimate sphere, the very truth therein was endangered.

When fascinated by the brilliant seductiveness of some "easy method" or "royal road" out of our difficulties, we must not forget that the tritest things in our medical experience are among the most mysterious, and we may turn with advantage to the works and practice of the true clinical physician, such as Sydenham, Trousseau, Graves, or Stokes. We shall then appreciate that empirical method which they adopted, and which, though often scoffed at, placed them amongst the greatest benefactors to suffering humanity. "Prove all things; hold fast that which is good."

"*Ars longa, vita brevis*," said that very learned man, Dr. Butts, the Court physician (*vide* the narrative of "The Lady Rohesia," by Thomas Ingoldsby, Esq.); and, unfortunately for us, both parts of that old aphorism are still true. But a

more hopeful prospect is held out to us in the "good time coming;" for then we shall no longer use such base material substances as iron, lead, arsenic, zinc, or even our old familiar friend, sulphate of magnesia, but bid them give way to fairer and more ethereal beings in the numerous progeny of that famous quartette: carbon, hydrogen, oxygen, and nitrogen. At least, that is what I gather from the following quotation:—

"The subject I have had to treat goes to the root of principle in the study of means for the cure—I am bold to say the cure, by true and certain scientific methods, of the diseases which most severely scourge the human family and many of the lower families in the scale of living organisation.

"Gradually—but surely as gradually—the curer of bodies will learn from the chemist and practical physiologist that his remedies, rapid in action, easy in administration, positive in result, must all come from the organic compounds, which are themselves a part of the organic nature.

"Thus learned, the physician will exchange dogmatism for wisdom, faith for knowledge, and doubt for certainty. He will compete with his fellows by the pure strength of intellect, he will be responsible for results without evasion, and his duties will be more solemnly his own; but he will stand where he never stood before, a conscious master in his art: he will know in what he doth believe, and the world, assured by his exactitude, will soon learn to know none but him in his vocation." (f)

This is not the dream of an ancient alchemist, intoxicated with the illusions conjured up by the idea of soon possessing the *elixir vitæ*, or the philosopher's stone; but it would really seem that, even in these prosaic days, the subtle influence derived from close communion with organic derivatives like "methyl and the allied compounds," will inspire with like visions the author of a paper read before the British Association of Science, and lead him thus sanguinely to prophesy the advent of the millennium of medicine.

I am well aware that Dr. Burdon-Sanderson, in his talented address on Physiology, at the past meeting of the British Medical Association, retorted on the physician that it was the latter "who attempted to apply the facts of recent experiment, without any sufficient knowledge of their bearing." (g) He instanced the present comparative disuse of mercury in certain well-known digestive derangements, as not being deducible from the investigations of the Edinburgh Committee. Against this ingenious shifting of the true position of the question—tried, I think, rather too soon—I must strongly protest. By referring to the discussion at Oxford in 1868, on the abbreviated report presented by Professor Hughes Bennett, one is struck with the unanimity with which every practical physician (including the president, Dr. Acland) spoke against the unwarrantable conclusions drawn by the originator and reporter of these researches. His inferences are even more absurd than those which Dr. Sanderson alleges throw undeserved discredit on his science, but I will only read one sentence—"Mercury was found in the Pharmacopœia, because it was copied from one to the other." (h)

Such rash statements as those which I have quoted seem very prevalent among the most eager prosecutors of the new science, and tend so much to lower unduly its position with cautious observers, that it will soon have to cry out in the words of the old maxim, "Save me from my friends."

The special object of my address has been to show the safeguards derived from a healthy individualism, both generally and technically; and to enforce the danger of allowing it to be swamped by mere popular opinion. For economy in teaching, the unit is lost sight of, and I consider it far from being the least advantage of this Society, that it is the only means in our educational system by which the expression of our individual ideas is fostered and encouraged, for elsewhere the student's judgment is overshadowed by that of his teachers or examiners, and he is only concerned in learning and reproducing their opinions. That a large element of the success of this College in the formation of judicious practitioners is due to this influence I am quite sure, and herein, as well as in promoting feelings of mutual attachment and forbearance, lie its chief claims to our support. A healthy individualism is also of great benefit to the Society, and in many of its best officers, under whose management its proceedings have been most flourishing and most useful, this characteristic has been very marked. Moreover, the Society appeals to the patriotism and affection of every King's man, for the name of nearly every one who has been taught here is inscribed on its records, and it is the most valuable legacy that has descended to us from our predecessors. Already it has become a sad memorial of such men as Todd, Salter, Brinton, Price, Tanner, Powles, Kempthorne, etc., who were in turn members of its executive, and who have passed from amongst us in the midst of their usefulness—their memories and their deeds now alone remaining.

Finally, gentlemen, the enunciation of such conservative opinions on education by one barely removed from the position of a student, may seem strange, and may have been little anticipated; but they are due to a strong impression, that we are increasingly affected by a tendency to form, and unhesitatingly act on, cursory judgments, based on superficial, and therefore unreliable results; and that it is too much the fashion to glorify our own period and our own work, forgetting that we are much too near and too interested to sum up impartially the effects of our own endeavours. I have therefore felt bound to reiterate the old but still necessary motto, "*Laus temporis acti;*" for as the fabled Antæus renewed his strength by contact with his mother earth, in like manner we, when baffled and almost crushed amid the clouds of speculative science, can always obtain fresh energy and vigour by returning to our *terra firma*—the examples and teachings of the fathers of "clinical" medicine.

REVIEWS.

Man and Apes: an Exposition of Structural Resemblances and Differences bearing upon Questions of Affinity and Origin. By St. George Mivart, F.R.S., V.P.Z.S., etc. London: Hardwicke. 1873. Pp. 200.

We welcome the appearance of this unpretending little work. It is a calm, dispassionate, and unprejudiced inquiry by a competent naturalist and anatomist into the value and truth of those doctrines as to man's relationship with the Simian families which, during the last ten years, have acquired such a rapid—but, as we believe, undue—development amongst large classes of society both in Germany and England.

Mr. Mivart does not place man, with Professor Owen, in a zoological sub-kingdom by himself, nor even, with Cuvier, in a separate natural order: he is content to put him where Linnæus and Professor Huxley would agree he should be zoologically placed—as a mere family (*Hominidæ*) of the sub-order *Anthropoidea*, of the order *Primates*.

We do not care to stop to inquire whether this classification, taking all the facts of the case into consideration, is the best or the truest. Its adoption at least proves that Mr. Mivart is ready to concede a large advantage to the supporters of a purely evolutionary hypothesis. But having made this concession, we think his book one of the most telling contributions to the anti-Darwinian side of the controversy which we have lately seen. In the first place he completely disposes of the claims of the gorilla to be the highest of apes and nearest to man, by showing that the huge brute is nothing of the kind. With regard to his brain characters, this indeed had been done long ago by Gratiolet; but the popular opinion of England has not been much influenced by the French estimate of the gorilla. Secondly, Mr. Mivart proves incontrovertibly that there is no one kind of ape which has any special or exclusive affinity to man, and that the resemblance between him and the lower forms is shared in not very different proportion by different species—some of them widely separated; that there is no regular ascensive approach to man in the Simian families, but, in the words of Schroeder van der Kolk and Vrolik, "the lines of affinity existing between the different Primates construct rather a network than a ladder."

With regard to the main question underlying the whole controversy, that of the descent of man from some ape form, we will allow Mr. Mivart to speak for himself in the following remarkable passage:—

"Let us suppose ourselves to be purely immaterial intelligences, acquainted only with a world peopled like our own, except that man had never lived on it, yet into which the dead body of a man had been somehow introduced.

"We should, I think, consider such a body to be that of some latisternal ape, but of one much more widely differing from all the others than such others differ one from another amongst themselves. We should be especially struck with its vast brain, and we should be the more impressed by it when

we noted how bulky was the body to which that brain belonged. We should be so impressed because we should have previously noted that, as a general rule, in back-boned animals, the larger the bulk of the body the less the relative size of the brain. From our knowledge of the habits and faculties of various animals in relation to their brain structure, we should be led to infer that the animal Man was one possessing great powers of co-ordinating movements, and that his emotional sensibility would have been considerable. But above all, his powers of imagination would have been deemed by us to have been prodigious, with a corresponding faculty of collecting, grouping, and preserving sensible images of objects in complex and coherent aggregations, to a degree much greater than in any other animal with which we were before acquainted. Did we know that all the various other kinds of existing animals had been developed one from another by evolution; did we know that the numerous species had been evolved from potential to actual existence by implanted powers in matter, aided by the influence of incident forces; then we might reasonably argue by analogy that a similar mode of origin had given rise to the exceptional being, the body of which we were examining.

"If, however, it were made clear to us—immaterial intelligences—that the dead body before us had been, in life, animated, not by a merely animal nature, but by an active intelligence like our own, so that the difference between him and all other animals was not a difference of degree, but of *kind*—if we could be made to understand that its vast power of collecting and grouping sensible images served but to supply it with the materials made use of by its intelligence to perceive, not merely sensible phenomena, but also abstract qualities of objects—if we become aware that the sounds uttered by it in life were not exclusively emotional expressions, but signs of general conceptions (such as predominate in the language of even the lowest savage), then the aspect of the question would be entirely altered for us.

"We should probably decide that if the body before us seemed to us to be so little related to the informing rational soul that its existence anterior to, and independent of, such rational soul was quite conceivable and possible, then its origin by process of natural evolution would, indeed, also be conceivable, and, indeed, *à priori* probable.

"But if, on the other hand, we were convinced, from whatever reason, that it was inconceivable and impossible for such a body to be developed or exist without such informing soul, then we should, with perfect reason and logic, affirm that, as no natural process would account for the entirely different kind of soul—one capable of articulately expressing general conceptions—so no merely natural process could account for the origin of the body informed by it—a body to which such an intellectual faculty was so essentially and intimately related."—Pp. 189 to 192.

For ourselves, we doubt not the philosophical truth of this conclusion, consonant as it is with the instincts of universal humanity. Mr. Mivart's little book, which is written in language "understanded of the people," will, we hope, supply an antidote to the unfounded assumptions and hasty generalisations of Mr. Darwin's "Descent of Man."

Fractures of the Elbow-Joint. An Essay to which was awarded the Second Prize of the Boylston Medical Society for 1873. By Walter Ela. Cambridge: Welsh, Bigelow, and Co., University Press. 1873. Pp. 57.

The author of this little monograph is a second year's student at Harvard Medical College. It is founded to a great extent upon information derived from the fracture-books of the out-patient department of the Massachusetts General Hospital. It is got up in the most highly finished style on glazed toned paper, with large clear type and wide margins. There are a few woodcuts, which and the Albertype were taken from drawings made by Dr. H. P. Quincy.

After two pages of general remarks upon fractures of the elbow-joint, a short account of the anatomy of the parts entering into the formation of the elbow is given—bones, ligaments, and muscles being briefly described; then a description of the mode of development of the humerus, radius, and ulna follows. In the greater part of the remaining pages the nature, frequency, causes, complications, diagnosis, mode of union, treatment, and prognosis of these fractures are considered.

The author deserves praise for the thorough manner in which he has consulted the works of authorities on fractures, the treatises on fractures about the elbow in works on general surgery, and the reports of hospitals upon the subject; but, in spite of his remarks in the first five lines of the introductory section, we cannot flatter Mr. Walter Ela by saying that we find anything in the pages of this little volume, under any of the headings we have mentioned, for which he is not indebted to well-known anatomical and surgical authorities.

We do not quite see how he can reconcile the two statements—(1) that one of the reasons for the obscurity which attends fractures in this region is "that the important structures are confined in so small a compass," and (2) that "the uncertainty in prognosis is, to a great extent, due to the extensive articular surfaces in this vicinity, which are often implicated in case of fracture of the joint"; and when he goes on to say "whereby inflammation is set up," we should like to know what the "whereby" means: has it reference to the *extensiveness* of the *articular* surfaces, or to the fact that extensive surfaces, or articular surfaces, or extensive articular surfaces, are *implicated?*

The anatomy of the bony structures of the joint is of the baldest character. No mention is made of one of the most important features of the trochlear portion of the humerus—viz., the obliquity of its margins, whereby this articular surface lies in the middle line of the bone posteriorly, and the prominence of the inner margin is greater anteriorly and that of the outer margin posteriorly. Yet this obliquity is of great importance. Then we must take exception to the statement that "the articular surface on which the head of the radius is received—the capitellum—is on the inferior extremity of the external condyle." A second-year student, even if he is not writing a treatise on the elbow-joint, ought to know that the articular surface for the radius is not simply and entirely on the inferior extremity of the external condyle; but consists of an eminence and a groove internal to it, upon the *antero*-inferior extremity, and that this articular surface does not extend to the posterior surface of the extremity at all. The articular ends of the ulna and radius are, too, very scantily outlined; yet if the anatomy of the part is introduced in a monograph of this sort, it ought to be minutely and completely described.

There is no necessity for us to dwell upon the accounts of the various kinds of fracture, but we feel bound to refer to a most carefully described case of fracture of the coronoid process, and impacted fracture of the neck of the radius, which Mr. Ela came across in the dissecting-room of the Harvard Medical School in November, 1872. It is described as a case of "fracture of the coronoid process, partial fracture of the olecranon, impacted fracture of the neck of the radius, and separation of the epiphysis of the internal condyle, followed by excellent motion"—as was ascertained upon inquiry of the woman's doctor, who says that motion was not impaired, nor was any deformity of the arm noticed after the injury. The parts of the joint after dissection are illustrated in four figures by Dr. Quincy.

This case is very interesting, and as rare as interesting. The author says he has not been able to find any mention of an impacted fracture in the upper extremity of the radius in any surgical writer, and thinks it has not been described. We cannot say that we are able to inform him of any report of such a case; but, whether or not, great credit is due for the acuteness shown in detecting the fracture in this instance, and for the care exercised in reporting upon it. The essay altogether deserves the prize which the Boylston Medical Society has awarded to it; though we do not advise all students who obtain prizes at medical societies to hasten to publish their successful papers. Let them wait awhile, and they will find that experience and matured judgment will enable them, later, to build upon the efforts of their earlier years a structure which will do them more honour than can fairly be expected from the earlier production.

Smith's Physicians' and Surgeons' Visiting List, Diary, Almanack, and Book of Engagements for 1874. (Twenty-eighth year.) John Smith and Co., 52, Long Acre.

We have so frequently expressed our sense of the value of "Smith's Visiting List," that it is unnecessary for us to say more than that the edition for 1874 is in every way equal to its predecessors. It will be found a most useful companion, not only to the general practitioner, but to the consulting physician and surgeon.

Medical Visiting List. Introduced by Alfred Sheen, Surgeon to the Cardiff Infirmary.

This is simply a few pages of paper ruled for names of patients and days of visits, in a stiff cover.

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, November 12.

The Introductories (*continued*). — Meath Hospital and County Dublin Infirmary—Richmond Surgical Hospital.

On November 3, Dr. Foot opened the winter session of the Meath Hospital and County Dublin Infirmary, with an address which was characterised by eloquence and earnestness, and, above all, pervaded by a vein of *sympathy* for the student, no matter what his standing. He commenced by stating that he found himself rather unexpectedly called upon to address them on this critical occasion. It had been arranged that his illustrious colleague, Dr. Stokes, should have spoken to them that day; but a sore accumulation of domestic trouble kept him temporarily absent. However, with the true interest Dr. Stokes ever felt for students, he had charged him to assure them of his deep sympathy with those about to commence their studies; to exhort to perseverance those with whose industry he was already well acquainted; while to those who had not yet exhibited any marked interest in their studies he sent a timely and affectionate warning to bestir themselves before their golden opportunities were lost for ever. As he (Dr. Foot) cast about in his thoughts how he could best carry out these instructions, and tried to think which of the many ideas fermenting in his mind under the influence of the occasion was the best suited to effect that object, he found perpetually turning up the principles dear to all true students —the principles of work and earnestness and persevering diligence—themes which could never be trite or threadbare as long as there were young students anxious to hear of the so-called secrets of success, and older ones willing to put these principles into practice.

After some prefatory observations on the difficulty of the task before him, Dr. Foot drew a vivid picture of the feelings of a beginner, who was in the uncomfortable position of a new boy in a school, and told them, from his own ease, how to get interested at once in hospital attendance, and so acquire the secret of punctual regularity. He advocated the mutual assistance of one another by students, and dwelt on the value to a beginner of the early cultivation of the senses, illustrating the wonderful differences in perfection between the taught and the untaught hand, eye, and ear. The best order of study, as founded on long hospital experience, was laid before the students. The picture of the different behaviour as to hospital attendance of the interested and the uninterested student was graphic and amusing, and seemed to have some very telling points for the audience. Tracing the chain of interest, enthusiasm, and work, with their interdependence on one another, he forcibly pointed out that it would not do to jog along with an easy indifference to exertion, content with avoiding gross violation of decorum. There were some by-roads they might thus travel—roads on which none they met would impede them as long as their appearance was genteel, and their dulness inoffensive; but, on the hard, rough, crowded highroad to success, thronged with onward-pressing enterprising, enthusiastic men, they would have no chance of even a footing in the Olympian competition unless they had early trained themselves to wrestle with intellectual athletes, acquired by their own exertions the steel mail of self reliance, and learned self-mastery, the parent of all other conquests. He was not so foolish or so mad as to suggest to them a contempt for the valuable assistance of those who had the power and might have the will to assist them, but he wanted to encourage any student present who had no friend or patron in the profession, and to tell such a one that he was not therefore exiled from even its highest honours. If the humblest man present would diligently incorporate into the essence of his daily life the principles he urged on them, the laurels of professional success would be within his reach, and a crown of their green leaves, slowly woven by his own unaided exertions, would grace his head in a far more noble and less envied manner than one manufactured by any other means, even though it were by a rapid patent process.

He turned then to the consideration of time, its value, how to make it, the inroads upon a student's time, by whom made, and how to avoid them. It did not occur to students at first to consider all the deep meaning that lay hidden in that one word "Past," but by-and-by as examinations became imminent, lightning-flashes of memory illuminated their frightened minds, giving them glimpses of the catalogue of unused yesterdays at the debtor side of their account with time. With great force and power he reviewed the reasons which made it so painful to see idlers refusing to accept their hospital privileges, the most painful thought of all being that of the hecatombs which thereby might fall at the shrine of their future experience. The senior pupils, who came under the lecturer's more immediate observation, were highly commended for their marked advance in clinical knowledge: the gentlemen who held the responsible positions of clinical assistants for the past twelve months came in for a well-deserved meed of praise. He went minutely into the different epochs of mental growth, observable by all clinical teachers in their students' progress, and, having quoted the celebrated passage from the writings of the Rev. Sydney Smith on the subject—"Great success, the fruit of great labour"—he wound up with some very touching remarks upon the disappointments likely to result from the neglect of early opportunities.

On Thursday, November 7, Mr. William Stokes, Professor of Surgery at the Royal College of Surgeons, Ireland, gave an introductory address at the Richmond Surgical Hospital. He said—"A twofold duty devolves on me on the present occasion: one is to bid you welcome to the Richmond Hospital—an institution hallowed by the memories of so many great men, who have so closely identified themselves with the progress of surgical science during the past half-century; and the other is to express how deeply I feel the honour and responsibility which my colleagues have conferred upon me by asking me to inaugurate this session, to mark, as it were, the commencement of our common, and, I trust, our happy toil." Mr. Stokes then proceeded briefly to review the work done in the Hospital by its past Surgeons. The treatment of aneurism by pressure was first conceived and put into practice in their wards. The introduction of this plan, known now all over the world as the "Dublin method," belonged to Charles H. Todd, the father of Robert B. Todd, the late eminent Physician of King's College Hospital. It is not long since the late Professor Smith mentioned to Mr. Stokes the particulars of the case in which this treatment was first applied. The case was one of popliteal aneurism, and pressure had been in the first instance applied in order to temporarily occlude the femoral until the calibre of the collateral vessels had increased, ligature of the main artery being at first contemplated. The pressure had been applied for upwards of three days, and Mr. Smith, then a junior student, with a few others, went with Mr. Todd into the ward where the patient was. Mr. Todd went up to the patient, put his hand on the tumour, and kept it there for some time. Then removing the pressure after a few moments, he looked up and said, to the astonishment of all present, "It is now still." The tumour eventually almost completely disappeared, for, the moment the pulsation ceased, that process began which was so characteristically described by the illustrious John Hunter when first he applied a ligature to the femoral artery for the cure of aneurism. "Now," said he to Mr. Peile, who was standing by, "the absorbents are at it, like mites at a cheese."

At a subsequent part of his address, Mr. Stokes called in question the doctrines of Sir James Simpson and Mr. Erichsen as to the excessive mortality in hospitals. In the Richmond Hospital during the past four years the lecturer had had thirty-eight amputations, with only two unfavourable results, and in the Meath Hospital the statistics were equally satisfactory; while Mr. Callender, Surgeon to St. Bartholomew's Hospital, one of the largest, if not the largest, in London, and situated in one of the most populous districts of the metropolis, thus writes: "For four and a half years there has not been one patient lost as a consequence of amputation, although during that time, under Sir James Paget or myself, thirty-five consecutive amputations have been treated in the same wards." Hospital reform should not consist in the substitution of a cluster of huts like a gipsy encampment for carefully constructed buildings, where arrangements can be made for having good ventilation, pure air, plenty of light, an even temperature

a perfect system of sewerage, carefully-cooked, simple, but nutritious food, and skilful nursing. As a proof of the vastly improved sanitary condition of the Richmond Hospital, Mr. Stokes mentioned that many of the so-called "hospital diseases," such as erysipelas, pyæmia, hospital gangrene, and cancrum oris, which were so frequently the subject of observation during the period of his pupilage, were now, it might be said, especially as regards the two latter diseases, almost entirely stamped out. During the time that he had been officially connected with the hospital he had not had an opportunity of seeing a single case of either of these two latter affections. This most gratifying and important circumstance could only be attributed to the vastly improved sanitary condition of the institution.

I cannot forbear to give the close of this discourse at length:—"And now, in conclusion," Mr. Stokes went on to say, "I wish to mention that quite recently, as you all know, two men who have done so much to make this hospital famous, have resigned their respective offices. These offices have been filled by the appointments of Dr. William Thomson and Dr. Thornley Stoker, both of whom, I need hardly say, have been cordially welcomed by their colleagues, and by all here who take an interest in the welfare of this institution, as they both have already, by their talents, attainments, earnestness, and social qualities, given proof that they are destined to merit very high distinction in our profession.

"Of one of those who have resigned (our late Senior Surgeon, and the honoured father of Irish surgeons, Robert Adams), I will only say that in retiring from the active duties of this institution he bears with him the sincere regard and esteem of his former colleagues and pupils, all of whom hope that he may often revisit the scene of his former labours, assist and guide by his sage advice, and encourage by his example; and that he may be long spared to look back with pride and satisfaction on his distinguished career—a career so beneficial to the public, so useful to the profession, so honourable to himself, and so creditable to the country of his birth.

"The voice of the other (of Robert William Smith) is now hushed in the stillness of death; the voice that for forty years has been heard so often within these walls, and who, until a fell disease prostrated and enfeebled him, worked with a vigour, a zeal, a fidelity, and an enthusiasm, combined with a pure love for truth, that has been in the annals of our profession, I may say, wholly without example, and who was rewarded by acquiring for himself an undying fame, and—what he prized far more—the deep respect of his professional brethren, the admiration of his countrymen, and the warm and lasting affection of his friends. Scientific workers may be divided into two great classes. There are those who advance it by patient investigation, by honest criticism, and by faithful endeavours to verify or disprove the opinions and theories of others. They are like the stars that shine by a reflected light; but worthy are they of praise and honour, for their work is useful and it is good. If they have not creative power, they have the power to adorn, to strengthen, and make permanent the work of others. But Robert Smith belonged to a nobler band of workers—those, namely, who illumine the rugged paths of science with lamps of their own—lamps which shed no borrowed light, and which they fashion by honest and bitter toil and light with their genius. No petty ambition for worldly honours, no sordid love of gain stimulated him to labour. His great aim, the goal he ever strove after, the one ambition of his pure, his blameless, his religious life, was, in the hitherto unexplored regions of the great art and science to which I may say from his early boyhood he devoted himself, to unfurl the glorious banner of truth: he felt and knew that by so doing he best advanced Christ's work here on earth."

GENERAL CORRESPONDENCE.

ADDRESSES ON PRESCRIPTIONS.

LETTER FROM MR. BALMANNO SQUIRE.

[To the Editor of the Medical Times and Gazette.]

SIR,—You have recently treated very fully on a subject of very general interest to the profession—viz., the guinea fee. May I bring under your notice another ethical question—viz., the stamping of the practitioner's address on the prescription.

Many practitioners bashfully avoid this, on principle, as a kind of undignified advertisement. I had recently occasion to consult at his house one of the most respected of the leaders of our profession on the case of a patient, and he politely invited me to write the prescription he had recommended myself. On my taking up a piece of his note-paper with his address stamped on it, he said "No! not the half with the address on; tear it in two, and take the other half to write on." Next day I was in the shop of a leading London chemist, and was referred to to diagnose the writing and initials of a physician who had written a prescription which the chemist was unable to make up, inasmuch as the total measure of the mixture as ordered fell far short of the sum of the measures of its ingredients. A reference to the "Medical Directory" failed to identify the writer, so that the chemist was left in a dilemma. He would have been in the same case if the accidental mistake had involved the prescribing of a fatally poisonous dose; but the address of the physician on the paper would have enabled the chemist to have sought a prompt rectification of the error. In the case of surgeons whose signatures happen to be fairly legible the address would not matter so much. I make the question one of a stamped (where possible) instead of a written address, because a stamped one would be sure to be always legible. Now, the stamped address on a private document—a letter addressed to the patient,—for so a prescription may be regarded,—is scarcely so glaring an advertisement as a bright brass-plate displayed on the house-door in the open street. The absence of it—if its presence serve, as it evidently must, the interests of the patient in case of error in the prescription by enabling the chemist to find the prescriber—is, I venture to say, a piece of conventional affectation; and I think it should be the custom—nay, that it should be the law—that every prescription should bear the address as well as the name of the writer.

I am, &c., BALMANNO SQUIRE.

9, Weymouth-street, Portland-place, W., November 25.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 11.

Dr. C. J. B. WILLIAMS, F.R.S., President, in the Chair.

A PAPER by Mr. JONATHAN HUTCHINSON was read, entitled "A Successful Case of Abdominal Section for Intussusception, with Remarks on this and other Methods of Treatment." The author first narrated the particulars of a successful case in which he had opened the abdomen for the relief of intussusception. The patient was a child aged two years. The intussusception had commenced at the cæcum, and was of such length that its extremity, presenting the inverted ileo-cæcal valve, was extruded several inches at the child's anus. The condition had been one month in course of development; latterly the case had been treated as one of prolapsus, and attempts had been made to keep the bowel in place by means of a cork pad. The child was very ill, and the author having failed in attempts to effect reduction by enemata, etc., and having had experience of several similar cases which had ended fatally, determined to operate. The child was put under chloroform, and the abdomen was opened in the middle line, below the umbilicus. The intussusception was then easily found, and as easily reduced. The after-treatment consisted only in the administration of a few mild opiates, and the child made a rapid recovery. The author next narrated briefly the particulars of three somewhat similar cases in which he had been consulted, and in which the intussuscepted bowel could be easily felt by the finger in the rectum. In all three, in spite of persevering treatment by injections, bougies, etc., the patients had died unrelieved. Without attempting anything like a statistical analysis of recorded cases, the author appended to his paper, in tabular form, the notes of a very considerable number of cases bearing upon the diagnosis and treatment of similar lesions. From the consideration of these the following conclusions were suggested:—1. That it is by no means very uncommon for intussusception to begin at the ileo-cæcal valve, and to progress to such a length that the invaginated part is within reach from the anal orifice, or even extruded. 2. That it is of great importance in all cases of suspected intussusception to examine carefully by the anus. 3. That in almost all cases of intussusception in children, and probably in most of those in adults, the diagnosis may be

made certain by handling the invaginated part through the abdominal wall. 4. That the prognosis of cases of intussusception varies much; first, in ratio with the age of the patient, and secondly, with the tightness of the constriction. 5. That in a large proportion of the cases in which children under one year are the patients, death must be expected within from one to four or six days from the commencement. 6. That in the fatal cases death is usually caused by shock, or by collapse from irritation, and not by peritonitis. 7. That in many cases it is easy, by estimating the severity of the symptoms (vomiting, constipation, etc.), to form an opinion as to whether the intestine is strangulated or simply irreducible. 8. That in cases of strangulated intussusception, whilst there is great risk of speedy death, there is also some hope that gangrene may be produced, and spontaneous cure result. 9. That in cases in which the intussuscepted part is incarcerated and not strangulated there is very little hope of the occurrence of gangrene, and it is probable that the patient will, after some weeks or months, die, worn out by irritation and pain. 10. That the chances of successful treatment, whether by the use of bougies or by the injection of air or water, are exceedingly small, excepting in quite recent cases, and that if the surgeon does not succeed by them promptly, it is not likely that he will succeed at all. 11. That the cases best suited for operation are those which have persisted for some considerable time, and in which the intestine is only incarcerated; and that these cases are also precisely those least likely to be relieved by any other method. 12. That in the cases just referred to, after failure by injections, bougies, etc., an operation is to be strongly recommended. 13. That the records of post-mortems justify the belief that, in a considerable number of the cases referred to, the surgeon will encounter no material difficulty after opening the abdomen. 14. That the circumstances which might cause difficulty are—(1) the tightness of the impaction of the parts; (2) the existence of adhesions; and (3) the presence of gangrene. 15. That, in selecting cases suitable for operation, the surgeon should be guided by the severity of the symptoms to an estimate of the tightness of the strangulation, and as to the probability of gangrene having already set in. 16. That in cases in which the patient's symptoms are very severe, or the stage greatly advanced, it may be wiser to decline the operation, and trust to the use of opiates. 17. That the operation is best performed by an incision in the median line below the umbilicus. 18. That in cases of intussusception in young infants (under one year of age) the prognosis is very desperate, scarcely any recovering excepting the few in whom injection treatment is immediately successful, whilst a large majority die very quickly. 19. That the fact just mentioned may be held to justify, in the case of young infants, very early resort to the operation. 20. That it is very desirable that all who, in the future, have the opportunity for post-mortem examination of intussusception cases should give special attention to the question as to whether an operation would have been practicable, and should record their results.

Mr. Spencer Wells said that in the case of his alluded to the child was moribund. Had the operation been performed sooner, no doubt it would have succeeded. He made only an incision large enough to admit two or three fingers. There was some difficulty in withdrawing the intussuscepted gut, which was a portion of the transverse colon, from the descending colon. In one case the cæcum had passed into the transverse colon. Nélaton had recommended opening the bowel in the right iliac region, and stitching it to the parietes. In this way the necessary relief could for a time be obtained.

Mr. Holmes referred to the case of an infant where he had no difficulty in withdrawing the gut. The case was acute, and the child died of inflammation. The absence of adhesions was interesting. He thought examination by the rectum might be useful. That could be done under anæsthesia.

Dr. Hilton Fagge did not think Mr. Hutchinson's views applicable to all cases. A distinction must be made between invagination and strangulation. Recently he had seen a child with a hard abdominal tumour, and recurrent pains once or twice a day. After two months no blood had passed. Two or three days after, blood appeared, and the child sank in two days, the cause being ileo-cæcal invagination. In another case the child began to have pain about 11.30 a.m. Its bowels were open about 1 p.m., and it was seen in the afternoon. A tumour was found in the abdomen, and inflation tried. The tumour disappeared, and the passage was restored. Some pain remained, and on the seventh day the tumour reappeared. Insufflation was again tried, but failed, yet on the eighteenth day both tumour and symptoms disappeared, and the child recovered. In such cases operation should not be too speedily attempted.

Dr. Thorowgood referred to a case where enemata were tried. After death there were no adhesions, and the parts readily separated.

Mr. Barwell mentioned a case where opium was freely administered after injections and inflation had been tried. After the opium was given the injections succeeded.

Mr. Eastes related the case of a child who had complained of pain, and had had an abdominal tumour for a week. Opium was given and insufflation tried, but failed; but the injection of a large quantity of water succeeded. He thought belladonna might do good, and that milk would suit better than water for injection.

Dr. Symes Thompson did not think belladonna so good as opium. In a case he had seen the paroxysmal pain was so great as to necessitate the use of chloroform.

Mr. Hutchinson said in reply that he was now able to add the fatal results of three operations on the Continent. He quite agreed in the practice of continuing insufflation as long as there was any hope of its success. In his case the bowel had been down a long time. We might diagnose the bowel being loose by its continually and gradually slipping downwards. In his case this had been going on for a month. If there was free bleeding the strangulation was probably very tight.

CLINICAL SOCIETY.

Friday, November 14.

Prescott Hewett, F.R.C.S., President, in the Chair.

Dr. George Johnson related the particulars of some cases of Poisoning by Homœopathic "Concentrated Solution of Camphor."—Case 1. Miss F., aged 20, having a cold and sore throat, took in water twenty-five drops of "Epps's Concentrated Solution of Camphor." She went to bed, and in a short time was found foaming at the mouth, black in the face, and violently convulsed. Mr. Drake, of Brixton, was sent for in great haste. For several hours she was unconscious. She vomited blood-tinged fluid smelling strongly of camphor, and had severe gastric pain. For several days she was partially paralysed, and six months afterwards she was still suffering from symptoms of nervous derangement. The preparation which caused these serious results is a saturated solution of camphor in alcohol, the proportion being an ounce of camphor to an ounce and a quarter of spirit. It is, therefore, stronger than the spirit of camphor of the British Pharmacopœia, in the proportion of 7·2 to 1.—Case 2. The Rev. W. R. was advised to take for a cold three drops of the same preparation every five minutes for an hour. After taking the eighth dose, he was seized with intense headache, which confined him to bed for forty-eight hours; and he was afterwards so weak and ill that he was unable to enter his pulpit for two months.—Case 3. Another case was communicated to Dr. Johnson by Mr. Delamerk Freeman. A young lady, aged 19, took for diarrhœa a teaspoonful of the same preparation, which rendered her comatose for several days, and caused a variety of nervous symptoms, which did not pass away for several days. Dr. Johnson remarked upon the notorious fact that many of the disciples of Hahnemann have passed from the irrational and ludicrous extreme of infinitesimal dilutions to the dangerous extreme of the greatest possible concentration of active and poisonous drugs. There is an obvious risk that this concentrated solution of camphor may be mistaken for the much weaker solution of the British Pharmacopœia—a mistake which, in spite of the printed directions on the bottle, was probably made by both the young ladies who suffered so seriously for their error.

Mr. Eastes thought that the concentrated solution of camphor was not the only homœopathic preparation in which uncertainty of the dose existed. He knew that Dr. A. S. Taylor had examined some powders of morphia prescribed by a homœopathic practitioner, and that he had found in each powder an almost poisonous dose of the drug—five-sixths of a grain—instead of an infinitesimal proportion.

Mr. Brudenell Carter remembered being, many years ago, told by a dispensing chemist in the West of England how shocked he (the chemist) had been by the statement of an assistant. The chemist had been in the habit of ordering from

London, of the makers, the different varieties of globules required by his customers. The assistant, who had lately come from the service of a homœopathic chemist, said that that was a needless piece of trouble, and that any other globules would do as well; that homœopathic chemists were in the habit of ordering their globules in a Winchester quart from a maker, and themselves sorted them out into differently labelled bottles; that the globules sold to the public were all alike; and that the chemists gave the same globules whatever their customers might order.

Dr. Hermann Weber had frequently seen patients who had been under homœopathic treatment. Their prescriptions showed that they had been taking large doses of mercury and other medicines, which other practitioners are in the habit of prescribing. Some of the leading homœopathic men in London declare that they do not give the minute doses recommended by Hahnemann. He knew of a leading practitioner who acknowledged to being a homœopath, and who, in a case of liver disease, had given, at different times on the same day, calomel, nitro-hydrochloric acid, and taraxacum. Another gave iron in large doses. Homœopathic physicians also prescribed mineral waters and full purgative doses of Carlsbad salts. He was very glad that Dr. Johnson had drawn attention to the subject, because this solution of camphor is now largely used as a remedy by the public—frequently, he thought, with harmful results. In one gentleman, who took, three or four times in twenty-four hours, five to eight drops of the solution, it caused, on three different occasions, great sickness and headache, followed by pain in the neck, shoulders, and arms, which lasted more than a week, all of which symptoms Dr. Weber considered due to the depression of the central nervous system caused by the drug.

Dr. Greenhow remarked that the concentrated solution of camphor is now largely employed as a popular remedy, even by people who are not homœopaths; these cases of Dr. Johnson's show that there is certainly danger in its being so taken. Concerning other homœopathic remedies, Dr. Greenhow went on to observe that he had lately seen a lady who had been under homœopathic treatment, and was taking "mercurius" in large doses, by which she had been mercurialised; the remedy was discontinued by Dr. Greenhow, and the patient recovered. We are wrong in the views we take of homœopathic practice. We think only of the infinitesimal doses, and consider *that* the central point of the system; whereas the absurdity of the thing lies in the theory "*similia similibus curantur*," which runs contrary to, and would upset, the collective medical experience of 2000 years.

Dr. A. P. Stewart thought it had been, as it should be, generally known that the homœopathic tinctures are very much stronger than those in ordinary use. He agreed with previous speakers as to the importance of this being known in regard to their tincture of camphor, which is now a very common domestic remedy. With other tinctures, the effects of ignorance of this point might be still more serious than in the case detailed by Dr. Johnson. One of Dr. Stewart's patients proposed to him, some years ago, that she should take some tincture of nux vomica, to which he assented, as he had often previously prescribed it for her with advantage; and, not knowing that it was the homœopathic tincture which she had in her medicine-chest, he ordered eight or ten minims for a dose. She stated that three minims had previously produced diarrhœa; consequently, two minims were ordered, and even this dose was followed by nausea and diarrhœa. He supposed that homœopathic practitioners, being identified in the mind of the public with their own absurdity of infinitesimal doses, and being unwilling publicly to renounce it, had recourse to these concentrated tinctures in order to produce an appreciable effect by very minute doses. That homœopathic globules are not always the inert things which Mr. Carter had described as made up wholesale, was proved by the case of a well-known Italian nobleman, who, some years ago, having forgotten to take one globule at the appointed hour, took two together, and died, with all the symptoms of poisoning by strychnia, the same night.

Dr. Anstie related the particulars of a Remarkable Case of Death from Meningeal Congestion without Inflammation. The patient was an active, intelligent lad of nearly thirteen years, previously quite well. At the end of his school vacation, he had a slight swelling of some cervical glands, and looked somewhat pale, but was quite cheerful and lively. He went back to school for a week, did his lessons with ease, played football, and sculled on the river; but during the whole time a sense of stiffness in the legs was gaining upon him. On October 5 the boy fell down on getting out of bed; and on Dr. Anstie visiting him, it was found that he had lost the power to stand, but could execute any movements of the legs when sitting or lying, though rather slowly. There were tingling sensations in the fingers and toes, but no other affection of sensation. There was a total absence of pyrexia; pulse 85, full but compressible. The upper limbs almost immediately became implicated in the loss of power; the right arm and (to a less extent) the right leg were more affected than the left limbs. Throughout the case, sensation of all kinds was only very slightly affected. There never was any fever, either subjective or as measured by the thermometer. The pulse continued to increase in frequency and to lose in power; it was 130 in the evening of the third day. On this day paralysis of the sterno-mastoids had been detected in the morning; and towards night paralysis of the respiratory muscles set in, and this last symptom steadily increased till it proved fatal at one o'clock the next day—viz., October 8, the fourth day (inclusive) since the commencement of actual paralysis. Neither speech nor swallowing were affected; and there never was the least interference with consciousness or intelligence till within five minutes of death. The affection was diagnosed on the third day by Dr. A. Clark, with the concurrence of Dr. Anstie, as congestion of the spinal cord and medulla oblongata. Post-mortem examination by Dr. Anstie and Mr. Warrington Haward entirely verified this diagnosis. The only pathological phenomenon was congestion, and that congestion was strictly and very remarkably limited to the vessels of the meninges of the cord and the medulla oblongata and the sinuses at the base of the skull. There was no trace of effusion either of serum, lymph, or blood. The absence of inflammatory products agreed with the symptoms during life, for there was no muscular rigidity or pain on movement, no pyrexia, and no paralysis of the sphincters of either rectum or bladder. Dr. Anstie remarked on the rarity of these cases of rapidly fatal congestion, and the little information that is to be found on the subject in the literature of nervous diseases. In Dr. Radcliffe's treatise, however (Reynolds's "System of Medicine," vol. ii.), the occurrence of rapidly fatal cases is alluded to; and Dr. Radcliffe had privately related several such instances to Dr. Anstie, in which death occurred on the fourth day from the first decided symptoms. Dr. Andrew Clark (whose absence was much regretted) had also, it appeared, seen some similar cases, and, what is more important, thinks he has seen one such recover. But there can be little doubt that the malady, coming on in the shape and with the rapidity shown in the case which formed the subject of the paper, presents very little ground for hope of success in treatment. "Derivation" of blood from the affected part would be the ideal treatment; and in the present instance it was attempted by means of diaphoretics, and would have been further attempted by means of purgation had not the case become too evidently hopeless. But Dr. Anstie thinks that it is more than doubtful whether effects of this sort can be really produced, either by these measures, or by leeching to the anus, etc. The etiology of Dr. Anstie's case was remarkably obscure. Of causes that have been assigned as capable of producing spinal congestion—viz., external cold, repressed hæmorrhoids, extreme over-exertion, etc.,—none were in operation; and it seemed impossible to give even a rational guess at the cause.

Mr. Barwell inquired as to the condition of the pupils and muscles.

Dr. Charles Carter related the following case, somewhat similar to Dr. Anstie's:—A young naval officer on the China station, a temperate man, and previously quite well, complained one day of pain and stiffness in the legs. He had taken a long walk—twenty to twenty-five miles—a few days before; and it was thought to be due to this. The pain and stiffness continued, and then were supposed to be rheumatic. He suddenly lost power in the legs, falling when walking, and was taken to hospital. There, in a few days, he died; the paralysis gradually creeping up the trunk, affecting the upper limbs and respiratory muscles till he died asphyxiated. There was no loss of sensation; the bladder and rectum were unaffected; the mind was clear to the last. At the necropsy, the spinal cord was examined, but nothing was found to explain the symptoms.

Dr. Southey mentioned the case of a gentleman whose legs, after a long ride, became stiff. Next day he lost power in both legs; and the paraplegia, at first partial, shortly became complete. He was ordered to give up all stimulants, to remain in a tepid bath one or two hours daily, to lie quietly in bed,

and take milk and lime-water. He had no medicine for three days; then he took twenty grains of bromide of potassium nightly for want of sleep. He recovered slowly, but completely.

Dr. Symes Thompson related particulars, sent to himself, of a case which occurred at Port Elizabeth. The illness began with pain and stiffness at the nape of the neck, to which succeeded paralysis of the legs, and then of the arms. There was an epidemic of the disease, involving thirty or forty individuals, sometimes ending fatally, and sometimes leaving nervous symptoms of a more or less chronic kind.

Dr. G. Harley described another case which in some respects resembled Dr. Anstie's. A young gentleman, aged 17, engaged in a City office, complained of having a cold for three weeks, and then had stiffness of the neck six days before his death. On the following day his limbs became stiff, but he went to his office. Next day he could not walk well, but went to the City. A third day also he went; but he then fell from his stool to the ground and staggered. Being sent home in a cab, he walked well from the cab through the hall, but could not mount the stairs. The paralysis increased. He could not void his fæces, but passed urine extra easily. On the day of his death he could walk across the floor, and was cheerful, saying he felt nothing at all wrong. The paralysis spread rapidly from the legs to the thighs, to the abdominal and to the thoracic walls—when his breathing became affected. Two days before death his pulse was 65; next day it was 84; and it rose to 120 just before death. He had also difficulty in pronouncing words and in swallowing water. Dr. Harley had often seen animals die in the same way. The symptoms were considered to be due to congestion of the spinal cord; so belladonna was injected, as it constricts the vessels of the cord; but the lad died asphyxiated. The necropsy was made by Dr. Lockhart Clarke. On removal of the brain, a large quantity of black blood welled up from the spinal canal. There was no morbid congestion of the front columns of the cord; in the posterior columns some of the axis-cylinders looked a little damaged. There were no naked-eye appearances of disease, except that the cord was raised in a few places by the congestion of its substance. No congestion of the meninges existed—only that of the cord itself.

Dr. G. Johnson suggested that perhaps some of the venous engorgement which had been found after death might have been due to the mode of death—viz., by asphyxiation.

Dr. Anstie, in reply, said that in the condition of the pupils there was nothing remarkable. The muscles were flaccid. Dr. Carter's case he considered to be of the same nature as his own. Dr. Southey's case was also one of spinal congestion; but was not the paralysis the result of alcoholismus? He was rather sceptical of the good to be obtained from bromide of potassium in these cases. He had, however, seen it benefit a man who had knocked himself up by excessive activity in conjugal duties, and in a few other instances. Dr. Hammond, of New York, gives ergot of rye for spinal congestion; but Dr. Anstie had had no experience with the drug. Dr. Thompson's case was one of cerebro-spinal meningitis, which involves rigidity of the muscles and pain on moving. Also the disease was epidemic. Dr. Harley's case was one of softening of the cord—"myelitis." Both that case and Dr. Thompson's case had affection of the bladder and rectum, which never occurs in simple spinal congestion. If any one had, four weeks before, told Dr. Anstie that congestion could produce such fatal symptoms, he would then have laughed him to scorn. He must now retract his former opinion. He was sure his case was not one of myelitis. In that disease, there is elevation of temperature; in his own case the temperature was not at all augmented. There must have been some sign of inflammation if it had existed; but there was nothing of the kind.

Decline of the Vienna Medical School.—The *Wiener Med. Zeitung* of October 21 states that the number of students continues to fast decline from year to year, and the lecture-rooms in which, when Oppolzer and Skoda taught, a place could only be obtained with difficulty, so crowded were they, are now nearly empty. Scarcely half the number of students of last year—which itself exhibited a deficiency of 300 compared with former years—have registered this year. At the same time the number of students at the Medical Faculties of Prague and Graz is said to be extraordinarily large. The same complaint, as we have already noticed, is heard at Berlin, while the medical schools at Leipzic and the smaller German Universities are very flourishing.

OBITUARY.

WILLIAM DALTON, M.R.C.P., F.R.C.S.,

Born at Swansea in 1802; entered the profession very young; served as pupil in his native town, afterwards in that capacity to Mr. Merryman, of Kensington; studied at Guy's and St. Thomas's, London; served as surgeon in a whaling vessel in the South Pacific for several years; settled down into steady practice at Winchcomb, in Gloucestershire; remained there seven years; then established himself in the neighbouring town of Cheltenham, in which place he had a leading practice for thirty years. He acquired a great reputation as an obstetric practitioner. He was subject to attacks of hæmatemesis, the first of which nearly proved fatal in 1856, and which finally laid him low on the 12th instant. He gave up practice in Cheltenham in 1869, and took up his residence at Bournemouth. He obtained the following appointments and honours: Vice-Pres. Roy. Med. Coll., Epsom; Fell. Med. Soc., London; Mem. Brit. Med. Assoc.; late Surg. Cheltenham Coll. and Ladies' Coll.; Cons.-Surg. Disp. for Diseases of Women and Children; Surg. Austral. packet, 1870. He was formerly Surgeon to 2nd Administrative Battalion of Gloucestershire Volunteer Rifles. He contributed to the *Lancet* "On the Anti-scorbutic Properties of the Raw Potato"; "On New Zealand Fern-root in Chronic Dysentery"; and papers on various subjects to medical journals.

EDWARD H. LINNECAR, M.R.C.S.,

One of the Medical Officers of the Barnet Union, died at his residence, at Henley, last week, at the age of 74. He studied anatomy under Joshua Brookes, and attended lectures on medicine at St. George's and St. Bartholomew's Hospitals. He became a Licentiate of the Apothecaries' Company in 1824, and shortly afterwards commenced general practice in New Basinghall-street, next door to the able and eccentric George Langstaff, whose museum at that time and for many years afterwards was one of the best in London. About thirty years ago Mr. Linnecar's health required residence in the country. He accordingly removed to Henley, and continued in tolerable health to the time of his decease. Mr. Linnecar was a thorough practical man, and brought good common sense in aid of moderate abilities and acquirements. For many years he was a constant visitor at the Medical Society of London, which then held its meetings in Bolt-court. He was a frequent speaker in that assembly, and was always listened to with attention and interest. He was a kind-hearted, genial man, and it may be justly said "beloved by all who knew him."

PHILIP HENRY DICKER, L.S.A.,

Died at 7, Priory-road, Everton, Liverpool, on the 11th inst., aged 63 years. The deceased was for many years well known in Oswestry and its neighbourhood. He had long practised in that town, and was the medical officer of several friendly societies of the district. His health broke down a few months ago, and he removed to Liverpool, where he apparently for a time rallied; but a change took place a short time ago, which ended fatally.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 20th inst., viz.:—

Aitkens, Louis Edwardes, Knaresborough, student of St. George's Hospital.
Donaldson, Henry, L.S.A., Hoxton, of Charing-cross Hospital.
Evans, Henry, L.S.A., Croydon, of Guy's Hospital.
Farr, Frederick Arthur, Dunstable, Bedfordshire, of Charing-cross Hospital.
Goicoechea, Francisco, M.D., Venezuela, Trinidad, of St. Mary's Hospital.
Hindhaugh, William, North Shields, of University College.
Hughes, Thomas Jones, Dublin, of the Dublin School.
Hyatt, James Taylor, Shepton Mallet, of Westminster Hospital.
Klien, Edward Hughes, M.B. Edin., Demerara, of St. Bartholomew's Hospital.
Knowles, Edmund, L.S.A., Cambridge, of St. Mary's Hospital.
Lambert, John, Farsley, Yorkshire, of the Leeds School.
Lang, Henry Charles, Berners-street, of University College.
Lewis, Henry Harman Dendy, L.S.A., Drummond-street, of Westminster Hospital.
Lovell, Walter Frederick, St. John's Wood, of St. George's Hospital.
Maclean, Norman Collier, Blockley, Worcestershire, of St. Mary's Hospital.

Parker, William Kitchen, F.R.S., L.S.A., Claverton-street, Pimlico, of Charing-cross Hospital.
Place, Modesto, M.D., Venezuela, Trinidad, of St. Mary's Hospital.
Smith, Roland Dunn, Chatteris, Cambs, of the London Hospital.
St. John, Leonard, M.D. McGill, St. Catherine's, Ontario, Canada, of St. Thomas's Hospital.
Strang, William Douglas, Penge, of University College.
Tootell, Edward, Maidstone, of St. Bartholomew's Hospital.
Tyrrell, Frederick, Haslington, Middlesex, of St. Mary's Hospital.
Watson, John Wilcocks, L.S.A., Heigham Hall, Norfolk, of University College.
Webb, Edward Robert, St. George's-road, S.W., of St. George's Hospital.

The following gentlemen passed the Primary or Anatomical and Physiological examination for the Fellowship on the 25th inst.:—

Black, James, student of St. Thomas's Hospital.
Carline, William Arthur, of King's College.
Clark, Henry Edward, L.R.C.P. Edin. and M.R.C.S. Eng., of the Glasgow School.
Clarke, Arthur, of University College.
Collins, John Wilkins, of St. Thomas's Hospital.
Duncan, Andrew, M.R.C.S. and L.S.A., of King's College.
Green, Frederick King, of St. Bartholomew's Hospital.
Jackson, Ernest Carr, of St. Thomas's Hospital.
Rendall, John, of Guy's Hospital.
Savage, James, M.R.C.S. and L.S.A., of the Hull School.
Stone, John Neesom, L.K.&Q.C.P. Ire. and M.R.C.S. Eng., of the Dublin School.

Seventeen candidates out of the twenty-eight examined, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for six months.

The following is a copy of the questions submitted to the candidates for the Fellowship on this occasion, all of which were required to be answered, viz.:—Give the dissection required to expose the trunk of the sympathetic nerve in the neck, and describe the relations of the nerve. Trace the cardiac branches from their origin to the cardiac plexuses. Describe the serratus magnus, the dissection by which you would display it, the various parts with which it is in relation, and the vessels and nerves by which it is supplied, and enumerate the muscles which are its antagonists. Describe the modes of origin, the structure, and the general management of the lymphatic and lacteal vessels, and the nature, sources, and destination of the lymph. Describe the structure of the human ovum, and give an account of the earlier stages of development up to the period at which the chorda dorsalis is formed.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a Certificate to practise, on Thursday, November 20:—

Verdon, Henry Walter, Manchester.

The following gentlemen also on the same day passed their primary professional examination:—

Hay, William Alfred Edward, Guy's Hospital.
Richardson, Joseph Berridge, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRAINE, WOODHOUSE, F.R.C.S.—Chloroformist to the Charing-cross Hospital.

HAMILTON, CHARLES W., L.R.C.S.I., L.R.C.P.E.—Medical Officer of Louisburg Dispensary, Dispensary District in Westport Union, County Mayo.

O'KELLY, RICHARD AMBROSE, L.R.C.P. Edin., L.A.H. Ire., C.M.—Medical Officer to the Workhouse, Cork Union.

SMITH, R. SHINGLETON, M.D. Lond., B.Sc.—Physician to the Bristol Royal Infirmary, *vice* Dr. Beddoe, F.R.S., F.R.C.P., resigned.

WALDO, HENRY, M.D.—Assistant-Physician to the Bristol Royal Infirmary, *vice* Dr. Spencer, promoted.

NAVAL APPOINTMENTS.

ADMIRALTY.—Dr. John M. Hunter, Staff Surgeon, second class, to the *Active;* Richard C. P. Lawrenson, Staff Surgeon, second class, to the *Victor Emmanuel;* John O'Neill and Dr. John R. Leech, Surgeons to the *Active;* James M'Carthy, Surgeon to the *Victor Emmanuel.*

BIRTHS.

ADAMS.—On November 23, at North Lodge, St. Matthew's Infirmary, Victoria-park, the wife of E. J. Adams, L.R.C.P., M.R.C.S., L.S.A., of a son.

BOLEY.—On November 23, at 1, Mortimer-road, Kilburn, the wife of John B. Boley, M.D., M.R.C.S. Eng., L.S.A., of a son.

EARLE.—On November 23, at Brentford, the wife of E. S. Earle, F.R.C.S., of a son.

GODWIN.—On October 28, at Agra, the wife of Surgeon C. H. Y. Godwin, Royal Artillery, of a son.

HOLMAN.—On November 18, at East Houthly, Sussex, the wife of T. Holman, M.R.C.S. Eng., L.S.A., of a son.

MYERS.—At Chefoo, North China, on October 2, the wife of W. Wykeham Myers, M.B., C.M., of a daughter.

RICE.—On November 20, at 8, Sloane-terrace, S.W., the wife of M. W. Rice, M.D., of a son.

MARRIAGES.

BROCK—CHEYNE.—On November 20, at Ivybridge, Devon, M. W. Brock, Esq., 17th Regiment, eldest son of Wm. Brock, Esq., of Belmont, Guernsey, to Aby Mackenzie, elder daughter of Alexander Mackenzie Cheyne, M.D., late of White Hall, Aberdeen.

BRUCE—BENTLEY.—On November 20, at St. Luke's, New Kentish Town, the Rev. W. H. Bruce, to Kate, eldest daughter of the late George Bentley, M.R.C.S., of Halstead, Essex.

GAFFNEY—ST. CLAIR.—On November 19, at the Church of St. Thomas, Fulham, John Burke Gaffney, L.R.C.S., L.A.H., Surgeon Indian Army, to Jessie Alice St. Clair, of Park Lodge, Fulham.

GARDNER—PEARLESS.—On November 18, at Kingston Church, Portsmouth, Surgeon-Major Thomas Turville Gardner, Army Medical Department, to Rose, second daughter of the late Edward Pearless, Esq., of Peterborough.

HARDINGE—HIGGINS.—On November 20, at the Abbey Church, Great Malvern, Thomas Samuel Hardinge, Esq., of St. Leonard's-on-Sea, to Caroline Josepha, widow of the late John Higgins, Esq., of Stratford-on-Avon, and youngest and only surviving child of Andrew Henderson, M.R.C.S. Eng., of Great Malvern.

KERANS—PALMER.—On November 18, at St. Anne's Church, Dublin, William Robert Kerans, L.R.C.S.I., Surgeon Army Medical Staff, eldest son of Lawrence C. Kerans, Esq., of South Park, co. Galway, to Annie, second daughter of Thomas Palmer, Esq., of Forster Park, in the same co.

MCFARLAND—ELLIOTT.—On November 24, at 7, Gardiner's-row, Dublin, Francis Edward McFarland, Surgeon-Major Army Medical Department, to Mary Georgina, elder daughter of John Hugh Elliott, Esq., of Gardiner's-row, Dublin.

PATERSON—CONRAN.—On November 19, at St. Thomas's Church, Upper Clapton, Walter Hugh Paterson, M.D., of Brigg, Lincolnshire, to Mary Agnes, second daughter of Edward J. Conran, Esq., of Templeogue, Dublin.

DEATHS.

BRUSHFIELD, PERCY R., second son of T. N. Brushfield, M.D., M.R.C.S. Eng., of Brookwood Mount, Woking, at Guildford, on November 19, aged 12.

COATES, GEORGES, L.S.A., for many years resident in Bloomsbury, at Bournemouth, on November 18, in the 72nd year of his age.

COWARD, WILLIAM, M.D., at 6, Dean-street, South Shields, on November 22, aged 66.

DICKER, PHILIP HENRY, L.S.A., late of Oswestry, Salop, at Liverpool, on November 11, aged 63.

MANSON, SUSANNA JONES, widow of the late Frederick Manson, M.D., of Park-street, Grosvenor-square.

PEARSE, EDMUND, M.R.C.S. Eng., L.S.A., at 17, Tavistock-square, after a week's illness, on November 18, aged 57.

PROBART, THOMAS BRERETON, L.S.A., late Lieutenant in the Royal Lincoln Regiment of Militia, at Tetford, near Horncastle, on November 19.

SEALE, ELIZABETH, wife of I. Lockyer Scale, L.R.C.P., at Ashton House, Steeple Ashton, Wiltshire, on November 19, aged 64.

TAYLOR, ALEXANDER DOUGLAS, M.D., L.R.C.S.I., Deputy Inspector-General of Hospitals, at Bootle, near Liverpool, on November 19, aged 62.

WALLACE, CATHARINE, widow of Richard Wallace, F.R.C.S. Eng., of Hackney-road, at 206, Richmond-road, Hackney, on November 21, aged 67.

WHITAKER, THOMAS HARPER, M.R.C.S. Eng., L.S.A., at his residence, Kirkby Lonsdale, Westmoreland, on November 14, aged 61.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

AMPTHILL UNION.—Medical Officer of Health. Candidates must be legally qualified and registered. Applications, with testimonials, to John Wright, Clerk to the Sanitary Authority, on or before December 3.

BEDFORD GENERAL INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before December 10.

BRISTOL ROYAL INFIRMARY.—Assistant House-Surgeon. Candidates must be F. or M.R.C.S., or M.S., and also possess medical qualifications.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Two Assistant-Surgeons. Candidates must be F. or M.R.C.S. Applications, with testimonials, to the Secretary, on or before December 9.

CONWAY UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Wm. Hughes, Clerk to the Guardians, on or before December 10.

GAINSBOROUGH.—Medical Officer of Health. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to the Clerk of the Union, on or before December 8.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—House-Physician. Candidates must possess a recognised medical or surgical qualification. Applications, with testimonials, to the Secretary, on or before November 29.

KENT COUNTY LUNATIC ASYLUM, BARMING HEATH, MAIDSTONE.—Two Assistant Medical Officers. Applications, with testimonials, to Messrs. Beale and Loar, Maidstone, before December 10.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

RIPON DISPENSARY AND HOUSE OF RECOVERY.—Resident Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to the Honorary Secretaries, on or before December 5.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, of whom particulars may be obtained.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, LOWER SEYMOUR-STREET, PORTMAN-SQUARE.—Surgeon to the Out Department. Candidates must be Fellows or Masters in Surgery, and registered. Applications, with testimonials, to the Secretary, on or before December 2.

ST. GEORGE'S (HANOVER-SQARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before December 29.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

TEWKESBURY UNION, FORTHAMPTON DISTRICT.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to George Budham, Clerk to the Guardians, on or before December 16.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser. Applications, with testimonials, to the Honorary Secretary, Exe Villa, Tiverton, Devon.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

APPOINTMENTS.

Barnstaple Union.—Joseph Harper, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., to the Second District.

Clifton Union.—Wm. Hodges, M.R.C.S. Eng., L.R.C.P. Lond., to the Workhouse.

Dolgelley Union.—John T. Jones, M.R.C.S. Eng., L.S.A., to the Talyllyn District.

Droitwich Union.—John H. Hughes, L.R.C.P., M.R.C.S., to the Ombersley District.

Kendal Union.—Wm. Wyllie, M.D., M.B., and C.M. Glasg., to the Kirkby Lonsdale District.

Middlesex.—Dr. T. Redwood as Analyst for that part of the County not included in the Metropolis.

Ulverstone Union.—Wm. H. Woodburn, L.R.C.P. Edin., L.F.P. and S. Glasg., to the Broughton West District.

THE M.B. DEGREE AT OXFORD.—The final examination for the degree of Bachelor of Medicine will commence in the museum on Tuesday, December 9, at 9.30 a.m. The first examination for the same degree will commence at the same place on Wednesday, December 10, at 9.30.

LORD HOUGHTON presided, and delivered an address, at an important meeting of medical practitioners at the West Riding Asylum, Wakefield, on Tuesday. Dr. Carpenter afterwards gave a lecture on the recent experiments by Professor Ferrier on the localisation of the functions of the brain.

CHOLERA is again on the increase in Munich.

THE United States census returns show that there are 525 women physicians and surgeons.

TESTIMONIAL TO A SURGEON.—On the 17th inst. a ceremony of an interesting description took place at the Grove Hall Asylum, Bow, by the presentation of a silver salver to Mr. J. A. Brown, late one of the medical officers, who, after a residence of twelve years, has resigned his post at that establishment.

MORTALITY OF LONDON.—There were 1674 deaths in London last week. The fatal cases of measles, diphtheria, and hooping-cough were excessive. The epidemic of measles shows an increasing fatality, the deaths from this disease having risen last week to 130. It has not been so fatally prevalent, says the Registrar-General, since the beginning of 1840.

THE CHOLERA IN PARIS.—The epidemic has now passed away, and from the subjoined figures it will be seen that it has not assumed any great extent, although the proportionate mortality has been large:—Between September 4 and November 13 there were treated in the various civil hospitals 432 cases; of these 160 were discharged, 254 died, and 18 remained under treatment.

A JOKE.—On imposing a fine of £15 on a milkman at Dublin, for selling as milk a mixture of 90 per cent. of water and 10 per cent. of milk, the magistrate stated that he had not inflicted the full penalty of £20, because he wished to leave himself a margin of £5 to meet the case of any enterprising trader who might carry adulteration to a yet further pitch.

ON July 14 last, Assistant-Surgeon T. Harvey Hill, 36th Middlesex Rifle Volunteers, passed the requisite examination prescribed by the Army Regulations for the Reserve Forces, and received a certificate of proficiency.

THE subject for the annual prize to be competed for by apprentices of apothecaries at the Apothecaries' Hall of Ireland in May next is "The Metallic Preparations of the British Pharmacopœia."

ABUSE OF CHARITY.—A man died of starvation in the Edinburgh Infirmary, a few days since, about whom nearly £50 was found concealed.

THE Holborn District Board has addressed a letter to the City Commissioners of Sewers, complaining that rabbits unfit for human food were sold in large quantities at wharves in the City, and brought to their district for sale to the poor. They therefore applied to that Court for their interference in the matter. It turned out on inquiry that the wharves referred to were out of the City, and the City inspectors had no power to seize the rabbits. We trust the guardians will pursue their efforts to check the sale of this unwholesome food till they ascertain the proper authorities who are responsible for its stoppage. This case shows the importance of giving adequate powers to a central authority. "Loopholes of retreat" to offenders against the public welfare under the present Act are simply disgraceful.

AT the last meeting of the Halifax Board of Guardians the following letter from Mr. T. M. Dolan, the Medical Officer of the Halifax Union, was submitted to the meeting. The letter was transmitted from the Local Government Board, asking for information on the subject. It was dated the 20th ult., and was as follows:—"I beg to inform you that, very much to my surprise, no inquest was held on the body of the man Anderson, of whose death I informed you. I do not know what cause of death was given, but have heard that the surgeon who advised the removal of the patient gave a certificate of death." No answer was agreed upon by the Board.

THE ROSS MEMORIAL HOSPITAL AT DINGWALL.—A cottage hospital of eight beds has just been opened at Dingwall, Ross-shire. It was erected as a suitable memorial to the late Dr. Ross, of that town, who was so widely known and esteemed, both professionally and publicly, throughout the northern counties of Scotland. The building stands on the shore of the Cromarty Frith, and is constructed according to the most modern designs, with complete sanitary arrangements, ventilation, and baths. The whole cost is over £1200, exclusive of the site and the price of furnishing. Dr. Bruce is the honorary medical officer of the hospital.

THE MEDICAL EDUCATION OF WOMEN.—On November 21, a deputation, consisting of the President, Honorary Secretaries, and members of the Council of the Obstetrical Society, had an interview with Mr. Stansfield, at Gwydyr House, on the subject of the present position of this country with regard to the education, training, examination, licensing, registration, and supervision of midwives. With Mr. Stansfeld were Mr. Hibbert, M.P., and Mr. John Lambert, and with the deputation were Dr. Tilt (President of the Society), Drs. Phillips and Aveling (Hon. Secretaries), Dr. Hall Davis, Dr. Madge, Dr. T. Chambers, Dr. Brunton, etc. Dr. Tilt reminded Mr. Stansfeld that on a previous occasion he had received a deputation of the British Medical Association, under Mr. Ernest Hart, on the subject of the registration of stillborn children, when the subject of midwives and their position came before him. The subject was one of wide importance, and the speaker said it was not necessary for him to enter before the President of the Local Government Board on the general results of the extraordinary neglect in this country of care in the parturition of the lower classes, for a state of things existed here in this respect which was not to be found in any other civilised country. In addition to the evils which had been brought before the President on the previous occasion by the present condition of things, the facility in child-murder and kindred crimes, the speaker said he would draw attention to the great excess of mortality among women and children, as well as a great deal of preventable disease arising from unqualified women who were thoroughly incompetent practising as midwives. This had to do with the Government and the State, as by the mortality of mothers young families were thrown upon the parishes for support; and by the mother being rendered incapable of work, as often happened, mother and family were together thrown upon the rates. Thus a vast expense, far

above anything like an expense which would be entailed by the education, examination, and licensing of these women, even if the whole expense should be borne by the public, fell upon the public purse. He stated that the Royal College of Surgeons would not interfere in this matter, and that the society represented there desired only to see something done in this important matter; and though they had no desire to have the matter in their hands, would give every assistance, either in providing examination boards or otherwise, to see carried out what their experience had abundantly proved to them was necessary for the public good. At present, women, he said, were practising upon diplomas granted by individuals, and the people were thus misled into trusting women who had no qualifications for the office of midwives. In answer to Mr. Stansfeld, the deputation said the giving of these individual diplomas was strictly unprofessional, and that they led to the most harrowing results of blundering ignorance. Mr. Stansfeld entered into a long conversation with Dr. Tilt, and said that though he was not departmentally responsible in this matter, it coming within the province of the Privy Council Office, yet he took an interest in the matter. Dr. Aveling then spoke, and said the main objects the deputation had were the public safety, the public economy, and the public happiness, for all these were involved in this matter. The parturient women were not safe in the hands of unskilled women, public economy was affected because the children of families whose mothers died or were diseased in consequence of maltreatment came upon the public purse for support, and their homes were frequently broken up from the same causes. With regard to the definition of these women, they should rather be regarded as midwifery nurses than as medical women, and he then dwelt upon the modes which could be adopted for their education, and laid down in a minute already sent to Mr. Stansfeld. The examination and licensing he regarded as most essential and necessary, and he drew attention to the systems in vogue in Prussia and France. In the first-named country itinerant inspectors visited the midwifery women and examined their diaries, and in France they had to hold diplomas proving their capability, while in all cases of difficulty they had to call in medical assistance of the highest class. Other points were pressed upon the President of the Local Government Board, and he, in reply, said he was favourable to the training, education, examination, and licensing of women in this important sphere, but he was not favourable to the class being kept at one standpoint—namely, that they should be midwifery nurses only. He thought women who had the qualification and means should be allowed to go a rank higher without undergoing a full medical examination. He said he would place the matter before Lord Aberdare, and he advised that the deputation should also consult that department. The deputation then thanked Mr. Stansfeld and retired.

The Royal Academy.—Mr. John Marshall, F.R.S., the recently elected Professor of Anatomy in the Royal Academy, in the vacancy occasioned by the decease of Mr. Richard Partridge, will commence the delivery of his first course of lectures to the students and Royal Academicians on Monday next, December 1, and continue them every Monday and Thursday up to the 18th proximo inclusive. Professor Marshall is the sixth gentleman who has filled the chair, in succession to the following distinguished members of our profession:—The first was Dr. William Hunter, the elder brother of the celebrated John Hunter, who held the office from the foundation of the institution in 1768 until his death in 1783, when he was succeeded by John Sheldon, who also occupied it until his death in 1808. He gratuitously dissected a horse and had casts made from it for the sole use of the students. It is stated that he was the first Englishman who made an experimental ascent in a balloon. Sheldon, who was much respected, was succeeded by Sir Anthony Carlisle, twice President of the Royal College of Surgeons, whose lectures were highly attractive; he resigned the chair in 1824, and was succeeded by Joseph Henry Green, whose lectures, more philosophical, were hardly less popular than those of Carlisle. He resigned the chair in 1851, when he was succeeded by Richard Partridge, who, without aiming at the eloquence of his predecessor, delivered most valuable discourses. He also wore the gown until his death a few months since. It is believed that Professor Marshall will reflect the greatest credit on the choice of the Royal Academicians.

New Central Hospital for Prisoners in Paris.—The Conseil-Général de la Seine has just voted 73,000 fr. for the erection at the prison of La Santé of a central infirmary for the treatment of prisoners suffering from serious diseases. Such an infirmary, indeed, already exists, having been formed at St. Pélagie during the siege, when an epidemic of scorbutus broke out in the prisons. The object of the vote is to transfer this provisional into a permanent establishment, which is to be organised like the hospitals. For the sake of hygienic considerations and the welfare of the patients, it would have been preferable to have improved the condition of the infirmaries attached to the prisons, so as to have enabled grave affections to have been treated therein. Why accumulate these patients in a single establishment, where they may become a centre of infection, while it would have been so easy to have disseminated them among several small infirmaries? What an infatuated liking we have for centralisation! and in matters of hospital hygiene it can always be said of us, "Hygiene proposes, the Administration disposes."—*Gaz. Heb.*, November 22. [Certainly some change is imperative, for at present all prisoners the subjects of serious disease are treated in the midst of the other patients of the ordinary hospitals!]

Prompt Operating in Strangulated Hernia.—In illustration of an opinion strongly held by M. Desprès, that the sooner the operation is performed the more likely is recovery to take place, he publishes the results of the thirteen cases of strangulated hernia that have occurred in his practice at the Cochin during eighteen months of 1872-73. In seven of these, in which no attempt at reduction was made prior to the operation, three recoveries were obtained; while of six upon which no operation was performed, only one recovered. He strongly protests against the use of the taxis and other modes of treatment now in vogue for the cases ordinarily brought to hospitals. The mortality from strangulated hernia, taken generally, in the French hospitals amounts to 70 per cent., while in those cases that are operated upon in good time it is only 58 per cent.—*Gaz. des Hôp.*, November 18.

Operation for Hernia in a Young Infant.—M. Guéniot related at the Société de Chirurgie the case of an infant, three months old, upon whom he had performed the operation for strangulated hernia. The child died the same evening, and at the autopsy the small intestine was found much distended, and having its convolutions agglutinated by false membranes from peritonitis. The large intestine was collapsed, and a noose of this had penetrated into the inguinal canal, and had become strangulated at both the external and internal orifices. M. Marjolin observed upon the excessive rarity of strangulated hernia prior to the age of thirteen months. He had never met with it in so young an infant as this. M. Panas stated that he had operated for inguinal hernia in a girl six months old, the sac containing, besides the intestine, the right ovary and tube.—*Union Méd.*, Nov. 22.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Sapo Mollis.—"Chemical Technology," by Rudolph Wagner, eight vols., 25s. J. and A. Churchill.

Inquirer.—The Director of the New York Meteorological Observatory has recently issued his report for 1872. The report is of a most interesting and instructive character, and it should be consulted by all who are interested in studying the meteorological phenomena which bear on health and disease.

Very Foggy.—You are not the only puzzled one; we are quite unable to give the information. All we have to report is that there was another meeting on the "Conjoint Scheme at the College of Physicians on Monday last, and that the Council of the College of Surgeons are not quite so unanimous as is stated on the subject."

A Metropolitan Teacher, and *J. W.*, who have addressed us on the subject, will be able to judge for themselves whether the standard for the fellowship of the College of Surgeons has been lowered, by perusing the questions published in another page of the *Medical Times and Gazette*, and also by the fact that seventeen out of twenty-eight were rejected. The pass examination for the Fellowship takes place this day, and will be continued next week.

R.A., Pimlico.—There is a painting of Dr. William Hunter, the first Professor of Anatomy at the Royal Academy, in the possession of the College of Physicians, from which there is an engraving in Pettigrew's "Medical Portrait Gallery." The large mezzotint representing him lecturing before the "big-wigs" of the Academy is well known. A painting of Sheldon is in the Council-room of the College of Surgeons. A very good likeness of Carlisle will also be found in Pettigrew's work. Messrs. Barraud and Jerrard have published a capital photograph of Partridge.

COMMUNICATIONS have been received from—

Professor Halford, Melbourne; H. K.; Mr. Hitchcock, Greenwich; Dr. Fairbank, Lynton; Mr. Poole, London; Mr. J. Chatto, London; Dr. Bruce, London; Dr. Russell, Birmingham; Mr. F. A. Mahomed, London; Sir Henry Thompson, London; Dr. Aveling, London; Mr. Head, East Grinstead; Sapo Mollis; Mr. B. Vincent; B. M. B.; Dr. Galabin; Mr. W. W. Reeves, London; Mr. W. R. Dalton, Dovercourt; Mr. Balmanno Squire, London; Dr. Wynter, Chiswick; Mr. Eastes, London; Dr. Shingleton Smith, Bristol; Mr. Braine, London; Mr. H. Wilbraham, Westport; Miss Dalton, Bournemouth; Typhus Mitior; Dr. Waldo, Clifton.

BOOKS RECEIVED—

Bradley's Manual of Comparative Anatomy and Physiology—Klein's Anatomy of the Lymphatic System, part 1—La Crémation des Morts en Italie, par le Dr. Prosper de Pietra Santa—Drysdale on the Granular Cell found in Ovarian Fluid—Macleod's Address delivered in the University of Glasgow—De la Médecine Capillaire, par le Dr. B. Riofrey—Budd on Typhoid Fever—Richardson on the Simplicity of Life—The Progress of Medicine and Surgery—St. Bartholomew's Hospital Reports, vol. ix.—Tyson's Introduction to Practical Histology—Agnew on Lacerations of the Female Perineum.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Nature—Gazette des Hôpitaux—La France Médicale—La Tribune Médicale—Le Mouvement Médical—Le Progrès Médical—Gazette Médicale—Philadelphia Medical Times—The Registrar-General's Quarterly Return of Births, Deaths, and Marriages in Scotland—The Students' Journal and Hospital Gazette—Gazette Hebdomadaire—Allgemeine Wiener Medizinische Zeitung—Pharmaceutical Journal—London Medical Record—Medical Press and Circular.

APPOINTMENTS FOR THE WEEK.

November 29. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

December 1. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Mr. Malcolm McHardy, "Preparation of Double Intussusception." Mr. W. D. Napier, "Instruments for the Detection and Removal of Calculus." Mr. Cripps Lawrence, "Case of Intestinal Obstruction from Fæcal Accumulation." Dr. S. O. Habershon (President), "Remarks on some Complications met with during the Recent Prevalence of Rheumatism." Dr. Wiltshire, "Particulars of a Case of Inflammation of the Sciatic and Brachial Plexuses associated with Articular Rheumatism." And other Communications.

Royal Institution, 2 p.m. General Monthly Meeting. Election of a President.

2. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

London Anthropological Society, 8 p.m. Meeting.

Pathological Society, 8 p.m. Report on Dr. Dowse's Specimen of Foreign Body in the Crico-Thyroid Pouch. Dr. Moxon—Two Cases of Osteoid Cancer of Lung. Mr. Andrew Clark—Lymphoma infiltrating Trachea: Tracheotomy performed twice. Dr. Payne—Pouches in Peritoneum giving occasion to Hernia; Thickening of Pulmonary Artery. Dr. Lockhart Clarke—Sclerosis of the Spinal Cord. Dr. Robt. King—Large Abscess of Liver without Ulceration of Intestine. Mr. Arnott—Sarcoma of Omentum in a Child. Mr. Morrant Baker—Rare Form of Oxalate of Lime Calculus. Mr. Tay—Necrosis of Lower Jaw. Mr. Coupland—Disseminated Nodular Growths in Liver, with Tuberculosis of Lungs. Dr. Fred. Taylor—Leucocythæmia with Lymphadenoma. Dr. Crisp—Imperforate Anus. Mr. Godlee—Ossifying Enchondroma. Dr. Dowse—Renal Calculi.

3. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Obstetrical Society (Meeting of Council, 7 p.m.), 8 p.m. Mr. Tapson, "Note on the Removal of Intra-uterine Tumours." Dr. McCallum, "On a Case of Extra-uterine Fœtation." Dr. Routh, "On the Use of Intra-uterine Pessaries in Uterine Disease." And other Papers.

Royal Microscopical Society, 8 p.m. Meeting.

4. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Harveian Society (Special Meeting of Council, 7¼ p.m.), 8 p.m. Mr. Balmanno Squire, "On Lupus and its Treatment."

5. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

Medical Society of London, 8 p.m. Meeting of Council.

VITAL STATISTICS OF LONDON.

Week ending Saturday, November 22.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·96 in. The highest was 30·30 in. on Monday morning, and the lowest 29·21 in. on Saturday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

LECTURE ON

INFANTILE PURULENT OPHTHALMIA.

DELIVERED AT THE MIDDLESEX HOSPITAL, MARCH 4, 1872.

By J. W. HULKE, F.R.S.

Gentlemen,—The purulent ophthalmia of newly-born infants is a complaint so destructive when allowed to run its course uncontrolled, and still more so when injudiciously treated, yet so amenable to proper measures, that no apology is necessary for again bringing the subject under your notice. In the lower classes of London population it is the most common cause of blindness in childhood. The mothers of infants attacked by it have so commonly at the time of their confinement a puriform vaginal discharge that it seems more than probable that the ophthalmia is often due to the direct inoculation of the child's eye with the maternal discharges. For the production of the ophthalmia there need not be gonorrhœa,—indeed, very often we feel confident that the vaginal discharge was not the result of impure sexual congress: the products of a simple leucorrhœa transferred to the ocular conjunctiva will provoke an acute suppurative ophthalmia. Analogy makes it probable (and observation, I think, confirms it) that infantile ophthalmia consequent on gonorrhœa is more severe than that induced by leucorrhœa. The condition of the infant also is not without its influence on the affection; for in puny, weakly infants the cornea offers less resistance, and more readily sloughs than it does in strong, healthy children.

Usually on the next or the second day after its birth the infant's eyelids are noticed to be a little swollen, the ocular conjunctiva is slightly reddened, and if the lower eyelid is drawn down so as to expose its inner surface, this also is found unduly red, and perhaps a flake or two of mucus is noticed on the loose folds of the membrane where it joins the eyelid and the eyeball. By the following morning the conjunctiva is much redder, it has also become slightly œdematous, and it exudes an abundant mucus; the swelling and redness of the eyelids are also greater. By the end of the day the dropsy of the conjunctiva (*chemosis*) is often so great that the distended membrane overlaps the border of the cornea and bulges between the distended eyelids. The discharge is now purulent. The child evidently suffers much; it is fretful and restless, and cannot sleep. If the intensity of the ophthalmia does not soon abate, the surface of the cornea loses its polish, it sheds its epithelium, the lamellar tissue becomes whitish-grey, sodden-looking, and opaque, it then sloughs and opens the anterior chamber, on which the aqueous humour, followed by the iris, gushes out. Upon this the lens, unsupported in front and pressed upon behind, is pushed forwards against the back of the cornea. When the corneal breach is small and the protruded piece of iris is not large, the eye is not necessarily lost. Often the exposed iris inflames, it becomes thickened and coated with exudation, granulations spring up in this and also from the edges of the corneal opening, the hernia shrinks, and there results a scar, technically called a leucoma, in which the iris is permanently entangled. Although very disfiguring, such a scar—when its edge is definite, and when it does not overhang the whole area of the pupil, but leaves part of this unobstructed—is not incompatible with useful sight. In course of time small scars often become inconspicuous, partly by a slow assimilation of the cicatricial tissue to the structure of the normal corneal tissue, and partly by the disappearance of the exudation and young cell-broods—inflammatory products evolved during the early stages of the process which ended in the gangrene of the cornea. In eyes bearing marks of a limited perforation of the cornea in early infantile life, and less frequently also where a faint corneal opacity without any corresponding adhesion of the iris (*anterior synechia*) points to a corneal lesion short of actual perforation, a minute white dot may sometimes be seen in the front of the lens. This is, I believe, the mark of a former contact of the lens and the back of the cornea. Where the cornea was actually perforated during the ophthalmia, the mechanism of this contact is perfectly plain; but even where the integrity of the anterior chamber was not broken, a little reflection renders it intelligible. The much greater convexity of its lens makes the distance between the anterior pole of this and the cornea much less in the infant's eye than in the adult's; hence, in ophthalmia, pressure exerted on the cornea by the œdematous conjunctiva and the distended eyelids, helped by the greater resistance to the recession of the eyeball into the orbit offered by the over-fulness of the orbital vascular system, and assisted possibly by a repletion of that of the choroid heightening the intra-ocular tension, may so lessen the small space between them as to bring the cornea and lens together. Where they touch, a minute bead of exudation shed from the cornea or iris on the lens (which latter becoms a little web of fibro-nucleated connective tissue), lessening the permeability of the capsule, checks the evolution of the developing lens-tissue, and causes a minute necrosis (an effect which simple pressure may also occasion), the residuum of which is an atheromatous speck. Where great part of the cornea sloughs away, the lens, together with some of the vitreous humour, is not infrequently instantly extruded, followed by collapse of the eyeball. Where this has happened the scar replacing the cornea is apt to bulge, although its thickness may after some time much exceed that of the normal cornea, and it may become so prominent that the eyelid can be closed with difficulty over it, or not at all. In some such cases a weak spot in the scar may burst from time to time, some of the fluid contents escape, and the projection temporarily lessen.

Treatment.—It would seem almost superfluous to tell you that you will not wisely employ alike in every case one inflexible mode of treatment. Ever keeping before you a guiding principle, you must always adapt your measures, whatever these may be, to your patient's circumstances. Thus, topical applications, which can only be safely applied by the skilled hand of a competent medical attendant, are out of place where, as in many country districts and in large poor-law and club practices, great distances and large demands on the practitioner's time make it impossible for him to see the patient daily. For this reason we seldom use the pure or diluted solid stick of nitrate of silver—a remedy recommended by foreign surgeons. This, again, is the reason why ice, an auxiliary much in favour with our foreign *confrères*, is so little used by us in these cases, because, unless the ice or ice-water is constantly applied, it promotes a greater reaction—its proper use demands such incessant attention as few patients in the working and in the lower middle classes can bestow or command; besides which, ice is mostly beyond the reach of the poor in towns, and not generally procurable in the country. The treatment which has been followed for more than a quarter of a century with much success at the Royal London Ophthalmic Hospital, the oldest and largest institution in this country specially devoted to eye diseases, consists in the frequent use of alum-water (generally gr. vj. ad ℥j. aq. dist.). First, the eye must be thoroughly cleansed from the discharge; and, as this cannot be done without some pain and struggling, it is well for the safety of the child's eyes, and in order to lessen the chance of the accidental inoculation of the nurse's eyes, to have the child completely under control. For this it is neither necessary nor proper to give chloroform. A simple and efficient way is to place the child with its arms straight by its sides upon a shawl or on a long towel, and then swathe it round a few times in this, leaving only its head out. So swathed it cannot move, and one person, unassisted, can do all that is required to the eyes. The eyelids being now gently separated without pressing on the eyeball, the discharge should be wiped away, and the eyelashes cleansed with tepid water and small pieces of rag, which should be immediately burned. Next, if the nurse is intelligent and has not clumsy hands, the conjunctival pouch under the upper and lower eyelid should be carefully syringed out with tepid water; for this a common pewter squirt will do. When the pus is thoroughly removed, some of the alum-water should be dropped into the eye, and diffused beneath the eyelids by moving these lightly over the cornea, or it may be injected under them with the squirt. After this the eyelids are dried, and a little simple ointment is smeared along their edges in order to prevent the eyelashes becoming glued together. If the ointment is softened to the consistence of cream by warming it, it may be very neatly applied with a brush. In an acute case the use of alum-water should be repeated frequently. At first every second hour will not be too often, and then as the ophthalmia yields the intervals may be increased, until, in a couple of days or so, six or four applications in the twenty-four hours will suffice. If

the surgeon can see the child daily, and he prefers to use nitrate of silver, the eyelid should be everted and cleansed in the same way, and the exposed conjunctival surfaces should be lightly wiped with the caustic-stick, or (which I think preferable) brushed with a solution of the salt—gr. x. ad ℥j. One such thorough application a day is enough, and in the intervals a little alum-water, pure or mixed with ext. belladonnæ (in the proportion of ℥viij. ad ʒj.), may be dropped three or four times into the eyes. The more powerful astringents or stimulants are to be used at longer, the milder at shorter, intervals. If you employ alum-water in the way I have described, you will rarely have to regret the loss of an eye. Such an occurrence is quite exceptional, and it seldom happens unless the cornea is already sloughing when the child is first brought to you. Implication of the cornea does not necessitate the discontinuance of the astringent remedy; its use should be persevered in, because in the speedy arrest of the ophthalmia lies the best hope of averting or limiting the destruction. A small hernia of the iris through a limited breach in the cornea may generally be left to itself; it will nearly always shrink as cicatrisation proceeds. Surgical assistance is seldom required except a considerable part of the cornea has perished, and a large piece of the iris, perhaps distended by the lens, protrudes. Under these circumstances the removal of the lens will hasten cicatrisation, and give a better scar; the eye is greatly damaged or wholly lost as regards sight. For this no special operative skill is required. Chloroform may be given; the iris should be cut with a thin, sharp knife, on which the lens will escape—if not, it may be removed with any small convenient scoop. After this the eyelids should be closed, and a small pad of cotton-wool secured on them with a roller. This is only exceptionally required. Not unfrequently, however, young children from two to four years old will be brought to you who have suffered from infantile purulent ophthalmia, and have the cornea replaced by a bulging opaque white scar, termed an anterior staphyloma. Such a prominent scar may prevent the eyelids closing, it is very liable to become inflamed, and it is very disfiguring. On these grounds the abscission of the front of the eyeball may be required. For this anæsthesia is almost necessary. The eyelids are held apart with a speculum, and the eyeball being fixed with a hooked forceps, a small puncture is made into it with a pointed knife behind the line of the ciliary processes, large enough to admit one blade of a scissors, with which the bulging part is cut off, care being taken that the line of the incision lies just behind the ciliary region. The lens is generally included in the piece cut off, but if not it must next be removed. If towards the horizontal equator of the eyeball the line of the incision is taken a little further backwards in the sclerotic, the lower and upper half-circles will fall together more neatly, and will not form the troublesome angle resulting from a truly circular abscission, which sometimes makes the fitting of an artificial eye difficult, and its use painful. In little children I never sew up the wound, and seldom apply anything but water-dressing.

An occasional and very troublesome sequel of infantile purulent ophthalmia is inflammation of the lachrymal sac. I think it is more frequent where an acute ophthalmia instead of thoroughly ceasing has lapsed into a subacute chronic form. If the sac suppurates the abscess cannot be opened too early, and if after the subsidence of the inflammatory swelling epiphora and a chronic mucous discharge continue, the lower lachrymal punctum and canaliculus should be slit up into the sac. Through this the contents may be gently pressed out several times daily; and once a day after emptying the sac in this manner a few drops of a solution of sulphate of zinc (gr. ij. ad ʒj.) may be dropped into the corner of the eye. If the nasal duct is strictured you will best adopt an expectant treatment until the child is older.

Algiers as a Health-Resort.—The writer of an article in the *Journal des Connaissances Médicales* on the climate of Algiers and its effects on patients, chiefly those affected with pulmonary diseases, concludes with the following remarks:—"The climate of Algiers calms the cough, and diminishes expectoration; it is favourable in the first stage of tuberculosis, and in the second, provided proper precautions be taken; it is injurious in the third stage, and in the case of patients afflicted with blood-spitting. In general, patients should go to Algiers in November and leave in April."

LECTURE ON
HOSPITAL PATIENTS, DOCTORS, AND NURSES.

By Dr. LIONEL BEALE, F.R.S.

(INTRODUCTORY TO HIS CLINICAL LECTURES AT KING'S COLLEGE HOSPITAL.)

(*Concluded from page* 573.)

And now, gentlemen, I have to speak upon a subject of the greatest importance to every member of the profession and to the public, rich as well as poor, and one concerning which much misconception prevails in many quarters.

No calling has undergone more wonderful changes—and for the better—in these last days than that of nurse, nursing sister, and superintendent of nurses. Nursing has become a profession, and in some hospitals—I wish I could say in all—a special department. The old "matrum" and her poor, overworked, ignorant, scrubbing attendants have either disappeared or have much changed in character. The poor, tired old charwoman no longer recoups her exhausted powers, after her hard day's toil, basking in the warmth of the ward fire, and supplied with her supper and a shilling in exchange for her modest services as "night nurse." The system did seem bad, and according to my experience it certainly was desperately bad, but no doubt it had its good points; for, as you know, there is good to be discovered in everything, if only you are far-seeing, and look far enough, and long enough, and deep enough. Every old nurse was eminently deferential, and in a way thoroughly under the control of the constituted authorities. Though the discipline seemed lax in some particulars, and the work was often most carelessly performed, there was never any doubt as to who was master and who served. In former days dismissal was summary, and on some occasions it was found necessary to interfere in advance instead of waiting until the offence had been actually committed in a legal sense. Thus, a nurse who might have been regarded as potentially tipsy, though actually sober, might have been transferred from the ward to the environment of the institution to develope the several phases of the alcoholic malady. Happily, all this is of the past. Nurses are now of an altogether different order. They are taken from a different class. They are, I may say, well educated. They are trained, and know their work. Many are proud of nursing the sick, but few will scrub the floor. Nurses are paid higher wages. They are devoted and trustworthy, but are of course more independent. Hospital nursing nowadays may be thoroughly well done, but of course it is more costly than the apology wrongly called nursing in former days. Still, at this time there exist two very different ideas of what a nurse ought to be. According to one, she is a sort of medical maid-of-all-work, to be generally useful; according to the other, she is a member of a profession, and has rights as well as duties. For the last twenty years many medical practitioners have been doing their utmost to raise the character of the nurse and increase her efficiency. Considerable success has attended these efforts, not only in large hospitals and in populous cities, but in villages; and the poorest cottagers in the country, as well as the sick inmates of our poor houses, have been gainers thereby.

I am glad to be able to say that we were among the very first to abandon altogether the old system of hospital nursing, and to take a new step in advance as regards hospital management. A system of nursing based upon (at that time) altogether new principles was introduced. The new nurses were members of a staff owing allegiance to a lady who undertook without remuneration the general superintendence of the nursing department of the hospital. She was assisted by other ladies, who, like her, gave their services to the good cause. The nurses under the sisters were not only well paid, but every care was taken for their well-being and comfort. About seventeen years ago, then, the responsibility of nursing our hospital was transferred from hospital servants to the sisters and nurses of St. John's House. No hospital could be better nursed than ours has been during these seventeen years. Year by year the excellence and thoroughness of the work have been acknowledged, and everyone who knows anything about nursing will confess that more thoroughly good work cannot be. The testimony of the staff has been all but unanimous.

It is well that you should learn how good nursing should be conducted, and you cannot be much in our wards without

gaiuing the informatiou. Hospital nursing demands iucessant care and attentiou, and no inconsiderable labour on the part of the nurse, who is almost incessantly moving about, and sometimes has many journeys up and down stairs to perform in the day. As an illustration of hospital nursing, I will refer to one or two of our wards. Take for example the Sambrooke ward, through which we have just passed. Consider what the sisters and nurses have to do there at this time—day by day, and night by night. At the eud of the ward is a patient just admitted in a highly feverish state, requiring constant watching. Opposite to him is a delirious youth, suffering from typhus, whose life is in jeopardy. Two nurses are required to manage him. Beef-tea or brandy is given every two hours, and for the next few days probably it will not be safe for a uurse to be absent from his bedside for many minutes at a time. He is in a very troublesome condition, for he is sometimes violent, and tries to fight his way out of bed; still, with the thorough care and attention he gets, he will probably recover. A few beds off is a case of cerebral disease. This patieut is sometimes unconscious for several hours together, and requires a good deal of looking after. Lower down we have a man suffering from rheumatic fever, who is perfectly unable to use either of his hands. He suffers much pain, and, though doing perfectly well, requires the constant assistance of the nurse. Opposite to him, as you know, is a very bad case of acute rheumatism, with pericarditis and pneumonia. This poor fellow will also recover, but will give much work for our sisters and nurses for some time to come. All these cases require most patient and constant watchiug. Without first-rate uursing there would be little chance of saving two out of these five cases. If thoroughly well nursed, a large percentage eveu of the very worst cases of rheumatic fever complicated with heart disease and lung mischief, as we know by experience, will recover. But in addition to the work just referred to, you must remember there are ten more cases in this ward, several of which are serious, and requiring a good deal of attention. Then there is the ordinary daily routine work of the ward to be done, such as giving the patients their meals and medicines, making their beds, and seeing to the numberless duties which afford almost constant occupatiou in the case of the nurse who has but a single patient to look after in a single sick-room.

And if you wanted to see in an individual case of sickness the result of thorough nursing aud constant patient care and attention, extendiug over a long period of time, I should recommend to your notice a little girl iu the Twining ward, whose case is also most interesting medically. She was admitted about five mouths ago, in a condition which seemed almost hopeless. There was well-marked pyæmia, and abscess after abscess formed in different parts of the body. There was extensive lung mischief and purulent expectoration. The emaciation was extreme, and for weeks the temperature ranged from 101° to 104°. The last abscess that formed was a large oue, occupying the calf of the right leg, and this, after being opened in two places, was followed by necrosis of the greater part of the shaft of the tibia. The dead bone has not yet thoroughly separated; but the child is gaining flesh, and thanks to good nursing will recover. Now, I doubt if during the five months she has been in the Hospital, more than an hour has passed without the nurse being required at the bedside of this child. Although she weighed only two stone and half a pound, she has had during the whole period of time six ounces of braudy per diem, besides beef-tea, milk, and a small quantity of good ale. She has also taken pepsiue and tincture of perchloride of iron during the whole period. Now, here was a case in which we should not have had the smallest chance of being useful unless we could depend upon thoroughly honest, tender, and intelligent nursiug care. A child suffering in this way is ofteu very irritable and excessively exacting. If the nurse is to be of the greatest use possible, she must be patient and in good temper during the progress of a tedious case like this, and if she can be in good spirits and always cheerful, so much the better for the little sufferer. Now, it is only by a thoroughly good system of training and a thoroughly good system of mauagement that we can hope to obtain—or retain, if we possess it—such service.

St. John's House is a comfortable *home* as well as a nursing institution, and when our nurses become old and can no longer work they receive a pension, which, though uot so large as we desire it should be, nevertheless represents an amount of capital which very few people in the enjoyment of an income far higher than that of a nurse can manage to save. Our nurses belong to a sisterhood—a religious sisterhood—the bishop of the diocese being our president.(a) You must not, however, allow yourselves to be misled by the word "sisterhood," which is applied to communities differing from one another in most important particulars, and which are conducted on very differeut principles. Our workers take no vows—they can come and go as they think right. They freely give their services, working in a way that must excite the illogical gratitude eveu of a thinking-machine. Such an institution and such a work is sure to be misunderstood and its motive misinterpreted iu these days. In King's College, however, we ought to fully understand it and sympathise with its aim, for the basis of the two institutions is the same. Now, I must beg you to bear in mind that in our sisterhood everything is *voluntary*. As Bishop Blomfield said when St. John's House was founded in 1848, "There would be no vows of poverty, mouastic obedience, or celibacy, no cloistered seclusion, no tyranny exercised over the will or the conscience, but a full, free, and willing devotion to the great cause of Christian charity.(b)

Some persons object to our system; some disapprove sisterhoods and religious communities of every kind; some disbelieve in work undertaken upon religious grounds; some disapprove religion of every kind whatever. *Quot homines, tot sententiæ.* Our country is, however, large enough to contain us all, and we may differ mightily from one another. Nor does it appear probable that as time goes on the differences will be less; but nevertheless the work of England will be so done that we shall not feel ashamed of our country. It would, however, be un-English on the part of one person or of many belonging to an institution or a community which rests upon certain defined prineiples, to attempt to undermine those principles in order to destroy that society—just as it would be un-English and wrong on the part of any of us, who differed from a co-worker, to co-operate in his work, to make him believe we were his friends, and then when we knew him, and were acquainted with his weaknesses as well as his strength, to use the knowledge we had thus gained for his overthrow should an opportunity occur. Such conduct in the abstract would be called base; in the concrete, a milder term is usually applied to it, and some think perhaps that it is only the legitimate advantage which a strong person must, according to the inexorable laws of natural selection, take over a weak one clearly unfitted to survive in the struggle for existence.

Theu there are people who take what they tell you is a thoroughly *practical* view of the matter. They eare not what those who are engaged in any work may think, or what they believe. The questiou for such practieal persons is simply this—Is the work done properly; are the people at their posts; do they do that which they engage to perform? If these questions can be answered affirmatively, not only will superstition be tolerated by the practical person, but he will be ready to bear honest testimony to the honest workers, and praise their work, though he may not agree with the principles upon which they work. But never mind! judge, if you choose, like our supposed praetieal business man, by the results,—and what will be your conclusion? Look at the state of our wards, and cousider what we gain by this thorough cleanliness. Do we not happily enjoy almost immunity from hospital maladies, such as pyæmia, spreading erysipelas, etc.? The contagious fevers we take in hardly ever afford evidence of their contagiousness by spreading in our wards; and on the rare occasions upon which fever is communicated, it is the poor nurse, uot oue of the patients, who is almost invariably the sufferer. We prove the excellenee of our system by appealing to the facts.

As I have had to touch upon the religious question, I shall take this opportunity of adding a few words upon that head; for at this time it is well that you should know what your teachers feel in connexion with a matter of such real import-

(a) "As a religious institution, its internal harmony and its steadiness and moderation as regards Church principles could only be secured by placing it always under the authority of the bishop of the diocese for the time being, as president and visitor."—"A Short Account of St. John's House and Sisterhood," p. 2.

(b) *Op. cit.*, p. 3. The present Council of St. John's House consists of the following members:—The Lord Bishop of London, Sir Rutherford Alcock, K.C.B., the Rev. Canon Barry, D.D., Professor Beale, F.R.S., W. Bowman, Esq., F.R.S., Robert Cheere, Esq., the Rev. Edward Coleridge, Robert Few, Esq., Bartle J. L. Frere, Esq., G. Frere, Esq., the Earl of Harrowby, the Right Hon. Lord Hatherley, the Rev. J. E. Kempe, B. Lancaster, Esq., the Lord Bishop of Lichfield, the Lord Bishop of Lincoln, the Right Hon. J. R. Mowbray, M.P., Dr. W. S. Playfair, Randolph Robinson, Esq., the Very Rev. the Dean of St. Paul's, W. H. Smith, Esq., M.P., G. A. Spottiswoode, Esq., John G. Talbot, Esq., M.P., the Rev. the Master of the Temple, the Rev. W. Tennant.

ance to us all; and although I daresay Mr. John Morley and others will tell you that my business is with teaching purely secular, while many of my scientific friends will not hesitate to affirm that I am a prejudiced supporter of the anti-scientific view of things, and others will try to set me down without giving any reasons at all, it is nevertheless right that I should speak. In these days it would indeed be foolish, on the part of conscientious advocates of the principles upon which our College has been founded, to flatter themselves that they were regarded with much respect by those who assume the title of philosophers, and seek to impose upon mankind their peculiar views, as if they were infallible, and on the ground that they belonged to the "advanced" school. "Advanced" their school certainly is as regards its professed knowledge of facts about to be, and its interpretation of what is now known. For the *advanced* is also the *prophetic* school of science, and it possesses other qualities which even unscientific people are beginning to discover and to appreciate. Some of us connected with this place may constitute the very last of those who desire to act up to the antiquated doctrine,—"That every system of general education for the youth of a Christian community ought to comprise instruction in the Christian religion as an indispensable part"; but were the number reduced to ever so contemptible a minority, I should certainly form one of that minority; and if I cannot give adequate reasons for the views I take, I shall at least be able to give full and sufficient reasons why I utterly reject the evidence upon which many of the new so called "laws of nature" are said to be founded.(c) There never was a time when a greater number of utterly untenable dogmas were palmed off as "fact and law," than have been palmed off during the past few years. What a few philosophers *desire* that the majority should believe to be truth, is represented by them in the most positive language possible to be actual scientific truth. But very many of these dogmas have been proved to be neither scientific nor true. Then it is said—"Ah, but even these certainly will be proved to be true at some future time!" Our views, and opinions, and beliefs, by which only we can be guided here, are to rest upon the facts, and laws, and discoveries of the science about to be! But already people are beginning to perceive that, while it is quite right to study with the greatest care, and minuteness, and skill, and patience all that relates to the subject of fog, it is also right to bear in mind during the whole course of the inquiry that there is blue sky beyond, which cannot be successfully investigated by aid of the same instruments and method of research as have been shown by experience to be admirably adapted for elucidating all the facts of importance connected with fog.

But it is to be observed that many—and of these not the least wise among the leaders of thought—have decided to change front a bit, and some are actually returning to the old views concerning the importance of religious teaching. If I might venture to prophesy, I should say that before long the opinion that the acquisition of branches of knowledge without instruction in Christianity "will be conducive neither to the happiness of the individual nor to the welfare of the State" will be more generally entertained (at least in England) than has been the case for many a long year. Views have changed wonderfully within the last year or two. People are beginning to find out that they are not mere machines, and that the positive assertions concerning the groundlessness of the religious idea are mere dogmas that cannot be justified. It is already admitted that little boys and girls may be taught that there is a God without any very dangerous consequences to the developing liberty of the growing subject. In my opinion, the fundamental principle of our College has not been really shaken, nor do I think it likely that it will be.(d) I therefore conscientiously give all the support it is in the power of a doctor to give to those who devote themselves to the good work of nursing our sick, although they are members of a religious body. I have long been a member of the Council of St. John's House, and I cannot conceive a connexion more natural or more likely to work well and be advantageous to both institutions than that which has so long subsisted between St. John's House and King's College Hospital. For the sisters and nurses I unhesitatingly claim—and in doing this I am sure I shall have with me my colleagues and many friends—the respect and support of medical practitioners and the public, on the ground that by thorough self-sacrifice and devotion, and the earnest discharge of their self-denying duties, it has been thoroughly earned. Nor can I conceive that Englishmen generally will allow themselves to be prejudiced against bodies of thoroughly useful, earnest workers, or refuse to accept the benefit of their labours, simply because they are influenced by religious views, which those who disbelieve that miracles have ever been performed and have implicit faith in physical causation, characterise as foolish, bigoted, or narrow. Gentlemen, in this sense I must plead guilty to failings such as many possess who have been already condemned as weak, and unscientific, and foolish,—for I am not afraid to confess my utter disbelief in the arguments of those who assert that the facts of science have shown miracles to be and to have been impossible, who assert that the facts of science have destroyed our belief in God, and proved Christianity to be only a kindly superstition.

(c) See "Protoplasm, or Matter and Life"; "Life Theories and Religious Thought"; "The Mystery of Life"; and "Bioplasm, an introduction," etc.

(d) I will, however, make this reservation – In case the prophecies relating to the formation of laboratory-bred organisms out of lifeless matter, and the discovery of the mechanical equivalent of consciousness (Huxley), should be actually fulfilled while I am a member of the staff, I will instantly resign. At this time, however, I regard these not only as very false, but as very foolish prophetic utterances.

ORIGINAL COMMUNICATIONS.

ON TREATMENT OF VESICAL CALCULI.(a)

By WILLIAM DONALD NAPIER, M.R.C.S.

During my attendance at the meetings of this Society it has always afforded me the utmost satisfaction to observe not only the generous forbearance of its members towards those who seek to bring forward any new idea, but the equally ready sympathy and kindly assistance which they as invariably extend to the most inexperienced.

Thus encouraged, I do not hesitate to present myself before you this evening, feeling sure that you make full allowance for the peculiar position in which I stand. In no society does the humblest effort towards the extension of science or increase of light stand less in need of an apology than in one composed of men whose best faculties are devoted to their pursuit, and whose very vocation tends to enlarge their sympathies and give breadth and completeness to their opinions. To be counted with them, if only in the desire to mitigate human suffering, is not unworthy the ambition of any man, and to be able to contribute in ever so small a degree towards the object that actuates them, would be to me a sufficient reward for the time, and thought, and labour that I have spent, and spent willingly, on the study of a special branch of the surgeon's art that has appeared to me to demand even more strenuous efforts than have yet been made to obtain for it the high place that can only be secured by the nearest approach to perfection that we are capable of raising it to.

Unable to devote any but my contracted leisure moments to the study of the subject in which I have taken such vivid interest, I have found eight years not more than sufficient to work out to my satisfaction the various schemes that have at different times suggested themselves to me, and that have resulted in the instruments that I am about to lay before you, hoping, as I do, that they possess at least the merits of simplicity and originality.

One of them I have been already permitted to bring before the notice of this Society; but as I did so hurriedly and without previous notice, and as it has since been greatly improved in manufacture, and is besides intimately connected with the others that I am anxious to call your attention to, I must hope for your pardon for including it in the series, which would be incomplete without it.

Rather than occupy your time with a dissertation on vesical calculi, which could be done much more advantageously to you by any of the eminent surgeons present, I shall confine myself to only such an exposition of my own views as is absolutely necessary for the explanation of the motives that guided my various experiments, and in illustration of the principles which are embodied in the mechanical appliances I have alluded to.

There has at no time been any hesitation in the mind of the profession as to the rank amongst operations of importance that should be assigned to the one commonly practised for the relief of persons suffering from stone in the bladder. But

(a) Paper read before the Medical Society of London, December 1, 1873.

perhaps its pains, its perils, and its jeopardies were never fully appreciated by the general public until an illustrious life lay in the balance a year ago, and the newspapers were teeming with surgical details, variation of symptoms, and auguries as to the chances for and against the termination of the struggle that was known to be going on between science and disease in that quiet room at Chislehurst.

How gradually but persistently the gravity of the malady forced itself on men's minds! How the desire for intelligence grew in intensity; and how deep and universal was the regret when it became known that the life that had weathered more storms, endured more of "the changes and chances of this mortal life" than is common to men, with all its varied experiences of struggle, of exile, of a throne, of triumphant success and humiliating defeat, of fierce physical suffering and immeasurable mental distress, had succumbed under the very treatment intended for its prolongation!

There was throughout England, in the days that succeeded that last bulletin, but one feeling of compassion for the man whose profound distress at the humbling issue of a disastrous campaign, with all its miserable concomitants, had been aggravated beyond description by intense anguish of body, so unfitting him for personal exertion that it must have been by an almost unparalleled act of fortitude that he in the first instance assumed the command of the army that, but for his grievous disability, might never have been led to shame. Is it too much to say that, but for the length of time that was permitted to elapse—let the reason for the delay have been what it may—but for the length of time, I say, that was permitted to elapse between the first suspicion of the existence of the disease and its establishment as a fact, a very different result might have been hoped for, not only to the man but to the nation?

I have alluded to the place held in professional estimation by the operation for the removal of stone, but were any testimony required in proof of it, none more convincing could be found than in the enormous number and almost incredible variety of the instruments immediately connected with it that were lately exhibited at the International Exhibition, each bearing silent witness to a fresh effort to divest the operation of some cause for anxiety, spare the sufferer some suffering, avoid some complication, attain some desired end, ward off some dreaded result.

Taken collectively, as they may fairly be, and tested by the laws that regulate supply and demand; what do they prove? Three points appear obvious to me—(1) the difficulty of early diagnosis; (2) the danger to life involved by the operation of lithotrity as now practised; and (3) the impediments to convalescence consequent on its successful performance. Under this last head I should be disposed to class the continuance in the bladder of fragments of stone too large to find their exit in a natural manner; the premature repetition of the first operation which the intense distress that their presence causes the patient is apt to render compulsory; and the protracted suffering consequent on abrasion of the mucous membrane from portions of the calculus being caught and drawn away—a process that not only considerably retards recovery, but occasionally results in permanent stricture.

I am taking in this rough grasp only such obstacles as may present themselves to the skilful operator—the man whose sense of hearing is quickened by constant use; whose touch is rendered delicate by familiarity with the cause of suffering; whose mastery of the instruments he handles renders his manipulation steady, gentle, and deliberate; and whose experience anticipates some of the evils he may not be able to avoid.

Given these impediments, or embarrassments, or perplexities,—whichever you choose to call them,—under such circumstances as these, and there need be little fear of over-rating the complications that may arise under less expert direction. This view of the subject having commended itself very strongly to me as the one that should be kept constantly before anyone who sought to improve the present method, I have worked continuously with one especial aim—to produce instruments that, by their simplicity of mechanism and manipulation, should insure efficiency in the hands of the less experienced practitioner.

I think I am correct in stating that there are few investigations into the primary cause of suffering in which accuracy is of greater importance in its bearing on the result than in that for the discovery of stone in the bladder; its removal in the first stage being so comparatively simple, but after a length of time so complex, as to rank when successful with the greatest triumphs of surgical art.

And there is in addition to this argument in favour of early detection another hardly less obvious. I mean the aggravated misery inflicted upon a person suffering from stone by mistaken diagnosis, and the consequently mistaken treatment that is apt to follow it. An instance comes to my mind of a patient with stone in his bladder being treated, although a young man, for enlarged prostate, and the application of a blister to the perineum being ordered for him, entirely in consequence of unsuccessful soundings.

That there is some imperfection in the present system of investigation is evidenced by the failure of one surgeon to detect the presence of a calculus which is discovered immediately after by a man only his own equal in ability, or possibly less experienced than himself. And this—being by no means a rare occurrence—points conclusively, I think, to something defective in the agent rather than in the operator.

To render a doubtful result to investigation conducted with ordinary care more exceptional than hitherto,—and I imagine that it is in the first stages of the disease that the percentage of uncertain issues is by far the greatest,—it seemed necessary to devise an instrument of peculiar sensitiveness and capability of application to minute objects.

Whether the one before you will fulfil these conditions in all instances remains to be proved. It has not failed me yet in the experiments to which it has been subjected. I believe it to be unique in its mode of action, depending as it does upon ocular instead of aural proof; and I cannot help hoping that, by reason of its exquisite susceptibility of impression, immediate manifestation of the existence of a foreign body may follow with absolute certainty its introduction into the bladder.

The calculus detector—for that is the name I have given it until a better can be found—is precisely similar in form to the ordinary sound. It is composed of steel up to the commencement of the curve, where it is reduced in diameter, and a coating of pure lead is cast round the smaller part of sufficient thickness to render the surface perfectly smooth and even along the entire length. The leaden extremity is then polished as highly as possible with a leather, and rendered keenly sensitive to the slightest contact with any rough or hard substance, of which it would be found to bear visible trace.

On some of these instruments I tried to increase the susceptibility by dipping the leaden end in a weak solution of nitrate of silver, or, what is better, chloride of platinum, which produces a black pigment on their surface; but further experiments have almost convinced me that this preparation is unnecessary, and that pure lead is perfectly efficient. The instruments that I showed before were coated with pewter, on which the use of lead is a great improvement, by reason of its readier impressibility.

Before the introduction of the detector it should be carefully rubbed with a leather, and submitted to the test of a magnifying-glass, so that no slight scratch or indentation previously incurred should, on its withdrawal, mislead the operator, who will find it satisfactory again to apply the same means for discovering the marks which contact with a hard substance may have produced during its employment in the bladder.

With regard to the other instrument, which I call the "calculus extractor," I may premise that I incline to confine its use to the removal of small stones—I trust that the day of large ones is at an end—and fragments of stone. And this because I do not myself believe that lithotrity should ever be resorted to when a stone has from any cause, such as absence from available medical assistance or the dread of the sufferer to submit to the necessary test, been allowed to attain to larger dimensions. Then the patient's chance for recovery must lie in lithotomy.

To be as concise as I can, I shall simply describe it as an instrument intended to withdraw from the bladder either a stone intact or crushed into fragments, so enveloped in a delicate elastic wrapper—I use the term advisedly, for, as you see, it literally folds itself round the substance in question—that injury to the passage will be simply impossible. It consists of a soft indiarubber tube, terminating at one extremity in a funnel-shaped orifice, greatly resembling the ordinary convolvulus flower, and is capable of containing a calculus or portion of calculus of considerable dimensions. Inserted into the bladder, its form and position render it the receptacle of such foreign substances as would, from the position of the patient and flow of urine, determine towards the natural outlet. This receptacle, enclosing such bodies within the folds of its delicate membrane, and permitting itself to be

gently withdrawn, retains them in its elastic envelope, and protects the urethra from direct contact with them.

After bringing it to the state of completeness in which you now see it, I was very much and very long perplexed as to the best means of introducing it into the bladder; and it was only after many trials, and as many failures, that I was able to see my way to the accomplishment of this, without which my instrument would be useless. My first idea had been to insert the convolvulus-shaped cup folded in the form and manner of a bud, and retained in its position by some adhesive substance that should permit it to expand on its introduction. But there were several objections to this.

At last it struck me that, inserted in a fine silver canula, it would be entirely at the direction of the manipulator, and I was successful in reducing my idea to practice; but then I was met by a difficulty that I feared at one time would be insurmountable. How was it possible to avoid the trouble that the insertion of a canula open at the end could not fail to give rise to? An artificial point appeared to be the only solution, and it seemed to me that cocoa-butter was possessed of a peculiar fitness for the purpose, and for this reason—that for a hard, dense substance its dissolubility under moderate heat is, I believe, quite without parallel, subjection to a temperature of 96° dissolving such a portion of it as my purpose requires with curious rapidity, in as nearly as possible one minute. There is, besides, the advantage that it serves as a lubricator during its entrance into the bladder.

And it is not in connexion with my instrument alone that this application of it will, I hope, be found to be a profitable discovery, but in every operation where it is expedient temporarily to close the mouth of a catheter or canula. I mean that I consider the cocoa-butter point *per se* worthy of attention.

I would now briefly suggest to your notice a further adaptation of the principle and form of the extractor that may be found useful. As a self-retaining catheter, I cannot help thinking it would prove as simple and effective an appliance as could be used, and I know that the increased demand for these instruments of late has called forth various improvements and emendations both in the means of introduction and retention.

After speaking so long of myself and my own labours, it is especially pleasant to me to turn from them to the more agreeable task of acknowledging—which I will do as briefly as possible—the obligations that I am under to those who have generously afforded me assistance that has been invaluable to me in surmounting the difficulties with which I have had to contend. Amongst my medical friends I must mention Mr. Barnard Holt, to whom I am indebted for sound practical advice. To Dr. Robert John Lee I owe more than I can express for the unwearying patience and kindness with which he has assisted me in my experiments on the dead subject; and to Mr. Warrington Haward, of St. George's Hospital, who deserves my warmest thanks, not only for facilities and personal help afforded me in the post-mortem room, but for the preparation now on the table, by which I hope to be able to exemplify practically the processes I have described.

The success that has attended the manufacture of the instruments is due in part to the care and attention bestowed on them by Mr. Charles Maw, of the firm of Maw and Son, Aldersgate-street, and in part to Mr. Jaques, the representative of the firm of Messrs. Warne and Co., Tottenham Indiarubber Works, who, in the cause of science and of suffering humanity, spared neither time nor trouble in bringing to perfection the indiarubber convolvulus-tube, devoting his best energies to the work in hand with unflagging interest until the end was accomplished. The calculus detectors which I have brought with me this evening were made by Mr. Hawksley, of Blenheim-street, Bond-street, who has taken especial pains to carry out my instructions.

For assistance in procuring suitable chemical agents for the solutions I have alluded to, my best thanks are due to Mr. Gale, of the firm of Bell and Co., Oxford-street, and to Dr. Flite, of the British Museum.

It remains only to commend the inventions to your criticism, and, if they meet with approval, to your adoption. That they are faultless, it would be too much to hope. Time and use would doubtless suggest improvements, modifications, and additions, but if the principles are sound, a step will have been gained. It would have been more satisfactory for you, and certainly for me, had I been able to bring evideuce of successful operations effected by their means. Perhaps on a future occasion some of the gentlemen present may be able to supply this omissiou; meantime I am content to handthem over to the profession for what they are worth.

ON EFFECTS OF ATMOSPHERE IN CUTANEOUS AFFECTIONS.

By GEORGE GASKOIN, M.R.C.S.,
Surgeon to the British Hospital for Diseases of the Skin.

There is a prejudice existing among the profession in London against sending patients to the seaside when suffering from eczema and some other skin complaints. This arises, no doubt, from common experience, though some more than others have partaken of it. Indeed, it is not uncommon to meet with patients who cut short their holiday and return to town with disgust. Instances of this, however piquant, need scarcely be given. The following I take from my note-book:—A. B., *Eczema*, presumably gouty—"The seaside is sure to bring it on." C. B., *Eczema manuum*, supposed to have come from drinkiug cold water when heated—"Only the seaside carries it away,"—so that I remain without a conclusion. Again, I see extensive and constitutional eczema, with or without asthmatic complication, in young people who return from the coast generally improved by their autumnal trip when allowed to accompany their brothers and sisters in the family circle.

So much may serve to introduce the notice of a case which has come before me in the course of the year. A young lad presented himself to me afflicted with that general and, so to speak, constitutional eczema that is seen in the lower classes, and which for the most part goes uncured while they struggle courageously with existence. This lad tells me that he has had it always, except once that he took a dip in the sea at Brighton, when he got freed from the eruption for three days, but he never had the opportunity of repeating the experiment. This seems to stand on a level with auother case which has occurred during the year. It occurred in a child two years of age. The mother informed me that the hooping-cough had cleared off the eczema in three days' time. On subsidence of the hooping-cough the eruption returned. The custom now much prevailing, of giving school-treats to parish children, is likely to furnish some items of disease. One of the worst cases I have seen of eczema capitis occurred in a school teacher in that way. This young man was of lymphatic constitution, and of Jewish parentage, residing in Houndsditch. The excitement, the heat, the sudden change to the air of Brighton, though but for a few hours, developed in him an eczema, whose copious flow and lingering effects made him an invalid for several months. "Disturbance" is the word which best explaius such cases. I have known it iu others who from London went for a day's holiday, or for a short spell into the country, and, curiously enough, sometimes when they visited their native place. In London shopgirls and shopwomen—rather a favoured class as regards diet and protection from weather—acne rosacea is very apt to follow on direct exposure, especially at the seaside, and when the day is warm. It is a complaint which is very apt to come on the coast, especially under a full dict, when there is a constitutional tendency. Among those of my patients who this year have received most benefit from country air, I may mention a case of urticaria in a national schoolmistress, which was wholly refractory to treatment. I recommended her going into the country for a while. The cure was rapid and complete. Two cases of alopecia have much benefited by the seaside. Let me here say a few words of the kind of weather which patients with eczema complain of most. This is what is generally termed "coarse weather," windy, damp, and wet. In another case of urticaria the patient complained more of the wind than of any siugle thing as increasing his distress; from whatever quarter the wind might come. In a French shoemaker from Toulouse now under treatment for eczema, I find him insist on the change of the moon as operative in increasing his discomfort. By a man of the condition of master mariner, who superintends work down the river, now suffering from a tedious sycosis, I am asked if "any of those fellows could have put it on him," which may be worth mention here as it serves to show that the superstition of the "evil eye" is uot yet, even in England, extinguished.

CHOLERA still lingers about her Majesty's 17th Regiment at Lucknow.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

OPERATIONS AT GUY'S HOSPITAL.

At the operations at this Hospital, on Tuesday, November 26, Mr. Bryant applied to an aneurism in the popliteal space a modification of the treatment which the late well-known surgeon, Mr. Moore, of the Middlesex Hospital, on one occasion tried upon a thoracic aneurism. The man was a young adult, with very considerable and advanced disease of the whole arterial system. The valves of the heart were much involved, and all the larger arteries of the body were degenerated. This being the case, Mr. Bryant was disinclined to subject the femoral artery either to compression or ligation. While the patient was under observation, however, Mr. Bryant received a note from Dr. J. Levis, of Philadelphia, in which that surgeon stated that he had lately had a man of about forty years of age under his care with a large sacculated aneurism of the subclavian and axillary arteries, extending from the innominate artery to the axillary border of the great pectoral muscle, whom he treated by passing into the sac, through a very fine puncture, twenty-four feet of ordinary horsehair. The introduction was effected with facility, and during the first week afterwards the pulsation gradually diminished until the aneurism was converted into a solid mass. No local irritation followed in or about the aneurism.

As the case now under remark was considered a fitting one upon which to repeat an operation attended with so favourable a result as in Dr. Levis's case, Mr. Bryant made a puncture with a very fine trocar and canula, and through the latter passed twelve pieces of fishing gut, each piece being from twelve to eighteen inches long. The details of this case will at some future time be made public either in these pages or elsewhere.

On the same day Mr. Bryant removed a large circular portion of the frontal bone from a patient the subject of constitutional syphilis. There was a large black mass of necrosed bone in view upon and a little to the left of the median line; around it there were raised, thickened, and red edges of skin, beneath which pus was burrowing. As the case had long been under observation, Mr. Bryant considered it best to give the patient chloroform, and remove the dead part. This he did easily, after dissecting up the skin all around by placing the point of an elevator beneath one edge and simply raising it. Some light dressing and a bandage were then applied.

Mr. Durham performed an amputation through the middle of the thigh upon a woman, suffering from constitutional syphilis, for suppuration of the knee-joint and extensive ulceration of the skin about the joint. The mode of amputation was by ordinary anterior and posterior flaps, the latter being somewhat the longer. In sawing through the bone Mr. Durham inclined the saw downwards and forwards, so as to make an oblique section of it, the object being to allow the superior flap to rest evenly upon the slanting upper surface of the divided bone, instead of falling abruptly over the sharp edge, as is the case when the section is quite vertical. In this way, too, there is no room left for the accumulation of pus or blood in a space between the flaps and the sawn surface of bone. This advantage is more especially marked, Mr. Durham considers, in amputation through the leg.

Mr. Howse amputated through the knee-joint of a woman who had previously been several times operated upon for talipes. The result of these operations, however, was a deformed, wasted, and useless limb, which sometimes caused her such distressing pain that she would often have permitted its removal there and then. Mr. Howse made a long anterior rectangular flap, out from which, after its formation, he dissected the patella; he then divided the ligaments of the joint, and cut straight through the soft parts behind. In his remarks, Mr. Howse expressed a strong objection to a long posterior flap taken from the calf, because of the large number of small arteries which exist there, and which, when once cut, give rise to a great deal of troublesome hæmorrhage. In this case Esmarch's elastic roller and constricting tube were used.

BIRMINGHAM GENERAL HOSPITAL.

A CASE OF ACUTE RHEUMATISM IN WHICH PERICARDIAL AND PLEURAL EFFUSION UNDERWENT REMARKABLE VARIATIONS AT DIFFERENT PERIODS OF THE CASE—TEMPERATURE RECORD.

(Under the care of Dr. RUSSELL.)

Dr. Handfield Jones, in writing on some cases of anomalous rheumatism (*Medical Times and Gazette*, January 4), comments very skilfully on the distinction between the phenomena of traumatic inflammation and those of transitory or fugitive inflammation as represented especially by the inflammations of rheumatic fever. The former inflammation "never shifts its seat, never comes to an end suddenly; the nutritive derangement of tissue-elements always subsides gradually;" "the tissue itself, its fibres and its cells, is principally affected, and the vessels and nerves only in an inferior degree." In the fugitive inflammations, on the contrary, he suggests that the vaso-motor nerves, and not the tissue-elements, are chiefly implicated, "so that when their paralysis ceases and healthy circulation is restored, the tissue-elements rapidly recover their normal state." He further observes, that locality seems to exert a material influence in determining the character of the inflammation, whether it shall be fugitive or permanent; and he quotes in illustration rheumatic fever, a disease in which the fugitive character of inflammation which is seated in the limbs is contrasted with the more permanent character of that which affects the thoracic viscera.

In the case of rheumatic fever which I have now to narrate, although it is true that the intra-thoracic inflammations did not assume a completely fugitive type, yet the singular fluctuations which their physical signs underwent approximated their phenomena very closely to those presented by the joints in an ordinary case of the same disease, as, indeed, was displayed by the patient herself. Moreover, the inflammation seemed almost confined to the production of a fluid effusion, the quantity of lymph upon the surface of the heart being apparently very small, and no evidence of solid effusion upon the pleura having appeared from first to last. In this case, too, the fugitive character of the effusion became a matter of much moment, and had direct bearing upon treatment, for the appearance of effusion in both pleura simultaneously suggested at once the question of paracentesis—a question which would be the more readily entertained now that the use of the aspirator probably diminishes materially the danger of tapping the chest in the acute stage of pleurisy.

A healthy young woman, aged 20, was admitted on August 31 with her second attack of acute rheumatism, then of two days' duration. Her lower extremities were painful, but the joints were not swollen. Over the cardiac space was faintly audible a single systolic sound, apparently exocardial. The temperature on the morning of admission was 104°, but the same evening fell to 100·6°, and continued at about 101° for the following three days.

No extension of præcordial dulness was discovered until September 3, when the extension was very limited; but on the next day it had reached the third rib, and incompletely the second, though without much lateral extension. The rub was faint and soft, and purely systolic; it never changed during the remaining period of the case. On this day the temperature ran up to 103°.

The rheumatic inflammation, which had fixed itself in the knees and ankles, was greatly relieved by a blister placed above each of these joints, but now the inflammation had passed to the left arm. I suspended the application of blisters to the last-mentioned limb on the assertion of the patient that she derived as much relief from a wet pack, in which the limb had been enveloped; and on the following day (September 5) both lower extremities and the left arm could be moved freely without causing pain; but now the right arm and shoulder were engaged in the inflammation, and were enveloped in a wet pack at her own request. On this same day the pericardial dulness had receded from the second intercostal space.

The right arm was relieved from pain on the following day (September 6), and thenceforward the pain in the joints wandered from joint to joint, leaving and returning, but not remaining fixed in any for more than twenty-four hours. On September 9, however, the second intercostal space again became dull, and on the 10th the dulness involved the first interspace, extending across the sternum to its right edge, and

in the other direction reaching beyond the left nipple line. The patient was very languid and distressed, and on this day passed urine in bed. During this period (from September 4 to 9) the evening temperature ranged about 103·6°, with morning remissions of two degrees. On the next day (September 11) the cardiac dulness had receded to the left edge of the sternum, and had so far descended as to render the first and second spaces quite clear, and the third space almost clear; but on the two following days it again extended, though not to reach its former area.

On the last-mentioned day (September 13) the posterior region of the chest, which had hitherto been resonant (with one doubtful exception), manifested the signs of pleural effusion on both sides, reaching on the right to the apex of the scapula, on the left not attaining so high a level. The commencement of this attack of double pleurisy was clearly marked by a pain on each side of the chest on the preceding afternoon. It is remarkable that on this day (the day of the access of double pleurisy) the temperature underwent a fall of nearly two degrees, remaining for that and the next day a little above 100°. With the occurrence of the pleurisy there was marked dyspnœa, and I visited the patient again in the afternoon, under the apprehension that surgical interference might be required to relieve the chest of fluid. I was relieved by finding that not only had no increase in the quantity of effusion taken place, but that the fluid occupied a decidedly lower level on both sides, and the respirations, which had previously varied between forty-two and fifty-four, had fallen to thirty-six.

The amount of the effusion in the chest, as indicated by the line of dulness, subsequently underwent considerable variations. Having diminished considerably, it rose again on September 18 on the right side, even to the middle of the scapula, the temperature having also risen two degrees the preceding day, but two days afterwards the fluid had entirely disappeared from both sides, and on that day the final decline of temperature to its normal standard took place. At no time could any pleural rubbing sound be distinguished. The cardiac dulness also again underwent further variations after the date of its last noted increase (September 13). The second intercostal space and the entire breadth of the sternum were again involved on the 16th, but on the 18th the dulness had declined, and on the next day had retreated finally within its normal limits.

Little need be added with reference to general symptoms, excepting that after the second day the urine was permanently without deposit, acid, and of specific gravity varying from 1013 to 1027, averaging about 1020. The tongue only presented a thin fur. Extreme languor and much expression of distress in the face were prominent symptoms throughout the case. Convalescence was not tardy and was complete.

The details of treatment have no important relation to the interest of the case.

THE ROYAL ACADEMY.—Professor Marshall, F.R.S., commenced his course of lectures at Burlington House on Tuesday last before a crowded audience, amongst whom were several distinguished academicians and hospital surgeons; his lecture was "On the Anatomy of the Foot," illustrated with diagrams, bones, and the living subject.

DINNER BY THE GOVERNOR AND COURT OF THE APOTHECARIES' HALL, DUBLIN.—On Thursday, the 27th ult., the Governor and Court of the Apothecaries' Hall of Ireland entertained a numerous company of the profession at dinner at the Shelbourne Hotel, Dublin. The chair was occupied by the Governor, Dr. Edward J. O'Neill. He was supported on the right by Dr. Brady, M.P. for Leitrim, Sir Dominic Corrigan, Bart., M.P., Mr. George H. Porter, Surgeon to the Queen, the President of the Obstetrical Society (Dr. Evory Kennedy), Mr. Wharton, Dr. Butcher, Dr. Macnamara, etc.; and on the left by Dr. Duncan, President of the College of Physicians, Dr. Denham, President of the College of Surgeons, Dr. Stokes, Dr. Hudson, Dr. Banks, Dr. Lyons, etc. In very felicitous terms he proposed the usual loyal toasts, the University of Dublin—"Our National University"—(coupling with this toast the name of the Regius Professor of Physic, Dr. Stokes), the College of Physicians, and the College of Surgeons. Very interesting speeches were made in response to the several toasts, and the guests separated after spending a most agreeable evening.

SATURDAY, DECEMBER 6, 1873.

INDIARUBBER LIGATURES AND THEIR USE IN SURGERY.

So prominently has the subject of elastic ligatures for the removal of tumours and for other surgical operations been brought under the notice of the profession by the case which is now in one of the metropolitan hospitals, that we think it right to keep our readers informed of the progress of the case in question.

The patient has suffered very little pain throughout, but she has been attacked by erysipelas, which, though it subsided for a few days, has since spread over the thorax and back. One-half the pedicle has ulcerated nearly through, but the ligature had yesterday to be tightened, as it was no longer constricting the tissues. The other ligature gave way shortly after the operation, so that there still remains half the base of the tumour to be strangulated.

It will be seen on referring to an abstract of Professor Dittel's communication to the *Allgem. Wien. Med. Zeit.*, which we publish this week in another column, that this is exactly the process which he has adopted in all his most recent cases—*i.e.*, the halves of the tumour are strangulated at different times, so that the operation is divided into two periods. By this mode of operating Dittel says he is able to see and feel whether he has left anything behind, and if so he can include it in the second ligature or apply a third.

No one can in future doubt the power of elastic bands to cut their way through breasts or limbs, but we confess that we fail to see, either in theory or from watching the case in University College Hospital, any reason why parts that have to be removed should be submitted to this more tedious, and to some extent offensive, process, rather than at once be cut away by a few strokes with a knife. It is only in cases in which an operation is desirable, but where nothing will induce the patient to undergo a cutting operation, or in which there is some hæmorrhagic diathesis, that the application of this treatment to tumours of the breast should be thought of. Except in some such rare instances surgeons will do well, we are assured, to keep to the knife in preference to the ligature.

It was no doubt well that the treatment should be tried in this country, and too much stress must not, of course, be laid upon the fact of erysipelas occurring during its progress. This might arise in any person after an operation, but, apart from this accident, the length of time required for the strangulation to be complete (which Dittel says is fifteen days for the breast), and the presence of a large sloughy mass of tissue in the pectoral region, will be objections strong enough for most surgeons. Another very grave argument suggests itself against the last modification of Professor Dittel's procedure. This is, that as only one-half, say, of a breast is strangulated at the time, there is likely to be an interchange of material going on at the free surface of the breast between the blood in the unligatured part and the dead fluids in the strangulated part, and thus a great risk of septicæmia or pyæmia. It is stated in favour of the elastic ligature that it does not give rise to suppuration, and that granulations speedily fill up the space voided by the retreating parts; but this will be found not invariably the case.

The conclusion, then, that theory and the facts we have before us lead to, is that the knife ought not, and is not likely, to be displaced by the elastic ligature, though the advantages of an elastic over an inelastic ligature are no doubt practical and good.

As to the question of priority in the use of the elastic ligature, we think it unimportant to discuss. As we stated last week, indiarubber bands and cord have been used for the removal of nævi, hæmorrhoids, and pedunculated tumours at different times since 1863 by some few English surgeons; and it is now well known that Dr. Silvestri in 1862 published in the *Gazetta Medica Italiana* an essay on the use of the elastic ligature, and that later on he became aware that it would cut through bone. Professor Vanzetti's essay is, too, no doubt in the possession of many British surgeons. Possibly, and probably, the idea has occurred independently to several, for, as Professor Dittel observes, discoveries have often been made two or three times. We imagine, however, that no one has had so much to do in bringing the subject before the profession as Professor Dittel.

THE PHYSIOLOGY OF VISION.

IV.—The Lens and the Vitreous.

By far the most important structure of the eyeball, optically considered, is the lens. In some animals it is nearly spherical, but in man it is a doubly convex structure, whose antero-posterior diameter is one-third less than that from above downwards or from side to side. Moreover, its convexity is much greater posteriorly than anteriorly, so that the front of the lens looks, comparatively speaking, flattened. Two elements enter into its composition—the cellular and fibrous structures of its parenchyma, and its investing membrane or capsule. The parenchyma is composed of two layers—an anterior, which is thin; and a posterior, which is thick. The anterior layer is composed of flattened polygonal cells, perfectly clear and transparent. These cells are of various sizes and lengths, the longest being directly continuous with the fibres of which the posterior portion of the lens is composed. These fibres in turn form lamellæ, arranged concentrically like the coats of an onion. The line where the different fibres composing these layers terminate or unite with others constitutes a raphe. These raphes are to be found both on the anterior and posterior surfaces of the lens, but do not correspond. The raphes on the anterior surface are about nine in number—they all radiate from a common point, the axis of the lens, and so the raphes assume a distinctly stellate arrangement. The arrangement posteriorly is not so distinctly stellate. These stellæ are of considerable physiological importance. The fibres which compose the lens are of different degrees of consistence, the most internal being the most consistent, but all are highly elastic. The capsule of the lens is devoid of structure, but is thicker anteriorly than posteriorly, where it is thinner; it too, is very elastic.

Intimately connected with the lens is a structure known as the ciliary muscle. This body, which on perpendicular section seems prism-shaped, the base of the prism being directed forwards, consists of unstriped muscular fibres. These run partly parallel to the sclerotic, ending anteriorly in a mass of connective tissue which encircles the eye, and posteriorly gradually thin out, ending in the tissues of the choroid, or vascular tunic. But, besides these fibres, there are others which encircle the eye and run parallel to the margin of the cornea. Other fibres there are, but these are the most important. Now, it is quite clear that contraction of the circular portion of this muscle must to a certain extent compress the lens; and it was first described by H. Müller, who discovered these fibres, as the compressor lentis. But the exact influence of the contraction of the meridianal portion is not quite so clear. It is a curious fact that in short-sighted people the circular fibres are much more highly developed than they are in long-sighted individuals. However acting—whether by compressing the lens and increasing its tension, or by relaxing the capsule of the lens and so reducing its tension,—it is generally granted that contraction of the ciliary muscle or of some part of it has the effect of increasing the convexity of the lens, especially in front, and so of increasing its converging power. On one theory, this is done by causing the lens to increase in prominence anteriorly by compression, the lens, as soon as the compressing force of the ciliary muscle is withdrawn, tending to recoil by virtue of its own elasticity, and to assume its natural shape. On the other supposition, the contraction of the ciliary muscle relaxes the tension of the capsule of the lens, and so allows it, by virtue of its own elasticity, to assume a more spherical outline anteriorly. When the muscular action ceases, the elasticity of the capsule is strong enough to make the lens reassume its wonted figure. Which of these is the true explanation is not easy to say, but as on either view increased lens-power is the result of muscular action, so on either a hardening or loss of elasticity in the lens would interfere with the adaptation of the organ. How important these changes are, will be seen in connexion with long and short sight.

Immediately behind the lens lies the vitreous. This used to be described as enclosed in a proper tunica—the so-called hyaloid; now, however, that is looked upon as a retinal structure, and is described as the membrana limitans retinæ interna. In the substance of the vitreous we mainly encounter three kinds of cells—1. Round cells with large nuclei and coarse granular protoplasm; 2. Fusiform and stellate cells which send out long processes with varicose dilatations, ramifying, and frequently containing vesicles of colossal size; but these vesicular cells are (3) also sometimes rounded. All the cells are contractile, and can change their shape if not their place. In the centre of the vitreous these structures are not so readily recognisable, only nuclei and shrivelled vesicles being there found.

THE WAR ON THE GOLD COAST.

A great deal of the bustle consequent upon the receipt of Sir Garnet Wolseley's requisitions has now subsided. The three picked European regiments have sailed, the 42nd Foot having embarked in the *Sarmatian*, at Portsmouth, this week; the hospital-ship *Victor Emmanuel* is on her way; another store transport—the *Dromedary*—has been despatched; and the last of this class of vessels purchased or hired by the Government—the *Thames*—is completing her cargo at Woolwich.

In addition to the long list of Army Medical Officers already on their way to the scene of operations which we recently

published, the following names must also be noted:—Surgeon-Major Clutterbuck and Surgeons Troup, McCarthy, Kynsey, and Usher (all attached to the 42nd Foot), and Surgeon Steele, who took passage in the *Victor Emmanuel*. It will thus be seen that an ample medical staff has been provided to meet the exceptional requirements of the campaign which we have in hand; and a glance at some of the arrangements which have been made for the comfort of the sick and wounded will suffice to show how earnestly the authorities have laboured to obviate, if possible, a heavy rate of mortality.

In the first place, then, the *Victor Emmanuel* will be stationed off the Coast for the reception of invalids as they may be brought down from the front, and are capable of removal to her. She will, moreover, be a store depôt for reserve supplies of medicines, instruments, surgical materials, hospital utensils, flannel underclothing, pea-jackets, water-beds, etc.; also for cots, bedding, and medical comforts.

Her Majesty's troopship *Simoom* has been ordered to take up her station at Porte Grande, St. Vincent, Cape de Verde Islands. In this spot she will act as a depôt ship for invalids in transit, having one of the small transports attached to her to act as tender in obtaining supplies. A fast steamer will leave Cape Coast Castle about every ten days, calling on its way at Sierra Leone, to convey patients to St. Vincent; and for their further removal (when in a fit state) to Southampton, arrangements have been made by the Government with the Union Company, whose packets leave the Cape of Good Hope three times each month, for these vessels to call at St. Vincent *en route*, each one guaranteeing to convey at least twenty-four invalids if necessary. The first of these packets calling at the island will be that which leaves the Cape on the 25th inst., and they will continue to put in there for the above purpose until the end of March next.

In addition to the foregoing, arrangements have been entered into with the British and African Steam Navigation Company to convey twenty invalids to this country by each of their steamers calling at Cape Coast Castle twice a month during the months of January, February, and March next; and as far as practicable the cases selected for transport by this route will be sufficiently convalescent to bear the voyage, without the necessity of removal to a hospital immediately on landing, the above steamers plying direct to Liverpool, in which town there is no military hospital of any size.

A further means of safe and rapid transit for invalids from St. Vincent has been provided by the Government through an arrangement with the Royal Mail Brazilian Steam Packet Company, whose packets, calling at the island on the 5th and 19th of each month, on passage from South America to Southampton, will take ten convalescents on each occasion, provided their condition is such as not to endanger the health of passengers and crew. These patients on landing will be taken to the Royal Victoria Hospital at Netley, as will those brought to Southampton by the Union Company.

A steam transport from the West Indies is also to be available for bringing direct from Cape Coast Castle to England or Gibraltar any large number of invalids in a condition to return, or should there prove to be too many to be accommodated at one time on board the depôt-ship *Simoom* at St. Vincent.

Finally, the transports *Tamar*, *Himalaya*, and *Sarmatian*, after disembarking the three regiments which they have conveyed from this country to the Gold Coast, will remain on the station fitted up as auxiliary hospital-ships for the reception and conveyance of invalids. Any hired vessels and mail-steamers taken up for the transport of sick and wounded will receive all necessary articles for the voyage home, in the shape of cots, medical comforts, hospital clothing, and utensils, from the stores on board the *Victor Emmanuel*, from which source hospital attendants and medical officers will also be provided.

No cases will be removed from the *Victor Emmanuel* unless they are considered well able to bear such removal, or unless change of air is recommended on medical grounds; but patients will, as far as practicable, be sent to the *Simoom* at St. Vincent, from whence they may more easily be transferred to England, as their condition permits. Arrangements will very possibly be carried out for the removal to Gibraltar and Madeira of such cases as are not deemed fit to encounter the voyage to England during the winter months; but some difficulties are likely to be raised by the Spanish and Portuguese Governments on the question of quarantine.

So much for the preparations for the comfort of our sick and wounded afloat. On shore at Cape Coast the arrangements projected by Deputy Surgeon-General Home, V.C., are as complete as the unsettled state of the country will allow. He himself having accompanied the first advance against the enemy made by Sir Garnet Wolseley, has acquired an experience of bush fighting which will no doubt be of infinite service when larger operations begin. Our own advices from the Gold Coast would seem to advocate the formation of a station hospital at the extent of every ten or twelve miles covered; so that if the march on Coomassie really takes place, and the distance be calculated at one hundred and ninety miles, there would have to be from sixteen to nineteen of these hospitals, in which everything should be found suitable for a hasty treatment of both sick and wounded in their transit from the front to the shore. And here, our correspondent informs us, in the transit of the invalids the main difficulty of the Medical Department may be expected to lie. The natives engaged to act as hammock-bearers are so little to be depended upon, that they would not hesitate to put down their loads and make off *en masse*, either from caprice or panic, unless carefully watched, leaving the sick and wounded to their fate; and there would seem to be nothing for it—if the system of stations be adopted—but to appoint a sergeant and a file of men to each one, who would convoy every train of invalids over that portion of the road placed under their control.

The latest accounts which have been received of the fighting which has taken place at Abrakrampa and Dunquah appears still further to confirm the opinion that at this season of the year the Bush is not so deadly to Europeans as has been supposed. Unquestionably the active operations in which the little force has been engaged have been of great benefit in keeping all minds employed. Every officer on Sir Garnet's staff is fully occupied with the work entrusted to him; and, with the sad exception of Lieutenant Eardley-Wilmot, who was shot through the heart at Dunquah, after having been previously hit in the arm, most of them seem up to the present time to have escaped the combined effects of war and climate.

The *Tamar* and *Himalaya*, with the reinforcements on board, will most probably arrive on the Coast about the 12th inst., and there is every reason to believe that the long march to Coomassie will commence immediately after. If the reports of the Ashantee retreat are to be credited, the country as far as the River Prah will be entirely cleared for working operations, and stations for hospitals may be selected and huts erected along this portion of the road before the troops take their departure from Cape Coast Castle. One of the advantages, therefore, of Sir Garnet Wolseley's prompt and energetic action against the enemy will have been to enable the medical staff to organise their arrangements over nearly one-half of the tract in advance of the main body of the expedition.

We must not too hastily assume, from the success which has up to the present accompanied our operations and the comparative immunity from effects of climate enjoyed by our men, that the campaign will be finished with equally trifling losses; but we may sincerely congratulate ourselves that at any rate the gloomy forebodings indulged in at the commencement of the war have not as yet been realised, and hopefully anticipate

a termination to these hostilities as triumphant as that which characterised our Abyssinian expedition, without an inordinate amount of either bloodshed or sickness.

POISONING BY COAL GAS.

We wish to call the attention of our readers to the following important case which was reported in the daily papers of Dec. 1. At the Arno's Vale Convent, at Bristol, a woman named Boylan, aged 28, who had just returned from a situation and gone to bed rather tired, was found in her room the next morning in a state approaching asphyxia, and died twenty-seven hours afterwards without completely rallying. Her bedroom was about nine feet square, and without grate or ventilation of any sort. It was lighted with gas and warmed by a gas-stove, and when she was found the gas-burner was half and the stove jets fully on. These must have been burning the whole night up to 6 a.m., when the gas was turned off at the main. The woman had thus been inhaling an atmosphere which was gradually becoming more and more vitiated by the products of gas-combustion, and there is no doubt that they caused her death. A coroner's jury gave a verdict of "Accidental death from gas-poisoning."

Instances like the above are happily rare, but we fear that a chronic form of gas-poisoning, manifesting itself by head-aches, anæmia, and general weakness, is not uncommon in London and elsewhere. Gas is burnt in sitting- and bed-rooms, and gas-stoves are used in halls and shops, etc., without proper provision for carrying off the combustion-products; often, it is to be feared, from total ignorance of the necessity of doing so. We must hope that the greater diffusion of scientific knowledge among the rising generation in schools will in time partially remove this ignorance. Medical men happily can do much towards the prevention of further mischief by a few simple suggestions and explanations in cases where gas-poisoning appears to be a source of disease. Gas can be made an efficient ventilator of rooms by placing the escape-pipe for foul air above the burner. Gas-stoves should be absolutely forbidden unless they are provided with flues opening into a chimney or the open air, so that their products do not escape into the room at all. Several gas-stoves were exhibited this summer at the International Exhibition which did not satisfy this requirement. We can scarcely wonder at the room in which Boylan slept being without any ventilation whatever, when we see how little attention architects pay to such matters in almost every house we enter.

THE WEEK.

TOPICS OF THE DAY.

At the meeting of the Senatus of the University of London, held on December 3, a communication from the representatives of the University in the Committee of Reference for a Conjoint Examining Board for England was received, presenting the scheme adopted by the Royal Colleges of Physicians and Surgeons, together with a first and second report presented by the Committee to the co-operating medical authorities. The representatives report that the scheme is the same as that previously submitted to, and approved by, the Senate. The reports have reference to details required for carrying the scheme into operation. These documents will come under discussion at the next meeting of the Senate.

A meeting of the Branch Medical Council for England will be held on the 13th of the present month. The question of the time at which the next meeting of the General Medical Council is to be held will then probably be discussed. The future home of the Council is still uncertain. Hope is still entertained that the present Government will provide the Council with suitable apartments. That they ought to do so, there can be no reasonable doubt. The General Medical Council is a State institution. It is placed in close relation with the Privy Council by the Medical Act, and the Crown nominates a large percentage of its members. The validity of these pleas has been admitted, it is said, by certain members of the Cabinet, and a virtual promise has been made that premises will be granted. For the fulfilment of that promise the Council is still waiting.

We understand that the new issue of the British Pharmacopœia, with the addendum containing new medicines, is now in a forward state, and will be published before long. The "Addendum," when it is issued, will be to be obtained separately.

THE HISTORY OF OVARIOTOMY.

We are glad to find that the very interesting article "Progress of Medicine and Surgery," which appeared in the *Edinburgh Review* a year ago, is being reprinted by the author, Dr. Wynter, as part of a volume entitled "Peeps into the Human Hive." Our contemporary the *British Medical Journal* last week made some comments on Dr. Wynter's article which, in the interest of truth in the history of surgery, must not be allowed to pass without correction. The writer says—

"The eulogy of Marshall Hall is unjust to Prochaska; and the account of the 'revival' of ovariotomy by Mr. Spencer Wells is simply absurd. The splendid achievements of Mr. Wells have been often and cordially recognised in these columns; but an historical sketch which deals with him as the solitary British figure concerned in the 'revival' of ovariotomy, and which omits all mention of his predecessors—Warne, Samuel Lane, Baker Brown, Clay—is deficient in a very important point. Baker Brown was not only Spencer Wells's predecessor, and his contemporary in the operation, but to some extent his preceptor; although, for many reasons, the pupil quickly outstripped his master. Nothing is gained by a barefaced sacrifice of historical accuracy."

It certainly is a "barefaced sacrifice of historical accuracy" to speak of Baker Brown as the *preceptor* or *master* of Spencer Wells in ovariotomy. His *predecessor* he was, but, as stated in the preface to the first volume of Wells "On Diseases of the Ovaries," when he (Wells) began to operate, in 1857, "Mr. Baker Brown (who between his first case in 1852 and 1856 had lost seven out of nine cases) had not operated for more than two years." It was not until after Spencer Wells' cases and papers had *revived* ovariotomy that Baker Brown began to operate again, and achieved his great success and chief claim to be considered as contributing to the spread of the operation by his treatment of the pedicle by the cautery.

BRITISH MEDICAL SERVICE IN INDIA.

The discontent among the officers of the British Medical Service in India is quite as general as it has been in this country. Two memorials have been got up on the subject; one dated from Simla, but, though emanating as it were from the very mount of inspiration, its inspiration was not sufficiently plenary to include the retirement of Surgeons-General after five years' service, and consequently, in a great measure, we are informed the number of signatures attached to it was comparatively small. The other memorial, got up by Surgeons-Major Maclean and Skues at Morar, is very strong on this point, and has, we understand, been signed by almost every medical officer of the British Service in India. It had official difficulties to encounter in having in the first instance been sent through the head of the department in India, who did not consider himself in a position to forward it. Another memorial, however, with an extra paragraph, was promptly printed, and has, we hear, been sent on through the military authorities. Strange to say, the Simla memorial bore attached to it a draft warrant, which drew down a gentle rebuke from his Excellency the Commander-in-Chief.

IMPORTANT DECISIONS UNDER THE RAILWAY ACTS.

A CASE of some importance to the medical profession was tried in the Court of Common Pleas on Friday last, before Mr. Justice Honeyman. It involves a very important principle, and we are glad, in the interests of the profession, that the verdict was for the plaintiff with immediate execution. It was an action to recover a sum alleged to be due from the defendant to a surgeon for fees, medicine, attendance, and consultations. It was said that the defendant had been injured in a railway accident, and that the plaintiff had agreed to charge him nothing, and to look to the company for his remuneration. The now defendant, however, was nonsuited in his action against the company, but he said that the now plaintiff had urged him to go on, and not to settle, as he should charge him nothing. His attorney also had, according to the defendant's statement, agreed to conduct the action gratuitously, but he had since "put in an execution, and swept away all his property." The plaintiff, of course, denied that he had ever entered into any such agreement as the defendant set up. On cross-examination, the defendant's antecedents were found to be very unfavourable, and the jury, after some discussion, found a verdict for the plaintiff for the amount claimed.

Another trial, involving the responsibilities of railway companies, was also tried last week. A passenger by railway having been injured by alleged negligence of the company, had been removed to an hotel at the suggestion of an agent of the company. The company disputed the hotel charges on the ground that they were not responsible for the action of their officer. The court and jury, however, decided otherwise, and awarded the plaintiff the full amount he claimed. This is a valuable precedent, particularly so far as the interests of medical practitioners are concerned. It will be, no doubt, recollected by our readers that medical gentlemen who had attended cases of injury on railways were nonsuited, on the ground that "the agent" had no authority to pledge the credit of the company for services rendered to injured persons on their lines. This, to us, extraordinary line of defence was endorsed by the presiding judge, who directed a nonsuit. The result of the above trial, however, is likely to put a stop to acts of gross injustice against medical practitioners. Surely if an hotel-keeper is entitled to recover his charges under the circumstances detailed, a surgeon is entitled to the same privilege. Railway authorities invariably shelter themselves under the plea of non-responsibility. We hope this subterfuge —most unjust, and now pronounced illegal—will not for the future be successful.

THE ALLEGED ADULTERATION OF SPIRITUS ÆTHERIS NITRICI.

ON Saturday last, Mr. George Fenton, surgeon and chemist, of Great Smith-street, Westminster; Mr. E. D. Doughty, chemist, of William-street, Knightsbridge; Mr. W. S. Saxby, chemist, 11, Tothill-street, Westminster; and Mr. W. S. Barton, of 8, Moreton-street, Pimlico, were summoned before Mr. Arnold, at the Westminster Police-court, for selling an adulterated drug known as "spiritus ætheris nitrici." Mr. Dupré, of the Westminster Hospital, the analyst, gave evidence to show that the article purchased from the above-mentioned tradesmen was adulterated with about 10 per cent. with spirits of wine and a little water. On cross-examination, however, he admitted that his opinion was based on the principles laid down in the British Pharmacopœia of 1867, which prescribed how the spirit was to be manufactured, and further explained that the spirit was formerly manufactured from nitric acid and spirits of wine, whereas the Pharmacopœia of 1867 had introduced the use of sulphuric acid and copper. He considered that if not made in accordance with the latter method the preparation must be termed adulterated. There was too much spirits of wine in the samples he had analysed; but he could not say whether the extra spirit had been added before or after the process of distillation. He admitted that there was nothing deleterious in the compound he had analysed, but contended that it was sold under a false name, and was therefore a fraud on the public. Mr. Wontner, who appeared for the defence, proceeded to show that in reality the present proceedings were the commencement of a crusade against the pharmaceutists of this country, which would be resisted to the utmost. He denied the power of the Board of Works to insist that this preparation should be manufactured in accordance with the Pharmacopœia of 1867, and called a witness to prove that ten tons of the old compound had been sold, as compared with one ton of the new. Moreover, he showed that as the spirits of wine, with which Mr. Dupré had stated the articles in question to be adulterated, was dearer than the article itself, there could be no adulteration within the meaning of the Adulteration Act, which applied to something done with a view of fraud and gain. Mr. Arnold asked if, in the face of the evidence, it could be possible to go on with the cases. Mr. Rogers, solicitor, who prosecuted, left the matter in the magistrate's hands, the result being that the proceedings were stopped, and Mr. Arnold allowed costs to all the defendants, remarking that he considered the present a dangerous experiment to try, while one case would have been sufficient to raise the legality of the question. Surely, at a time when adulteration is being carried on to a large extent in articles of every-day use, it would be better to look out for cases of some utility to the public to be exposed, rather than to raise a legal question as to the method of manufacturing an official preparation, which the most liberal stretching cannot after all call actual adulteration.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE first meeting of the present (the thirty-sixth) session was held in the anatomical theatre of the School of Physic, Trinity College, on Saturday last, the 29th ult. Before taking the chair, the President (Dr. Kidd) spoke of the irreparable loss sustained by the Society in the death of one of its founders, and its Secretary for thirty-five years—the late Professor R. W. Smith. Dr. Barton exhibited specimens of medullary cancer from the body of a young woman, including a large tumour, the size of a cocoanut, engaging the sternal end of the left clavicle, and cancerous deposits in both lungs and in the upper portion of the shaft of the right humerus. Mr. George H. Porter, Surgeon to the Queen, showed a remarkably large ovarian cyst which he had removed. It was of fifteen months' growth, and when emptied of its contents (210 ounces of fluid) after removal weighed one pound fifteen ounces. It was unilocular, and presented no malignant appearances. Mr. Porter also showed a fractured os calcis, in a lad aged 13, who had been run over by a tram-car. Dr. William Moore presented a specimen of enteric ulceration of the ileum. Violent hæmorrhages had occurred on two occasions in the course of the fever—the first, to the extent of thirty ounces, had been followed by a fall of temperature amounting to five degrees. The axillary temperature rose to 108° shortly before death. The President announced that the Council had selected as the subject for the prize essay, "Injuries and Diseases of Articular Cartilage." The following officers for the session 1873-74 were then elected:—*President:* Robert D. Lyons. *Vice-Presidents:* Robert Adams, Sir Dominic J. Corrigan, Bart., M.P., George H. Kidd, John Denham, George H. Porter, and Henry Kennedy. *Council:* Arthur Wynne Foot, John M. Purser, Benjamin G. MacDowel, Thomas Hayden, James H. Wharton, William Stokes, jun., Samuel Gordon, James Little, John Thomas Banks, Henry H. Head, William Moore, T. Joliffe Tufnell. *Honorary Secretary:* William Stokes. *Secretary and Treasurer:* Edward H. Bennett. *Secretary for Foreign Correspondence:* Robert McDonnell. The in-coming President (Dr. Lyons) subsequently took the chair, and a vote of thanks

to Dr. Kidd, the out-going President, was proposed by Dr. James Little, seconded by Dr. R. McDonnell, and adopted unanimously. Dr. Kidd having briefly replied, the Society adjourned.

A FATAL METAPHYSICAL DISPUTE.

THE following is taken from the report of the proceedings at Southwark Police-court on November 24 :—

"Eugene M'Gann, aged 38, warehouseman, was placed at the bar, before Mr. Partridge, charged with causing the death of John Pugh, by throwing him down in the Black Bull public-house, Freeschool-street, Horselydown."

Pugh was taken to Guy's Hospital, where he died four days later, from rupture of the bladder. Just before his death he made the following declaration :—

"I, John Pugh, do firmly believe I am at the point of death. I shall not recover. And I do hereby state that, last Tuesday night, at a quarter to twelve, I was in the Black Bull public-house, Freeschool-street, Horselydown, drinking with Eugene M'Gann, when a controversy arose between us. I said that the seat of life was in the heart. He said it was in the brain. M'Gann said that if I repeated my statement again he would throw me over. I repeated it, when he caught me round the neck, put his foot behind me, and threw me heavily on my back, falling on my stomach. I felt very much hurt at the time. M'Gann assisted me in rising, and I left the house to go home, but when I got a few yards I was unable to walk any further. I met two police-constables, who took me home in a cab. We were previously hail friends, and bore no ill-will to one another."

SURGICAL SOCIETY OF IRELAND.

THE opening meeting of the present session took place in the Albert Hall, Royal College of Surgeons, Stephen's-green, on Friday evening, November 28. There was a very numerous assemblage. The President delivered an address suitable to the occasion. He dwelt particularly on the topics of the non-routine treatment of disease, Professor Lister's antiseptic method, and anæsthetics. Allusion was made in appropriate terms to the death of Professor William Barker, and of the Vice-President of the Society, Professor R. W. Smith. Several interesting communications were made by members; and papers were read by Mr. Tufnell, Vice President, "On the Cure of Popliteal Aneurism by Position and Rest," and by Dr. W. J. Wheeler "On a New Instrument for the Treatment of Transverse Fracture of the Patella." The following are the office-bearers of the Society for the present year. *President:* John Denham. *Vice-President:* T. Joliffe Tufnell. *Council:* William Hargrave, Charles Benson, Christopher Fleming, M. Harry Stapleton, Richard G. H. Butcher, Hans Irvine, George H. Porter, Thomas Byrne, Philip Bevan, B. Wills Richardson, James H. Wharton, James S. Hughes, Rawdon Macnamara, Edward Dillon Mapother, William Colles, Edward Hamilton, Humphrey Minchin, Archibald H. Jacob, Henry Gray Croly, John Morgan, and Albert Walsh. *Honorary Secretaries:* B. Wills Richardson and Humphrey Minchin.

PEST-HOUSES.

ATTENTION is drawn by *Iron* to an important fact in the following remarks. It states that "this is the period of the year when the foundations of pest-houses are laid. The brickmaking season is over, and the fields from which the clay has been abstracted are being filled in with 'dry' rubbish without a fee, or wet with a fee. On this surface, houses which can hardly face the wind and easily absorb the water will next year be 'posted' side by side, and about every tenth building will be nothing better than a 'pest-house,' for it will be built with no foundation upon the clearing of some cesspool, or, as we saw the other day, a cartload of putrid fish disguised in dust. From time to time families will go into these houses, and be constantly leaving, minus one or two of the most promising members of the family, because they have 'taken the fever.' It is not too much to ask that such habitations should be put under quarantine, renewable at the will of the inspector of nuisances, until their owners can show a clean bill of health. Ships come near, but not within our midst, and quickly depart; but houses remain as standing nuisances." Such houses undoubtedly cause much of the rheumatism prevalent amongst the artisan class.

A WHOLESOME SUGGESTION.

DR. MACCORMACK, Medical Officer of Health for Lambeth, in his report to the Vestry states "that it would be true economy if the Guardians of the poor instructed their medical officers to report all cases requiring a supply of food, firing, and clothing, three great essentials in arresting the spread of mortality from those diseases which were originated by, and were dependent upon, the want of the vital power." No one can so well judge as the medical officer of the need of these necessaries in many cases of sickness and incipient diseases. No doubt it would be true charity and economy, and much disease and mortality might be arrested by a timely provision of food, firing, and clothing. We think Dr. MacCormack's suggestion should be generally adopted; we fully endorse his recommendation.

THE POISONOUS SNAKES OF INDIA.

OUR readers are aware that the experiments which have been made to test the value of artificial respiration in the treatment of snake-bite have at least demonstrated the fact that life may be prolonged for many hours by its use. The committee appointed, at Dr. Fayrer's suggestion, by the Government of India have, as to this point, amply confirmed the experiments which were made by Dr. Fayrer and Dr. Lauder Brunton with cobra poison sent to this country. We are glad to learn that a large number of the experiments in artificial respiration performed by the Calcutta committee will be recorded in a permanent form in a second edition of Dr. Fayrer's magnificent work on the Indian Thanatophidia, which we understand will be published before Christmas.

CHOLERA IN HOLLAND.

OUR correspondent at Rotterdam writes that since the date of his last communication (see *Medical Times and Gazette*, November 1) cholera had increased a little and afterwards diminished. From October 26 to November 1 there occurred 34 deaths; from November 2 to 8, 36; from November 9 to 15, 39; from November 16 to 22, 28; and from November 23 to 29, 24 deaths. In Rotterdam the mortality was, for the same dates—4, 4, 5, 12, 9; in Gouda, a town with 16,000 inhabitants, at the mouth of the river Wesel, 10, 22, 19, 5, 8. Disinfection is carried on in Rotterdam on a large scale.

HORSEFLESH AS FOOD.

THE Committee formed for the propagation of horseflesh has forwarded the following statements to *Galignani* for publication :—

"The consumption of this article of food is making continual progress in France; during the third quarter of 1873 in Paris alone 1548 horses, 140 donkeys, and 15 mules were killed, yielding 303,970 kilos. of meat. In 1872 the figures were 1046, 95, and 3 respectively. In the capital there are forty butchers for this article inspected by veterinary surgeons. The price is about half that of beef. As it has been shown that horseflesh is a wholesome and nutritious article of food, and moreover economical, we see no reason why it should not form a substitute in this country to the flesh of beeves and sheep. The prejudices against it being once overcome, and culinary preparation properly carried out, it would be a great boon not only to the poor, but to thousands of the struggling middle-class."

EPIDEMIOLOGICAL SOCIETY.

The Secretary of the Epidemiological Society wishes us to announce that at the next meeting of this Society, on Wednesday, December 10, at No. 11, Chandos-street, Cavendish-square, W., at 8 p.m., a communication will be read from Dr. Tholozan, Physician to the Shah of Persia, "On the Development of Plague in the High Grounds of Europe, Asia, and Africa"; and that Dr. Gavin Milroy will read a paper "On Quarantine in Relation to Epidemic Cholera." Visitors for the evening are invited to join in the discussion to follow this paper.

A HEALTHY VILLAGE.

In Pavenham, Beds, a village of over 500 inhabitants, there has not been one death since December 6, 1872. Four deaths only were registered in the previous year. The sanitary condition of the village is excellent—a favourable contrast to some villages in the same county, in which the water-supply is execrable, and disease and mortality something frightful.

ROYAL MEDICAL SOCIETY, EDINBURGH.

At a meeting of the Society on the 28th ult., the following gentlemen were elected presidents:—G. T. Beatson, B.A., Alexander James, M.B., C.M., J. Stevenson Forrester, L.R.C.P. and S. Edin., and C. Watson McGillivray, M.B., C.M., L.R.C.P. and S. Edin.

FROM ABROAD.—PROFESSOR DITTEL ON THE ELASTIC LIGATURE.

The following is an analysis of the communications which Professor Dittel has published concerning the elastic ligature:—He relates in the *Allgem. Wien. Med. Zeit.*, 1873, Nos. 7 and 8, that his attention was forcibly drawn to this subject by a case which fell under his notice in March, 1872. A girl aged 11, the victim of the utter neglect of her stepmother, was admitted into the hospital, her hair, swarming with vermin, collected in a net. The questions which were put to her were answered with a hesitation that seemed to betray intimidation, and the exactitude of her assertion that the net had not been removed from her head for a fortnight seemed to require some confirmation. As, however, she complained of pain in the head, this was very carefully examined, and a suppurating wound was found in the hairy scalp, at the bottom of which lay the fine, thin elastic cord which had secured the net to the hair. It was only visible in part, being also partly overgrown by granulations and even lying deeply in the corroded occiput and right parietal bones. Although after its removal the wound soon granulated, the girl died of meningitis. The autopsy exhibited, besides general anæmia, not only meningitis, but also gangrene of those portions of the dura mater which corresponded with the greatest loss of bone. The ulceration of the soft parts corresponded to a furrow running around the occiput below its tuber, and which was continued on each side to the tubera of the frontal bone—constituting, in fact, a circular furrow around the skull-cap, the portions of the skull situated above the elastic cord being held to the lower only by fragmentary bridges, measuring altogether from ten to twelve centimetres out of the forty-two centimetres which constituted the entire periphery. It was found at a later period that the stepmother had prevented the child loosening the ligature.

Taught by this fearful incident the potent action of an elastic ligature, Professor Dittel employed it (November, 1872) in treating a nævus, for which he had already employed insect needles and waxed threads. As after some days these lay loose in the suppurating wound which they had created, in place of again tightening the ligature he wound a caoutchouc drainage-tube around the mass of needles. When the child was brought again in a week he learned that this elastic ligature had been much easier borne than the threads had been, while the nævus had fallen, and a granulating wound, with commencing cicatrisation, had replaced it.

This success induced him to extend the practice to telangiectasis, fistula ani, prolapsus ani, sinuous passages, carcinoma of the breast, and ligature of the various arteries. The procedure, he observes, although simple, requires a certain amount of carefulness and exactitude, which are readily acquired by patience and attention. All unnecessary pain through the too tight constriction of the ligature and tearing of the parts must be avoided, the parts to be embraced being duly supported by an assistant. The ligature must of course be firmly applied, and secured by two knots. The pain upon the whole is not considerable, and often is quite trifling, and scarcely ever lasts more than an hour. The depth of the furrow produced by the ligature will depend upon the amount of constriction and the resistance of the tissues; but the constriction may be made much less stringent than was once deemed advisable, as the pressure acts continuously until the elastic ligature regains its primary size. The separation of the parts is brought about by this continuous pressure, which compresses the canals and vessels until these are "thrombosed" and the access of nutritious fluids is completely interrupted. Caoutchouc has another peculiarity in not giving rise to suppuration, granulations speedily filling up the space voided by the retreating parts. When the constricted part has separated, the ligature by its elasticity escapes from the wound, forming then a closed ring, the orifice of which is so small that it can scarcely be penetrated by a probe or needle. According to the thickness of the pedicle and the solidity of the tissues, the process of separation requires from three to fifteen days, the latter term being required in cancer of the breast. Febrile symptoms have not been met with, even when the surface operated upon has been a large one, and the pedicle a thick one.

In a communication to the *Wiener Zeitung*, No. 29, 1873, Professor Dittel states that since his former paper he has employed the ligature fifty-two times in the human subject and twice in animals. Of these cases, ten were examples of adenitis with sinuous passages in the inguinal region, thirteen were cases of fistula ani, four of prolapsus ani, three of hydrocele, three of phymosis, thirteen of malignant and other growths, one of castration, one of elephantiasis labii, and three of amputation of the leg.

Among his observations on these cases we may notice that he states that in adenitis the affected gland or periadenitic abscess may be completely separated in from two to eight days, the pain being usually trifling, and feverish reaction, when it does take place, only lasting a few hours. The wound which results is always a broad and gaping one, unfavourable to the detention of pus, while the linear opening made by the knife favours the formation of collections requiring future operations. The formation of wounds with large surfaces is a peculiarity of this method, which, with all its advantages, labours under a "cosmetic" disadvantage—*e.g.*, in the extirpation of tumours that are still covered with skin. That success attended the treatment of all the thirteen cases of fistula ani, some of which were of a complicated character, was also doubtless much due to this character of the wound as contrasted with the linear aperture made by the knife, for it opened up the fistula by means of a broad open wound, which greatly facilitated the future procedures necessary for success. Time was not even lost, for during the separation of the ligature granulations and new skin had begun to form, and the longest case only required forty-five days. In prolopsus ani from twenty-eight to forty-two days were required, the patient in most cases not being confined to bed until after the separation had taken place, prior to when there is only slight œdema in front of the ligature. In hydrocele the ligature may be carried by means of a needle through the tunica vaginalis, and tied above, the fluid trickling out, and the two punctures becoming slits

or the fluid is discharged in the ordinary way by the trocar, which is then pushed through the opposite side of the scrotum. The ligature is then passed through the canula and tied. In from four to eight days this has made its way, leaving a broad open wound. In these cases the operation has been attended with both fever and pain. Two cases which have occurred since this report was written induce Dr. Dittel to regard this procedure with increased favour. Of the thirteen cases of tumours operated upon, in two only (both of cancer) was there great reaction; and it is to be regarded as a circumstance very favourable to the ligature, that among these patients seven were from forty-seven to seventy-eight years of age. As to amputations, Professor Dittel has no intention of recommending the substitution of the ligature for the knife; but he thinks that in certain cases of compound fracture where further loss of blood is desirable, the ligature may be used with advantage.

In his last communication to the same journal (October, 1873, No. 42), Professor Dittel thus describes his most recent mode of operating by the ligature:—

"I have now so modified my procedure that I can secure the operative results as certainly as with the knife itself. The thing is very simple. I divide the operation into two periods. Say that I have a tumour of the breast to remove. Exactly as formerly I conduct the elastic ligature behind and around the tumour by means of the curved needle, but now I only tie the lower ligature. When this has separated, things are exactly as if I had executed with a knife the lower half of an elliptical excision. I am now able to see and feel whether I have left anything behind; and if this is the case, I can remedy the defect either by applying another ligature or by including what has been left within the upper ligature. If the first ligature have fallen, and the surface of the wound has been examined, I then occupy myself again with the tumour, carrying the ligature by means of the needle from the middle of the wound upwards and behind the tumour, so that it is embraced within the two cords, just as by the old method the entire tumour was. In this manner the operation is as complete as if performed by the knife, lasting several days longer, but causing much less pain."

In this same number Professor Dittel replies to a claim of priority in the use of the elastic ligature made in favour of Dr. Silvestri, of Vicenza, who is stated to have performed operations by its aid in 1862. With this Dr. Dittel says that he has nothing to do, as the means was brought under his notice in the curious manner which he has related; but, as he truly adds, whoever first discovered it, he is the person to whom is due any of the reputation it now enjoys, and which, he thinks, will be durable. Discoveries have often, he observes, been made a second or even a third time before they have borne fruit and taken root.

LETTERS FROM MADRAS.

No. V.

A First Lesson on the Leprosy—Three Different Diseases called by that Name—The Leprosy of the Middle Ages was the Elephantiasis of the Greeks—Anæsthesia and Atrophy—Sketch of a Leper's Hand—Leper Beggars—Mass at St. Lazarus.

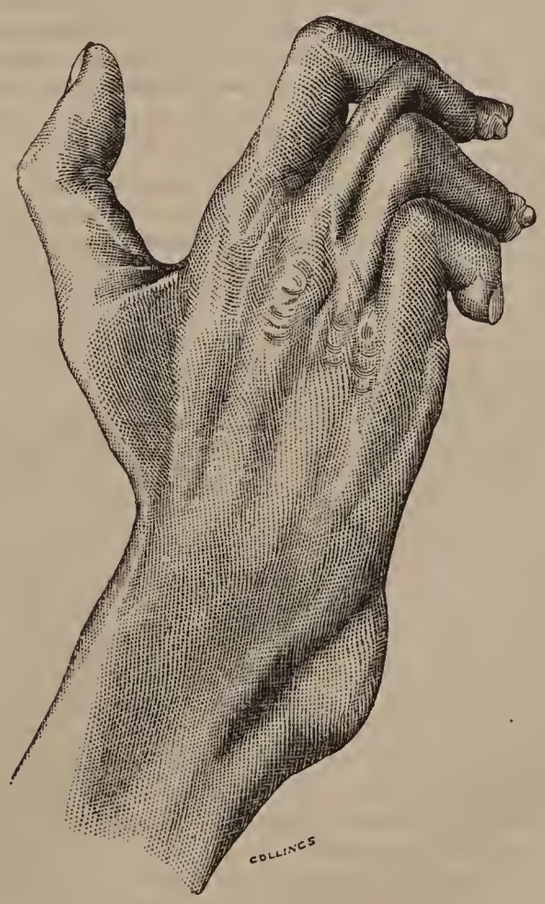
One of the medical sights to be seen here is the Leper Hospital—a large collection of single wards, situated in an ornamental garden just out of the town. The gaily coloured furniture and decorations of the wards, combined with good diet and skilful medical treatment, testify to the humanity and ingenuity of the physician—Dr. Van Someren—in cheering the fretful, despondent minds of a large number of poor creatures afflicted with one of the most lingering, loathsome, and hopeless of human ills.

There are three conspicuous diseases which have received the name of "leprosy." There is the true lepra, described by Hippocrates and Paulus Ægineta—the scaly or scurfy disease, as its etymology shows. There is the elephant-leg, or Barbadoes-leg, which is a huge pachydermatous tumour of one leg or of the scrotum: this is now commonly called "elephantiasis" simply, or elephantiasis Arabum. Then there is the tubercular leprosy of the middle ages, the elephantiasis Græcorum—so-called because described by Celsus and Aretæus under the name elephas, or elephantiasis. This was once common in Europe, now almost extinct there, though lingering in Spain and Norway, and still prevalent enough in the East. The subject has, too, a mysterious interest from the notices of it in the Old and New Testament.

The first lesson I got on leprosy was this. One morning, at the General Hospital, Dr. George Smith brought a patient into the verandah, and invited me to look at him. He was a boy of seventeen, an East Indian,—that is, of mixed European and Indian blood,—and slightly marked with the small-pox, but there was little else very noticeable at first sight.

On being asked what was the matter, he held up his right hand and complained that he could hardly use it. Even then there was nothing very obvious, till my kind instructor made me compare the two hands and demonstrated the morbid changes in the right. He bade me notice the tendency to a stiffened, birdclaw-like attitude of the hand, with apparent shortening of both flexors and extensors; insomuch that the knuckles and first phalanges were bent backwards, and the last phalanges forwards; the muscles of the hand atrophied, as shown by the thinness of the fold between the thumb and forefinger, and by the wasting of the muscular cushion on the metatarsal bone of the little finger. When once pointed out and compared with the left hand, these things were obvious enough; still, they were in themselves not conspicuous. No more were certain other marks which Dr. Smith made me notice, and especially that the ulnar nerve above the right elbow was cordy and prominent. Besides, there was a very little thickening of the eyebrows and loss of their hair, and the slightest possible thickening of the ears, from the presence in or under the skin of flat indolent swellings; and a very little flat tubercular thickening of the soft palate, with a hoarse voice. This Dr. Smith showed me as an example of an early stage of leprosy.

Soon afterwards another victim came under notice, in whom the same appearances exist in the right hand, of which I present a drawing by M. Moonesawmy Moodeliar, the draughtsman to the Medical College. The hand is depicted upright, so as to show the wasted forearm, the thinned fold between the thumb and fingers, the wasting of the muscles of the little



finger, so that the os pisiforme sticks out like a heel, the bent-up fingers, the atrophy of the ring finger (without any ulceration), and the still greater atrophy of the middle finger, the last phalanx of which is reduced to the merest stump crowned by the vestige of a nail. In this patient the ulnar nerve above the elbow is large, prominent, and carries in it a swelling as big as a large pea. There seems, to a superficial observer, nothing else the matter with the patient—his voice is clear, the throat, face, and ears quite free from change, and his skin seems as clean as possible; but Moodeen Sheriff (the accomplished Mahommedan surgeon to the Triplicane Hospital) told me that there was considerable anæsthesia of the right arm, and some loss of pigment, and that these symptoms had been considerably benefited by the full diet of the Hospital—a thing which all observers say effects an immediate though transient check to the disease.

But with regard to this patient it must be added that in addition to this mediæval leprosy, or elephantiasis Græcorum of his right hand, he has also had the quite independent disease, the elephantiasis Arabum, or tumour in the scrotum, which has been removed by Moodeen Sheriff. Of this more anon. There is nothing very astonishing in the fact of meeting two very common diseases of the country in one patient, but the two diseases are radically distinct *ab initio*. The one is an example illustrating Professor Laycock's doctrine of local change in nutrition following disease of the nerves, and so thoroughly diffused that it affects in time the most distant parts of the body; the other, the elephantiasis Arabum, does not travel beyond the original seat, when cast off does not return, and is not known to have anything to do with the nerves.

To resume. The above two cases of withered hand show one variety of leprosy; but the beginning may be far more insidious. There may be merely a spot of skin which is insensible to the touch; and this for years may be the only precursor of the terrible disease which follows, the symptoms hitherto described being those of the atrophic and anæsthetic variety of the disease. The tubercular condition may precede or may follow, and it is this which was described so well by the Greek physicians as elephantiasis or leontiasis, from the resemblance of the features to those of an elephant or lion. I shall never forget the first morning when I visited the Leper Hospital with Dr. Van Someren, as case after case was shown, —some of mere anæsthesia and disturbed pigmentation of the skin, some in which the peculiar tubercular swellings had given that extraordinary animal aspect to the face: the forehead swollen, the hairless eyebrows protruding, the ears projecting forward and of enormous size, the upper lip pouting and swinish, the nose first flattening then falling in, and the eyes in time following.

I forbear to give anything like a description of the leprosy which I saw here, because I hope Dr. Van Someren himself may be induced to give your readers the results of his own prolonged experience, and especially of the results of various methods of treatment, including the temporary relief obtained from the external use of the cashewnut-oil and an improved diet. I do but give the impressions made on a stranger and passer-by, and only pretend to show things as they seem, without aspiring to treat of them as they are.

This disease seems to be a kind of "missing link," combining the features of cancer, scrofula, tertiary syphilis, lupus, tuberculosis, and phthisis. Of exudation or tumour there is abundance, especially into the structures of the face, whence the extraordinary perversion of features. The existence of similar deposit in the nervous trunks and centres accounts for the anæsthesia and atrophy of the parts supplied. The atrophy of the hands and feet may be aided by ulceration or dry gangrene, so that toes and fingers vanish by interstitial absorption or drop off one after another. But yet there is usually very little pain—the anæsthesia forbids that; so that a leprous beggar may stump after you on a foot little more than a heel, and may hold out a hand reduced to the metatarsal bones. Abscess, ulcer, sloughing, and every form of skin disease may be superadded.

Shocking enough it is to see these poor people under the humane discipline of the Leper Hospital; still worse is it to be pestered by them as beggars at large. There is a little chapel in an out-of-the-way place near the sea, in the village called St. Thomé, about three miles from Madras; it is dedicated to St. Lazarus, and is believed by the common people to have special privileges of healing attached to it, and on every Tuesday morning mass is said there, which is attended by crowds of people of "all denominations," who have the common bond of disease and superstition. Hindoos with the staring mark of Vishnu or Siva on the their foreheads, Mahommedans, and Christians—all come in the hope of cure, whether sick themselves or on behalf of some sick person at home. The building is a small chapel, and is crowded to repletion. The people surge up so as almost to touch the priest at the altar, and whilst he is saying his service in a low tone, devotees in the chapel one by one sing hymns in the vernacular Tamil to native tunes of the wildest and rudest sort. Then, in order that the people present may have something to carry away with them, showers of peppercorns are from time to time scattered over the congregation, which are eagerly caught, and treasured by the devotees present as being excellent remedies against small-pox and other diseases of the skin consisting of pimples or pustules. At last mass was over, and the priest left his half-suffocated congregation, when there was a general move, everybody coming forward to pluck each a leaf or flower from the bouquets which had been placed on the altar, or to touch some consecrated object or light a taper on the altar; whilst, as the chapel became empty, people on their knees were eagerly picking up the peppercorns from the pavement. Outside it was that the horrors of leprosy struck me, as they are shown in persons who are not cleansed nor cared for as they would be in a hospital, who throng around you, mixed with the blind, lame, and diseased of all sorts clamouring for alms, I think I have seen a feeble attempt to pourtray the Veiled Prophet in Tom Moore's "Lalla Rookh;" but nothing can be imagined more horrible than some of the spectre-like creatures with projecting ears and eyebrows, and with a hole for a nose, stumping about on their mutilated feet, and holding out the remnant of a hand. They come as near as they can, and trust to their horrible aspect to be bought off. "Master please don't give him, sar; him very bad beggar, sar," said a respectable native to me, as he thought I was going to give one of them a few piee to buy him off. There was besides, all the hubbub of a country feast or fair, sellers of toys and gimcracks, of cakes and sweetmeats, and of *objets de piété*, wax tapers, garlands, and waxen models of arms and legs to serve as votive offerings.

I have been informed that the peppercorns are scattered by people who have skin disease, which they hope will be scattered as the peppercorns are; and that others scatter salt and jaggery—*i.e.*, sugar—in the faith that their diseases may vanish as these melt.

We cannot without thankfulness think of the absence of this disease from civilised Europe at present, considering that it was so prevalent once, as Sir James Simpson tells us in his most interesting "History of Lepers and Leper Hospitals."(a) From the eighth to the sixteenth century it prevailed all over Europe, where it is now confined to Norway, Iceland, and Spain. Leper hospitals were founded everywhere, and an order of knights, the Knight Hospitallers, devoted themselves to the care of the sick; these knights are supposed to exist still in an Order of St. John that is heard of in time of war. The disease was called "leprosy" by the educated, who followed the word *lepra* in the Vulgate; but in the words of the common people it was known as *se mycle adl*, in old English "the mickle ail," the great disease, *la grosse maladie* of Froissart. In most of the languages of India it is called "the disease," or "the great disease." As once in Europe, so still in India, it pervades all climates, and is more prevalent on the high and dry plateau of Bangalore than on the sea-shore at Madras. I visited the Leper Hospital at Bangalore in company with Surgeon-Major Oswald, who also has charge of a lunatic asylum adjoining, where the cheerful gardens and the savoury steams of the kitchen bear witness to the mental and bodily care of the afflicted.

No age, sex, nor rank is exempt. At Madras it is said that even European members of the medical profession have suffered; the only broad fact that comes out being that it seems to prevail generally in proportion to the misery and poor diet of a people. It lingered in Scotland after it was unknown in England, and the last place in which it was found in Great Britain was in Shetland.—(Simpson, *ut supra*.)

Although the unscholarly part of mankind are apt to sneer at the ancients, yet anyone who reads the old medical classics, with due regard to the state of general science at the time the writers lived, must admit that they were men of acute observation, careful describers, and conscientious in their treatment. Nowhere do these eulogies belong more justly than

(a) *Edinburgh Medical and Surgical Journal*, vol. lvi., No. 149, October, 1841, and vol. lvii.

to the mediæval writers on leprosy, quoted by Sir James Simpson. Thus Bernhard Gordon of Montpellier, whose "Lilium Medicinæ" was written about 1305, mentions "atrophy of the muscles, especially of those between the thumb and forefinger, and insensibility of the extremities" amongst the infallible signs of leprosy, after the "enlargement of the eyebrows and loss of their hair"; rotundity of the eyes, swelling of the nostrils; aspect of the face terrible, with a fixed stare, etc. And, considering that when a man was condemned as a leper he was shut up for life in a lazaretto, or else turned out as a wild beast, it is satisfactory to find the great minuteness with which the premonitory signs were watched, the good diet prescribed by Guidus de Cauliaco, and the fact quoted by Simpson, that persons wrongly suspected and shut up for leprosy might appeal to the king, who might issue a writ in Chancery for examination by the best physicians, which, as in the case of one lady recorded, ended in an acquittal—a fortunate thing so far as she was concerned, for the existence of a leper, whether shut up or at large, must be a most dismal thing. But, besides their deformity, they seem to suffer little; they do not die of the leprosy, but are weak, irritable, capricious in appetite, and prone to fall victims to phthisis, diarrhœa and dysentery, and disease of the kidneys. They marry when they can, and beget children. Some observers whom I have asked confirm the old statement that they are much given to sexual indulgence; others say that they are like the rest of the world in that respect. The offspring of leprous parents may be healthy and fine children; but no one doubts hereditary transmission. But as for the exciting cause of the disease *de novo*, or for the question of propagation (which Dr. Tilbury Fox very properly distinguishes), no two opinions agree. Dr. Van Someren does not believe in contagion.

(*To be continued.*)

REVIEWS.

A System of Midwifery, including the Diseases of Pregnancy and the Puerperal State. By William Leishman, M.D. Glasgow: Maclehose. 1873.

Considering the rapid strides that have been made in the science and art of obstetrics during the last few years, it is a wonder that no new work on the subject has been given to the profession.

The author boldly declares in his preface that his object has been to furnish to students and practitioners a complete system of the midwifery of the present day, and assures us that "he has made himself familiar with the modern works of approved merit, whether British or foreign."

To condense in one systematic treatise the opinions of the various obstetric authors of the present day is no mean task, but to accomplish this in such a manner that the student, in place of being bewildered by the *tot sententiæ*, can glean the experience of so many counsellors, reflects great credit upon the author.

In his introductory chapter he briefly sketches the history of obstetrics, commencing with Hippocrates, "who was the first to bring a profound intellect and a truly scientific mind to the observation of the phenomena of parturition," and who for so many years hindered the progress of obstetrics by his assertion that the head was the only natural presenting part. The comparative anatomy of the pelvis will prove of great assistance in arriving at a proper understanding of the mechanism of parturition.

Space will not allow of more than a brief reference to the more important subjects; suffice it to say that for the most part the anatomical and physiological chapters are clearly and concisely given, and are all that could fairly be expected in a "system of midwifery," although, without entering fully into many controversial subjects, it would have been well had the opinions of those with whom the author does not agree been fairly stated or at least referred to. The anatomy of the placenta, with the vexed question of the placental circulation, is not given so fully as the importance of the subject demands, Hunter's views being those accepted by the author.

His description of the changes that take place in the cervix uteri during the latter months of pregnancy, even though the author limits it to primiparæ, is not quite in accordance with the experience of most modern authors, Dr. Matthews Duncan having clearly shown that the shortening is more apparent than real. A reference to the elaborate plates of Professor Brown, of Vienna, where he gives us a section of a pregnant uterus immediately preceding labour, is also opposed to the author's statements.

Dr. Leishman lays more stress upon "quickening" as a guide to the time of pregnancy than we are inclined to endorse, regarding it as very fallacious.

In treating of extra-uterine fœtation, we think the author relies too much upon the expectant treatment, considering the formidable risks incurred by allowing gestation to go on until rupture of the sac probably occurs, and the life of both mother and child is sacrificed. Cazeaux's plan of passing electric shocks through the abdomen to destroy the life of the fœtus is not only sound treatment, but also practicable; and even Scanzoni's method of perforating the sac by a trochar per vaginam in many cases is certainly advisable.

When the pregnancy has advanced to the eighth month or later, and the diagnosis is clear, gastrotomy offers a better chance to both mother and child than leaving the case to nature, providing only we leave the placenta *in situ*, and do not attempt its extraction, as Dr. Leishman seems to think is requisite, although he clearly appreciates "the great and special danger" of so doing.

Considering the prominence that has been given to this subject of late, we think the author might fairly have advocated a more active plan of treatment.

The disorders of pregnancy are ably discussed. The employment of local sedatives in cases of excessive vomiting deserves, however, a more extended trial than the author accords them. In the treatment of retroversion of the pregnant uterus we think the necessity of inducing premature labour might in a considerable number of cases be averted by confining the patient to her bed or couch for a week or two after the uterus has been replaced, with instructions to lie on her face as much as possible. We have thus succeeded in many instances where previous miscarriages had been frequent.

We do not agree with the author in his management of the third stage of labour. We object *in toto* to traction upon the cord, or even in the majority of cases introducing the hand into the uterus, Crede's system of expression by compressing the uterus externally being far preferable and much simpler as well as efficacious, the risk of post-partum hæmorrhage being thereby greatly diminished, and the efficient contraction of the uterus insured, and thus the probability of after-pains materially lessened.

The mechanism of labour, as we should expect from the author having devoted so much consideration to it previously, is ably and clearly given, and deserves careful study, for, without a proper understanding of the question, operative midwifery should never be attempted.

In the management of transverse presentations, we regret the author has not laid more stress upon ascertaining the abnormal position early by external manipulation; for though he alludes to it he evidently does not place that reliance upon it that those who have read Wigand's views and practised them will feel inclined to support.

Instead of "waiting patiently till full dilatation has been attained, or till rupture of the membranes takes place," we strongly urge upon all who practise midwifery familiarising themselves with this simple method, whereby version, or at least rectification, can be readily accomplished, irrespective of dilatation of the os, the danger to both mother and child being thus materially lessened.

In reference to funis presentations, the author says—"When that stage is reached at which the dilatation of the os is what we call complete, the membrane being as yet unruptured, it may occasionally be a matter of some difficulty to determine upon what principle we are to proceed in the management of the case." In place of resorting to the ingenious expedients suggested by most authors, we should depend upon placing the patient in the knee-shoulder, not the knee-elbow position as stated, and in the event of reposition by simple means being unsuccessful, turn and deliver as Mauriceau strongly advised, more especially as since the employment of the external and the bimanual method the facilities for doing so are so greatly increased, and the risk diminished.

The subject of premature expulsion of the ovum is well given, and though "under ordinary circumstances abortion is attended with little risk to the mother," we quite agree with Dr. Leishman "that no more fruitful source of menstrual disorder or of chronic uterine disease exists than what arises

from a want of due precaution at this critical period of a woman's existence."

The treatment of placenta prævia is one of great importance. The views of different authors who have written upon the subject are fairly given, and the various methods conveniently epitomised. The author thinks "that the operation of turning is that in which the great majority of experienced practitioners still place the greatest confidence."

In describing the preventive treatment of hæmorrhage after delivery, beyond the mere general advice to promote labour when the pains are feeble, no mention is made of applying the forceps and so shortening the duration of labour, and thus lessening the risk of hæmorrhage. Nor is the importance of following up the contraction of the uterus by external manual compression sufficiently insisted on. Transfusion is briefly referred to, but not so amply as we should have expected.

In describing the treatment of inversion of the uterus, Dr. Barnes's recent method of nicking the os in several places is not alluded to; this being a great improvement upon the method described by him in 1869, and promising fair to supersede "the only possible remedy in severe cases—viz., the removal of the inverted uterus."

In citing the cases requiring the use of forceps, the failure of the *vis a tergo*—familiarly known as "uterine inertia"—is stated to be the most frequent cause necessitating operative interference. This, we do not hesitate to affirm, is in our experience a condition that should never be allowed to supervene, arising as it most frequently does from some slight disproportion between the fœtal head and pelvic cavity; or, still worse, from contraction of the brim, where the unaided efforts of nature are insufficient to complete delivery. It is in these cases that by a timely application of the long forceps much needless suffering is spared the patient, and the fœtal mortality greatly diminished. Forceps should be looked upon not as a "*dernier ressort*," only to be employed when nature fails in her efforts, but as a valuable aid to be employed whenever nature intimates that she is unequal to her task. The risk in employing them has been greatly exaggerated—the danger generally is in having waited too long before resorting to them. We regret much that Dr. Leishman has failed to express in these chapters—more perhaps than in any other portion of his work—the prevailing notion of most of our modern obstetricians; and we trust that in his subsequent editions he will see fit to urge more prominently a more frequent and early resort to their application.

We differ also from him in his preference for the short over the long forceps: those who have given both a fair trial cannot fail to have experienced the great advantage of the latter over the former in the large majority of instances requiring their employment.

The subject of turning is ably discussed and well illustrated, the bipolar version being justly regarded as "one of the most important improvements in modern obstetrics."

In the treatment of rigidity of the os, the use of belladonna is advocated, but nothing is said about chloral, which has proved so successful of late.

The remaining portion of the work, especially the chapters on puerperal complications, is well written, and will prove a valuable guide to the accoucheur; the author evidently possessing a practical acquaintance with his subject, and much power of expressing his opinions tersely and explicitly.

We may as well state at once that, after a careful perusal of the work, we feel we owe a debt of gratitude to Dr. Leishman for having devoted so much time and labour in giving to the profession such a valuable "System of Modern Midwifery," and we confidently expect that it will have a large and rapid sale. It is a work that every obstetric practitioner should possess, for it stands alone in being the only volume that expresses the modern views upon this important branch of the profession. We can conscientiously recommend it as a work of great merit.

The Baths and Wells of Europe: their Actions and Uses; with Notices of Climatic Resorts and Diet Cures. By John Macpherson, M.D. Second edition, revised and enlarged. London: Macmillan. Pp. 378.

Dr. Macpherson has contrived to produce a thoroughly readable book out of materials which are only too abundant, and which, being so, would in most other hands—after being condensed as they are—have afforded only a sorry bill of fare to the reader in the shape of a dry *résumé*. Dr. Macpherson's book is more than this, but it lacks that fulness of information which a conscientious medical practitioner should seek to acquire before sending his patient abroad to any but the best-known watering-places. Even of the watering-places best known by name, how many have been visited by those who are in the habit of sending abroad patients to this or that spa, without any certainty that it is likely to suit them! Most of the good to be derived from a foreign watering-place depends on its exposure, on the kind and quality of food procurable, on the walks obtainable in the neighbourhood, and so on. Yet few details can be acquired on these important points, save by an actual visit to the place. Dr. Macpherson has personally visited many of the spas, and the details he gives are thoroughly reliable, but his space is far too limited to give more than the merest sketch even of the principal spas, to say nothing of grape cures, herb cures, whey cures, water cures, air cures, and spring cures, to be found all over the Continent.

A Treatise on the Principles and Practice of Medicine. Designed for the Use of Practitioners and Students of Medicine. By Austin Flint, M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College. Fourth edition. Philadelphia: H. C. Lea. London: Trübner. Pp. 1070.

In the present volume Dr. Flint publishes his first preface dated 1866, and his last dated 1873. Not much need be said for a work under such circumstances. It is an established success; and, in truth, Dr. Flint deserves it. His book is a very good book, the fruit of much reading and of much practice. All we need say is that the present edition is somewhat enlarged; that the chapters on nervous diseases especially have been revised and increased—in short, that it is made fully abreast of the times, and worthy of confidence in every respect.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

Paris, November 17.

Lists of Lecturers—Sée on Cerebro-Spinal Nervous Disorders—Béhier on Typhoid—Lasègue on Method in Research—Richet on Lipoma in the Neck—Gosselin on Popliteal Aneurism—The Discussion on Cholera—M. Le Fort's Opening Lecture.

As announced in my last, the lectures at the School of Medicine were opened on the 4th instant. To the list of the Professors then given may be added the names of MM. Liouville, Chef de Laboratoire, and Hardy, Chemical Assistant at the Hôtel-Dieu. MM. Cornil, Pozzi, Coyne, and Daremberg (the latter as Chemical Assistant) are attached to the laboratories of the Charité Hospital, and M. Nepveu at la Pitié. These gentlemen carry out investigations in morbid anatomy and pathological chemistry, and give demonstrations once or twice a week in their respective branches; the student is at the same time instructed in the art of dissection, histological preparations, and in chemical manipulations relating to pathology. In addition to these there are a number of professors who lecture *ex officio* on the different branches of medicine and surgery. Some of these are specialists, and for the eyes alone there are no less than eight—namely, MM. Fano, Galezowski, de Wecker, Desmarres, Abadie, Meyer, Sichel, Piéchaud. For the throat—MM. C. Fauvel, Krishaber, Mandl. Urinary organs—MM. Mallez and Reliquet. Accouchements—MM. Verrier and Chantreuil.

The clinical lectures have also begun at the different hospitals. These are, as usual, most interesting, and the professors seem to vie with each other, not only as to the manner of delivering their lectures, but they all seem earnestly desirous of imparting their stock of knowledge and experience to those who care to follow them. I cannot in a single letter give even a summary of these lectures; I may, however, refer briefly to some of the subjects touched upon. At La Charité, Professor Sée selected for his winter lectures the diseases of the nervous system, or, more properly speaking, affections of the cerebro-spinal system, not only as regards the nerves themselves, but their influence on other organs, such as the heart, brain, etc. By a remarkable coincidence there are at

present to be found in his wards specimens of almost every variety and form of neurotic affections, from simple hysteria to epilepsy and locomotor ataxy. M. Sée repudiates the division of nervous and other affections into "essential" and "symptomatic," as, according to him, there can be no symptom without a lesion, as there can be no smoke without a fire; and if at autopsies we sometimes find nothing, it is because our knowledge and our means of investigation are defective. Physiologists, he continued, and particularly those of the French school, have rendered great service by their researches in this class of diseases, but their experiments were, if we may so say, too highly refined; so much so, that the symptoms observed at the bedside of a patient did not altogether tally with the results produced by experiments. In the pathological department there has been real progress; but if sometimes the symptoms during life are not confirmed by post-mortem appearances, it is because those who had undertaken such researches, and committed their observations to print, had to deal with a class of patients which could bear no comparison with another as regards age, habits of life, etc. For instance, MM. Vulpian and Charcot, than whom no living physiologist and pathologist have done more to throw light on the nature or mechanism of this most difficult class of diseases (neuroses), yet the results of their researches were not always in accord with the observations of others equally eminent but differently situated as regards the subjects they had to deal with. MM. Charcot and Vulpian are attached to the Salpétrière Asylum, where its inmates are in a state of decrepitude: their observations of disease, whether before or after death, cannot possibly tally with those taken at a hospital where its inmates are in the prime of life. This would account for the discrepancy in the description given in different books of one and the same disease, and it is only by clinical observations in a *general* hospital that a just estimate can be formed of the nature of any particular malady.

At the Hôtel-Dieu, Professor Béhier, with his usual eloquence, opened his lecture by a few remarks on the necessity for clinical observation or study before one can aspire to be anything of a practitioner. Experimental medicine, he said, may have its advantages, but it is at the bedside alone that one can study the different phases of disease. The experimental method without clinical observation (he added) is a dead letter, which only tends to lead young minds to form an erroneous conception of that more complex process termed "pathogeny." Several cases of typhoid fever having lately presented themselves in his wards, M. Béhier took occasion to lecture on the subject, and pointed out the advances that have been made in the diagnosis of this affection, and dwelt particularly on the utility of instruments of precision in clinical investigations in general. Thus, with the thermometer and sphygmograph alone, we can often diagnose a case of simple typhoid fever from any other disease of an adynamic or typhoid character. He then referred to the thermometric signs of typhoid fever and to the correlation that exists between these and the characteristic lesions of the affection—that is to say, the temperature in typhoid fever is constantly in relation to the extent or condition of the lesion in Peyer's patches, so that with the aid of the thermometer one is enabled to describe the progress of these lesions. For instance, when the lesion is only in its congestive stage, the temperature of the body gradually rises until it reaches its maximum of 40° C. or 41° C. In the ulcerative or eliminative stage this temperature remains stationary for a short time, and then it gradually falls. Here commences defervescence, which corresponds to the stage of cicatrisation, and when the temperature reaches its normal standard (37° C.) the patches are quite healed, and the patient is in a state of convalescence. This, indeed, may be observed even in surgical affections. Take, for instance, a common abscess. Here, as in typhoid fever, we have, though in a less marked degree, the three stages—that of ascension, which corresponds to the stage of congestion; the *periode d'état*, or when the fever is stationary, which corresponds with the process of suppuration; and the stage of defervescence, or decline, with that of cicatrisation.

At La Pitié, Professor Lasègue opened his course by a lecture on what he terms "Méthodologie," or the science and art of method in the investigation and research adopted by physicians, those resorted to by surgeons, such as the sense of touch and palpation, as an illustration of which he cited among other examples the advantages he derived by the use of the touch in the diagnosis of diseases of the throat, in which, in his opinion, this method of examination is generally neglected. By this method of exploration one may be enabled either directly or indirectly to ascertain, as in nervous affections of the throat, the different degrees of sensibility (anæsthesia or hyperæsthesia), of direct or reflex contractility, or of motor paralysis of the different parts connected with this region.

The surgical *cliniques* were not wanting in interest, but as there was nothing particularly new to note, I shall not trouble your readers with details. I may, however, observe that at the Hôtel-Dieu Professor Richet removed on Tuesday last a lipomatous tumour, about the size of a man's fist, from the right axilla of a female patient, which was effected by enucleation. The patient had another on the left hip, but M. Richet did not think proper to remove it at the same sitting. The Professor then went through the differential diagnosis of tumours, and said that the case under notice reminded him of a similar one he had removed from the throat of a man about 72, residing in Normandy, adding that it was the first time in his practice he had met with a lipoma in that situation, and he is not aware of any being on record. The microscopic examination of the tumour, after its removal, confirmed the diagnosis he had made. But the most remarkable part of the patient's history was that he was so little incommoded by the presence of the tumour of such a size and in such a situation. The act of deglutition was not interfered with, and the function of respiration scarcely impeded, and the man's health was good. The tumour was removed by the knife, and the patient made a good recovery.

At the Charité Hospital, Professor Gosselin's first lecture for the session was devoted to a case of spontaneous popliteal aneurism in a man aged about 35. It was about the size of a small orange, and situated in the popliteal space of the right leg. The patient was admitted some months ago, and could not give any information respecting its origin. M. Gosselin, however, was of opinion that the tumour belonged to the class of spontaneous aneurisms, but which are developed under the influence of an atheromatous condition of the vascular system. For the cure of the aneurism steady digital compression was first resorted to, and kept up without interruption for thirty-eight hours, but as the man got impatient from the increase of his sufferings, this method of treatment was given up, and replaced by ligature of the main trunk that fed the aneurism. On July 14 last the femoral artery in Scarpa's triangle was taken up and tied, which produced a favourable result, the pulsations in the tumour having completely disappeared, and the aneurism itself became hard, and was considerably reduced in size. The circulation in the limb seemed to be unimpeded, and the patient was doing well, when, about the twelfth day after the operation, the pulsations became again apparent in the tumour, without, however, any increase in its size. The aneurismal sac had evidently become permeable to a fresh current of blood, but M. Gosselin imagined that this latter was supplied by the collateral branches. He was, however, soon undeceived, as the tumour continued to pulsate, increase in size, and began to soften. This, he said, was evidently a renewal of the aneurismal tumour, which, however, was produced by a different mechanism, and the tumour now assumed the character of aneurisms known under the name of diffuse aneurism. Shortly after this the tumour became inflamed, the patient suffered a good deal from pain in the part, and as this was accompanied by a general febrile condition, M. Gosselin was afraid that suppuration was setting in. The doubt, however, was removed by the use of an exploring trocar, which gave issue to a few drops of thick blood without any trace of pus. But as there was no amendment in the condition of the patient or tumour, M. Gosselin thought the time had arrived when amputation was necessary for the safety of the patient's life, as he was afraid of rupture of the aneurism taking place. To this, however, the patient would not consent, and M. Gosselin had recourse to moderate compression, hoping that with rest, and keeping up the strength of the patient, the tumour would disappear by absorption. On my return to the ward a day or two ago to follow up the case, I found that, instead of the tumour, the man himself had disappeared, as he obtained, at his own request, his discharge from the Hospital.

In my last I mentioned that the discussion at the Academy of Medicine on cholera was closed. I find, however, that at the request of some of the members who were absent the discussion has been resumed. M. Chauffard and others have taken up the subject, but nothing new has been advanced; and the discussion, like the disease itself, may be said to be dying out, the mortality for the week ending November 10 having been reduced to four in the hospitals and town.

M. Le Fort, recently appointed Professor of Operative Surgery, delivered his maiden lecture at the School of Medicine on Saturday, the 8th instant, on which occasion the building was literally thronged. M. Le Fort, who is a relative of the late M. Malgaigne, is very popular, and his lecture was a perfect success. After having paid a graceful tribute to his predecessors, he went through the history of surgery from its earliest times, and pointed out the intimate connexion that exists between this branch of the art of cure and medicine properly so called. He endeavoured to show that the progress of medicine depended upon the degree of liberty that the human mind enjoyed at the different periods of its history. Thus, during the period of philosophical liberty, important discoveries were made in medicine and surgery; whereas during the rule of intolerance and absolutism progress was all but in complete abeyance. Progress, he continued, is neither the property of an individual nor of a nation. He enjoined his hearers to make themselves acquainted with the discoveries of other nations, for which it was indispensably necessary they should acquire a knowledge of foreign languages. "You may, if you please, forget your Greek and your Latin, but study the living languages if you wish to keep pace with your neighbours." "This advice," he continued, "is given not only for your personal interest, but for the welfare of France, which it is the duty of all loyal citizens to render great and happy."

GENERAL CORRESPONDENCE.

THE ELASTIC LIGATURE.

Letter from Mr. Henry Lee.

[To the Editor of the Medical Times and Gazette.]

Sir,—Upwards of two years ago, in consultation with Sir James Paget, I proposed to remove a breast with the elastic ligature. The tumour was very large, and bled so freely that amputation appeared out of the question. The operation was agreed upon, but was delayed from one cause or another until it could no longer be undertaken. In 1866, Mr. Blaise, of St. James's-street, obtained at my request some elastic material adapted for such an operation, and it has constantly been kept in St. George's Hospital since that time. There was great difficulty in getting this material, and Mr. Blaise, having failed to obtain it in London, had to send to Derby for it. Previous to that time I had been in the habit of operating with the elastic thread, such as is used in the sides of boots. This answered the purpose sufficiently well, and with it, and more recently with that supplied by Mr. Blaise, I have removed a considerable number of small tumours. The mode of operating is especially adapted for hæmorrhoidal tumours, nævi, and warts, and I should have used it more frequently than I have done had not experience proved the superiority of the curved clamp and the actual cautery where there is no objection to their use. With these I recently removed a considerable portion of the tongue, in St. George's Hospital, with scarcely any hæmorrhage. I am, &c., Henry Lee.

9, Savile-row, November 29.

UMBILICAL HERNIA IN INFANTS.

Letter from Mr. John Gorham.

[To the Editor of the Medical Times and Gazette.]

Sir,—In Mr. Wood's lecture on umbilical hernia, published in the *Medical Times and Gazette* of November 29, I notice that this gentleman recommends, as "the readiest way of applying pressure to the umbilical ruptures of children, common adhesive strapping placed over a flat piece of lead or pewter, or, what is usually more at hand, a penny-piece. This should be first enclosed in folds of strapping applied with the sticking side outermost, so as to adhere to the skin over the tumour. Over this broad strips of soap or adhesive plaster should be placed across the entire abdominal surface, and surrounded by a belt or bandage." This, says Mr. Wood, "though a valuable temporary expedient, can with difficulty be long maintained, on account of the constant trouble of changing, the liability to soreness of the skin, and a certain degree of skill which is demanded for its proper application." Mr. Wood then proceeds to notice an ingenious pad, devised by himself, consisting of "an indiarubber ring adapted to the size and shape of the edges of the opening, which should press only on the edges with the same tendency to close them as by pressure with the fingers in reducing the protrusion."

An experience of forty years of active practice enables me to speak very decidedly as to a plan of treatment which has been adopted, and in every case with uniform success, so that I am not able to point to a single instance in which it has failed. I am induced therefore to request an insertion of the plan adopted in the pages of the *Medical Times and Gazette*. It is as follows:—Having placed the child on its back in the mother's lap, the hernia is pushed in with the forefinger. The skin of the abdomen on either side is now pinched and folded up with the finger and thumb, and brought over so as to make both folds meet. The hernia now lies underneath the folds, which are represented by two parallel lines in contact with one another. Holding the folds in close apposition, by applying the thumb and forefinger of both hands above and below, the mother or an assistant now applies six strips of diachylon plaster—four transverse, two oblique. The transverse are three inches long by half an inch wide; the oblique are four inches long by half an inch wide. The small belly-band which has been used from time immemorial is now applied, and serves to keep the plasters in their place. These plasters will remain on, although the infant is washed well every night and morning, for four days, when they can be removed, and fresh ones substituted. It may be as well to notice, however, that the whole of the strips should not be removed at once, but one by one; and as fast as one strip is removed another fresh one should replace it. In this way the chances of protrusion during the crying or coughing of the child are much diminished.

I was induced to follow this mode of treatment from a remark made so long ago as 1805 in Dr. Underwood's book "On Diseases of Children," in which the author says he has for some years succeeded well by the ingenious contrivance of Mr. Kelson, of Sevenoaks. "This consists only in bringing the parts together by means of three or four strips of plaster applied star-wise across the navel, which are to be removed as occasion may require." After a little while, the mother, with the assistance of the nurse, generally becomes sufficiently adroit to apply the plasters herself, and I have had several cases in which they have been thus applied for months or even a year with perfect success. When once the mother can take upon herself the duty, it is doubly advantageous, because a child is less likely to cry under the manipulations of one with whom it is so familiar, and because it prevents the repetition of visits, which, to parents of slender means, is a consideration.

I am, &c., John Gorham.

THE CAUSATION OF DICROTISM OF THE PULSE.

Letter from Dr. A. L. Galabin.

[To the Editor of the Medical Times and Gazette.]

Sir,—In his paper on the sphygmograph, published in the *Medical Times and Gazette* of November 1, Mr. Mahomed, while criticising my view of the causation of the dicrotic wave of the pulse, has advanced a theory of his own which differs quite as much as mine from any of those hitherto accepted. The explanation of the dicrotic wave is so important, as the most elementary step in the study of the pulse-curve, that any contribution to the discussion which tends towards the settlement of the question may be considered of value. While fully appreciating the valuable results of Mr. Mahomed's practical researches with the sphygmograph, I am unable to avoid the conclusion that his theory on this point is mechanically unsound.

Mr. Mahomed, like myself, believes that the closure of the aortic valves plays only a secondary part in the production of the dicrotic wave, but its primary cause he considers to be simply the contraction of the elastic coat of the aorta, which he says is the result of a distinct mechanical power—namely, that of elasticity. That elasticity is a mechanical power is a proposition which it would be difficult either to deny or to affirm; but mechanical power is a term which has been rather consecrated by usage to mechanical appliances of practical use—such as the lever, the wedge, or the screw.

We both of us agree that the dicrotic wave is a wave of expansion, proceeding from the centre towards the periphery. By the principles of hydro-dynamics it must therefore be at the same time a wave of increased pressure, the expansion being the result of the pressure within. Being, therefore, the transmission of an increased pressure, its origin, at whatever point that occurs, must itself be an increase of pressure; and the point is to explain how that should arise.

Now, the contraction of an elastic surface is simply the result of the diminution of tension, and the contraction of the aorta is in this way due to the diminished pressure within after the cessation of the heart's contraction. The mere fact of contraction, therefore,—itself an effect of lowered tension—could not at the same time be a cause of such a raised tension as would be required to produce a second increase of fluid pressure. The theory of Mr. Mahomed, in fact, amounts to supposing that the lowering of pressure is by itself the cause of an elevation of pressure; if not at the same point, yet at a little distance off.

I do, indeed, myself believe that the dicrotic wave is due to the contraction of the large arteries, but that this result only occurs because, owing to acquired velocity, their expansion is carried beyond that point at which the tension of the tube would be in equilibrium with the pressure within. The effect of this is that the contraction takes place with such a spring-like recoil as to carry it again within the point of equilibrium, and so cause a second increase of fluid pressure; and this oscillatory movement may be several times repeated. The dicrotic wave would thus be the first of a descending series of waves of expansion and contraction. These are constantly observed in experiments with elastic tubes, when the contractions of the artificial heart are made at sufficiently long intervals, and the second of the series, or tricrotic wave, is now and then seen in the pulse when the tension is very low, but the rate not rapid. These waves have some analogy to those which occur when a stone is thrown into water, for that case affords an instance in which the production of one wave gives rise to a series of waves, each smaller than the last, not reflected, but travelling in the same direction as the first and largest wave.

I agree, therefore, with Mr. Mahomed so far as to consider that the elastic distensibility of the arterial walls is a necessary condition for the production of the dicrotic wave; and that, other things being equal, that wave becomes lessened if such distensibility be diminished, and conversely. I believe, however, that a second necessary condition is to be found in the effect of the inertia of the arterial walls, and that without this the dicrotic wave would not occur at all. For a statement of the evidence in support of my view I must refer to a paper published in the last number of the *Journal of Anatomy and Physiology*.

I am, &c., A. L. Galabin.

DR. CHAPMAN AND THE METROPOLITAN FREE HOSPITAL.

Letter from Dr. Charles R. Drysdale.

[To the Editor of the Medical Times and Gazette.]

Sir,—Will you favour me by space in your much-respected journal to say that I was not one of the gentlemen who signed the resolution recommending Dr. Chapman to resign on account of his now well-known article in the *Pall-mall Gazette*.

I am, &c.,

Charles R. Drysdale, M.D.,
M.R.C.P. Lond., F.R.C.S. Eng.,
Senior Physician to the Metropolitan Free Hospital.

London, December 2.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 25.

Dr. C. J. B. Williams, F.R.S., President, in the Chair.

Dr. Samuel Gee gave the history of a case of Calculous Disease of Both Kidneys in a man who had suffered from gout. In the pelvis of the right kidney there were found—(1) a great stone, weighing thirty-six ounces and a quarter; (2) eight smaller stones, each larger than a cherrystone, weighing from nineteen grains to fifty grains; (3) about a thousand flattened stones, like melon-seeds in shape; (4) a large quantity of gravel. In the pelvis of the left kidney was found a stone weighing nine ounces and three-quarters. The chemical composition of the greater part of the large stones, and of the smaller stones and the grit, was phosphate of magnesia and ammonia, nearly pure. The large stone had a nucleus of oxalate of lime, phosphate of magnesia, carbonate of lime, and uric acid.

Mr. Charles Hawkins had seen nothing of the kind. He believed it the result of a stone lodged in the pelvis of the kidney, and gradually causing absorption of the organ. He had removed a stone similar in composition from the body of a gouty patient, whose health and comfort were wonderfully little affected. He had a patient who one year would have a fit of gout, and the next one of gravel.

Mr. Arnott said Dr. Murchison had shown a stone about half as large to the Pathological Society. The patient had passed crystalline cholesterin in the urine, and had long suffered from intermittent hæmaturia. One kidney was an abscess, the other filled with shining crystals. The stone had not been made out during life.

Mr. F. Clarke thought it interesting that the deposits were symmetrical. Was there any trace of stone in the bladder, or any idea of operation?

Mr. T. Smith understood that the enlargement had been considered scirrhous, so there was no idea of operating.

Dr. Gee, in reply, said he had not seen the patient during life. He had been admitted during holiday time, and the case was not fully investigated. He did not know if he had ever passed blood or stone during life. His account was defective, but he was anxious to put the case on record.

Dr. T. Snow Beck read a communication from Sir William Jenner, Bart., on a case of Fatty Degeneration of the Contractile Tissue of the Uterus, with some Remarks on the Nature of the Cauliflower Excrescence of the Os Uteri. The following case was first seen in October, 1871:—A spinster, aged 59 years, without any appreciable alteration in her previous good health, and in whom the catamenia had ceased for nine years, was suddenly seized with a gush of blood from the vagina, with a considerable thick, slightly yellow-coloured discharge. This discharge, always worse at night, gradually increased, and became very copious. At first it was thin, serous, and slightly yellow-coloured; afterwards became whitish, slightly yellow or greenish, without any offensive odour until it had existed for about three years. During the fourth year, and especially towards the end, it became very offensive. This discharge was accompanied, at uncertain intervals, with an escape of blood, sometimes so slight as only to colour the discharge red, at other times accompanied by the formation of small coagula. Three or four times a considerable amount of blood was lost, and towards the last severe hæmorrhage occurred. But from the first to the last there was neither ache nor pain present. The appetite became impaired, and ultimately extinguished; the tongue red, coated, and tremulous; the bowels always constipated, pain at the epigastrium after eating, much flatulency, frequent sickness, distressing hot flushes, occasional giddiness, and sleepless nights. There was comparatively little loss of flesh, and nothing in the general appearance to indicate the presence of serious disease. After the affection had existed for three years, the lips of the uterus were found swollen, the external orifice open to admit the end of the finger, and several small fleshy prominences a little within it, which freely poured out blood, of an arterial character, on the slight pressure of the finger during examination. A month later the soft growths protruded through the external orifice; and three months later the upper part of the vagina was filled with a soft pulpy mass, much resembling, to the touch, the fœtal portion of the placenta. The woman became weaker and weaker, and died, four years after the first indication of the disease, by a sudden gush of blood from the vagina. In the examination of the body after death, the uterus was found somewhat enlarged, and the cavities filled with a soft shaggy tissue, which hung down, for about an inch and a half, into the upper part of the vagina, and filled this portion of the canal. With the exception of a thin shell at the fundus, the whole of the contractile or muscular tissue of the uterus was converted into the soft shaggy tissue, which ceased abruptly at the external orifice where the vagina begins. With the aid of the microscope, the contractile fibre-cells at the fundus were seen slightly altered; lower down they contained in their substance a varying amount of fat-globules; still lower down, all form of the contractile fibre-cell was lost, and, instead, collections of large-sized fat globules mixed with diffluent tissue were seen; and at the lowest portion it consisted of structureless diffluent tissue mixed with the numerous and various-sized fat-globules. The symptoms in this case closely resembled those given by Sir Charles M. Clarke as indicating the presence of

cauliflower excrescence of the os uteri, yet differed from them in some material points. Cauliflower excrescence was described as being attached to the surface of the os uteri—never extending into the cavity of the uterus,—being sometimes so large as to fill the vagina and project through the labia, when it was of a bright flesh-colour. It might be completely cured by excision, or even by the assiduous use of local astringents, and had proved fatal at the early age of twenty; whilst in the case recorded the disease was essentially one involving the cavity of the uterus, was most probably incurable, and probably only met with after the middle period of life. The preparation of cauliflower excrescence of the os uteri preserved in the Museum of the Royal College of Physicians, presented by Sir Charles M. Clarke in 1829, was examined This preparation was found to be one of those villous growths which spring from the surface of mucous membranes, well known under the name of "papilloma." Cauliflower excrescence of the os uteri, as shown in this preparation, was essentially distinct from the fatty degeneration of the contractile tissue in the previous case, and also distinct from any forms of malignant disease—cauliflower excrescence consisting, in the words of Professor Rindfleisch, "of a number of arborescent groups of villi, and of nothing else," and "having nothing whatever to do with cancer."(a) A case of cauliflower excrescence of the os uteri recorded by Sir James Y. Simpson was referred to; also seven cases reported under the name of cauliflower excrescence by Dr. J. Braxton Hicks.(b) But those cases recorded by Dr. Hicks did not present any of the characteristic symptoms of cauliflower excrescence; and were examples, not unfrequently met with, of "encephalomatous" and other malignant disease of the lower portion of the uterus, attended with the usual severe pains and offensive discharge of these diseases.

Mr. Arnott had seen two or three portions of the so-called cauliflower excrescence removed for examination. He found only a villous outgrowth covered with epithelium, which last was readily shed after soaking in alcohol, and gave the growth a leaflet-like appearance. Sometimes malignant growths of the os threw out villous excrescences, but these were not to be confounded with the cauliflower excrescence. This was a true papilloma, and malignant only by virtue of its discharge of blood, and consequent drain on the system.

Dr. Routh said the disease ordinarily called cauliflower excrescence was not the same as that described by Sir Charles Clarke. In the ordinary form the base is hard, and it is distinctly malignant. The symptoms were by no means characteristic. The growths were, he thought, epitheliomatous; but the patient got well if they were snipped away and caustics applied.

Dr. Snow Beck said the hæmorrhage came in gushes; beyond this there was neither ache nor pain. Sir Charles Clarke's specimen was evidently a papilloma.

THE PATHOLOGICAL SOCIETY.

Friday, November 18.

Dr. Dickinson, Vice-President, in the Chair.

Mr. Kesteven exhibited Sections from the Spinal Cord of a case of Paralysis in which the symptoms were bilateral and affecting both upper and lower extremities, but in which the lesion was found to be unilateral. The grey substance on the left side was throughout the length of the cord, up to the medulla oblongata, smaller than the right, and its constituent parts had undergone varying phases of atrophy. This was very strongly shown about the middle of the dorsal region. In rather more than an inch of its extent the anterior horn was atrophied and had so lost its normal shape as to appear simply a mere narrow curve of grey matter. The multipolar cells were also small, misshapen, and granular. The cut ends of the nerve tubes in the white columns on the left side showed also this same condition of atrophy when contrasted with those of the right side.

The Chairman thought the term reflex had been wrongly used, inasmuch as there were well-defined alterations in the cord.

Dr. Murchison was about to ask why the term reflex was used. The changes in the cord were quite enough to account for the symptoms.

(a) "Manual of Pathological Histology," p. 454.
(b) "Guy's Hospital Reports," vol. vii., p. 245.

Mr. Kesteven quite agreed, but read the paper as sent to him. He considered the change a subacute inflammation.

Mr. Pugin Thornton exhibited two specimens of Cancer of the Œsophagus taken from cases which had been under Dr. Morell-Mackenzie's care at the Throat Hospital. In the first case—that of a woman aged 31, the carcinoma had extended into the trachea, and during the last few weeks of her life had caused complete aphagia. Her symptoms had commenced about July of the present year, and she died October 20. She had suffered from an enlarged thyroid gland, which after a month's treatment by injections of iodine had been reduced three-quarters of an inch. The post-mortem showed the thyroid gland to be enlarged, the lobes embracing the œsophagus from the cricoid cartilage to the tenth ring of the trachea, the canal between these situations being obliterated by a new formation, the centre portion of it projecting into the trachea, forming a growth of the size of a hazel-nut. In the second case the carcinoma was situated at the orifice of the œsophagus, and had been followed by a cervical fistula. The patient, a woman aged 42, had experienced uneasiness in swallowing in January, 1873. This trouble increased, and in April she could only at times take a little minced meat, and that occasionally brought on hæmorrhage. The laryngoscope showed a growth, extensively ulcerated, springing from the lower part of the posterior wall of the pharynx, blocking up the œsophagus, and covering the arytenoid cartilages. She grew rapidly worse. An abscess formed on the right side of the neck, through which, after it had burst, all the food she took passed. She died on October 23. A growth after death was found arising from the posterior wall of the pharynx above the level of the epiglottis to below the cricoid cartilage, forming a very tight stricture for a distance of half an inch at its lower part. There were also large masses on each side of the pharynx, which pressed the arytenoid cartilages forwards towards the epiglottis. A fistula near the cricoid cartilage, large enough to admit the little finger, passed forwards to the right side of the neck. The left lung had numerous strong adhesions; otherwise all the internal organs were healthy. Both these specimens had been examined by Dr. Gowers, and pronounced to be epitheliomatous. The tissues of the thyroid gland in the first case were normal.

Mr. John Wood next showed a specimen of Cancer of the Male Breast in a patient aged 68. It had been growing nine months, and began as a hard lump near the nipple. It became lobulated, and the nipple was drawn in. About three weeks ago some hæmorrhage occurred from the nipple, and the growth seemed to take a fresh start. When removed, section showed it to be a hard cancer with dilated canals filled with blood. Cancer of the male breast was rare; Sir W. Fergusson had seen three cases, but they were not all scirrhus.

Mr. Hulke had seen three examples, all scirrhus.

Dr. Cayley asked if there was the same tendency to recur and to infect the system as in the female.

Mr. Goodhart asked the microscopic structure.

Mr. Hulke said that in one of his cases the behaviour of the tumour was just as in the female breast.

Mr. Goodhart showed a specimen of Mediastinal Tumour, from a patient the subject of exophthalmic goître. No history could be obtained, as the patient (a woman aged 26) died under chloroform. There was general enlargement of the lymphatics, and the thymus was enlarged; so, too, was the thyroid, and its veins were dilated. From it a mass of gland tissue ran down the neck to the pericardium. It seemed a kind of outgrowth of the connective tissue in the mediastinum. A large ganglion of the sympathetic was examined and found healthy, but its capsule was thickened. The heart was rather thick. He thought enlargement of the thymus at such an age rare. Another instance in exophthalmic goître was recorded. He considered the malady due to an intracranial neurosis.

Mr. Arnott asked for evidence on this point, but there was none.

Dr. Crisp asked if the blood had been examined for white blood-corpuscles.

Dr. Powell asked if there was any difficulty in separating the thymus. He had shown a specimen where there was much greater thickening and adhesion.

Dr. Gibbon thought the malady due to a blood, not a nerve, change.

Mr. Goodhart had not examined the blood. The thymus was encapsulated. There was nothing in the orbit.

Dr. Dickinson said he also had failed to find anything unusual in the orbit in such cases.

Mr. Butlin showed a specimen of Nerve illustrating the

Effects of Former Injury. The patient, a male, died of a broken back. Fourteen years before, he had been wounded in the arm; he consequently lost all sensation in its inner side, but after a time partly recovered. The hand wasted on the ulnar aspect, and the nerve was found atrophied. There was no connexion between its upper and lower portions. In the central portion the nerve fibres were found normal, but hardly any were to be seen in the peripheral division. Both ends were bulbous, and some distance apart—the upper three-quarters of an inch above the point of section. In reply to Mr. W. Tay, he said no difference in temperature had been noted; and to Mr. John Wood, that it was not observed whether the communication between the median and ulnar was enlarged.

Dr. Broadbent said such a renewal of sensation had been noticed in other cases. There seemed to be some means of conveying sensation from points near the divided nerve.

Dr. G. Harley said that if one axis cylinder remained, that was quite enough; and if one was found, it was probable that many more escaped notice.

Mr. Butlin said sensation returned in about six months. He thought finding an axis cylinder was not enough; we should also find the mode of communication.

Mr. Kesteven then exhibited Sections from the Brain and Spinal Cord of a case of Puerperal Mania. In this case a very remarkable lesion was found. The horns of the grey matter were throughout smaller on the right than on the left side; but in the dorsal region for about the extent of a third of an inch there was observable an absence of the cells of the posterior vesicular columns. Above and below this point, for about half an inch each way, the cells gradually reappeared until the columns presented their normal characters. The person from whom this cord had been removed had been the subject of repeated attacks of puerperal mania, through which Mr. Kesteven had attended her, and in the last of which she had died from exhaustion. She had never shown any evidence of disease that could be referred specially to the spinal cord. The brain of this patient, a section of which was on the table, exhibited a great abundance of points of miliary sclerosis, varying in size from $\frac{1}{300}$th to $\frac{1}{800}$th of an inch in diameter, crowded together to the extent of between three and four thousand to the inch.

Mr. Kesteven also exhibited a brain he had received from Mr. H. P. Harris, of Mildenhall, Suffolk. It had been removed from the head of a boy who had fallen from the top of a cartload of straw, having in his hand at the time a hayfork with the tines upward. One of the tines entered the head, an inch behind, and on a level with, the lobe of the left ear, passing upwards and backwards its whole length. It was with difficulty withdrawn by a fellow-workman, and its point found to be bent upon itself to the extent of two inches. No other wound was made than that caused by the entrance of the fork. Some blood was lost, and he vomited before the arrival of the surgeon, three-quarters of an hour after the accident. He was lying on his side with his legs drawn up, and was cold and almost pulseless. He was unconscious, and could be roused only to indistinct mutterings. About a teaspoonful of brain substance had escaped from the wound during the act of vomiting. The principal subsequent symptoms and results were—unconsciousness, convulsions, opisthotonus, paralysis of the sphincters, partial temporary recovery of consciousness, exhaustion, and death on the ninth day after the accident. The fork had passed through the edge of the left lobe of the cerebellum, and had ploughed its way through the left hemisphere of the brain, driving before it a fragment of the occipital bone.

Dr. Crisp asked if there was any special symptom due to injury to the cerebellum.

Mr. Kesteven said the only symptoms were opisthotonus and convulsions.

Dr. Dickinson said that the so-called miliary sclerosis of the brain was often due to preserving the specimens in spirit. They even presented crystals.

Mr. Kesteven said he had often seen these scleroses, however the specimen was preserved.

Dr. Crisp showed a Cast of the Crop of a Cock, which had become enormously distended. He opened it, and the opening did not heal. The animal wasted, and was killed. The obstruction lay between the stomach and gizzard, in the form of a piece of ligamentum nuchæ from some Australian meat. In another cock was a traumatic aneurism from a pin, which had penetrated the gastric artery, and seemed to give rise to no inconvenience.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, November 5.

E. J. Tilt, M.D., President, in the Chair.

Dr. Playfair exhibited a specimen of Malignant Sarcoma, apparently originating in the right broad ligament, but which at death nearly filled the whole abdominal cavity. The points of interest in the case appeared to be—first, the difficulty and obscurity of the diagnosis during pregnancy, there being nothing in the physical condition of the patient to cause the least suspicion of the real nature of the tumour; secondly, the extremely rapid growth of the tumour after delivery. This pointed to the probability of the growth having been kept in abeyance, as it were, possibly by the presence of the gravid uterus.

Dr. Wiltshire thought the case might be an example of a polypoid growth arising from a clot which had become organised.

Dr. Playfair exhibited a specimen of Necrosis of the Pubic Bones following delivery, which, he said, was a form of puerperal disease of extreme rarity. Three weeks after labour an abscess burst at the anterior portion of the left labium, and a highly offensive discharge came from the vagina. The upper part of the thigh became œdematous. An incision was made, from which bad-smelling pus was evacuated. The patient soon after died from exhaustion. The ossa pubes were found necrosed, and the symphysis destroyed. Dr. Playfair thought the disease originated in some obscure form of septicæmia, rather than in a purely mechanical cause.

Dr. Aveling asked if the measurements of the pelvis were taken. From the bones exhibited he thought it must have been below the normal size. If this were the case, inflammation might have been set up in the symphysis in consequence of mechanical disturbance taking place during delivery.

Dr. Routh asked if the patient had received any blow on the pelvis before confinement.

Dr. Meadows and Dr. Squarey stated that they had seen similar cases.

Dr. Hayes asked if the case began with the ordinary symptoms of puerperal fever.

After some remarks by Drs. Grigs and Wiltshire, Dr. Playfair replied he had not measured the pelvis, as it appeared to him of the usual size. There was no history of the patient having received a blow.

Dr. Aveling exhibited a New Instrument, which he called a "Loop Saw," which he believed might be used with ease and advantage in some cases where the écraseur was at present employed. It consists of two tubes, with pulleys at the upper end, over which a loop of whipcord or chain works. The two tubes are united by a hinge at the handles, and the tumour is divided by drawing alternately upon the ends of the cord. As the loop divided the tissues from below upward, there was no passing of the cord over the tumour, as was the case with the écraseur.

Dr. Squarey read a note on the Cure of Flexions of the Uterus by Flexible Stems. The author had been induced to try the curative effects of flexible stems, in consequence of his belief that inflammation was sometimes set up by stems which were rigid. His stem speedily cured pain resulting from the retention of the catamenial discharge, and the removal of this pain had a curative effect upon flexions. There seemed a natural tendency to recovery when the most troublesome symptoms were removed.

Dr. Aveling stated that he had exhibited to the Society in 1866 a flexible intra-uterine stem of coiled wire, and suggested that Dr. Squarey's instrument might be improved by the introduction of a coil inside the indiarubber. It would then have the power of straightening in the uterus, which it at present lacked.

Dr. Rogers said that he had found great use from the employment of flexible stems.

Dr. Routh hoped he would have the opportunity of entering upon the whole question at the next meeting.

Dr. Heywood Smith thought it best to use stiff stems, and keep patients quiet until they could bear them.

Dr. Playfair could not understand how a stem which adapted itself to flexed conditions of the uterus could have a curative effect.

Dr. Godson had seen great relief given by the use of flexible stems similar to Dr. Squarey's.

Dr. Farr read a paper communicated by Dr. Block on a Case of Spontaneous Salivation associated with Pregnancy. The mother of four children, pregnant for the fifth time, suffered from such excessive salivation that it was considered necessary to propose the induction of premature labour. The symptoms, however, suddenly abated upon the occurrence of quickening, and the patient speedily regained strength and required no further medical treatment.

Dr. Alfred Wiltshire read a paper on the Common Skin Diseases of Children. The forms of skin disease described were of two classes—parasitic and inflammatory; scabies and ringworm in the former, and erythema, eczema, and impetigo in the latter. The author dwelt on the importance of looking to the general health in the parasitic skin diseases, as well as to the local treatment. He also pointed out that the seats of eruption in the infant and little child varied somewhat, and explained why. The treatment thought most appropriate was indicated. Stress was laid on the importance of diagnosing the superadded skin affections in the parasitic forms—such as urticaria, eczema, ecthyma, etc., from the eruption proper to the parasite. With reference to the inflammatory skin diseases, it was pointed out that much clearer ideas of the pathology of the various forms of eczema, erythema, and impetigo were gained by regarding them all as varieties of dermatitis. The clinical and diagnostic features of each variety were detailed, and remarks were made on some peculiarities as regards these affections in children. The paper concluded with practical remarks on treatment.

Dr. Cleveland remarked upon the necessity of attending to the general health. Local remedies without this were often useless. He had found arsenic useful in scabies, exposure to the air and a solution of nitrate of silver in impetigo. With regard to eczema, he had found arsenic and zinc ointment useful.

Dr. Rasch had seen many cases of itch amongst the Polish Jews, who were very dirty; they had it all over their bodies, and whole families were smitten with it. He had never given anything internally for it, having found external treatment perfectly satisfactory.

Dr. Hayes said that he had always found sulphur ointment would cure any case of itch.

Dr. Phillips remarked that he did not think constitutional remedies were necessary in itch. The importance of recognising the influence of improper food in producing eczema should not be overlooked. Now we had a national education plan, he thought we ought to have some elementary teaching in physiology. We could not expect to have decreased mortality among children until women knew how to feed them.

Dr. Wiltshire agreed with Dr. Cleveland's views as to the necessity for constitutional treatment. Arsenic was of most use in chronic eczema.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH, IRELAND.—Nov. 24.

(Before the Lord Chief Justice, Mr. Justice O'Brien, and Mr. Justice Fitzgerald.)

Lawlor *v.* Alton.

This case was specially stated for the opinion of the Court. An election took place for the post of surgeon to the County Kerry Infirmary, in July, 1869. Three candidates appeared—Dr. Lawlor, Dr. Alton, and Dr. Fitzmaurice. Twelve governors were present, six of whom voted for Dr. Lawlor, four for Dr. Alton, and two for Dr. Fitzmaurice. The last-mentioned gentleman's name was then struck out, and on a vote being again taken, six voted for each candidate. A casting vote was given by the chairman in favour of Dr. Alton, who was accordingly declared elected. Dr. Lawlor subsequently applied in the Queen's Bench for a *quo warranto* to test the validity of the election, contending that Dr. Alton was not properly qualified, inasmuch as he had not letters testimonial from the College of Surgeons in Ireland. The Court held that this objection was good, and that Dr. Alton was not properly qualified on account of the absence of letters testimonial. Dr. Alton having, pending the proceedings in the Queen's Bench, exercised the duties of the office, the grand jury presented him with £47. Dr. Lawlor then brought an action against Dr. Alton for having had and received the money, and claimed the £47. The question now for the Court was whether Dr. Lawlor was entitled to recover the £47. The Court decided in favour of the plaintiff, but on the money count for the defendant. Counsel for plaintiff—Mr. Murphy, Q.C., and Mr. Hickson; for the defendant—Mr. Gerald Fitzgibbon, Q.C., and Mr. P. O'Brien.

NEW INVENTIONS.

EXTRACT OF ENGLISH BEEF.

We have received from Messrs. Harvey and Reynolds, of Leeds, some specimens of extract of beef, prepared according to Liebig's process, which are of great excellence. Their extract makes very palatable beef-tea, and it will bear the test of being eaten cold with a biscuit. It has a full flavour of fresh meat. Patients, we can assert, take it readily; and as far as we have been able to judge from the trials we have made with it, it is a valuable addition to the dietary of the sick-room. Messrs. Harvey and Reynolds inform us that it is made from the best English beef, from which they maintain a far better extract can be obtained than from the beef of South America or Australia. Hay-fed beef does not yield so good an extract as grass-fed, and it seems only reasonable to believe that the succulent pastures of England would produce a finer kind of meat extract than the plains of a hotter and drier country. Messrs. Harvey and Reynolds assert that comparisons they have made between extracts prepared by their own process from Australian beef and the extract of English beef fully support this opinion.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 27:—

Redmond, John, York Town, Surrey.
Travers, Otho Robert, Cheam.
Turnell, Arthur Pythias, Brixworth, Northamptonshire.
White, James Benjamin Kelly, Whitechapel, E.
Whitten, William John, Commercial-road, E.

The following gentlemen also on the same day passed their primary professional examination:—

Barlow, Thomas Carey, of Guy's Hospital.
James, Walter Culver, of Guy's Hospital.
Hames, George Henry, of St. Bartholomew's Hospital.
Makins, George Henry, of St. Thomas's Hospital.
Paxon, Herbert Elliott, of the London Hospital.
Pettigrew, Augustus Joseph W., of St. Thomas's Hospital.
Snook, William Ernest, of Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Atkins, Francis Thomas, M.R.C.S., L.R.C.P. Edin., L.S.A.—House-Surgeon at the Kent and Canterbury Hospital.

Chestnutt, Joseph Wallace, B.A., M.D., L.R.C.S. Edin.—Medical Officer for the Ahoghill Dispensary District of Ballymena Union, co. Antrim.

Maunder, Charles F., F.R.C.S. Eng.—Consulting Surgeon to the Merchant Seamen's Orphan Asylum, Snaresbrook, *vice* Mr. Startin, deceased.

Robertson, William, M.D.—Medical Officer for the Whittingham District of Rothbury Union, Northumberland.

NAVAL APPOINTMENTS.

Admiralty.—In accordance with the provisions of her Majesty's Order in Council of February 22, 1870, Staff-Surgeon of the second class Frederick Piercy has been placed on the retired list from the 22nd inst.

BIRTHS.

Mactier.—On November 25, at Strone House, Blairgowrie, Perthshire, the wife of W. F. Mactier, M.D., late Bengal Medical Service, of a son.

Myers.—On October 2, at Cheefoo, North China, the wife of Wykeham Myers, M.B., C.M., of a daughter.

Watson.—On November 26, at Little Huthwaite, Wortley, near Sheffield, the wife of Alfred M. Watson, M.D., of a daughter.

MARRIAGES.

Bell—Ringwood.—On November 29, at Leney Church, Westmeath, John Albert Bell, M.R.C.S. Eng., L.S.A., Rochester, to Anne Selina, eldest daughter of the late Rev. John Ringwood.

Brock—Robinson.—On September 11, at New South Wales, F. Aungier Brock, son of Frederick G. Brock, Esq., of Shortlands, Kent, to Bessie Fraser, daughter of J. Robinson, M.D., late of Aberdeen.

Burroughs—Warren.—On December 1, at All Saints' Church, Finchley-road, N.W., George Edward Elton Burroughs, L.K.Q.C.P., L.M., M.R.C.S. Eng., L.S.A., of Prees, Shropshire, only son of G. F. Burroughs, Esq., of Battersea-park, S.W., to Frances Mary Anne Bramley (Fannie), only daughter of the late Henry Warren, Esq., of St. John's-wood, and Morda, Oswestry.

CUMMING—BAILLIE.—On November 25, at St. Jude's Church, South Kensington, William Gordon Cumming, Esq., Captain Royal Engineers, third son of the late G. W. Cumming, M.D., Madras Army, to Grizel Mary, second daughter of the late William Robert Baillie, Esq., W.S., Edinburgh.

EDGER—LUCAS.—On November 29, at St. Giles's Church, Oxford, Alfred J. M. Edger, son of John W. Edger, M.D., L.S.A., of Kirkby Stepheu, Westmoreland, to Amelia, third daughter of the late W. Lucas, Esq., of Oxford.

GRAY—HULL.—On November 6, at Benares, Surgeon-Major R. Gray, H.M.'s Bengal Medical Service, Civil Surgeon, Mooltan, to Alicia Dawson, youngest daughter of the Rev. John Dawson Hull, Vicar of Wickhambrook, Suffolk.

HALPIN—MONSELL.—On November 27, at the British Embassy, Brussels, Druitt, only son of the late Charles Halpin, M.D., Cavan, Ireland, to Catherine Georgina, only surviving daughter of the late Wm. Monsell, Esq., Windsor.

NIXON—WOODWARD.—On November 27, (chorally), at the Church of St. Mary Magdalene, St. Leonard's-on-Sea, Henry Cotton Nixou, of Mostyn, St. Leonard's-on-Sea, youngest son of the late Henry George Nixon, Esq., of Canterbury-place, London, to Alice Mary, only surviving child of the late Thomas Charles Woodward, M.R.C.S., of Penton Mewsey, Hants.

SKENE—ROBINS.—On November 27, at St. John's, Buckhurst-hill, William Skene, M.D., F.F.P.S.E., to Eleanor, third daughter of C. T. Robins, Esq., of King's-place House, Buckhurst-hill, Essex.

SLADDEN—POTTER.—On November 26, at St. John's, Lewisham-road, Francis Nixon, third son of the late John Sladden, M.R.C.S. Eng., L.S.A., of Ash-next-Sandwich, to Edith, third daughter of the late Robert Potter, of Shepherdswell, Dover.

SYME—ATHERTON.—On November 27, at the Church of St. Michael and All Angels, Paddington, James Syme, son of the late Professor Syme, Surgeon-in-Ordinary to the Queen in Scotland, to Jessie Annie, fourth daughter of the late Sir William Atherton, M.P., her Majesty's Attorney-General, and granddaughter of T. J. Hall, Esq., late Chief Stipendiary Magistrate.

WHITTY—NELSON.—On November 27, at Holme-next-the-Sea, Norfolk, Charles Richard Whitty, B.A., M.B., C.M., of St. Edmund's, Hunstanton, son of the Rev. David La Touche Whitty, to Annie, eldest daughter of Matthew Nelson, Esq., of Holme.

WILSON—SHEPPERSON.—On November 26, at St. Thomas's Church, Ponder's Bridge, Whittlesea, J. Mitchell Wilson, M.B., Chatteris, to Mary Ann, only daughter of W. Shepperson, Esq., of Underwoods, Whittlesea.

DEATHS.

BURGESS, FANNY, wife of F. J. Burgess, L.R.C.P., F.R.C.S. Eng., L.S.A., at 254, Bethnal-green-road, on November 27.

CROSS, WILLIAM, M.R.C.S. Eng., Medical Officer at the Sand Heads, at Calcutta, on October 25, aged 57.

HENSMAN, WILLIAM VALENTINE PATRICK, son of Surgeon William Hensman, 14th Hussars, at the Royal Barracks, Dublin, on November 17, aged 3 years and 9 months.

MCTERNAN, JAMES, Deputy Inspector-General of Hospitals R.N., at Blackheath, on November 26, in his 83rd year.

MEREDITH, HELEN, widow of the late E. T. Meredith, M.R.C.S., L.S.A., at 3, Darlington-street, Bath, on November 29, aged 69.

MURIEL, SUSAN, the beloved wife of J. Muriel, F.R.C.S., L.S.A., J.P., D.L., at Ely, Cambridgeshire, on November 27.

RICHARDS, DINAH, widow of the late Joseph Richards, M.R.C.S. Eng., L.S.A., formerly of St. Clement's Danes, at 17, Oxford-terrace, Islington, on December 1, aged 70.

WAUGH, ARTHUR, eldest son of John Neil Waugh, M.D., M.R.C.S. Eng., L.S.A., at Brisbane, on September 7, in the 5th year of his age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BEDFORD GENERAL INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Committee, on or before December 10.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. of Great Britain or Ireland. Applications, with testimonials, to the Chairman of the Medical Committee, Temple-row, Birmingham, on or before December 20.

BRISTOL ROYAL INFIRMARY.—Assistant House-Surgeon. Candidates must be F. or M.R.C.S., or M.S., and also possess medical qualifications.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Two Assistant-Surgeons. Candidates must be F. or M.R.C.S. Applications, with testimonials, to the Secretary, on or before December 9.

CHELSEA.—Resident Medical Officer for the New Infirmary and Workhouse. Candidates must be duly qualified and registered. Applications, with testimonials, to W. Miller, Clerk to the Guardians, Arthur-street, Chelsea, on or before December 10.

CONWAY UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Wm. Hughes, Clerk to the Guardians, on or before December 10.

GAINSBOROUGH.—Medical Officer of Health. Candidates must be legally qualified medical practitioners and registered. Applications, with testimonials, to the Clerk of the Union, on or before December 8.

GERMAN HOSPITAL, DALSTON.—Honorary Medical Officer to the Eastern Dispensary. Candidates must be natives of Germany and be duly qualified. Applications, with testimonials, to Dr. Walbaum, Hon. Secretary, on or before December 29.

GENERAL HOSPITAL, NOTTINGHAM.—Physician. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before March 10, 1874.

KENT COUNTY LUNATIC ASYLUM, BARMING HEATH, MAIDSTONE.—Two Assistant Medical Officers. Applications, with testimonials, to Messrs. Beale and Hoar, Maidstone, before December 10.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Assistant-Surgeons. Applications, with testimonials, to P. Goldschmidt, Esq., 100, Albert-square, Manchester.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, of whom particulars may be obtained.

ST. GEORGE'S (HANOVER-SQUARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before December 29.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

TEWKESBURY UNION, FORTHAMPTON DISTRICT.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to George Budham, Clerk to the Guardians, on or before December 16.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser. Applications, with testimonials, to the Honorary Secretary, Exe Villa, Tiverton, Devon.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Driffield Union.—Mr. A. Moore has resigned the Weaverthorpe District; area 14,430; population 1676; salary £30 per annum.

Halstead Union.—Mr. E. Andrews has resigned the Fifth District; area 7700; population 3251.

Hartley Wintney Union.—Mr. T. A. Freeman has resigned the Hartley-Wintney District; area 10,075; population 3480; salary £60 per annum; and the Workhouse, salary £40 per annum.

Smallburgh Union.—Mr. E. Meade has resigned the Barton District; area 10,841; population 2574; salary £40 per annum.

Tewkesbury Union.—The Forthampton District is vacant; area 8297; population 1912; salary £55 per annum.

APPOINTMENTS.

Chesterton Union.—Joshua S. Grubb, L.R.C.S. Ire., L.R.C.P. Edin., to the Waterbeach District.

Denbighshire.—Mr. John Jones Bancroft, as Analyst for the County.

Plomesgate Union.—Henry J. Robbins, M.B., C.M. Aber., L.S.A., to the Aldborough District.

Stroud Union.—Richard C. Gardner, L.R.C.P. Edin., L.F.P. and S. Glasg., to the Sixth District.

ROYAL COLLEGE OF SURGEONS.—At the examinations for the Fellowship which were brought to a close on Saturday last, ten candidates offered themselves, all of whom were members of the College; of this number only five were successful. The list cannot, however, be published until submitted for confirmation to the Council on Thursday next. The following were the questions on Pathology, Therapeutics, and Surgery at the written examination; all the questions were required to be answered:—1. Give the different forms of stricture of the œsophagus, and their usual seat; and describe the symptoms, diagnosis, and treatment of each form. 2. What are the causes of, and pathological changes occurring in spontaneous gangrene, say of the foot? Describe the process of natural separation of the gangrenous part, and the subsequent repair. 3. State what you understand by the term "cancer." In the examination of a tumour recently removed, describe fully the characters by which you would be led to the conclusion that it is cancer. 4. A man receives a punctured wound in the middle of the anterior part of the thigh, followed by profuse arterial hæmorrhage. The external bleeding is arrested by pressure, but the thigh becomes rapidly distended and tense. What condition does this indicate? What course is the case likely to take? and what treatment would you adopt for the sequences of this injury at their different stages?

ARTS EXAMINATION.—The half-yearly examinations in Arts, etc., for the diplomas of Fellowship and Membership of the Royal College of Surgeons, will commence at Burlington House on Tuesday next, and be carried on through the week: it is stated that there are 71 candidates for the Fellowship, and 188 for the Membership.

MR. SYDENHAM J. KNOTT has been appointed Medical Tutor and Curator to St. Mary's Hospital Medical School, and Superintendent of Galvanism to the Hospital. The office of Resident Registrar and Chloroformist to the Hospital (which Mr. Knott has held for the last four years) thus becomes vacant.

THE Burton-on-Trent, Lichfield, and Peakridge Rural, and the Lichfield and Rugeley Urban, Sanitary Authorities propose to appoint a medical officer of health jointly.

School of Physic, Trinity College.—The Haughton Clinical Prize Medals for the session of 1872-73 were awarded to Mr. James W. Eakin in medicine, and to Mr. Charles Young in surgery. Dr. John Barton, House-Surgeon to Sir P. Dun's Hospital, has been appointed to the Demonstratorship of Anatomy in the School, vacant by the appointment of Dr. T. E. Little as University Anatomist.

Typhoid fever is very prevalent at Stretford, Manchester.

We regret to notice a report that Dr. Gore, an Army Medical Officer, has been wounded in the recent operations against the Ashantees.

Typhoid fever has been for some weeks past prevalent in some of the colleges at Cambridge, and the epidemic is increasing. The students are leaving several of the colleges in large numbers.

There were 1585 deaths in London last week, being 105 below the average. Of these 121 were from measles.

Mr. Sharman, the Medical Officer of Norwood Schools and of Norwood Out-relief District, has had his salary increased from £100 to £125 per annum.

Notwithstanding the precautions taken by the Holborn Guardians for preventing the spread of ophthalmia in the Mitcham Schools, the disease still continues very prevalent.

The Hospital Sunday collections in Melbourne this year amounted to about £4000.

An examination for eighteen appointments as Surgeon in the Indian Medical Service will be held in London in February, 1874. Copies of the regulations for the examination may be obtained on written application to the Military Secretary, India Office.

Académie des Sciences.—At the meeting of the Academy on November 24, Professor Williamson was elected Corresponding Member in the Section of Chemistry, the whole of the forty-four members who were present voting for him.

Dr. Frankland, in his report on the quality of the water delivered during November by the metropolitan companies drawing their supplies from the Thames, states that it was greatly inferior to that delivered in October. The water distributed by the Chelsea and Lambeth Companies, and by the Grand Junction Company in a lesser degree, was polluted, owing to inefficient filtration. The New River and East London Companies' water was greatly superior to the Thames water, and it was efficiently filtered.

A Quarterly Court of the Governors of the Hospital for Consumption and Diseases of the Chest at Brompton was held last week. The report of the Committee of Management stated that the works for the extension of the Hospital were progressing satisfactorily; that two more of the houses opposite to the Hospital were being fitted up as wards for male patients, and would be brought into use as soon as ready. The number of patients admitted since August 7 was 262; discharged (many greatly benefited), 229; died, 30; new out-patient cases, 3380.

Condensed Swiss Milk is in our opinion one of the most valuable foods for infants. We have tried it in numerous instances, and have never found it produce the bad effects so often referable to the use of ordinary cows' milk, even when diluted and sweetened. Messrs. Kaltenbach and Schmitz have submitted for our opinion a specimen of their "Alpina" Swiss condensed milk. It is a very good specimen of milk thus prepared. It has preserved the flavour of fresh milk in a higher degree than most condensed milks we have seen, and it is scarcely so thick and paste-like in consistence. We think it would be well adapted for use in the nursery or sick-room.

Royal Institution of Great Britain.—At the general monthly meeting, held on Monday, December 1, George Busk, Esq., F.R.S., Treasurer and Vice-President, in the chair, the following letter to the family of the late President was unanimously adopted by the members present:—"The members of the Royal Institution beg to be permitted to express to the family of their late President, Sir Henry Holland, their deepest sympathy in the great loss they have recently sustained. It is a loss in which the Institution largely shares; and it has to deplore a President esteemed by all for his distinguished scientific and literary attainments, for the abilities and varied experience he brought to the performance of his duties; and beloved for the uniform kindness and consideration with which he discharged them. In the published record of his life, Sir Henry Holland has ackuowleged that his connexion with the Royal Institution has been very valuable to him. It is now for the members of the Institution to testify their profound sense of the exceeding advantages conferred by that association upon the Royal Institution. In it, as he himself has related, he stood by the cradle of some of the most wonderful discoveries of the age, and watched their progress to maturity and fame. He was one of the earliest to witness the production of the alkaline metals by Davy, and among the first to see the small luminous spark elicited from the magnet by Faraday. In later times he was foremost in establishing the Royal Institution Research Fund, and was unceasingly generous in his own large persoual contributions to it. As President he was always at his post, ever prompt with assistance and counsel; a sound adviser and a courteous friend. The recollection of his presence in the Institution will not soon be forgotten, and will long remain to be cherished by its members with affection and regard. The close of such a career must be noted with no ordinary feelings of interest and regret, and the members of the Royal Institution desire to assure the family of their lamented President how fully they enter into the universal sorrow for his death." The Duke of Northumberland, D.C.L., was unanimously elected President of the Royal Institution, in the room of the late Sir Henry Holland. The following lecture arrangements for the ensuing season were announced:—*Christmas Lectures* (adapted to a juvenile auditory):—Professor Tyndall, D.C.L., LL.D., F.R.S.—Six lectures "On the Motion and Sensation of Sound," on December 27 (Saturday), December 30, 1873; January 1, 3, 6, 8, 1874. *Before Easter*, 1874.—Professor Rutherford, M.D., F.R.S.E.—Eleven lectures "On the Nervous System," on Tuesdays, January 13 to March 24. Professor P. M. Duncan, F.R.S.—Seven lectures "On Palæontology, with reference to Extinct Animals and the Physical Geography of their Time," on Thursdays, January 15 to February 26. Professor W. C. Williamson, F.R.S.—Four lectures "On Cryptogamic Vegetation," on Thursdays, March 5 to 26. Professor G. Croom Robertson, of University College, London.—Four "Lectures on Kant," on Saturdays, January 17, 24, 31, and February 7. R. Bosworth Smith, Esq., M.A.—Four lectures "On Mohammed and Mohammedism," on Saturdays, February 14, 21, 28, and March 7. Charles Thomas Newton, Esq., M.A., Keeper of Greek and Roman Antiquities, British Museum. Three "Lectures on Ephesus," on Saturdays, March 14, 21, and 28.—The Friday Evening Meetings will commence on January 16, at 8 o'clock p.m. The discourse will begin at 9 o'clock. Friday Evening Discourses during the season will probably be given by Professors Tyndall and Sylvester, Sir Julius Benedict, Mr. A. H. Garrod, Dr. Doran, Mr. Vernon Heath, Mr. Francis Galton, Dr. Burdon-Sanderson, M. Cornu, Dr. Carpenter, and Professor Ramsay.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Dr. Drysdale, Port Chalmers.—Enclosure received.

Dr. A. Weber, Tokomairiro.—Enclosure received.

Dr. Sorley, Dunedin.—Enclosure received.

Mr. W. De la Porte, Steiglitz.—Enclosure received.

Country Practitioner.—We cannot advise as to whom you should consult gentlemen pretising in the special department you mention are attached to all the London hospitals.

J. F. B.—The new wing to the Queen's Hospital, Birmingham, was opened on the 7th ult.

Osmond T.—There are, we understand, about fifty medical officers under orders for the West Coast of Africa.

Dr. McM.—There will be a preliminary examination in Arts, etc., next Tuesday. If your son passes the ordeal, he could commence his hospital studies at once, and thus only lose half a session. Address yourself at once to Mr. Trimmer or to Mr. Stone, at the College.

A Senior Student.—Write to Professor Marshall; and if not contrary to any regulations of the Royal Academy, we feel sure he will admit you to his lectures at Burlington House. They are delivered on Mondays and Thursdays.

Associate, King's College, Stockwell.—We believe about £700 or £800 has been subscribed for the portrait of Sir William Fergusson. It is not stated that an engraving of it will be presented to subscribers.

Puerperal Mania and Chorea.

To the Editor of the Medical Times and Gazette.

Sir,—I should feel obliged if some of your readers would refer me to any case of puerperal mania occurring to a subject of chorea, or to any work where such a complication is described. I am, &c., F. W. J.

THE STUDENTS AT ST. THOMAS'S HOSPITAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me space to contradict certain statements made in the *Daily News* of the 2nd, which are absolutely unfounded accusations against the students of this Hospital, and which have been repeated with equally gratuitous comments in other papers. What really occurred was as follows:—At 4 p.m., nearly a hundred students had to go from one lecture theatre to another, passing on their way a room in which an inquest was being held; the lecturer had not arrived, and some noise was made in the theatre while the men were waiting his arrival. After waiting about twenty minutes (the lecturer having been unable to come), the men left the theatre and proceeded down the corridor to the cloak-room prior to leaving the hospital. Not more noise was made than ordinarily occurs under such circumstances. I can positively affirm, having been there, that the statement that the men paraded the corridor in dozens, uttering ear-piercing shouts, cat-calls, groans, etc., is altogether untrue; nor was the noise in the lecture-room, made with any intention of annoying the coroner, as few, if any, of the students were aware that an inquest was being held at the time. I think the coroner has acted with scant courtesy to the authorities of St. Thomas's Hospital, through whose kindness he is permitted to use the room in which he holds his court, and to which he has no manner of right. If he had any complaint, real or imaginary, to make against the students, he should have laid it before the Dean, Dr. Peacock, instead of encouraging the publication of a libel on the conduct of the students here, with but small chance of refutation. I may add that an explanatory letter sent to the *Daily News* was refused insertion. I am, &c.,

St. Thomas's Hospital, December 4. F. HAMILTON PECK.

COMMUNICATIONS have been received from—

A COUNTRY PRACTITIONER; F. W. J.; THE SECRETARY OF THE EPIDEMIOLOGICAL SOCIETY; Mr. R. B. NORMAN, Great Yarmouth; Mr. G. CUTCLIFFE, London; Mr. A. C. FOSTER, Leeds; Dr. LIONEL BEALE, London; Mr. POOLE, London; Mr. G. GASKOIN, London; Mr. J. CHATTO, London; Dr. EDIS, London; Rev. CHARLES DRUITT, Weymouth; Dr. B. FOSTER, Birmingham; Mr. W. D. NAPIER, London; Miss DALTON, Bournemouth; Mr. J. GORHAM, Tunbridge; Mr. B. VINCENT, London; Mr. HENRY LEE, London; Dr. PEACOCK, London; Dr. J. W. MOORE, Dublin; Mr. C. J. CULLINGWORTH, Manchester; Dr. J. S. FORRESTER; Dr. CHEADLE, London; Mr. F. SORDON BROWN, London.

BOOKS RECEIVED—

Barnes's Diseases of Women—Maclachlan and Stewart's Pathological Charts: No. 1, The Brain—The Conservation of Energy, by Professor Balfour Stewart—What to Wear, by Elizabeth Stuart Phelps—Du Massage des Frictions et Manipulations, par N. Laisné—Jeffries on White Sarcomatous Intra-ocular Tumour Enucleation.

PERIODICALS AND NEWSPAPERS RECEIVED—

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·64 in. The highest was 30·01 in. on Tuesday at noon, and the lowest 29·29 in. on Thursday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE ON RUPTURE OF THE AORTIC VALVES FROM ACCIDENT.

DELIVERED AT THE BIRMINGHAM GENERAL HOSPITAL, NOVEMBER 17, 1873.

By BALTHAZAR FOSTER, M.D., F.R.C.P.,
Physician to the Hospital;
Professor of Medicine in Queen's College, Birmingham;
and Consulting-Physician to the West Bromwich District Hospital.

GENTLEMEN,—The case of heart disease to which I wish to call your attention to-day is of much interest, as illustrating one of the rarer causes of valvular incompetency. The man H. was admitted some ten days ago suffering from great dyspnœa, palpitation, and œdema of the legs, with the physical signs of aortic insufficiency. His expression was anxious, face pale, carotid pulsations very distinctly visible, cough frequent and troublesome, with little or no expectoration, respirations 48, radial pulse jerky and thrilling, beating 112 times per minute. On further examination the lung percussion-note was found to be healthy, and the breath-sounds natural anteriorly, but posteriorly there was dulness at both bases, extending as high as the inferior angle of scapula on the left side and into the axilla as far as the heart dulness. Over the dull area the breath-sounds were indistinct, and there was diminished vocal fremitus on the left side. The heart's area of dulness was greatly increased, and extended from the second to the seventh intercostal spaces, and from one inch beyond the right edge of the sternum to the dull pulmonic region outside the nipple-line. There was no distinct apex-beat, but a diffused systolic heaving seen in the fifth, sixth, and seventh intercostal spaces, and in the epigastrium. Auscultation gave the following results:—At the base of the heart there were heard two murmurs—viz., a short blowing, almost flapping, murmur with the first sound, followed by a loud, harsh murmur which replaced the normal second sound. The systolic murmur was heard most distinctly at junction of second right costal cartilage with the sternum and over the midsternum opposite third and fourth ribs. It was not propagated with any distinctness, either along the great vessels or towards the apex. The diastolic murmur was heard loudest at midsternum, opposite the third costal cartilage, was distinct at the ensiform cartilage and at the manubrium sterni, and was audible under both clavicles and in the carotids, replacing the second sound; it was not propagated towards left apex, but was audible down the spine in the interscapular region. At the apex of the heart there was audible a murmur with the first sound, louder and longer than that heard at base, and propagated towards the axilla. The diastolic murmur, so loud at the base, was scarcely audible at the left apex, but became more distinct as the stethoscope approached the ensiform cartilage. The abdomen was rather full, especially in the upper part from the enlarged liver, which extended three finger-breadths below the costal arch, and was tender on pressure. There was also evidently some fluid in the abdominal cavity. The urine was scanty, high-coloured, with a copious deposit of urates and about one quarter of a column of albumen. There was some œdema of the lower limbs.

From these data we concluded that our patient had insufficiency of the aortic valves, with slight aortic obstruction, and secondary insufficiency of the mitral valve, leading to engorgement of the lungs, liver, and general venous system, and to serous effusion into the pleural cavities and peritoneum. The case was regarded at the time of admission as illustrating defective compensation and the supervention of asystoly.

Our next step was to find out, as far as possible, the circumstances which had led to these troubles. His previous history gave us the clue. He had been originally brought up as a jeweller, but some fourteen years ago he enlisted in the Royal Marines, served in India, China, and through the Abyssinian expedition, and then, having completed his first period, asked for his discharge. Throughout the period of his service, as previously, he had enjoyed splendid health; never had syphilis, never had rheumatic fever, and although he drank freely, never suffered from it. After his discharge he returned to Birmingham, and worked for a time at Soho. In February, 1872, he emigrated to America, but, finding no occupation, he enlisted in the American service as a marine. At this time he was in good health, and passed his medical examination as a sound, strong man. His ship was ordered to Valparaiso, and while on the voyage he volunteered to act as cook, and did the baking for the ship's crew (500 men). During the voyage there was some very heavy weather; and one day, on coming up on deck, he was thrown violently forward by a lurch of the ship. He made a great effort to save himself, and partially did so with his right hand by catching hold of the side of the hatchway, but was struck in falling on the left side of the chest. He felt faint and hurt internally, was taken below, and for two days was unable to continue his work. When he resumed it, however, he found the cooking too much for him, and he was obliged to give it up. Shortly afterwards, while on watch one night, and all being quiet, he thought he would lie down on deck. He was much surprised, however, to find that the perfectly horizontal position made his breath, which had been short since the accident, much worse—so bad, indeed, that he was obliged to get up and walk the remainder of his watch. He mentioned this to his medical officer, who examined him, and on his arrival at Valparaiso invalided him, and sent him back to Norfolk Island, whence he was discharged, and sent home to England. On the homeward voyage he was very ill; his legs and body began to swell, and on landing at Liverpool he was sent to hospital. He recovered sufficiently to return to Birmingham in August last, and from then to time of admission (November 7) he has been troubled by cough, shortness of breath, and more or less œdema of his limbs.

From this history, which told of no rheumatism nor other cause of heart mischief, but of perfect health (confirmed by the medical examination for admission to the American service) up to the date of an accident, we could draw but one conclusion—that the aortic insufficiency was primarily due to a tear of the valve segments produced by the fall, or rather by the effort he made to save himself.

For some days after admission he improved a little, and under the use of morphia, given hypodermically, he had more refreshing sleep than he had had for weeks, and his dyspnœa became less urgent. Several attacks of syncope, however, occurred; his stomach refused nourishment; and although for two days these syncopal attacks were averted by the free use of liq. ammoniæ, ether, and brandy, he died quite suddenly early one morning from syncope.

The post-mortem examination was made by the Resident Pathologist, Dr. A. H. Carter. On opening the thorax, the lungs were seen to be widely separated by a very large heart. The pericardium was empty, but each pleural cavity contained serous fluid—the left about a pint, the right less. There was also a moderate quantity of fluid in the peritoneum. Lungs: The right—upper lobe emphysematous; lower lobe nearly solid from large hæmorrhagic extravasation, not very recent, and undergoing inflammatory change. Several smaller and more recent spots of hæmorrhage in same lobe. The left lung had the upper lobe emphysematous, and a recent large wedge-shaped extravasation into lower lobe and anterior angle of lower lobe. The liver was firm, granular, undergoing contraction; weight 47 oz. Kidneys enlarged and congested. Spleen and other viscera healthy. The heart showed a well-marked white patch on anterior surface near apex; all the cavities were full of uniform black blood-clot. Weight of organ when emptied, 18 oz. Both auriculo-ventricular orifices were dilated—the right admitting four fingers and the thumb, the left four fingers. The tricuspid, mitral, and pulmonary valves were healthy, but the papillary muscles of the mitral valve were thinnish and undergoing degenerative changes near their apices. The aortic valves, tested by water, were freely incompetent. When further examined, this incompetency, as you can now see, was found to be due to a rupture of the posterior and right segments at their angles of attachment. The posterior segment was torn down five-sixteenths of an inch at its angle of attachment to the left segment; the other (right) angle of attachment of this segment, together with the neighbouring angle of the right segment, were torn down to almost the same depth (five-sixteenths of an inch). The angle of attachment of the right aortic segment to the left aortic segment was also torn down about one-sixteenth of an inch. The posterior segment, which was the most incompetent, had its right angle of attachment torn towards the corpus arantii, but contracted, thickened, loose, and retroverted towards the ventricle, so as to flap idly in the blood-current. The corresponding half of the right segment was attached to wall of ventricle on a level with the attached part of the posterior segment, and was thickened and sloped obliquely from

the middle of the valve to its attachment. The other half of this segment, although slightly torn down as described above, was healthy and competent. Both the ventricles were greatly dilated, and to a less degree hypertrophied, and their walls were undergoing degeneration. The aortic orifice measured three inches and one-eighth in circumference. The extreme length of the left ventricle was four inches and a half, while its greatest diameter was three inches and a quarter. The walls were three-eighths of an inch thick near apex, eleven-sixteenths of an inch at mid-point, and three-quarters of an inch at base. The aorta showed patches of recent atheroma near valves, but in other parts was healthy.

The phenomena observed during life, and the facts of the man's history, were thus found to be consistent with the conditions discovered after death. The valvular injury was clearly traceable to the accident, and occurred to healthy valves. The few weeks which had elapsed since his medical examination for admission to the American service, as well as his previous good health, strongly corroborate this view. I refer to it because some of you have seen with me tears in valves previously softened by degenerative change. Only last week, indeed, we had a specimen of such a rupture. The tear of a valve previously healthy is much rarer, and has special interest for us in the manner of its occurrence, in the symptoms which it occasions, and the effect it has on the duration of the patient's life. These points will demand our attention later on, but first I wish to make a remark or two on the murmurs we heard in the case of H. The systolic murmur heard at the left apex was due—as was held during life—to regurgitation through the enlarged auriculo-ventricular orifice, and was a necessary consequence of the dilatation of the ventricle, and the weakened and degenerating papillary muscles. The aortic murmurs are explained by the condition of the aortic valves. The systolic murmur was caused by the loose valve segment, which gave the special blowing and flapping character to the murmur. Twice previously in other cases of ruptured valves have I noticed similar characters under similar conditions; and this peculiarity may possibly guide you to a correct opinion in these cases. The diastolic murmur finds its explanation in the utter incompetency of the valves to act as stop-valves. There is only one feature of it on which I would dwell: it is this—the diastolic murmur was not propagated towards the heart's apex, but was propagated towards the ensiform cartilage, and was more audible over the right ventricle than over the left, into which the reflux occurred. This, indeed, is the rule as regards the conduction of diastolic aortic murmurs. Only a few days ago, however, we had a case of aortic insufficiency in which the diastolic murmur was very distinct at the apex—equally, if not more so, than over the ensiform cartilage. How are we to account for this variation? In this last case the post-mortem, as I predicted, showed that the regurgitation took place through *incompetency of the left aortic segment*. The regurgitant blood-column fell on to the upper segment of the mitral valve, as we could prove by experiment after death, and as the thickening of the upper segment of the mitral valve showed it had during life. This, then, as I have several times shown to you in other cases, is the explanation of the conduction of a diastolic aortic murmur to the left apex. It depends on the regurgitation taking place through incompetency of the left aortic segment, either at its posterior angle or through perforation of its curtain. My attention was first called to this by an instance of rupture of this segment through effort (case of M. W.), which you will find described in the *Pathological Transactions*, vol. xviii., p. 49. In that case the diastolic murmur was distinct at the apex, and some observers thought it was generated at the mitral orifice. It was really produced by rupture of the left aortic segment and perforation of its curtain, so that the regurgitant current fell on to the mitral valve, and the murmur was thus carried with the stream so that it was heard in the same position as mitral murmurs usually are. This point, then, I wish you to remember—viz., that an aortic diastolic murmur, propagated to the heart apex, usually means incompetency of the left aortic segment. I believe we may also say that a similar murmur propagated towards the ensiform cartilage indicates incompetency of the right and posterior segments, by which the regurgitant current is thrown more upon the septum of the ventricles. I dwell upon the point because, as we shall see soon, it is not merely a matter of curious diagnosis, but has a possible bearing on the prognosis in this form of valvular defect.

(*To be continued.*)

ORIGINAL COMMUNICATIONS.

ON DIPHTHERIA: WITH ESPECIAL REFERENCE TO A RECENT EPIDEMIC IN ITALY.

By ROBERT HUNTER SEMPLE, M.D., M.R.C.P.L.,
Physician to the Bloomsbury Dispensary.

(*Continued from page* 606.)

Dr. Leopoldo Nesti, who writes from personal experience of the epidemic of diphtheria in and around the city of Florence, especially during the years 1870-71, confirms the general opinion that the disease appears to show a predilection for infancy, although no period of life is really exempt from its attacks. Children from two to six years of age were the chief victims, but above that age a progressive diminution of attacks was noticed up to the age of fifteen, and beyond that period of life the cases became more rare and less fatal. Children at the breast were seldom attacked, but still Dr. Nesti observed some well-marked cases which were followed by death; but he saw none under the age of six months, and those which he did see were almost always in houses where diphtheria had already appeared. He mentions one instance in particular where a child of three years old having died of the disease, his infant brother at the breast, six months old, was attacked two days afterwards, and died also about the third or fourth day. The mother who was suckling the infant was also attacked at the same time, but in her the disease assumed a mild form, and she recovered in five or six days. On the other hand, he saw a case where an infant of six months old was the first of the family attacked, but recovered; and a brother and sister, aged seven and six respectively, took the disease, of which the latter died.

Diphtheria co-existed with the common causes of mortality, as small-pox, measles, and hooping-cough, but the other diseases did not remarkably participate in the diphtheric character except that in the case of surface-wounds there was a great disposition to be covered with diphtheric exudations.

There was no remarkable difference in the sex of those who were attacked, for although at different periods there was sometimes an excess of one sex over the other, yet on the whole there was a perfect equilibrium when the totals were summed up.

The physical constitution and the temperament exerted no influence on the development of the disease, the weak subjects being as liable to the attacks as the robust; but the results were very different, for in the lymphatic, the weak, and the cachectic, and in the scrofulous and in those who were exhausted by previous diseases, the malady ran a more rapid course and was more fatal.

As in the case of the epidemics observed by Bretonneau and Trousseau, and in those of Great Britain, that of Florence sometimes seemed to run here and there into distant districts by leaps (*saltuariamente*) but more generally (as in the case of the former epidemics just mentioned) it invaded the adjoining places. When once it appeared in a street or a house, its victims were almost always multiplied in such a manner that it seemed rather to spread in districts or in groups than in an isolated and indiscriminate manner (*alla spicciolata*). If it appeared in a family it was seldom limited to a single person, but it generally attacked several, either successively or contemporaneously, and sometimes all of those who were of juvenile years. Occasionally only those escaped who happened to be away from home at the time of the visitation. Sometimes when the disease had altogether ceased, it returned, after a long interval and in a different season, to visit the same localities and the same families.

The contagious character of diphtheria has, it is well known, been asserted by some authorities and doubted by others; but Bretonneau and Trousseau have given some striking instances in support of the affirmative side of the question. In the Italian epidemic, Dr. Nesti states that the disease was transmitted by preference to the persons who had most frequent relations with the patients—such as the mother, the grandmother, the friends, the nurses, the servants, and sometimes even the medical attendant himself. He thinks that the disease is propagated in different ways—sometimes by imperceptible emanations, either solid, fluid, or gaseous, proceeding from the patient, and constituting around him a kind of

atmosphere of infection; and sometimes by immediate contact of the products of the diseased mucous membrane, whether expelled in some way or artificially extracted. He thinks that the easiest and most frequent mode of infection is by the vaporous and fluid form of emanation, and that in this case the period of incubation is shorter than when the disease is transmitted by the contact of solid matters. He has observed in many persons who were assisting the patients, and who took every precaution in respect to the expelled matters, that they were attacked by the disease in all probability from having breathed the infected air of the room in which the patients were lying.

Dr. Nesti himself is convinced that he took the disease while assisting a little patient in the last stage of the malady; for while he was engaged in extracting from the fauces the numerous fragments of half-detached and hanging pseudo-membrane which embarrassed the respiration, a violent fit of coughing threw in his face several small pieces of the corrupted and sanious membrane—which, however, did not reach his lips or his mouth. Nevertheless, he felt during a movement of inspiration the pestilential odour of the membranes reach to his throat, and he suddenly thought that he had contracted the disease. The suspicion turned out to be well founded, for scarcely had twenty-four hours elapsed of perfectly good health when he was suddenly seized at bedtime with the preliminary morbid phenomena in the tonsils, which symptoms were, however, removed by treatment on the fifth day.

The fact of a person being once affected with diphtheria did not protect him from subsequent attacks, and Dr. Nesti saw some persons who had suffered in 1871 again seized with the disease the next year. He says, however, that he never saw any relapses among those who had had very severe attacks; but he adds that the reason probably was that the instances were rare of recovery under such circumstances.

A peculiarity which diphtheria shares with some other infectious maladies is the tenacity with which its active principle (whatever that may be) remains attached to certain localities, maintaining its pernicious power in spite of the most diligent attempts at disinfection. Dr. Nesti gives an instance where, in consequence of the death of several persons in a family, a young man was removed by way of precaution; but, being brought back after it was thought that all traces of the disease had disappeared, he was soon attacked with diphtheria and died.

Dr. Nesti gives other instances of a similar kind, and they are entirely in accordance with facts previously observed and recorded by Bretonneau and Trousseau in the French epidemics.

Again, it has been observed that sometimes a person who returned home after visiting infected patients has been attacked with the disease, and has communicated it to others of his family, or to the domestics, and has thus become, as it were, the first source of infection in a locality previously exempt from the scourge. A remarkable instance is given of such an occurrence where a young woman had gone to pay a visit to a relative who was suffering from diphtheria, and, after remaining some time in her company, returned to her family. She was soon seized with the disease in a most aggravated form, and on the fourth day from the attack she died, apparently from suffocation. At the time when her malady was increasing, other persons of the same family were attacked, and all of them in nearly the same manner, so that out of seven cases five died, the eldest victim being nine years old, and the youngest a child at the breast. The father of these children survived, and also a youth of fourteen, who was sent out of the house, yet nevertheless took the disease; but both these survivors remained for some time affected with paralysis of the lower limbs.

The fearful mortality of the recent Italian epidemic is shown not only by the general accounts given by practitioners in various parts of the kingdom, but more especially by the perusal of the official returns published by the Florentine authorities. Many cases occuring in the rural districts of Italy are not tabulated, and, although it appears that Naples has been lately visited very extensively by the epidemic, I have not seen any Neapolitan official returns. But Florence is divided into eighteen medical districts, and from each of these, returns of the course of the disease were received, the particulars including the number of attacks, the proportion of recoveries to deaths, and the sex and ages of the patients. The tables thus obtained by the Municipal Board of Health (Ufficio Municipale di Sanità) have been arranged, and their contents classified, by Signor Tiburzi, and from them we learn that in a single district (that of St. Salvi) there occurred in about twelve months (years 1871-72) 180 cases, of which 133 recovered and 47 died; that in all the districts of Florence, in the first six months of the year 1872, 820 cases occurred, of which 435 died and only 385 recovered; and that in the whole year 1872, in all the districts, 1058 cases occurred, of which 563 died and only 495 recovered. This enormous mortality shows in itself that none but genuine cases of diphtheria are reported, and there is evidence, moreover, that other fatal diseases are not introduced in order to swell the returns, for the mortality from other epidemic maladies is entered in separate tables.

The unsatisfactory character of the official returns made during the epidemic of diphtheria in Great Britain in 1856 and following years arises from the fact that cases which did not at all belong to the diphtheric category were returned together with those that did; and the mortality tables at that period, notwithstanding the zeal and labour of the Registrar-General and his staff, were consequently of comparatively small value. It was well known that cases of scarlet fever were often returned among the diphtheric ones, especially at the commencement of the epidemic, when the distinctions between the two diseases had not yet been clearly pointed out. Another source of confusion was that fatal cases of diphtheria were often entered under the head of "croup," but it was remarkable that, as the epidemic continued its ravages and the features of diphtheria became more generally known, the deaths from "croup" were greatly diminished in the official returns, and those from diphtheria were largely increased, the reason, of course, being that the so-called cases of croup were really instances of laryngo-tracheal diphtheria. On the other hand, there is very little doubt that many cases of malignant disease of the throat, such as cancer and tertiary syphilis, not to mention malignant scarlet fever and cancrum oris, have lately figured among the mortality returns as diphtheria. It must also be observed that since the name of diphtheria has become popular an enormous number of cases, comparatively trifling, and some not really presenting any diphtheric character, have passed under that name, and hence we find a host of infallible remedies almost daily recommended to the notice of the profession and the public, and a multitude of cures are announced of a malady which in all probability never existed.

Such sources of fallacy are no doubt in existence at all times and in all countries in reference to the treatment of disease; but whatever may be the erroneous views, intentionally or unintentionally published as to the cure of dangerous epidemics, it is the duty of the medical profession at least to tell the truth—to take care that the diseases mentioned should be really those which their names denote, and, if any means of cure really exist, to recommend such means for general adoption.

In reference to this part of the subject the Report presented to the Committee of Practical Medicine in Florence offers some valuable remarks, and the deliberation on the Report by the Medico-Physical Society of the same city is worthy of all respect and imitation. "All diseases," says the Report,(a) "not excluding those which assume the features of epidemic maladies, may sometimes present themselves with such a mild character that the most simple methods of treatment, and even the healing power of nature alone (*la sola forza medicatrice della natura*)—which is as much as to say the physiological powers of the system—are sufficient to cure them. Thus even diphtheria in some epidemics has appeared in so mild a form as not to excite all the alarm which it now inspires, and it has credited some remedies as specifics, which will be administered in vain when the experiment is made in more serious circumstances."

The discussion on the value of the proposed remedies on the part of the Medico-Physical Society, and the resolution then passed, show that the difficulties of this part of the subject were fully appreciated; for after a long deliberation they declined to pronounce in favour of any specific method of cure, and gave a very guarded opinion even as to the value of local applications, and a still more guarded one as to the admissibility of tracheotomy—an operation which, it may be observed, has not been popular in Italy in the treatment of laryngo-tracheal diphtheria.

I will only observe, in conclusion, that the question of the identity or non-identity of laryngo-tracheal diphtheria and pseudo-membranous croup having been ably discussed in

(a) "Studi sulla Difterite." Rapporto del Dottore Faralli, p. 35.

all its bearings by the same Society, they unanimously came to the conclusion that the two were identical, the so-called croupous form and the diphtherie form appearing to the Society to be only phases and modifications of one and the same morbid process.

NOTES OF

A REMARKABLE SPECIMEN OF TAPEWORM, TÆNIA LOPHOSOMA (COBBOLD).

By CHARLES J. CULLINGWORTH, M.R.C.S.,
Surgeon to St. Mary's Hospital, Manchester.

A RESPECTABLE married woman, named Ann H., forty years of age, residing in Salford, brought to my out-patient room at St. Mary's Hospital, Manchester, on September 3, 1873, a few segments of tapeworm as a sample of what she had been passing per anum for about two years. Although never in the habit of taking meat absolutely raw, she told me, on inquiry, that she was particularly fond of tasting it when only partially cooked. The segments were unlike anything I had seen before, and I took them home for examination, ordering the patient meanwhile a draught containing a drachm of the oil of male fern, and giving her strict injunctions to bring to me every fragment that passed away as a result.

On September 17 she brought me portions of a tapeworm corresponding throughout to the segments I had already seen, and measuring altogether nine feet in length. Unfortunately, the head was not to be found. Along the middle line of every segment in the body a crest or ridge runs longitudinally, and in the centre of the margin of this crest the genital pore is situated.(a) Underneath the segment there is a longitudinal groove, and the lateral portions are folded together by the apposition of their under surfaces. When hardened in spirit, the section of a segment presents a three-branched appearance, the branches being of unequal length, but placed at equal angles. The uterus sends vessels into the crest as well as into the sides of the segment; and the contained ova are exactly like the ova of an ordinary Tænia medio-canellata. Wedged in between, or attached to the segments here and there, is a stunted and ill-shaped joint, with irregular and unequal sides. A mature joint measures from five-eighths of an inch to three-quarters of an inch in length, and about half an inch in breadth, and the breadth or depth of the crest is usually one-eighth of an inch.

Remarks.—There are only two specimens that I can find on record at all similar to the one here described, and both of these differ from it in several important particulars. Küchenmeister mentions, as a variety of Tænia medio-canellata, a tapeworm sent to him from the Cape of Good Hope by Dr. Rose.(b) This worm possessed a longitudinal ridge, but he describes its mature segments as "extremely massive"—more than an inch in length and 3-5‴ in breadth. The genital pores, too, were irregularly alternate, and not situated on the crest. On March 20, 1866, Dr. Cobbold exhibited to the Pathological Society of London(c) a specimen of crested tapeworm which had been discovered in the museum of Middlesex Hospital, and to which he proposed to give the name Tænia lophosoma (λόφος, crest; σῶμα, body). The reproductive papillæ were all on one side of the chain of segments, a peculiarity which entirely distinguished it from the Cape of Good Hope variety of Küchenmeister. The head of the creature was wanting. It will thus be seen that my specimen does not correspond with either of these in the situation of the genital aperture. Here it is placed in the crest itself, and not unilaterally, as in Dr. Cobbold's specimen, or alternately, as in Küchenmeister's. It further differs from the Cape variety in the more moderate dimensions of its proglottides. I have adopted, however, the name suggested by Dr. Cobbold in the communication referred to, inasmuch as it sufficiently indicates the principal distinguishing feature of the specimen. I may mention, in conclusion, that Dr. Cobbold saw the specimen during his recent visit to Manchester, and that he regards it as a most remarkable and unique abnormality.

(a) In 304 segments examined, only four had the genital opening placed laterally. One segment had two openings—viz., one at the lateral margin and the other in the crest.

OUTLINE OF OBSERVATIONS AND INVESTIGATIONS ON YELLOW FEVER.

By JOSEPH JONES, M.D.,
Professor of Chemistry and Clinical Medicine, Medical Department, University of Louisiana;
Visiting Physician of Charity Hospital, New Orleans.

No. I.—Notes upon the Early History of Yellow Fever.

(*Continued from page* 575.)

If the history of yellow fever in the Western Hemisphere be critically examined, it will be found that the accounts and dates of its origin varied with the extent and character of the information of the writers in each city, locality, or island; and each one in turn was tempted to assign to the disease a foreign origin. No city or place has been found to claim the honour of the origin and continuous propagation of yellow fever. Thus, the French writers called this disease *mal de Siam*, and held the *tradition* that the disease had been imported in the ship *Oriflame*, which sailed with French colonists from Siam in the latter part of the year 1690. Monsieur Pouppe Despertes, who practised at St. Dominique from 1732 until 1748, says that this fever was so called from its first being taken notice of in the island of Martinique at a time when some vessels were there from Siam.—("Hist. des Malad. de St. Dominique," vol. i., pp. 191, 192). But it is well known that the *Oriflame* touched at Brazil when yellow-fever had been prevailing for several years, and Father Labat, who arrived at Martinico on January 29, 1694, tells us that the passengers of this ship caught the disease in Brazil.

Equally incorrect was the account given by Dr. Warren of its introduction into Barbadoes between the years 1732 and 1738. Dr. Warren concluded that the yellow fever which he saw at Barbadoes in 1732 and the following years was a continuation of the *plague* which in 1720 and 1721 had been brought from Palestine to Marseilles, and which he imagined had been brought from the latter place to Martinico, and thence to Barbadoes in 1721 by the *Lynn* ship of war.

Dr. Tiyne, who lived and practised as a physician at Barbadoes at the time of the alleged introduction of the plague from Marseilles (1721), and who wrote in 1724 (before the arrival of Dr. Warren) on yellow fever under the denomination of *febris ardens biliosa*, made no allusion to any such importation, but considered it as an endemic disease in the West Indies to which Europeans were subject upon their first arrival.

Mr. Hughes says, in his "Natural History of Barbadoes," that Dr. Gamble remembers that it was very fatal in 1691, and that it was then called the "new distemper," and afterwards "Kendal's fever," also the "pestilential fever," and "bilious fever." This statement is also confirmed by captain Thomas Phillips, who was at Barbadoes with a large ship in 1694, and says, in the account of his voyage to Africa and Barbadoes, that it was the fate of that island to be then "violently infected with the plague."—(Churchill's Collect., vol. i., p. 253).

It appears, however, from the statement of Mr. Richard Vines, a planter and practitioner of physic in Barbadoes, that yellow fever prevailed with destructive effect as "an absolute plague" as early as 1647; and Dr. Edward Nathaniel Bancroft, in his essay on yellow fever, suggests that it was called "a new distemper" in 1691-94, because all who had had any accurate knowledge of it in 1647 were probably dead or removed.

Mr. Richard Ligen, in his history of Barbadoes, published in 1657, says that when he arrived there in 1647, in the early part of September, the inhabitants of the island and shipping too were so seriously visited by the plague (or as deadly a disease) that "before a month was expired after our arrival the living were hardly able to bury the dead." In considering the causes of this disease—whether it was brought thither in shipping, or was occasioned by the irregularities, debaucheries, and ill diet of the people, and the unhealthy, low, marshy situation, subject to overflow—he inclined to the latter.

A similar fever, and probably from the same causes, prevailed at the same time at St. Christopher, Guadaloupe, and other islands, and there died at St. Kitt's and Barbadoes each five or six thousand inhabitants.

P. Du Teste also mentions this disease, and calls it the plague. He says that it began at St. Christopher, and in

eighteen months carried off one-third of the inhabitants, and that it was accompanied with violent pain in the heart, great debility of the limbs, and a constant vomiting; and that in three days it sent the patient to the grave.

Dr. Hillary, who enjoyed a high reputation as a successful practitioner and learned physician in Barbadoes, affirms that the disease was indigenous and endemic to the West India Islands.

The testimony of Alexander Humboldt is similar to that of Dr. Hillary, and is worthy of the most careful consideration in the light in which it presents the history of yellow fever. In his "Political Essay on the Kingdom of New Spain," this distinguished traveller, naturalist, and philosopher says:—

"The typhus, which the Spaniards designate by the name of 'black vomiting' (*vomito prieto*), has long prevailed between the mouth of the Rio Antigua and the present port of Vera Cruz. The Abbé Clavigero(a) and some other writers affirm that this disease appeared for the first time in 1725. We know not on what this assertion, which is so contrary to the traditions preserved among the inhabitants of Vera Cruz, is founded. No ancient document informs us of the first appearance of this scourge; for throughout all the warmer parts of equinoctial America, where the termites and other destructive insects abound, it is infinitely rare to find papers which go fifty or sixty years back. It is believed, however, at Mexico, as well as at Vera Cruz, that the old town, now merely a village, known by the name of La Antigua, was abandoned towards the end of the sixteenth century(b) on account of the disease which then carried off the Europeans.

"Long before the arrival of Cortez there has almost periodically prevailed in New Spain an epidemical disease called by the natives 'Matlazahuatl,' which several authors(c) have confounded with the *vomito* or yellow fever. . . .

"It is certain that the *vomito*, which is endemical at Vera Cruz, Carthagena, and Havana, is the same disease with the yellow fever which since the year 1793 has never ceased to afflict the inhabitants of the United States. This identity, against which a very small number of physicians in Europe have started doubts,(d) is generally acknowledged by those of the Faculty who have visited the island of Cuba and Vera Cruz, as well as the coast of the United States, and by those who have carefully studied the excellent nosological descriptions of MM. Makilbrick, Rush, Valentin, and Tuzuriaga. We shall not decide whether the yellow fever is perceptible in the *causus* of Hippocrates, which is followed, like several remittent bilious fevers, by a vomiting of black matter; but we think that the yellow fever has been sporadical in the two continents since men born under a cold zone have exposed themselves in the low regions of the torrid zone to an air infected with miasmata. Wherever the exciting causes and the irritability of the organs are the same, the disorders which originate from a disorder in the vital functions ought to assume the same appearances.

"It is not to be wondered at that at a period when the communications between the Old and New Continents were far from numerous, and when the number of Europeans who annually frequented the West India Islands was still small, a disease which only attacks the individuals who are not seasoned to the climate, should have very little engaged the attention of the physicians of Europe.

"In the sixteenth and seventeenth century the mortality must not have been so great.—1st. Because at that period the equinoctial regions of America were only visited by Spaniards and Portuguese—two nations of the South of Europe less exposed, from their constitution, to feel the fatal effects of an excessively hot climate than the English, Danes, and other inhabitants of the North of Europe who now frequent the West India Islands. 2ndly. Because in the islands of Cuba, Jamaica, and Hayti the first colonists were not assembled together in such populous cities as were afterwards built. 3rdly. Because on the discovery of continental America the Spaniards were less attracted by commerce towards the shore, which is generally warm and humid, and preferred a residence in the interior of the country, on elevated table-lands, where they found a temperature analogous to that of their native country. In fact, at the commencement of the conquest the ports of Panama and Nombre de Dios(e) were the only ones where there was a great concourse of strangers; but from 1535 the residence at Panama(f) was as much dreaded by the Europeans as in our times a residence at Vera Cruz, Oma, or Porto Cabello. It cannot be denied from the facts related by Sydenham and other excellent observers that, under certain circumstances, germs of new diseases may be developed;(g) but there is nothing to prove that the yellow fever has not existed for several centuries in the equinoctial regions. We must not confound the period at which a disease has been first described, on account of its having committed dreadful ravages in a short space of time with the period of its first appearance.

"The oldest description of the yellow fever is that of the Portuguese physician Joam Ferreyra da Rosa,(h) who observed the epidemic which prevailed at Olinda, in Brazil, between 1687 and 1694, shortly after a Portuguese army had made the conquest of Pernambuco. We know in the same manner with certainty that in 1691 the yellow fever manifested itself at the island of Barbadoes, where it went by the name of 'Kendal' fever, without the smallest proof appearing that it was brought there by vessels from Pernambuco. Udoa,(i) speaking of the *chapetonadas*, or fevers to which Europeans are exposed on their arrival in the West Indies, relates that, according to the opinion of the people of the country, the *vomito prieto* was unknown at Santa Martha and Carthagena before 1729 and 1730, and at Carthagena previous to 1740. The first epidemic at Santa Martha was described by Juan Josef de Gastelbrude,(k) a Spanish physician. Since that period the yellow fever has several times raged out of the West India Islands and Spanish America, on the Senegal, in the United States,(l) at Malaga, Cadiz,(m) Leghorn, and, according to the excellent work of Cleghern, even in the island of Minorca.(n) We have thought it proper to relate these facts (many of which are not generally known) because they throw some light on the nature and cause of this cruel disease. The opinion that the epidemics which since 1793 have nearly every year afflicted North America differ essentially from those which for centuries have prevailed at Vera Cruz, and that the yellow fever was imported from the coast of Africa into Grenada, and from thence into Philadelphia, is equally destitute of foundation with the hypothesis formerly very generally believed—that a squadron from Siam introduced the *vomito* into America.(o)

"In all climates men appear to find some consolation in the idea that a disease considered pestilential is of foreign origin. As malignant fevers easily originate in a numerous crew cooped up in dirty vessels, the beginning of an epidemic may be frequently traced to the period of the arrival of a squadron; and then, instead of attributing the disease to the vitiated air contained in vessels deprived of ventilation, or to the effects of an ardent and unhealthy climate on sailors newly landed, they affirm that it was imported from a neighbouring port, where a squadron or convoy touched at during its navigation from Europe to America. Thus we frequently hear in Mexico that the ship-of-war which brought such-or-such a viceroy to Vera Cruz has introduced the yellow fever, which for several years had not prevailed there: and in this manner during the season of greatest heat the Havana, Vera Cruz, and the ports of the United States mutually accuse one another of communicating the germ of the contagion. It is with the yellow fever as with the mortal typhus known by the name of 'Oriental pest,' which the inhabitants of Egypt attribute to the arrival of Greek vessels, while in Greece and Constantinople the same pest is considered as coming from Rosetta or Alexandria."(p)—("Political Essay on the Kingdom of New Spain," vol. iv., pp. 135-143.)

The preceding facts show the fallacy of attempting to decide the date of the origin of yellow fever from the statements of the writers of any one locality; and they also show the im-

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CHARING-CROSS HOSPITAL.

CASE OF CHRONIC PYLORIC OBSTRUCTION, WITH DILATATION OF THE STOMACH.

(Under the care of Dr. SILVER.)

Mrs. M., aged 40, was admitted into Charing-cross Hospital on April 30, 1873, complaining of severe vomiting and great debility. The patient gave the following account of herself:—She enjoyed good health until eleven years ago, when she had a sudden and severe vomiting of blood. This seems to have been a true hæmatemesis; she fainted, brought up a large quantity of blood, and had no relapse. There were no gastric or other symptoms before, and only debility after. About a month afterwards she began to suffer from occasional sickness, bringing up a dark liquid like what she is at present vomiting, and which will be afterwards described. Such vomiting, however, did not happen more than once a month. She cannot say distinctly when she recovered completely. For the next six years she continued well: there were no gastric symptoms whatever, and she had frequent and easy confinements. Two or three months after her last child was born—*i.e.*, five years ago—she began to suffer from the symptoms of which she has never been clear up to the present time. Without any previous symptoms of indigestion or a delicate stomach, she was taken with sickness and vomiting, abdominal pain, and swelling of the belly. She is confident that these symptoms appeared rather suddenly at first, but quite as sure that there was no evident cause for them. She did not over-exert herself, over-eat herself, nor receive any injury. The symptoms began with a feeling of fulness and abdominal distension, which have never disappeared: pain occurred at intervals of months or weeks at first, but now much more frequently; sickness was rare at first, but lately was more frequent, and now it is seldom absent for many days at a time. For the last three years these symptoms have been more frequent and severe; during this time the patient has been almost unfit to do her household work. For the last three months she has been sick almost every second or third day; the character of the vomited matter has been various. For the last six months or so (she cannot be quite precise) it has been brownish, as it is now. She has all along been subject to very sudden vomitings of quite clear fluid, in large quantities, preceded by very sudden feelings of sickness, and followed by a sense of relief. She has had no hæmatemesis again. She has not been able to eat freely these last five years; any indulgence in this respect brought on pain, swelling, and sickness. Her bowels have always been confined; they have never been too loose. Her tongue has never been sore. She has never had jaundice. For the first two or three years of this illness she lost flesh after the attacks of pain and sickness, but for the last few months she has never regained her strength—*i.e.*, she has been steadily getting weaker. For the last nine months she has menstruated regularly; the preceding nine months she had amenorrhœa. On admission, a very pale, thin, somewhat anxious-looking woman, confined to bed, but anxious to rise for a short time daily. She complains of fulness in the belly, pain in the stomach and back, and vomiting, with debility. The abdomen is distended and irregularly tympanitic; there are no signs of ascites. In the line between the ensiform cartilage and the umbilicus is a well-defined tumour as large as a pear, its inferior border touching the latter point. It is firm and somewhat tender, and is dull on percussion. Frequent movements are observed on the abdominal surface. The region around the umbilicus and tumour and the left hypochondrium are tympanitic on percussion. Dull percussion-sound is irregular, both in distribution and intensity, over the rest of the abdomen. Complete anorexia. Tongue dry, rather brownish in the centre, with a slight general fur; constipation. The hepatic dulness in the right vertical nipple-line extends from the lower border of the fifth rib to the inferior margin of the thorax. No jaundice; no distinct splenic dulness. Cardiac dulness small; signs not otherwise abnormal. General resonance of the lungs. Pulse frequent, very small, and very weak. No œdema of any part of the body. Spirits rather depressed. To take two tablespoonfuls of sulphate of iron and magnesia mixture three times a day.

May 8.—To-day profuse vomiting of what is called by the nurse "a coffee-ground substance," with great feeling of sickness. Cantharides plaster to the epigastrium.

13th.—About eighty ounces of a similar coffee-ground material vomited to-day. The belly is more tympanitic; the physical signs otherwise are as on admission, except that the tympanitic percussion-area is somewhat differently distributed. The blister to be repeated and the surface sprinkled with morphia. An enema administered.

14th.—A spontaneous and natural-looking stool.

16.—Patient vomited last night thirty-six ounces of a dirty thin liquid, with a brown frothy scum, a greyish-brown granular sediment, and a sour smell. Microscopically the sediment consists of particles of food, abundant torulæ, and a few doubtful sarcinæ. Over the belly there is very loud succussion sound. The patient feels better since the vomiting. To take ext. opii liq. ℥v., spt. chlor. ʒ ss., ex mist. bismuth.

17th.—Last night thirty ounces of a similar fluid were rejected after extreme feeling of distension and sickness, which were relieved by the vomiting. The physical signs are much as before. Constipation.

19th.—Sixteen ounces vomited; severe gastric and dorsal pain.

21st.—Ninety-six ounces of fluid vomited last evening. Debility is so extreme that the patient is almost unconscious.

22nd.—Condition improved, but the patient is still excessively weak and as pale as death. Pulse 160. Considerable abdominal pain and distension.

23rd.—Better; no sickness since the 21st. The tumour in the epigastrium is very distinct to the eye and hand.

26th.—The patient is better than she has been since admission; no sickness; an abundant loose brown stool. To have a hypodermic injection of morphia every night. There is no feeling of sickness, abdominal pain, or distension. Appetite fair. Pulse 120, weak.

June 3.—The patient says she has not felt so long well for some years.

6th.—Sickness returned yesterday; several ounces of the usual vomit have been rejected. The debility has not increased. A blister to the epigastrium.

9th.—The patient is very much worse; she has vomited frequently since the last note. Within the past twenty-four hours 160 ounces of the same fluid as before have been ejected. Complete prostration. Pulse 144. The voice is nearly inaudible; great paleness and emaciation of the face.

10th.—Patient vomited sixty ounces of fluid after the above note was taken yesterday. Weakness gradually increased, and she died after being slightly delirious for several hours.

A post-mortem examination was not granted.

As to the nature of this case there could be no reasonable doubt, though no post-mortem examination was made. The patient undoubtedly suffered from cancer of the pylorus obstructing the passage of food, and so gradually giving rise to dilatation of the stomach. One notable peculiarity was the pain she suffered, which was sometimes excessively severe. The mode taken to relieve this, though not fully brought out in the above notes, is worth bearing in mind; it consisted in the removal of the cuticle by a blister, and sprinkling the raw surface with morphia, half a grain being so applied. Such procedure never fails to give relief in the worst cases—even more than the hypodermic injection of the drug gives. To use it efficiently the part should be painted with blistering fluid, and a warm poultice applied. This will very soon raise the cuticle by a copious formation of serum. The blister should be snipped round the edges, and the cuticle carefully removed, after which the morphia is to be lightly dusted over the raw surface.

The Holborn Guardians have resolved to send no more children to the workhouse schools at Mitcham until the epidemic of ophthalmia, now seriously prevalent, has subsided.

MEDICAL REMUNERATION.

We publish this week in another column a letter from "A Provincial Doctor" on the subject of medical remuneration, which may be supposed to represent the views of a section—albeit most probably a very small section—of medical practitioners on the subject of an increase in the amount of medical charges. His views may be epitomised thus:—That a large amount of medical practice is pursued amongst the comparatively poor and struggling—the underfed respectable classes, in fact,—and that these are not capable of paying more than they are now charged by their medical attendants. That medical, like lawyers', charges are disagreeable, and there being but little to show for the expenditure, it cannot be a matter of surprise that people should grudge their amount, and avoid liquidating them as long as they possibly can. That medical men are laid under a kind of conventional black-mail by their relatives and acquaintances, who expect them to give them the benefit of their skill, besides their time, without remuneration. That the so-called medical charities injure medical practitioners; that the trouble given by individual cases varies greatly; lastly, that the medical practitioner who does not hasten to attend anyone who may send for him is open to the charge of inhumanity; and our correspondent concludes by expressing his belief that an increase in the amount of medical fees would only benefit the leading practitioners, and would leave the rank and file to the harsh words and small pay which he thinks are to be the lot of doctors as long as doctors may be required on this planet.

The letter of our correspondent suggests that it is written either before success in the profession has been achieved or at an age when success is no longer to be expected. We may take it for granted that the former is the case, and that "A Provincial Doctor" is now undertaking the uphill and toilsome task of making a practice. To him and to others in a like position we may say—"It is not to you that the profession look to teach the public the lesson that medical fees have not increased in proportion to the depreciation of the value of money and the augmentation of expenses of living." The lesson must be taught and the example set by the leaders in London and elsewhere, and its influence, together with causes already in action—such as the improvement in medical education, and a consequently greater difficulty in entering the ranks of the profession,—cannot fail to raise the professional status and remuneration throughout the country. This may be laid down as a general principle. But, admitting it, there is much in our correspondent's letter which seems to suggest comment and correction. First, with regard to the struggling respectable classes—how are they to pay the doctor more than they do? We say, by teaching them to pay a regular and fixed sum yearly to a medical practitioner, who shall thereupon undertake to attend them whenever necessary. Take, for instance, a lawyer's clerk, who earns perhaps £150 a year for the maintenance of himself, his wife, and two or three children. It is quite true that if this man has a doctor's bill of £20 to pay in any one year it will greatly cripple him. But medical attendance will be quite as necessary to him as grocery and beer; and there is no reason why the doctor should be paid less regularly than, and after, the grocer and the brewer. Let persons in this class, then, be taught to pay their medical attendants a certain sum monthly or quarterly, whether they are ill or well, which payment shall give them the right to professional assistance in all emergencies. Where the income of a family is under £300 a year a very moderate percentage paid regularly would be found practically to remunerate the medical practitioner far better than the present haphazard system, and would be felt as a burden far less by the class of persons of whom "A Provincial Doctor" writes.

With regard to the artisan classes, the same principle applies, and is already in action in the system of the sick club and the provident dispensary. But here clearly there is great room for improvement. Considering the present rates of wages, the payment of 5s. or even 7s. a head to the club doctor per annum is far too small. If the profession would but be true to themselves, the payment for sick clubs throughout the kingdom might be at once doubled or trebled. The provident-dispensary system is looked on with suspicion in many quarters; and rightly so, for it is too often made the means of unfairly excluding professional men from the general practice of the neighbourhood. But we cannot see why either each practitioner should not take the artisans amongst his patients on a fairly remunerative provident scale of payment, or at least why the provident dispensary in a town should not be the joint property of all the properly qualified practitioners in the neighbourhood. With regard to the argument that persons do not like to pay medical men because their services are not pleasant, and there is often but little to show for them: this is at least equally true of law, and we are not aware that lawyers are in the habit of waiving their claims.

Our correspondent then touches on the immense amount of gratuitous prescribing which the medical profession is expected to do. With regard to this, we can only say that we think the medical profession is greatly to blame for doing so much as it does. Far be it from us to advise the setting up of any hindrance or barrier in the stream of professional charity. But it is no charity to prescribe gratis for a man, who can well afford to pay a fee, because he happens to be an acquaintance or even a relative. It is no charity to the man himself, and the prescriber injures either himself or some other practitioner. With regard to rendering our services to professional people gratuitously, we think that the line should be drawn somewhere, and should probably include only the unbeneficed clergy not having private means, daily governesses, and medical men and those of their families dependent on them.

In previous articles we have directed attention especially to the urgent necessity which exists for the increase of the fees of the consulting practitioner, and we have proved beyond question that medical remuneration is proportionately, in the

consulting rank, at least two-thirds less than it was in the early part of the eighteenth century. We believe that the example of increase of required remuneration must be set in these ranks, and that, it being there established, it will rapidly permeate all classes of the profession. At present the leaders, both in surgical and medical practice, are underpaid, and are consequently falling in position below the most successful of the banking and commercial classes. An increase in their fees would probably diminish their number of patients, but it would husband their physical and mental resources and increase their incomes. Many persons who consult them upon comparatively trivial ailments would apply to other physicians and surgeons, who would be proportionately benefited, and we should hear far less than we do of two interviews granted for one guinea fee. A check would be given to a practice which we know is gaining ground in the higher walks of practice—we mean that of obtaining the services of the best talent in the profession for ordinary ailments without the intervention of the general practitioner, the fee given being the usual guinea. Lastly, the general practitioner would by degrees be raised to a status and position more befitting his education and power of benefiting society. We believe, moreover, that a general movement throughout the profession for an increased remuneration for their services would before long certainly extend to the public medical services, especially to that of the Poor-law; and thus one of the blots on our system, which has often prevented the poor from having the advantage of the best local medical skill, would be removed. These benefits we believe to be fairly within grasp, and, obtained, they would once more give the practitioners of medicine their proper place in fact, and not merely in name, amongst the professors of the arts which benefit mankind.

THE EDINBURGH SCHOOL OF MEDICINE.

The success of an institution, like the success of an individual, awakens a certain amount of laudable curiosity regarding the circumstances of its origin and early progress. In the case of the individual this curiosity is associated with the group of ideas embodied in the aphorism that "the child is father of the man"; and in the case of the institution it arises from an analogous understanding that the conditions of its origin and the provisions for its early development determine to a considerable extent the character of its maturity. It would be difficult to find a better illustration of this principle than that afforded by the history of the Medical Faculty of Edinburgh University. For many years the fortunes of this Faculty have been on the ascendant. Under circumstances which might have justified the anticipation that the number of Edinburgh medical students would undergo a temporary diminution, the yearly returns have shown a steady and considerable increase. During the present winter session the total number of students at Edinburgh University is 1738. Of these 683 are medical, and 214 first-year medical students. Last winter the medical students numbered 648; in 1871-72 the number was 615, and in the previous year 563. A comparison involving still earlier dates shows that for some time back the Edinburgh Medical School has enjoyed increasing prosperity. And that this prosperity results to no inconsiderable extent from the nature of its early constitution, will, we think, be evident on a cursory consideration of its inauguration and early history.

The constitution of the Edinburgh University was completely altered by the passing of the University Act of 1858. Previously to the adoption of that measure it differed from other Scottish universities, inasmuch as in Glasgow, Aberdeen, and St. Andrews the whole administration of affairs was conducted by the Senatus Academicus, while in Edinburgh the management of the University was in the hands of the municipal corporation. A recollection of this fact is necessary to an understanding of the influence exercised by the Edinburgh Town Council in the establishment of the Edinburgh School of Medicine.

During the latter half of the seventeenth century an impression existed amongst the influential members of Edinburgh society that that city was capable of educating her own physicians. Scotchmen, after distinguishing themselves at Continental schools, had returned to their native country and established such professional reputations as commanded universal attention. About 1670 Sir Robert Sibbald, having spent several years of observation and study at Leyden, Angers, and Paris, endeavoured, on his return to Edinburgh, to establish some means of promoting the study of natural science, with a view to the advancement of the medical art. He established the elements of a botanical garden, founded the College of Physicians, and was the first to lecture as a professor of medicine in connexion with the University of Edinburgh; but the preliminary steps towards the inauguration of an Edinburgh medical school were embarrassed by several impediments. Some of these were evident to the promoters, while others arose directly from their own line of conduct. As a first obstruction, there existed the active prejudices and mercenary jealousy of an incorporate body of "Chirurgeon-Apothecaries." In the second place, the recognition of a new branch of university study depended upon the approval and support of laymen embodied in the Town Council. Another serious drawback was the non-existence of a hospital; and, above all, the prospects of a successful issue to the scheme were blasted by the want of any means of prosecuting the study and teaching of human anatomy. These were the adverse circumstances depending upon social conditions, but, at the same time, the promoters of a scheme of medical education fostered in themselves an adverse influence by their adherence to a foreign university system inconsistent with the conditions by which they were surrounded. They procured the establishment of professorships in connexion with the University, but, instead of these professorships being associated with teaching in the University, they were analogous to foreign and English appointments. They attached to the title of University Professor the privilege to lecture "in private colleges." Under existing circumstances, this arrangement could only lead to the establishment of intermittent private lectureships, and in most cases resulted in no teaching being performed at all; so that the early professorial appointments in medicine were analogous, not to present university professorships, but to extra-academical qualifications to teach medicine.

But to counterbalance these disadvantages there existed certain elements of success. In the existing University there was a well-established and celebrated school of learning; there were physicians of marked distinction in their profession available as teachers; there was a growing demand for home medical education, and a Town Council which at all times appears to have been willing to grant the reasonable requests of their learned petitioners. Under these circumstances it is interesting to watch the gradual early development of the Edinburgh Medical School up to the time when Provost Drummond and Professor Monro, properly estimating the conditions of success, wrought harmoniously in their different capacities towards the successful establishment of a vigorous Medical School.

In 1670, Sir Robert Sibbald, acting in co-operation with a few friends, had obtained from the Abbey gardener "ane enclosure of forty feet each way" for purposes included under the name of a "medicine garden." There is no historical doubt that from this humble origin the Edinburgh Medical School arose. The Corporation of Chirurgeon-Apothecaries

were sagacious enough to anticipate such a result, and dreaded an inundation of home-made physicians.

They accordingly opposed the scheme, but fortunately the influence of Dr. Balfour, a colleague of Sibbald, was sufficient to convert their opposition into an active co-operation. The result of this combination was that the ground belonging and adjacent to Trinity Hospital was granted on a nineteen years' lease by the Town Council for the promotion of natural science. This neighbourhood, now adjoining the Edinburgh North Bridge, is still well known as the Physic Gardens. Modern improvements, however, have necessitated the removal of the Botanic Gardens—first, we believe to Leith-walk, and subsequently to Inverleith-row, where they now are.

In 1681, Sibbald and his friends, in order to withstand the opposition of the Chirurgeon-Apothecaries to the interests of the Physicians, obtained a charter for the College of Physicians; and the Fellows of this College, both individually and as a corporation, exercised a potent influence in the development of the Medical Faculty of the University. In the department of natural science, Sibbald procured the co-operation of Sutherland, who is regarded as the first professor of botany, and who by virtue of his original abilities and powers of observation had advanced himself from the condition of a common gardener. Sutherland published the "Hortus Medicus Edinburgensis," with special reference to medical botany, and instituted that collection of dried plants which constitutes one of the distinctions of the Edinburgh gardens.

Sibbald was appointed first Professor of Medicine to the University. He seems to have delivered Latin lectures at his own house. In the same year (1685), Drs. Halket and Pitcairne were also appointed to be Professors of Medicine, but it does not appear that either of them ever instituted a course of lectures. In the significant language of the Town Council, these early nominees were appointed professors "to the college and the city." Charles Preston succeeded Sutherland, and advertised lessons in botany in May, June, July, and August, in the Physic Gardens. George Preston succeeded Charles with a salary of £10 sterling. In 1713 James Crawford was appointed Professor of Chemistry, and in lieu of salary obtained the use of two rooms in the University. He did not deliver a regular course of lectures.

It is evident, however, that medical teaching, as far as it had as yet been established, even if it had assumed the form of permanent lectureships, would not have provided the education necessary for the production of Scotch physicians. There was no anatomy to provide the basis, and no hospital instruction to supply the materials of a knowledge of practical medicine. At that time Pitcairne was the most famous of European physicians, and, through a surgeon named Monteith, he employed the force of his local influence to provide for anatomical instruction and investigation.

In 1694, the Town Council, in answer to an appeal from Monteith, agreed that in exchange for his services in attendance upon the "town's poor," he should receive for anatomical purposes the bodies of all those who, having been sent to the correction-house for proven gross immoralities, had died during their term of imprisonment, and also all foundlings dying on the breast. A sanitary condition was attached to this grant requiring that all the "gross intestines" should be buried within forty-eight hours, and the whole body within ten labouring days. In a few days the Town Council made a more liberal grant to the Corporation of Surgeons, and attached the condition that the petitioners were to build an anatomical theatre within three years, and conduct dissections only in winter. From this time till five years after the appointment of the first Monro, such public dissections and demonstrations as were conducted in Edinburgh were carried on in the Surgeon's Hall. In 1705, Robert Elliot, who had been elected dissector to the Corporation of Surgeons under their new grant, applied to the Town Council for a ratification of his appointment. The result was that he was appointed first Professor of Anatomy. On condition of his protecting the "varieties" of the College, he was granted the salary of £15 per annum. The fact stated in the first Monro's manuscript "Life"—that Elliot dissected a body once in two or three years—shows that his public labours at least were not of an arduous nature. On the other hand, there is some reason to believe that privately dissection was carried on with energy. Monro's early knowledge was to some extent acquired by his being allowed to assist at the anatomical dissections which occurred in the private practice of Edinburgh physicians. Where the subjects came from for these private dissections may be partly inferred from the statement that very shortly after the anatomical grant of the Town Council the burial-ground of Greyfriars was desecrated. This was the first of several occasions on which the devotees of anatomical science in Edinburgh have sacrificed the sanctity of sepulture to the interests of scientific discovery. As Professor of Anatomy—nominally of the University, but attached to Surgeons' Hall,—Drummond succeeded Elliot, and had M'Gill as a colleague.

From 1720 onwards a new spirit seems to have been inspired into the promoters of the Edinburgh Medical Faculty. Both Provost Drummond and Professor Monro *primus* had commenced to use their influence in behalf of the University. In 1724 the Town Council resolved upon the advisability of establishing a complete system of medical teaching such as would enable the sons of citizens and others to procure such an education as would prepare them for graduation as Doctors of Medicine. Porterfield was appointed Professor of the Institutes and Practice of Medicine on the condition that he was to deliver a regular course of lectures. It is doubtful, however, whether he ever fulfilled that condition.

In the meantime, Preston, Professor of Botany, had allowed the Physic Gardens to come to grief; and St. Clair, Rutherford, Plummer, and Innes having previously purchased a chemical laboratory in the neighbourhood, applied to the Town Council to permit them to take into their own hands the custody of the Physic Gardens for the promotion of medical science. This was granted in 1724. During the succeeding two years the four physicians had been so successful in the prosecution of their schemes, that in 1726 the Town Council recognised that it would be of great advantage to have the teaching of medicine incorporated with the duties of the University. They accordingly appointed Rutherford and St. Clair to act as Professors of Practice of Physic, while Innes was elected Professor of the Institutes of Medicine, and Plummer Professor of Chemistry. At the same time the Faculty of Medicine was absolutely recognised by the arrangement that two out of these four professors should during alternate years assist in the deliberations of the Senatus Academicus. It was a further advantage that the University, by having a certain number of physicians connected with its own corporation, could grant medical degrees independently of the recommendation of physicians unconnected with it.

But though the physicians of Edinburgh and the Town Council of the city had for some time been drifting fortuitously to the establishment of an Edinburgh medical school, and accumulating elements for its construction, the honour of erecting from the available materials a vigorous and harmoniously constructed whole fell to the lot of two able men, who took advantage of an almost absolute influence in the communities with which they were respectively connected not only to lay the foundation, but almost to complete the superstructure of an admirable school of medicine.

In itself the University could take no action. The Town Council was the administrative body of its affairs; so that, on

the one hand, the Council was at the mercy of the learned classes for suggestions regarding the profitable management of their trust, and the University was at the mercy of the Council for the power and means of promoting its interests. Thus it is evident that a fault on either side would be fraught with evil consequences to the University. Fortunately, however, it happened that at this critical period in its history the University and the Town Council were each subject to the control of a man pre-eminently qualified to project and consummate extensive measures, which at one and the same time promoted the welfare of the general community and secured for the city of Edinburgh a medical school worthy to rank amongst its foremost institutions. On the one hand, George Drummond, one of the ablest and most honourable of civic rulers, was Lord Provost of Edinburgh; on the other, Alexander Monro *primus*, equally able and respected, acted for the University. Three things were absolutely necessary to secure the satisfactory establishment of a medical school—(1) regular courses of lectures, (2) the construction of an hospital, and (3) the means of conducting constant anatomical work. Monro had been appointed Professor of Anatomy in 1720, and at once commenced to deliver a regular course of lectures. He enrolled fifty-seven students—a number which filled himself and his supporters with pleasant astonishment. In 1732 the number had reached 111, and in 1746 a maximum of 182. At the outset of his career as a teacher it no doubt became painfully evident to Monro that, unless provision could be made for the complete instruction in medicine of so large a number of students, their studies would require to be completed at other schools. In 1721 (the second year of his appointment) we find him agitating for the erection of a hospital. In 1725 the want of subjects was so great that the community were again thrown into a state of intense excitement by the practice of nefarious exhumation. Monro's class-room at the Surgeons' Hall was besieged, and in the ensuing riot the preparations which he had already accumulated were within an ace of being sacrificed to the popular fury. Influenced by the consideration that a repetition of the riot might involve the destruction of Monro's "varieties," the Town Council resolved that in future the Professor of Anatomy should have a theatre within the walls of the University. This in itself was a further step towards the consolidation of the Faculty. Actuated, no doubt, by the scarcity of subjects and the general requirements of the faculty, Monro continued to agitate for the construction of a hospital till (in 1729) he, with the co-operation of Drummond, rented a small house for the reception of patients. Previously to this the town had provided pecuniary and medical relief for the poor who were "free of the city." Others were attended gratuitously by medical men. Monro and Drummond's scheme flourished: funds increased, and in 1736 the Charter of the Royal Infirmary was obtained. In 1738 the foundation-stone was laid, and the building progressed in the most gratifying manner. It speaks volumes for the sagacity of the Edinburgh community that the populace who, ten or twelve years before, had entertained feelings of intense animosity to Monro and his craft, now came to his assistance in a manner which, for cordiality and self-sacrifice, is perhaps unequalled in the annals of charity. The funds were soon exhausted, but the workmen continued to build. Many gave their services gratuitously, and many more deferred their claims for wages to promote the progress of erection. Those who could not subscribe money brought materials, and, under the personal superintendence of Monro and Drummond, the work proceeded surely to a successful issue. With a breadth of view in advance of the times, the managers of the infirmary threw it open not only to those who were "free of the city" and to inhabitants who were not so privileged, but to the poor and afflicted of all nations. By this decisive measure a step was taken not only greatly in advance of the position hitherto held by the elementary medical school, but in advance of other similar institutions. In 1746-47 the hospital was first opened to students for a fee, and in the same year another step was taken which still further secured the superiority of the new school, and which, as an indication of penetration on the part of its promoters, will remain as a permanent honour to the Edinburgh Faculty of Medicine. It was resolved that clinical lectures should be regularly delivered in the Hospital. The resolution was at once carried into effect in a manner essentially the same as that practised at the present day. Professor Rutherford conducted the clinical course. An inspection of his lectures, of which Professor Laycock, of Edinburgh University, possesses two volumes in manuscript, shows that his course must have been highly instructive and calculated to promote the practical study of medicine. Thus it may be seen that in the short space of twenty years, and principally under the admirable administration of Monro, there was developed in Edinburgh a model school of medicine. In 1720 Monro inaugurated the system of giving regular courses of lectures. In 1726 the Senatus Academicus recognised and minuted the existence of a Medical Faculty. In 1746-47 a hospital based on universal principles was opened for the purposes of clinical study; and in the same year Dr. Rutherford commenced, by virtue of a resolution to that effect, the system of clinical instruction which was subsequently sustained by Monro *primus*, Cullen, and Whytt, and which since then has been nobly maintained as one of the greatest ornaments of the Edinburgh School. It is impossible not to admire the energy and administrative ability which, from crude materials little in advance of the original element of "ane enclosure forty feet each way," evolved a compact and comprehensive school of medicine. At the same time we must conclude that the great success which of late has fallen to the lot of the Edinburgh Medical Faculty is to no small extent traceable to the fact not only that their school has secured the services of many teachers of merited distinction, but that from its very origin the constitution of the school has been sound, liberal, and comprehensive.

THE PHYSIOLOGY OF VISION.

V.—The Retina.

If the lens be the most important organ in the eyeball considered optically, undoubtedly the retina is of most importance from a physiological point of view. Its structures are arranged in certain definite layers, but we shall confine our attention mainly to its nervous elements—that is to say, the special structures which respond to the stimulus of the waves of light, and serve to propagate this stimulus in the ordinary fashion to the brain.

Diverse as they may outwardly seem, the organs of sense have a curious family likeness when examined more minutely. Whether we investigate the structure of the taste-corpuscles on the outer surface of the circumvallate papillæ, the olfactory region of the nose, or the nerve-structures of the ampullæ of the ear, we find the same broad outline. A nerve pierces a membrane of greater or less density, in which it loses its medullary sheath—provided it has any; on the surface of this it forms a plexus of exceedingly fine fibres, which send off branches towards the free surface. These branches bear nucleated enlargements, and terminate in fine hair-like processes, projecting more or less distinctly beyond the free surface, and are supported by epithelial cells of the cylindrical kind, between which these hairs protrude. But the retina and the organ of Corti in the cochlea are much more highly specialised, and, though we can trace the same general outline, the details are different. The optic nerve penetrates the eyeball to the inner side of its axis, not by a distinct opening, but by a series of minute orifices constituting a cribriform

plate. Arrived in the interior of the eye, the nerve-fibres tend to ramify in every direction; but the spot where they enter is marked by an elevation composed of the connective tissue which has entered into the composition of their sheaths and the sclerotic; and in the centre of this, which is the optic papilla, there are seen to emerge two vessels—the arteria and vena centralis retinæ—which are distributed to the interior of the eyeball. Two branches of these vessels are always notable; they both pass outwards, one arching upwards, one downwards, so as to enclose a space in which no vessel is seen. In this space is the macula lutea, the central spot of the retina—a spot of the utmost physiological importance.

Ramifying immediately beneath the membrana limitans interna, the fibres of the optic nerve form frequent unclear masses, and from these masses of nerve-matter are sent outwards branches not very easily traced, but forming a double series of enlargements, also nuclear in character, before they reach the thin membrana limitans externa. Through this apparently, too, they pass, and abruptly terminate in the homologues of the sensitive hairs already spoken of, but which in the eye assume the well-known characters of rods and cones. Beyond these we come to the absorbing material—sometimes spoken of as the pigment layer of the choroid, sometimes as the uvea,—by which all light is arrested. In the retina we find no supporting epithelium, but in its place abundance of that fine and soft connective tissue, also found in the brain, called neuroglia. Thus it will be seen that certain nervous and other structures, including bloodvessels, are made to interpose between the more transparent parts of the eye and the sensitive rods and cones. This is not, however, the case in every part of the retina. In that portion already described as the yellow spot or central point, which has no vessels directed to it, and which corresponds to the optical axis of the eyeball, the textures are thinner. Here a certain thinning of the retinal structures takes place so as to give it a cup-like form, and this thinning is at the expense of the structures which ordinarily intervene between the vitreous and the layer of rods and cones. Here, however, the rods are almost superseded by the cones, which, moreover, are here more readily reached by the rays of light; and these rays are precisely those which have been least deflected in passing through the various optical media, seeing that they correspond to the optical axis of the eyeball. Knowing all this, we might almost conclude *à priori* that here the sense of vision would be keenest,—and so it is; just as at the spot where the optic nerve enters, and where the elements we call rods and cones are deficient, there is in every eye, however strange it may seem, absolute blindness.

THE WEEK.

TOPICS OF THE DAY.

Amongst the Knight Commanders of the Bath who were invested with the insignia of the second class of the Order at the investiture held by her Majesty at Windsor on Monday last was Surgeon-General William Mure Muir, M.D.

The reception given to Sir Samuel Baker and his wife in the theatre of the London University on Monday last by the Prince of Wales and the Royal Geographical Society is certainly the scientific event of the week. Sir Samuel Baker gave the geographers a glimpse of the hitherto *terra incognita* of Central Africa, and a history of the heroic achievements of his expedition, which were of unsurpassed interest. There can be now no doubt that inside the malarial districts of the coast a large portion of Central Africa is a magnificent country, capable of supporting vast populations and of supplying all the needs of civilisation. If, as certain philosophers of the present day affirm, man is only a delicately constructed machine, deriving all his energy from the sun, some of the negroes with whom Sir Samuel Baker came in contact are very peculiarly made, and the sun must have a good deal to answer for. Here is his description of the working of a human machine—the king of a place called Masindi:—

"This young man had distinguished himself by murdering his whole family under these circumstances:—When a king dies his body is placed upon a sort of huge gridiron, and is then toasted by a fire kindled beneath. The body then lies in state unburied and is the signal for civil discord. The sons fight until one of them is victorious and he sticks his spear into the body of his parent as a symbol of victory. Then the funeral rites take place, corresponding with those recorded of the ancient Scythians. A large pit is dug, in which some of the deceased king's wives are put, and the corpse is lowered down till it rests on their knees. Then there is a raid on some neighbouring villages, and the people captured are brought to the brink of the pit, where their arms and legs are broken, and in this mutilated condition they are thrown down to the corpse beneath. Then the earth is piled upon them, the people stamp it down upon this mass of writhing humanity, and the horrid rites are complete. Such had been the ceremony observed at Masindi, and the son who had succeeded to the throne then invited his relations to dinner and caused them all to be massacred."

It appears that the amount of typhoid fever in the colleges at Cambridge has been made the subject of exaggerated reports. A full investigation of the cause of the outbreak has been set on foot under the superintendence of the Regius Professor of Physic. There have been a few cases at Caius College, and one has terminated fatally; but it is not true that the College has been entirely deserted, although many of the students have left. As yet the source of the fever does not seem to have been satisfactorily made out; it has been supposed to have been derived from infected milk, but there is no evidence to bear out this theory.

YELLOW FEVER AND THE GOLD COAST EXPEDITION.

The arrival of the African Mail Company's steamer *Ambriz* from the West Coast has confirmed the unwelcome rumours of an outbreak of yellow fever in that locality, thirteen deaths having occurred on board this vessel from the malady since the date of her leaving St. Paul de Loanda on October 27 last. Amongst the foregoing were three of her stewards, five seamen, one fireman, and three coal-trimmers. The *Ambriz* was immediately put in quarantine off Cape Coast Castle, and her mails transferred to the *Biafra*, but the latter vessel is reported to have lost six or seven men by the same disease since she started for this country.

The foregoing information is of greater importance to us at the present moment from the fact of our troops intended for the Coomassie expedition being almost due on the Coast; and it is to be hoped that the prompt action of the authorities in placing the *Ambriz* in quarantine at Cape Coast Castle may have averted all danger of a visitation of yellow fever at that station.

It is possibly from this cause, and from information which it may have received on the subject, that the Medical Department has considered it necessary to place a further contingent of army medical officers under orders for immediate embarkation for the Gold Coast.

Special instructions were issued to those on board, before the *Victor Emmanuel* sailed, having reference to such a contingency as an outbreak of yellow fever or other epidemic amongst the British troops on the Coast, and suggestions were prepared calling attention to the importance of isolating all the earlier cases which might occur, and for carrying out a perfect system of disinfecting clothes, bedding, etc.; or, in the event of any sickness spreading with so much rapidity as to elude all efforts for checking it, it was recommended that no fresh cases should be taken on board, but that the hospital-ship should be con-

sidered to be in quarantine, and should even, if deemed necessary, be removed from the Coast to another latitude.

We may therefore fairly assume that all due precautions will be taken to prevent, if possible, the appearance of this disease, and to check to the uttermost its spread, should it unfortunately break out, amongst the troops and others employed at the seat of the war.

It is very much to be hoped that Sir Garnet Wolseley has by this time recovered from the slight attack of fever from which he was reported to be suffering about the middle of last month. As he has organised the whole of the arrangements for the forthcoming operations it is evident that no one else would have so great a chance of success, or be so likely to bring to a satisfactory termination a campaign embracing all the peculiar features of the present, as the originator of the plans to be adopted during the march into the interior. If everything has gone well, the *Tamar* and *Himalaya*, with the Rifle Brigade and 23rd Regiment on board, will by the time these lines are published have arrived at Cape Coast Castle, and before our next edition appears it is probable that the great march upon Coomassie will have begun.

The only other item of intelligence which will be of interest to our readers is the confirmed report of the improvement in health of Commodore Commerell, who appears to be slowly recovering from the severe wounds which he received at the outbreak of the present hostilities.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At a meeting of this Society, on Tuesday last, after a paper by Dr. George Harley, "On Some of the Therapeutical Effects of Conium," an important communication, "On the Cure of Aneurism by Position," was made by Mr. Joliffe Tufnell, who had come over from Dublin on purpose to be present. The subject-matter of the paper consisted of a description of three cases, with remarks on the treatment generally. The first case referred to was one of aneurism of the abdominal aorta, cured in thirty-seven days. The patient was a male, aged 31 years, a shipwright by trade. The patient died from albuminuria five months after consolidation of the contents of the sac. The second case was also one of aneurism of the abdominal aorta, cured in twenty-one days. This patient was also a male, aged 78 years, a pensioner from the army. He died three years subsequent to recovery, from old age and general decay. The third case was one of aneurism of the popliteal artery, cured in twelve days. This patient, too, was a male, 37 years of age, a trooper in the Royal Dragoons. He is still serving in that regiment. After the reading of the paper several well-known surgeons took part in the discussion, which was prolonged and interesting, the details of which will in due time appear in our reports. It may be taken for granted that a communication from Mr. Joliffe Tufnell on any subject connected with aneurism, followed by remarks by Messrs. Holmes, Callender, Savory, Durham, and Gant, and Drs. Sibson and Andrew, secured for the Society a successful and instructive evening. Surgery is, indeed, greatly indebted to the Dublin surgeons for their researches and treatment of aneurism; and the paper of Tuesday evening was provided by one of the ablest of their number.

KILLED BY THE FOG.

Not killed *in* the fog; for, sensational though the heading may seem, it is only too true of a certain number of the members of our community. Dwellers in London are familiar enough with fogs, and, to a certain extent, also with the raw cold of an east wind, but we seldom have fog and cold combined to such an extent as at the present season. Now, the fact that the fall of the thermometer below a given degree means death to many an aged individual, and is the sure precursor of a list of centenarians in the columns of the daily papers, has been thoroughly brought home to us by the reports of the Registrar-General. But the influence of a fog is not so apparent to those of the outer world. When, however, the two are combined—a low temperature, a low barometric pressure, and the air filled with irritating particles of smoke,—the condition is eminently unfavourable to many poor sufferers the subjects of heart and lung disease. Easy breathing means a comfortable change both of the air and blood of the lung. But to an irritated lung the combination of cold and smoky air is particularly unbearable. Violent coughing ensues; and whilst the patient coughs he cannot breathe, and cough materially interferes, moreover, with circulation. The extreme discomfort we have seen in some cases during the last few days has been distressing to witness, and has in some instances ended in death; but an easy death is almost preferable to the sufferings of some who yet remain, but whose condition is hopeless. Not long ago we were advised on high authority—strictly non-medical, of course—that to keep our health we were to clothe ourselves warmly, and throw all our doors and windows open—that, in short, ventilation was everything. But it is just as well that people should know that there are certain poor creatures to whom this means death; for whom there is no safety save in closing door and window and trusting to a good fire for ventilation—that, in short, there are conditions under which warmth must, even on scientific grounds, be preferred to ventilation. A clear, bright, frosty day, to one well filled and well clad, may bring joy and exhilaration from active exercise; but for the poor who are suffering in our panper infirmaries and hospitals it means something quite different.

DEFECTIVE REGISTRATION IN DUBLIN.

The Registrar-General for Ireland, Mr. Donnelly, C.B., has placed himself in communication with the Boards of Guardians of the North and South Dublin Unions as to the very defective state of the registration of births, deaths, and marriages in these union districts. He recommends that the registration sub-districts should be divided, a dispensary medical officer to act in each of the resulting areas. When the suggestion was laid before the Guardians of the North Dublin Union, a resolution was unanimously adopted to the effect that "the proposed alteration was needless, and would lead to confusion." The clerk also stated that he had by him the returns for the past six or seven years, and there seemed to him to be no irregularity. This may be quite true of his own union, but it most certainly is not so of the South Dublin Union. Under date November 10, 1873, the Registrar-General wrote "*No deaths have been returned as having occurred in the South Dublin Union Workhouse for the last two weeks.*" A week later, forty-five deaths were returned *in globo* from this institution, and the death-rate of Dublin was artificially raised from 22 to 35 per 1000. Exactly the same thing has recurred in the past three weeks, the Registrar-General writing on December 1, 1873, "*No deaths have been returned as having occurred in the South Dublin Union Workhouse for the last two weeks*"! But the assertion as to *defective* registration is remarkably borne out in the following curious way:—The deaths *registered* in the Dublin District in the seven years ending 1871 numbered 57,343. In the same time the burials in the three large city cemeteries amounted to 60,429—in other words, *more than* 3000 *persons were buried who had never died!* As a matter of fact, too, comparatively few persons dying in the Kingstown, Blackrock, and Donnybrook sub-districts, which are included in the Dublin registration area, and which have a population numbering 47,401 souls, are interred in the cemeteries referred to. We believe that in some sub-districts in Dublin it has been found that 25 per cent. of the deaths have not been registered. Truly a pretty state of things! The birth-rate of Dublin also is

so remarkably low, when compared with that of London, Glasgow, and Edinburgh, that the inference of defective registration is irresistible. In eight years ending 1872 the birth-rate per 1000 was—in Dublin, 27·38; in London, 35·25; in Glasgow, 41·12; and in Edinburgh, 36·00. We are inclined to agree with the Registrar-General that there is a "screw loose somewhere." The stationary condition of the population of Dublin, also, can scarcely be explained by mere emigration, which is comparatively slight. It is more likely that the published death-rate is considerably below the actual death-rate.

LARYNGEAL PHTHISIS.

Most of us are aware of the difference of opinion which exists amongst pathologists in respect to the relation of chronic disease of the larynx to phthisis of the lungs, some describing the one, and some the other as the primary affection. The question has lately been subjected to experiment by Sommerbrodt, who gives a description of the results he obtained, and the conclusions at which he has arrived, in the *Archiv. f. Experiment. Pathol. u. Pharmac.*, 1873, vol. i., page 264, and *Centralblatt*, 1873, September 27, No. 44. Sommerbrodt experimented on rabbits by inserting a glowing wire in the larynx and upper part of the trachea and there leaving it, where it acted as a chronic irritant, causing death in from four to ten weeks. On examination at various periods, the following was discovered to be the sequence of events:—Some eight days after the operation, small cheesy centres were found in the subcutaneous tissue near the wound. The mucous membrane of the trachea at the same spot was ulcerated, and the cartilage laid bare. The inflammation thereupon spread more or less rapidly along the air-passages to the finest bronchi, thence to the peribronchial tissue, and finally into the pulmonary alveoli. It was easy to trace with the microscope the inflammatory process advancing from the neighbourhood of the bronchi into the alveolar septa, by the thickening of the latter, and their infiltration with lymphoid cells. At the same time there was found combined a desquamation of the intra-alveolar epithelium (Buhl's *peribronchitis purulenta* and *desquamative pneumonia* without purulent softening of the tissue). The experimenter concludes that chronic inflammatory irritation of the trachea leads to purulent peribronchitis, and thence to phthisis. Sommerbrodt was able to show by crucial experiments that the pulmonary disease was not secondary to the infectious centres, or cheesy masses described as occurring subcutaneously at the seat of wound. The lung disease which is secondary to these or other cheesy masses in rabbits, is of the nature of a caseous lobar pneumonia, without the characters of bronchial affection above noticed. It is worthy of remark that dogs similarly operated on never gave the same result—never died of phthisis. Their "constitution" is, therefore, entirely different from that of rabbits.

CORROBORATIVE EVIDENCE.

At a meeting of the Shoreditch Vestry, on Tuesday, the report of a special committee appointed to investigate certain charges made by a Mr. Butler, baker, at Hoxton, against Dr. Stevenson, the analyst of the parish, was considered. It appeared that in the bread which had been analysed by Dr. Stevenson the alum was imperfectly and irregularly mixed in the bread. The Committee submitted the sealed sample, at the suggestion of Dr. Stevenson, to Dr. Dupré, of the Westminster Hospital, and analyst for St. James's, Westminster, care being taken not to let him know from whom it came. Dr. Dupré made the following report:—"I have carefully examined the sample of bread, and find it adulterated with a considerable portion of alum. The bread, part of a small loaf, was very dry, and somewhat mouldy. It consisted of dry matter 85 per cent., moisture 15 per cent., and contained 0·507 per cent. of alum. Now, assuming that the bread had originally contained 44 per cent. of moisture (the usual average), the above proportion would be equivalent to 46·76 grs. of alum in the 2-lb. loaf. No other kind of adulteration was detected." In a letter to the Vestry, Dr. Stevenson stated that Dr. Dupré's report confirmed his statement that the alum was imperfectly and irregularly mixed in the bread. No chemist was at all times infallible. He expressed a hope that what occurred would not shake their confidence in his analytical skill. It was suggested in future that the analyst, on giving his certificate on any sample, should state the result of his examination in a quantitative form. The report was adopted without discussion. We do not see upon what grounds the Vestry should lose their confidence in the analytical skill of Dr. Stevenson. On the contrary, as Dr. Dupré's analysis confirmed that of Dr. Stevenson, the confidence of the Vestry in this gentleman should be strengthened.

SCRIVENERS' PALSY (WRITERS' CRAMP).

It is a question whether a fictitious unity of origin and an excessive pathological importance have not been given to the symptoms commonly designated under this heading. It is still doubtful whether there be any one disease which owes its origin merely to long and continuous writing. Were it so the affection would probably be more common; but there are many local conditions and certain symptoms due to faulty positions of desk, pen, paper, or writer which may induce cramps or even paralysis of the various sets of muscles concerned in scribbling. We are glad to have the testimony of Dr. F. Runge to the existence of local conditions in some of these cases (*Berliner Klinische Wochenschrift*, 1873, No. 21, and *Wiener Medizinische Wochenschrift*, No. 32). In one case Runge found a chronic periostitis (in other words, a node) on the external condyle of the humerus. This node was extremely sensitive to pressure, and this pressure evoked spasmodic contractions of the extensor muscles originating there of precisely the same character as those suffered from when the patient persisted in writing. The actual cautery was applied over the inflamed spot, and this, with six weeks' entire rest, cured the patient, who was still well twelve months afterwards. In the second case an in-growing nail (of the right thumb of the patient) was the original cause of the cramps, for it compelled the patient to alter the mechanism—in other words, the position—of his hand in writing. When this was healed, and the matrix of the nail no longer tender, the cramps all ceased, and the patient was well. Runge, therefore, strongly advises that these local conditions should be carefully looked for, and treated when discovered, in all cases of writers' cramp. He mentions one case which supervened after an apoplectic seizure, and resisted all treatment. In a fourth case he diagnosed a neuritis ascendens of the musculo-spiral nerve, and directed the use of galvanism (ascending current), which gave considerable relief after five weeks; the case afterwards made still further progress, so that at the time of writing he considered it cured. In some cases there is no doubt that the mere abstraction of heat by means of the metallic portion of the penholder is a potent cause of cramp, just as cramp in other muscles is more common in old persons and in cold weather. Apart, however, from local conditions such as those named above, there can be but little doubt that faulty positions in the act of writing are the chief predisposing causes.

WOMEN DOCTORS.

A deputation from the Obstetrical Association of Accoucheuses waited upon Mr. Stansfeld on Monday, at the office of the Local Government Board, to present a memorial setting forth the existing disabilities under which women of a

higher education laboured when they desired to practice midwifery. They stated that the College of Surgeons would not allow them to undergo an examination unless they had been at a "recognised" medical school for four years, but no such school existed where women were admitted. The deputation urged that the Government should establish another board for the proper examination of midwives. They charged the Obstetrical Society of London with being their avowed enemies. He stated that he saw no reason why females should not be afforded facilities to fit themselves for all such functions, and thought the College of Surgeons ought to consider whether it was a just claim on the part of women to be educated and trained for the higher duties of the midwife. The question was a medical one, and therefore not in his hands, but as he was interested in the subject through his connexion with the Poor-law Board, it should have his attention. We have been always in favour of the efficient education of women for the fulfilment of the duties of midwives, whilst we are as much opposed to their pretensions to act as physicians and surgeons, for which office they are wholly unfit.

SUCCESSFUL OPPOSITION TO THE VACCINATION ACTS.

Our contemporary, the *Morning Post*, in a recent article on vaccination, says, considering how recently the country has been visited with an epidemic of small-pox, it is rather startling to learn that the Compulsory Vaccination Act is now a dead letter in several parts of England. They (the *Post*) have no means of knowing whether the change in the law which has produced this singularly unfortunate result was due to a mere blunder, or whether it was inspired by a misplaced confidence in the wisdom of local authorities. But what seems tolerably certain is that part of the machinery which was constructed with so much care, in order to make vaccination universal, has now come to a standstill, for the simple reason that boards of guardians have been left to work it or not to work it at their discretion, and that in several unions they have chosen not to work it. It is the same old story, which has recently been repeated in so many forms, of an original Act that has been made nugatory by an ill-judged amendment. The framers of the amending Acts of 1871 might have seen reason to doubt whether, in spite of the weight of the committee's report in favour of compulsory vaccination, it would be quite safe to leave the enforcement of the law at the discretion of a body like the guardians. Guardians are compelled to appoint an officer to issue warning notices to parents who omit to secure the vaccination of their children; they are no longer compelled to back up these notices by the adoption of legal proceedings. It appears (adds the *Post*, from a local paper which was before them) that the Guardians of Cheltenham, Dewsbury, Ulverstone, and Gainsborough have all resolved not to enforce vaccination in their unions, and it will not be wonderful if many other guardians, with these examples before them, decide to adopt a course which not only effects a considerable saving in the sums paid to the union surgeons, but concedes something to the noisy agitation which a few honest but mistaken people and a good many quacks have for some time been carrying on against vaccination. The question is a serious one. It is plain that the law must be amended without delay. A speaker at the meeting of the local authority at Gainsborough "congratulated himself on being able to inform the guardians that in the next session of Parliament a member of the Government would bring in a Bill to repeal the Vaccination Acts." We (says the *Post*) have no fear that Government will do anything so foolish. But it must no longer be left to what is pleasantly called the discretion of boards of guardians to determine whether small-pox is to be invited or to be stamped out. Half-and-half legislation on so vital a question is a serious mistake. It gives rise not only to the progress of a loathsome disease, but stimulates the energies of ignorant, though they may be "honest," agitators. It moreover raises a doubt in the minds of many reasonable people of the confidence of the Government itself in the protective powers of vaccination. The alteration of the Act in 1871 was a great blunder. It is absurd to suppose that, if the Legislature had made the Act more stringent, eventually it would not have silenced opponents and made the Act effective.

THE TEMPERATURE IN TYPHOID FEVER.

Wunderlich states ("Das Verhalten der Eigenwärme in Krankheiten," second edition, p. 279) "that abdominal typhus is not present when, even on the first day, or on the second morning of the disease, the temperature rises to 40° Cent. (equal to 104° Fahr.)." As a general rule, there can be but little doubt that this great thermometric observer is right. There are, however, occasional exceptions to this canon, and it is well from time to time to note such exceptions. If we translate such exceptional cases into common language, we should say that occasionally enteric fever assumes the usual features of typhus in the thundering manner of its invasion and its rapid march. Some cases quoted at the monthly meeting of the South Australian Medical Association appear to have been of this kind. It is not, however, quite clear from the report in the *Australian Medical Journal* for June, 1873, page 184, that the speakers referred to morning temperatures. That we may not appear to distort their meaning, we extract the report *verbatim*:—

"Mr. Jay then read a paper 'On the Use of the Thermometer in Disease.'

"Afterwards a discussion ensued, during which Mr. Ellison referred to two cases of peculiarity in temperature, which had been met with lately in the hospital. One was that of the cook of the hospital, a remarkably robust man, who was seized suddenly on a Saturday with shivering. On the Sunday he was drowsy and feverish, and his temperature was 104·6°. He had one of the most malignant attacks of enteric fever that we have seen lately, with head symptoms, and died in ten days. There were large patches of ulceration in the ileum.

"The other case was that of a boy who was suffering from idiopathic erysipelas. In this case the morning temperature was invariably higher than the evening throughout the course of the disease.

"Dr. Whittell stated that he had seen several cases of enteric fever like that mentioned by Mr. Ellison, where the temperature was above 104° on the second day. They were generally severe cases, and, in fact, as a rule the patients died.

"In this colony, therefore, the rule is not absolute that when the temperature rises above 104° on the second day it is not one of enteric fever."

DR. REDWOOD'S APPOINTMENT.

The Local Government Board have approved of Dr. Redwood being appointed analyst for the portion of the county of Middlesex beyond the limits of the metropolis—the grounds assigned by the Clerkenwell Vestry to the Board for withholding their sanction to such appointment being in the opinion of the Board insufficient. Certainly no more efficient analyst could be found than Dr. Redwood. Upon this ground, then, the objections of the Vestry are more than overbalanced.

UNHEALTHY EMPLOYMENT OF WOMEN.

In a recent report by Mr. Fitton, factory sub-inspector, he refers to the employment of women in salt-works. He had heard that women were employed all night at certain works in Droitwich. He accordingly went to the works, and states he can swear—and it is not denied—that he saw women stripped and ready for work at night, who all ran off and hid themselves as soon as he entered the shed. One of them had a salt-box in her hand. He should be glad, he adds, if the employment of women at salt-works was altogether prohibited,

as—although he by no means desires to see the employment of female labour in factories generally put an end to—he believes that the semi-nude working at salt factories is in every way bad for women, and it is especially injurious to nursing mothers, and their infants, who are brought into the steaming sheds to be suckled. Mr. Fitton's recommendation is fortified by humanity and common sense. We trust it will be carried out by the proper authorities.

SMALL-POX IN MONTREAL.

The Fifty-first Annual Report of the Montreal General Hospital states *inter alia* that "the most noticeable feature in the medical history of the institution during the year was the persistence of small-pox during the earlier months, the severe epidemic of that disease, which began the year before, not having ceased, although the ratio of mortality had considerably declined. The number of persons admitted into the Small-pox Hospital in 1871-72 was 114, of whom 33 died, a ratio of 1 in 3·45. In 1872-73, 118 cases of that disease were treated, of whom 19 died, or 1 in 6·21." The *Canada Medical Record*, from which we take the foregoing particulars, does not state how many cases in the above were vaccinated efficiently or inefficiently. This is an omission which is to be regretted.

CHOLERA HOSPITAL AT HOWTH, NEAR DUBLIN.

At the usual weekly meeting of the Guardians of the North Dublin Union, held on Wednesday, the 3rd inst., a resolution was adopted authorising the Master of the Workhouse of the Union to have a suitable wooden hospital erected at the north-east point of the hill, capable of accommodating twenty patients, and providing rooms for medicine, nurses, and a doctor—the expenses not to exceed £100.

FROM ABROAD.—THE MEDICAL FACULTY OF LEIPZIG—THE PRUSSIAN UNIVERSITIES.

Dr. D'Espine, of Geneva, in a communication to the *Gazette Hebdomadaire* of December 5, gives an interesting account of "A Recent Visit to the Medical Faculty of Leipzig." Leipzig, he observes, is at the present time the great German university, Berlin only occupying the second rank as to the number of its students, and a far lower rank still with regard to its hospitals and laboratories. One of the principal causes of this pre-eminence, and a principal source of the greatness of the University of Leipzig, is the immense funded property which it possesses, and the intelligent disposal of its revenues, which has enabled it to construct palaces of science, and to employ as professors men of the highest merit. The Faculty of Medicine has especially benefited by this exceptional good fortune, its building constituting almost a district at the gates of the city, where we meet with physiological and chemical laboratories, a pathological institute, and an immense shed-hospital. Descriptive anatomy is alone taught amidst the other faculties at the Augusteum in the centre of the town; but for this also a huge edifice is being constructed near the physiological laboratory, which will be completed by the winter. There are two professors of normal anatomy, one of whom (Professor Braune) has special charge of regional anatomy, and the other (Professor His, from Basel) teaches descriptive anatomy and embryogeny. His labours in embryogeny have created an epoch in that science, and his lectures on development are much frequented. Sections, attached to portable microscopes, are circulated during the lecture, the Professor then demonstrating on a beautiful series of wax models, made after his own indications, the various phases of development. These models have their importance in the study of the subject, for Professor His states that it was not until after the construction of these wax figures that he was enabled to seize certain details which were quite incomprehensible from mere sections.

Among the new academical buildings that line the Hospital-Strasse, the most celebrated and the earliest in date is the Physiological Institute, constructed on the plans furnished by Professor Ludwig, and inaugurated by him, and having attached to it buildings for physical apparatus, chemical investigations, and microscopical observations. All are under the general direction of Professor Ludwig, as are the specialists engaged in the various departments. And it may be well believed that the secret of the amount and importance of the physiological work done in Germany a good deal depends upon this unity of direction on the one hand, and on the other upon the association in the same institution of men engaged in special labours, and capable of rendering each other mutual assistance. The Professor devotes the largest share of his time to instruction, and, while himself directing all the experiments and generally proposing the subjects of study, he causes most of the work to be executed by his students. This labour in common does not, as might be supposed, interfere with the originality of the disciple; for what is wanting most to young investigators is not always so much ideas as the means of execution. The technical procedures constitute the stumbling-block to many young experimenters. Moreover, the personal influence of the teacher is one of the great moving powers of medical instruction in Germany; and surely we cannot say that originality of investigation has sustained much harm from this. The biography of Louis also strikingly shows us that in France, too, among celebrated men those only create schools who give themselves up to their pupils, and daily pass over again with them the paths which they had so painfully toiled up alone. Many of Ludwig's pupils fill chairs in Germany and Russia, and several among them have produced important works.

The Pathological Institute is quite new, and is an agreeable building of one storey, situated at the extremity of the enclosure of the hospital. The autopsy-room, Dr. D'Espine says, is the finest that he has ever seen, and is furnished with the only luxuries permissible in such a locality—plentiful supplies of light and water. Caoutchouc tubes convey water to every dissection-table, and allow of the effectual washing of the organs as they are removed far better than the traditional watering-pot. Every autopsy is made and dictated to a pupil by the professor of pathological anatomy or one of his assistants, as at all the German universities. Alongside are also rooms for microscopical examination and putting up preparations. The museum, which is placed on the floor above, although recent, is already of considerable size. For practical purposes this museum is usefully divided into two parts. The museum, properly so called, containing the rare preparations, is under lock and key; while the museum for study, intended for the use of the students, consists of many specimens of the most ordinary lesions. The Professor of Pathological Anatomy, Dr. Wagner, is well known to us all by his works. He has also charge of a polyclinic or dispensary, and is one of the consulting physicians of the King of Saxony; so that the separation between science and practice would not seem to be so distinct at Leipzig as in other German universities.

The hospital, which has been rebuilt during the last two or three years, consists of fourteen large sheds (if such a name can be given to what are really elegant pavilions), connected together by a covered gallery, and looking on to the garden. Each wooden shed rests on a stone support of about a metre in height, this facilitating ventilation. Warm air also is generated by a calorifer, which heats the sheds far better than the large Leipzig stoves, which in winter do not give sufficient warmth. Ventilation also takes place by the roof, which is open at the sides, windows protecting from the cold during a portion of the day in winter. Each shed contains from twenty to twenty-four

beds, a separate chamber, baths, a small kitchen, and the closets, which are in the ward itself—any ill effect which might arise from this last arrangement being effectually prevented by the employment of earth-closets, of which the medical officers speak in high terms. Water is laid on to each shed, and in the centre of the ward is a large lavabo, with cocks for cold and warm water. The ward communicates through an ante-chamber with the gallery, except in the case of two or three of the sheds, which are isolated for contagious diseases. The central portion of the hospital is of stone, being, in fact, the old building, now exclusively devoted to paying patients, who have each their separate room. The sheds constitute the clinic, under the direction of Professor Thiersch for surgery and of Professor Wunderlich for medicine. The Maternity is in the town, no lying-in women being admitted into the hospital. During the twelve months August 1872-73, Professor Thiresch has performed 266 serious bloody operations, and has not lost a case from pyæmia; while, prior to the construction of the shed-hospitals, he lost from forty to fifty amputations from this cause annually. Whether such a splendid result will be maintained, or whether these wooden hospitals themselves will not become infected, remains to be seen; at all events, the resource of burning them at the end of a certain number of years remains. Professor Thiersch adopted Lister's mode of dressing in 1867 with all the enthusiasm of a believer, employing it rigorously and exclusively; but the results were far less favourable than those which he now obtains. This year he has tried, concurrently with Lister's procedure, that of Rose of Zurich, of dressing in free air; and although the stumps produced by Lister's method are very much better, yet the ultimate results obtained from Rose's procedure are more favourable. In a healthy locality like that of the Leipzig Hospital he now discontinues Lister's dressing about the third or fourth day, the plastic barrier having by this time formed, and the surface being more easily watched for secondary hæmorrhage; while cicatrisation, which is impeded by that application, advances much more rapidly. Professor Wunderlich delivers his clinical lectures at the bedside; and it need not be stated that the thermometer and temperature-curves play a very considerable part in his service, prognosis and diagnosis being regulated by the position of the mercurial column. This also decides whether the typhus patient shall have his cold bath, this being in general given whenever the thermometer exceeds 39·8° C. Pulmonary complications, including pneumonia, are no contra-indication; and certainly cold water in the treatment of febrile thoracic affections is not attended with the danger that might be feared. The two absolute contra-indications admitted by Wunderlich are intestinal hæmorrhage and albuminous nephritis. The baths are easily rolled to the bedside, from four to five being generally given to typhus patients daily; but sometimes as many as eight are given at a temperature of 20° C.

In conclusion, the Obstetrical and Gynæcological Clinic is under the direction of Professor Credé, whose procedure of delivery of the placenta by expression has throughout Germany replaced that of traction by the cord. The maternities are not the portions of the German hospitals which make most figure, and that of Leipzig is no exception in this particular.

We may append to the above an enumeration of the Prussian universities, contained in the *Union Médicale* of December 6. The nine Prussian universities, the Academy of Münster, and the Lyceum of Braunsberg, together, counted during the summer semester of 1873, 434 professors, 177 extraordinary or supplementary professors, 216 privat-docenten—total, 827; of which number, 79 taught evangelical theology, 29 Catholic theology, 85 jurisprudence, 229 medicine, and 405 philosophy. Berlin had 178 professors, Bonn 100, Breslau 98, Göttingen 85, Greifswald 54, Halle 82, Kiel 54, Königsberg 68, Marburg 62, Münster 27, and Braunsberg 9. The total number of matriculated students was 7199, 966 of these not being Prussians; and these are divided among the faculties as follow:—Evangelical theology, 798; Catholic theology, 406; jurisprudence, 1722; medicine, 1587; and philosophy, 2686. To these are to be added 1685 persons who are authorised to attend courses of lectures without matriculation, making a total of 8884 individuals attending the lectures in the Prussian universities. Of this number, Berlin claimed 3051, Bonn 834, Breslau 1022, Göttingen 879, Greifswald 531, Halle 961, Kiel 174, Königsberg 581, Marburg 392, Münster 339, and Braunsberg 20.

LETTERS FROM MADRAS.

No. V.

(*Concluded from page* 643.)

THE LEPROSY OF MOSES—VARIETIES OF SKIN DISEASE IN LEPERS.

Now for a few words on the leprosy of Moses. What was it?

Here we are met with the fact that when the Old Testament was translated into Greek by the seventy elders of Alexandria, about 250 (?) years before Christ, they took the word *lepra* to signify the *tsorath* of Moses. Moreover, the term λέπρα was adopted in the New Testament, in the Vulgate Latin Bible, and by the Arabian physicians as the name of the tubercular disease, and so has come to us. So that here a double question arises. Was the *tsorath* or Mosaic leprosy a merely trivial scaly disease, like the λέπρα of Hippocrates, or had the sense of the word *lepra* become enlarged amongst the Greek-speaking Jews of the East and the Arabian physicians, so as to include the worst skin diseases? The latter supposition is not impossible, as is shown by the use of our word "scurvy," to denote diseases that have no scurf. Moreover, it might be difficult to distinguish the skin frightfully swollen with chronic eczema, or psoriasis, or with the common elephantiasis covered with crusts and ulcers, from a skin whose initial lesion was true leprosy; and so the name of one (lepra) might have been popularly applied to all three.

Now, in endeavouring to form for oneself an answer to this enigma, there are three things to be done: first, to extract the naked facts as they are described in the Bible; secondly, to estimate the value of the terms employed; and thirdly, to come to such conclusion as may be reached by the aid of collateral evidence. The advange of getting at the exact meaning of the word employed was suggested by Dr. Oppert, the Sanskrit Professor in the University of Madras, who is well known for the acuteness with which he has solved more than one enigma in archæology and ethnology—to wit, the identification of the "Three Kings of Cologne" and of the mysterious "Prester John."(a)

The cases of leprosy described as affecting individuals are five—first, that of Moses, whose hand became "white as snow" (Exodus iv., 6); secondly, the case of Miriam, who became "white as snow," and who is described also as like a dead person—like an abortion thrust untimely from the mother's womb, with half the flesh eaten up (Numbers xii., 12); the third case is of Naaman, whose flesh is described as being quite the opposite to that of a healthy child; the fourth is that of Gehazi (2 Kings v., 14, 27), also described as being "white as snow." From these cases we get the fact of whiteness of the surface, and of a state of withering, or other bad condition, like that of an abortion.

Next, as to the value of the terms employed. The word *tsorath*, constantly translated "lepra" in the Greek LXX. and Vulgate, and "leprosy" in the English Bible really signifies, according to Dr. Oppert, a stripe, blow, smite, or infection. It is frequently used with another word—*nega*,—which also signifies a blow, striking, mark, or wheal. *Nega tsorath* is rendered in the Latin Vulgate Bible as *plaga lepræ*, whence our "plague of leprosy"; for the word "plague," like the Latin *plaga*, and the Greek πλήγη, means a blow, stripe, or wheal. The Septuagint makes it ἁφὴ λέπρας, or touch of leprosy. Thus, in the cases of Moses, Miriam, and Gehazi, the passages might be simply rendered, "He was smitten white as snow."

So, also, in the fifth case, that of King Uzziah, the whole

(a) See the *Journal of the Ethnological Society*, 1870.

passage refers to smiting. "The Lord had smitten him" because he attempted to do a priestly act; the word "smitten" being that which is elsewhere translated *plaga* or *plague* (*Sensisset plagam Domini*, ἤλεγξεν αὐτον κύριος, say the Vulgate and LXX.). It is important to notice that the name of the disease implies "*the* stroke"—the stroke of God (2 Chronicles xxvi., 20).(b)

So far, all, though vague, is simple. For vagueness and complexity we must plunge into the precepts of Moses respecting leprosy in Levitieus (chapters xiii. and xiv.), which were to guide the priest in the distinction of leprosy from less important diseases. The importance of this distinction is clear when we consider that, if leprosy were detected, the patient was not merely "unclean" in a ceremonial sense, but was driven from the camp or city, forced to dwell apart, with ragged clothes and bare head, and a covering over his upper lip (perhaps to prevent contamination by his breath).

The morbid conditions enumerated are called "risings" or swellings (*sahat*), scabs (*sappahat*), bright white spots (*behereth*), "boils" or cicatrices of ulcers (*sheehen*), and scales; and the key to the whole subject seems to be found at the end of chapter xiv., where it is said that the object of the "law for all manner of leprosy and scale," and for risings, scabs, and spots, was to teach when they were "cleau" and when "unclean." Of the so-called leprosy of garments and houses we can only conjecture that they were some kind of mould or mildew.

The first distinct morbid appearance described is *sappahat* "scab" in the English; "scabies" in the Vulgate; rendered "pustula" and "impetigo" in later Latin versions from the Syriac, etc., in Walton's Polyglot (Lev. xiii., 1-8).

The second, *sahat lebaneh*, is very obscure. It is some white condition, which might cover the patient from head to foot with ulceration. This was undoubtedly to be pronounced unclean at once, without the need of shutting up the patient to watch the course of the disease (Lev. xiii., 9-11). With this is conjoined another state of whiteness (morphœa, leucoderma?) which might cover a patient from head to foot without rendering him unclean, provided there were no ulceration (*ib.*, verses 12-17).

The third is a scar after a boil or ulcer (18-23).

The fourth, a scar or ulcer from a burn (24-28).

The fifth, a dry scall on the head or beard (*nethek*, Heb.; *Grind*, German; scab, scurf, etc.; θραῦσμα, LXX.; *pustula* and *porrigo* in sundry Latin versions (29-37).

The sixth is a white bright spot (*behereth*, verse 38); and the seventh is baldness (verse 40).

Now, with regard to what some of these seven names mean, there may be some uncertainty. For instance, the *sahat* is rendered—a rising, tumour, diversus color, cicatrix, nævus, φύλη σημασίας ἤτηλαυγής ("conspicuous scar of a mark"), in divers versions. But nothing can be clearer than the following five physical facts pointed out, according to which they were mere scab, scall, baldness, etc., or something worse.

Thus, if any one of them were spreading (Lev. xiii., 7, 8); if excavated below the level of the skin (verses 3, 20, 26, etc.); or if it showed a raw ulcer on an old scar (verse 14); or if the hair in it became white or yellow and downy (verses 3, 10, 25, 30); or if there were ulceration on a bald head (verse 42), they subjected the patient to the necessity of being shut up a week or two for quarantine and future examination (although there was no need of preliminary shutting up if the patient were "perspicuæ immunditiæ" (verse 11); and if still spreading, they made him "leprous and unclean."

On the other hand, with the selfsame diseases, if the "spot" did not spread; if there were no downy, thin, decoloured hairs on it ("subtilis pilus," Vulg.); if it were "fading," which seems the sense of "somewhat dark," and "darkish white" (verses 6, 39, etc.); if there were no elevation of the edges (for this would cause the centre of a sore to seem sunken to the sight), no ulceration on a bald head, then the patient was "clean." "It is but a scab, he shall be clean" (verse 6); "it is but a boil" (23); it is but a "burn"; it is but a *behek* (or freckle?) (39). All these lesions *per se* might be of little consequence, but if a scab spread (verse 8), or if one of the certain other four signs were added, it was a "leprosy," and unclean.

We must now come to the question, Was this or was it not the true tubercular leprosy? or rather, was the tubercular leprosy one of the chief forms of *tsorath?*

It may be maintained, on the one hand, that the LXX. translators would never have used the word λέπρα for *tsorath* if it had been Ἐλεφας, and if it were not the *lepra* of Hippocrates. Now, λέπρα is described by Hippocrates as a disease attended with itching of the skin (*epidem*), as one of the maladies of spring (Aph. III., 20), and he ranks it with itching, psora, lichen, alphos, and alopecia, as blemishes rather than diseases. So also does Celsus. The LXX. translators knew the words of Hippocrates, and they use his term ἄλφος for the *behek*, the trivial white glistening spots or freckles of Lev. xiii., 39. Therefore, it may be argued, the *tsorath* was a trivial scaly disease, and the patient only made unclean for ceremonial reasons. (*See* Hayman, in Smith's "Dictionary of the Bible.")

But here steps in collateral evidence, which renders inevitable the conclusion that the *tsorath* included the genuine tubercular leprosy, or elephas of the Greeks. This is a disease which can be traced. It was mentioned by Lucretius (B.C. 100) as common in Egypt, and by Celsus, Aretæus, etc. The Jews were always in closest social and political alliance with Egypt. The "boil of Egypt" (Deut. xxviii., 27, 35), is commonly considered to be elephantiasis. The regulations in the Old Testament for persons unclean with *tsorath* are the same as described in the New Testament for lepra. They are given by Paulus Ægineta for elephas, and are identical with those handed down to our forefathers, who took the name leprosy from their Vulgate version of the Bible, which followed the Septuagint, in which it was first assigned to the disease. It would be unintelligible if lesser skin diseases were treated by absolute exclusion, and the true leprosy not so. So then, although admitting that what we consider the distinctive marks of true leprosy were omitted by Moses, and that his descriptions, side by side with the use of *lepra* for *tsorath* in the Greek Bible, admit of the interpretation that they refer to skin disease alone, yet the continuity of custom, the treatment of tubercular leprosy down almost to our own time after the manner prescribed by Moses for *tsorath*, and the difficulty of believing that a scattered and wandering race like the Jews could be exempt from an Egyptian disease, make me believe that the *tsorath* was "leprosy."

The general drift and spirit of the Mosaic regulations were very strongly impressed upon my mind by the information I gained from Dr. Van Someren, in one of my visits to his clinique, when he paraded forty or fifty lepers (including half a dozen coolies just landed from Isle de Bourbon) in the garden for inspection. Now, all the signs of leprosy given by Moses are those of visible skin disease; and although, as a matter of science, we may dwell upon the inner affections of the nerves, which Moses says nothing about, yet we must not forget that all leprosy as a rule is attended with skin disease. As Moses showed, lepers have skin disease, but it is neither the scab, nor spot, nor scurf *per se* that constitutes leprosy. Amongst the skin affections of the lepers pointed out to me were—first, irregular accumulations of black pigment in spots and streaks (it is singular, by-the-bye, that in malarious disease the distribution of the pigment is disturbed on the backs of the fingers); secondly, diminution of pigment in large patches of light-coloured skin, generally anæsthetic; thirdly, *morphœa*, patches of glistening white skin thickened as if infiltrated with waxy deposit; fourthly, leucoderma, patches of skin of natural thickness, simply deprived of its pigment, the hairs in it also as white as snow; fifthly, psoriasis, which Dr. Van Someren showed me in all varieties, from psoriasis guttata (petty scaly spots peppered all over the body) to large patches of psoriasis, or the Hippocratic lepra, in its usual seat about the elbows and knees, and besides this a general indescribably unhealthy state of portions of skin (thickened, wrinkled, scaly, glistening or dusky, and greasy-looking); lastly, leprous ulcers (sordid, indolent excavations, surrounded by the thickened and apparently worm-eaten layers of cuticle). I was in the General Hospital one morning, when Dr. Paul, looking at an ulcer on a man's heel, said "That looks leprous." My uninstructed eyes could only see such an ulcer as I have just described; but Dr. Paul's diagnosis was verified by further examination: for one little finger was found atrophied to a stump, with a patch of leucoderma in the hand; and all the skin about the ankle unhealthy. But each and all of the skin affections just reckoned up may occur to persons who are not leprous. "It is but *behereth* or *behek*," says Moses; he is "clean."

What was the feature in leprosy which made it white as snow—the leucoderma, or the white scaly psoriasis? I should

(b) On this principle, the phrase "stricken (*nagua*), smitten of God" (Isaiah liii., 4), is explained by Delitzsch by a reference to leprosy as a type of sin.

think the latter; for mere whiteness of patches of skin (though it may attend lepra and secondary syphilis) is *per se* a mere atrophy, like baldness or grey hair.

The "white leprosy" is a common designation in Sanskrit, where, as Dr. Oppert and Mr. Ramachendra Row tell me, it signifies a new and not an old leprosy. In the Sanskrit, say my informants, there are eighteen terms for varieties of leprosy, seven severe, eleven less severe. The generic term for it is *Ku-sthā* = Anpatz = the "wasting state." Then there are *Svita kushtham*, or white leprosy, *Rakta kushtham*, or coloured leprosy, and *Kristna kushtha*, black leprosy. Other significant terms are the "great disease," *Mahāroga; Vyādhi*, "*the* disease" *par excellence*, or *Mahāvyadhi*, the great disease. Other terms signify "skin disease," "skin contamination," spots, etc. Haughton's translation of the "Institutes" of Manu gives "elephantiasis" as a translation of *Kushthi*, and it seems as if reckoned as one kind of leprosy. In the Tamil and other Dravidian languages of Southern Indian, leprosy is called the "great disease." Lepers are looked upon with abhorrence for their frightful appearance and loathsome breath and ulcers, and are put away or shut out by the natives whenever possible.

The "Institutes" of Manu(c)—the great lawgiver who is the Moses of the Hindoos—warn young men against marrying into ten kinds of families: the irreligious, that which has produced no male children, that in which the Veda has not been read, that which has thick hair on the body, and those subject to hæmorrhoids, to phthisis, dyspepsia, epilepsy, leprosy, or elephantiasis. As the Brahmans consider all present misfortune as a penance for sin committed in the present or in some past state of existence, so they ascribe leprosy as the penalty for one who steals clothes. There is a vestige of the idea that wearing another person's clothes might be contagious, as well as in the history of Gehazi; for, according to their system, "wherein ever a man sin, in the same is he punished" —a pickpocket with whitlows, a slanderer with stinking breath, a stealer of food with sickness, a horse-stealer with lameness, and so on. Anyhow, like the Jews, they regard leprosy as a special scourge of God.

THE STATISTICAL REPORT ON THE HEALTH OF THE NAVY FOR THE YEAR 1871.

The Statistical Report on the Health of the Navy for the year 1871 has just been issued. From this it appears that the mean force on the home station, corrected for time, was 22,100, and the total number of cases of disease and injury entered on the sick-list 20,886, giving a ratio of 945 per 1000. This shows an increase compared with the preceding twelve months equal to 11 per 1000. Of these 612 were invalided, and 148 proved fatal, the former being in the ratio of 27·6, and the latter of 6·6 per 1000. Compared with the preceding twelve months there was a decrease in the invaliding rate to the extent of 1·4 per 1000, and in the death-rate of 22·7 per 1000. The high ratio of mortality, however, in 1870 was altogether exceptional, being occasioned by the melancholy loss of the *Captain*.

Small-pox did not prevail very extensively in any of the ships; the necessity for the adoption of so extensive a measure as the revaccination of every man and boy in the service being fully justified by the results of the operation. A carefully compiled table shows the total number of men vaccinated to have been 10,154, the result being in 5936 a perfect vesicle, in 2278 a modified vesicle, 1869 no result, and 91 not ascertained. This latter number were cases of men operated on and drafted from their ships before sufficient time had elapsed to enable an opinion to be formed. From this it may be assumed that of the total number revaccinated considerably more than one-half had lost all the protective influence of primary vaccination, and that in more than one-half of the remainder it was much diminished. In about one-fifth of the whole the vaccine virus failed to produce any effect.

Of measles 62 cases, 97 of scarlet fever, 1 of typhus fever, 28 of enteric fever, 191 of simple continued fever, one of relapsing fever, 123 of ague, 1 of remittent fever, 100 of mumps, 25 of influenza, and 41 of erysipelas, were under treatment during the year. Of rheumatism 1187 cases, or 53·7 per 1000 (precisely the same ratio as in the preceding year) were entered on the sick-list; 51 being invalided, and 2 terminating fatally. The average number of men daily ineffective from rheumatism was 61.

There were 792 cases of primary and 336 of secondary syphilis recorded during the year, showing a decrease of 2·6 per 1000 in the former, but an increase of 1·4 per 1000 in the latter, as compared with the preceding year. It is observed that although but few medical officers of the navy have stated their views with reference to the result of recent legislation as regards the Contagious Diseases Act, there is a perfect unanimity amongst them as to the advantages which have accrued to the public service from the operation of this Act even in its present limited application, and a wish is strongly expressed that it may be still further extended.

Thirteen cases of poisoning occurred during the year—viz., 2 by oxalic acid, 1 by perchloride of mercury, 1 by tobacco, and 9 by alcohol. Of this number 2—1 from perchloride of mercury and 1 from tobacco—proved fatal. There were 20 cases of delirium tremens, and 2 deaths from pyæmia, not specially appearing on the tables, but probably entered under the head of some other diseases of which they proved the sequelæ.

There were 3986 cases of wounds and injuries, 188 of burns and scalds, 22 of submersion and drowning, 1 of suicidal hanging, and 2 of asphxia placed on the sick-list during the year; and of these 36 of wounds and injuries, and 1 of burn and scald were invalided; and 11 of wounds and injuries, 18 of drowning, and the case of suicidal hanging proved fatal.

Further, there are statistical reports from eight stations of the Royal Navy abroad, giving full particulars of the different diseases treated, and details of invaliding and mortality at each; and an appendix of over two hundred pages, containing medical and surgical reports for the year 1871, of the different Royal Marine Divisions in this country, and of the dockyards, naval hospitals, etc., concluding with some notes and statistics relating to the recruiting and training of boys for the Royal Navy in 1872, by Staff-Surgeon Seaton Wade, R.N., and some observations on the Dietaries of British and Foreign Navies, by Staff-Surgeon (second class) John M. Hunter, M.D., R.N.

The medical and statistical returns for the total force of the Royal Navy employed at home and abroad during the year 1871 close the volume proper; to these, for the first time, an age table is appended. The results show that 50·04 per cent. were between the ages of 15 and 25; 35·61 between 25 and 35; 11·66 between 35 and 45; 2·50 between 45 and 55; and ·16 between 55 and 65. In time it is believed that this information will become exceedingly valuable in showing the proclivity of certain diseases to certain periods of life, and the resisting power of certain periods of life to certain forms of disease, thus possibly affording some basis for selection for special duties, or for service in special localities.

When it is considered that the ratio of invaliding for the whole force during the year 1871 was 32 per 1000 (being a decrease of 3·2 per 1000 on the previous year), and the death ratio 8·5 per 1000, it will be readily admitted that the present report is a very satisfactory one, evidencing a careful supervision on the part of the administrative, and a thorough and enlightened attention to their duties on the part of the executive medical officers attached to the Royal Navy.

REVIEWS.

Diseases and Injuries of the Eye: their Medical and Surgical Treatment. By George Lawson, F.R.C.S., Honorary Fellow of King's College, London; Surgeon to the Royal London Ophthalmic Hospital, Moorfields; and Surgeon to the Middlesex Hospital. Second edition, with eighty-eight wood engravings. London: Henry Renshaw, Strand. Pp. 400. 1874.

The best test of the merits of a work designed to satisfy an acknowledged want is that it attains its object. Before Mr. Lawson first published his manual on Modern Ophthalmic Medicine and Surgery, in 1869, there was no work on the subject which was at once a text-book for students and a clear, concise, and practical guide for the practitioner. How admirably Mr. Lawson succeeded in supplying this deficiency in surgical literature is very evident from the fact that the first edition has long been out of print and a second has been required within four years.

(c) Translated by Haughton. Third edition, 1863. Parts of this work probably date from 800 B.C.; some parts may be much later.

In this new edition the information imparted is brought well up to the standard of knowledge of the day. Many articles which the advances of the last few years had rendered incomplete or obsolete have been rewritten or expunged, and much new material has been added. The book is divided, as in the first edition, into eleven chapters, the subject-matter of each of which is arranged and grouped as before. At the end of the volume is a formulary, containing all the various applications and medicines used in ophthalmic prescriptions; and this is supplemented by a very valuable formulary for children, which will give confidence to the young practitioner in dealing with the diseases of infant eyes.

There is no need for us to specify the deletions and additions in the several parts of the work—our readers may take it for granted, and those who are familiar with Mr. Lawson's writings will know, that these have been done with a master hand by a surgeon of very considerable reputation, and by a teacher of knowledge and experience who has a right to speak with authority.

In the corrections and improvements, as in the original text, conciseness has been studied, but not at the cost of completeness; and while the author's object plainly is to equip his readers with a full and efficient knowledge, he has sought to do this by clearness and simplicity of statement. The success with which, in this manner, Mr. Lawson has described the "Anomalies of Refraction and Diseases of Accommodation" in chapter vi., and the "Diseases of the Orbit" (including aneurism and tumour of the orbit) in chapter xi., is very marked. His mode of handling these subjects alone will gain him the gratitude of his readers and secure for his excellently finished little book a continuance of that favour and appreciation with which it was in the first place received and greeted.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

December 8.

PROPOSED WATER BILL FOR LIVERPOOL—EPIDEMIC OF SCARLET FEVER IN WEST DERBY—CASES AT THE LIVERPOOL MEDICAL INSTITUTION.

THE Water Committee of the Liverpool Corporation have given notice of a Bill which will be introduced at the ensuing session of Parliament, some of the provisions of which are intended to guard against waste and contamination of the water. No adequate powers at present exist for dealing effectively with the serious evil of infiltration of impurities into some of the wells still employed as sources of public supply. Clause 10, therefore, of the proposed Bill will give power to inspect wells, streams, drains, etc., which communicate with the waterworks; while, by Clause 11, the Corporation is to have power to contribute to the cost of abating cesspools, etc., where contamination is apprehended rather than actually ascertained.

An epidemic of scarlet fever, of a very virulent type, has prevailed for some weeks in the district of West Derby, near, or part of, Liverpool. Many of those attacked died within the first few days, some in forty-eight hours. In more than one instance the disease was communicated by means of infection conveyed in clothes returned from the laundry. This fact points to the advisability of careful inquiry into the health of the households of those who wash and mangle clothes. During one week the linen from three laundries (in two cases in very large quantities) had to be removed to the disinfecting ovens of the Local Board, in consequence of deaths from infectious diseases having occurred. Two of these deaths were from scarlet and one from typhus fever. And in one of the scarlet fever cases the linen that had been sent for the purpose of being washed was found being freely used about the dead body of a young woman who had died of the disease, and on the table of the room in which she was lying. The risks *of* washerwomen are no doubt great, but these facts show that the risks *from* washerwomen are equally so; for, if the Medical Officer of Health had not been made acquainted in time with the circumstance that disease was present, there is no doubt that the disease would have been widely disseminated by the clothes, and much injury in all probability done. Indeed, as it was, three cases were clearly traced to clothes sent from one of the houses, before it became known to the authorities that scarlatina was present in it. These three cases all occurred in one family—the only one, happily, for whom the laundress washed. The epidemic is now on the decline, there having been no fatal case during the week ending Saturday, the 6th inst. During the previous week there were seven deaths.

The Liverpool Medical Institution never was in so flourishing a state as at present. The first of its ordinary meetings was held on Thursday, October 23. Among the pathological specimens exhibited were an ovarian tumour which had been successfully removed from a woman, who gave her age as 60, by Dr. Graham, Surgeon to the Northern Hospital; an aneurism of the aortic arch, by Dr. Alexander; and a large cancerous tumour of the liver, by Dr. Glynn, Physician to the Royal Infirmary. The tumour removed by Dr. Graham was a very large one, and had caused an immense amount of inconvenience to the patient from its size and weight. Some few adhesions had to be broken down before it could be removed from the abdomen, but the woman made a rapid and complete recovery. The case exhibited by Dr. Alexander illustrated a fact which does not seem to be generally recognised, although it has been established by a series of very interesting cases by Dr. Axel Key, translated by the late Dr. D. W. Moore, of Dublin, and published a few years since in the *Medical Times and Gazette*—viz., that aortic aneurisms, however large, and however near to the heart they may be, do not cause enlargement of that organ so long as the semilunar valves are competent. Although in the case in question the aneurism was a large one and near to the heart—occupying a portion of the ascending and transverse parts of the arch—that viscus appeared to be smaller than usual, although its tissue was healthy. The points of interest in Dr. Glynn's case were—that the tumour, although undoubtedly malignant, was single, occupying almost the whole of the left lobe, which was greatly enlarged; that the increase in size was entirely upwards and posteriorly, the edge of the liver never having descended below the margin of the thorax; that a large thrombus had been formed in, and completely blocked up, the portal vein, causing extensive ascites during life; and that almost up to the period of death there had been an absence of any very severe symptoms. With reference to the last point, the President (Dr. Cameron) remarked on the frequency with which, in extensive cancerous disease of the liver, there was a similar absence of symptoms; and Dr. Carter mentioned that at the first meeting of the Society in the previous year he had exhibited a liver universally infiltrated with cancerous nodules, and weighing nearly eleven pounds, which he had removed from the body of a patient who had died after a few days' illness in the Royal Northern Hospital, and who, almost up to the time of his admission, had been working as a labourer on the hospital building—as he himself said, without any inconvenience or consciousness of ill-health.

GENERAL CORRESPONDENCE.

PRESCRIBERS' NAMES ON PRESCRIPTIONS.

LETTER FROM MR. BALMANNO SQUIRE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Since writing to you on the subject of the prescriber appending his address to his prescription, I have been told that the British Pharmaceutical Conference recently held at Bradford "respectfully urges upon medical men the importance of the prescriber's full name and address being written on *all* prescriptions, to facilitate communication between the prescriber and dispenser." I feel consequently rather ashamed of having presented the appearance of a proposer, when in truth I am only a seconder of what I believe to be a useful suggestion. It will not be impertinent for me to say that I think the quarter from which the suggestion has originated gives it all the more value, since we have recently given dispensers the right to legislate in the regulation of prescriptions, by admitting representatives of the Pharmaceutical Society into the editing committee of the British Pharmacopœia, and since the disadvantage which I pointed out is one that comes more immediately under the cognizance of the dispenser than under that of the prescriber. The "Conference" I have quoted, furthermore suggests that "the bracketed initials of the prescriber's signature should be written immediately after any unusual dose." This also, I think, is a sensible proposition. I am, &c., BALMANNO SQUIRE.

9, Weymouth-street, Portland-place, W., December 4.

PROFESSIONAL REMUNERATION.

[To the Editor of the Medical Times and Gazette.]

Sir,—No one would be less disposed than I to assert that medical men are properly paid; and yet there are two or three matters in connexion with this subject which have not been touched upon by the writers of the admirable articles and letters which have recently appeared in the medical papers.

Medical attendance bears no relation to the income and position of a family, though the demand for the luxuries and most of the necessaries of life does. It often happens that men with large families and small incomes most need the doctor. These same people, if unable to afford meat every day, are content to have it only three or four times a week; but the doctor's visits may be needed every day, sorely against their will.

Even in such a town as this the number of persons to whom a few pounds more or less are nothing is small, and the doctor is frequently compelled to cut down his charges, and often fails to receive any remuneration at all.

Again, no person likes to pay either doctor or lawyer, and few people entertain very much affection for the occasions on which they have had to consult their medical and legal advisers. Perhaps this feeling is natural, but it acts as a serious difficulty in the way of obtaining payment, and many a man grudges his doctor two guineas who willingly pays his tailor fifty.

There is yet a third consideration, and one of great importance. The ease of medical attendance varies in every town and village, and with every patient.

No one, it is perfectly true, except a rogue, would dream of going to a grocer, and asking him for a pound of sugar for which he had no intention of paying; but many people feel no compunction in evading payment of a bill for medical attendance, often because the expense exceeds what they expected, sometimes because they cannot afford to pay what the doctor charges, and always because there is nothing pleasant in and nothing to show for the doctor's visits.

These things, combined with the indiscriminate relief offered by the medical charities of this and every other town, and the difficulty in which a medical man is placed who attempts to recover by legal means for attendance, are enough to account in a great measure for the loud outcry the doctors raise.

But these things do not exhaust the causes which reduce the fees: there is the peculiar relation in which the doctor stands to very many of his clients—that of a friend,—a relation which, in my case at any rate, causes me to write half a dozen prescriptions a week for acquaintances from whom I never can demand a fee; and there is the impression, strong in the mind of the public, that a doctor is bound in common humanity to hasten to the assistance of any person who is or who fancies himself ill, and in consequence it is almost impossible to avoid doing a large amount of work for nothing, and no abstract resolutions of medico-ethical societies can ever alter this state of things, and the doctor will have to go whenever called out, and those who need him oftenest and most will frequently be those who are least able to pay.

For my part, I am convinced that even in this wealthy suburb a general rise in the fees would only benefit a dozen men of distinction; and most certainly a large increase in the fees of the leading men, though their patients might be willing and able to pay, would not affect the condition of dozens of the club doctors of the town. I may be wrong, but it seems to me that the doctors will always have to be content with harsh words and small pay; and I think that the failure of the many efforts that have been made to increase their fees is the best proof that the difficulties are at present practically insurmountable. I am, &c., A Provincial Doctor.

December 4.

DEPRESSED STATE OF THE BAROMETER AS A CAUSE FOR FRONTAL HEADACHE.

Letter from Dr. F. I. De Lisle.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have lately been reminded of a fact that I have observed in different parts of the world—viz., that some relation exists between a depressed state of the barometer and the prevalence of frontal headache; and although this fact has doubtless been observed by others, I believe that it is not generally known, and that its communication may prove interesting to some of your readers.

During the first five days of this month the barometer was exceedingly low, ranging from 29° to 29·30° or 29·40°, and three members of my household and several of my acquaintances suffered from frontal headache of a more or less intense kind, and, in addition to the headache, a sense of general languor and a slightly bruised sensation of the lower extremities. The headache was somewhat alleviated by the exhibition of guarana powder. This is the only instance in which I have observed the two phenomena concurrent in our latitudes.

When an east wind blows at Gibraltar the same symptoms make themselves very generally felt; and a resident at the Rock can always tell if the wind is east on awaking in the morning, before he leaves his bed. During the sirocco wind in Syria and the hot winds in Australia the same is experienced; and from the description that I have had from those who have felt the pamperos of South America, I am in a position to state that the identical unpleasant and depressing effects manifest themselves.

Except the sirocco and the hot winds of Australia, these several winds have nothing in common save the depressed state of the barometer; and the rapidity and extent of its fall on the approach of these winds, and its equally rapid return to the former height on their departure, has been a subject of much marvel and comment. The east wind of Gibraltar is cold and damp; the sirocco and hot winds of Australia are warm and almost entirely devoid of moisture; while the pampero is cold and dry.

I beg to leave the explanation of this phenomenon to abler men, and content myself with stating the fact.

I am, &c., Frederick Irving De Lisle, L.R.C.P.,
Physician to the Hospital of St. Peter Port, Guernsey.

TUMOUR IN THE VESICO-VAGINAL SEPTUM.

Letter from Mr. A. Leslie Mease.

[To the Editor of the Medical Times and Gazette.]

Sir,—I send a short account of a case of tumour in the vesico-vaginal septum, which may prove interesting to some of your readers:—

Mrs. H., aged 39, was admitted into the Co. Cavan Infirmary, March 30, 1872, complaining of retention of urine. Bowels confined. Ordered calomel gr. v., pulv. Doveri gr. iij., to be followed in two hours by ol. ricini ℥j. As it was receiving day at the Hospital, I could make no particular examination of her case till evening. At this time (8 p.m.) her condition was as follows:—Pulse feeble, 120; cramps down thighs; pain in back and over pubes; bearing-down pains at intervals; slight nausea; tender on pressure over the bladder. Has missed two menstrual periods, and believes herself to be pregnant. Has had eight children and two miscarriages. Bowels had acted once. Urine dribbling away and wetting the bed, but the bladder not distended. Has been ill twelve days, during two of which she says she was "astray in her mind." Illness began with inability to pass water at night, which gradually became complete. She had received a fright, and was suffering from great mental anxiety about money matters. To have liq. opii (Battley), spt. chloroform āā ℥ss. in water at once.

March 31.—Had not slept; bearing-down pains less; pulse 120, feeble; bladder distended; catheter introduced, and over a quart of clear urine removed. 8 p.m.: Over a pint of clear urine removed with the catheter; bearing-down pains ceased. A round, firm tumour can be felt with the finger between the anterior wall of the vagina and the bladder. ℞. Hyd. chloral. gr. xx,, syrup. zingib. ℥j., aq. ad ℥j., to be taken at night. Her bowels had acted five times during the day, and her pulse was 100, but feeble.

April 1.—Had slept; no bearing-down pains; less pain over pubes and in bladder. Removed half a pint of clear urine. Pain in bladder always very severe after removal of urine. ℞. Pil. hydrarg., ext. conii āā gr. iij., bis die. ℞. Nitrat. potass. gr. x., spt. eth. nitric ♏xx., tinct. digitalis ♏x., aq. ad ℥j., ter die. 8 p.m.: Pulse 120; pain very severe over pubes, and great tenderness on pressure in left hypochondrium. Drew off one pint of clear urine. To have chloral draught as before.

2nd.—Slept; spasms about the heart; no other pain; drew off half a pint of acid urine. Same remedies. Beef-tea. 9 p.m.: Easy all day; pulse 150. Drew off eight ounces of urine. Chloral draught as before.

3rd.—Slept badly; catheter not required; pulse feeble, 140.

Cease present mixture, and substitute bicarb. potass., acetat. potass. āā gr. viij., tinct. calumb., tinct. buchu āā ʒ ss., in water, ter die. Continue pills.

4th.—Had good night; catheter required; pulse very weak, 120. Tumour diminishing. Port wine two ounces, beef-tea.

5th.—6 a.m.: Had severe labour-pains all night, and great pain in back and thighs. Pulse 120, scarcely perceptible. Urine had dribbled through the night, although catheter had been used at 9 p.m. Drew off a quart of pale urine, slightly cloudy; tongue moist and brown; a tendency to rigors. Ordered a draught of Battley's liquor and spt. chloroform at once, and some hot negus. 11 a.m.: Pulse 120, very weak; pain ceased; hysterical dilatation of pupils; abdomen tympanitic. Omit pills. Continue mixture, and give hyd. c. cret. gr. v., ext. conii gr. iv. each night at bedtime.

6th.—Catheter not needed; pulse 100, feeble.

7th.—Catheter not needed; pulse 90, feeble.

8th.—Had good night; retention cured; tumour disappeared; pulse 90. To sit up a little. From this time she improved steadily, and about seven months after was delivered of a healthy child.

I wish just to call attention to two points in this case. First, although the uterus was in its proper place, as was fully made out, the symptoms in many particulars resembled those of anteversion. Secondly, the hysterical aggravations of her symptoms to which she was liable. For instance, on the 4th she was better, and the primary cause of the mischief (the tumour) diminishing, and yet on the 5th I found her apparently almost moribund, pulse 150, and in dreadful pain, with hysterical tympanites and dilatation of pupils. It seemed as if the violence of the hysterical tendency had spent itself in this attack, for from this time her progress to recovery was unchecked.

I am, &c.,

Armagh, Ireland. A. Leslie Mease, M.B.

TESTIMONIALS.

[To the Editor of the Medical Times and Gazette.]

Sir,—There is hardly a man of eminence in any branch of science who has not been repeatedly applied to for a testimonial in favour of some applicant to an office of position and trust. In many cases these applications are made on the most remote pretence that the person applied to can have had any personal knowledge as to the applicant's fitness for the office. Hence arises the great scandal of men being placed in situations they have not the slightest competence to occupy. In a profession where skill is of vastly greater importance than mere personal recommendation, ability should be the test of a candidate's fitness to occupy a situation. Especially ought this to be the case in the medical profession, where the lives and comfort of hundreds depend on the skill of those who are placed in positions of importance. It may be urged that medical men have all passed some form of examination, and are supposed to be fully qualified. But what, in many instances, are these examinations? A mere cram. The candidate may possibly have never been examined in the speciality in which he is now applying for a situation. Then, again, years may have elapsed since his examination, and all the knowledge he has ever had has become rusty from want of use; or, even if he has been employing it, he may not have kept pace with the progress of the science.

We may take, for instance, the subject of mental diseases. There are men appointed to our asylums, with the care of perhaps thousands of poor lost humanity. In how many cases are they quite unfit for their work? They have had no special qualification; in fact, it often happens that an ignorant man is preferred, it being thought unadvisable to have one "who knows too much." The appointments are not made by men who can form an opinion of the applicant's fitness, but by our local justices—a race of men who, though very worthy in their way, are not remarkable for intelligence, especially in matters pertaining to a science they can know nothing of. These men must necessarily form their opinion of the ability of the candidate from the number and character of his testimonials. Hence it is to a great extent mere chance if he is fitted for the post, for the testimonials cannot always state this, or only in general terms, and there must always be a prejudice in favour of that person who can obtain the signatures of the biggest men, or whose recommendations speak most highly of his personal character. Men can only judge by what they understand: a gentleman can understand the qualifications of a gentleman; but it requires, in addition, the knowledge of a specialist to estimate a man's true worth for asylum work.

This mode of obtaining situations is most unfair to the applicant himself. He has no standard by which he may endeavour to qualify himself. He may see himself superseded by men whom he knows are infinitely his inferiors. The most trivial circumstance may turn the scale against him—a blot on his testimonials, a pimple on the tip of his nose, some physical blemish, the cut of his coat, his provincial accent, and numerous other peculiarities are sufficient.

Not long ago a rejected candidate for an appointment was applied to by the successful applicant for instruction in his duties. The man who had got the place went to the one who lost it for information as to what he had to do, and paid him for imparting the knowledge by a series of lessons. Only fancy the rejected one's feelings! What encouragement had he in perfecting himself in a subject for which he received such thankless returns?

Then, again, consider the mean subterfuges, the toadying to great little men, the degradation of personal canvassing, that candidates have to perform. A man of honour and high intelligence would scorn to stoop so low, and consequently fail in his application.

Now, the remedy for these evils is clear, and ought to be insisted on again and again till it be employed. It is simple enough, and easy of application. There should be boards of examiners formed, who should examine candidates for positions in any speciality. They should be men occupying the highest position in that particular branch of study. Thus we might have examinations in mental science, for Poor-law and special hospital appointments, medical officers of health, analysts, etc. There are the Commissioners in Lunacy already—men probably of the highest standing in mental science: their duties at present chiefly consist in examining buildings, etc. Perhaps they might be induced to extend their examinations to the men who have charge of the buildings. Surely it would not be a great tax on their time to have stated periods when men who wish to obtain a standing in their special department of the profession might present themselves, and receive, not merely certificates, but also have placed against their names in some permanent record the position they have occupied, as shown by a certain number of marks, in that examination. And it should further be established by rule that a man may present himself as often as he pleases, so as to allow him at some future time to obtain a higher position than he previously occupied. But on no account must the fee exacted, if any be needed at all, be higher than one guinea. The plan of charging exorbitant fees for medical diplomas defeats the object for which the examinations is designed; it biases the minds of examiners against rejecting a candidate.

Of course, it is not pretended that this plan of having an examining board for each speciality will introduce perfect men into our asylums and other offices, but it will tend to raise the standard of a man's qualifications; he must at any rate study the subject before he applies. And a man who knows that there is some power qualified to give honour where honour is due will strive to make himself master of the subject, and raise himself intellectually above his fellows. Then shall we have in these places of trust men who are capable of doing good work, and many a poor lunatic or weak-minded individual, or pauper, or householder, or tradesman, will be glad of having placed above them a man intellectually as well as morally fitted for his duties. Then may we hope to see the subjects these men handle day by day improving with the fresh light, even the light of knowledge, that is being shed on it.

As a well-known philosopher observes—"To cease to strive is to begin to die physically, morally, and intellectually." So when a man as an asylum medical officer has no higher motive for exertion than the mere getting money and credit by pampering to the Commissioners and Committee, he begins to die intellectually as far as his medical knowledge is concerned; for, having no special object to strive for, he ceases to perfect himself in the study of mental disease.

I am, &c., An Asylum Medical Officer.

UMBILICAL HERNIA IN INFANTS.

[To the Editor of the Medical Times and Gazette.]

Sir,—Speediness in the cure of the above, combined with simplicity in the means employed, is, I hold, the great desideratum. What more simple than strips of plaster applied

erosswise, or—as I have done during the last ten years—to apply a small pad of lint and one broad strip of adhesive plaster? No case has failed; no soreness have I ever seen, "so far as my memory serves me." The information I should like is as to the time it takes to effect a cure under these several methods. I am, &c., COUNTRY DOCTOR.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY.

FRIDAY, NOVEMBER 28.

PRESCOTT HEWETT, F.R.C.S., President, in the Chair.

DR. GEORGE JOHNSON read a paper "On Cases of Temporary Albuminuria the Result of Cold Bathing." The first case was that of a medical student, aged 22, who, about noon on June 19, after bathing for a quarter of an hour in the Marylebone Bath, had a sense of fatigue and headache. Four hours after the bath, the urine was tested, and found albuminous. In the evening there was still a trace of albumen. The next day the urine was normal, and continued so until June 28, when he again bathed. The bath was again followed by headache, and in the course of the day the urine was found albuminous. From that date until July 17 every specimen of urine passed was tested, and albumen was present at some period of the day on all but five days. Since July 17 the urine has remained normal. The subject of these observations is in good health, and has never been seriously ill. The second case was that of a medical student, aged 25, who one day in July bathed in the Lambeth Bath for an hour. He felt no inconvenience. The urine passed an hour after the bath contained a sixth of albumen. The urine was not tested again for three or four days, when it was found normal. The experiment has not been repeated. The third case was that of a medical student, aged 23, who on three occasions found his urine normal before bathing in the sea in August and September; and on each occasion, after remaining in the water from a quarter to half an hour, found a moderate quantity of albumen in the urine. In a few hours this had disappeared. He felt no inconvenience from the bathing. Four other students, after bathing from half an hour to an hour, and on one occasion for an hour and a half, found no albumen in the urine. The fourth case was that of a boy, aged 16, looking pale and feeling languid, who was found to have albumen in the urine to the extent of one-eighth on June 28. It was of pale colour, and contained no casts. On September 23, when next seen, only a trace of albumen remained. On October 23 the urine was quite normal. Until within a few days of the time when the albuminuria was first discovered, he had been bathing almost daily in the sea from half to three-quarters of an hour at a time. He had felt fatigued and chilled, and on one occasion had vomited, after coming out of the water. The only previous illness had been diphtheria ten years before. The transient albuminuria is believed to have been caused by the repeated and prolonged immersion in cold water; and it is suggested that, as acute Bright's disease is not unfrequently excited by exposure to cold and wet, there is danger lest the frequent recurrence of temporary albuminuria the result of prolonged cold bathing, and the consequent repression of the cutaneous secretion, may lead to permanent mischief and to structural degeneration of the kidney.

Dr. SOUTHEY said such examples of albuminuria from cold were common, but he had not known they might be so temporary. All swimmers must have felt headache, heaviness, and depression after a prolonged bath; but if these, together with the albuminuria, persisted, he would hardly think the kidneys had previously been sound. Often acute cases arose where there was some previous lesion of the kidney. Swimming by itself could hardly be a potent cause of albuminuria.

Dr. POWELL thought it would be interesting to know if there were any other signs of kidney lesion besides the albuminuria, as casts, etc. Swimmers in active exercise and entirely immersed would be less likely to suffer than ordinary bathers.

Dr. GREEN remarked that it had not been stated whether the albuminuria was considered due to any inflammatory change in the kidney or to a mere mechanical congestion. Inasmuch, however, as the albumen continued some time after, the latter supposition seemed least tenable. If truly inflammatory, that would lead to tissue changes.

Dr. H. WEBER had seven or eight years ago seen a gentleman suffering from hæmaturia, who, after traversing a high mountain pass and being greatly fatigued, fell into a river. He was carried to the hotel, and waited for a meal before going to bed. When seen again in London there was no blood, but still albuminuria, which continued for five or six weeks. The specific gravity was, however, normal, and the urine contained casts both epithelial and hyaline. In three months this was quite gone. He had seen several patients with albuminuria after coming from abroad and being exposed to cold and wet; they soon recovered. Formerly, such cases were apt to occur in water-cure establishments, but not nowadays. In these there was no element of fatigue.

Dr. GREENHOW considered the facts interesting as bearing on intermittent hæmaturia. He had seen two or three cases apparently similar in character, but without colouring matter. These were also brought on by exposure to cold. He thought they contained a nervous element.

Dr. G. JOHNSON only saw one of the subjects—viz., the boy. The urine here was pale, and contained no casts. He had no doubt they could induce acute Bright's disease by cold and wet, without any previous lesion. He did not speculate as to the exact cause, but thought it would be the action of the cold on the skin. He alluded to the existence of albumen in the urine of famished rabbits.

Mr. ARNOTT narrated a case of Excision of the Knee-joint, in which he had employed Professor Esmarch's so-called "Bloodless Method," early in August of the present year. It happened to be probably the first operation of any magnitude in which this ingenious suggestion of Professor Esmarch was employed in England, although Mr. MacCormac had already used it in some cases of removal of necrosed bone, and the author therefore brought forward the case as a peg on which to hang a discussion on the merits of the proceeding by the hospital surgeons present. The case was an ordinary example of old disease of the knee, in which it was determined, on exploring the joint under chloroform, to excise it at once, the patient having refused to submit to amputation. The limb was tightly bandaged with elastic webbing from the toes to the thigh, and, before the removal of the bandage, a stout elastic cord was twisted firmly round the limb above the bandage and fastened with hooks. The compression was kept up for more than thirty minutes, with the effect of rendering the operation absolutely bloodless until the elastic tourniquet was removed. Convalescence was slow, but presented nothing unusual which could be attributed to the pressure employed during the operation. The points dwelt upon by the author in commenting on the case had reference to (1) the possibility of sloughing following the use of the constricting band, and the length of time during which the pressure might be safely maintained; (2) the effect on the circulation of the compressed limb on the removal of the elastic cord; (3) the difficulty of using the method without chloroform; and (4) under what circumstances the method might be wisely avoided. In briefly remarking on these heads, it was suggested that much of the pain and sudden engorgement of the vessels with blood might be prevented by gradually relaxing the constricting band; and, in enumerating the cases in which the employment of the method might be attended with danger, reference was made to instances of septic abscess, the clot-occluded veins about a compound fracture, and limbs already gangrenous. It was also suggested that a possible risk of apoplexy was incurred by suddenly overfilling the circulatory system of aged people, with brittle arteries; and that, although generally beneficial in town practice, the visceral congestions caused by the subsequent plethora in cases of large amputations in robust subjects might seriously interfere with recovery.

Mr. EASTES said he was responsible for the statement that in five out of seven amputations at Guy's by this method sloughing had taken place, but probably he ought to mention that carbolic acid spray had been also used.

Mr. HEATH said the process was not so new as supposed; something of the kind had long been employed in Scotland. An ordinary tourniquet sufficed quite as well as elastic bands and ligatures. The limb was raised whilst chloroform was being given, and the finger run along the vessels in a backward direction; the broad band of the tourniquet was then quite enough. Usually there was free bleeding when the elastic ligature was relaxed, but that could be done gradually with the tourniquet. The results of the whole system were as yet uncertain.

Mr. CLOVER had used a band in some amputations some

years ago. The operations were not quite bloodless, but very nearly so. It was objected that the internal congestion might be injurious: another objection was that the indiarubber band might break suddenly, especially if used more than once. He thought that an ordinary band tourniquet might suffice, but that something more than merely raising the limb was required to empty it of blood.

Mr. MacCormac said that nothing novel was contended for in Esmarch's method, but it was very simple and perfect. He was hardly prepared for the complete bloodlessness of the parts; even the bones were dry. The principle had been adopted even by Sartorius. Heretofore it had not been generally adopted, but Esmarch's plan spread like wildfire. No great amount of compressing force was required, but the return of the blood to the parts was sometimes very painful. It should only be permitted gradually, and the elastic band should be left on a minute or two before the ligature was applied.

Mr. Barwell thought Esmarch's plan better than Lister's. In an operation so performed no blood escaped during its performance, but oozing went on for twenty-four hours after. Ultimately it did well.

M. Koch had seen the operation done by Esmarch for necrosed bone. The parts were quite dry. Esmarch accounted for this dryness by the veins of the soft parts drawing the blood out of the bones as they expanded after compression. No sloughing followed, and he had seen no sloughing here.

Mr. Willett thought nothing so good had been introduced since chloroform, as far as the surgeon was concerned; for the patient, that remained to be seen. The bone was not always quite bloodless. In one case of his there was slight oozing, which formed a clot. Sloughing followed in one amputation, the subject being an old and debilitated woman. He thought the elastic band better than the tourniquet.

Mr. Morris also thought Esmarch's plan better than that mentioned by Mr. Heath. Mr. Hilton used to bandage before applying the tourniquet, but the results with the elastic band were better. He had seen quite as severe hæmorrhage after removal of the band as if it had not been used. He thought it would be well to use an elastic band with a tourniquet to relax gradually. Sloughing in many instances had followed the plan. At Guy's they had used the carbolic acid spray at the time. In one old man there had been no attempt at union, and he thought it of questionable value in old people. He thought it should not be used over suppurating cavities.

Mr. Arnott said they had often used carbolic acid spray, but no sloughing had followed. The fact that the cord might prove brittle was important. A tube was better than a solid cord.

THE PATHOLOGICAL SOCIETY.

Tuesday, December 2.

Sir William Jenner, Bart., President, in the Chair.

Dr. G. Harley and Dr. Powell reported on Dr. Dowse's specimen of Foreign Body in the Crico-Thyroid Pouch. It consisted of necrosed bone, and seemed to be a portion of the ossified cricoid cartilage.

Mr. Tay exhibited a child between four and five years of age whose Lower Jaw had become Necrosed, and had been nearly entirely removed. At first the child was supposed to be injured, but of this there were no definite signs. Three weeks after the gums ulcerated, and in a few days were partly bare. The teeth were loose, so that the child picked some of them out; but the rough edges of the alveoli seemed to stand in good stead in their place. In about five months new bone had begun to form, and the old was removed in three divisions. The child did very well. The necrosis was too complete and rapid for phosphorus-poisoning; possibly it might have occurred after typhoid.

Mr. Maunder said that three years ago he removed a portion of the jaw for a myeloid growth, saving the periosteum. The patient soon recovered, but little or no new bone was formed. He had had a similar experience in another case.

Mr. Nunn showed a specimen consisting of a very large Pectoral Tumour, removed from the body of a female patient. She had been a patient at University College Hospital, but afterwards came to the Middlesex. There was a large cystic mass, whence fluid was drawn by aspiration. It looked colloid. She died from difficulty in breathing. The mamma was not involved. The mass consisted of a softened enchondroma. (Referred to Morbid Growth Committee.)

Mr. Beck said he had seen the patient at University College Hospital some months ago. He had removed some of the fluid by aspiration. From the characters of this the tumour was diagnosed as a softening enchondroma.

Dr. Cayley said no part was like cartilage, but was rather like colloid.

Mr. Andrew Clark next showed a specimen of Lymph-adenoma of the Trachea from a female, aged 75. She had been healthy up to nine months before death, when she was seen complaining of pain and swelling in the neck, with occasional attacks of dyspnœa. He found a growth in the middle line, which seemed to be part of the thyroid. This diminished under treatment, but after a time she had an attack of violent dyspnœa, which was relieved by heat; but other and more severe attacks came on, and tracheotomy had to be performed. She did well; the tumour disappeared, and she went out. Later she returned with bronchitis, and tracheotomy had again to be performed, but the patient died. A tumour was found behind and to either side of the trachea, the mucous surface of which was covered with small growths, which, together with the larger masses, were lymphomatous in character.

Dr. Payne showed certain Pouches in the Peritoneum which had contained Herniæ. The subject, a female, died of some other disease; but on post-mortem examination there were found two pouches between the ascending colon and the abdominal wall. The lower was formed by the mesocolon, and lay partly behind the cæcum. There was no strangulation in this case, but there often was from this cause. He considered that there were three kinds of these pouches—one duodenal, at the site of the inferior mesenteric artery; a second sub-cæcal, as here; and a third sub-sigmoid. There was a good example of the first kind in St. Thomas's Hospital, prepared by Sir Astley Cooper.

Dr. Payne next proceeded to show another specimen, consisting of Thickening of the Pulmonary Artery, from a female who died of metritis. The deceased suffered from pneumonia, and the base of the right lobe was solidified, but not as in acute pneumonia. The whole of the division of the pulmonary artery going to this part of the lung was found greatly thickened, especially its outer coat, which was greenish, semi-transparent, and fibroid-looking. The same kind of material was not found elsewhere. The structure was something like that of a syphilitic gumma, but there was no history of syphilis. The new growth was partly nucleated, partly granular, and partly fibro-nucleated. There were also signs of catarrhal pneumonia.

Dr. Pye-Smith said that a description had recently been given by Lancereaux of a condition resembling this, which he attributed to congenital syphilis in infants.

Dr. Green asked if there was any thickening of the pleura or alveolar walls. It seemed as if the whole base was tough from chronic pneumonia. In all cases of fibroid change that began round the artery.

Dr. Powell remarked that the pulmonary was blocked. Was this secondary to the other changes? The bronchi were usually thickened in such cases.

Dr. Payne said there was a good deal of induration, even near the surface; but the bronchi and pleura were not thickened. There were no signs of degeneration in the clot; it seemed to be post-mortem.

Dr. Lockhart Clarke showed certain specimens illustrative of Sclerosis of the Posterior Columns of the Spinal Cord. The condition had been repeatedly described by himself and others. In it the connective tissue became greatly increased, and fatty globules or compound granule corpuscles could be made out. The present case was one of subacute inflammation. The blood-vessels were destroyed. In reply to Dr. Dowse, the symptoms were described as gradual paralysis, with contraction. There was no cerebral sclerosis.

Dr. Dowse said he had made a post-mortem examination of a man who had died of phthisis, having exhibited no signs of cerebral or spinal sclerosis. Yet he found the grey matter of the convolutions greatly hardened, so that it could be peeled off from the white tissue beneath.

Dr. Payne said the signs were sometimes few and ambiguous. A female, who had been greatly neglected, died of bed-sores. She had, however, been going about no long time before. Yet after death he found large masses of new material in the grey substance of the cord, though of this there had been no sign during life. There was something like it in the brain.

Dr. King showed specimens from a woman, aged 53, who

up to last Christmas had shown no sign of illness. About ten days before admission she began to complain of pain and tenderness over the liver and in the epigastrium, and the liver was enlarged. After admission she began to shiver, and her temperature rose. The pain also increased, and she died collapsed. The right lobe of the liver was found enlarged, and its shape altered. It contained a quantity of green pus filling a large cavity. No distinct origin could be traced, but there was no ulceration of the intestines.

Mr. Arnott exhibited a specimen of Sarcoma of the Omentum from a boy aged 4. His mother had noticed some hardness and fulness on the morning he saw the child, and there had been some loss of appetite. On examination, he found a mass the size of an orange, without pain or tenderness, near the navel. There was, however, a small nodule in the skin, and from these general characters he diagnosed a sarcoma of the omentum. In a week, both nodule and mass were larger, though the child seemed well up to two days before his death. The nodule had by this time grown to the internal mass. The child was suddenly collapsed, and died of peritonitis. A large tumour was found involving the omentum and invading the colon, and masses of the same kind were found in the liver, kidneys, and epididymis. In structure it was a lymphoma, and probably originated in the submucous tissue of the colon.

Mr. Morrant Baker showed a very Rare Form of Calculus. It consisted of pure and crystalline oxalate of lime. It was removed by lithotomy from a child who had suffered from stone for years. It had been sounded for stone without result. This was probably due to the existence of a kind of pouch near the opening of the ureters.

Mr. Coupland showed some nodular growths in the liver of a man who suffered from ascites. He had had a cough for eight months, but was not very ill. He was tapped, and the fluid coagulated spontaneously. It reaccumulated, and he was again tapped, but soon sank. The peritoneum was thickened. The size of the liver was normal, but it contained nodules, small-celled on the surface, granular in the interior. The mesenteric glands were enlarged, and the lungs contained old tubercle. The nodules were either tubercular or syphilitic.

OBITUARY.

THOMAS HARPER WHITAKER, M.R.C.S., J.P.,

Died at his residence, Kirkby Lonsdale, on November 14, aged 61 years. The following paragraph, taken from a local newspaper, will show the great esteem and love felt for him by all classes, poor as well as rich:—"The town and neighbourhood of Kirkby Lonsdale received a severe shock on Friday week by the announcement of the death of Mr. Whitaker, after a short illness of two days. Indeed, many never heard of his illness until the fatal termination was made known. For upwards of thirty years Mr. Whitaker was engaged in active professional duty, and no man was more deservedly respected and beloved in the large circle where his sterling good sense, his cheery countenance, and kindly manner made him always welcome as friend and physician. Valued for his medical skill and thoroughly unselfish nature, he was almost a part of every family, where his long career had won him high esteem, and his name was familiar as a household word. His almost sudden removal, in the fulness of bodily and mental vigour, is to all who knew him a deep sorrow, to many an irreparable loss. The funeral took place on Tuesday last, and was attended by the whole town: every shop was closed. The volunteer corps, of which he was a member, preceded the coffin, and in the long train of mourners were members of every family, both gentry and clergy, from the wide district over which his professional practice extended. Wreaths of exquisite white flowers were placed on the coffin by the Earl of Bective and the Marquis of Headfort, and the grand office for the burial of the dead closed amidst tears of sorrow from many of those who stood around the grave. A few months since Mr. Whitaker was appointed a magistrate for the County of Westmoreland, and qualified at the last Quarter Sessions at Kendal only a few weeks ago."

JAMES McTERNAN, R.N., Deputy Inspector-General of Hospitals and Fleets,

Died at Blackheath a few days since, in his eighty-third year. He became an Assistant-Surgeon in the Royal Navy in 1809, and served in the *Northumberland* at the destruction of two French frigates and a brig off L'Orient in 1812, and in the following year was promoted to be Surgeon of the *Cleopatra*. Served also in the *Dragon*, in all the operations in the *Chesapeake*, and on the coast of America, including the capture of Bangor, Hampden, etc. In January, 1844, he was appointed Surgeon of Greenwich Hospital, and in July, 1855, became retired Deputy Inspector-General of Hospitals and Fleets. We are not aware that he contributed anything to the literature of the profession.

LEGAL INTELLIGENCE.

UNQUALIFIED PRACTITIONERS: IMPORTANT CASE AFFECTING MEDICAL MEN.

On Tuesday last, at the Halifax County Court, before Mr. Sergeant H. Tindal Atkinson, the case of "The Apothecaries' Company of London *v.* Richardson" was set down for hearing. Mr. Godfrey Rhodes appeared for the plaintiffs, and Mr. England for the defendant. It appeared from the opening of Mr. Rhodes that the defendant (Mr. James Richardson) had for some time past carried on the practice of a surgeon and an apothecary at Elland, near Halifax, he not being duly qualified; and that the proceedings had been instituted by the plaintiffs to recover the sum of £20, being the amount of the penalty which the defendant had rendered himself liable to pay by reason of such practices. The defendant carried on an extensive practice, and the leading practitioners in the parish of Halifax signed a memorial to the Apothecaries' Company requesting that these proceedings should be taken with a view to prevent the defendant from continuing his practice and from invading their privileges with impunity. The defendant had visited patients and dispensed medicines, and had made the usual professional charges for attendances. He had, however, thought fit to pay the penalty, and the matter now came before the Court as to the question of costs. Mr. Rhodes stated that the money was not paid five clear days before the Court-day, and submitted that he was entitled to costs. His Honour made an order for payment of costs.

NEW INVENTIONS.

LYNCH'S IMPROVED FEEDING BOTTLE.

The Infant's Feeding Bottle patented by Messrs. Lynch and Co. is fitted with a wooden or earthenware cap which is fastened on the principle of the bayonet catch: that is, there are grooves in the cap which correspond with projections on the neck of the glass bottle. When the cap is applied, the grooves receive the projections, a half turn is then given to the cap so that the projections no longer correspond to the groove, and the cap is then securely fastened. By this simple arrangement safety in fastening, freedom from leakage, cleanliness, and easy removal of the cap are obtained. To remove the cap it is of course only necessary to reverse the half-turn so that the projections again correspond to the grooves, and the cap can be directly withdrawn. The improved feeding bottle is likely to be a very useful and popular nursery appliance.

MEDICAL NEWS.

University Intelligence.—University of London.—The following are lists of candidates who have passed the recent examinations:—

M.D. EXAMINATION.

Anderson, Tempest, B.Sc., B.S., University College; Aveling, Charles Taylor, M.S., St. Thomas's Hospital; Barnes, Edgar George, St. George's Hospital; Burn, William Barnett, B.Sc., St. Bartholomew's Hospital; Cane, Leonard, B.S., University College; Carr, William Ward, B.S., University College(a); Dalton, Benjamin Neale, Guy's Hospital; Humphreys, John Henry, University College and Middlesex Hospital; Langmore, John Wreford, B.S., University College and Middlesex Hospital; Oliver, George, (Gold Medal), University College; Roberts, Richard Lawton, University College; Sawyer, James, Queen's College, Birmingham; Shewen, Alfred, University College; Smith, Richard Thomas, University College; Wall, Alfred John, B.S., St. Mary's Hospital; Warner, Francis, King's College; Wyman, John Sanderson, St. Bartholomew's Hospital.

LOGIC AND MORAL PHILOSOPHY ONLY.

Ingoldby, Joseph Theodore, Guy's Hospital; Price, William, University College; Spencer, George Owthwaite, University College.

(a) Obtained the number of marks qualifying for the Medal.

SECOND M.B. EXAMINATION.

EXAMINATION FOR HONOURS.

MEDICINE.

First Class.—Addy, Boughtou, (Gold Medal), St. Thomas's Hospital, and Skerritt, Edward Markham, B.A., (Gold Medal), University College (equal); Dodson, Andrew, Birmingham and Guy's Hospital; Cockburn, John Alexander, King's College; Barlow, Thomas, B.Sc., University College, and Benham, Henry James, University College (equal).

Second Class.—Coupland, Sidney, University College and Middlesex Hospital; Rayne, Charles Alfred, University College.

Third Class.—Dyson, William, B.A., University College; Pope, Harry Campbell, Liverpool Royal Infirmary aud University College.

OBSTETRIC MEDICINE.

First Class.—Addy, Boughton, (Scholarship and Gold Medal), St. Thomas's Hospital; Skerritt, Edward Markham, (Gold Medal), University College(b); Dodson, Andrew, Birmingham and Guy's Hospital(c); Benham, Henry James, University College, and Bomford, Gerald, King's College (equal); Colgate, Henry, University College.

Second Class.—Petch, Richard, King's College; Bird, Cuthbert Hilton Golding, B.A., Guy's Hospital; Barlow, Thomas, University College; Cockburn, John Alexander, King's College; Dyson, William, University College.

Third Class.—Rayne, Charles Alfred, University College; Pope, Harry Campbell, Liverpool Royal Infirmary and University College; Firth, Charles, St. Bartholomew's Hospital; Railton, Thomas Carleton, Manchester and St. Bartholomew's Hospital; Coupland, Sidney, University College and Middlesex Hospital.

FORENSIC MEDICINE.

First Class.—Colgate, Henry, (Scholarship and Gold Medal), University College; Bird, Cuthbert Hilton Golding, (Gold Medal), Guy's Hospital; Benham, Henry James, University College; Barlow, Thomas, University College; Cockburn, John Alexander, King's College; Coupland, Sidney, University College and Middlesex Hospital.

M.S. EXAMINATION.

Godlee, Rickman John, B.A., (Gold Medal), University College.

B.S. EXAMINATION.

First Division.—Barlow, Thomas, B.Sc., University College; Colgate, Henry, University College; Lucas, Richard Clement, Guy's Hospital; Rayne, Charles Alfred, University College; Skerritt, Edward Markham, B.A., University College.

SECOND B.A. AND SECOND B.Sc. EXAMINATIONS.

EXAMINATIONS FOR HONOURS.

(B.A and B.Sc. conjointly.)

LOCAL AND MORAL PHILOSOPHY.

First Class.—Gotch, Francis, B.A., (Scholarship), University College; Leverson, Benjamin James, B.A., University College.

Second Class.—Chuckerbutty, Henry Scott Ryan Goodeve, B.A., University College; Lovett, Richard, B.A., Cheshunt College, and Witton, James Cecil, B.Sc., Royal School of Mines (equal); Hollings, Edmund Raven, B.A., private study, and Simmons, Lawrence Mark, B.A., City of London School and private tuition (equal).

Third Class.—Savile, Alfred George, B.A., private study, and Thompson, Joseph William, B.A., University College (equal); Foxwell, William Arthur, B.A., Wesleyan College, Taunton, and Norburn, Henry, B.A., private study (equal).

(B.A. only.)

CLASSICS.

First Class.—Shaw, James, (disqualified by age for the Scholarship), Queen's College, Belfast; Bamford, William, St. Cuthbert's College, Ushaw; Hughes, Walter, Owens College.

ANIMAL PHYSIOLOGY.

First Class.—Mare, Henry, (disqualified by age for the Prize), private study; Norburn, Henry, private study.

Second Class.—Waugh, Henry Dunn, University College; Tyrer, Richard, private study; Wood, John Edwin, Wesley College.

(B.Sc. only.)

CHEMISTRY.

First Class.—Napier, Arthur Samson, Owens College, and Witton, James Cecil, Royal School of Mines (equal).

Third Class.—Hullard, Jean Arthur, University College, and Lyell, Leonard, private study (equal).

GEOLOGY AND PALÆONTOLOGY.

Second Class.—Roberton, Henry Shoveller, Old Trafford School and Owens College; Vines, Sydney Howard, Christ's College, Cambridge, and Guy's Hospital; Lyell, Leonard, private study; Fuller, Arthur Walton, Owens College and Emmanuel College, Cambridge.

Third Class.—Worthington, William Barton, Owens College; Napier, Arthur Samson, Owens College.

ZOOLOGY.

First Class.—Marshall, Arthur Milnes, (Scholarship), St. John's College, Cambridge.

Second Class.—Vines, Sydney Howard, Christ's College, Cambridge, and Guy's Hospital; Lyell, Leonard, private study.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, December 4:—

Arthur, Walter, Oakley-street, Chelsea.
Barnes, Arthur Richard, Faversham.
Charnley, William, Lancaster.
Mason, Samuel Butler, Denham, Uxbridge.

The following gentlemen also on the same day passed their primary professional examination:—

Armstrong, Henry George, of St. Thomas's Hospital.
Bernays, Herbert Leopold, of St. Thomas's Hospital.
Evans, David Thomas, of Guy's Hospital.
Higgs, Augustus William, of St. Mary's Hospital.
Rees, Charles, of Guy's Hospital.
Smith, Sydney Lloyd, of St. Thomas's Hospital.

(b) Obtained the number of marks qualifying for the Scholarship.
(c) Obtained the number of marks qualifying for a Gold Medal.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BETHUNE, DAVID, L.R.C.P. Edin., L.F.P.&S. Glasg.—Medical Officer for the Workhouse and Medical Officer for the Ponteland District of Castle Ward Union, Northumberland.

FLETCHER, THOMAS BELL ELCOCK, M.D., B.L., F.R.C.P. Lond., M.R.C.S. Eng.—Consulting Physician to the Birmingham and Midland Counties Orthopædic Hospital.

KITTSON, EDWARD JOHN, L.K.&Q.C.P.I., L.R.C.S.I., L.M.—Surgeon to the Tipperary County Gaol, Nenagh.

MAGRATH, J., M.D.—Physician to the Metropolitan Dispensary, Fore-street, E.C.

SYMES, WILLIAM SANDHAM, L.R.C.S.I., L.K.&Q.C.P.I., L.M.—Medical Officer and Public Vaccinator for the Maryborough Dispensary District of the Mount Mellick Union, Queen's County.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—Dr. George B. Beale, Staff-Surgeon, second class, to the *Fantome*.

WAR OFFICE.—MEDICAL DEPARTMENT.—Surgeon-Major John Copeland Knipe has been placed upon temporary half-pay; Staff Surgeon Daniel O'Donovan, M.D., from half-pay, to be Surgeon-Major, *vice* James Edward Scott, M.D., who retires upon half-pay; Surgeon Edmund Hoile, M.D., to be Surgeon-Major, *vice* Robert Henry Beale, deceased; Surgeon George Herbert Clifton, M.D., resigns his commission; Surgeon Mark Anthony Kilroy retires upon temporary half-pay; Surgeon-Major William Henry Pollard retires upon temporary half-pay; Surgeon William Henry Garde, from half-pay, to be Surgeon, *vice* Wilton Everet, promoted.

BIRTHS.

DICKSON.—On December 6, at Fairfield, Upper Norwood, the wife of Walter Dickson, M.D., R.N., of a daughter.

INCE.—On November 9, at Rawalpindi, Punjaub, the wife of Surgeon-Major John Ince, M.D., Civil Surgeon, of a son.

MUMFORD.—On December 5, the wife of William Lugar Mumford, M.D., of a daughter, stillborn.

RHODES.—On December 6, at 5, Royal-terrace, Weymouth, the wife of Charles Rhodes, M.D., of a son.

SEXTON.—On September 15, at Rajkote, Bombay Presidency, the wife of E. Sexton, M.D., Surgeon-Major H.M.'s 18th Regiment N.I., of a daughter.

WALKER.—On December 2, at Grosvenor-street, W., the wife of Joseph Walker, M.D., of a son, surviving his birth only a few minutes.

MARRIAGES.

HILL—GOODY.—On December 4, at St. Peter's, Regent-square, London, John Daniel Hill, F.R.C.S., to Annie Elizabeth, youngest daughter of the late James Goody, Esq.

NOBLE—BRISTOW.—On December 2, at St. John the Evangelist's, Penge, the Rev. William Noble, vicar of Newbottle-cum-Chalton, Northampton, to Anna Clara, daughter of the late John Charles Bristow, Esq., of Ensmere-hill, Westmoreland, and stepdaughter of William Henry Tayler, M.D., of Anerley, Surrey.

RUNDLE—BOSWELL.—On November 19, at Cobourg, Ontario, Canada, George Edward Rundle, surgeon, only surviving son of the late Wm. John Rundle, M.D., of Audrey House, Gosport, Hants, to Emma Catherine, second daughter of the late W. N. Boswell, Esq., barrister-at-law, and granddaughter of the late Hon. Captain Walter Boswell, R.N., of Beech Grove, near Cobourg, Ontario.

THORNTON—PATERSON.—On December 2, at St. Stephen's, Kensington, John Knowsley Thornton, M.B., C.M., son of the Rev. John Thornton, vicar of Aston Abbots, Bucks, to Eleanor Philippa, daughter of the late Capt. George Dacres Paterson, 98th Regiment, and stepdaughter of Vice-Admiral Hornby, of Knowsley.

WHITEFOORD—COLE.—On December 4, at Stapenhill Church, Burton-on-Trent, Adam John Whitefoord, L.R.C.P. Edin., M.R.C.S. Eng., second son of Charles Whitefoord, Esq., of St. John's-wood, London, to Ellen Mary, only daughter of the late Henry Cole, Esq.

DEATHS.

EDMONDSON, JAMES, M.R.C.S., L.S.A., at 260, Wandsworth-road, on November 29.

GODBY, EDWARD ARCHIBALD, fifth surviving son of the late Augustus Hardy Godby, M.D., of Newport, Salop, at Hertford, on December 4, aged 8.

LAMB, ROBERT, L.R.C.P., M.R.C.S. Eng., L.S.A., at his residence, 56, Richmond-road, Barnsbury, of rheumatic fever, on December 2, aged 38.

MILLER, PENELOPE GARDEN CAMPBELL GORDON, widow of the late James Miller, F.R.C.S. Edin., Professor of Surgery in the University of Edinburgh, at 29, Charlotte-square, Edinburgh, on December 5, aged 60.

WYATT, MARY JANE, widow of the late George Nevile Wyatt, M.D., late H.E.I.C.S., at her residence, Lampton Lodge, Spring Grove, Isleworth, W., on December 1, in her 88th year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. of Great Britain or Ireland. Applications, with testimonials, to the Chairman of the Medical Committee, Temple-row, Birmingham, on or before December 20.

BRISTOL ROYAL INFIRMARY.—Assistant House-Surgeon. Candidates must be F. or M.R.C.S., or M.S., and also possess medical qualifications.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CHELTENHAM GENERAL HOSPITAL AND DISPENSARY.—Junior House-Surgeon. Candidates must be qualified and registered. Applications, with testimonials, to the Secretary.

GENERAL HOSPITAL, NOTTINGHAM.—Physician. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before March 10, 1874.

GERMAN HOSPITAL, DALSTON.—Honorary Medical Officer to the Eastern Dispensary. Candidates must be natives of Germany and be duly qualified. Applications, with testimonials, to Dr. Walbaum, Hon. Secretary, on or before December 29.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Assistant-Surgeons. Applications, with testimonials, to P. Goldschmidt, Esq., 100, Albert-square, Manchester.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, of whom particulars may be obtained.

ST. GEORGE'S (HANOVER-SQUARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before December 29.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to Dr. J. C. Hall, Hon. Sec., on or before December 24.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

TEWKESBURY UNION, FORTHAMPTON DISTRICT.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to George Budham, Clerk to the Guardians, on or before December 16.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser. Applications, with testimonials, to the Honorary Secretary, Exe Villa, Tiverton, Devon.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WESTMINSTER HOSPITAL.—Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Each candidate must attend (with his testimonials) the House Committee on February 10, 1874.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

VACANCY.

Barnet Union.—The Third District is vacant; area 5470; salary £60 10s. per annum.

APPOINTMENTS.

Dursley Union.—Benjamin Simmons, M.R.C.S. Eng., L.S.A., to the Second District.

Portsea Island Union.—Thomas Diver, M.D., M.R.C.S. Eng., L.S.A., to the Railway District.

SUPERANNUATION ALLOWANCE.

Mr. J. Blackshaw, after thirty years' service as Medical Officer for the Stockport District and the Workhouse of the Stockport Union, has been awarded a retiring allowance of £100 per annum.

DIPHTHERIA is terribly prevalent in Melbourne.

A NOTICE has been issued by the Home Secretary, disapproving of the employment of police officers as inspectors of nuisances, and requiring that such duty be discontinued from the 31st inst.

THERE were registered in London last week 1484 deaths, showing 230 below the average. The fatal cases of measles, which in the two previous weeks had been 130 and 121, were last week 118.

ON Friday, December 5, the third meeting of the session of the West Kent Medico-Chirurgical Society was held (Dr. F. Moon, President, in the chair), when J. C. Thorowgood, M.D., read a paper on "Asthma, its Nature and Treatment."

THE report of the Registrar-General recently presented to the Council of Ceylon on the census of the island states that the taking of the census of Ceylon in 1871 was the first attempt of the kind in the island. Of the entire population, 1 in 723 is insane, 1 in 860 is deaf and dumb, and 1 in 357 is blind.

MARIAN F. PFYFFER, a young nurse at the Boston City Hospital, died on the 19th ult. Her death was, we are sorry to say, immediately followed by the suicide of Mr. Arthur Foster, a medical novice and house officer of the institution. Mr. Foster was called in the night to prescribe for Miss Pfyffer, and mistook her symptoms for those of hysteria; and upon her death he was so chagrined at his failure to recognise the indications of opium, that he went to a bath-room and killed himself by opening the femoral artery. He was greatly esteemed.

THE annual report of the General Committee of the Walsall Cottage Hospital has recently been issued. It gives a satisfactory account of the management and success of the Hospital. In the course of the year there had been 208 cases treated in the in-patient department; of these 167 were cured, 11 relieved, 5 were removed for various causes, and 17 died.

A SENSITIVE EXECUTIONER.—Le Roi, called to a patient in all haste, and in whom he found venesection urgent, engaged a bystander to hold the basin. The blood had hardly begun to flow, when the assistant fainted away. Next day Le Roi was not a little surprised to learn that this impressionable person was the public executioner of Versailles; and his wife stated that the sight of blood always produced this effect upon her husband.—*Union Méd.*, December 2.

ACADÉMIE DE MÉDECINE.—At the last meeting, M. Laboulbène was elected into the Section of Pathological Anatomy. At the first *scrutin* he obtained forty-one votes against the thirty-five of M. Empis; but as forty-two constituted the majority of the voters present, another trial had to be made, which ended in his obtaining forty-nine to M. Empis' thirty votes. The Committee had placed him second on the list of candidates. That this list was not very fairly drawn up is seen from the fact of so eminent a pathologist as M. Lancereaux only occupying the fourth place.

AUGUSTE DE LA RIVE.—At the meeting of the Académie des Sciences, December 1, M. Dumas, in announcing the death of this philosopher, characterised, in the happy manner of which he is the most eminent of masters, some of the features of his scientific career. All physicists, he observed, knew how well that life had been passed, especially those conversant with the progress of electrical science, the portion of physics to which De la Rive almost exclusively devoted his attention. Among his principal labours were those which at a later period led manufacturers to the electrical application of gold and silver over the baser metals. He also referred to the ingenious experiments on which he founded his theory of the aurora borealis, showing the striking analogy existing between the auroral phenomena and electricity in vacuo and in rarefied media. M. Dumas had been in intimate relation with De la Rive since 1816, and therefore felt himself better able than most persons to know and state the noble uses which he made of his large fortune in always placing it at the service of science for the pursuit of his own investigations and those of other persons. His house at Geneva, also, became a centre of hospitality; and all those who, under any title whatever, could be called cultivators of science, were always certain of a sympathetic reception, and, if necessary, of generous aid. At first a correspondent of the Academy, De la Rive was in 1864 elected one of the eight foreign associates in the place of Plana.—*L'Institut*, December 3.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN NOVEMBER, 1873.—The following are the returns (by Dr. Letheby) of the Society of Medical Officers of Health:

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction .	17·73	0·051	0·129	0 002	14·0	3·3
West Middlesex .	17·63	0·038	0·164	0·001	14·0	3·3
Southwark & Vauxhall . . .	19·84	0·074	0·126	0·002	15·0	3·8
Chelsea . . .	17·53	0·098	0·107	0·002	14·0	3·3
Lambeth . . .	19·81	0·086	0·128	0·002	15·0	3·8
Other Companies.						
Kent	28·31	0·006	0·216	0·000	21·8	5·6
New River . .	19·17	0·010	0·010	0·001	14·8	3·3
East London . .	19·13	0·029	0·116	0·002	14·5	4·0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in those of the Grand Junction, the Southwark and Vauxhall, the Chelsea, and the Lambeth Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Society of Medical Officers of Health, 115,326,807 gallons; and the number of houses supplied was 505,595. This is at the rate of 34·4 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 24·9 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

MORTALITY IN MELBOURNE.—The Registrar-General's Report of the vital statistics of Melbourne and suburbs during August last states that the deaths for the month were 339, out of an estimated population of 225,203, or 1·55 per 1000. Nine of the deceased were aged from seventy-five to eighty-four. Of the whole number 81, or 24 per cent., occurred in public institutions. Of children under five years, 101 died, or 34 per cent. of the whole.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

R. F. Snape, Bolton-le-Moors, Lancashire.—The degree in question is utterly worthless, and the "shop" where such were sold has been suppressed.

Melbourne.—We have read the article in the *Melbourne Age* with respect to the election of a professor to the Melbourne University. We see no grounds for the "ousting" of the late professor, who appears to have performed his duties in an exemplary manner. We are wearied with having so constantly to refer to the medical squabbles of our Australian brethren, and especially regret that the political press is occupied with these disgraceful differences. The bringing our disagreements before the general public is most inimical to the interests of our profession. It would be wiser if the medical practitioners in Melbourne were "to wash their dirty linen at home."

CHEMICAL NOMENCLATURE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—When and on whose authority was the German mode of naming chemical compounds introduced here? We used to say "nitrate of silver," "hydrate of chloral," and so on; now we hear of *silver nitrate*, *chloral hydrate*, etc. Is the new terminology sanctioned by the College of Physicians? I am too ignorant of chemistry to be critical about these terms, and am simply asking for information. I am, &c.,

December 5. QUÆRENS.

AUSTRALIAN WINES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me to inform the medical profession through your columns that, by order of the Commissioners from the South Australian Government, all the wines exhibited this year at South Kensington from the colony may be sampled in my cellars at this address until Monday, the 15th inst., on presentation of a card; after which date the remainder will be handed to the hospitals. At the meeting of the Society of Arts last evening, Monday, the 8th inst., was announced in mistake as the latest date on which these wines could be tasted. I am, &c.,

50, Old Broad-street, London, E.C., December 4. P. B. BURGOYNE.

FRACTURE OF THE FEMUR AT THE AGE OF EIGHTY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Fracture of the femur at the age of eighty is not so particularly rare that it must needs be put in print; but the following case presents, in my opinion, some features of interest. It occurred to an elderly lady of eighty, who lives for the most part all alone. On a visit to her sister, she tumbles down the strange stairs, and breaks her femur—not at the hip, but in the lower portion of the lower third. Set in cardboard, or rather millboard splints, previously soaked in boiling water, with boxes and pillows to keep the position necessary for comfort, etc., it is united firmly at the end of three weeks, a great amount of callus thrown out, and its length equal to that of its fellow. The fracture, too, I believe to have been nearly, if not quite, transverse. I am, &c., COUNTRY DOCTOR.

COMMENTARIES ON MEDICAL MATTERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was much interested in reading in the *Medical Times and Gazette* for 1872 some remarks by Mr. Prescott Hewett on "Gouty Phlebitis." I have suffered in my own person two attacks of gout—hereditary—which assumed this form in a most severe degree. The first attack (in 1871) was in the right lower extremity, the second (in 1872) in the left. The skin showed all the colours of the iris; the discoloration was especially pronounced on the sides of the knee-joint, on the calf of the leg, and on the ankle-joint. There was considerable tumefaction with hardness; and any movement caused great pain, and greater nausea, and sense of sinking. In 1872 I was confined to bed for five weeks. I suffered much fever in the first days—oppression of the respiration—and I had great fear of falling a victim to embolia. I took much bicarbonate of soda with iodide of potassium and some colchicum; afterwards, pepsine, iron, Madeira wine. Locally I employed frictions—iodine, narcotics, the grease of the tapir and of the ounce; afterwards, blisters on the most indurated points. I am of a spare habit—most abstemious as to diet—not a hard worker, as my patients are most considerate in sparing me as much as possible all avoidable fatigue. For many years I suffered frequent attacks (severe ones) of intestinal hæmorrhage, but for some time these have ceased. The more nutritive meats (as beef and mutton and kid) my intestines do not support, nor can I digest the feculent roots (as manioc, yam, sweet potato, etc.). I suffered greatly from dyspepsia in 1871-72, but since rising from my sick-bed in November, 1872, have enjoyed a degree of health to which I had long been unaccustomed. My age is now fifty-five. I had suffered for some time a papulous eruption, with elevation and redness of the skin of the face, which has also disappeared. I considered myself in danger, and neither I nor any other of the physicians of this city (who represent the practice of many countries) had ever met with a similar case. I am not ashamed to publish that I made a vow to Saint Elizabeth of Hungary, and render devout thanks to Almighty God for my recovery. As Mr. Hewett, in his address to the Clinical Society, spoke of this form of gout as rare, and the cases he adduced terminated fatally, I am induced to give an account of my case. I have now reason to modify a statement I formerly made that gout—regina dolorum—was unknown here. It is most rare, but I have seen a very few cases. An arthritic diathesis is, however, not uncommon, and anomalous symptoms substitute regular gout. The arterial system is, I think, often chronically the seat of the arthritic ravages. I now employ largely the carbonate of lithia in such cases, and have lately made use of the iodide of lithium. As an allied topic, I will mention that I have used propylamine in cases of chronic rheumatism with good results. I select the muscular form, and especially those cases in which the patient complains of a sensation of cold. In similar cases a strong infusion of sassafras (fruit or bark) in rum (a wineglassful every morning) is an excellent remedy; so also mezereon, so also velame (*Croton campestris*), also cod-liver oil. I am, &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin., Brazilian Citizen.

Campinos, Brazil, September.

HEPATIC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Victor Jacquemont, aged 28, a tall, dark-complexioned French naturalist, with good teeth, short sight, a pleasant manner, and of scientific reputation, arrived in India in 1829, where—travelling three years and a half in Thibet, Lahore, and Cashmere—he worked hard collecting every information about plants, stones, and animals. There are professional points of interest about him well worth discussing. In after-dinner language, it is a matter of regret this duty has not devolved on more able men. However, under the punkah in the darkened room, during blazing hot weather, I proceed—with the assistance of two volumes partially written by Jacquemont—to *write* out his case and proceedings.

On the voyage out he first appears on the professional scene, assisting (by tying the arteries—five in number) at an amputation of the forearm, the natural inference being that he had some medical education, which he endeavoured to improve by button-hole and brain-picking whenever he met the faculty. Also he treated his servants and friends; for instance, an officer suffering from fever, the remedies employed including purgatives, emetics, sinapisms, camphor, quinine, *secundum artem*. Also he treated himself, depending at first on temperance, abstinence, and exercise, on a little box of infallible medicines, but, above everything, on his syringe—the best in India—having (Frenchman-like) every confidence in enemata. In the course of his travels, one night, thieves breaking into the tent, mistaking pewter for silver, triumphantly carried away his sheet anchor, which was never heard of more. Jacquemont—disconsolate, desolate, in despair—eventually borrowed another from a military hospital (one of the old pattern, useless and obsolete), and from that time almost dates the commencement of ill health. It should be mentioned that although he had good letters of introduction his private means were small; thus two or three visits to grand houses would be succeeded by great discomfort, indeed privation, in a wretched tent—the bad food, bad water, miserable attendance, contrasting sadly with the luxuries enjoyed at Lord Wm. Bentinck's table. Often reckless about the sun, catching cold, bathing, over-fatigue, he fared on milk and water, brandy, *eau sucrée*, spices, sugar, sulphur, rancid butter, all kinds of abomination, including cheap fine old port picked up at a sale. All this time enduring many privations, he worked hard in the endeavour to advance the science of natural history, hoping one day to return laden with his treasures, and to settle down with an old scientific bachelor crony in a little cottage in *la belle* France. On one occasion, out alone in May, 1831, in camp, whilst suffering from hæmoptysis, he applied sixty-five leeches (caught in the river) to his chest; also had two sheep killed daily, to eat as much as possible, and thus gained strength. Occasionally, too, want of appetite, abdominal cramps, flatulence, induced great mental depression—manfully, indeed injudiciously, contended against; for instance, riding from Meerut to Delhi (forty miles) directly after breakfast.

In July, 1832, occurred a sharp attack of dysentery, treated by calomel, rhubarb, opium, magnesia, cream of tartar, castor oil, ipecacuanha, and a mild lavement of gum arabic. He improved, but on October 30, having made arrangements to return home, he was stricken with sickness at Bombay, commencing with irregular attacks of fever, debility, and disordered bowels, with a feeling of uneasiness in the præcordia. From the very beginning his will was made, affairs set in order, the beloved manuscripts, the treasured specimens packed for final destination, whilst he calmly awaited results—anticipating the worst. For thirty-one nights he did not sleep, yet the time did not appear so desperately long; and, stretched out on his back, he contrived with a pencil to write "Farewell"; also to tell relations and friends how dear they were to him at the last; and that he, dying in a distant land, was neither deserted nor unnoticed. Now to epitomise the symptoms and treatment. Dr. MacLennan found heat and pain about the sacrum; pulse 84; evacuations frequent, offensive, attended with tenesmus; foul tongue, fetid breath. *Ordered:* Sixty leeches to sacrum, warm bath, strong dose of calomel, a few grains of pulv. ipecacuanha and opium. Next day better, excepting pain about navel. *Ordered:* Sixty leeches to hypochondrium (right), warm bath, more calomel—substituting henbane for opium, followed by thirty leeches at night and castor oil next day. The stools were copious, liquid, brown, with a putrid smell, but no blood noticed. From November 1 to 6 the same treatment maintained, the strength supported by soups and wine. Ptyalism slight, symptoms more decided. Hepatic abscess now diagnosed. Laxatives were prescribed, also open-air exercise in a palanquin tried and abandoned as inducing fatigue; the pulse, skin, and tongue meanwhile satisfactory. November 15: A small swelling in the right hypochondrium was relieved by repeated blisters,—only temporarily, however, for on December 2 appeared a tumour pointing towards the edge of the ninth rib, neither fluctuating nor adherent. Nausea, fever, thirst, dyspnœa, abdominal cramp, uninfluenced by fomentations or sedatives, steadily increased; culminating at three o'clock in the morning of December 7 in acute lancinating pain round the pubes, agonising dysuria, coffee-ground vomiting, frequent syncope, and extreme prostration. All day long pitiably he lingered, perfectly sensible until six o'clock in the evening, when death mercifully put an end to suffering. At the post-mortem they found an abscess, situated in the posterior part of the liver at a short distance from the backbone, had burst its contents (100 ounces of clear fluid) into the cavity of the abdomen. No other lesions recorded. The reader will note this poor fellow was only thirty-one years of age when a bright and brilliant career became suddenly checked. In addition to typhoid and rheumatic fever, there are cases of abscess of the liver now under treatment, particularly interesting, terribly depressing; but doubtless eventually worth recording when sufficiently numerous. D.V., I hope to write many papers, but *we all* have livers, and life is *very* precarious in INDIA.

COMMUNICATIONS have been received from—

Mr. Horatio Stokes, Gibraltar; Mr. H. K. Hitchcock, Lewisham; Mr. A. Kendall, London; Dr. Louisa Atkins, Birmingham; Dr. F. A. Hartsen; Mrs. Whitaker, Kirkby Lonsdale; Messrs. Brown and Green, London; Dr. Orange, Broadmoor; A Birmingham Doctor; Mr. Balmanno Squire, London; Dr. W. S. Symes, Maryborough; Dr. Balthazar Foster, Birmingham; Quærens; Country Doctor; Mr. C. Offer, London; Dr. Sparks, London; Dr. Carter, Liverpool; Dr. W. H. Pearse, Plymouth; Mr. Christopher Heath, London; Mr. J. Chatto, London; Dr. B. W. Richardson, London; Dr. Fayrer, London; Mr. C. J. BOOKS RECEIVED—

Waters on Diseases of the Chest, second edition—Dun's Veterinary Medicines—Winslow's Manual of Lunacy—Studies from the Physiological Laboratory in the University of Cambridge, part i.—Dwight on the Structure and Action of Striated Muscular Fibre—Rumbold's Description of New Instruments for making Examinations and Applications to the Cavities of the Nose, Throat, and Ear—Rumbold on the Function of the Eustachian Tube—Abstracts and Proceedings of the Bombay Medical and Physical Society—Curtis's Introductory Lecture on the Protoplasm Theory—Liddle's Report on the Sanitary Condition of the Whitechapel District of the Board of Works—The Value of European Life in India, by Dr. Mouat—Census of Ireland, part 2, vol. i.—Report and Tables relating to the Status of Disease—Davies on the Preparation and Mounting of Microscopic Objects—Don Carlos: a Tragedy, by Schiller, translated into blank verse by Andrew Wood, M.D., etc.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Nature—Gazette Hebdomadaire—Students' Journal and Hospital Gazette—Food, Water, and Air—Le Progrès Médical—La France Médicale—Carlisle Express—L'Union Médicale—Pharmaceutical Journal—Gazette Médicale de Paris—The Allahabad Pioneer—Gazette des Hôpitaux—New York Sanitarian—The Edinburgh Courant—Allgemeine Wiener Medizinische Zeitung—Philadelphia Medical Times—Edinburgh Daily Review—The Scotsman.

APPOINTMENTS FOR THE WEEK.

December 13. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

15. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Dr. Farquharson, "Cases of Infectious 'Tonsillitis.'" Dr. Pearson (communicated by Dr. Farquharson), "An Epidemic of Sore Throat with marked Constitutional Symptoms." Dr. Dowse, "On Cerebro-spinal Meningitis, with Clinical Records."

16. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

London Anthropological Society, 8 p.m. Meeting.

Pathological Society, 8 p.m. Dr. Fred. Taylor—Leucocythæmia with Lymphadenoma. Dr. Crisp—Imperforate Anus. Mr. Godlee—1. Ossifying Enchondroma; 2. Peri- and Myo-carditis from a Case of Blood-poisoning following Whitlow. Dr. Dowse—Renal Calculi. Mr. Nunn—1. Cast of an Enchondroma; 2. Pendulous Tumour from the Pubes of a Man. Mr. James Adams—Deformity of the Knee-joint. Mr. Cripps—Spleen and Lymphatic Glands from a Case of Adenoid Disease.

Statistical Society, 7¾ p.m. Meeting.

17. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

18. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

19. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

Medical Microscopical Society, 8 p.m. Meeting.

EXPECTED OPERATIONS.

Royal Free Hospital.—The following Operation will be performed on Saturday (this day) at 2 p.m.:—

By Mr. Gant—Extirpation of Eyeball.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 30·28 in. The highest was 30·46 in. on Thursday morning, and the lowest 29·39 in. at the beginning of the week.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE ON RUPTURE OF THE AORTIC VALVES FROM ACCIDENT.

DELIVERED AT THE BIRMINGHAM GENERAL HOSPITAL, NOVEMBER 17, 1873.

By BALTHAZAR FOSTER, M.D., F.R.C.P.,
Physician to the Hospital;
Professor of Medicine in Queen's College, Birmingham;
and Consulting-Physician to the West Bromwich District Hospital.

(*Concluded from page* 658.)

I WOULD now call your attention to the mode in which the valvular mischief occurred in this case. Clearly it was the result of the accident. The ruptures took place in valves till then sound, under the influence of the effort which the man made to save himself when thrown forward on the deck. In all the cases of this kind on record it is some vigorous bodily effort—made generally with the chest well filled with air, and its walls fixed—that gives rise to the injury. Under such circumstances, the tension in the aorta is at its highest, and the strain becomes too great for the delicate valvular folds. So it was in the case of M. W., who, stretching across a copper with his abdomen compressed, made a violent effort to seize one of his cooking-utensils placed on a shelf opposite; so also was it with S. (case below), who ruptured his aortic valves in endeavouring to throw an unusual weight of coal. In the present case we had two elements in the accident—the effort to save himself by grasping the side of the hatchway, and the fall on to his chest. It is impossible to say to which of these elements the accident must be referred, but it seems to me, from a study of the cases on record, that the muscular effort had more to do with it than the blow.

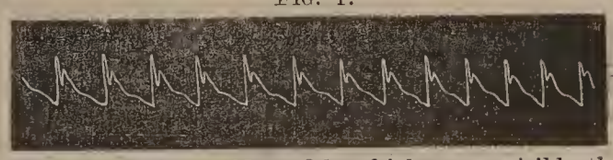
In most of the cases this accident has been followed by well-marked symptoms, but from H. we obtained no clear history of how he suffered immediately after the accident. There can be no doubt that such a rupture as he suffered from must have produced very marked symptoms. We cannot conceive a considerable imperfection of such important valves occurring suddenly without some effect on the circulation. *A priori*, we should look for a temporary disturbance of the balance between the contents of the arterial and venous systems, with engorgement of the lungs and general venous congestion, which would pass away as the heart became more a match for the altered conditions of its work. The following case, which some of you may remember, gives us a very clear illustration of the immediate effects of such accidents:—

Thomas S., aged 33, stoker, was admitted into the General Hospital on August 22, 1870, apparently dying. He was cold, pulseless, livid in the face, with his skin covered with cold sweat. The House-Physician, Dr. J. B. Welch, diagnosed great congestion of the lungs, and very properly bled him from the arm. The blood flowed with difficulty, but he rallied a little, and he was placed in bed in warm blankets, hot bottles were applied to his feet, and sinapisms to his chest and legs. As soon as he could swallow, hot brandy-and-water was administered, and afterwards fifteen minims of ozonic ether every quarter of an hour. At the end of four hours he showed decided signs of reaction, and the alarming symptoms gradually subsided. He coughed a good deal, and expectorated bloody mucus, and complained of difficulty of breathing and acute pain in the præcordial region. On the morning after his admission a double aortic murmur was detected.

On inquiry we found that his family history was good; that he had never had any serious illness, and no rheumatic fever. When about eighteen years old he enlisted, and served in the Crimea and through the Indian Mutiny and in China, where he suffered from rheumatic-like pains in the legs, but was never laid up. He stated that he had never had syphilis and had always been fairly temperate. After leaving the army he became a stoker at the gas-works, and when there he had a bronchitic attack, but was not confined to his bed. He afterwards went to the axle-works at Saltley, where he was at work when seized with his present illness. The mode of the attack was as follows:—Whilst lifting and throwing, in his capacity as stoker, an unusually great weight of coal, he felt a sudden and severe pain in the epigastrium, which stopped his breath and made him gasp for a moment or two. His head went light and everything looked dim, he fell down, and some of his fellow-workmen brought him some brandy, which revived him for a moment, but after this he remembered nothing until he began to recover in the hospital.

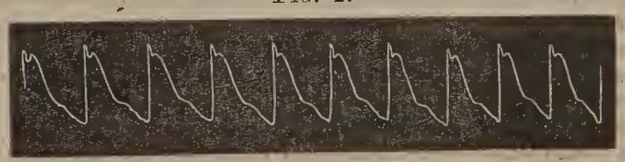
He mended day by day, but still complained of his breath and cough. About a week after the accident the following notes were made:—Lung percussion, which had daily improved posteriorly, had become at this time healthy all over his chest. The heart-sounds were normal everywhere, but were rather feebler over right lung posteriorly than over left. Heart: Apex-beat rather forcible below sixth rib, just inside nipple line. Cardiac dulness extended laterally from nipple line to right edge of sternum, and from above fourth rib to below sixth. On auscultation there were heard at base two murmurs, one systolic, the other diastolic. The systolic murmur was soft, short, blowing, and faintly flapping in its character, and was loudest at mid-sternum opposite fourth rib; it was not conducted upwards very distinctly, and was inaudible at apex. The diastolic murmur was loud, creaking almost in its character, masking second sound, and extended quite through the long pause. It was most distinct at the second right costal cartilage at its junction with the sternum, and also opposite fourth cartilage. It was loudly heard all down right edge of sternum, from manubrium sterni to ensiform cartilage. It was louder under right clavicle than under left, and could be heard in carotids replacing second sound, and was audible all down the spine posteriorly. It was not heard well at apex; there it was faint and more indistinct than midway between apex and ensiform cartilage. At this time the radial pulses were jerky, and gave the following trace with the sphygmograph:—

FIG. 1.



The pulsations of carotids and brachials were visible, though less so than three weeks later, when he requested his discharge. When discharged the cardiac dulness had decidedly increased, and extended as low as the seventh interspace, and there was also marked epigastric pulsation. The heart-sounds had not altered, except that a more purring than creaking character was noticed with the diastolic murmur, and a distinct thrill could be felt with diastole over sternum and base of heart. The impulse was heaving and diffused; the pulse, more bounding and of higher tension, yielded the following trace, which shows clear signs, when compared with the former tracing, of the increased power of the left ventricle. The liver projected

FIG. 2.



one inch and a half below the costal arch; splenic dulness was normal; urine free from albumen, but scanty and loaded. Expression of face anxious, and its colour somewhat paler and sallower than natural. He had been kept on a generous diet during the last fortnight of his stay in the hospital, and had taken—in addition to occasional purgatives—a mixture containing perchloride of iron and chloric ether. He was directed to live as well as he could, to take a fair amount of meat, and to continue his medicine.

Only two months later he was brought into the hospital moribund. His legs were greatly œdematous; his breathing laboured; both lungs congested and œdematous; heart's action tumultuous, and the beats irregular and unequal; pulse with same character—104, thrilling, and of low tension; face dusky. He was, in short, in a state of asystoly, from which he never rallied, and died eighteen hours after admission. We learned from his wife that he had tried to work after his discharge, but had been unable to do any heavy work, and had consequently maintained himself by odd jobs, and at times had been very short of proper food. He had got daily worse for two weeks before his readmission.

The post-mortem examination disclosed the following points of interest:—On opening the thorax, the right lung was found to be adherent. In the left pleura there were some

seven ounces of fluid. Both lungs were congested, and in both were spots of recent hæmorrhage. The liver was large, and weighed four pounds six ounces. Kidneys both congested, and spleen also, but not much enlarged. There were twenty ounces of fluid in the peritoneum. In the pericardium were three to four ounces of serous fluid. The heart was greatly dilated and enlarged, and weighed twenty-one ounces. All its cavities were full of blood-clot, fibrinous and black. The right cavities were dilated, but their valves were perfect. The left cavities were also dilated, especially the left ventricle, which was greatly so, while its walls were not hypertrophied to a corresponding extent. The mitral valves were thickened somewhat, and were less transparent than in health. The mitral orifice was dilated, and admitted four fingers. The aortic valves were incompetent. The incompetency was caused by the right coronary segment, which was torn from its attachments, and had its free margin thickened and retroverted towards the ventricle. At its angle of attachment to the left coronary segment it was torn down five-sixteenths of an inch; and in the angle between these segments thus formed, the chief regurgitation seemed on testing to take place. The other attachment in connexion with the left or mitral segment was torn down to an equal extent; but the mitral segment overlapped the angle thus formed, and partially prevented the regurgitation. The mitral segment was torn slightly at its right attachment to the extent of about one-twentieth of an inch, and the valve itself was softened, and undergoing rapid degeneration. The aorta was atheromatous to a moderate degree above the valves—no doubt as a consequence of the injury, as higher up and throughout its course it was healthy. The cardiac muscle (left ventricle) was undergoing fatty degeneration: this was especially the case with the papillary muscles.

This case teaches us very forcibly that the symptoms of a suddenly created imperfection of the aortic valves are what we might *à priori* expect. Here, crowded into the space of a few seconds, we had all the phenomena of obstructed intracardiac circulation, which generally take months to develope. When the rupture occurs, the immediate effect is for the blood to pour through the rent into the left ventricle. That cavity, surprised, as it were, by the novel rush of blood from the aorta, in addition to the accustomed stream from the auricle, staggers under the load, falters in its action, and hence the syncope. When the ventricular muscle rallies again to its work, it cannot for a time cope with the increased blood-charge. Whatever flows back from the aorta must keep back some of the contents of the auricle, and so distend that cavity, and soon congest the lungs. The ventricle dilates, however, under the extra blood-pressure, and thus throws at each systole into the aorta a larger quantity than the normal charge. In time this extra charge becomes large enough to allow for the regurgitation, and still keep up an approximation to the normal contents of the arterial system. For a time a healthy cardiac muscle would be competent for this increased effort; but its reserve power would not last long, and its nutrition would suffer: therefore the next change soon occurs. Not only does the cavity dilate to contain more blood, but the walls thicken, so as to propel the larger quantity with sufficient power. This hypertrophy renders the left ventricle a more equal match for the valve defect, and when the hypertrophy and dilatation are so nicely adjusted to the lesion that each ventricular systole propels into the aorta a charge of blood sufficient to allow for the reflux, without robbing the arterial system of its due, the compensation is practically perfect, and the normal balance between the arterial and venous contents is maintained. In this way the compensation was effected in both the cases before us. How comes it, then, that it was only temporary? To answer this question we must consider the mode in which the heart is nourished. Working as the cardiac muscle does constantly, with only that fitful rest which it obtains between each systole, its nutrition must be most active, in order to support the wear and tear of its constant work. This active nutrition is provided for by the position of the coronary arteries, which, arising from the first part of the aorta, are so situated that for each cardiac contraction a double wave of blood enters them. They receive some blood from the cardiac systole, but the aortic systole fills them more thoroughly, causing the blood to bound, as it were, from the tense aortic valves into the open mouths of the coronary arteries. It is no doubt this second or diastolic wave which gives the heart most of its blood-supply; for it is during this period of diastole, when, mark you, the ventricular muscles are relaxed, that the nutrient current can circulate most readily through the ventricular walls. Now, in all forms of imperfect action of the aortic valves, the rebound of the blood-column from the closed valves is weakened, and therefore the diastolic blood-wave is sent into the coronary arteries with less force. In all these cases, too, the aortic tension is lessened by the regurgitation; and the less the tension in the aorta, the less perfect the impletion of its coronary branches. These are the reasons why all cases of aortic insufficiency are sooner or later followed by failure of the cardiac muscle. The work for the ventricle to do is excessive, the nourishment it receives is defective, and the inevitable consequences are—muscular degeneration and failure of compensation. Many cases of aortic insufficiency, however, go on for years; the compensation is maintained so perfectly that scarcely any inconvenience is the result. In all such cases that I have met, the valve-lesion has been the consequence of disease, and not of rupture from accident; and I think I may also say the regurgitation must have been slight. In the cases of insufficiency from disease the valves are often increased in size and substance by inflammatory products, and the insufficiency is due to a want of perfect adaptation of the valves at their edges of junction. In cases of rupture of healthy valves, on the other hand, the lesion is generally greater, and by its position at the base or attachment of the valve allows more free regurgitation. This is, I believe, the reason why these cases of ruptured aortic valves live so short a time after the accident. In no case, as far as I can find, in which the rupture has been found after death has its occurrence been referred to a date more than four years and a half previously. In the three cases which I have brought before you, the duration of life after the accident was three months (S.), about eighteen months (H.), and about twenty-three months (M. W.). Between the longest period and the shortest there is a considerable difference, due, I have no doubt, mainly to the extent of the lesion, and partly to the conditions under which the patient has been placed after its occurrence. The seat of the rupture has, however, I am strongly inclined to believe, a considerable influence in determining the duration of life. Two of the segments have above them each a coronary artery, which is filled by the blood-column as it rebounds from their curtains. When these segments are torn down and retroverted, the regurgitant blood-current running past the mouths of the coronary vessels must to some extent diminish the amount of diastolic blood-wave which they receive, and consequently impair the heart-nutrition. When the aortic segment immediately below the coronary artery is imperfect, the filling of the artery, probably both at the time of the ventricular systole as well as at the time of the aortic systole, must be impeded. It was to this point I alluded when I said that if my explanation of the propagation of an aortic diastolic murmur to the left apex were correct, it was not a matter of mere curious diagnosis, but had a bearing on prognosis. That segment of the aortic valves, by whose incompetency we believe a murmur is specially carried to the left apex, has no coronary artery above it, and therefore, when it is affected, we should expect the coronary circulation to suffer less than when either of the other segments is imperfect. The coronary arteries, when this segment is torn, would have no regurgitant current running at right angles close to their orifices, and no thickened valve to divert the systolic wave from their mouths, and would suffer only in proportion to the general loss of tension in the aorta. As far, then, as the coronary circulation is concerned, imperfection of the mitral or non-coronary aortic segment should, *cæteris paribus*, be less serious than a similar imperfection of either of the other segments. There is, in my experience, reason to believe that this is so. Of the three cases of rupture of these valves to which I have referred to-day, that case, in which the non-coronary segment was the injured one, lived the longest time. In the other two cases in which the segments below the coronary arteries were torn, and in cases recorded by other observers in which similar injuries existed, the duration of life after the accident was less. The hypothesis I have advanced contains, I think, the elements of the explanation of the short period which these cases of ruptured valves survive, and I am sure a more minute study of the finer features and the position of valvular lesions will give us the clue to the long or short course which a case of aortic insufficiency may run. The investigation of such details will at all events improve our powers of observation, and so far make us better practitioners, even if it does not—as I think it will—lead to more far-seeing prognosis and more scientific treatment.

ORIGINAL COMMUNICATIONS.

ON THE BENEFICIAL INFLUENCE OF SEA VOYAGES IN SOME FORMS OF DISEASE.(a)

By THOMAS B. PEACOCK, M.D.,
Physician to St. Thomas's Hospital, etc.

I HAVE been asked to read a paper to the Hunterian Society, and have thrown together the following remarks on the influence of sea voyages in the restoration of health, which I hope may prove of interest to the members.

There are several different forms of indisposition about which we are frequently consulted in which we may recommend the patient to try the effects of a sea voyage.

1. The simplest and most common class of cases is that in which, in consequence of too close application to professional work or business, the general health becomes impaired. The patient suffers from dyspeptic symptoms and biliary derangement, becomes much depressed in spirits, and has great inaptitude for his ordinary pursuits, and especially for work involving mental exertion. In cases of this kind all that is required is a cessation from the ordinary occupation and a change of scene, and I know no plan which offers a better prospect of speedy and complete restoration of health than for the patient to take a short sea voyage. Persons of active habits do not generally benefit from entire rest at the seaside or at a watering-place. The want of occupation palls in a few days, and the invalid, if such he may be called, longs for his wonted engagements, and, as he can still be reached by letter or telegram, he is never entirely free from his business anxieties. To benefit by change, it is better that he should go away and have an entire change of scene, in which his mind may be occupied by new thoughts, and pleasurable excitement be maintained. This a sea voyage affords him. If a bracing climate be thought most desirable, he may cross the North Sea to the west coast of Norway or to Sweden, passing by the River Gota and the canals and lakes to Stockholm and Upsala, or he may go up the Baltic to Copenhagen, Riga, Revel, or Cronstadt; or if he be more enterprising and desires a longer relaxation, he may go to Iceland and visit Hecla and the Geysers, or cross the Atlantic to the United States or Canada. If a milder climate be considered preferable, he may go by sea to the Peninsula, entering by the north of Spain, Lisbon, Cadiz, or Gibraltar; or go down the Mediterranean, visiting Morocco, Algeria, the Italian ports, Egypt, or the Levant; or he may take a voyage to the Atlantic islands, Madeira, the Azores, the Canaries, or Cape Verde Islands. Any of these trips may be accomplished in from a month to six or eight weeks, and they afford the opportunity not only of exposure to healthy sea-breezes, but of a few days being spent in places in themselves full of interest, and which in their features present a marked contrast to home scenes. No one also who is a fairly good sailor need be deterred from undertaking such excursions by the fear of sea-sickness. Few persons suffer much in that way for more than a few days, unless the weather be exceptionally bad; and such need hardly be expected at the season of the year in which such excursions would be advised. Cases of simple anæmia, whether occurring at the commencement of adolescence or at other periods of life, are also much benefited by a sea voyage.

2. We are often consulted about cases which, while similar to those just named, are of a more threatening character—when, the first evidences of overtaxed powers having passed unheeded, the symptoms of indisposition have become more marked, and apprehensions are entertained of commencing organic disease of the digestive organs, or of the brain and nervous system. Cases of this kind may equally be benefited by any of the trips which I have mentioned; but as the indisposition has been of longer duration, and is more marked, it will be necessary that the cessation from work must also be more prolonged. The patient must stop for a longer period at the place which he visits, or he may undertake a voyage which allows him the opportunity of staying from time to time at different places on his route, so as to remain away as long as may be thought necessary.

3. A sea voyage is also often very beneficial in a different class of cases, as when a young man, perhaps always somewhat delicate, becomes seriously out of health about the period of puberty or when passing into manhood. He is pale, thin, and altogether anæmic and ill-nourished, has a feeble circulation, and his appetite and digestion are impaired. He becomes unduly susceptible to cold, and an ordinary catarrh gives rise to cough, which is not readily got rid of. On examining the chest, however, nothing seriously amiss is detected, though there may probably be a general want of clearness on percussion at the upper parts, and of full and free respiration—which are so often the first indications of pulmonary weakness. These symptoms are also to be regarded with more apprehension if similar delicacy has manifested itself in other members of the family, and especially if either parent has died of consumption. In cases of this kind the greatest benefit may result from a sea voyage, combined or not, as may be thought most desirable, with a residence for a longer or shorter time at the place visited. The voyage selected must, however, be somewhat different from those named, and preference should be shown to one which will take the patient away during winter. He should leave this country in August or September, and not return before May or June. For this purpose a trip to the Cape of Good Hope or to Natal, and a journey on the table lands of Cape Colony or the Free States, to New Zealand or Tasmania, or to different parts of the Australian Continent—Victoria, South Australia, New South Wales, or Queensland,—often answers very well, preference being generally given to the cooler climates over those which are warmer; and I think I have seen the best results from visits to South Africa. The same purpose may also be well accomplished by voyages down the Mediterranean undertaken at the same period of the year, the invalid stopping from time to time at different places so as to remain from home during the winter. Not unfrequently it is proposed to send a delicate person to the East or West Indies or to China; but these voyages are less eligible, for, however short be the stay at the destined port, there is danger of the patient suffering from the climate. I have known a young man—previously only slightly out of health—go to Demerara, and while there to take endemic fever, and return home with his health very seriously deranged, and with decided signs of pulmonary disease. I have also been asked whether, in such cases, Rio de Janeiro might not be the destination of the invalid; but to this there are great objections. Our winter—when the patient requires to be away—is the hottest and most unhealthy season in Brazil, and though within a few hours of Rio by rail and carriage there is a cool mountain climate to which visitors may go, a residence in Brazil at that season is attended with risk. Probably, however, the voyage to Rio, the River Plate, and through the Straits of Magellan to Valparaiso and the west coast of South America, might be advised with advantage. I also think it necessary when a young person is sent from home to give a caution against field sports, as fever may in this way be contracted, and seriously endanger the patient's life or even prove fatal.

If, however, in cases of this kind the destination be well selected, the best results attend the change in a large proportion of cases. The invalid during the voyage gains flesh and strength, and often returns home with his health completely established, and capable of entering upon an active career.

4. We may also often advantageously recommend a sea voyage where disease has already commenced in the lungs,—in persons who have been for some time losing flesh and strength, suffering from shortness of breath, cough and expectoration, and occasionally bringing up sputum marked with streaks or specks of blood, and in whom examination reveals some localised congestion or inflammation in some part of the lung. In cases of this kind any of the voyages which I have mentioned may be undertaken, preference being shown, in persons of relaxed habit of body, to the more bracing climates; in those of a more irritable temperament, and suffering from tendency to congestion or inflammation, to the milder climates.

Of late years the idea has gained ground that in many cases of pulmonary disease greater benefit is obtained by the endeavour to brace the patient than from the attempt to protect him from cold; and, under this impression, patients have been sent to the Engadine and various other mountain climates in Switzerland and elsewhere; and there is no doubt that advantage often results from this plan. It might appear, also, that a sea voyage to the colder countries of Europe would afford similar advantages, and this view is probably correct; but it must be borne in mind that, delightful as a voyage in

(a) Read before the Hunterian Society on Tuesday, November 13.

such climates may be when the weather is fine, the higher latitudes are less to be depended upon, and few phthisical invalids have sufficient vigour to bear with impunity a rough sea voyage, should they experience bad weather. I have, however, known a patient, suffering from symptoms very decidedly threatening pulmonary disease, leave home at the commencement of winter and go to Copenhagen, and thence up the Baltic and Gulf of Bothnia as far north as Tornea, and remain away the whole winter, during which he was exposed to very intense cold, yet return home decidedly benefited. I should add, however, that this voyage was undertaken for commercial objects, and without my sanction. The objection raised applies with less force to persons who are able to perform the voyage in a vessel entirely at their own disposal, as in that case they can generally—as on the west coast of Norway, for instance—lay by when the weather is unfavourable. As a general remark, however, it is better for a phthisical invalid rather to be sent to the more temperate climates and lower latitudes, where there is less risk of severe weather or of their suffering from cold.

I have been often asked whether the occurrence of previous attacks of hæmoptysis is to be regarded as forbidding the patient being sent to sea. The question is one requiring careful consideration. On the one hand, it has been supposed that the sedative influence of a marine climate and of the movement of the ship would lessen the tendency to hæmoptysis; on the other, that bleeding might occur from the violent retching during sea-sickness. The former opinion was, I learn from a notice in Dr. Copland's Dictionary, the idea of Dr. Gregory, and it has been concurred in by Dr. Davy and others. The latter certainly seems to me to be a danger to avoid; and partly on this account, but chiefly from knowing that a patient, if seized with blood-spitting, would on ship-board be very unfavourably placed for successful treatment, I have generally opposed the idea of a sea voyage in persons who have shown a tendency to hæmoptysis. I have heard of a vessel bursting during the retching of sea-sickness, and the patient bled to death, and have known at least two other cases in which profuse hæmorrhage occurred in phthisical patients while at sea; and of these one was landed at Rio, to die almost immediately: the other reached home, but sank shortly after. I do not, however, think that a patient having once had an attack of hæmoptysis, even though the attack may have been a severe one, should forbid his being sent to sea, if a considerable interval has elapsed since the occurrence, and all evidences of tendency to bleed have subsided. Still less, as I have before said, do I regard the existence of slight streaks or specks of blood in the sputum as interdicting the voyage.

The cases which appear to derive the most benefit from a sea voyage are those in which the disease assumes a slow or chronic form, in which it has commenced with dyspeptic, catarrhal, or laryngeal symptoms, and in which there is marked anæmia or a tendency to congestive and inflammatory affections of the lungs or pleuræ, or to disorder of the liver and bowels. The benefit to be derived is also likely to be greater in proportion to the early period at which the patient is sent away. When, as is often the case, the invalid does not return in the same ship, but remains for a longer or shorter time at the port to which he is sent, it is of course difficult, if benefit be derived, to know what share of the improvement is to be ascribed to the voyage, and what to the residence on shore; but I have often known patients say that their improved condition had rather occurred at sea than on shore.

5. There are yet other cases of consumption, in which the physician's opinion as to the desirableness of sea voyage is often asked, and in which, if it be recommended at all, it must be under peculiar circumstances, and with very decided qualifications. I allude to cases in which the disease is fully confirmed, and the patient's strength much exhausted. In some such cases a voyage undertaken in a private yacht, and in calm seas and a mild climate, may be recommended to a patient who has great desire of change, but inability to bear the fatigue of a land journey. For this purpose the Mediterranean, at a suitable period of the year, answers very well; for there are ports within two or three days' sail of each other at which the invalid, if it be thought desirable, can land, and make such stay as is agreeable to him. Such cases should, however, on no account be sent to a hot climate. In such the progress of the disease is almost sure to be hastened, and the patient will rapidly sink, exhausted by perspiration and diarrhœa. There are yet other cases in which the physician, while he cannot recommend, may yet not oppose the proposition that the invalid should be sent a sea voyage,—as when there is advanced disease, yet the patient has firmly convinced himself that a sea voyage may save him. I have known two instances of the kind in which there was no prospect of benefit, and too much reason to fear that the unavoidable fatigue might hasten the fatal event. In both of them, after telling the friends plainly the state of the patients, I left the decision in their hands; and though the result was what was to be anticipated, I believe in both the friends were fully satisfied that they had done right in acceding to the wishes of the invalids. In cases of this kind, the Mediterranean should be selected for the voyage—not only for the reasons given, but also for the opportunity it affords of the patients being reached by their friends at any time within a week or ten days.

In some of the cases which have been mentioned, there is no doubt that very great benefit is often derived from a sea voyage, provided the voyage recommended is suitable to the case, and the patient is able to bear the fatigue and willing to take proper care of himself while at sea. In some cases all the symptoms and signs of disease disappear, and the patient —who perhaps left home in a very critical state—returns in good health. In others, though there may not be an entire cure, very great relief may be gained: the general symptoms may be alleviated, the local disease become quiescent, and the strength increase. And in yet others which do not present such good results, the voyage may not be without its advantages in affording cheerful excitement of mind and retarding the progress of disease. In expressing this opinion of the beneficial influence of sea voyages in certain cases of phthisis, I may appear to be placing myself in opposition to the inferences deduced by M. Rochard, from an elaborate and able investigation of the subject in a paper published in the *Memoires de l'Académie Impériale de Médecine* for 1856. It is, however, not so. M. Rochard has shown, from a large collection of facts as to the deaths and invaliding in the French navy, and from other sources, that phthisis is of very frequent occurrence in sailors, and that its symptoms are aggravated on shipboard, and especially in hot climates. It is, however, obvious that there are sources of disease to which the crews of ships are exposed, from which the passengers are free; and in this way we may explain the very frequent occurrence of phthisis in sailors, both officers and men, as shown by M. Rochard, and of which we have evidence in London, both from private and public practice, without concluding that a sea voyage may not be advantageous to those who are placed in entirely different circumstances.

6. Patients who are unduly susceptible to cold, so that the slightest exposure is followed by bronchial irritation, and in whom there is an undue amount of dyspnœa, so that the case threatens to run into asthma, often obtain great relief from a voyage so arranged as to take the invalid into a warm climate for the winter and spring. In cases, however, of decided asthma, though a marine atmosphere may be beneficial, —for different cases of asthma are benefited by very different kinds of climate,—the most advantage is usually derived from a warm and dry air such as is obtained on the north coast of Africa or Egypt, or in South Africa or Australia.

7. We are all familiar with the benefit which is constantly derived in scrofulous cases from a residence at the seaside. This may be in some degree due to the emanations given off by marine plants on the shore, but is doubtless also partly referable to the marine atmosphere, and this must of course be obtained in all its perfection at sea. In several cases which have fallen under my notice scrofulous children have been kept at sea for several voyages, and have derived great benefit from the treatment, both the local and general symptoms being much relieved. Indeed, I have known patients derive advantage from a voyage, when it was very improbable they would have survived for any length of time if on shore.

8. The beneficial influence of a marine atmosphere has been long known and fully appreciated in cases of climatic disease, and it has often been the practice of medical men in the tropics to send their patients to sea as the most effectual means of restoring health. Indeed, patients are sent home from India and China and other parts by sea, who could not possibly bear the journey overland, and they very generally arrive at home, if not well, at least very much better than

when they left. Some years ago, when at Ascension, I was told that if a patient suffering from Coast of Africa fever lived to reach the island, where the climate must be thoroughly marine, they almost always rapidly recover. At home we see less of the advantage gained in cases of this kind; but I suppose we are all often consulted by patients labouring under the diseases of tropical climates or under pulmonary or cardiac or other symptoms superinduced upon such affections, in which we are told that the patient was put on board ship in an almost hopeless condition; yet when we see him he is generally much better, and often gets quite well after a short residence at home.

9. Closely allied to the class of cases now mentioned are those in which persons suffering from malarious affections are also the subjects of syphilis. I have seen several cases of this kind in which the patients have apparently been saved by being sent home from India by sea; and, though medical treatment may be required, they are generally much relieved while on board ship, and I have known them get quite well without any treatment at all while at sea. I have no experience of the beneficial effects of a marine climate in uncombined secondary or tertiary syphilis, but from the analogy between such cases and those named I should certainly expect great advantage to result from sending the patient so affected to sea.

10. Cases of chronic cerebral disease are also often much relieved by a voyage. The absence of all excitement, the regular habits, the sedative influence of the climate (and possibly also of the motion of the ship), and the constant exposure to fresh air, tend to quiet the nervous system and improve the general health. Cases of this kind should not, however, be sent to latitudes in which there would be likelihood of rough weather, and the cooler climates should also be selected—or at least, if it be thought desirable to send the patient a long voyage which would take him through the tropics, he should be specially cautioned to avoid exposing himself to the sun during the heat of the day.

(To be continued.)

OPERA CLINICA.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

TOOTH-EDGED CUTTING SCISSORS.

I HAVE recently had constructed for my use a pair of tooth-edged cutting scissors on the plan shown in the diagram. The scissors are of the ordinary construction in all respects except in the cutting edge. The cutting edge of each blade, instead of being even and sharp, is divided into finely-pointed teeth, each tooth being directed with a slight inclination towards the handle of the scissors. When the blades meet the teeth cross each other, and as they pierce any structure that may lie between them, they crush also, between their surfaces.

If a piece of moderately firm substance be placed between the blades—a piece of paper or of thin card, for example—the scissors perforate it in a series of perforations resembling what is seen in the postage-stamp—that is to say, they do not cut clean through the substance so as to leave it in two distinct parts at once. A little lateral or half-rotating movement of the closed blades is, however, sufficient to tear through the still connected lines of substance and to complete the separation. The same occurs if the substance placed between the blades be a portion of soft animal structure, only that more force is required in the lateral or rotating movement to cause complete separation. The parts punctured are crushed between the teeth, and are separated by the twist or torsion.

I find these scissors useful in dividing directly and quickly structures in which there are many minute bloodvessels, and which, when divided by the knife, bleed freely. These toothed scissors, as they can be made at one and the same time to pierce, crush, and twist, control bleeding remarkably.

It occurred to me at first to modify a pair of torsion forceps so as to make them cut with toothed edges at the part where they compress, and I used a forceps thus modified with success. Mr. Perkins, jun., of Baker-street, brought me one day a patient with an epulis. The gum beneath the base of the tumour was much thickened and vascular, but with my toothed forceps I cut through easily, and removed the whole mass quickly and thoroughly, effecting a good cure. But I found a want of purchase in handling the forceps, so I determined to carry out the method with scissors as above described. Mr. Perkins, who, as a dentist, is as mechanically skilful as he is energetic, earnest, and intelligent in his professional work, was good enough to make a model of my design out of a pair of ordinary surgical scissors, and from this model Messrs. Krohne and Sesemann, with their usual facility, have constructed the special instrument figured in the diagram.

I have put the scissors to a good test in a case of epulis, in a patient under the care of my friend Dr. Davson. In this instance the tumour was increasing rapidly, and three teeth were involved in it. It was very vascular, had a broad base, and might at first sight have been taken for a malignant rather than for a fibrous tumour. The three teeth being extracted, I found I could get a deep grasp of the tumour between the blades of the scissors. I carried the teeth of the scissors well through the base of the tumour, crushing some portion of bone in the way, and gently and easily twisted the mass off, and lifted it away upon the blades without the loss of any blood whatever. The healing in this case was rapid and good.

These tooth-edged scissors may, I think, be usefully modified. Made with longer handles and a little curved in the blades, they could be used for removing abnormal growths from the surfaces of internal organs—such as the uterus—by the combined processes of pierce, crush, and twist. Made with very delicately formed teeth, and altogether small, they might be used for removal of abnormal growths from the ear, the nostrils, or the eyelids. They could easily be constructed for the removal of the tonsils, and they are ready for use in cases of piles. They will probably turn out serviceable in operations for removal of portions of the tongue.

Good old Benjamin Rush, speaking an eulogy on Cullen, says, I remember, with much simple force, that "there are mites in medicine as well as in charity." From whence he draws the conclusion that no new thought or fact, however unimportant it may appear, should be allowed to pass without having attention drawn to it. In this spirit I add this mite to the "Opera Clinica."

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

COMPOUND FRACTURE OF RIGHT ARM—GANGRENE—AMPUTATION AT SHOULDER-JOINT—RECOVERY.

(Under the care of Professor JOHN WOOD, F.R.S.)

[FOR notes we are indebted to Mr. Rose, Surgical Registrar.]

E. H., aged 51, a clerk of the sewer works; temperate; admitted October 13, 1873. A week before admission the wheel of a cart passed over the right arm at the junction of the upper and middle third, causing a compound comminuted fracture of the humerus at that point, together with laceration of the brachial artery and large nerves, and considerable contusion of the soft parts in the neighbourhood. There was a small opening at the posterior and inner part where the integument had given way, through which the finger could be introduced and the fragments of bone distinctly felt. The hæmorrhage at the time of the accident, and after, was not excessive. The general practitioner who first attended the case made an effort to save the arm, and applied evaporating lotion; but on gangrene fully establishing itself, he sent the patient into the hospital.

On admission the whole of the right arm up to within six inches of the shoulder was in a state of moist gangrene. The patient states that immediately after the accident his arm became cold, devoid of sensibility, and quite powerless, and continued in the same condition until now. There is great constitutional disturbance, and a pallid and anxious expression. The pulse is weak, 116; temperature 100·4°. The tongue is moist, and covered with a white fur.

October 14.—Delirious during the night. This morning there is a distinct, though irregular, line of demarcation about five inches and a half from the shoulder. Mr. Wood therefore determined to amputate, and at 2 p.m. the patient was placed under chloroform, and amputation at the shoulder-joint was performed. The outer flap was made by transfixion. Very little blood was lost during the operation. The axillary and seven other bleeding vessels were secured by ligatures. The flaps were sponged with a solution of chloride of zinc and carbolic acid, and a drainage-tube was inserted through the lower part of the posterior and outer flap. A few doubtful-looking portions of tissue were removed, and the parts were secured by several points of suture. Carbolic dressing and a broad bandage was then applied.

The patient suffered considerably from shock after the operation, the temperature at 4 p.m. being 95·4°; pulse feeble, 134. At 9.30 p.m. he expressed himself better. The temperature rose to 102°; pulse 128. Ordered milk diet, with beef-tea, and twelve ounces of brandy.

15th.—Delirious during the night. Took thirty grains of chloral without effect. Tongue moist, white fur; temperature 101·4°; pulse 118.

16th.—Slept four hours. No pain in stump.

17th.—Dressings changed. Flaps looking well. Slight lough at lower angle of wound.

20th.—Wound looks well. Discharge healthy. The upper part of the flaps has united. Has slept well. All ligatures away except that on the main artery.

21st.—Ligature away from main artery. Granulations healthy. Ordered to take three times a day ferri sulpho-carb. gr. iv., tinct. quinæ co. ℥xx., acid. sulph. arom. ℥xx., aquæ ℥j.

26th.—Doing well. General health good. Brandy reduced to ten ounces. To have a mutton chop daily. Pulse 108; temperature ranging between 99° and 100°. Tongue clean. Drainage-tube removed. Sinuses still discharging from lower angle, and syringed out with carbolic lotion.

November 10.—Abscess opened at lower angle of flaps.

13th.—Another abscess opened and a drainage-tube re-inserted.

The temperature lately has been rather higher—102°; the pulse slightly intermittent, 108 to 116. Is now on fish diet.

December 1.—Wound closing fast. Less discharge.

15th.—Brandy reduced to six ounces. Meat diet. Lower angle of wound almost healed. Will leave the hospital in a few days.

UNIVERSITY COLLEGE HOSPITAL.

MYELOID TUMOUR OF LOWER END OF FEMUR—AMPUTATION—ANTISEPTIC DRESSING—HEALING ALMOST, IF NOT QUITE, WITHOUT SUPPURATION.

(Under the care of Mr. BERKELEY HILL.)

Joseph D., aged 18, a cutler, was admitted on June 20, 1873. A strumous-looking lad; his father died of consumption; has one sister who is very delicate; mother healthy. No history of cancer in the family; has had scarlet fever. About a month before Christmas, 1872, he caught a severe cold, which kept him in ten days. About a week after he was taken with pain in right knee; but he had not to keep his bed until the end of February, 1873. He had lotion applied to it, and a knee-cap to wear; but the knee not getting any better, he came to see Dr. Gowers in April, 1873, who blistered the knee, gave him iron internally, and called the disease of the knee "rheumatism." He had kept his bed until he came into this Hospital. The patient is pale; no marked anæmia; considerably emaciated. Several ecthymatous pustules on the right leg; the right lower limb is altogether much smaller than the left. Right thigh, ten inches above lower border of patella, eleven inches; left thigh, at a point ten inches above lower border of patella, fourteen and three-quarter inches in circumference. There is great deformity about the right knee, consisting apparently almost entirely of a large rounded swelling at the upper part of the joint. This extends downwards on both sides as far as lower border of patella, but at this level in front it exists but to a slight extent; it reaches upwards to six inches above lower border of patella, and is most marked and reaches highest on the outer side. The whole of this swelling is very soft and elastic, but at no point is the sense of fluctuation perceptible; but throughout the mass there is distinct expansile pulsation. There appears to be no thickening of the femur above the level of the swelling. The inner condyle of femur is to be felt of apparently normal size; the outer condyle cannot be felt at all. Three or four of the glands in Scarpa's triangle are distinctly enlarged, the lower of these being the largest. The skin over the joint is cool. Slight movements of flexion and extension, especially the former, are possible, and cause but little pain. There is tenderness in the position of the outer condyle, but nowhere else. The pain that he feels varies in amount, being sometimes of a dull aching character, and at others stabbing. It is generally worse at night, and he feels considerable pain in the hip and heel, generally more painful after manipulation.

June 26.—Chloroform having been administered, Mr. Hill first passed a grooved needle into the elastic and pulsating mass over the outer condyle. No fluid coming out, Mr. Hill thrust a small scalpel in near the same point, but still no fluid came out; so amputation in the lower third of thigh was, by means of lateral flaps, commenced. First of all the outer flap was formed by means of transfusion, and then the inner one in the same way. After the bone had been sawn through it was noticed to be very vascular, so another inch had to be taken off, and the bone even then seemed to be very vascular. The whole operation was done by the antiseptic method. The flaps being plentiful, a deep suture had to be put in; eight other wire sutures, which kept the edges of the flaps together. In addition to usual antiseptic dressings, there was a towel soaked in carbolic lotion (1 in 40) placed under the leg on the operating-table during the operation. As soon as the operation was over, a large piece of gauze soaked in carbolic lotion was placed over the stump, two pads of the same on either side of the flaps, and finally the usual gauze dressing over the stump. After the operation the pulse became exceedingly weak.

27th.—The leg was examined immediately after the operation. The skin was divided longitudinally over the joint, and a flap reflected on each side. The tendon of the extensors with patella were then thrown downwards, opening the joint. A soft, fluctuating tumour was thus displayed, occupying principally the outer condyle, but extending inwards just beyond the interval between the condyles. The length of the tumour was four inches; it had involved the whole thickness of the condyle. The cartilage was much expanded, and was quite thin in the part occupied by the tumour. The other structures of the joint were perfectly healthy, and the soft parts were not involved at all. Small prominences of gelatinous appearance existed in the notch behind the condyles, evidently consisting of projections of the tumour into the joint. Afterwards a section was made longitudinally through the bone, but slightly obliquely, so as to pass through the outer condyle. In this way the tissues of the shaft were seen to be more vascular than natural, the redness having, moreover, a somewhat patchy distribution. On cutting through the tumour, a dark-red clear fluid escaped from three or four cysts of small size. The substance of the tumour was extremely soft, in the greater part of a brownish-red colour, mottled with patches of a rather bright yellow; but at the anterior part there was a layer, nearly an inch thick, of a very soft brain-like material of homogeneous structure and yellowish-grey colour. In the section made there were three or four patches, where extravasation had taken place, of a very dark red, almost black, colour. The most vascular part of the shaft was that next above the tumour. The compact tissue of the bone was eaten away by the growth, which appeared to be extending chiefly on the medullary side, but also in a thin layer beneath the periosteum. A fresh scraping of the soft anterior layer showed a number of round cells with large nuclei, a few fibro-plastic cells, and a great number of clear oval nuclei, similar to those in the rounded and fibro-plastic cells; but, besides these, there were a considerable number of characteristic myeloid cells; all of these contained large fatty granules. A section of the tumour hardened in alcohol showed the characteristic appearances of myeloid growth.

August 11.—Patient went out on Saturday.

20th.—Two or three days ago patient returned with a minute abscess in the line of the incision, which, on investigation, was found to contain a silver suture uncut. In other parts the flaps were well and firmly united. The glands in the groin are decidedly smaller than on admission, and there is a distinct improvement in the development of the glutei and the muscles of the thigh. Patient in good health.

BRISTOL GENERAL HOSPITAL.

TUBERCULAR BASILAR MENINGITIS—DOUBLE OPTIC NEURITIS.

(Under the care of Dr. MARTYN.)

ROSINA L., aged 16, was admitted September 23, 1873. Patient had not been feeling well for the last four months—had been losing flesh, complained of pains in her head and a general feeling of weariness, but was able to go to school until a fortnight ago, when she had a convulsion. The convulsion was a severe one: she foamed at the mouth, and drew her legs up, and would not speak unless roused. She has remained in this semi-conscious state ever since.

Present Condition.—Lies on her side, with her thighs flexed on her belly; will not put them down when told to do so. Face slightly flushed; pupils somewhat dilated; can be roused to speak with great difficulty; puts out her tongue when told. When touched on the head, she apparently feels pain. Passes urine and fæces involuntarily. The temperature in the evening was 100°.

September 24.—Temperature in the morning, 99·4°; evening, 101·4°.

25th.—Temperature in the morning, 100°; evening, 102·4°. Lies in much the same state.

26th.—Temperature in the morning, 101·4°; evening, 102·4°. Has been screaming out at intervals during the last twenty-four hours. Lungs: dulness on percussion at bases. Respiration tubular, with some crepitant râles. Urine acid, specific gravity, 1026; albumen one-fifth of an inch.

27th.—Temperature in the morning, 100·4°; evening, 100°.

28th.—Temperature in the morning, 99·4°; evening, 97°.

29th.—Temperature in the morning, 98·4°; evening, 100°. Had two convulsions to-day. The convulsions are a clonic spasm of the right upper extremity. She moves her arm up and down, and scratches the bedclothes. There is no paralysis of the extremities. Pupils dilated. The nurse says she moans a great deal and puts her hand to her head, as if in severe pain.

30th.—Temperature in the morning, 98·4°; evening, 100·4°. Had one convulsion in the night, and two this morning. There is complete ptosis of the left eye, and paralysis of all the muscles supplied by the third and sixth nerves; the fourth is not affected, as there is some rolling of the eyeball; the pupils are widely dilated, the left more so than the right. No paralysis of the muscles of the right eyeball. There is very acute double optic neuritis.

October 1.—Temperature in the morning, 100°; remains in much the same state. Died at 3.30 p.m.

Autopsy on October 2.—Body greatly emaciated. On opening the skull, the dura mater was normal. The vessels of the pia mater were intensely injected; the membrane itself was dull, and had lost its shining appearance. There were several small pale white bodies, scattered all over the surface of the hemisphere, particularly the right. The base of the brain was covered with exudations of yellow lymph; a piece of this about the size of a cherry was pressing on the optic commissure. The velum interpositum and choroid plexuses were soft. The lateral ventricles were full of serous fluid. The brain was large, and the substance somewhat soft. Chest: Lungs congested; the bronchial glands were enlarged and cheesy in structure. Heart normal. Liver, spleen, and kidneys congested; otherwise normal. Intestines normal. Mesenteric glands were not enlarged, neither was there any tubercle in the peritoneum.

IMPURE SOAPS.—The *Grocer and Oil Trade Review*, writing on the adulteration of soap, says:—"Even the Castile soap, made from olive oil, and selected for medicinal purposes on account of its comparative purity, contains a considerable quantity of visible impurities, to which its mottling is due. This arises from the fact that it is made from the refuse of olive oil. And the most honest of commercial soaps are impure for a like reason, the manufacture of pure soap from chemically pure materials being almost an unknown, or at least unpractised, art. There is, however, one kind of commercial soap which is very nearly, if not quite, chemically pure. This is resin soap, and oddly enough it is the cheapest and coarsest of all commercial soaps."

SATURDAY, DECEMBER 20, 1873.

THE RECENT DISCUSSIONS ON THE TREATMENT OF ANEURISM.

IT may with truth be said that now, as of old, a discussion upon any of the various points of importance connected with that hydra-headed subject, Aneurism, is always capable of awakening fresh interest. In Aristotle's time, and subsequently until the death of Rufus of Ephesus, the nature of the disease in its crudest form was not agreed upon, though often discussed, and no distinction was made between tumours of veins and tumours of arteries. In Galen's time nothing like unanimity of opinion existed as to what kind of lesion produced aneurism—whether it was due to an anastomosis, a rupture, or a dilatation of an artery. Vesalius was the first to describe an aneurism as arising from the *rupture* of a *dilated* aorta; and Lancisi, Quattani, and Morgagni opposed the doctrine advanced by others, that every aneurism was due to a dilatation of the coats of the vessel. Then came Scarpa, who opposed the view of these last named—viz., that aneurism is produced either by rupture or by dilatation of the coats of an artery, or by a combination of the two processes; for he thought that the disease always involved the rupture of the proper coats of the artery, and that the aneurismal sac was formed by the condensed cellular sheath of the vessel.

At the present time, however, while professional opinion is fairly well agreed as to the causes, the varieties, the nature, and to a great extent the mode of cure of the disease, the treatment of aneurism, and especially of internal aneurisms, is occupying, and has for some time occupied, a prominent place in the surgical mind. This is no doubt easily explained since the use of carbolised catgut, the application of compression to abdominal and iliac aneurisms, and the more extended trial of the expectant treatment have produced results which have gratified, if they have not somewhat surprised, surgeons.

Different, however, as the two methods of compression and rest seem at first sight, there is perhaps little doubt that the one has done much to advance the other. The success attending

upon compression of aneurisms of the limbs had established the truth that complete cessation of the flow of blood through the sac is not absolutely essential for a cure, so that encouragement was given, in dealing with internal aneurisms, to any general treatment by which the force, quantity, and frequency of the blood-stream through the sac is diminished. On the other hand, with such strong evidence as we now possess of the complete cure of aneurisms by simple and entire rest and restricted diet, the question forces itself as to how far the recovery of many of those cases which is attributed to prolonged and interrupted compression is in reality due only to rest in a recumbent position and a moderate, unstimulating diet.

We have within the last few days enjoyed the opportunity of hearing the merits of the treatment by rest and the treatment by compression attested to by two extra-metropolitan surgeons of eminence. On Tuesday, December 9th, Mr. Joliffe Tufnell, of Dublin, communicated a short paper to the Royal Medical and Chirurgical Society on the Cure of Aneurism by Position and Restricted Diet, and on Friday, December 12th, Mr. Wheelhouse, of Leeds, read to the Clinical Society the report of a case of "Aneurism of the External Iliac cured by Pressure with Liston's Tourniquet." The discussion which followed each was of more than usual interest and earnestness, and yet it cannot be said that anything new was contributed to our knowledge, except the records of some hitherto unpublished successful cases.

There are now a goodly number of known cases of aneurism which have been cured by the use of the abdominal tourniquet since the publication of the first case by Dr. Murray, of Newcastle. There are, too, it must be confessed, several known unsuccessful cases; and no doubt there are, besides, others unsuccessful but not generally known.

Mr. Wheelhouse has added another to the list of cures by this treatment, while Mr. Joliffe Tufnell's paper furnishes the report of two cases of aneurism of the abdominal aorta cured in thirty-seven days and twenty-one days respectively, and of one case of popliteal aneurism cured in twelve days, by rest and restricted diet.

In his paper Mr. Tufnell advocates the same views which he has very ably set forth in his pamphlet on the "Successful Treatment of Internal Aneurism," published in 1864. These views may be briefly described thus:—To consolidate a circumscribed aneurism of the abdominal or thoracic aorta (for if diffused nothing can be done but to alleviate pain), the difficulty we have to contend against is the distensile action of the heart, the flow of blood from which has the effect of thinning and destroying the sac. The circulation, therefore, must be modified; and this is to be effected by rest, regimen, and remedial agents. Valsalva's plans are radically wrong, in so far as repeated bleedings in most cases act injuriously (1) by removing the fibrine, which, too, cannot be renewed if starvation be combined with the bleeding; (2) by producing a watery state of the blood; (3) by quickening the circulation; and (4) by weakening the patient and producing anæmia. In the treatment advocated, however, the health of the patient is to be kept as good as possible; and, as the fibrine of the blood is the material of repair, the blood must be kept in a highly fibrinised state. But the heart's action in force and in frequency must be reduced, and the quantity of blood in the system must be lessened by diminishing the supply of fluid, and stimulating its excretion by the skin, kidneys, and bowels. By weakening the heart's action the aims are to prevent enlargement of the aneurism, to allow the sac to contract, and to favour the deposition of laminated fibrine from a reduced and wave-like blood-current. Fibrinisation is to be effected by (1) maintaining the quality of the blood, and (2) preserving the patient's health.

All that is sought for will be attained by the recumbent position and restricted diet. By restricted diet is meant three meals a day, served at regular intervals, and consisting in kind and amount of two ounces of white bread and butter with two ounces of cocoa or milk for breakfast; three ounces of broiled or boiled meat, with three ounces of potatoes or bread, and four ounces of water or light claret, for dinner; two ounces of bread and butter and two ounces of milk or tea for supper—making, altogether, ten ounces of solid and eight ounces of fluid food in the twenty-four hours. But the main point to be attended to is the recumbent position, for if this be not maintained for two months, or ten weeks, without, if possible, the patient sitting even once erect, all other treatment will be neutralised. Recumbence is the secret of cure. It places the same check upon the circulation in internal aneurism which is mechanically produced in external aneurism.

In one of the cases referred to in Mr. Tufnell's paper the difference in the frequency of the pulse in the upright and recumbent postures was thirty-five beats per minute, so that in twenty-four hours, if recumbence was maintained, the number of pulsations in the aneurism was reduced 50,400. So too, in a case of abdominal aneurism (Case 6 described in the pamphlet), Mr. Tufnell reckoned that the aneurismal sac was distended no less than 43,200 times less frequently in the recumbent position; or, granting that under ordinary circumstances the patient would be in bed for twelve hours out of the twenty-four, then the diminution in the number of distensions would be 21,600 per day. It is clear, the author states, that no remedial agent in the Pharmacopœia will produce such a result as this; still in most cases assistance in the treatment will be derived from anodynes, aperients, and tonics.

In the three cases described in the paper, we think, writing from memory, that Mr. Tufnell mentioned only the use of morphia and chloral hydrate; but in the pamphlet, lactucarium, with hyoscyamus or lupulin, is chiefly recommended as an anodyne; jalap powder, colocynth, and aloes as aperients; and opium as a narcotic for the relief of pain. Medicines however, are mere adjuvants in the treatment, whereas, if restricted diet and long-continued recumbence be relied on, it will be found that internal aneurism is not the hopeless affection hitherto supposed; and it may be confidently anticipated that a large number of external aneurisms will be found capable of cure by the same treatment.

Mr. Tufnell's observations are based on the results of experience. We have before us now the records by him of nine successful cases, and we believe he has succeeded in curing sixteen out of eighteen cases in which he has tried this treatment. But, in the face of these successes, it must of course be expected that recumbence and spare diet will often fail to bring about the hoped-for result. Otherwise, how is it that an aneurism occasionally develops while a person is recumbent and on low diet in the ward of a hospital? and how is it that most surgeons have seen aneurisms go on enlarging under similar conditions?

If asked what kind of case is suited for this treatment, Mr. Tufnell's answer, we surmise, would be somewhat as follows:—A circumscribed aneurism recognised in its earlier stages, and before, by pressure, the tumour has injured important structures in the neighbourhood, or the sac of the aneurism has ruptured; while the hope of cure will be greater in a patient whose heart is enlarged and (though the prospect of another aneurism forming under these circumstances is of course considerable) whose aorta is atheromatous, so as to be passively recipient of blood and not capable of transmitting it with force—so as, in fact, to favour that kind of deposit of fibrine which is sometimes seen in a dilated portion of the arch of an atheromatous aorta.

If the term "expectant" is applied to this kind of treatment, and the question be asked what is "expected" from it, Mr. Tufnell would answer more explicitly than by saying—"A cure is expected." It is not by the plugging of the

artery below the sac by the chance detachment of a piece of fibrine; nor by the compression by the tumour of the feeding artery above it; nor by blood extravasated from the ruptured sac, as in Sir A. Cooper's celebrated case; nor by inflammation of the sac and the consequent formation of a plug in the artery, that a cure is looked or waited for. It is a so-called spontaneous cure, brought about by the deposit from the blood upon the inner surface of the sac, in its passage through it, of layer after layer of fibrine, so that the cavity of the tumour is by degrees lessened and ultimately entirely filled. This is the goal towards which the "expectant" or the "rest and diet" treatment is systematically and scientifically directed, and, as we now know, has been and may be directed with satisfactory results.

But if by this simple and apparently safe course internal aneurism can be cured, the questions arise whether the compression of the abdominal aorta, with all its great risks, for aneurism of the abdomen or pelvis, is ever justifiable; and, if so, in what cases is it right to use such a dangerous and, it must be admitted, so uncertain a remedy?

Mr. Wheelhouse's case and several others already published, including Dr. Murray's, Mr. Durham's, and Dr. Greenhow's, are sufficient to prove that the use of the abdominal compress is permissible. The treatment is no doubt surrounded by danger, but the disease is a profoundly grave one, and, like other grave diseases, warrants the employment of a very grave remedy, providing means no less dangerous avail. Had it not been for Mr. Wheelhouse's case, in which there was evidently somewhat general arterial disease, we should have thought that compression of the abdominal aorta ought to be limited to patients free from arterial atheroma and heart disease; whose visceral organs are sound, and therefore better able to resist the ill effects of direct pressure from the tourniquet, or indirect pressure from arterial, capillary, or venous distension; and in whom the aneurism continues to increase or shows no sign of being cured under the treatment advocated by Mr. Tufnell.

The brilliancy of the success which has attended abdominal compression in several cases was likely, no doubt, to lead to a freer and less deliberate use of it than this success justifies. For this reason we think Mr. Holmes did great service by so forcibly pointing out in his professorial lectures at the College of Surgeons, in 1872, what and how great are the dangers of protracted and deep pressure of the aorta—dangers which some even of the successful cases have verified.

Still, for aneurism of the iliacs and the lower part of the abdominal aorta, compression is now, we believe, rightly regarded as a legitimate operation; and even for aneurism where the pressure, to be proximal, has to be made immediately below the xiphoid cartilage, it must be remembered that, in spite of *à priori* objections, success has resulted.

Whether in those cases in which proximal pressure cannot be employed (as where the aneurism is seated close to the cœliac axis), distal pressure will at any time be found at all adequate, we cannot say. At present there is only one case known in which it has been tried, and in this one, though the aneurism was cured after nine hours' compression, the patient lost his life. It would be well, however, to try, as Mr. Holmes has suggested, whether some of these cases might not be cured by gradual and partial pressure instead of complete compression.

After every consideration of the hazardous character of the treatment,—of the chances of failure, of anatomical lesions, and even of death itself,—and of the great caution, dexterity, and watchfulness required for its application, it must be said to its honour, and the honour of those who have originated and established it, that abdominal compression has marked a distinct advance and made an undoubted triumph in the surgical practice of this generation.

THE PHYSIOLOGY OF VISION.

VI.—Perfect and Defective Vision.

Perfect vision implies, among other things, these:—First, that the various optical media of the eye shall be in their usual clear and transparent condition, so as not to obstruct the rays of light; secondly, that the rays which are to constitute the picture on the retina shall be accurately brought to a focus there; and thirdly, that the sentient surface of the retina shall be in a condition fit to receive and to transmit the impulses communicated to it by the rays of light.

Now, defects in the former respect are only too well known to us, notably in two forms—opacity of the cornea, and opacity of the lens as in cataract,—which may or may not admit of remedy. Of the same kind, but of less importance, seeing that they are habitually present and habitually overlooked, are the so-called muscæ volitantes, commonly assigned as due to partially opaque bodies in the vitreous.

One of the most interesting of physiological phenomena connected with varying degrees of opacity in the media of the eye is connected with the curious structure of the lens already alluded to. When we look at a luminous point (like a fixed star), it does not seem to us a mere luminous point, but to send out rays, as it were. Hence the conventional figure of a star is not a dot, but a rayed object (*). This is due to the existence of these stellate lines on the surface of the lens.

The defects of the second order are also sufficiently well known, especially in the form of long and short sight, but there are also some defects due to spherical and chromatic aberration. In looking at a body near at hand, and the rays of light from which are more than usually divergent, it is plain that to bring them to a focus one or other of two things will be necessary. The photographer, in adjusting his camera, moves his glass plate which corresponds to the retina backwards or forwards as may be required, until an exact image of the object is depicted thereupon; but the same object may be attained by increasing or decreasing the lens-power, and this seems to be the mode of adjustment adopted in the eye. The way in which this accommodation is effected has been already indicated in dealing with the relations of the lens to the ciliary muscle. In certain abnormal conditions of the eye, it is true, we have the other kind of defect, due to the retina being too near or too far away from the lens (for undoubtedly we do have eyeballs which are too short and eyeballs which are too long), but the other kind of defect, due to imperfect accommodation, is perhaps more familiar to us. In adjusting our eyes for near vision, we are conscious of a strain on the eyeball—due, no doubt, to the action of the ciliary muscle,—and, however this muscle acts, it undoubtedly has the power of increasing the antero-posterior diameter of the lens. But as people grow older, the lens hardens and loses its elasticity, and it moreover undergoes certain changes in colour, which has lately been assigned as the true reason for the defective colouring of artists as they advance in life, as well illustrated by Turner and Mulready. This hardening and loss of elasticity is felt chiefly in this, that the ciliary muscle ceases to have the power of altering the shape of the lens and rendering it fit for near vision; whilst the eye being normally set, so to speak, for distant vision, the aptitude for observing distant objects remains unimpaired as long as the media are sufficiently transparent. Such is the condition in old people, and to it is given the term presbyopia, the term myopia being applied to the opposite condition of short sight, to whatever cause due, and whether in young or old.

Of course the more curved the surface of any lens the greater is its converging power; but it sometimes happens in the human eye that the curvature is greater in one direction than in another—say from above downwards than from side to side. That being so, the perpendicular rays of light will be more powerfully refracted, and will come to a focus earlier than will

the horizontal rays; and hence the same surface represented by the two different kinds of rays will appear to be in different planes. This defect, which is not very common, is termed astigmatism, and may be remedied by invoking increased lens-power of an artificial kind for the aid of the less curved surface; and this may be done by means of cylindrical glasses.

We all know, from the simple experiment of Sir Isaac Newton, that white light is a compound of various coloured rays. These are composed of waves, differing vastly in length and in refrangibility; so that, in passing through ordinary transparent media of the lens kind, some of these tend to come to a focus more speedily than do others. Hence an object examined by means of such lenses is apt to be surrounded by various coloured circles, representing the different kinds of coloured rays. We are all aware that our eyes seem to present no such defect, and the question has long been a vexed one, Is the human eye corrected for chromatic aberration —*i.e.*, is it perfectly achromatic? The story of this discussion is a long and interesting one. Suffice it to say that it concludes in one way: the eye is not perfectly achromatic. And it may be proved thus. We take a piece of coloured glass which has the power of absorbing all the middle colours of the spectrum, and through it survey a luminous point at a distance. If we are so situated as to see this luminous point by means of red rays as a red light, we shall also see it surrounded by a halo of violet light—that is to say, the red rays have been brought to a focus on the retina, the violet have not. But the whole subject of colour is too interesting to be so briefly discussed.

THE LATEST NEWS FROM THE GOLD COAST.

The news which has reached us by the recent mails which have arrived in this country from the West Coast of Africa is not quite of such a cheering nature as preceding reports have prepared us to expect. The effects of that climate which has over and over again been stigmatised as "the worst in the whole world" are beginning to tell upon the constitutions of the gallant and energetic staff which accompanied Sir Garnet Wolseley upon his difficult mission. First and foremost the indefatigable chief has himself been rendered *hors de combat*—not by exposure to the sun, as has been erroneously reported, but from an attack of fever. It is a source of much gratification to learn that the seizure was not severe, and that Sir Garnet had so far recovered as to justify the sanguine expectations that he would be ready and able to place himself at the head of the European force upon its arrival at Cape Coast Castle.

That active employment in the Bush, in moderation, is better for our officers and men than enforced idleness would appear to be proved by the fact that the little force of Europeans quartered at the different stations has not suffered so severely, with all their fighting and exertions, as the crews of the vessels doing duty on the Coast. Thus her Majesty's ship *Druid* is reported to have a sick-list of thirty men, and the *Barracoota* one of twenty-seven men; and the latter has been ordered to Ascension with invalids for the recovery of their health. The *Simoom* hospital-ship has, it is stated, also been ordered off for a cruise to St. Helena and Ascension; she is stated to have sixty-two invalids on board, one of the most serious cases being that of Lieutenant the Honourable A. Charteris, who was suffering from a severe attack of fever. Of the medical staff, Surgeon Connellan has been invalided home, but the absence of any mention of the remainder leads to the hope that at the date of the last advices they were all in tolerable health.

One of the stringent orders which has, we believe, been laid down for the guidance of the leaders in the march upon Coomassie, is that no camping-ground for our troops, or hospital station, is to be selected at, or near, any of the spots which are known to have been occupied as resting-places by the Ashantee invaders. The wisdom of this order may easily be understood by anyone perusing the sickening account given by the special correspondent of a daily paper, of a visit made by him to the camp of that portion of the Ashantee force which so recently attacked our small detachment of men entrenched at Abrakrampa. He says—"The Ashantees must have laid in scores upon the ground; here and there a lean-to roof of palm thatch had been built, probably for a chief: wherever one of these was found the rags, pots, guns, knives, calabashes baskets, stools, brass-pans, scales and weights for gold-dust skulls and bones of enemies murdered, beads, rattles, bags, and ammunition-boxes, all the paraphernalia of savage ornament and war, lay scattered about in heaps. About halfway to Addismadi, such things as these had been thrown down in heaps, so as to make a flooring eighteen inches deep. Such an awful stench never man smelt. Foul odours will arise when masses of black men get together too thickly, and the sickening smell of disease can easily be imagined, but such are nothing to the dreadful reek of an abandoned camp of negroes suffering from want and sickness. It was not the odour of putridity, though now and again a horrid whiff came from the Bush,—it was the stench of mere starvation, leprosy, small-pox, and festering wounds, which made one retch all the return journey."

Such spots as the one described, and their environs, must of necessity be saturated with poison, and with the predisposing nature of the climate would inevitably lead to a fearful sick-list should a halting-place, by any mistake, be chosen in their vicinity; and as these camps have doubtless been selected by the enemy from some local advantage as regards clear space and water supply, it will tax the powers of the quartermaster-general's department to the utmost to provide halting-places for our troops possessing equal advantages with those which will thus be peremptorily barred from their occupation.

The 42nd Regiment will probably by this time have arrived on the Coast, but whether they will be pushed forward in support of the advanced force has not yet transpired. If everything progresses satisfactorily the commencement of the new year may bring us important, and let us hope satisfactory, intelligence of the movements of the little band of pioneers who are to humble the power which has so long done its best to prevent trade and civilisation from penetrating into the interior of the vast African continent.

PRISON HYGIENE IN CEYLON.

We have before us the reports of a Commission appointed by the Governor of Ceylon to inquire into the causes of a very serious amount of disease and mortality which prevailed in the years 1870, 1871, and 1872 in the prison at Willikade, in Colombo, the chief penal establishment in the island.

This Commission consisted of the chief justice, three puisne judges, and an officer of the public works, with whom was associated the principal military medical officer serving in the colony.

It appears that up to the middle of the year 1870 the prison had been healthy, eight deaths having occurred up to the month of June. At this time a case of cholera appeared, which was speedily succeeded by others, and by the end of the year fifteen cases of cholera had occurred, of which eight proved fatal. At the same time diarrhœa was prevalent.

In the latter part of this year a large number of convicts from other stations, who are described as having been in an advanced state of disease, and, without exception, mere skeletons, were introduced into the prison to replace others who had been sent elsewhere. It does not appear that these men were

separated from the others; they were dispersed through all the wards and cells, and great overcrowding ensued—as many as three, and sometimes five, being confined in a cell constructed to hold but one. With this overcrowding, and with great neglect of sanitary precautions, the sickness increased, and by the end of the year 1870 fifty-three deaths had occurred.

In the year 1871 the same condition of overcrowding and neglect continued. The number of deaths in this year amounted to eighty; and this state of things prevailed during 1872, so that up to November the deaths amounted to 104, making a total in the three years of 237. The sick were now removed to another building, and an inquiry was instituted. A divergence of opinion arose in the Commission as to the causes of this great mortality. The learned judges were led to seek for these in alleged misunderstanding and want of co-operation between the medical officer and the governor of the prison. This view appeared to Mr. Watt, the principal medical officer of the troops, to be so insufficient and unsatisfactory that he prepared a separate report, in which he has with remarkable ability traced the mortality to entire neglect and disregard on the part of the medical authorities of sanitary laws and precautions, and to this alone. He has entered fully into all the details of locality, buildings, food, water, clothing, and occupation, and has shown that in all these particulars no cause can be found to account for such unwonted suffering. The immediate cause of this existed, past all doubt, in excessive overcrowding and in the introduction of numerous persons affected with dysenteric disease, so that the whole place became poisoned, and disease was no longer amenable to treatment.

But the worst feature in the case is the condition of the hospital. The building is stated to have been insufficient and unsuited to the purpose, imperfectly ventilated and lighted. At the visit of the Commission seventy sick were found crowded into a space which afforded to each man but 560 cubic feet and 21·7 of superficial area. These seventy men were found lying huddled together on the floor; near each of them was an unglazed earthen chatty for all necessary purposes. These vessels are stated to have been emptied twice daily, and very imperfectly cleansed. In this polluted atmosphere the sick were locked up from 5.30 p.m. to the same hour next morning. They had no change of clothing, nor any provision for personal cleanliness. No wonder that, in such a lazar-house, disease, and especially dysenteric disease, did not yield to treatment. Yet all this misery seems to have attracted no notice from the medical authorities, but during two years to have been regarded as a matter of course.

It appears that the report of Mr. Watt was at once adopted by the government. The sick were removed to another place with immediate benefit; and it is to be expected that due medical supervision will in future be efficient in all the penal establishments. It is but too manifest that a vigorous reform is required in the civil medical department of the colony, if it has not already been effected.

This department was originally organised by the military medical officers soon after the settlement of the government of the island. It comprised a number of native officers of moderate pretensions, who were dispersed through the island and attached to the various public establishments. Among these, however, there have been several native gentlemen of high cultivation and acquirements, who have obtained diplomas from the Calcutta Medical College and even in England. From time to time a few English officers have been engaged in the department, but its advantages are not sufficient to attract a high class of candidates.

We learn that until about fifteen years ago the control of the department was in the hands of the principal medical officer of the troops, and was conducted by him in a manner closely resembling that in which the duties of the army are performed. It is not assuming too much to say that under such control calamities such as we have above described could not have taken place. Circumstances to which it is not necessary to allude led to a separation of the civil medical department from the control of that officer; but in such a case as that before us we are enabled to discern how great is the value of the services of an officer of large experience and superior to all local interests.

THE WEEK.

TOPICS OF THE DAY.

SCIENCE has sustained a great loss in the death of Professor Agassiz. His position was in its foremost rank. The author of works such as the "Poissons Fossiles" and "Monographies d'Echinodermes," of the "Bibliographia Zoologiæ et Geologiæ," will not soon be forgotten. Professor Agassiz was the foremost man of authority in science who has consistently and to the last refused to accept the Darwinian and evolutionary theories of the present day. A hundred years hence whose opinions will be in the ascendant—those of Agassiz or of his opponents?

The English Branch of the General Medical Council met on December 13. We believe they separated without fixing the date of the meeting of the General Council. With regard to the ultimate residence of the Council, nothing is yet fixed. It seems that they have a right to remain for another twelvemonth in the house in Soho-square should they desire to do so. The Addendum to the Pharmacopœia is, we hear, complete. It contains, amongst other things, chloral hydrate, a form for mustard-leaves, and some other preparations of value. There are also some pharmaceutical elegancies—such as a tincture of fresh orange-peel.

Dr. Livy, the Medical Officer of Health for the Borough of Bolton, has resigned his office for the reasons which he states in the following letter, addressed to the Sanitary Committee of the Council of the Borough of Bolton:—

"Gentlemen,—I beg most respectfully to tender you my resignation as Medical Officer of Health for the borough for acceptance at your earliest convenience. I have found that the efficient discharge of the duties of the office requires more time than I had anticipated, or than I have at my disposal. I have also felt that I have been obliged in the interest of the public health to condemn property against the wishes of, and without full and ample compensation being awarded to, its owners. Some of these owners are poor and advanced in years, others are orphans entirely dependent upon it for their maintenance. I consider that the rights of a solitary individual are as sacred as those of a million, and that law is never so odious and hateful as when it is made the instrument of oppression and injustice. I have therefore a decided objection to continue in an office where, even for the best of objects, I am compelled unjustly to deprive persons of property which has hitherto received the sanction and the protection of the law.—I remain, Gentlemen, your obedient servant, JOHN LIVY."

This letter speaks for itself, and it raises the question of the duties of corporations with regard to the owners of properties condemned on hygienic grounds. There is no doubt, as is urged by an able leading article in the *Bolton Chronicle*, that if a man's property is required by a railway or for a street improvement, his fortune will probably be doubled by the compensation he will receive; whilst if it be condemned as injurious to the public health, he will probably be ruined. At first sight, at least, there is an injustice in this. We know that it may be answered that holders of house property in boroughs are bound to keep their premises in such a condition as not to injure the health of the inhabitants or their neighbours. This is perfectly true theoretically. But then we must recollect that England is an old country, and that our ancestors had not the same scientific light to guide them in the matters of building and drainage that we have; and cer-

tainly to deprive a man of an old building because it was built before sanitary legislation was thought of, and to give him no compensation, must appear to the owner in question a public robbery. There ought at least, we think, to be a fair compensation given by corporations for the value of the building, assessed by an unprejudiced authority, whenever, for public hygienic reasons, it is found necessary to condemn house property.

THE MEDICAL PROFESSION AND POOR-LAW GUARDIANS.

USEFUL as the Poor-law system undoubtedly is, it has its drawbacks. One of these is too often seen in the relations established between local boards and their medical officers. The assumption of authority by the former over the latter becomes irksome and offensive. A case in point has been presented to our notice in connexion with a recent occurrence in Dublin. As our readers may remember, the Local Government Board for Ireland last July appointed the Board of Guardians of the South Dublin Union the "nuisance authority" of the port of Dublin, with the view of taking measures to prevent, if possible, the introduction of cholera by sea. The guardians accordingly appointed four medical officers in turn to visit and inspect vessels arriving in the port from infected localities, the names of these gentlemen being Drs. Mapother, Burne, Cameron, and Minchin.

Matters appear to have gone on smoothly for some time, but the Dublin *Daily Express* of the 12th contains an account of certain proceedings at the weekly meeting of the South Dublin Union Board of Guardians, held on the preceding day, which appears to us to have more than a mere local interest, and to closely concern the medical profession. We therefore extract the passage referred to at length :—

"*The Inspection of Infected Ships.*

"Mr. Byrne drew attention to a matter which he thought required immediate action. On the night of the 4th November last the ship *Magnet*, of Rotterdam, arrived in Dublin, and as Rotterdam was an infected port, the constable on duty reported the arrival of the ship to the medical officer appointed by the Board for the purpose of inspecting her. It happened that the vessel arrived at midnight, when Dr. Cameron was on duty as inspector, but he had requested Dr. Burne to act on his behalf. The constable communicated with Dr. Byrne, who inspected the ship, and gave the master a certificate. Dr. Minchin alleged that he had been sent for, and that he inspected the ship, and for doing this he claimed his usual fee. The Board would not pay the fee, because he had not been called upon to visit the vessel by any of the authorised officers of the Board—namely, the officers of her Majesty's Customs, and the members of the Dublin police force, who are sanitary inspectors. When the Board declined to pay the fee, Dr. Minchin wrote to the Local Government Board, complaining of the action of the guardians, and protesting against the retrospective action of the resolution adopted as to the proper persons to call for an inspection, and condemning the insinuation contained therein, as not only unjustifiable, but uncalled for. It was incumbent on the Board to call upon Dr. Minchin to withdraw that language unconditionally, and if he declined to do so to dismiss him from the office he held in the house.

"Mr. Sykes asked whether Dr. Minchin knew that the vessel had already been inspected.

"Mr. Byrne: He was shown the certificate of the previous inspection.

"A resolution, in accordance with Mr. Byrne's observations, was then passed, calling on Dr. Minchin to withdraw the language he had used respecting the Board."

Now, to say the least of it, this seems to be rather a high-handed way of dealing with a well-known, much respected, and senior member of the profession, and accordingly we have taken some pains to sift the matter thoroughly. It would appear that on the evening of November 4 a private letter was sent to Dr. Cameron by the owners of the *Magnet*, to say that she was expected about midnight, and to ask him to inspect her. Dr. Cameron, not being well, forwarded this letter to Dr. Burne, with a request that he would act on the occasion. Dr. Cameron's hours of duty terminated at 3 a.m., when Dr. Minchin's duty began in rotation. The vessel arrived at midnight, but Dr. Burne received no official notification of the fact until 6 a.m.—*i.e.*, in Dr. Minchin's period of duty. He visited the ship shortly afterwards, and signed the necessary certificate. Meanwhile, the shipowners, finding that no one came to inspect the vessel for upwards of six hours, sent a request to Dr. Minchin that he would perform the duty. He arrived immediately after Dr. Burne's departure, reinspected, and countersigned the certificate. As he had been sent for *within his hours* by the shipowners, he claimed a fee. As stated by Mr. Byrne in the extract already given, the Board of Guardians refused to pay him that fee, "*because he had not been called upon to visit the vessel by any of the authorised officers of the Board, etc.*" Mr. Byrne and his colleagues seem to forget that Dr. Cameron had been called to visit the vessel by the very same persons who several hours later sent for Dr. Minchin. And, further, the official notification of the Board, dated August 21, 1873, as to who were the Medical Inspectors of Ships, is addressed "To the Officers of Her Majesty's Customs, the Dublin Metropolitan Police Force, *and to all whom it may concern.*" Surely, if these last few words mean anything, it is that "all whom it may concern" are to apply to the Medical Inspectors, if need be; and certainly shipowners would especially come under this class. Under these circumstances we cannot but think that Dr. Minchin was perfectly justified in appealing to the Local Government Board.

ST. PANCRAS GUARDIANS AGAIN.

THE St. Pancras Guardians at their last meeting had before them a communication from the Holborn Union, asking that they should find room for 200 poor children at Leavesden Schools for a period of six months. The application was made in consequence of the epidemic of ophthalmia which prevailed to a serious extent in the Holborn schools at Mitcham; and the object of the guardians was to save the healthy children from the danger of contagion by accommodating them in another establishment. Dr. Bridges, of the Local Government Board, had suggested the removal of the children yet unaffected by ophthalmia to other workhouse schools. Under such circumstances as these it might have been supposed that the St. Pancras Guardians would have willingly afforded as much assistance as they could by placing the unoccupied rooms at the Leavesden Schools at the disposal of the neighbouring authorities. They, however, not only declined, but their refusal was grounded on what we must characterise as very sordid reasons. During the discussion it was stated that there was ample room for 200 children at Leavesden Schools; that the guardians would be glad to receive them for a period of two or three years, "as it would greatly relieve the ratepayers by reducing the *pro ratâ* charge of each child; but the Holborn Guardians having asked accommodation for only six months, it would be no advantage for so short a time." A resolution to that effect was afterwards moved and adopted. The reason assigned by the St. Pancras Guardians for refusing to accommodate the poor children of the Holborn Union scarcely surprises us. Whenever a question involving money is concerned, the St. Pancras Guardians always take a selfish view of the matter, forgetting or ignoring higher and more praiseworthy motives. In this particular instance we think they have acted not only unjustly, but with the utmost unkindness. For the sake of a small pecuniary advantage they leave the poor children of the Holborn Union in a very unhealthy and even dangerous state. If there is no appeal against their resolution there ought to be; but surely the Local Government Board have the power to interfere in a case the circumstances of which are so grave.

THE FOG.

The recent fog will be long remembered as one of the most disastrous this generation has known. To persons with cardiac and respiratory disease it has in numerous instances proved fatal. The accidents were, moreover, sufficiently numerous, and in several instances in the East of London deaths by drowning in the canals and river occurred. From inquiries we have made at the principal hospitals we learn that at the Charing-cross Hospital there were thirty or forty cases of accidents, and that the patients in the Hospital suffered severely, especially those affected with heart and lung disease. The death-rate during the days the fog lasted was unprecedented—in fact, higher than since the Hospital has been established. In one day six post-mortem examinations were made. At St. Thomas's a man was brought in dead from having fallen from his cab. He had a scalp wound and bruises on the scalp; and a boy was brought into the Hospital burnt in the face with a torch. At King's College Hospital there were two cases of accident—one a crushed hand, another a crushed toe. At Guy's there were four. A man at work upon the leads of a City warehouse in the fog walked off the building, and fell headlong to the ground. He fractured his skull, and was taken to Guy's, where he died shortly after admission. A fog signalman was run over. At Bartholomew's there were no accidents, but an increase of in-patients. From the Royal Free we have reported the accelerated death of in-patients. At University College Hospital there were no casualties. At the Middlesex a case of fractured fibula was received, and a patient suffering from concussion and scalp wound from falling off a mail-cart. At St. Mary's the in-patients are reported to have suffered severely. At St. George's there was a case of burn from a torch, and a case of bruise from falling over the park railings. The in-patients at St. George's and also at the Westminster Hospital are reported to have suffered severely.

THE LATE MR. TURNER, OF MANCHESTER.

We regret to observe announced the death of Mr. Turner, of Manchester, the founder of the Manchester School of Medicine—the first provincial school that had a recognised curriculum. In an early number we shall furnish a sketch of Mr. Turner's career.

PRACTICAL AND SUGGESTIVE.

Dr. Whitmore, Medical Officer of Health for Marylebone, in his report for the month of November, states that the mortality of the parish during that period showed a large increase, caused principally by the present excessive fatality of measles, which destroyed the lives of twenty-four young children; and he adds, one obvious cause for its rapid extension is, that precautionary measures for checking its progress, either by means of isolation or by the use of disinfectants, are to a very great extent disregarded. Less intensely contagious than either small-pox or scarlet fever, and generally less fatal, it fails even when it becomes epidemic to excite any great amount of public attention. In carrying out the system which has for some years been in operation in this parish, of disinfecting rooms in which cases of fever, small-pox, or other contagious diseases have occurred, he has constantly met with the difficulty of not being able to make the disinfection complete. A way of meeting this serious difficulty would be for parochial authorities to rent small houses in each of the poorest and most densely populated parts of their respective districts, to be kept as houses of reception for poor families during the six or eight or possibly twelve hours that it would take properly to disinfect their rooms. In so large a parish as St. Marylebone the annual expenditure for rent and management of the required number of houses for this purpose might amount to £200 or £250, a sum incalculably small when compared with the advantages that would result. We always notice the excellent reports of Dr. Whitmore with great satisfaction—they are thoroughly practical and suggestive; and if his recommendations were carried out with spirit on the part of the authorities, great public good would be effected.

DEFECTIVE LEGISLATION.

The reports of the Sanitary Committee of the Westminster District Board of Works on the result of the recent prosecutions under the Adulteration Act was a subject of some discussion at the monthly meeting held last week. It was remarked that the analyst took upon himself the responsibility of summoning tradesmen, and this Board had no power, their sole privilege being, in case of failure, to pay expenses. It was thought that the Legislature never contemplated placing so much power in the hands of one individual. The Hon. Ashby Ponsonby stated, in reply, that the Act gave power to the analyst to take proceedings without obtaining the authority of the committee. That the inspectors were to obtain samples of articles suspected of being adulterated, which they were to take to the analyst, and upon receiving his certificate proceedings could be taken out. The great uncertainty was the manner in which the magistrates would view the case, for it was a most extraordinary thing, that one magistrate convicted in a case which another one would dismiss. He did not wish to say one word against the London magistrates, but, as a magistrate who sat to hear appeals against their decisions, he could not help making that remark. He had even known a London magistrate omit to endorse a certificate with a previous conviction. He simply meant to say that magistrates looked at Acts of Parliament through different spectacles. Acts of Parliament are frequently drawn in so negligent a manner that they become inoperative.

THE ARMY MEDICAL SCHOOL AT NETLEY.

Surgeon-Major W. A. Mackinnon, C.B., whose period of service as Assistant-Professor of Military Surgery at the Royal Victoria Hospital has nearly expired, has been succeeded in that appointment by Surgeon-Major Joshua Henry Porter. Mr. Porter was for many years attached to the 97th (the Earl of Ulster's) Regiment, with which corps he served during the Crimean campaign, and afterwards in the suppression of the Indian Mutiny of 1857. We believe that Dr. Mackinnon has left this country for Madeira, to organise all the preparations necessary for the reception there of invalids to be despatched from the Gold Coast during the forthcoming operations against the Ashantees.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

The seventh anniversary session of this Association will be held at Willis's Rooms, King-street, St. James's, on Tuesday, December 30, at 5.30 p.m., when the President (C. A. Lockhart Robertson, M.D., F.R.C.P., etc.) will deliver an address on "The St. Andrews Medical Graduates' Association: A Retrospect." In addition to the general business, an important resolution affecting the future of the Association will be submitted by the Council to the members. The usual dinner will commence at 7 p.m. at the same rooms; Dr. Lockhart Robertson in the chair. Members intending to dine are requested to send their names at once to Dr. Sedgwick, 2, Gloucester-terrace, Hyde-park; or to Dr. Paul, Camberwell House, Camberwell, S.E.; or to the Hon. Secretary. Tickets, half a guinea each, not including wine.

WELL-DONE WORK.

At the monthly meeting of the Local Sanitary Board of Ovenden, Halifax, the chairman at the close of the meeting said he was glad that, as a general rule, they had no difficulty

whatever in removing nuisances. When the attention of the owners of property was drawn to an existing nuisance it was invariably removed immediately. He congratulated the members on the ease with which their work was got through, and thought the Board was now in a most prosperous condition. We infer from this statement that the medical officer of health and his subordinates are faithful and energetic servants.

DR. M'KENDRICK ON OZONE.

Dr. M'Kendrick read a paper giving an account of an experimental investigation made by Dr. James Dewar and himself on the physiological action of ozone, at the Royal Society, Edinburgh, at the first ordinary meeting of the present session, held on the 1st inst. Dr. M'Kendrick described, in the first place, the method pursued by Mr. Dewar and himself of producing the ozone. He then detailed numerous experiments made on frogs, mice, birds, rabbits, and on Dr. Dewar and himself, with the view of determining the action of ozone on the living animal, and the action it exerted on the living tissues of the body. The general facts observed were—(1) The inhalation of an atmosphere highly charged with ozone diminished the number of respirations per minute; (2) the pulsations of the heart were reduced in strength, and this organ was found beating feebly after the death of the animal, which showed that life was not destroyed by direct action on the heart; (3) the blood was always found in a venous condition in all parts of the body, both in those cases of death in an atmosphere of ozonised air and of ozonised oxygen; (4) ozone exercised a destructive action on the living animal tissues if brought into immediate contact with them, but it did not affect them so readily if they were covered by a layer of fluid; (5) ozone acted as an irritant to the mucous membrane of the nostrils and air-passages, as all observers had previously remarked. These effects the authors attributed partly to the fact that the density of ozone was slightly more than that of the carbonic acid of the blood, so that the diffusion of the gases in the air-cells of the lungs was retarded, and there was a consequent accumulation of carbonic acid in the blood. At the same time ozone had also a subtle effect on the blood which further experiments might discover. The authors exhibited the apparatus employed in the experiments, and showed how ozone could be readily produced. The apparatus consisted of arrangements by which a diffuse discharge of electricity from a powerful induction-coil could be sent through a stream of air or of oxygen passing through a glass tube, so that during the action of the coil ozone issued freely from the end of the tube.

A GOOD SUGGESTION.

Mr. John Little, Medical Officer of Health for the Whitechapel district, concludes his quarterly report ending September 29 last with the following practical suggestion:—

"If any alteration should be made in the constitution of the Metropolitan Board of Works, it would be desirable to add to its functions that of a sanitary supervision over the whole metropolis, with power to appoint a highly qualified medical officer of health, who, from his position, administrative talent, and scientific attainments, would command the respect of the metropolitan health officers, and who, in all cases of doubt or difficulty, might be consulted by them. A system of uniformity in all the reports of the medical officers of health should be adopted, and a copy of each report should be sent to the superintending medical officer, who should be required to make a digest of them for publication and general distribution."

THE CORPORATION OF DUBLIN AND THE LOCAL GOVERNMENT BOARD.

At a meeting of the Corporation of Dublin held on Monday, the 15th inst., Sir John Gray proposed that a petition should be addressed to the Local Government Board for Ireland, on behalf of the citizens of Dublin, relative to the pollution of some tributaries of the Vartry river close to the Roundwood Reservoir, in the County Wicklow. In the debate on the proposition, the following remarks, amongst others, were made:—

"Mr. Dennehy did not think the Local Government Board had any power to afford a remedy. An indictment in the Queen's Bench was, in his opinion, the proper means to adopt. As for the Local Government Act, there never was such a piece of bungling legislation since the Union, and he defied any lawyer to interpret it.

"Alderman Plunkett thought it a degrading thing to 'petition' the Local Government Board. Who were they at all?

"A Member: They are a queer lot. (Laughter.)

"Alderman Plunkett said the Corporation ought to 'require' the Local Government to do what was necessary, and not to 'petition' them.

"Sir J. Gray observed that, according to the language of the Act of Parliament, they must 'petition,' and if they adopted any other word instead of 'petition,' it would simply be a non-compliance with the Act of Parliament.

"The question was then put, and the resolution passed."

Did it ever occur to Alderman Plunkett that for him not to know the Chief Secretary for Ireland, the Marquis of Hartington, President of the Local Government Board; Sir Alfred Power, Vice-President; Mr. McDonnell and Mr. Bellow, the members of the Board,—did not detract from their position but merely argued himself unknown?

FROM ABROAD.—PROFESSOR LEIDESDORF ON SATURNINE EPILEPSY—PROFESSOR CROCQ ON CAPILLARY PUNCTURES IN GLANDULAR ABSCESSES.

In the number of the *Allgemeine Wiener Med. Zeitung* for November 4 there is a lecture delivered by Professor Max Leidesdorf upon "Saturnine Epilepsy," of which the following is a copious abstract:—

J. W., a journeyman house painter, twenty-five years of age, had a year ago an attack of lead-colic, and for some time has suffered from tremors of the limbs. A week before his admission into the hospital he had eight epileptic attacks one after the other, which left his mind in a very disturbed state. When admitted he refused to go to bed, tore his shirt off, and spoke disconnectedly. He was of a sallow, unhealthy aspect, the mucous membrane of the lips and throat being pale, and the gums discoloured. The upper and lower extremities trembled, and the extensors of the former were paralysed. The pupils were dilated; the tongue, though in a state of tremor, was straight, and speech was distinct. At the apex of the lungs bronchial respiration was heard, and the heart-sounds were accompanied by metallic tinkling. The pulse was small, and 74. The abdomen was inflated and sensitive, and the catheter had to be employed to relieve the distended bladder. The urine was alkaline, but not albuminous. The patient was for the most part unconscious, but at intervals he answered promptly the questions that were put to him. The general aspect left scarcely any doubt of its being an example of "saturnine encephalopathy." In the night of the third day after his admission the patient was seized with epileptic fits, which lasted five or six minutes, and recurred at short intervals. The pupils became much dilated, and were insensible to light. The fits continued to recur frequently, and the patient could not be roused out of his sopor. He died on the fifth day after admission. The diagnosis which had been made of anæmia and œdema of the brain and tubercle of the lungs was confirmed by the autopsy, performed twelve hours after death. The membranes of the brain were tense and thin, the convolutions were greatly flattened, and the substance of the organ was soft and devoid of blood, the ventricles containing half a drachm of clear serum. The lungs exhibited several cavities. Microscopic examination detected nothing abnormal in the brain or its membranes; but chemical analysis exhibited a small quantity of lead in the urine, as also of the sulphuret and the sulphate in the brain.

The diagnosis in this case was easily derived from the history of the patient, the appearance of the countenance and the mouth, and the characteristic paralysis of the extensors of the forearm; but in the absence of these data the case might easily have been mistaken for one of delirium tremens, on account of the presence of general tremor, the drunken-like unconsciousness, and the movements of the patient as if engaged in his occupation. The epileptic seizures, soon followed by coma, and apparently accompanied by amaurosis, might have been attributed to uræmia had not the quantity of urine secreted and its normal condition precluded any such idea.

As the psychical disturbance and epileptic attacks did not occur until a year after the lead-colic, they must be regarded as independent of it. According to the observations of Tanquerel and Desbois, saturnine encephalopathy may occur in individuals who have never before suffered from disease arising from lead, and Tanquerel reports six instances of this from among seventy-two cases of disease from lead. Saturnine epilepsy is therefore one of the special forms of disease produced by lead-poisoning. Tanquerel observes that in these cases there is no anatomical change produced in the brain, but that they belong to the class of cerebral neuroses generated by poisons Traube, having met with granular kidneys in two cases of saturnine epilepsy, started the hypothesis that the lead-poisoning gives rise to degeneration of the kidney and uræmia, whence proceed the epileptic seizures; and although Tanquerel expressly states that he has not found albumen in these cases, yet both Ollivier and Lancereaux relate cases of Bright's disease occurring in lead-poisoning. In order to decide the question, Dr. Rosenstein, of Gröningen, published in Virchow's *Archiv* for 1867 the account of his experiments on dogs. From these he comes to the conclusion that chronic lead-poisoning gives rise to neither albuminuria nor considerable anatomical changes in the kidney, and that life is often terminated by attacks of epilepsy which resemble uræmic convulsions, as in both amaurosis is present and diuresis is diminished by lead-poisoning. In animals so killed lead is detected in the brain. The diminished urine is concomitant, not causative. The substratum of the epileptic attacks is the anæmic condition of the brain.

Acute œdema of the brain was found by Rosenstein in two cases, but it was absent in two others; and Tanquerel reports that although it is a frequent it is not a constant appearance. When œdema is present it contributes to an increase of the anæmia, but it cannot be regarded as the cause of this. The mode in which anæmia of the brain is induced in lead-poisoning has not as yet been explained; but in face of Gusscrow's statements as to the considerable deposit of lead in the voluntary muscles, the influence it may also exert on the muscular fibres of the cerebral vessels may be worth consideration. According to the researches of Heubel, next to the liver and spleen, which serve for the expulsion of the lead from the economy, the brain and spinal cord are the organs in which relatively larger quantities of it are found, and it possesses a great affinity for the nervous substance in general. He is also of opinion that the chronic occurrences, such as headache, sleeplessness, stupor, melancholia, loss of memory, etc., may be due to the deposit of the lead in the brain, and that the acute symptoms arise from the cerebral œdema and the consequent anæmia.

Professor Crocq, of the University of Brussels, in a recent clinical lecture (reported in the *Presse Médicale Belge*, November 23) described the treatment which he has been in the habit of pursuing during the last ten years in suppurating glandular abscesses. Situated as these usually are in the neck, unsightly scars are often produced, even when they are treated as recommended by Velpeau—by a narrow puncture executed as soon as fluctuation is apparent, and repeated if necessary. Even this leaves a scar, which indeed may become very conspicuous when, as often happens, the little aperture ulcerates and becomes fistulous. Professor Crocq avoids these inconveniences in practising the puncture by means of a grooved exploratory needle or a fine exploratory trocar. Pressure is then made over the swelling so as to expel as much matter as possible. If the abscess is extensive, or the fluid does not issue freely, he makes two, three, four, or five punctures at different points, repeating them daily or every other day, either at the same or at other points. Sometimes it is sufficient to press the tumour somewhat firmly in order to secure the flow of the pus from one of the punctures already made. After some days the matter becomes less abundant and more serous, taking on a reddish tinge, which is a sign of an approaching cure. Sometimes there is now observed a more or less considerable soft and doughy swelling, which if punctured only yields a little blood and serosity. This swelling soon disappears, and the punctures, which at first remained as little reddish points, soon become pale, so that after the cure of the abscess no traces of them remain. This procedure is employed for acute abscesses as soon as fluctuation has become evident, and in chronic cases before thinning and detachment of the skin has occurred. But even when this condition exists it is not a contra-indication, care being taken, however, not to puncture the most thinned portions of the skin, in fear of subsequent ulceration. After the punctures these parts fall in and retract, a depression as from loss of substance resulting; but in general this usually disappears with the lapse of time. Even if it did not do so its aspect would be far less repulsive than that of a cicatrix due either to a natural or artificial solution of continuity. Professor Crocq has never found ulceration succeeding these punctures. He points out that his plan is different from those of Mr. Lawson Tait and Dr. Lorentzer, which combine the employment of aspiration with minute puncturing; and he prefers his own as more simple and more efficacious.

He has also employed the same procedure in opening suppurating bubo, avoiding thus the disagreeable scars that are usually left. Applied in good time, when the collection has well formed, and before the skin has become thinned or detached, it always succeeds, except in the case of "chancrous bubo," when the presence of a virulent pus necessarily leads to ulceration. In the great majority of cases the bubo is a simple inflammatory tumour.

Any subcutaneous abscess which is not of very large extent may be treated in the same manner. Thus M. Crocq has frequently met with great success in treating abscess consequent on erysipelas of the face, and especially in the abscesses consecutive to variola, of which he met with a great number of cases during the epidemic of 1865.

Several cases are given in illustration, for which we have not space.

THE Marylebone Vestry has awarded £50 to the assistant of the analyst of food for his services since the commencement of the Adulteration Act.

ACTION AT LAW FOR A DEATH FROM CHLOROFORM.—A Madame Caron some months since was taken by her husband to a dentist at Lille, to have a tooth drawn. Chloroform was administered in his presence, and his unfortunate wife died. The dentist was condemned by the Criminal Tribunal at Lille to a month's imprisonment and 500 francs fine for "homicide by imprudence." On appeal, the imprisonment was struck out of the sentence. Thereupon the husband, although he had completely authorised the use of the chloroform, brought a civil action for damages, demanding 20,000 francs in his own interest and that of a son, a minor. The Tribunal, considering the fact of homicide by imprudence having been established by the judgment of the criminal court, condemned the defendant to pay 4000 francs damages, 1000 to go to the husband and 3000 to be put out at interest for the son until he attained his majority.—*Union Méd.*, Dec. 11.

LETTERS FROM MADRAS.

No. VI.

Varicosity of Lymphatics: Chyluria; General Characters of Disease; Moral Aspect of the Patients—Crows and Bandicoots.

In the General Hospital there were some cases new altogether, and many more whose characters and the type of treatment required were of foreign aspect. Almost the first case shown me by Dr. Paul was one of varicosity of the lymphatics of the scrotum, attended with some slight enlargement of the glands in one groin. From time to time the scrotum swells and becomes painful, and the lymphatics on its surface stand out distended and shining. Then suppose them punctured on purpose, or that they give way of themselves at some point: there spouts out a clear stream of liquor sanguinis or lymph—a faintly pinkish-white fluid, which, when collected, coagulates, and becomes just as blood would, minus the red particles. The patient is a good deal exhausted by this daily drain. Varicosity of the lymphatics may be found in dropsy from heart disease; but here it is a local hypertrophy.

Side by side I may mention some cases of chylous urine, because it was suggested that this might depend on just such a state of the lymphatics of the kidneys, bursting and bleeding out their lymph into the urine. The urine, of a decidedly pinkish colour, coagulated into a mass of loose gelatinous consistence. But Dr. George Smith, under whose care the patients were, was led by experience to connect the attacks with a disordered state of the circulation in the abdominal viscera; for they were always aggravated by errors in diet. The experiment was tried of confining the patients to a milk diet, but neither in this nor in diabetes does an exclusive milk diet seem to answer here. The attacks of chylous urine were decidedly worse; and in diabetic cases it brought on symptoms of purpura. Search was made both in the urino and in the blood of these patients with chylous urine for the filaria which has been described as infesting the human blood in large numbers; but they have never been found here.

One thing which strikes a European visitor at first sight is the number of cases which have been treated by native remedies, most of which remedies, so far as I have seen, are either imbecile or cruel: the cruel predominate. There are compounds of irritating shrubs with milky juice with red pepper, and coarse preparations of copper and mercury, which are recklessly applied for abscesses, tumours, and rheumatism, to discuss the humours; and they are like some brushes which a Frenchman advertised for rheumatism—if they don't take away the pain, they do the skin. One man, for instance, was brought in with a slough over the sacrum, which had gone clean down to the bone. But this is nothing to the damage done to the eye by irritating compounds put into it, sometimes to rouse a patient from lethargy, or coma, or epilepsy, and sometimes to relieve diseases of the eye by extracting the tears, which is accomplished to perfection. One case I saw of the results of native treatment which was lamentable enough. A poor man had broken his thigh,—and, by some recondite sense of fitness, the persons who treat fractures are potters, who apply bamboo splints, and then plaster the limb with clay. The result in this case was gangrene of the lower leg, and the poor fellow was brought in with the tibia and fibula perfectly denuded of flesh, and the calf rotted away up nearly to the knee. The only thing that could be done was to amputate as near above the seat of fracture as the tissues were sound, and the poor fellow might have done well, but was carried off by tetanus a few days after the amputation.

The general characteristics of the cases to be seen here are the magnitude to which they attain, owing to the reluctance which the native inhabitants have to coming under European treatment, and the time wasted in native treatment. Tumours of such sizes, and strictures so complicated with fistulæ, are not to be seen in Europe. Then there must be noted the tolerant nervous system, so that a very small degree of "constitutional irritation" is produced even by such frightful conditions as the gangrene of the leg just described. In the next place, there is an exuberant tendency to tumours or morbid growths of all sorts, especially epithelioma of the mouth. The most prevalent diseases amongst the natives are phthisis and Bright's disease. This may perhaps stagger some of our brethren at home, who are in the habit of considering a warm climate—and most justly—as a panacea in pulmonary and renal disease, so I will take another opportunity of speaking more fully about it. But it is the *ensemble*, the moral aspect and character of the patients, which is stranger than their diseases to an European. Here is a man, a priest of some petty temple, with his forehead marked with the horizontal lines in white ashes which show that he is a worshipper of Shiva. He is carefully irrigating his knee, which is affected with synovitis from the presence of a guinea-worm just outside. And I may mention, in passing, that simple irrigation with cold water, effected by a skein of thread leading from a bottle by the bedside to a fold of linen on the diseased part is found a perfectly effective mode of quelling synovitis, which is very common. The poor man has a precious little parcel secured round his neck with a string; he begs to be excused from showing it, stating that it is his Swamy, or god. It is no doubt a small silver Lingam. Opposite to him is a poor fretful fellow, a Mohammedan, who is always complaining of his diet. He is treated with the greatest indulgence, and allowed to choose what he would like. So he chose chicken, which he has had for nineteen days running, but now discovers that he can't eat the chicken any longer, because he is afraid that the word *Bismillah* is not pronounced when the creature is killed. Near him there is a grand-looking fellow, a Jew who has come from Babylon, and been admitted here for strangulated inguinal hernia, which was operated on with entire success save that recovery was retarded by an abscess in the scrotum. He is now nearly well, and is pouring out in sonorous terms his thanks and blessings on his benefactors,—a grand old fellow, who might have served as a model for that sublimest of figures, Michael Angelo's Jeremiah in the Vatican. But this venerable personage absconded that evening. 'Tis a way they have; they would sooner go by a petty stratagem out at the back door than go out in the regular open way. Not that they are ungrateful, but tricky. Next comes to my mind an old man with an enormous scrotal tumour, probably weighing one-third of his whole body; he is in a wretchedly dilapidated state of health, with emaciation and diarrhœa, but is most eager to have the tumour removed, and threatens to go and drown himself if it is not done. In noticing the moral aspect of the wards it would not be fair to omit all notice of those most impudent and voracious crows who infest them, and who are always ready to pounce upon anything eatable, especially if the patient is weak and helpless. A native friend, pointing out their voracity, impudence, and insatiable restlessness, asks—If these are not the embodied souls of wicked men, what are they? We may ask the same about the horrible bandicoot rats that haunt the sewers, and creep up into the wards by night. These wretches are not nice at all in their feeding, and when the physician, in his morning visits, asks to see the phthisical sputa, he is not surprised to learn that the bandicoots have gobbled it up in the night.

CONTAGIOUS OPHTHALMIA.

On December 16, Mr. Brudenell Carter read a paper at the Conference of Chairmen and Vice-Chairmen of Boards of Guardians, "On Contagious Ophthalmia as Influenced by the Arrangements of Workhouses and Pauper Schools." He said the subject presented two aspects—the medical or surgical, and the administrative. Glancing briefly at the first of these, he dwelt on the contagiousness of the disease:—

"The contagious matter is the secretion of the membrane that lines the eyelids; and this secretion passes along the tear-passages into the nostrils, and is driven out with the expired air at every breath. Besides the chances of direct contact that must exist when a child with ophthalmia is in the same room, lavatory, or playground with others, the child with ophthalmia is perpetually sending into the atmosphere what I may describe as a spray of contagious particles. The period of contagiousness is often extremely protracted. Until the eyelids are quite well, they remain in a state in which any chance irritation, the entrance of a particle of dust, or of an insect, or even some temporary disturbance of the health, may reproduce a secretion of the most active character. At the various hospitals we constantly see children who have had the disease, on and off, so to speak, for long periods, and who have

been to a succession of public institutions, carrying infection with them." Mr. Carter quoted two cases in illustration of the obstinacy of the disease and the frequency of its recurrence. "My second proposition is that the magnitude of the evil is not so much to be measured by the original severity of individual cases in an outbreak, as by the actual number of the sufferers, and by the duration of the cases. Different outbreaks differ much in severity, and an outbreak in which there is a large percentage of loss of eyes during the early stages of the disease is calculated forcibly to impress the imagination, and to be regarded as a far more serious affair than an outbreak in which the immediate loss of eyes is comparatively small. But in a public institution, where all the cases are under observation from the beginning, the loss of an eye in the early stage should be an occurrence of extreme rarity. We have lately read, in a letter in the *Times*, that the loss of eyes was stopped in the Hanwell Schools, as soon as Mr. Bowman took the superintendence of the treatment; while it is also mentioned, as a comparatively small matter and seemingly as a curious fact in natural history, that 'the smouldering embers were ever there.' The writer of these words was probably not fully acquainted with the fact which it is my object now to state—namely, that the gravest results, in the aggregate, of contagious ophthalmia, are produced long after the acute stage has subsided, and are produced by the continuance of that smouldering which he describes. The ophthalmia leaves behind, when the acute stage is over, a chronic thickening or fleshiness of the lining of the eyelids; and, as an example is better than any amount of description, I have in attendance a little girl who shows this state extremely well. If you draw down her lower eyelids, you will see the thickening of which I speak. Now, this thickening seems a small matter; but it cannot be got rid of without months of exceedingly careful and well-directed treatment; and if it is not got rid of it may entail disastrous consequences. It is liable to undergo a very slow process of degeneration and contraction, by which the form of the eyelids is distorted and their inner surfaces are rendered hard and rough. The eyelids no longer fit the surface of the eye, and therefore they cease to wipe away the particles of dust which float in the atmosphere, and which are constantly deposited from it. Their internal surfaces become themselves sources of irritation, and their altered curvatures bend the eyelashes inwards and cause them to exercise friction upon the eyeball. These changes occur so slowly that many years may elapse before they are fully produced, and their connexion with the original ophthalmia may then easily be lost sight of. They are almost irremediable, because nothing can restore the natural shape, texture, and pliability of the lids, and because operations for altering the position of the eyelashes are often defeated by the continuance of the contraction, which in a few months may reproduce the deformity. The patients are, perhaps, more forlorn and to be pitied than any other class that fall under our notice. They are in a state of constant pain or uneasiness, tormented by every movement of their eyelids, tormented by every particle of dust which falls into their eyes, tormented by their eyelashes, tormented by constant overflow of tears, seldom with sufficient vision to follow any employment, dependent upon the rates or upon charity, half blind and wholly miserable. Such are the ultimate results produced by contagious ophthalmia, when the patients pass away from under treatment before they are completely cured. My third, and perhaps most important proposition, is that contagious ophthalmia is not an affection which can be introduced into, and propagated among, a community of healthy persons. If you take a drop of matter from an eye in the acute stage, and put it into a healthy eye, or if you expose the healthy eyes of a nurse to the manifold chances of direct contact, and to the concentrated atmospheric contagion, of a ward containing a number of infected children, some kind of inflammation will, no doubt, be produced. But before it can spread in the ordinary manner, contagious ophthalmia must find persons prepared for its reception by the existence of an antecedent morbid condition. This antecedent condition is not one of mere ill-health, or debility, either inherited or acquired; but it is something definite, manifested by the development, in the lining membrane of the eyelids, of certain little bodies which are not unlike grains of boiled sago, and which are commonly called after this resemblance. In technical nomenclature they are known as 'follicular granulations'; but to-day I will call them 'sago grains.' They are concealed by the eyelids when these are in their natural position; and when once ophthalmia is set up they are soon concealed altogether, by the swelling and the increased redness of the parts in which they are found. Here, again, example being better than description, I have a patient in attendance who has the 'sago grains,' but who has not yet suffered from ophthalmia. The very existence of these 'sago grains' remained unknown until the year 1848, when they were discovered by Dr. Löffler, the surgeon to a Prussian regiment employed against the Danes. Soldiers on active service have often suffered greatly from contagious ophthalmia, and it prevailed so much in the regiment in question that many men were disabled. Dr. Löffler, in order to treat every case at the very beginning, caused the whole regiment to be paraded daily for inspection, and he examined the inside of the eyelids of every man. In a large proportion of the apparently unaffected men he found these 'sago grains,' and at first he did not know what they were or what they signified; but after a while he found that the men who had sago grains were sooner or later attacked by ophthalmia, and that the men who had no sago grains remained exempt. The inquiry was next taken up, and diligently pursued in the British army, chiefly by Drs. Frank, Marston, and Welch. They confirmed the conclusions at which Dr. Löffler had arrived, and they established that the prevalence of the sago grains is the necessary antecedent of an epidemic of contagious ophthalmia. They furnish, to repeat a figurative expression I have already used, the soil in which the seeds of the disease germinate; and, if the soil is wanting, the seeds either remain quiescent, or, at most, produce disease of a comparatively harmless character. Drs. Frank, Marston, and Welch further established that, when a large number of persons are brought together in close aggregation, and are exposed to insanitary conditions of living, they become the subjects of these sago grains; so that the presence or absence of sago grains affords a delicate test of the sanitary state of a school, regiment, or any similar community. In a regiment the proneness to the development of sago grains is found to decrease as life advances—that is, to be much greater in young soldiers than in old ones; and, by a parity of reasoning, it is assumed to be greater in a community of children than in a community of adults. In any individual, and therefore in any community, the sago grains may disappear without producing mischief. But, as a matter of fact, sources of irritation to the eyes abound in the world, and when these sources of irritation act upon eyelids in which sago grains are already present, they often excite the contagious form of ophthalmia. It is therefore very rare for a community in which sago grains are prevalent to remain for any length of time free from an outbreak. The next step in the inquiry was to determine the nature of the sago grains; and this has been accomplished only within the last two years. Speaking broadly, they may be regarded as enlarged glands, and as bearing considerable analogy to the enlarged glands sometimes seen in feeble or scrofulous children. You know that glands are natural structures, which, in their healthy state, are not discoverable externally either by sight or touch, but which, in certain unhealthy conditions, become manifest as hard prominences on the sides of the neck and in other situations. When thus manifest, they may either remain passive, or, as it is said, indolent, and may after a time disappear by returning to their natural state, or they may undergo an unhealthy form of inflammation and become the seat of abscesses, which often give rise to unsightly scars. The case of the sago grains is almost precisely parallel, for just as a child will not have scrofulous abscesses in its neck unless glandular enlargement has first existed, so a child will not have contagious ophthalmia unless sago grains have first been developed in its eyelids. In this fact, therefore, we possess a clue to the prevention of the disease. When contagious ophthalmia has once taken root in an institution, it can only be got rid of by very troublesome and costly proceedings, which must be continued, as the experience of Hanwell and Anerley has shown, over long periods of time. I have discussed these proceedings at length in the St. George's Hospital Reports, and need not now refer to them. My object here is to show reason for the belief that the disease might, perhaps, be prevented and kept away by measures of a simple kind. At present, concerning the origin and causes of the sago grains, we know only what I have said already—namely, that they appear whenever a large number of people are placed together and are exposed to insanitary conditions of living, and that they are produced more readily in children than in adults. There is only too much evidence that insanitary conditions of living have prevailed—nay, that they still prevail—in many or even most of the establishments under the control of

the Local Government Board; and I think the main problems before us are to find out how it is that these conditions have been suffered to exist, and how they may most effectually be remedied. For my own part, I can explain their existence on no other ground than because there is no system of sanitary inspection for these establishments, as distinguished from general inspection; or, at least, no such system as they require. I assume that the Local Government Board, being charged with the duty of seeing that the Poor-law is applied in its integrity, is bound to employ a machinery of inspection for that purpose; and I presume it will be admitted on all hands that the Poor-law inspectors render most valuable assistance to boards of guardians, in respect of many portions of their responsible and arduous duties, especially in respect of questions of relief, of administration, and of the interpretation of the law. But boards of guardians are not concerned with these matters alone. They are also the directors of a great organisation for sanitary purposes, and my argument is that in this branch of their duties, also, they should be placed in close relation with the central authority by means of skilled inspectors, who would bring to the guardians themselves, and to their officials, the advantages, not only of careful supervision, but also of a wider experience than any which local authorities are themselves likely to possess." After referring at length to the case of Anerley, and contrasting the state of county pauper lunatic asylums with that of schools, Mr. Carter concluded: "I can entertain no doubt that, so long as efficient sanitary inspection of workhouses and schools is neglected, so long will these institutions yield a perpetually recurring crop of abuses; nor can I doubt that these abuses will be infinitely more costly, in sickness, in death, in blindness, in reputation, than the supervision by which they might be kept in check. If a man of Dr. Crichton Browne's position and attainments feels that an efficient medical inspection is a valuable aid to himself and to asylums generally, how much more would his words apply to institutions that are placed in many respects in a less advantageous position? It is implied, of course, in the term efficient inspection that the recommendations of the inspectors are to be carried into effect. There is one point more, and one only, to which I have to refer, and it is the possibility that the formation of sago grains may be due to a single cause among the many insanitary conditions by which the children at Anerley and other schools have been surrounded. The records of medical science are full of examples of diseases which, at one period, could only be explained by the use of a general phrase, but concerning which the evidence was at last narrowed down to some single detail. [Mr. Carter instanced Devonshire colic and scurvy.] Such an inquiry could not be conducted by novices or amateurs, but only by persons thoroughly skilled in investigations of the kind, who would go from institution to institution, and would ascertain all the points of difference, in respect of conditions of living, between the schools that suffer from ophthalmia, or in which the children have sago grains, and the schools that are exempt. Among the latter there are some where the managers attribute the exemption to the observance of some particular precaution, and it would be important to test the correctness of their opinions by the light of experience obtained elsewhere. In the words of my former paper on the subject, it might be that the persons who conducted such an inquiry would ascertain some simple factor of ophthalmia which might be easily and cheaply excluded. It might be that they would point out an effectual remedy which yet, by reason of the expense that it would entail, could hardly be preferred to a total change of system. It might be that they would say, 'These schools are wrong in principle, and must be abandoned.' But at any rate, they would learn and declare the truth; and for the prevention of ophthalmia, or of any other evil, knowledge of the truth is the first and most indispensable condition."

The Managers of the Edinburgh Infirmary on Monday resolved to refuse women students admittance to the operating theatre at the same time as the male students.

The deaths registered in London last week numbered 1759, showing an increase of sixty on the average numbers. There were 133 fatal cases of measles during the week, which exceeded the number returned in any week since the commencement of the present epidemic, and were ninety-one above the average.

REVIEWS.

Annali Clinici dello Ospedale dei Pellegrini di Napoli. Vol. II. Decembre, 1872. (Anno II., Fascicolo 5 e 6).

The volume before us, consisting of about 300 pages, contains a detailed account of all the cases of *wounds*—contused, punctured, and incised—admitted into the Hospital dei Pellegrini at Naples from July 1 to October 31, 1872. We shall pass over the cases of *contused* wounds as presenting nothing of special interest to the English surgeon, and speak only of the punctured and incised, which are very numerous, and remarkable for being in ninety-five cases out of ninety-six of a homicidal character—that is to say, stabs with a knife, dagger, or stiletto.

Stabbing is fortunately not a common crime in England, and it would probably be a long time before the experience of the surgeons of all our large London hospitals together would be equal to that of the surgeons of the Hospital dei Pellegrini in the short space of *four months*. Comparing the number of cases of stab taken in by University College in 1871, St. Bartholomew's in 1872, and St. Thomas's in 1872, as supplied by the Surgical Registrars' reports, we find *four* cases only for the three hospitals. The existence of this relatively enormous number of cases of stabbing at Naples is probably due to several causes: to the hot blood and hasty temper of the southern population; to a chronic state of weak and irresolute government under which the Neapolitans have until recently been living, and to the inefficiency of the police,—both causes likely to foster crime; and lastly, to the narrow, dark, and intricate streets, which allow of a ready escape to a murderer after striking his blow.

Of the ninety-five cases, the larger number were stabs of the chest and abdomen, but in several there were three or more wounds, and in one as many as nine. The histories are given in considerable detail, and arranged according to the region of the body in which the principal wound (if multiple) was inflicted; and there is a summary at the end of each division of the cases in it with remarks on any special points of interest in the injury or its treatment.

There were seven cases of stab of the head and face, all of which recovered. In one Stenon's duct was cut across, and salivary fistula resulted, which healed after repeated cauterisation with nitrate of silver. It was found that the *incised* wounds of this region in the majority of cases suppurated, and became complicated with erysipelas, even though the edges were brought together at once with twisted or interrupted sutures. There were seven punctured and incised wounds of the *neck*; two were fatal. One was a student aged 16, struck by a poniard at the upper third of the external border of the left sterno-mastoid muscle. The wound was four centimetres long, and one broad. The hæmorrhage was so great that the common carotid had to be ligatured. At the post-mortem the upper part of the internal carotid was found divided.

Another case died from pyæmia after ligature of the common carotid for a stab in the left parotid region, and very near the lobule of the left ear, extending to the left mastoid process, and cutting large vessels.

Ligature of the internal carotid was done in one case, which recovered, for a stab in the left side of the neck. One case of stab high up at the back of the neck showed an incomplete hemiplegia of the right side while the wound was in course of cicatrisation. Professor Riverso, the author of the report, remarks that wounds (stabs) of the neck are not only dangerous from the damage which may be done to the large vessels and nerve-trunks, as well as the trachea and œsophagus, but also from injury which may happen to the cervical aponeurosis, which extends to all the anterior region of the neck, and "gives it a certain resisting power, so that it maintains a kind of equilibrium in deep inspirations, and liberates the trachea from the powerful compression of the external atmosphere." Wounds of the neck (stabs), even if they do not penetrate the air-passages, may kill by suppuration in the connective tissue and infiltration of pus. Of the wounds of the *thorax*, eight penetrated into the cavity, and of these three patients died. There were twenty-six cases of non-penetrating wounds, all of which recovered. The wound was not probed or examined with the finger in any of these cases, but the probability of penetration or not was deduced from the size of the weapon in relation to the wound, the blood expectorated,

the direction and force of the blow (where ascertainable), and the presence or absence of emphysema. All wounds suspected to be penetrating were dressed with a view to their healing by first intention, and treated with absolute rest, with the thorax half-raised, and low diet, while snow(a) in small quantities was given with digitalis or opium internally, and bladders of snow applied locally for the first two or three days. The continuous application of bladders of snow to the chest was found most valuable in cases of laceration of the lung; but general bleeding was never, and leeches scarcely ever, used. It was found that the cases of wounds of the thorax without penetration were mostly slight, and the patients could leave the hospital in a week or ten days. Almost all the cases of stabs penetrating the thorax were complicated with wound of the lung, and Professor Riverso believes it to be rare for the lung to escape. He mentions one case in which a stab entering the pleural cavity at the fifth left intercostal space spared the lung, but a second blow penetrated the diaphragm and entered the stomach, and the patient died on the second day. In another case a man received four stabs with a poniard, one of which, striking the spine of the seventh dorsal vertebra, entered the cord, and produced paraplegia, with paralysis of the bladder and rectum, and death on the eighth day.

There were twenty-four cases of wound of the abdomen, *all penetrating*, and of these six died. The intestinal wound was found healed on the twelfth day in a fatal case where the gut was pierced and sewn up with its serous surfaces in contact in the usual way. Death arose from peritonitis, probably due to blood extravasated at the time of the injury. In a case that recovered, and in which omentum protruded, and there was a suspicion of wounded intestine, Professor di Sena, surgeon on duty, enlarged the opening in the abdominal wall, and drew out a loop of intestine which corresponded to the centre of the wound, but, finding it uninjured, he returned it with the omentum, and closed the wound with the twisted suture (*sutura incavigliata*). The patient left the hospital well on the twelfth day. There were seven cases of protrusion of omentum, in which Professor Riverso successfully used a method which he advocates strongly in such cases—namely, plugging the wound (*lo Zaffo*). The abdominal wounds in which he believes plugging to be indicated are, to use his own words, "those in which, through the oblique direction of the wounds, the omentum or loops of intestine protrude, and get strangulated between the fibres of the oblique muscles." Here the wound must be enlarged, and the cutaneous opening made to correspond with the muscular, and then plugged. The plug consists of clean lint spread with simple cerate (*compressa bucata spalmata di unguento cerato*). It must not be allowed to remain in the wound too long, but be removed after about twenty-four hours, and some less rigid and smaller body be substituted for it. In all cases absolute rest was ordered; the thighs were semiflexed on the pelvis, and bladders of snow applied to the abdomen, and snow given internally with opium, while food was given in a concentrated liquid form.

The cases of wounds of the pelvis were six in number. One of them died of peritonitis without wound of any viscus; the others all recovered under the same methods of treatment as used for the stabs of the abdomen. There were three cases of combined punctured and incised wounds of the arms, of which one died after wound of the brachial from septicæmia. The artery, which was wounded in the lower third of the left arm by a stiletto cut, was tied in the wound above and below, and the ligatures came away on the tenth day, but the man died on the twenty-second day with high fever and delirium. All the other cases of wound of the arm and leg, twelve in number, healed well, though some, which were treated in the hope of union by first intention, suppurated and healed by second intention, and one or two were complicated with erysipelas.

Professor Riverso makes a few remarks at the end of his report on gunshot wounds, several cases of which were in the hospital during this period. He recommends tar as of great value in flaccid and atonic wounds of this kind, for "it removes the incipient mortification of their surface, and sets up healthy granulation." "Large applications of unguentum hydrargyri gave rise in the majority of cases to resolution of traumatic inflammation complicating such wounds."

He warns against the too protracted application of ice to gunshot wounds, as it prevents the return of blood to the injured parts, and tends to accelerate gangrene.

(a) Snow, being more easily procured than ice, is in general use in Naples instead of the latter.

In conclusion we may state that this volume contains statistical tables of the number of in- and out-patients attending the hospital during the year 1872, and of the various fractures, dislocations, and wounds of all sorts treated during the months of May to August of the same year.

GENERAL CORRESPONDENCE.

THE HISTORY OF OVARIOTOMY.

LETTER FROM MR. L. BROWNE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am sorry to see that a very temperate refutation of Dr. Wynter's error in putting forward Mr. Spencer Wells as the solitary "reviver" of ovariotomy meets with such strong disapproval from you.

I have the very highest regard for Mr. Spencer Wells as a bold and most deservedly successful operator. There cannot, however, be the least doubt that to Dr. Clay, of Manchester, and to the late Mr. Baker Brown, the credit belongs of having placed the operation of ovariotomy on a sure foundation. I will, however, confine my remarks to Mr. Brown, and I trust that the following facts will sufficiently prove that "Baker Brown was not only Spencer Wells' predecessor and his contemporary in the operation, but to some extent his preceptor." Mr. Baker Brown first performed ovariotomy (having previously from so early a date as 1840 attempted many less radical measures with varying success) in 1851. His first three operations were unsuccessful. The subject of his fourth was his own sister, and success followed his boldness, the lady having since married, borne a large family, and being still alive.

It is quite true that Mr. Brown ceased to operate in 1856; but this abstention was not due in any degree to doubt on his part as to the value or justifiability of the procedure, but simply because he met with such determined opposition on the part of his colleagues at St. Mary's Hospital, one of whom indeed went so far as to threaten him with an inquest the next time a death followed an ovariotomy performed within the walls of that Hospital. It may be interesting to note *en passant* that this gentleman became afterwards an ardent ovariotomist, and succeeded in having a cottage built at the back of St. Mary's for the reception of patients who underwent ovariotomy.

It was in consequence of this opposition, joined with the conviction that the air of a general hospital is unfavourable to recovery after abdominal section, that Mr. Brown founded the London Surgical Home, and he immediately recommenced ovariotomy. The brilliant success that Mr. Brown attained with this operation in that institution (nineteen patients dying out of eighty-five operations) was due, first, to improved sanitary, hygienic, and nursing conditions; secondly, to the employment of the actual cautery. It is "a barefaced sacrifice of historical accuracy" to state that it was "not until after Spencer Wells' cases and papers had revived ovariotomy that Baker Brown began to operate again." Mr. Brown first operated at the London Surgical Home, October 20, 1858. At that time Mr. Wells had performed only two operations—one on February 19, 1858, and one on August 11, 1858. Mr. Wells did not publish any paper until February, 1859. Meantime, from October, 1858, to February, 1859, Mr. Brown had performed five operations, or fourteen in all. Mr. Wells' paper was based on the results of four cases. Further, Mr. Baker Brown was present at Mr. Wells' first operation, and, confining myself to the latter gentleman's own words, "afforded zealous assistance." There are eye-witnesses living who can testify to the value of this assistance. All who knew Mr. Brown would readily believe how zealous he would have been to encourage and assist a brother-surgeon.

But, granting that Mr. Brown was not the actual preceptor to some extent of Mr. Wells, the many accounts he had published of his previous efforts to establish the operation, and the frank manner in which he always discussed the causes of failure, must have taught Mr. Wells many valuable lessons. It is the pioneer of an operation who bears the brunt of the opposition. When Mr. Wells commenced to operate, the way was comparatively clear.

The successes of Dr. Thomas Keith in Edinburgh, of Dr. Tracy in Melbourne, and of many others, no more detract from the merit of Mr. Spencer Wells than do his magnificent achievements obscure the fact that Mr. Brown was, from the

earliest date of his career—even in his student days—an enthusiastic and consistent believer in the cure of ovarian dropsy by operation; and future historians will not be influenced in this matter by the erroneous statement of a clever popular essayist in a lay review. I am, &c.,

LENNOX BROWNE.

41, Welbeck-street, Cavendish-square, W., Dec. 9.

TYPHOID FEVER AT CAMBRIDGE.

LETTER FROM DR. FREDERICK J. LOWES.

[To the Editor of the Medical Times and Gazette.]

SIR,—As typhoid fever, which is now prevalent at Cambridge, is supposed by some people to depend on defective sanitary arrangements, and by others to be caused by impure milk, I should be rather inclined myself to attribute the origin of it to bad drainage, for exactly two years since several cases occurred amongst undergraduates who were down for the vacation.

I remember being requested to see a prizeman of his college, the name of whom I do not now remember. He was a fine young man aged 20, and had worked very hard the last term. His father told me that he thought he had caught cold on the ice with his brothers, but I immediately detected that he was suffering from typhoid fever, which turned out to be a very severe attack; and although he was going on favourably for some time, yet, owing to a little imprudence on his part, a relapse occurred, and after some days petechial spots were diffused over different parts of his body. He became comatose and died. During his illness a letter was sent to him, telling him that three other men from his college had been attacked at their respective homes, and two of them had died.

May not the same cause that produced the disease two years ago have been undiscovered and become the *materies morbi* of the present epidemic? I am, &c.,

FREDERICK J. LOWES, M.D.

72, Park-street, Grosvenor-square, Dec. 15.

"INERTIA" OR "ELASTICITY" AS THE CAUSE OF DICROTISM.

LETTER FROM MR. D. C. MCVAIL.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your columns of December 6 is a letter by Dr. Galabin, written to correct a statement by Mr. Mahomed in a previous number of your journal, in which that gentleman attributes the dicrotic wave to elastic recoil of the aortic wall. In his communication Dr. Galabin affirms that not the *elasticity* of the aortic wall, but its *inertia*, is the cause of the wave in question; and for his arguments in support of this position he refers to his article in the current number of the *Journal of Anatomy and Physiology*. I feel interested in this subject, as at the October meeting of the Medico-Chirurgical Society of Glasgow I read a paper on "Dicrotism," in which I advanced the theory that the dicrotism manifested by any particular part or segment of an artery is produced by elasticity in that very segment itself, as an after-effect of the passage through it of the great primary pulse-wave. The equilibrium of each particular segment being disturbed in succession from the heart outwards, each, ere again returning to equilibrium, passes through a vibratory phase, the agent immediately producing this vibration being the elasticity of the vessel-wall. Dr. Galabin combats the notion of elasticity, saying that the *inertia* of the aorta is the cause of the wave in question. It seems to me that an attempt at a hyper-metaphysical refinement of expression has led Dr. Galabin into an erroneous view of this matter. A tube of metal or of glass possesses inertia, and yet would give no secondary wave, and so it is absurd to say that it is the inertia, and not the elasticity of the vessel-wall, that produces the movement spoken of. The elastic tube of course has inertia—indeed, matter in any form without inertia is inconceivable; but it is the quality of elasticity over and above this inertia that is the cause of the recoil,—it is this *special* factor of the tube as distinguished from factors which the tube shares in common with all matter, to which the particular movement is due; and so the description of the wave as being caused by inertia, and not by elasticity, amounts to an obscuration, if not to a complete perversion of language. To what would Dr. Galabin ascribe the recoil of a billard-ball from the cushion—to inertia or to elasticity? If to the former, dried clay might be made use of for balls, and the provision of an indiarubber cushion would be unnecessary; for, let it be what it would, it and the clay balls would have inertia as truly as the indiarubber and ivory. In a note appended to his article in the *Journal of Anatomy and Physiology* in which he controverts Mr. Mahomed's view that the aortic elasticity is a sufficient explanation, Dr. Galabin says of the aorta, "its contraction is not an active proceeding"; and further on he says, "the mere fact that it contracts cannot at the same time be the cause of an increase of that pressure originating a second wave." Is it meant by this indirectly to convey the idea that the inertia is the active agent? Surely not; and yet, if not, the language is meaningless. Altogether, Dr. Galabin fails to establish his "inertia" theory, or in any way to shake the "elasticity" theory

I am, &c., D. C. MCVAIL, L.R.C.P. Edin.

96, New City-road, Glasgow.

CAPSICUM IN DELIRIUM TREMENS.

LETTER FROM MR. C. S. WILLS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following case may be interesting to your readers, as bearing additional evidence to the efficacy of large doses of capsicum in the treatment of delirium tremens:—

J. G., a warder in the Military Prison, had a violent attack of delirium tremens on the afternoon of August 6. When I say a *violent* attack, your readers will know what I mean without further description. His bowels being constipated, I ordered a brisk purgative at once, and sixty grains of chloral to be taken at 9.30 p.m. He continued delirious and outrageous all night, except from 10 till 10.30 p.m., when he appeared to sleep. I saw him at 8 a.m. on the 7th, when he had to be held down by two men. I then ordered him thirty grains of powdered capsicum, in bolus, every third hour. After the second dose he fell asleep and slept for five hours, and at my evening visit he was calm, but still raving, having taken sixty grains of capsicum. I ordered thirty grains more to be taken at 9 p.m., soon after taking which he fell asleep and slept about seven hours, waking perfectly conscious and quiet. From this date he had no recurrence of the delirium, and made a rapid recovery.

I am, &c.,

Barbadoes, September 28. C. S. WILLS.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 9.

Dr. C. J. B. WILLIAMS, F.R.S., President, in the Chair.

MR. TUFNELL read a paper on the Successful Treatment of Aneurism by Position and Restricted Diet, which was illustrated by cases, preparations, and drawings. The cases were—1. Aneurism of the abdominal aorta cured in thirty-seven days. The patient, a male, aged 31 years, was a shipwright by trade. Died from albuminuria five months after consolidation of the contents of the sac. 2. Aneurism of the abdomical aorta, cured in twenty-one days. The patient, a male, aged 78 years, was a pensioner from the army. Died three years subsequent to recovery, from old age and general decay. 3. Aneurism of the poplitcal artery, cured in twelve days. The patient, aged 37 years, was a trooper in the Royal Dragoons, and is still serving in that regiment.

Mr. T. HOLMES said few people could have long read the history of the surgical treatment of aneurism without seeing that many operations had been performed when the chances of success were desperate. Statistics were really useless, but they tended to show that the mortality was swelled by cases where there was no reasonable hope of success; often the operation had itself caused death by opening the sac, where the vessels were hopelessly diseased, or in anatomical conditions where recovery was impossible. If the cases had been duly selected, operations would have shown better results. If it were true that many cases could be cured by rest and diet, no doubt the statistics would be modified, and no doubt this was true of the subclavian and descending aorta. He had tried the plan and had been disappointed, having to deal with broken-down individuals, but Mr. Tufnell had now fourteen cases of external and internal aneurism so cured, and Luke's case had long been

before the world. He thought people should always study the behaviour of an aneurism under rest, for they often grew owing to exercise, and rest would tend to cure these. This was especially true of aneurisms near the heart. He was horrified at the rashness of sending down a pad on all the organs lying in front of the aorta till rest had been tried.

Mr. CALLENDER thought this plan compared favourably as regards results with either cutting or pressure. It was very definite, and necessitated selection and careful carrying out. He had tried it in one case, under the care of Dr. Andrews, in a woman aged 42. She was placed in position very carefully, and her food was regulated. She complained only of thirst. At the end of two months she was much better, the sac was thicker, and the pain was gone, when she insisted on going out. He thought the plan must be carried out in its integrity.

Dr. ANDREWS found it impossible to carry the cure out to the end, owing to the self-will of the patients and the impossibility of getting them to bear the want of food. He now had a case where the condition was greatly improved, but the patient was suddenly made to start, since which he had not been so well. He had seen an aneurism in an old gentleman cured by the method.

Mr. DURHAM thought Mr. Tufnell exceptionally fortunate. Had he not seen other cases where the plan failed? There was a certain number of all maladies which could be cured by rest, but a certain number of patients who could not or would not rest. A large number will be restless and call for relief, and insist on something being done. In one of his pressure cases low diet and rest had been kept up for a month before pressure was tried, and he attributed the subsequent fatal result to the patient being thereby reduced in bodily strength. He thought Mr. Holmes too severe on the subject of pressure. He had treated two thus, and one of the patients was now quite well and at work as a plasterer. In the other there was no compression of the duodenum or pancreas; but in another instance at Guy's there was, the pressure being too low down. It should be made as high up as possible.

Mr. HOLMES said he quite agreed with Mr. Durham that, if rest and dieting did not succeed, he would certainly try compression.

Mr. GANT asked under what conditions Mr. Tufnell would recommend the laying aside of rest for pressure. Recently he had had two good cases of popliteal aneurism cured by pressure.

Mr. SAVORY said that the series of cases recorded that evening seemed to show what could be done by rest. The great advantage of the plan seemed to him that it did not interfere with operation by ligature, which compression sometimes did. If one had a case of popliteal aneurism to deal with, he would place the patient at absolute rest, and make a careful examination day by day. If all went well, well; but if there was any increase, the question would arise, how long should he wait? No doubt surgeons operated in desperate cases, but there were also cases where they were bound to operate at once. There were aneurisms and aneurisms. The size, the shape, the relations, the thickness of the walls, all bore on the question of treatment. We were not yet in a position to determine all things satisfactorily, but we should try.

Dr. SIBSON said we might help the patient to rest by morphia subcutaneously. Rest and restriction of food as to bulk, to lower the force and fulness of the pulse, were what was required; but to diminish the quantity of food too much was to lessen the chance of consolidation.

Mr. BARWELL stated that Mr. Savory's opinion as to the compression being an obstacle to the use of the ligature was not held in Dublin. What was the origin of the renal disease in this case?

Mr. J. TUFNELL, in reply, said that he could not assign any definite cause for the renal disease. The diet was only restricted in quantity, not in quality. His cases were not selected, and his recoveries amounted to 90 per cent. He had had cases of men becoming discontented, and going out. Good compression did not, he thought, interfere with subsequent operation. The whole thing must be systematically done.

THE BISHOP OF WINCHESTER opened, on Saturday last, the chapel in connexion with the National Hospital for Consumption, at Ventnor, Isle of Wight. Amongst those present at the ceremony were the Right Hon. Sir Laurence Peel, A. Baillie Cochrane, Esq., M.P., Colonel Pratt, C.B., Colonel Hemell, etc. The building is capable of accommodating 200 persons.

OBITUARY.

WILLIAM AUGUSTUS HILLMAN, F.R.C.S.

Mr. HILLMAN, whose death occurred on the 11th inst., at 2, Argyle-street, Regent-street, was the elder son of the late William Hillman, a retired Surgeon of the Royal Navy. After receiving a sound general education at the school of what was then termed "The London University," and under private tutors, he matriculated as a medical student at University College in 1836, and became a Member of the College of Surgeons in 1841, very shortly after which (in the same year) he had the honour, after competitive examination, of being elected to a studentship in human and comparative anatomy of that College. He highly valued that position, and those who remember him there well know with what zeal and singleness of purpose he worked at the duties which devolved upon him; indeed, he held the appointment for three months longer than the stipulated period, being engaged with Mr. Stanley and Mr. (now Sir James) Paget in making the new catalogue of the pathological department of the museum, and at the termination of that time a very flattering report was sent up to the Council by the Museum Committee as to the way in which he had fulfilled the duties of the appointment. In April, 1845, he became a fellow (by examination) of his college, and in the December of that year he was elected Surgeon to the Farringdon General Dispensary, which office he resigned in consequence of being elected Assistant-Surgeon to the Westminster Hospital, in the medical school attached to which he became Lecturer on Physiology and General Anatomy, and continued the course for ten years. In 1869 he was elected without opposition one of the surgeons of the Westminster Hospital. He thus obtained one of the great objects of his ambition, and the fulfilment of one of his most cherished wishes. Unfortunately he was compelled by the state of his health to resign his appointment at the commencement of 1871, when he received both from the House Committee and from the General Board of the Hospital most gratifying expressions of regret at his forced retirement from his official duties. He had, in fact, long been suffering from some amount of dilatation of the heart; his health having been gradually undermined by the fatigue consequent upon his professional duties combined with that from long and unwearied devotion to his sick and suffering father. Under this constant strain his health broke down; his heart affection became more troublesome, and permanent congestion of the bases of the lungs supervened, so that for four years before his death he was never once able to lie down in bed or on a couch. Anasarca also came on, and though this was prevented from accumulating in consequence of eczematous ulcerations of the lower extremities, from which a constant discharge took place, the pain from these surfaces added at times greatly to his sufferings. During these years he was constantly attended by his friend Dr. Hare. Mr. Hillman was deeply attached to the surgical department of his profession and to the college of which he was a fellow. As an operator he was always ready for any emergency, but he was ever careful not to interfere with the knife unless such a procedure was clearly necessary. Above all, he was careful in the after-treatment of his cases, and always spoke in the strongest manner against any meddlesome interference with parts recently operated upon, which he constantly asserted to be the cause of fatal results in many cases which might otherwise do well.

Mr. Hillman died at the age of fifty-four, and was interred on Tuesday last in Highgate Cemetery. The chief characteristics of Mr. Hillman's mind were unflinching industry and perseverance. No man could have been more persevering and painstaking than himself. He was unquestionably a good surgeon, although, perhaps, not to be placed in the highest class of surgeons. He laboured at diagnosis, at demonstrations, and in surgical procedure. His name is not associated with any special improvements in surgery, but he published in 1846 the "Study of Physic and Surgery."

THE next meeting of the Society of Medical Officers of Health will be held on Saturday, December 20, at the Scottish Corporation Hall, Crane-court, Fleet-street, when J. Rawlings, Esq., of Hartlepool, Medical Officer of Health for Easington Rural Sanitary District, will read a paper on "The Sanitary Arrangements in the Durham Colliery District, and their Effects upon the Morality of the Population."

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent B.S. examination for honours :—

First Class.—Colgate, Henry, (Gold Medal), University College.
Second Class.—Skerritt, Edward Markham, B.A., University College; Lucas, Richard Clement, Guy's Hospital.
Third Class.—Barlow, Thomas, B.Sc., University College; Rayne, Charles Alfred, University College.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.—At the Michaelmas Term examination for the degree of Bachelor of Medicine, held on Thursday and Friday, December 4 and 5, the following candidates were successful :—

Barton, Samuel.		McBride, Robert.
Bluett, George.	Equal.	Moore, Henry Ogle.
Gwynne, Charles.		Hannan, Francis J.
McCarthy, Charles.		

The examination for the degrees of Master and Bachelor in Surgery took place on Monday and Tuesday, December 8 and 9, when the following passed :—

Stack, Theodore, scholar of Trinity College.	Barton, Samuel.
	Drapes, John B.

The names are arranged in the order of merit.

An examination for the diploma in State Medicine was held on Wednesday, Thursday, and Friday, December 9, 10, and 11, when Dr. Thomas W. Grimshaw obtained the diploma on very distinguished answering.

At the Winter Commencements, held in the Examination Hall, on Wednesday, December 17, the following degrees in Medicine and Surgery were conferred by the Right Hon. Sir Joseph Napier, Bart., Vice-Chancellor of the University :—

Baccalaurei in Medicinâ.

Barton, Samuel J.	Gwynne, Carolus Nelson.
Bluett, Georgius.	Hannan, Franciscus Johannes.
Greene, Johannes Josephus.	M'Bride, Robertus.

Magistri in Chirurgiâ.

Barton, Samuel J.	Drapes, Johannes Benward.

Doctores in Medicinâ.

Boileau, Johannes Petrus Hamilton.	Malony, Patricius Johannes.
Fitzgerald, Carolus Edvardus.	Smith, Gilbart.
Finny, Johannes Magee.	Wade, Arturus Law.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Fellows of the College on the 13th inst., viz. :—

Cameron, John, M.D. Glasg., 17, Rodney-street, Liverpool.
Turnbull, James Muter, M.D. Edin., 86, Rodney-street, Liverpool.

The following gentlemen were admitted Licentiates on the same day, viz. :—

Appleyard, John, 38, Harrington-street, N.W.
Bennett, William Henry, 33, Sloane-street, S.W.
Birch, Robert, King's College Hospital, W.C.
Colgate, Henry, 41, Albert-street, N.W.
Davies, Henry Naunton, Cymer, Pontypridd.
Ellis, Herbert Mackay, Chudleigh, Devonshire.
Hale, Charles Douglas Bowdich, 48, Westbourne-park-road, W.
Johnson, John James, Newcastle-on-Tyne.
Nicholson, Arthur, King's College Hospital, W.C.
Paul, Frank Thomas, Guy's Hospital, S.E.
Pilkington, William Binns, Crawshawbooth, Rawtenstall, Manchester.
Skerritt, Edward Markham, University Hospital, W.C.
Stericker, William, Victoria Park Hospital, E.
Syme, William Holland, 241, Kennington-road, S.E.
Thomas, George Tucker, 8, Ampton-place, W.C.
Wilkins, James Sutherland, Guy's Hospital, S.E.

The following candidate having passed in Medicine and Midwifery, will receive the College Licence on obtaining a qualification in Surgery recognised by this College :—

Fry, John Farrant, Guy's Hospital, S.E.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At examination meetings of the College held on Tuesday, Wednesday, and Thursday, December 9, 10, and 11, the following candidates obtained the licence to practise Medicine :—

Allen, Richard Maurice.	Redmond, John Joseph.
Finegan, John Stephen Francis.	Roberts, Arthur Milsom.
Fitzgerald, Joseph.	Ross, James.
Grier, Henry.	Shanahan, John Francis.
O'Farrell, Henry.	Sparrow, William Christopher.
Palmer, John Mansergh.	Turner, Herod.
Panter, James Robert.	Walker, Anster Fitzgerald.

The diploma in Midwifery was granted to—

Allen, Richard Maurice.	Ross, James.
Finegan, John Stephen Francis.	Shipsey, Edward Thomas.
Grier, Henry.	Sparrow, William Christopher.
Palmer, Joseph Mansergh.	

ROYAL COLLEGE OF SURGEONS.—The following Members of the College having undergone the necessary examinations for the Fellowship, were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and, at a meeting of the Council on the 12th inst., were admitted Fellows of the College, viz. :—

Franklin, George Cooper, L.R.C.P. Lond., City of London Hospital for Diseases of the Chest, Victoria-park, diploma of Membership dated November 15, 1870, student of St. Thomas's Hospital.
Penhall, John Thomas, L.S.A., Surgeon to the East Sussex Infirmary, St Leonards-on-Sea, April 23, 1855, of St. Thomas's Hospital.
Saunders, Henry William, M.B. Lond., Royal Free Hospital, April 20, 1869, of St. Thomas's Hospital.
Thomas, Andrew Appleby, L.R.C.P. Lond., her Majesty's Indian Army, July 21, 1869, of Guy's Hospital.
Woodman, Samuel, L.R.C.P. and L.S.A. Lond., Surgeon to the Ramsgate and St. Lawrence Royal Dispensary, Ramsgate, April 22, 1863, of St. Mary's Hospital.

Five candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months. The next half-yearly examination for the Fellowship will take place in May.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

MURRELL, C. F. F., M.B., M.R.C.S. Eng., L.S.A.—House-Surgeon to the Hospital, Great Yarmouth.

NETHERCLIFT, W. H., M.R.C.S., L.S.A.—Resident Medical Officer to the New Chelsea Workhouse Infirmary.

NAVAL APPOINTMENTS.

ADMIRALTY.—Dr. W. J. Rankin, Surgeon, to the *Malabar*; and John Allen, Surgeon (additional), to the *Aboukir*.

BIRTHS.

ARGLES.—On December 8, at Hermon Lodge, Wanstead, Essex, the wife of Frank Argles, M.R.C.P., M.R.C.S., of a daughter.

BLAKER.—On December 7, at The Grange, Robertsbridge, Sussex, the wife of Walter C. Blaker, M.R.C.S., of a daughter.

DONAHOO.—On December 7, at 129, Blackfriars-road, the wife of T. M. Donahoo, M.R.C.S. Eng., L.S.A., of a son.

GIRAUD.—On November 23, at Poona, the wife of Surgeon-Major Byng Thomas Giraud, M.D., of a son.

HARLEY.—On December 14, at 78, Upper Berkeley-street, Portman-square, W., the wife of John Harley, M.D., F.R.C.P., of a daughter.

WADE.—On November 21, at Sheffield, the wife of Nugent Wade, Surgeon Army Medical Department (late 75th Highlanders), of a daughter.

WATERS.—On December 11, at 41, Bloomsbury-square, W.C., the wife of John Waters, M.R.C.S. Eng., L.S.A., of a son.

MARRIAGES.

ATTHILL—PECK.—On December 10, at St. Faith's, Stoke Newington, Robert Chapman Atthill, L.R.C.P.E., L.S.A., of St. Osyth, Essex, to Sophia Jane, only daughter of Edward Peck, of Ipswich.

DUDDEN—SPENCER.—On December 10, at the parish church, Chippenham, Frederick Homes, second son of the late W. P. Dudden, Esq., of London, to Caroline Georgina, second daughter of Francis Spencer, Esq., F.R.C.S., of Chippenham, Wilts.

HOWLETT—O'DONNELL.—On October 16, at St. John's, Fauresmith, Orange Free State, South Africa, Sidney, second surviving son of the late Henry Howlett, M.R.C.S., of London, to Marianne Agatha, youngest daughter of the late Hugh O'Donnell, Esq.

JOHNSON—RAINES.—On December 16, at St. John's Church, Hull, C. Hargitt Johnson, M.R.C.S., 12, Albion-street, to Isabel, youngest daughter of the late Henry Raines, Esq., all of Hull.

MANSON—MCSWINEY.—On December 6, at Holy Trinity Church, Chesterfield, David Manson, M.A., M.D., of Chesterfield, son of Alexander Manson, Esq., of Kilblean, Aberdeenshire, to Mary Louisa, elder daughter of James Joseph McSwiney, Esq., of Gloucester-road, Regent's-park, London.

PATON—ALEXANDER.—On December 11, at 25, Elmbank-place, Glasgow, John Wilson Paton, M.D., Rock Ferry, Cheshire, son of Robert Paton, Esq., Ayr, to Janet Ann, daughter of John Alexander, Esq.

PURNELL—GELDARD.—On December 13, at Rathmell Church, Yorkshire, Edward Kelly Purnell, son of the late W. A. Purnell, Physician-General Bombay Army, and grandson of the late Lieutenant-Colonel Edward Kelly, formerly of the 1st Life Guards, to Elizabeth, eldest daughter of the late Christopher John Geldard, Esq., of Cappleside, in the county of York.

RICHARDSON—ADAMS.—On December 9, at St. Ann's Church, Dublin, Edward, eldest son of the late John Richardson, Esq., of Poplar Vale, County Monaghan, to Annie Charlotte, youngest daughter of Robert Adams, M.D., Surgeon to the Queen, 22, Stephen's-green North, Dublin.

TALBOT—HAYWARD.—On December 11, at Folkestone, Gilbert, eldest surviving son of the Rev. J. H. Talbot, rector of Newton Blossomville, Bucks, to Annie Ruth, eldest daughter of the late Henry Hayward, F.R.C.S., of Aylesbury, Bucks.

VERNON—WEBB.—On December 10, at St. Stephen's, Dulwich, Bowater John Vernon, F.R.C.S. Eng., L.R.C.P., of 44A, Wimpole-street, Cavendish-square, W., to Alice Marian, youngest daughter of the late Charles Webb, Esq., of High Grounds, Hertfordshire.

WARDROPER—HOLWAY.—On December 4, at St. Bride's Church, Liverpool, Walter Wardroper, third son of William Wardroper, M.R.C.S. Eng., F.S.A., to Emily, third daughter of William John Holway, Esq., of Taunton, Somerset.

DEATHS.

ANDERSON, MARY, widow of the late Dr. James Anderson, Inspector-General of Hospitals and Fleets, at 14, Elgin-road, Paddington, on December 11, aged 85.

BASAN, HORACE, L.R.C.P. Edin., L.F.P.S. Glasg., L.S.A., L.M., at 77, Welbeck-street, Cavendish-square, on December 9, aged 40.

BLACKETT, AGNES, wife of Edward Ralph Blackett, M.D., B.A., L.R.C.S.I., L.S.A., at Wangford, Suffolk, on December 11, aged 39.

BLACKMORE, SAMUEL, M.D., M.R.C.P. Lond., M.R.C.S. Eng., L.S.A., at his residence, 74, Pulteney-street, Bath, on December 14, aged 66.

BURT, GEORGE, F.R.C.S. Eng., formerly of Ely-place, at Wood-green, on December 14, in his 86th year.

ELAM, OLIVE MARGARET, infant daughter of Charles Elam, M.D., of 75, Harley-street, Cavendish-square, W., on December 8.

HILLMAN, WILLIAM AUGUSTUS, F.R.C.S. Eng., late Surgeon to the Westminster Hospital, at Argyle-street, Regent-street, W., on December 11, aged 54.

SKAIFE, JOHN, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., late of Northampton-square, London, second son of the late R. T. Skaife, surgeon, Easingwold, at Easingwold, Yorkshire, on December 12, aged 40.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. of Great Britain or Ireland. Applications, with testimonials, to the Chairman of the Medical Committee, Temple-row, Birmingham, on or before December 20.

BRISTOL ROYAL INFIRMARY.—Assistant House-Surgeon. Candidates must be F. or M.R.C.S., or M.S., and also possess medical qualifications.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CHELTENHAM GENERAL HOSPITAL AND DISPENSARY.—Junior House-Surgeon. Candidates must be qualified and registered. Applications, with testimonials, to the Secretary.

CITY OF LONDON LUNATIC ASYLUM, STONE, DARTFORD, KENT.—Assistant Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Committee of Visitors, under cover to Henry F. Youle, Clerk to the Committee, Guildhall, London, on or before January 15, 1874.

COTON-HILL INSTITUTION FOR THE INSANE.—Assistant Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Dr. Hewson, Coton-hill, Stafford.

GENERAL HOSPITAL, NOTTINGHAM.—Physician. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before March 10, 1874.

GERMAN HOSPITAL, DALSTON.—Honorary Medical Officer to the Eastern Dispensary. Candidates must be natives of Germany and be duly qualified. Applications, with testimonials, to Dr. Walbaum, Hon. Secretary, on or before December 29.

GODSTONE UNION.—Medical Officer for the Southern District. Candidates must be duly qualified and registered. Applications, with testimonials, to E. Alston, Clerk to the Guardians, East Grinstead, Sussex, on or before December 23.

HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.—Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to the Honorary Secretary, on or before January 15, 1874.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Assistant-Surgeons. Applications, with testimonials, to P. Goldschmidt, Esq., 100, Albert-square, Manchester.

QUEEN ADELAIDE'S DISPENSARY, POLLARD-ROW, BETHNAL-GREEN-ROAD.—House-Surgeon. Applications, with testimonials, to the Rev. Thomas Peckston, 260, Cambridge-road, E., on or before January 2, 1874.

RADCLIFFE INFIRMARY, OXFORD.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before January 10, 1874.

ROYAL LONDON OPHTHALMIC HOSPITAL.—Assistant House-Surgeon. Candidates must possess a knowledge of diseases of the eye. Applications, with testimonials, to the Secretary, on or before January 1, 1874.

ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Assistant-Secretary, on or before January 12, 1874.

ST. GEORGE'S (HANOVER-SQUARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before December 29.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to Dr. J. C. Hall, Hon. Sec., on or before December 24.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Senior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before January 1, 1874.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser. Applications, with testimonials, to the Honorary Secretary, Exe Villa, Tiverton, Devon.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WESTMINSTER HOSPITAL.—Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Each candidate must attend (with his testimonials) the House Committee on February 10, 1874.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Sudbury Union.—Mr. E. Andrews has resigned the Gestingthorpe District; area 2609; population 769; salary £10 10s. per annum.

APPOINTMENTS.

Carmarthen Union.—John A. J. Timmins, M.D., M.C., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., to the Llangenderne Upper District.

Chippenham Union.—Henry M. Jay, M.R.C.S. Eng., L.S.A. Lond., M.R.C.P. Edin., F.R.C.S. Edin., to the Pewsham District and the Workhouse.

Holsworthy Union.—Thos. L. Ash, M.R.C.S. Eng., L.S.A., L.R.C.P. Edin., to the Fourth District. Edward T. Pearce, L.R.C.P. Edin., L.F.P.&S. Glasg., to the Workhouse and the Third District.

Huddersfield Union.—Wm. Pinck, B.M. and M.C. Glasg., L.R.C.S. Edin., to the Fulstone District.

Keynsham Union.—John Moir, L.R.C.P. Edin., L.R.C.S. Edin., to the Keynsham District.

Pocklington Union.—Robt. E. Deane, L.R.C.P. Edin., L.S.A. Lond., to the Second District and the Workhouse. Frederick Wright, L.S.A., to the Bishop Wilton District.

Wycombe Union.—Wm. H. Hayden, M.R.C.S. Eng., L.S.A., to the Wooburn District.

INCREASED FEES.—At the last meeting of the Council of the College of Surgeons, Mr. Spencer Wells gave notice of a motion for discussion at the next meeting for the appointment of a committee to prepare a scale of fees for visits, consultations, operations, journeys, etc., for the guidance of the Fellows and Members of the College.

SCARLET FEVER is very prevalent at Lofthouse, near Wakefield, Carlton, and the neighbourhood.

A FRESH outbreak of typhoid fever is reported from Penwortham, near Preston.

FIVE out of ten cases of cholera in the 17th Foot, at Lucknow, have proved fatal.

MR. W. H. NETHERCLIFT has been appointed Medical Officer of Chelsea Workhouse Infirmary, at a salary of £250 a year.

THE Guardians of St. George's-in-the-East and of Mile-end Old Town have ordered prosecutions in cases of several persons in their districts, who, after notices had been served upon them by the vaccination officer, refused to have their children vaccinated.

WE are sorry to notice that there have been other deaths referable to the outbreak of typhoid fever at Cambridge. Mr. F. V. Simpkinson, of Caius College, died on the 15th instant, at North Creake, Devon, from typhoid fever; and Mr. A. D. Winslow died at Caius College, on December 8, of the same fever. Mr. Winslow is, we believe, a relative of Dr. Forbes Winslow.

THE third central conference of chairmen and vice-chairmen of boards of guardians from various counties in England and Wales was held on Tuesday at the Social Science Association, Adam-street, Adelphi, to discuss subjects connected with the administration of relief generally, and the public health in connexion therewith. Sir Baldwin Leighton, Bart., read a paper "On the Duties of Guardians in relation to the Public Health Act." In the discussion which followed, the difficulty of working the recent Act of Parliament was dwelt upon. Amongst the other subjects entered for discussion was "Contagious Ophthalmia, as Influenced by the Arrangements of Workhouse and Pauper Schools," by Mr. Brudenell Carter, Ophthalmic Surgeon to St. George's Hospital. An abstract of this paper will be found in another column.

NOTES, QUERIES, AND REPLIES.

"He that questioneth much shall learn much."—*Bacon.*

Iskender.—Pray let us see it.

Dr. David W. Cheever, Boston, U.S.A.—Enclosure received.

Deus Sap., Soho-square.—Mr. S. S. Savory has succeeded Mr. Hilton as a member of the Dental Board.

Juvenis, Guernsey.—As far as we can at present perceive, our correspondent acted with perfect propriety; and unless there be some special local Act compelling a medical practitioner to register a death *under any circumstances*, we consider the conduct of our correspondent was highly praiseworthy.

T. H., St. Bartholomew's.—The next primary and pass examinations for the diploma of Member of the College of Surgeons will take place on Saturday, the 10th, and Friday, the 16th, of January respectively. You can obtain the necessary blank forms on application to the Secretary.

Cuvier, Belgravia.—Mr. Kitchen Parker, F.R.S., who will deliver the next course of lectures on Comparative Anatomy at the Royal College of Surgeons in the temporary absence of Professor Flower, was recently admitted a Member of the College.

Effects of the Fog.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As people send accounts to the papers of strange matters simply to record them, I give to you a bit of curious experience. Here we have had—like the Londoners—three days of dense fog with frost. On one of these days I walked out with a friend, and had repeated small attacks of dyspnœa, each of which ended in the expectoration of ordinary mucus, mixed with a patch of black matter. The last fit occurred just as I reached home, and I took the opportunity of examining the stuff under the microscope. It consisted of mucus, coloured with amorphous matter of a deep brown colour—nothing like a granule being visible with a good half-inch object-glass—and of a quantity of blood-globules. The phenomenon ceased after I had returned to the house. The matter is only interesting in connexion with the illness from which certain cattle and (I understand) some individuals have suffered during a corresponding fog and frost in London.

Clifton, Bristol, December 15. I am, &c., Medicus.

A Pupil.—You are too late; the examination in Arts took place on Tuesday. The next recognised one will be that of the Apothecaries.

Argus, Norwich.—The person named is *not* a Fellow of the College of Surgeons. The title "Fellow-elect" is unknown.

L.D.S., R.C.S., and F.R.C.S., Great Yarmouth.—The person named is not a Licentiate in Dental Surgery of the College of Surgeons, neither can the name of the person giving him a testimouial be found in the list of the *Fellows* of that institution.

Odontologist and J. M.—Had the writers in the *British Journal of Dental Science* applied, as we have, to the Secretary of the College of Surgeons, they would have learnt that the diploma in dental surgery is not likely to be altered until the Conjoint Scheme has been adopted, when it is stated all the diplomas of the College will undergo a great alteration.

Political Doctors.—It is no discredit to our profession that during unsettled times of political parties, and when the fate of a Cabinet is uncertain, some of the most eminent and trusted physicians should be employed to sound the inclinations of politicians and to carry messages of conciliation between rivals. In the days of the Prince Regent, who trusted his physicians as a luxurious hypochondriac is wont to do, the Court physicians were pretty actively employed in political work. Sir Henry Halford was constantly employed in the vexatious and (as it now seems) tyrannical treatment of the Princess Charlotte, with reference to her governesses, household, and lovers. Baillie, Clive, and Keate sent in a "rouud robin" as to the necessity of change of air. How odd it seems in these days that the journey of a princess from London to Weymouth for the sake of health should be made a matter of State importance. The "round robin" in question got into the *Morning Chronicle*, and Dr. Baillie was employed to find out who sent it to the editor. The autobiography of Miss Knight tells all the histories of the intrigues of that day.

King's College Hospital.

The medical students of King's College gave a dramatic performance on Wednesday, the 10th inst., in aid of the Hospital Funds. In spite of the dense fog, the Bijou Theatre at Westbourne-grove was well filled, and we have reason to know the entertainment will result in a handsome offering to the Hospital funds. The pieces selected were "A Wilful Ward," "An Old Score," and "Briganzio the Brigand." They were admirably played by Messrs. Lavies, Willau, Bird, Sibbald, Griffiths, and others. The prologue, from the pen of a well-known member of our profession, was well spoken by Mr. Willans. It was full of fun and wit, as the following extract shows:—

"Prospectus is before me," he commences,
"Euclosed, a 'family' guinea towards expenses.
I like your notice,—largely advertise it;
I'll take the liberty to *criticise* it.

"You've acted wisely to seek, first of all,
The patronage of your good Principal.
(Printer, a *wag*, however,—see his spelling!—
He thought, no doubt, it would be far more telling
To treat our Cannon to an extra letter,
And make the entertainment 'go off' better.)

"Committee *next* in order—right again—
With mighty Nobles following in their train
(I hope you'll not appeal to *them* in vain);
Then in the list two Baronets we see,
Aud after them a talented M.P.

"Next come 'The Staff,'' adorned by Ladies fair;
Bells of *both* sexes we perceive are there.

"(Printer once more his waggery displays,
For after all the *B*'s he puts the 'Hayes,')
No matter, *such* a Staff must needs be good,
Composed, as 'tis, in part, of worthiest *Wood*.

"If more attraction 's needed, with 'a claw'
Cartwright appears, and *he* is sure to 'draw.'
And Playfair, whose renown doth daily grow,—
The Playfairs are *all* 'men of Letters' now!
One will, they say, a new 'crest' shortly boast,—
Lion, with upturned gamb (upon a Post),
A bag of guineas coming down to meet it,—
Motto, '*Consequitur quodcumque petit.*'

"Invidious 'twere, when *each* distinction claims,
To run the gauntlet of illustrious names.
But *this* I'll say—for 'tis my firm conviction
And, what is more, I *challenge* contradiction—
Your 'Staff' 'gainst any *other* may be matched,
Held by a Sheppard, newly (Colney) hatched.

"The pieces you have chosen are *first-rate*.
I only hope their *names* will not create
A fear you *men* may have imbibed a drop o' the
Puerile stream that's known as Homœopathy.

"For, *will full Wards* by *a* '*wilful Ward*' be improved?
An '*ancient debt*' by '*an old score*' removed?
And lastly, folks will ask, 'Can it be fitting
'To *heal wounds* by burlesques that are *side-splitting*?'

"Let them attack,—you must return their banter;
Pay in your coin—beat them in a canter
Similia similibus curantur."

Kahn's Museum.—Thanks to the Society for the Suppression of Vice, this notorious exhibition is closed. Some of the most disgusting preparations are still in possession of the police at Marlborough-street, and will be effectually destroyed.

Thomas Guy.—Yes; Vice-Admiral Sir Astley Cooper Key, C.B., who received his additional honours from her Majesty on Monday last, is a son of the late Mr. Charles Aston Key, of St. Helen's-place, Surgeon to Guy's Hospital, and formerly a member of the Council of the College of Surgeons.

J. M.—Consult the catalogue of Messrs. J. and A. Churchill. Perhaps you could not make a more interesting Christmas offering to your young country practitioner than the second edition of Dr. Fayrer's magnificent work on the Poisonous Snakes of India, interesting both to the naturalist and physiologist.

Dr. M.—The late Mr. William Augustus Hillman, F.R.C.S., was elected one of the students in human and comparative anatomy at the College of Surgeons in 1841. His colleagues holding a similar appointment were Professors Crozier (subsequently of the Queen's Indian Army), and Quekett (afterwards conservator of the Museum). Of the eighteen gentlemen who have held this appointment only eight survive, viz.:—Messrs. John Williams, F.R.C.S., E. C. Hulme, F.R.C.S., J. T. Arlidge, M.D., D. H. Monckton, M.D., F.R.C.S., John Falconer, H. V. Carter, J. L. Lizars, and H. R. Silvester. Mr. Hillman received his professional education at University College.

*** We republish from the pages of the *Edinburgh Medical Journal* the following speech by Professor Maclagan, the chairmau at the centenary of the Edinburgh Æsculapian Club. The speech is in itself delightful, and is a good example of the genial humour of the esteemed Professor; moreover it shows that the social qualities which so highly characterised "Auld Reekie" are not lost in the present generation. May the Æsculapian live and flourish another hundred years.

Æsculapians,—The toast that I have now to propose to you is to be regarded as the toast of the evening. It is to the health of our guests who have done us the honour to come here to celebrate the hundredth anniversary of the Æsculapian. We are met here as social men to enjoy social intercourse. We have surrounded our table with those who may be regarded as the representative men of the Scottish metropolis, and from their presence we may infer that the community which they represent is not out of sympathy with the aims and objects of the Æsculapian. To enjoy social festivity, however, something more is required than merely that the host should be hospitable, and the guest willing to be entertained. There must always be some reserve, possibly stiffness, where they do not know each other thoroughly, and are not acquainted with each other's personal and domestic history. We know our guests—they may know us individually—but I suspect many of them do not know us in our corporate capacity, and I therefore may be permitted to give them some account of the Æsculapian. I am enabled to do this by having had access to two most interesting volumes of Minutes, which, under an interchange of very formal documents, are deposited in the library of the Royal College of Physicians of Edinburgh. The Minute bearing date April 2, 1773, without any preamble, states briefly, and in a business-like style, the origin of the Æsculapian:—

"The Æsculapian Club was conceived in a happy moment, and in due time brought forth. Drs. Duncan and Hamilton, Messrs. Hay, Bell, M'Lure, and Dewar assisted at the birth on the first Friday of April, 1773. They also stood godfathers at the christening. The various rites and ceremonies usual on these occasions, such as eating a good supper, etc., were concluded with a bumper recommendatory of the Club to the peculiar care and patronage of Apollo (this is intelligible, because Apollo was the father of Æsculapius), Bacchus (this is intelligible, because it shows that the Æsculapians did not intend to sit dry-lipped), and Venus."

This rather formidable-looking dedication is explained by the Minutes, which show that it means that they were to meet upon Friday, *Die Veneris*.

They seem at first to have contemplated doing something towards the promotion of medical science, for in 1777 they proposed to institute a gold medal for the best essay on some scientific subject. They appear, however, to have very soon discovered that they had quite enough to do in taking charge of the social concerns of the Æsculapian, for they abandoned their idea of the prize medal in 1778. There appears to have been some diversity of opinion upon this subject, for Dr. Duncan wanted to resign the office of secretary. He did not do so, however; and we learn from the subsequent Minutes that he continued to act as secretary until

December 1, 1827. It is probable, I think, that this abandonment of the plan of giving a medal for the promotion of science led to the formation, in 1782, of another society—the Harveian—which is now approaching its centenary, and which continues still to give from time to time a prize for an essay upon some experimental subject.

Along with this Minute we have the list of original members of the Society. They are as follows:—Mr. William Chalmer, Mr. Andrew Wood—and here it is interesting to note how Æsculapianism runs in families, for we have his grandson, in the person of my friend Dr. Andrew Wood, to-night discharging the duties of croupier at our festival—Dr. James Lind, Dr. James Hamilton. Dr. Hamilton is well known to us by his *sobriquet* of "Cocky" Hamilton, as he continued, up to a period within the recollection of many of us, to wear the *chapeau à trois cornes*, the Court-cut coat, knee-breeches, and silk stockings, with his chubby hands exposed to the cold in the sharpest weather. Mr. Thomas Hay, who, my Lord Provost, afterwards became City Chamberlain, Mr. Benjamin Bell—here we have another example of Æsculapianism running in the blood; for we not only have the pleasure of seeing his namesake and grandson among us to-night as a respected Æsculapian, but we have the pleasure of receiving among our guests his great-grandson in the person of my friend Dr. Joseph Bell,—Mr. Forrest Dewar, Mr. Hamilton M'Lure, Mr. Colin Lauder, Mr. John Balfour, who was, I rather think, a member of the old family of Balfours, of Pilrig, and if so, was at least a collateral ancestor of our guest, Dr. G. W. Balfour, the editor of the *Edinburgh Medical Journal*. Dr. Nathan Spens: his face is known to most of us from a very admirable portrait of him in his capacity of an archer, by Raeburu, in the Hall of the Queen's Body Guard, and which is known to many more by the admirable engraving of it. Mr. Alexander Wood: This gentleman is better known to all of us by his designation of "Long Sandy Wood." It is interesting to us to bear in mind that he is the great-great-grandfather of the sons of the Right Honourable and learned Lord Justice-General, who sits on my left hand. Mr. Alexander Hamilton: This gentleman was afterwards Professor of Midwifery in the University of Edinburgh, and was the father of my former teacher, the late Professor Hamilton. Dr. James Hay: He afterwards became Sir James Hay, of King's Meadows, and was the ancestor of the present baronets of that title. Dr. John Hope, who was Professor of Botany in the University of Edinburgh, and father of my late instructor, Dr. Thomas Charles Hope, Professor of Chemistry. Mr. Thomas Wood, who was a brother of "Long Sandy," and, lastly, Dr. Andrew Duncan. Dr. Duncan many of us are old enough to remember. He retained his vigour and energy up to a very late period of his life, continuing to ascend Arthur's Seat upon May morning until he was nearly, if not actually, an octogenarian, cultivating his garden out in St. Leonard's with the motto *Hinc sanitas* upon the door; and many of us remember him going about the streets of Edinburgh as an old man, with, what my colleague the Professor of Botany would call, his specific character of an umbrella with a hooked ivory handle. Such were the original members of the Æsculapian. The remarkable characteristic of the Minutes is the constant recording of bets made among the members. These were always either in magnums of punch or magnums of claret, and the magnum of claret was also the maximum, for no higher bet was permitted to be taken. They were always even bets; on no occasion do I find odds given, except when in one instance Dr. Monro bets two melons to one. It is clear that these bets were essentially an ingenious device by which the fluids necessary for the consumption of the party were provided by individuals. In fact, I find that in 1790 Drs. Hamilton and Wardrop, without the formality of a bet, confess the loss of a magnum each *pro bono publico*. Everything and anything seems to have been enough to become the subject of a wager. Occasionally they indulged in a good-humoured way in discussions on politics. Thus, in 1782, we find a bet taken as to the chances of Lord North being out before the end of the session. Later in that same year, a bet is taken that Mr. Fox is to be out in a year; and we find subsequently discussions with regard to a person who is called Mr. William Pitt, Dr. Duncan offering to give claret if he is Premier in five years, Mr. Wood offering the same if he is not, and Mr. Benjamin Bell offering to give it for the national good whether Pitt is in or out. We thus see that this great surgeon, so distinguished by his surgical writings, was equally versed in therapeutics and hygiene, and saw the national importance of the Æsculapians getting their due supplies of claret. Passing events occasionally engaged them. Thus we have—of course again a bet of punch or claret—a wager that Lord Howe will have an engagement with the allied forces before his return home. This was in October, 1782, when Lord Howe sailed for the relief of Gibraltar, landed men, ammunition, and provisions, and offered battle to the allied fleets, which they refused, esteeming discretion the better part of valour. Among passing events we have one of a rather touching character. Dr. Duncan bets that Miss Kitty Morrison shall be married in twelve months to a friend whose name he whispers into the ear of Dr. Rutherford, the grandfather of our present Æsculapian, Dr. Daniel Rutherford Haldane. I regret that I have not been able to find any record of what became of Miss Kitty Morrison, whether she became a wife and a happy mother of children, or whether she spent the remainder of her days in single blessedness. It has just occurred to me that it might be possible to get some interesting information upon this point by referring it to my honourable and learned friend Lord Ardmillan, who might possibly be able to make out whether Miss Kitty was a sister or other relative of Mary Morrison, who has been made immortal by Burns in one of his sweetest songs. Professional questions, which are with us now *vetitum nefas*, occasionally make their appearance. Thus in 1790 some claret is staked upon this issue, that Mr. David Stewart's child, when it recovered from hydrocephalus, did not get any mercury; and for the settlement of this question reference is made to the books of Mr. Alexander Wood; and in another Minute we find Mr. Thomas Hay betting that he will produce certain very disagreeable effects within two hours upon any individual, by administering to him a drachm of ipecacuanha infused for twenty-four hours in one ounce of vinegar. Philology is not neglected. Thus we have a discussion upon the word "Bartisan," but all the information that we have with regard to it is that Dr. Hay produced a learned Greek work bearing on the subject. Ethics are also discussed, Mr. Alexander Wood staking a magnum of punch upon the thesis that a man most attentive to his own interests is the most generous man. How this was settled I do not know; but probably by seeing that his own interests in the matter of liquor were duly attended to, he may have found himself to be most generous to his brother Æsculapians. Literature also makes its appearance, Mr. M'Lure referring to the votes of the company the question, if the poet Burns is "superlative in his degree." If Mr. M'Lure, who seems to have supported the negative in this question, were alive now, I think he would find himself in a minority. They do not hesitate even to deal with questions of law. Thus we find—of course again under the sanction of a wager of claret—the statement made, that a card, though holograph, is not strictly binding in law; and the settlement of this question is referred to the Dean of Faculty. One grave omission I observe in the Minutes with regard to this, which is, that the Dean of Faculty does not appear to have been asked to dinner on the occasion of his delivering his opinion on the matter. I hope, however, that my learned friend, the present Dean, will understand that we have no intention to endeavour to extract from him any opinion upon this intricate subject, otherwise than in the regular way of memorial by the hands of an agent. There is a variety of subjects of wager which I can classify in no other way except as miscellaneous, of which I give only one example. Mr. Lauder pays a pint of claret for having a bigger belly than Mr. Hay. This seems to have been a sort of fine inflicted upon him for being *totus teres atque rotundus*. They do not scruple even to discuss questions of theology, for I find—of course again as the subject of a bet—a discussion as to the question, whether or not the whole tendency of Mr. Ritchie's sermon to the volunteers, on January 1, 1796, is to support the doctrine of predestination, and this is referred to Dr. Moodie and other divines. The great subject of bets, however, in almost every Minute, is their matches at golf. This seems to have been the great athletic exercise of the Æsculapians, sometimes in twosome, sometimes in foursome matches; and we have records of not merely who lost or won, but occasionally of the number of strokes played in each match, four rounds of Leith links being in general the extent of their golf competitions. And in reference to this I have to note a curious feature in these old Æsculapians. They had from time to time what they call a Gymnastic Convention, when they met to compete for prizes in various athletic exercises, chiefly golf, bowls, and swimming. A number of them were members of the Royal Company of Archers, and were prize-winners there; and I am happy to think that the practice of drawing the long-bow in the field is not extinct among Æsculapians, for my brother Æsculapian, Dr. Dunsmure, now present, is at this moment the holder of the much-coveted prize of the silver arrow given by the city of Edinburgh. The records of these gymnastic feats consist in the medals appended to the three silver cups which are before me on the table. Many of these are very interesting, merely as recording the date upon which well-known individuals joined in these gymnastic competitions. Some of them are in English, many of them in Latin. I quote only one example of the latter. It bears this inscription, that *Gulielmus Cheyne, inter natandi studioso e conspectu quidem telluris pontum pectore pulsans, victor renavit*. This idea of a doctor swimming out of sight of land, like a sea-going steamer, appears to us rather a strong statement in these modern days; but what the medal does not tell, tradition explains, and we are told that on the occasion in question, when the party had met for their swimming competition, there was, *horresco referens*, a deeided "easterly haar"; that Dr. Cheyne was the only man who ventured into the water; that he soon lost sight both of land and of his companions, and, speedily returning, claimed and obtained the prize. They seem not to have been contented, however, merely with their gymnastic conventions and their social meetings, for once or twice they gave evening parties for the benefit of their wives and families. Thus, in 1791, we have it stated in the Minutes that there was to be a "Grand Corruscation" or oyster-party, and we have not only the fact recorded, but we have the names of the gentlemen and their partners who formed the assemblage. These are mere samples of what is contained in the Æsculapian Minutes, and I have confined my remarks to the earlier periods, not wishing to occupy your time by tracing them on to the period of our own existence.

I have looked back at the history of the Æsculapian from its beginning. May I be permitted to look forward? I am led to indulge in a little bit of fancy from seeing present among our guests the great-grandson of one of the original founders—Dr. Joseph Bell; and I am led to think of some little Bells in a house in the west end of the town, who I hope at this hour of the evening are sleeping the sleep of innocence in their respective cribs, but who probably a few hours ago were chiming out peals of merry infantile laughter in a certain nursery in Melville-street; and it seems to me possible that some one of these,—still very young

Porrigens teneras manus,
Dulce rideat ad patrem,
Semihiante labello—

may, in 1973, looking back to a long and honourable line of Æsculapian ancestors, be called upon to preside at the second centenary of the Æsculapians when the gravestone of your present chairman is moss-green and weather-beaten. The Æsculapian may perish—like all other human institutions, *absit omen*, it may decay; but though it perishes, its principles will remain, for they are immortal. Viewed apart from the social entertainments, which are merely accessories, the principles of the Æsculapian are neither more nor less than these: to promote in our own circle, and, so far as our example goes, beyond our circle, peace on earth, by cultivating goodwill between man and man. It may be said that, after all, our meeting is merely a piece of epicureanism, and that we are merely men engaged in an arduous profession, who like to meet together from time to time and enjoy our meat and wine and social chat, to exclude from our minds those carks and cares which are inseparable from every arduous profession. I do not mean to say that even upon this very low ground the Æsculapian is not defensible. Men who are engaged in any anxious profession, be they doctors or lawyers, or what not, are fairly entitled to refresh their minds from time to time by changing the currents of their thoughts, just as they are entitled, at their holiday season, to change the air that they breathe, and so refresh their bodies. But Æsculapianism means something better. If we do not know it from our own experience, we have it told us by the highest of all teachers, that "it must needs be that offences come;" and the object of Æsculapianism is not merely to prevent offences from growing, but by clearing the ground properly to prevent them from ever germinating; and if I wished to express truly the basis upon which Æsculapianism rests, I would be content to rest it upon this one short but pregnant sentence of the great apostle to the Hebrews, "Let brotherly love continue."

Æsculapians, these remarks, addressed to the company generally, have been only introductory to the toast, which I now more especially address to you, of "Our Guests." We drink to them collectively. We know them individually; and I ask you, on looking round at those who surround our table, whether it was a rash statement that I made in the outset of these remarks, that we had with us to-night the representative men of the Scottish metropolis. We have present among us divines whom we always gladly welcome to any of our social meetings; we have the brave defenders of our country; we have men learned in science belonging to this and other Universities; we have the majesty of the law represented in those potent, grave, and reverend seigniors, whom we are always so glad to meet in their social capacity, and whom we all earnestly eschew in the discharge of their official functions; we have art represented by the genial President of the Royal Scottish Academy; and we have literature with us, not merely

medical literature, in the person of the Editor of the *Edinburgh Medical Journal*, but general literature as represented by Dr. John Brown, or rather I should say by Rab among his Friends. We should be glad to hear one and all of these individuals in replying to this toast; but the timepiece behind me warns me that the hours are fast passing away, and that I have consumed an inordinate amount of their constituent minutes. I shall, therefore, connect this toast with the health of one who is well entitled to be the representative of the representatives. To you it is unnecessary that I should say anything with regard to the Lord Justice-General, for you all know him as well as I do. You have all marked his brilliant career at the bar, his important and useful work in Parliament, the benefit of which I, in common with all other Professors of Scottish Universities, am now enjoying. You have marked the dignity and ability with which he discharges his high official duties, and I ask you, therefore, to connect his name with this toast. Rise, then, Æsculapians, show that our hearts are warm and our lungs sound, by a hearty cheer to The Guests of the Æsculapian. *Nunc est bibendum.*

An Old Member, Epsom.—In February last Mr. Hancock delivered the Hunterian Oration, which is now given *biennially*; consequently there will be no Oration next February.

J. C., St. Bartholomew's.—The "singularly happy and striking likeness" of the late Mr. F. C. Skey, alluded to in the Reports of your hospital, forms one of the admirable series published by Mr. Stone, of the College of Surgeons.

Murphy Secundus.—There is an old proverb that a warm October predicts a cold February, and—

"If there's ice in November that will bear a duck,
There'll be nothing after but sludge and muck."

COMMUNICATIONS have been received from—

Dr. Sparks, London; Mr. Ingpen, London; Dr. McVail, London; Dr. Pitman, London; Juvenus; Mr. C. Heath, London; Mr. Leonard Rudd, London; The Rev. C. Hillman, London; Mr. H. W. Verdon, London; Mr. Brudenell Carter, London; Dr. Lowes, London; Mr. Barraclough, Catford-bridge; Dr. Peacock, London; Mr. J. Chatto, London; Dr. B. W. Richardson, London; Mr. William Rose, London; Mr. T. M. Stone, London; Dr. Balthazar Foster, Birmingham; Mr. J. Howell Thomas, Bristol.

APPOINTMENTS FOR THE WEEK.

December 20. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

22. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Dr. Farquharson, "Cases of Infectious Tonsillitis." Dr. Pearson (communicated by Dr. Farquharson), "An Epidemic of Sore Throat with marked Constitutional Symptoms." Dr. Dowse, "On Cerebro-spinal Meningitis, with Clinical Records." Mr. Nelson Hardy, "A Specimen (living) of Persistent Papillary Membrane."

23. *Tuesday.*

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 30·42 in. The lowest was 30·38 in. at the beginning of the week and on Tuesday morning, and the highest 30·48 in. on Friday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL COMMUNICATIONS.

ON THE BENEFICIAL INFLUENCE OF SEA VOYAGES IN SOME FORMS OF DISEASE.(a)

By THOMAS B. PEACOCK, M.D.,
Physician to St. Thomas's Hospital, etc.

(*Concluded from page* 689.)

The beneficial influence of a sea voyage in the treatment of disease may be ascribed to the peculiarities of the marine climate, to the constant movement of the ship and the free exposure to the air, and to the entire change of scene and habit.

There does not appear to be any very marked difference between the atmosphere at sea and on land, so far as the proportion of the chemical constituents—the oxygen, nitrogen, and carbonic acid—is concerned. The air is, however, very moist, and the vapour contains the constituents of sea-water, and the inhalation of these must affect the system. The chief peculiarities, however, of the marine atmosphere are the purity of the air and the equability of the temperature. In the ocean there must be an entire absence of all animal and vegetable emanations which can generate disease; and from the currents excited by any change of specific gravity resulting from increased warmth, evaporation, or other cause, the temperature of the water, and consequently of the air above it, is kept remarkably equable—so that there is but little difference between the temperature of the day and night and of the different seasons and regions. The heat of the day and of the warmer climates is lessened, and that of the night and colder regions raised. Indeed, if we except the narrower and smaller seas—such as the Mediterranean, and the limited belt of the Atlantic which intervenes between the north-east and south-east trades to which the term of "horse latitudes" is given, and in which there is a constant succession of calms and squalls, with heavy rain and great heat,—the heat at sea is never very great. I have myself noted a temperature of 76° Fahr. in the south-east trade, with a vertical sun, at midday. We all of us also know how remarkably our own climate, and that of north-western Europe generally, is mitigated by the currents flowing from the tropical seas. The effect of this remarkable equability of climate at sea is to enable an invalid to be in the open air for a larger portion of the twenty-four hours, without the risk of taking cold on the one hand, or of suffering from exposure to the sun on the other, than he would possibly be if on shore in the same latitude.

In the higher latitudes, however, and in the smaller seas, where greater extremes of temperature obtain, care must be exercised to prevent the invalid suffering either from the cold or too great heat, and the time of taking the voyages should be regulated so as to avoid the extremes. The Cape of Good Hope and Cape Horn, if possible, should be passed during the summer, when the weather is warmer and there is less likelihood of storms occurring. I have known patients who had been to Australia or New Zealand, and had greatly benefited by the outward voyage, suffer very much on their return round the Horn and lose all the benefit which they had received, and reach home in a worse state than when they left. So, also, the Mediterranean is much too hot during the summer for a health-voyage. On a recent trip we had a strong south-east wind, or sirocco, all the way from Gibraltar to beyond Malta, and the heat and dampness were far from pleasant, and could not but have been injurious to an invalid.

Another peculiarity which has been considered to conduce to the restorative effect of a sea voyage is the constant motion of the ship; and that this is influential is shown by the effect produced on the peristaltic action of the alimentary canal. Constipation is very generally experienced at sea; and this, too, entirely independently of the diet, and when there is an ample supply of fresh meat, vegetables, and fruit, and it is doubtless due in part to the motion of the vessel. The free exposure to the air, and the constant though imperceptible change, must also conduce to health; and it is, indeed, an important element in the beneficial influence produced by a sea voyage. Were it not for this, the mildness and dampness of the atmosphere would be very relaxing; whereas it is a matter of universal experience that a moderately bracing effect is produced, so that the appetite at sea is increased, and digestion and assimilation assisted.

Much, however, of the advantage derived from a sea voyage results from the rest and absence of excitement, the entire change of scene, and the regularity of all habits,—the times of rising, taking food, and retiring to rest. These are specially useful to persons suffering from general and local debility the result of overwork of body and mind, and which, indeed, often depends upon the artificial habits of modern society, and the neglect—wilful or unavoidable—of proper precautions for the preservation of health. It is also quite possible that the little inconveniences which almost necessarily attend, more or less, a sea voyage may not be without their advantages by increasing the contrast with the habits of home life. The exchange of our sombre and misty skies for a bright and clear atmosphere must also exercise a beneficial influence. The effect of the climatic conditions which I have named must be to excite the functional activity of the skin, to lessen the irritability of the bronchial mucous membrane and lungs, and to increase the appetite and promote healthy digestion and assimilation; while the moral influences tend to remove the weariness and gloomy forebodings which almost necessarily attend prolonged illness, and encourage a cheerful and hopeful state of mind,—all of which are eminently conducive to the restoration of health.

In considering the desirability of sending a patient to sea, there are various circumstances that must be taken into account. In the first place, the inclinations of the patient must be ascertained. It is useless to recommend a course of treatment which is distasteful to him, when there are other plans which offer equal—or nearly equal—advantages. Ability to bear the fatigue and privation which may have to be experienced must also be considered; and especially it must be ascertained whether the patient is a good sailor, and not likely to suffer severely from sea-sickness. I have already said that to most persons this is not of much moment. Few suffer for more than a few hours or a day or two, unless the weather is exceptionally bad. In a steam-vessel a voyage to the South takes the traveller into comparatively quiet latitudes in three or four days, and even in a good sailing-vessel similar progress is made in about a week or ten days—after which the vessel will run into 30° or 40° of south latitude without any trying weather; and then the invalid is generally sufficiently habituated to the motion of the vessel to bear some additional movement without suffering. Some persons, however, seem to be quite incapable of becoming acclimatised. We are all familiar with the case of our great admiral, who never went to sea, after being some time on shore, without being more or less sea-sick. I have been told by the captain of one of the mail-steamers between Hull and Gottenburg, that when his ship had been laid up for two or three months during winter, the first voyage always affected him more or less; and in crossing the Atlantic I sat at the same table with a stout, strong, and healthy-looking man, who told me that he had been in the regular practice of visiting Europe at least once every year, and sometimes twice, for fifteen years, yet he was seldom able to leave his cabin if the sea was at all rough, and, I think, never remained at table in the calmest weather till a meal was finished. For persons so susceptible as this, a sea voyage as the means of restoring health is clearly inapplicable.

It is essential, if a long sea voyage be decided upon, that it should be undertaken in a good and well-found ship, and it would be better that it should be a vessel not carrying emigrants or many passengers, and that the invalid should have a cabin to himself. It is impossible that much benefit can be derived from the voyage unless the traveller has a sufficient amount of good wholesome food, and sleeps in a roomy, well-ventilated cabin.

The time of commencing the voyage is also important. He should leave home at the end of August or early in September, so as to get out of the Channel before the equinoctial gales set in, and be able to pass the Cape of Good Hope in advanced spring or summer. Much, also, will depend upon his habits on shipboard. He should rise early, so as to enjoy the exquisite freshness of the morning. After being on deck for a time, he should have a bath, and then dress for breakfast. In the forenoon he will do well to devote some time to some regular pursuit. It is quite true that laborious study is almost impossible on shipboard, but by steady resolution much work can be got through, and the regular habit of devoting a

(a) Read before the Hunterian Society on Tuesday, November 13.

portion of the day in that way will lessen the tedium which otherwise is apt to be felt during a long sea voyage. Especially I would recommend the traveller to take an interest in the shipping matters—to note the course of the vessel, the daily run, and the peculiarities of the winds, etc. He will find charts and books on board relating to these matters, and the study of them will form a very pleasant occupation.

After lunch, if he take that meal, he will do well, especially in warm latitudes, to lie down and rest till shortly before dinner, after which, and for the remainder of the day, he can remain on deck. Nothing can exceed the delightfulness of the evenings at sea in the tropics, with the fresh air, the clear skies, and the brilliancy of the stars and moonlight; and there is not the danger of suffering from the evening air which is so common in warm climates on shore. The patient may remain on deck till his cabin is cool, and he can retire to bed with the prospect of refreshing sleep. I have often heard a sea voyage objected to as being too sedentary; but this is incorrect. In a large vessel an ample amount of exercise can be taken, and there is something in the motion of the ship which seems to promote the tendency to walk.

The clothing must also be considered: it must be sufficient to keep the patient warm, but not so heavy as to promote perspiration; and in all latitudes some slow conducting material—silk or woollen—should be worn next the skin; and the latter, in consequence of its absorbent properties, should be preferred in warm climates.

As to diet, the invalid should content himself with plain but nutritious food. He does not need much stimulant, and will do well to limit himself to a little bitter ale or some light French wine. I should also recommend him not to smoke; or, at least, to indulge very sparingly in that special temptation of sea life.

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, etc., etc.

(*Continued from page* 577.)

Case 11.—James C., aged 33, a farmer, living on McCullum's Creek, nearly four miles from Talbot, was on November 27, 1869, bitten twice on the left hand by a very savage large brown snake (diemenia superciliaris), five feet long, whilst endeavouring to kill it. Blood issued freely from the four punctures. The man began to suck the parts, and his wife within a few minutes tied a ligature firmly round the wrist. This was about nine o'clock; and having drank about two wineglassfuls of brandy, he started to walk to Dr. Dowling's house. He afterwards said that he had felt all right until he got to the upper end of the township, and then noticed that the houses seemed running about and getting upside down; soon drowsiness came on, with a feeling of nausea and faintness, oppression about the chest, and increasing difficulty in walking—to use his own words, he felt "fast going." He had two more glasses of brandy before Dr. Dowling saw him, which was at twenty minutes past eleven. Dr. Dowling proceeds to say:—"The left hand was only very partially strangulated by the ligature. The man appeared anxious and distressed, and, without adequate obvious pain, was unable to keep still; the breathing was irregular and distressed; pupils rather contracted; pulse 60, small and feeble; surface cold and clammy. He complained of nausea, giddiness, and faintness, with drowsiness, and a sensation (to use his own words) 'as if I was going.' Soon general clonic muscular spasms set in, just short of convulsions. It was now half-past eleven, when I laid bare the median basilic vein in the right arm, and gently injected twenty minims of ammonia solution, strength two-thirds strongest liq. ammoniæ, specific gravity 880, to one-third water. Almost immediately he looked relieved, and said he felt better. In about ten minutes I injected another similar quantity. Within two minutes after this he looked up naturally and brightly, like one aroused and refreshed from a sleep, and said, 'I feel all right now.' The restlessness and the muscular spasms were gone, and the countenance had lost its deadly pallor, and the pulse was stronger. I now let him lie down, and kept talking to him. Soon I noticed a restless movement of the limbs, which gradually increased to periodic clonic spasms, and these soon became a general and pretty constant convulsion. The pulse began to get more feeble, and he appeared to have a vacant look, although he kept saying he was all right. At half-past twelve I injected another similar quantity into the same vein, and almost instantaneously the vacant look disappeared and the convulsions subsided into a more gentle spasm. He said, 'I am awake now, but how long have I slept?—why did you let me go to sleep?' and got up from where he was lying to go to another spot. I now gave him half a drachm of liq. ammoniæ in half a tumbler of water to drink. The muscular spasms were now pretty frequent, but (to use his own expression) were 'getting weaker.' To ease himself, and because he found the spasms less troublesome when moving, I let him walk about with a man at his side, and he continued so doing until half-past three o'clock, when all spasms had left him. He now said he felt all right, and so he looked. Pulse 82, natural and good. By my wish, but against his own inclination, he took a basin of soup, the first food since his seven o'clock breakfast. At 6 p.m. I removed the ligature, and at 7.30 p.m., having smoked a pipe, he began to feel worse again, and as I was not directly at hand, the bystanders gave him about two ounces of brandy, which temporarily seemed to relieve the faintness that was stealing over him. At ten o'clock I saw him. He complained of sickness and a drowsy sensation, and the muscular spasms had again become nearly incessant. I now laid bare the median cephalic vein in the left arm, and injected twenty minims of a stronger solution of ammonia (liq. ammoniæ fort. ℥xv., aquæ ℥v.). Hardly any perceptible effect was produced, so after waiting twenty minutes I injected another twenty minims, and in a few minutes he said he felt better, breathing freely and looking cheerfully around; the spasms getting less and less. After this no further active treatment was required." Dr. Dowling adds that there were four punctures, indicating two separate bites. This case is interesting in showing how frequently the ammonia may have to be repeated, and also how a return of the bad symptoms may be brought about by loosening the ligature. It is this which makes the application of a ligature an uncertain proceeding, for if it be sufficiently tight to prevent circulation, a time comes when it must be loosened, and then absorption of any poisoning about the wound occurs, and the symptoms become as dangerous as if no ligature had ever been applied. An eye-witness to the treatment of this case thus writes:—"When I went to see the man, I was quite sceptical of the ammoniacal injection; but its action is so startling, I may say so magical, that if a man on seeing it could not be convinced, he must be singularly constituted indeed."

Case 12.—A middle-aged woman was bitten on the morning of November 20, 1869, at Jarraville, Gipps Land. Soon after she became sick and vomited. When seen by Dr. Eccles she was cold, pulseless, insensible, and apparently on the point of dying. Dr. Eccles injected fifteen minims of liq. ammoniæ fort. in one drachm and a half of water, and the pulse immediately became perceptible, and consciousness returned in twenty minutes. After this she was allowed to sleep, and upon waking was quite well. Dr. Eccles states—"I am fully convinced that had it not been for the injection of the ammonia the case would have terminated fatally."

Case 13.—A woman having been bitten, ammonia was injected, both into a vein and also subcutaneously, by Drs. Cooke and Hutchinson. This had the effect of rousing her, but the subcutaneous injection produced afterwards very ugly sores. The case was also complicated with the administration of brandy and ammonia internally.

Case 14.—About 1 p.m. on December 24, 1869, Mrs. D., in crossing a log fence at Redesdale, noticed a brown snake coiled round her foot. She fell down, and on getting up saw the snake escaping. She noticed a spot of blood upon her stocking. Having taken during the afternoon two glasses of brandy, and rubbed ammonia and iodine on the wound, she was brought at 6 p.m. to the Hospital at Kyneton, under the charge of Dr. Langford. At this time the only symptom was drowsiness, but, as this seemed to increase up till midnight, brandy was occasionally given—in all about four ounces. But she became worse; could not be kept awake without shaking; the pupils got dilated, and the extremities cold and clammy. Having consulted with Dr. Geary, Dr. Langford injected twelve minims of liq. ammon. fort., diluted with twice as much water, into a vein of the forearm. The patient roused at once, and said, "I do not feel a bit sleepy now." In a few seconds the veins of her forehead became distended, she broke out into a perspiration, and complained of headache and burning hands; she retched a little, but soon said she felt quite

well, and, in fact, walked up and down the ward without help. In the morning she took her breakfast, and returned to her home.

This case fell under the care of the same medical practitioner that treated her little boy (Case 8) twenty-seven hours after the bite, and failed to produce any good effect by injecting ammonia. Dr. Langford has since assured me of his great delight at the instantaneous effect of the treatment in this case, and of his thorough reliance upon it. He says—"Having used the injection three times in the boy without effect, I used it in this case with the full expectation of failure, and was never more surprised than when I saw my collapsed patient rise up and walk away."

Case 15.—A boy aged 12 was bitten at Devil's Creek, and, after having had the parts freely excised and brandy given pretty frequently, became in an hour's time comatose and totally helpless; the countenance pale, the eyes fixed and glassy, and the pulse scarcely perceptible. After waiting an hour and a half, and still giving brandy and ammonia, six drops of liq. ammon. fort. with two drachms of water were injected into a vein of the forearm by Dr. Walpole. Consciousness at once returned, the pulse became good, and recovery soon after followed.

Case 16.—A man was bitten by a snake at 12.30 p.m.; at 4.30 p.m. he reached Colac in a perfectly comatose and apparently dying state. The pupils were widely dilated and fixed, and the surface of the body and extremities cold. Dr. Rae injected ammonia of gradually increasing strength into a vein in each arm until as much as one drachm and a half of liq. ammon. fort. had been used. Improvement followed each injection; the pulse and breathing were well restored; the jaw, which had fallen, drew up; the pupils responded to the stimulus of light; consciousness returned; and, to the surprise of everybody present, the man walked away unassisted two hours after his arrival.

Case 17.—A woman was bitten at Bambra, and soon after became drowsy and helpless. On arriving at Winchelsea, a distance of fourteen miles, she was completely comatose. The pupils were fixed and widely dilated. Dr. Meyler injected ten minims of liq. ammon. fort. mixed with fifty of water into the cephalic vein. During the operation she was quite insensible. Before half a minute had elapsed she roused up into consciousness, the pulse became fuller, and the temperature of the body sensibly increased. In a quarter of an hour she began to eat bread and butter, and from that time rapidly recovered. Dr. Meyler concludes by stating—"The treatment of this case was not only decidedly successful, but exceeded my most sanguine hopes, and finally removed any lurking doubts that may have lingered in my mind as to the value of this mode of treatment."

Case 18.—A woman was bitten between 9 and 10 a.m. at Tumbacumba, New South Wales. Ammonia was injected beneath the skin, but by 5.30 p.m. she had become quite helpless, pale, and nearly insensible. Twelve minims of liq. ammon. fort. mixed with twenty-four of water were injected into a vein of the arm. It had almost an instantaneous and magical effect. Consciousness returned, the muscular power was restored, and she became cheerful. This did not last long; she became as bad as ever. The injection was twice repeated; each time she improved, and after the last rapidly got well. She had no recollection of anything having happened after the stupor first set in. I may remark that for the particulars of this case I am indebted to Mr. R. D. Matthews. It was his syringe and ammonia that were used, and although he is not a medical practitioner, I feel his account is thoroughly reliable. A remark is made in this case about the forgetfulness of everything that happened after a certain time. If I have not mentioned this peculiarity in the other cases, I may at once state that it is a usual accompaniment of the stupor of snake-poisoning.

Case 19.—A child, seven years old, was supposed to have been bitten by a snake in the morning. No particular symptoms occurred till 7.30 p.m. He was then seen by Drs. Bennett and Keating, and was pale, cold, and clammy, the pupils widely dilated, very drowsy, but easily aroused, and able to answer questions sensibly. Liq. ammon. was injected into the median basilic vein. The child rallied, and was put to bed quite easy and comfortable; pulse 90, skin warm, and the pupils natural. When seen by Dr. Bennett the next morning, the neck, cheeks, and tongue appeared swollen. At 1 p.m. he refused to swallow, the pupils were again widely dilated, the extremities cold, pulse 130, and drowsiness constant. Injections into the vein were now made four times at intervals of a quarter of an hour each. The child improved very much; his colour returned, he could drink easily, the pupils were less dilated, he became quite sensible, now and again talking voluntarily to his mother. Drs. Bennett and Keating left perfectly satisfied with the progress of the case, but on returning soon after 10.30 found him greatly changed; pulse 160, very weak. "I wished," says Dr. Bennett, "to inject again, but the mother would not allow it, and I have only to regret that I did not enforce it." Soon afterwards the child died.

It is interesting to note the similarity of the symptoms in this case and that of the little boy (Case 8). In both cases there was no certainty of a snake having caused the symptoms, but I agree with Drs. Langford and Bennett, that there can be little doubt that these were cases of snake-poisoning. I would further remark that, taking the symptoms of this case in their insidiously progressive character, they may be looked upon as a very dangerous type. The widely dilated pupil, with only a little drowsiness, intellect unimpaired, but after some hours stiffness of the neck, although not apparently so formidable as the helpless stupor in other cases, are in reality fraught with the greatest danger. They are, moreover, as will be seen further on (Case 22), so likely to lull the fears of the medical practitioner—to put him off his guard, as it were, rather than to look forward to a fatal termination. Of the treatment of this case nothing could have been more reassuring. I will not say that fuller doses of the ammonia at the last might have saved the child; Dr. Bennett evidently regrets not having insisted on a further injection. I will only remark that the poor mother acted probably as most parents would have done—let her child die in peace rather than suffer its last moments to be disturbed by another injection. Alas! surgeons know too well that yielding to the feelings of nature will not always do, that to the last our duty must be done, and that when we give way to other influences we have too often to regret it.

Case 20.—On November 1, 1870, at half-past one in the afternoon, a boy, aged 11 years, the son of Mr. Patrick G., was bitten just above the ankle by a snake. The punctures of the fangs were distinctly visible, and blood was flowing from them. A ligature was applied, and about half a tumbler of strong spirits was given in two doses. The symptoms increasing in severity, a piece of skin was taken from over one of the most prominent veins of the bend of the elbow, the point of the syringe carefully introduced into the vein, and ten minims of prepared ammonia injected. The relief was almost instantaneous. Some time after, the foot having become painful below the ligature, this was removed, and soon the worst symptoms of snake-poisoning returned—viz., total loss of power over the limbs, cold, clammy skin, breathing almost imperceptible, and all that could be felt of the pulse was an occasional fluttering. Ten more minims were injected into the same vein. In two minutes the pulse could be again detected, a decided improvement set in, and by seven o'clock the same evening the boy was well, laughing as heartily as anyone could wish.

This case illustrates again the inconvenience of the ligature, for when it was removed absorption of fresh poison evidently occurred, needing a further injection of the ammonia. It is also another instance of the remedy having been used in the absence of a medical practitioner. My informant, Mr. Stevenson, was evidently by his letters to me both well educated and well informed in matters of general science.

Case 21.—The following case I transcribe literally from a letter to me from James Jackson, M.D. Lond., Assistant Colonial Surgeon of South Australia. Dr. Jackson had previously seen me experimenting on dogs when I first began seeking for remedies, and had he not left Melbourne for the appointment he now holds I feel convinced I should have derived great benefit from his suggestions and assistance. However, it will be seen that, just as on the earliest symptoms appearing I injected my dogs, so did he his patient, and with exactly similar results. I cannot too strongly recommend the details of this case, uncomplicated as they are by any other mode of treatment, to the attention of the reader.

"To Professor Halford.—My dear Sir,—I beg to furnish you with the following brief notes of a case of snake-bite which was treated by me at McDonnel Bay on December 23 last (1870):—

"I had just driven into the yard of Lodie's Hotel, when I was summoned to see the servant, who, while hanging out the clothes among the rushes, had been bitten by a large brown snake (diemenia superciliosa) on the back of the hand about

ten minutes before. I found the woman in a state of extreme agitation, declaring that she had been bitten by a snake about four feet long; and on carefully examining the back of the hand, I found a wound such as would be produced by the bite of a snake.

"I immediately excised the bitten portion, including a piece of skin about the size of a sixpence. I sucked the wound, and then washed it with a strong solution of ammonia.

"The patient was then placed in the recumbent position, and still remained very much agitated, though up to this time there were no special symptoms of snake-poisoning. I determined, therefore, to wait for symptoms. In about twenty minutes nausea was complained of, with a feeling of internal distress at the epigastrium, followed by violent and persistent retching. I now considered my patient under the influence of the poison, and determined to lose no time in injecting the ammonia. I accordingly opened the median cephalic vein, and injected fifteen minims of the ammoniacal solution. The vomiting ceased immediately, and the woman expressed herself as being very much relieved. In about half an hour the retching returned, as violent and persistent as before; another fifteen minims were injected, which again gave immediate relief. For three-quarters of an hour the patient lay on the sofa quite comfortable, at the end of which time the vomiting again returned. For the third time I injected fifteen minims of ammonia, when the vomiting ceased as suddenly as before. I remained with the patient for half an hour after the third injection, and was then obliged to embark for Adelaide.

"I left the patient in the hands of Dr. Cotter, of McDonnel Bay, who throughout gave me valuable assistance. This gentleman found it necessary to repeat the ammoniacal injection twice more, after which the woman gradually recovered, and is now in the enjoyment of perfect health."

I will only add to this most valuable account that from what we now know of the impunity with which ammonia may be thrown into the circulation, it is most probable that had larger doses been used the injection would not have been required so repeatedly.

"TOOTH-EDGED CUTTING SCISSORS."

By C. F. MAUNDER, F.R.C.S.,
Surgeon to the London Hospital.

To-day I happened to be in the shop of Messrs. Krohne and Sesemann, and was shown Dr. Richardson's new invention. I had arranged to operate on a case of internal hæmorrhoids in the afternoon, and determined to try the instrument. The case was a typical and uncomplicated one of internal piles, which I proposed to ligature. Having seized one hæmorrhoid, I proceeded to sever with the scissors the mucous membrane at its junction with the skin at the base of the pile, in order to form a groove for the ligature to lie in. This instrument effected my object most readily, and *without bleeding*, the structure divided requiring perhaps two applications of the toothed scissors where one of the common scissors suffices. My colleague Mr. McCarthy, and Mr. R. Kershaw, late House-Surgeon of the London Hospital, who assisted me, noted the absence of bleeding. Five hæmorrhoidal tumours were thus treated.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

RHINOPLASTIC OPERATION.

(Under the care of Professor JOHN WOOD, F.R.S.)

For the notes of the following case we are indebted to Mr. William Rose, Surgical Registrar:—

J. P., aged 23, was admitted May 28, 1873, with destruction of the entire nose, the result of lupoid ulceration.

Six years ago ulceration of the soft palate set in, which was arrested by nitrate of silver. A year after this a fresh patch of ulceration appeared on the left nostril, which in spite of treatment spread to the right side. This was attended with little pain. Soon after he was taken into the Bristol Infirmary, where chloride of zinc was applied with some success. The ulcerative process had, however, entirely destroyed the alæ, and small portions of necrosed bone were repeatedly coming away from the interior. The septum at that time was unaffected. After the lapse of one year from his discharge from the Infirmary, there was a recurrence of the ulceration in the skin over the bridge of the nose, between the eyes, which extended deeply very fast. The septum then necrosed and was removed. No history of syphilis; no family history of importance; father, mother, and sisters alive and healthy. The patient is of a strumous habit, and is a native of South Wales. The whole of the nose has disappeared; skin, cartilage, and the following bony structures—the nasal bones and the lachrymal, the nasal process of the superior maxilla, the lower turbinated, the vomer, and the whole of the ethmoid with the exception of the cribriform plate,—so that a chasm is left extending back to the muscles of the soft palate, which can be seen in action during deglutition. All sense of smell is lost. The interior of this cavity is covered by a scab, on removing which an irregular suppurating surface is brought into view. The lower opening of the lachrymal duct is visible on either wall. On the upper lip a little to the left is a white cicatrix, the result of some of the previous ulceration.

June 7.—Chloroform was administered, and Mr. Wood performed the first operation, which consisted in making a columna for the new nose, and also in bringing the cheeks closer together, and thus diminishing the size of the opening. (The integument of the cheeks and forehead is fortunately very lax in this patient.) Two vertical cuts were made through the upper lip, so as to leave a central piece free, about five-eighths of an inch broad: this was turned up. The lateral portions of the upper lip were then brought together by harelip-pins. The upturned portion of the lip was then split from below upwards, so as to make the mucous and cutaneous surfaces continuous and facing inwards, the raw surface looking outwards. Then, having dissected up the cheeks from their deep attachments on either side for a distance of about an inch and a quarter, and having pared their edges at the lower part, Mr. Wood easily brought them together in the median line across the lower part of the chasm in such a way that their deep raw surfaces should be in contact with the raw surface of the upturned flap. The parts were held in position by wire sutures, and tension was taken off the flaps by a stout harelip-pin, which transfixed both cheeks.

11th.—Pins removed from upper lip. Perfect union has taken place. Flaps look healthy and are also uniting.

16th.—The cheek-flaps have firmly united in the median line. Pin transfixing them removed.

23rd.—Mr. Wood has inserted below the edge of the united cheek-flaps two small rolls of adhesive plaster, one on each side of the base of the upturned flap from the lip, so as to form openings for the future nostrils. A slightly projecting incisor tooth has been removed. There has been some œdema about the lower lid of the right eye, but it has now disappeared. Since the operation the patient has regained to some extent the power of smell.

July 2.—Two portions of skin about half an inch square from the newly formed flaps immediately over the openings of the future nostrils were respectively reflected and turned in, being kept in position round these apertures previously made raw, in order by the presence of integument to prevent their too great cicatricial contraction, and possible subsequent closure.

August 6.—Third operation.—A flap with broad pedicle was taken in the usual manner from the forehead, and twisted down—the edges of the opening having first been pared, and the integument covering the newly-formed flaps over the lower part having been dissected from below upwards, so as to expose an extended raw surface on which to implant the forehead flap. Deep and superficial wire sutures were used to keep the parts *in situ*. Warm-water dressing to flap.

8th.—Transplanted flap looks well; no sloughing.

11th.—Some of the wire sutures removed.

18th.—The new nose has united firmly except for an extent of one inch opposite the inner canthus on either side. Wound in forehead granulating vigorously.

21st.—Pedicle of flap divided to-day, a good-sized vessel supplying it being cut, which had the effect of making the nose feel cold and look slightly congested. At the same time an attempt was made to close the chinks on either side between the eyes. There was great difficulty in doing this, as the

destructive process had stopped just short of the lachrymal sac, which was only thinly covered by skin; but by carefully paring the edges, they were brought together by wire sutures. Warm-water dressing to be kept constantly applied to nose.

25th.—Wire sutures removed. Circulation in nose quite established, but there is a slight superficial slough, about the size of a fourpenny-piece, where the pedicle was divided.

September 1.—Only partial union has taken place at the sides of the new nose at the upper part: the opening on the right side is now half an inch in length, on the left nearly an inch. A piece of No. 10 gum-elastic catheter is constantly kept in each nostril, the openings of which show a great tendency to contract. Throughout the stages of the operation the patient's health has been remarkably good. There has been some inflammation of the conjunctivæ, which yielded to the application of astringent lotions. Wound in forehead quite healed. It is interesting to observe that if the point of the nose be touched with anything, such as the end of a pencil, the patient, with his eyes previously and still closed, when told to place his finger on the part irritated, will immediately raise his hand and put his finger on the cicatrix in the forehead.

October 4.—The openings on either side of the nose still remain, and to-day Mr. Wood pared the edges of that on the left side, and brought them together with wire sutures.

11th.—Wire sutures removed. Union has taken place. Opening on left side completely closed.

22nd.—Operation for closing the opening on the right side performed to-day in the same way as that for the left side. The difficulty seems increased by the fact that the patient has been accustomed to breathe through these openings, and therefore the air has a constant tendency to re-open the wound.

29th.—Wire sutures removed from right side. The opening is quite closed.

November 19.—Patient discharged with directions to keep the nostrils open by inserting the catheter tubing. His sense of smell is now almost perfect.

THE ABUSE OF THE IODIDES IN SECONDARY SYPHILIS.—Professor Gamberini, the well-known syphilographer of Milan, has lately called attention to the way in which nowadays the iodides of potassium and sodium are prescribed "in all the forms of secondary syphilis," and deprecates such practice strongly. He says—"The iodides are used as if mercury were no longer of any value. I have examined a large number of cases treated in this way, and have been able to prove that ordinarily the iodides are not beneficial, and that the virtues assigned to them are only the expression of the natural pauses in the course of the syphilis. It is my firm belief that the prolonged use of the iodides as an exclusive remedy in secondary syphilis only serves, as a rule, to impoverish the blood, and so to accelerate the appearance of syphilitic chlorosis." Professor Gamberini recommends those who are sceptical of the truth of his assertions to compare for themselves cases as nearly similar as possible treated with mercury and with the iodides. Is not the warning given above as applicable to English as to Italian medical men?

SATURDAY, DECEMBER 27, 1873.

ANNUS MEDICUS 1873.

REGARDED from the weather point of view, the year has not been a very pleasant one. It was not so almost continuously wet as the year 1872, but in general character it might be instanced to justify the saying of a foreign cynic and wit, that "in England there is no climate, they have only weather." We had two short bursts of fine, hot summer weather, and a short early St. Luke's summer, while the rest of the year was cold and very often wet. But, *en revanche*, the year was very healthy; at least, the rate of mortality was very low. During the first quarter it was lower for the whole country than in any year since 1862, and for London the rate was even below that for the whole of England; and during all the year it has been below the average. Whether this may be taken as denoting a high state of health and vital power is, perhaps, questionable; but we have as yet no statistics for striking a general sickness-rate, and no means of judging the general state of health; we can only tell the general death-rate, and that, as we have said, has been low. During the autumn some alarm was felt lest we might, by importation from abroad, suffer from Asiatic cholera, but the port of London and our chief seaports were placed under strict and active sanitary inspection and care, and, thanks to the prompt and efficient action of their medical officers of health, no such calamity has occurred. In the port of London, at any rate, more than once cholera has been imported, but the vigilance of the medical officer has prevented all spread of the disease. And till lately the year had been distinguished by the absence of any severe and wide-spread epidemic; during the last two or three months, however, measles has been very prevalent in London, and very fatal. Until October the average weekly death-rate from measles in London for 1873 had been only 20·1, and the weekly mortality had never exceeded 33; but since the beginning of October it has risen rapidly, and in the week ending Saturday, November 22, 130 deaths were registered in London from this disease, 116 of

which occurred in the North, East, and South districts, and only sixteen in the West and Central districts. The Registrar-General informs us that this is the highest mortality from the disease which has been returned since 1840, when the weekly returns of deaths were first published. He also tells us that an epidemic of measles is due in England in 1874; but we cannot affect to think that this information, however interesting it may be, is at all consoling. If, indeed, it could have any effect in leading our politicians to put aside party, to shelve "sensational" measures, and to legislate for mankind, it would be incalculably valuable. But, alas! when can we hope to see a great party "educated" up to a living practical faith in the cry of "Sanitas sanitatum, omnia sanitas!" or a time when politicians will feel the hope, or the demonstrable certainty even, of saving thousands of lives yearly by wise and well-considered sanitary measures for stopping preventable deaths, as potent a charm to persistent action as is a battle over Acts to extend the franchise to the ignorant and uneducated, or for the spoliation and destruction of institutions for the teaching of that which our forefathers held to be a faith to be lived by and died for, but which, according to "the spirit of the age," we are to look on as an enslaving superstition or an effete myth?

In September and August a very remarkable and serious outbreak of enteric fever occurred in the West-end of London. In the first week of August, Dr. Whitmore, the Medical Officer of Health for Marylebone, found good grounds for suspecting that it was caused by contaminated milk, supplied by the Dairy Reform Company, and communicated his suspicions to the Company; and on the 7th of the month Sir William Jenner and Dr. Murchison wrote to the Company that they had been called in to see a large number of cases of enteric fever; that of thirty-seven families, in which it had come to their knowledge that the fever had occurred, thirty-five were supplied with milk from that dairy; and that they considered the evidence so strong that the milk had been the medium of carrying the poison that they hoped the Company would suspend the issue of it till the cause of the outbreak had been thoroughly investigated. They added that Mr. J. N. Radcliffe had been deputed by the Privy Council to inquire into the matter. The Company could not believe that their milk—"pure milk, coming from the country"—could possibly have been the vehicle by which the poison had been spread; but on the 12th of August they deputed Dr. Corfield, Professor of Hygiene in University College, and Medical Officer of Health for St. George's, Hanover-square, to accompany Mr. Radcliffe and Dr. Whitmore on a visit of inspection of the farms supplying the milk distributed by the Company. On the evening of the same day it was discovered that there was typhoid fever "on or in the neighbourhood of" one of the Company's farms, and the supply from that farm was immediately stopped. This is not the place for any expression of opinion as to whether the Dairy Company acted with sufficient promptness and decision, or paid such attention as might be expected to the opinions of such authorities on typhoid fever as Sir W. Jenner and Dr. Murchison. It will be enough to add to the above, that having learnt, from what may almost be called a pathological experiment, the lesson that milk may be the vehicle of disease, the Company took excellent measures for insuring its purity. They ordered weekly reports from medical men and veterinary surgeons of the health of all individuals, biped and quadruped, on their farms, and took various other admirable precautions for securing the stable-door in the future—all, no doubt, in the purest spirit of philanthropy, and in furtherance of what they "have always desired to be," viz., "an useful and reliable instrument in the hands of the physicians of London." When Dr. Whitmore reported to the Marylebone Vestry at the end of September on this outbreak of typhoid fever, he stated that ninety families had suffered from it, and that the number of persons attacked had been 320. The exact percentage of death could not be learned, for in many cases the fever had declared itself only after the sufferers had left London, but about twenty fatal cases were then known of, though only some five or six of these had ended in Marylebone. One had died in France, one in Wales, and others in different parts of the country. Each case in which the poison of the fever was thus carried from London became a possible new focus of infection, and so disease might be spread enormously. Milk has now been indisputably proved to have been the vehicle by which the infecting poison has been spread in several outbreaks of enteric fever, and in more than one outbreak of scarlet fever, and it is clear that all dairies and dairy-farms ought to be placed under frequent and careful sanitary inspection. But, while fully admitting that a free supply of milk may possibly be turned into a great evil and danger, instead of being, as it ought to be, an unmixed good, we must give a word of warning against any hasty assumption that milk is always or very often the source of mischief in outbreaks of zymotic disease, and there does just now appear to be some danger of "a run" on milk-infection. In the London outbreak the public were greatly indebted to the medical men we have named for the skill shown in tracing out the source of infection, and the promptness and boldness with which they acted. Dr. Murchison was, we believe, the first to suspect the milk, his suspicions having been excited while endeavouring to trace out the source from which three of his own children, who were attacked on July 22, had been infected with the typhoid poison; and the greatest credit is due to him for the sagacity, perseverance, and courage displayed by him in his inquiries and in his communications with the Dairy Company.

Only one Bill directly affecting our profession was passed by both Houses of Parliament, and received the Royal assent, this year—the short Bill, namely, for giving the University of London the power to unite and co-operate with any two or more of the colleges and bodies named in the Medical Act of 1858, in conducting examinations. One of the clauses in the Bill provides that the assent of one of her Majesty's principal Secretaries of State shall be necessary to give force to any arrangement between the University and the co-operating bodies; and that one of such Secretaries of State may, at any subsequent time, revoke such assent if he think fit to do so. One more step has thus been made towards the formation of one Conjoint Examining Board for England; and we believe that the Apothecaries' Society have obtained the promise of the support of Government to enable them to obtain like powers next year. But supposing that done, and an English Conjoint Board formed, it remains to be seen whether any benefit will arise therefrom to either the profession or the public. We own to a suspicion that the establishment of a Conjoint Board for each division of the kingdom may prove to be by no means an unmixed good, but it appears to us that an attempt to work a Conjoint Board in England only must be productive of great mischief. Invidious distinctions will almost certainly, and naturally, be drawn between medical men possessing the different diplomas; and it appears at the least probable that the medical educational establishments and the examining bodies in the other divisions of the kingdom will gain at the expense of the like institutions in England.

We were threatened with a Medical Acts Amendment Bill,—Mr. Headlam having introduced one, which might be called, we suppose, the Bill of the British Medical Association, or perhaps, more strictly, the bill of the British Medical Association journal,—but it did not come to anything. A formidable show of opposition was very early made against it by Dr. Lyon Playfair, Mr. Maclaren, the Marquis of Huntingdon, and Dr. Lush; and Government gave, to say the least, very

little encouragement to its supporters, and it died, and made no sign.

Mr. Fowler and a few agitators brought in a Bill for the repeal of the Contagious Diseases Acts of 1866 and 1869, but it was opposed, on the motion for its second reading, by Sir John Pakington, who was seconded, in a powerful speech, by Mr. J. D. Lewis, and the Bill was rejected by a large majority. Sir C. Adderley brought forward a lengthy, and, on the whole, valuable Bill, embracing certain amendments of the Public Health Act of 1872, recommended by the Sanitary Commission. The Government assented to the Bill, but had neither time nor power to push it through the Houses of Parliament. The Bill met with great opposition in committee, and Sir C. Adderley withdrew it early in July. There was no popular panic to give momentum to it; and when Government is strong it occupies itself with what it is pleased to call "large measures of reform," while, when weak, it has too much to do with nursing its own health to be in earnest about such a comparative trifle as a Public Health Act.

The General Medical Council met on March 26, and again met in the inconvenient and undignified apartments they hire in the Dental Hospital, Soho-square, neither of the Royal Colleges being able to offer them accommodation. The session of the Council was, as usual, opened by an address from the President, from which it appeared that difficulties, which should not have been quite unexpected, had arisen in the perfecting of the English Conjoint Examination Board. The University of London and the Apothecaries' Society had been in communication with the Secretary of State for the Home Department on the subject of obtaining an Act enabling all licensing bodies to join in forming conjoint boards. The Secretary had approved of the project, and had promised that the Government would introduce an enabling Bill; and on the strength of this the two bodies immediately concerned had relied, and had patiently waited for a draft of the Bill from the Home Office. As the time for the meeting of the General Medical Council drew near, however, and no draft Bill had been received, the Apothecaries' Society grew uneasy, and wrote to inquire after it, and, to their surprise, received an answer from the Privy Council Office stating that the Lord President had decided not to introduce into Parliament any such measure as that they had written about. His Lordship thought that "any Bill to be introduced on the part of her Majesty's Government for amendment of the Medical Acts ought to be such as would cover all the grounds where amendment of the Medical Acts is wanted." The President of the General Medical Council felt confident that the Conjoint Board schemes would eventually be carried out, and "hoped it would be done without any sacrifice of the honour and dignity of the profession, and without any interference with, or infringement of, the independence and the power of self-government, of which the profession was very proud and (he thought very wisely) jealous." This was very pretty, but not very wise confidence, for, as we have often pointed out, the Privy Council has shown a determination not to do anything for the profession except at a sacrifice of its independence, being convinced that it can govern the profession much better and more wisely than it can govern itself. In the long and warm debate to which this negation of action on the part of Government gave rise some very curious and interesting revelations were made. It appeared that the "Privy Council people" having found out what had been going on between the University of London and the Apothecaries' Society and the Home Office, took that office to task for poaching on their preserves. This is an educational question, said the Privy Council, and you of the Home Office have no right to meddle with it; and perhaps the Privy Council intimated in official language that the matter was beyond the comprehension, as well as beyond the powers, of the Home Office. At any rate, it was more than hinted that there had been a sharp conflict between the two departments as to which should have the handling of the subject, and the Privy Council won the day. The Medical Council were also informed that the Under-Secretary to the Home Office had stated that Lord Ripon—the Lord President of the Privy Council—had been willing to introduce a general enabling Bill, on conditions that the fees of candidates should not be raised above the present standard in any case without the sanction of the Privy Council, and that the rules of the various conjoint boards, when framed, should be submitted to the Privy Council for approval—an outspoken expression of the intention of that department to place the profession, if possible, under its control. Many hours were spent by the Medical Council in discussing what they should do under the circumstances—whether they should ask for an interview with the Lord President, and if so, whether it should be simply to inquire if the Government would aid in the removal of any legal difficulties that stood in the way of the formation of conjoint boards. Eventually a deputation from the Council had an interview with the Lord President, Lord Granville, and Mr. Bruce, and were enabled to inform the Council that the Lord President was not much disposed himself to introduce so small a measure as an enabling Bill, but that he was disposed to be favourable to such a Bill if one should be introduced by a private member, and had even been gracious enough to name a private member of the Upper House as a very fit person to bring in the Bill. The total result, so far, has been, not the obtaining of a general enabling Bill, but that the University of London has got an enabling Bill for itself; the Apothecaries' Society has yet to try to get one. During the session of the Council a great amount of time was given up to discussions on the position taken, or thought or feared to have been taken, by the Government with regard to conjoint boards, on the Irish conjoint board scheme, and on conjoint board schemes in general. All who took the trouble to read the debates must have felt, we think, that an increased dread or distrust of the effects of the general conjoint scheme, if it should ever be carried out, was plainly shown by some of the members of the Council, and that no real advance was made towards the formation of even imperfect divisional conjoint boards. A very full and elaborated scheme was presented from the Irish bodies, and was approved and sanctioned by the Council; but it is an imperfect scheme, the Queen's University in Ireland and the Apothecaries' Hall having been unable to join in it. The latter has since done so, but the Queen's University still stands, and, for aught that appears to the contrary, is likely to stand, aloof. But of course the Council "desired to express a strong hope" that those bodies may be able to co-operate in the scheme. Hope never dies in the heart of the General Medical Council.

From Scotland no attempt even at a scheme came, and it seems very improbable that the Scottish examining bodies ever will voluntarily produce a conjoint scheme. The opinion expressed by Dr. Alexander Wood, that "it would repress and cramp the mind of students to put them all into one Procrustean bed of examination, and torture them to the same arbitrary standard," appears to be very generally held north of the Tweed.

Another and very important subject was discussed at great length, and with more satisfactory results. The "Report of the Committee on the Visitation of Examinations," which was dated July, 1871, but had been held over, was taken into consideration, and the Council passed a resolution recognising the benefits that had arisen from the former visitations, and expressing the opinion that "the time had come when the alternative afforded by the Medical Act be adopted, and the aid of competent persons, not members of the Council, should be obtained to aid in performing the duty," and a committee was appointed to prepare a scheme for drawing out such a

plan, including the due payment of the visitors." Later in the session the report of the committee was presented, and gave birth to long discussions and many amendments; the final result being, we believe, that power was given to the Executive Committee "to appoint a visitor or visitors, not members of the Council, and to make the necessary arrangements for the visitation of examinations by them, conjointly with the members of the Council." That this was a good step in a right direction hardly can, *pace* Sir Dominic Corrigan, be seriously disputed. The effects of the previous visitations were marked and most beneficial. Dr. Storrar asserted that the visitors' reports had been productive of much good, as regarded even such a body as the University of London; and the suspension of them by the Council caused great regret and surprise. We may hope that the resumption of them in the manner now determined on may lead to the work being entrusted to men of high attainments, of considerable practical professional experience, and not members of the Council. This would necessitate high salaries, but the Council ought to be able to afford that.

The report of the "Committee on the Medical Education of Women," obtained last year by Dr. Acland, was considered, and—well, we will not say that a great deal of time was wasted on it, but much time was consumed by it, and, judged by the standard of cost, the time of the Council is very precious. Nothing more need be said about it here, because the Committee was reappointed, and empowered to find out, for the information of the Council, whether any public institutions exist that provide for the education and examination of women as midwives, dispensers, or superintendents of nurses and of medical institutions, and to report whether, and in what manner, a public register of persons obtaining these qualifications might be kept.

It was resolved that "it is expedient that, under any future legislation, power should be granted to the Council to register a qualification in State medicine, after such qualification had been granted according to regulations approved by the General Medical Council."

The Council had the pleasure of learning that the then Chancellor of the Exchequer had caused information to be conveyed to Dr. Quain, "that an official communication had been made to Mr. Ayrton on the subject of housing the Medical Council in the house hitherto occupied by the savings-bank at the corner of St. Martin's-lane," and that he hoped the matter would be satisfactorily arranged in a few days. It was felt that this recognition of the official relation of the Council to other departments of public business was highly gratifying; and the situation of the building named left nothing to be desired. But put not your faith in Governments! our readers have lately learned from our columns that the Council have been informed that they can have the house mentioned, but must pay a rent of £600 a year! Such a mode of "satisfactorily arranging" for the housing of a public body needs no comment.

The Council adopted the report of the Pharmacopœia Committee, recommending a reprint of the Pharmacopœia, and an appendix supplying information respecting "new medicines, and new forms of medicines, that have become established or been introduced to the favourable notice of the profession." We hear that this appendix is now completed and ready for publication.

The Royal Colleges of Physicians and of Surgeons have openly censured the system of advertising medical works, which has gained ground more and more of late. The College of Surgeons was content to express disapprobation of "the practice of frequently advertising medical works in the non-medical press"; but the College of Physicians spoke out more fully and more explicitly, passing the resolution that "the practice of medical authors frequently advertising their own works in the non-medical journals, and especially with the addition of laudatory extracts from reviews, is not only derogatory to the authors themselves, but is also injurious to the higher interests of the profession." It would have been well if the Colleges had also seen fit to express an opinion against the practice of advertising distinguished medical and surgical patients; but it is to be hoped that this is never done with the sanction or knowledge of the physician or surgeon named as being in attendance on such and such a distinguished, eminent, or celebrated person; and probably the Colleges thought that no censure of theirs would affect the press-feeders or indiscreet friends. Of course we do not allude to Royalty bulletins—they are necessarily and rightly signed by the professional attendants.

In February, some important alterations, conceived in a just and liberal spirit, were made in the by-laws regulating the admission, or rather the nomination, of Members to the Fellowship of the Royal College of Physicians. The selection of the names of the Members to be submitted to the Fellows for election rests with the Council, a body of nineteen; but it was necessary that a majority—*i.e.*, ten—of these should vote in favour of any Member, so that in a small meeting of the Council two or three black balls would exclude a Member. Now fifteen members of the Council must be present to constitute a quorum. Also, any one Fellow (instead of any two) may propose any member to the Council for nomination. And the qualifications for the Fellowship (to be set forth in the proposal papers) are—standing in the College, academical honours, distinctions in literature and science, professional eminence, public appointments, and social position (whatever that may mean). About six-and-twenty Members have since been elected to the Fellowship—some of whom certainly ought to have been offered that distinction many years ago. Dr. Burrows was again re-elected President of the College, a recognition of the admirable way in which he has watched over their interests that honours the Fellows as much as it does Dr. Burrows.

The Baly Medal, for physiological research, was awarded to Dr. Sharpey, an acknowledgment of his eminence as a physiologist that was hailed with satisfaction by every man of science, and conferred additional lustre on the medal as an honourable and desirable distinction.

We cannot conclude our notice of the College of Physicians without a very brief reference to Professor Rolleston's very able and valuable Harveian Oration. We had the pleasure of publishing it in full in our pages, and need not therefore allude here to its special merits; but both as a literary and scientific production it is admirable, and has rarely, if ever, been surpassed by any of the long list of Harveian orators.

On July 1 the Council of the College of Surgeons elected Mr. John Marshall and Mr. Timothy Holmes members of the Court of Examiners, in place of the late Mr. Richard Partridge and of Mr. S. A. Lane, who had completed his five years' term of office; and on the 3rd of the month the annual election of Fellows into the Council of the College took place. There were four vacancies and eight candidates, one of whom (Sir James Paget) had retired by rotation, and stood for re-election. Sir James was of course successful, and was returned at the head of the poll. Messrs. Haynes Walton, George Southam, and John Marshall were the three other successful candidates. Some of the candidates ran each other very close: Mr. Marshall stood only seven votes below Mr. Southam, Mr. Cooper Forster but one below Mr. Marshall, and Mr. Savory only ten below Mr. Forster.

Both of the Royal Colleges were called upon at various times to consider very elaborate reports from the Committee of Reference upon the method of carrying out the conjoint board examination. The President of the College of Physicians observed, in his address to the College in April, that "the

Committee had found it necessary to deviate in some minor particulars from the strict letter of the original scheme agreed upon by the co-operating medical authorities, and had been compelled to ask for the sanction of the College to their modifications;" and that it was essential that the College should, "in a question of such novelty, intricacy, and difficulty, grant to its representatives a certain discretion, and accord to them a large amount of confidence." Some of the Fellows thought that the Committee of Reference were in some points altogether exceeding the powers conferred on them, and that some parts of their reports did not merit the approval of the College; but the College as a body responded to the President's appeal, and gave the Committee "a large amount of confidence."

The forty-first annual meeting of the British Medical Association was held in the metropolis, and will be remembered for its brilliancy and success as long, we should think, as the Association lasts. More than 2000 members attended the meeting, and certainly nothing was spared or wanting to make it notable, impressive, and eminently satisfactory—except more space in the halls and rooms opened to it. But certainly it was the fault of the members themselves that any inconveniences were felt. The Reception Committee had over and over again implored all the members who meant to attend to send up their names beforehand; but only about 700 did so, and when splendid weather and other attractions finally brought up 2000, it was no wonder that some overcrowding and other inconveniences and disappointments occurred. It was rather a wonder that, owing to the indefatigable exertions of the Reception Committee, all passed off so well as it did. The meeting was opened by an address from the President, Sir Wm. Fergusson. The addresses in medicine, physiology, and surgery, given by Professors Parkes, Burdon-Sanderson, and John Wood, were in every way worthy of the occasion, and of the reputation of the men who delivered them; and it would be difficult to give higher praise than that. The sections were very fully attended, and were richly supplied with valuable papers, which gave rise to some good and instructive discussions; and the museum well deserved more time and attention from the members than could possibly be spared to it. In the halls and rooms of King's College, where the meeting was held, most of our eminent physicians and surgeons, metropolitan and provincial, were at various times to be met, and many of our illustrious foreign *confrères*. And if the work was exceptionally remarkable, not less so was the social part. The Royal College of Surgeons gave a *conversazione* to the members, while University College and the Lord Mayor gave elegant and brilliant receptions, which were attended by ladies as well as gentlemen, and were only almost too well appreciated and thronged. Windsor Castle, Clevedon, and Lambeth Palace, and the picture galleries at Stafford House, Grosvenor House, and Mr. Holford's were thrown open; excursions were arranged to Hampton Court and the Brighton Aquarium; and the benchers of Lincoln's Inn granted the use of their beautiful hall for the public dinner, which was graced by the presence of the Prime Minister. But have not these and other glories been duly recorded and frequently expatiated on in the organ of the Association?—which, if powerful, is certainly not without its trumpet-stop. The meeting was really a remarkable success; and the Association is said to have added nearly 1000 members to its strength during the year.

The St. Andrews Medical Graduates' Association do not hold their annual meeting until the 30th of the present month; Dr. Lockhart Robertson is the President for the year. The Association held an extra-general session on February 8, when Dr. Lyon Playfair addressed the graduates on the "One-Portal System," to which he is strongly opposed.

The British Association for the Advancement of Science held their forty-third meeting at Bradford, under the presidency of Professor A. A. Williamson. It was a very successful one, and some of the papers on anatomical, physiological, and sanitary subjects excited unusual interest and attention. Dr. Allman, the President of the Biological Section, gave a very able and valuable address, indicating the present position and value of the evolution theory in biological science. Professor Ferrier's address on the "Localisation of Functions in the Brain" was extremely able and lucid, and drew a crowded audience, who listened with the utmost interest and attention to the Professor's description and exposition of physiological researches that are certainly among the most remarkable that have been made in recent times. We cannot even enumerate here the many other papers of note—such as those by Professors Rutherford and Burdon-Sanderson, and some papers on "The Purification and Utilisation of Sewage,"—but abstracts of many of the most important of them were published in our columns at the time, and we must be content to say that the meeting was signalised by some addresses and papers of universal interest and value.

The various medical societies of the metropolis have been active, and doing good work. The session of the Pathological Society was distinguished by the discussion on the anatomical relations of pulmonary phthisis to tubercle. The subject was introduced by Dr. Wilson Fox, who occupied one whole evening with his very able and interesting exposition of his own views on the subject, and two other evenings of the Society were given up to the speeches of such well-known workers in pathology as Moxon, Cayley, Payne, Douglas Powell, Charlton Bastian, J. E. Pollock, C. J. B. Williams, and others. The discussion was interesting and valuable, and must be of service in one way at least—viz., by exciting attention to the danger of making the morbid anatomy of disease too exclusively the basis of medicine, of neglecting too much the life-history of a disease even in its pathological classification.

The Medical Society of London has taken possession of its handsome and very convenient new rooms in Chandos-street, has celebrated its centenary, and entered on its second hundred years of life with renewed vitality and power. The oldest of the medical societies of the metropolis, it has this year been as active and vigorous as the youngest among them. Though it meets every week, the meetings have been fully attended, there has been no lack of good and practical papers, and the discussions have been animated and instructive. "*Floreat semper!*"

The year has not been kind to the medical women and their supporters. They cannot well feel that they have had "a good time." Even abroad they have met with what we should be inclined to call very uncomfortable rebuffs and discouragements. In Edinburgh the law has been interpreted against them; and it seems at present as if they mean to give up the fight and retire from the field. In June, the judges of the Second Division of the Court of Session, after having formally consulted the other members of the Scottish Bench, delivered their decision in the case of Miss Jex-Blake and others *versus* the Chancellor and Senatus of the University of Edinburgh. They decided that the legal rights claimed—viz., that women be admitted as students to the classes of any professor in the University on precisely the same footing as male students, etc.,—"could not be maintained and enforced, irrespective of the regulations adopted by the University Court." In this view "all the consulted judges, without exception," had agreed; and Lord Justice Clerk and Lord Giffard, who had held a contrary view, confessed they had been in error. And, further, the majority of the judges were clearly of opinion that the University Court had no power to confer any such legal right as regards the Faculty of Medicine, and that the regulations by which the professors were "permitted" to give instruction in medicine to women were not only beyond the powers of the Court, but were a manifest encroachment on those of the Crown and Parliament. Consequent on

this judgment, the University Court determined to suspend the regulations for the education of women in medicine; and the Senatus came to the conclusion that, in the present state of affairs, it was undesirable to admit women to the medical preliminary examination in arts. Shortly after this, Mrs. Garrett-Anderson, M.D., wrote to the *Times* a long letter, in which, *inter alia*, she recommended women who wish to practise medicine to give up England and Scotland, and go to Paris, where they can get a degree. It is true that foreign degrees are not registrable, and cannot therefore give the licence to practise; but that may be changed some day. The Ladies' Association for the Promotion of the Medical Education of Women applied to the Council of Queen's College, Birmingham, for the admission of women to the medical classes; but the Council, though "fully recognising the right of women to occupy any field of employment for which they may deem themselves qualified, and desirous to afford any facilities in its power towards the higher education of women," considered that it could not under existing arrangements conveniently admit female students to any of its departments, and was not prepared to make such alterations as the admission of female students would require. Forty out of fifty of the male medical students of the College had signed a memorial against the admission of women to the classes.

But the "unkindest cut of all," we think, came from Bristol. Dr. Eliza Walker was appointed House-Surgeon to the Children's Hospital there, but managed somehow to behave to one of the physicians in a way that could not be overlooked, and the whole of the honorary staff resigned. This led to the resignation of Dr. Eliza Walker, and in a letter to the daily papers she complained bitterly of the action of the medical staff, because, she says, "They must have known how important it was to the cause I represent that the experiment of my appointment should prove successful." She acknowledges that "an outbreak of anger placed her at the mercy of Dr. Bush,"—she refused to obey orders, we believe,—and says, "of this, as a natural consequence of my weakness, I do not complain"; but she cannot see, apparently, that such "natural consequences" are just what those fear who think women are unfitted to be doctors,—nor that the medical staff had to consider the interests of their patients and the orderly working of the hospital, and not "the cause she represented." We much fear that this little *contretemps* must be considered decidedly unfavourable to the medical women's cause. And discouragement has come from abroad also. Miss Emily Faithful, a strong supporter of "women's rights," wrote some time ago a letter to the *Times* from the American University of Michigan, in which she said, "After a considerable trial, the mixed-class system has been abandoned in the medical department; and this I am informed has been the case in all the American colleges." And news came not long ago from Zurich that was not at all encouraging to the advocates of the admixture of the sexes in universities. Dr. Eliza Walker, at an agitation meeting at Birmingham, said that in Zurich "the professors had often told her that they had observed a change for the better in the conduct of the men in the mixed classes," but the Russian Government has taken up a strongly hostile position with regard to the mixed-class system, and the vast majority of female students in Zurich are Russian. The *Pall-mall Gazette* published an account of the matter, taken from an official organ of the Russian Government, in which it stated that "very unfavourable reports had reached the Government relative to the conduct" of the Russian female students in Zurich, and that, "in order to put an end to this abnormal state of things, it is hereby announced to all the Russian women who attend the lectures at the University and the Polytechnic School of Zurich, that such of them as shall continue to attend the above lectures after January 1, 1874, will not be admitted, on their return to Russia, to any examination, educational establishment, or appointment of any kind under the control of the Government." Some of the reasons which caused the Russian Government to act thus will be found in page 629 of our first volume for this year.

Sunday, June 15, was chosen to be the first "Hospital Sunday" for London, and the collections made for the medical charities of the metropolis on that day amounted in the whole to £27,700 0s. 1d.—not a large sum, certainly, when we consider the enormous wealth of London, and that the sum thus raised is about £8000 short of the annual expenditure of one hospital—the London—alone. We mention that one because it is the chief hospital taking share in the fund; the great endowed hospitals are of course left out. But the experiment is new, as applied to such an agglomeration of cities as London is, and it may well be that, as the committee of management hope, the sum raised will be larger as the movement becomes better and more perfectly organised, and more generally recognised. The distribution of the fund has met with not a little criticism, but in the main we think it was a good and just one. It was that of encouraging and giving most support to institutions which provide indoor maintenance and relief for the sick, rather than those that furnish medicine and advice indiscriminately to out-patients. The Committee observe in their report—"Our hospitals are, and it is to be hoped always will be, purely charitable institutions, relieving the poor and afflicted without fee or payment of any kind, and therefore not competing with the medical practitioner. The dispensaries seem to stand in a different position, and may perhaps be used gradually as the best available machinery for collecting such payment as the upper working-class can afford for the doctor who attends them." If the Committee can help to the well solving of the out-patient problem they will do a great good. We have at different times pointed out some of the dangers that it appears may arise from the "Hospital Sunday" system; but we most willingly acknowledge that great credit is due to Sir Sidney Waterlow and the rest of the "Committee of the Metropolitan Hospital Sunday Fund," for the ability and devotion with which they organised and carried out all the arrangements connected with it. They awarded £24,571 to fifty-four general and special hospitals, and £2153 to fifty-two dispensaries and other medical charities.

We have had the satisfaction of again recording some, though certainly not many, honours, distinctions, and special rewards that have been conferred on our bretheren. Mr. J. Cordy Burrows, of Brighton, has received the honour of knighthood; Surgeon-General W. M. Muir, M.D., who was already a Companion of the Bath, has been made a Knight Commander of that most honourable Order; while Inspector-General of Hospitals and Fleets J. Rees, M.D., Inspector-General of Hospitals R. Dane, M.D., and W. B. Marlow, M.D., and Surgeon-Major J. Wyatt, have received the distinction of the Companionship; and Surgeon Henry Bellew, Bengal, has been made a Companion of the Star of India. Inspector-General Alexander Nisbett, M.D., and J. R. L. Dickson, M.D., have been knighted. A vacancy having been made in the medical department of her Majesty's household by the death of Sir Henry Holland, Dr. Burrows has been appointed one of her Majesty's Physicians-in-Ordinary, and Dr. Sieveking was made one of her Physicians Extraordinary, in succession to Dr. Burrows. All these honours bestowed on the practising members of our profession have been noted with great satisfaction and approval by the profession at large, while a still wider spread approval greeted the bestowal of the Companionship of the Most Honourable Order of the Bath on that eminent and venerable veteran in natural science, Professor Owen. It is truly a small honour for a man of such world-wide fame, but, in England at least, the devotees of science must be thankful for small mercies from the Government.

There was high festival of the intellectual kind, and a grand gathering in the fine old hall of St. Bartholomew's Hospital, on June the 26th, on the occasion of the presentation of the testimonial portrait of Sir James Paget. Professor Humphry, of Cambridge, had been selected to deliver the presentation address, and acquitted himself right well, describing, in a well-ordered speech and in eloquent terms, Sir James's brilliant career, and depicting the qualities of head, heart, and mind which had won him "the high admiration, the unfeigned gratitude, and the sincere respect" of so many friends. "Two life-like portraits of Sir James by the greatest of living artists, John Everett Millais," were then presented to Sir James and Lady Paget. Many of our readers will have seen the original portrait in this year's exhibition at the Royal Academy, and admired its life-like truthfulness and vigour, and the copy was in no whit below the original. Sir James returned thanks in one of those perfect speeches which he is well known to have the power of making—speeches that very few, indeed, can hope to equal, and none can surpass; and he never was more happy, more interesting, more simply and genuinely eloquent than now. After speaking briefly of his early struggles, the beginning of success, and the increasing flow of reward for his exertions, he alluded with affecting simplicity to the time, not long ago, when "it seemed as if his life of active work had come to an abrupt close, and he was uncertain what would follow. He was then very ill." But renewed health, happiness, and honours came, and life again became bright. "He had never, however, had it in his mind to reach this great honour; but having reached it, he was profoundly grateful." He added that he laid no claim to any self-denial, for he had all his life loved work, loved his profession, loved his hospital, and loved teaching; and to these he had devoted his life with ever-increasing satisfaction. Then, in his own and Lady Paget's name, he presented the original portrait to the Hospital, and promised to leave the copy to one of his sons, who "promised to be all that a parent could wish."

When Dr. Druitt was compelled, by continued illness, to give up his home, his professional labours, and his literary pursuits, and go abroad to seek a renewal of health, those who best knew and could appreciate his works desired to present him with some token of sympathy and friendship; and 107 of the leading members of the profession constituted themselves a general committee for this purpose. Their wish was largely shared in by the profession, and it was with very great gratification that we recorded in this journal that the result was the presentation to Dr. Druitt of a cheque for £1215 in a silver cup, given "by 370 professional and other friends, in evidence of their sympathy with him in a prolonged illness, induced by years of generous and unwearied labour in the cause of humanity, and as a proof of their appreciation of the services rendered by him as author and sanitary reformer to both the public and the profession." This expression of feeling was, we know, most gratifying to Dr. Druitt; and, we may add, scarcely less so to all who know, and therefore admire him. One thing only can please them still more—viz., to see Dr. Druitt come back among us with renewed health and strength.

We have had the pleasure—and it has been a real pleasure—of recording several other instances of honourable and affectionate appreciation of the services of members of the profession; but want of space prevents our particularising them here, while the great eminence of Sir James Paget, and our known connexion in work with Dr. Druitt, will, we are sure, be accepted as sufficient excuse for our having made room to again note the testimonials presented to them.

It would be easy—alas, too easy!—to extract from our pages a sadly long roll of names of our brethren who during the year have passed away from among us. We will not say, of "names once heard, but heard no more," for the names of many of them will for long years be in the mouths of wide circles of friends, and of grateful and trusting patients; and of not a few the names will live in the memories and hearts of numbers who never even saw them, and in some cases will be enshrined in the history of the science and art of medicine. Sir Henry Holland, after a life of singularly unbroken health, prosperity, and success, was taken from us, after a very short illness, on his eighty-sixth birthday. And we have recorded the deaths of many others at a ripe old age—thus, Dr. William Cooke, Mr. John Harrison, and Mr. John Griffith died at the age of 87; Sir W. Rae, M.D., Mr. Joseph Jordan, and Mr. T. Binwell at 86; Mr. C. E. Bissett at 84; Dr. J. Montgomery at 83; Mr. John North at 82; Mr. B. J. Crisp at 81; Dr. R. Pennell, Mr. R. Dobie, Mr. Stephen White, and Mr. Turner (of Manchester) at 80; while Inspector-General Dowse, Dr. Hamilton Roe, Mr. W. Harvey, Mr. A. Eaton, Dr. G. F. Evans, Mr. John Bishop, Mr. Henry Sterry, Mr. R. Partridge, Dr. T. Thompson, Dr. W. Hand, and Messrs. J. Soper Strecter, T. L. Pridham, and J. Grantham had all attained the age of 70 or more. More sad and unwelcome has been the task of recording the loss of men who were still at a more vigorous working period of life—at an age when we might have looked for many more years of active good work from them. Mr. Startin died at the age of 66; Mr. E. V. Austin at 63; Dr. Downing Toogood at the same age; Dr. A. Dymock, Dr. Thurnam, and Mr. John Wynne at 62; Mr. Hugh P. Fuller at 61; Dr. W. T. Dalby at 60; Dr. Bence Jones and Mr. Edward Moore at 59; Dr. Dalrymple at the same age; Dr. Tyler Smith and Mr. J. Butterworth Walker at 58; Dr. Benjamin Hobson at 57; Mr. Holmes Coote, Mr. Henry Bedwell, and Mr. W. A. Hillman at 54; and Mr. Gilbert Love and Dr. Edward Latham Ormerod died at the age of 53; and even while we write comes the sad news of the death of Dr. Fuller, of St. George's Hospital, and of Dr. Collet, of Worthing. Men like these, and such men as Mr. Carden (of Worcester) and Dr. R. W. Smith (of Dublin) leave behind blanks in life which will be long felt. But a yet more aching void remains when death strikes down in the spring-tide of professional life a man who has already done work that has justified the faith his friends had in him, and has seemed to change into certainty the promise of fame and success; and the profession has had to mourn the loss of not a few such men. Dr. W. Colston Warne died at the age of 22; Mr. A. H. Walpole died at an early age of typhoid fever; Mr. Frank Langley, at 28, was crushed to death when helping to cut away a mast on board an emigrant ship; Dr. A. M. Gray, of the Broadmoor Lunatic Asylum, died at 30; Dr. Franklyn Gould, at 33, of Indian fever; Mr. W. Frith Hunter at 32; Dr. Gwynne Harries, at 33, of scarlet fever; and Dr. John Murray, of London, at the age of 29, and Professor H. C. Cutliffe, of Calcutta, at 41—both died of œdema of the larynx. *Multis ille bonis flebilis occidit.*

We must also give a line to again record the death of Nélaton, the most eminent surgeon of the day; Romberg, pre-eminent among neuro-pathologists; and Czermak; and among men of science, Liebig and Coste.

We will now give, as has been our custom, a brief summary of the principal contents of our two volumes for the year. We believe that our readers find this summary of use to easily remind them of the chief subjects that have been treated of in our pages; and we also put it before them as the justification of our hope that the journal has at least maintained its high character as a useful and faithful record of professional work.

Under the heading of "Original Lectures" we have had the satisfaction of publishing the valuable lectures of Dr. Grainger Stewart, "On the Waxy and the Inflammatory Forms of Bright's Disease," and "On Cirrhosis of the Kidney"; of Dr. Peacock, "On Diseases of the Heart"; and of Dr.

Hnghlings-Jackson, "On the Diagnosis of Tumours of the Brain"; Dr. Andrew Clark's excellent and snggestive "Clinical Remarks on a case of Renal Inadeqnacy"; Dr. Edgar Sheppard's "Lectures on Insanity"; Professor Laycock's, "On brief Recnrrent Apnœa as a Cause of Sleeplessness in Cardiac Diseases"; and Dr. Eustace Smith's "Commentaries on Diseases in Children"; Clinical Lectures—by Dr. Handfield Jones, "On Three Cases of Anomalous Rheumatism," "On Cases of Peritoneal Strnmons Disease," and "On Two Cases of Acute Phthisis"; by Dr. Henry Thompson, "On a Fatal Case of Chorea," "On Two Cases of Acute Rheumatism with High Temperatnre," and "On a Case of Otitis, Cerebral Abscess, and Malformation of the Heart"; and by Mr. J. W. Hulke, "On Cases of Rodent Cancer," "Cases of Epithelium of the Hip," "Cancer of the Rectum," "On Sarcoma," "On the Evolution of Cancer," and "On Infantile Purulent Ophthalmia"; selected extracts from Mr. Jonathan Hutchinson's clinical lectures "On Diseases of the Skin," and Dr. Tilbury Fox's lectures "On Pityriasis Rubra and Pityriasis Pilaris," and "On Lichen Planus." We have also been enabled to give our readers lectures—by Professor Dolbeau, "On Retro-Uterine Hæmatocele"; by Professor John Wood, "On a Case of Diseased Knee-Joint," and "On Umbilical Hernia"; Dr. Symes Thompson, "On Dnst-Inhalation as a Canse of Lung Disease"; Dr. H. Letheby, "On the Right Use of Disinfectants"; by Dr. Lionel Beale, "On Hospital Patients, Nurses, and Doctors" (a lectnre very largely admired and appreciated); and a clinical lecture by Dr. Balthazar Foster, "On Rnpture of the Aortic Valves from Accident."

Under the title of "Original Communications" we have as usnal been privileged to give to the profession valuable papers from many of the best-known, most able, and most trustworthy workers inthe profession. Among these articles we may mention Dr. John Cockle's "Contribntions to the Pathology of Tumours of the Neck"; Mr. J. Beswick-Perrin's "Record of Irregular Muscles, 1868-71"; Dr. J. Fayrer's papers on "Fibrinous Concretions in the Right Side of the Heart as a Cause of Death after Surgical Operations," "On European Child-Life in Bengal," "On Experiments on Poison of the Rattlesnake," and on other subjects; Dr. J. B. Garrod's "On Renal Calculus, Gravel, and Gonty Deposits, and the Valne of Lithium Salts in their Treatment"; Dr. W. H. Broadbent's "On a Study of a Case of Heart Disease, probably Malformation"; Dr. Snckling's "On a Rare Case of Monstrosity"; Mr. Bevan Lewis's "On Lead-Poisoning"; and Inspector-General Lawson's "On Two Cases of Death from Fibrinous Concretion in the Right Side of the Heart; communications by Dr. B. W. Richardson "On Methylene Ether, or Ethyl," and on "Opera Clinica"; by Mr. J. Hntchinson "On Subcoracoid Dislocations of the Humerus," etc.; by Dr. D. J. Brakenridge "On Oxide of Zinc as a Remedy for the Diarrhœa of Infancy and Children"; Dr. Stephen Ward "On the Treatment of Chronic Dysentery"; Dr. Peacock "On Five Cases of Paracentesis Thoracis occurring in Private Patients," and "On the Beneficial Influences of Sea Voyages in some forms of Disease"; and by Dr. L. Beale "On the Nnrsing of the Sick in Hospitals, Private Families, and among the Poor." Also Dr. M. Sarell's "Ovariotomy snccessfully performed for the first time in Constantinople"; Mr. T. Bond's "Poisonous Effects of Carbonic Acid"; Mr. H. Jalland's "Case of Scnrvy in a Child ten months old"; Mr. W. Johnson Smith's "Case of Injury to the Upper Portion of the Spinal Cord"; and Assistant-Snrgeon N. Alcock's "Interrnpted Correlation of Respiration, Pulse, and Temperature, in a Case of Gangrenous Abscess of the Lung," and his papers from Pirogoff's "Gleanings in War Sanitation." Fnrther, we have had the pleasnre of publishing valuable papers—by Dr. R. Druitt, "On Two Cases of Intermittent Hæmatinuria"; by Moodeen Sheriff, "On the History of the Epidemic of Dengue at Madras in 1872"; by Dr. W. Moxon, "On a Case of Acute Cancer of the Liver, simulating Suppuration"; by Dr. G. B. Halford, "On Snake Poisoning and its Treatment"; by Dr. Handfield Jones, "On a Case of Hydroa," and "On Cases of Heart Disease affording evidence respecting the Action of Digitalis"; by Dr. Lewis Shapter, "On Motor Inco-ordination (or Locomotor Ataxy)"; by Dr. T. Stretch Dowse, "On Acute Ataxy"; by Dr. R. H. Semple, "On Diphtheria"; Dr. J. W. Ogle, "On Sleeping Sickness"; Dr. John Macpherson, "On the Seasonal Prevalence of some Erruptive Fevers in India"; Mr. C. J. Egan, "On the Erruptive Fever in Kaffraria"; and Dr. James M'Craith, "On the Practice of Medicine in Smyrna"; Dr. J. Haddon's papers "On Small-pox"; and Mr. Arthnr Farre's "On Small-pox, its Erruption, and the Pathology of its Distribution"; Mr. Lawson Tait's report of "Death under the Administration of Methylene Ether"; Mr. Pandurang Gopal's "Observations on Fatty Urine," and Mr. T. E. Amyot's "Case of Fatty or Chylous Urine"; Dr. W. R. Spencer Jeffries' "Case of Comminuted Fractnre of the Cranium, Right-sided Hemiplegia, Aphasia, Recovery"; papers by Mr. C. F. Maunder, "On Coincidences in Snspected Strangulated Hernia," "On Lumbar Colotomy," and other subjects; by Mr. F. A. Mahomed, "On the Physiological and Clinical Use of the Sphygmograph"; by Dr. David Nelson, "On Constipation simnlating Diarrhœa"; by Mr. W. MacCormac, "On Professor Esmarch's Mode of Performing Bloodless Operations"; by Mr. F. Irving De Lisle, "On a Case of Malignant Facial Carbuncle," a case of "Thoracic Anenrism, Consolidation of the Tumonr under Treatment," and "On the Treatment of Delirium Tremens and Allied Diseases by Large Doses of Digitalis"; by Mr. W. Donald Napier, "On the Detection and Removal of Vesical Calculi by a New Method," and "On the Treatment of Vesical Calculi"; by Dr. G. W. MacNalty, "On a Case of Syphilitic Gummata in the Heart"; by Dr. J. Von Tunzelmann, "On Cases of Lead-Poisoning by Drinking-Water"; and Professor Joseph Jones's "Outline of Observations and Investigations on Yellow Fever"; and communications from Drs. T. Laycock, Edwyn Slade-King, and T. Savage; and Messrs. F. W. Lowndes, G. Gaskoin, C. S. Jeaffreson, W. F. Teevan, Philip Foster, Stromeyer, Little, and many other valued contribntors.

We may note here, also, some very valuable papers and lectnres which we have published during the year, though they were not placed nnder the head of either "Original Lectures" or "Original Communications"; snch are Dr. Peyton Blakiston's admirable "Clinical Reminiscences"—we have felt much honoured by being permitted to publish these recollections of a physician of his sagacity, acuteness, and ripe experience; Professor Hebra's lecture "On some Affections of the Skin occnrring in Pregnant and Pnerperal Women"; Professor Depaul's lecture "On Congenital Hydrocephalus in relation to Parturition"; Professor Jaccoud's "On Endocarditis in relation to Erysipelas of the Face"; and Professor Skoda "On Constipation in Pneumonia"; papers "On the Medical Uses of Electricity," "On Aspiration," and "On the Physiology of Vision"; papers "On the Physiology of the Secretion of the Bile," and "Of Menstrnation"; "On the Estimation of Urea in the Urine"; "On Megrim, or Sick-Headache"; "On Researches in the Physiology and Pathology of the Brain"; "On the Action of German Yeast and of Pasteur's Fluid upon Animalcules," by Dr. Leo Popoff, of St. Petersburg; Professor Virchow's "Description of a Hermaphrodite," Dr. James Johnstone, of Shanghai, "On Cases showing the effects of Atropia as an Antidote to Opium"; "A New View of the Genesis of Tubercle"; and abstracts of Dr. Ballard's "Report on the Outbreak of Enteric Fever," and of Dr. B. W. Richardson's Croonian Lectnre "On Muscular Irritability after Systemic Death." The papers "On Guaiacum Blood-Tests" and on Dr. Cornil's "Recent Investigations concerning

Phthisis Pulmonalis" will have attracted notice; and we are sure that the admirably written "Notes on Madras as a Winter Resort" will have been read with great interest.

In our editorial articles we have endeavoured to notice and comment on everything that concerned the honour or welfare of the profession, or that in any degree affected its interests, or the relations of the public to medicine. Thus, we have given articles on "The Causation of Enteric Fever," on "Two Outbreaks of Enteric Fever," on "The Propagation of Zymotic Disease by Milk," on "The Dairy Reform Company and the Outbreak of Enteric Fever," and on "Sewage and Disease"; also on "Vaccinal Syphilis," on "Quarantine," on "Infant Deficit Abroad," on "The Medico-Legal Importance of Intracranial Abscess," on "The Medical Superintendence of a Cottage or Village Hospital," on "The Northampton Provident Dispensary," on "The Durham Poisoning Case," on "The Pollution of Rivers" and on "Metropolitan Slaughter-Houses"; on "The Contagious Diseases Act Repeal Bill," on "The Treatment of Malingerers," on "The Registration of Births and Deaths," on "The Propagation of Cholera" and "The Exclusion of Cholera," on "The Relations between Prescribers and Dispensers," on "Hospital Medical Officers and Hospital Committees," and on "The Guinea Fee." We have had leaders on "The Lessons to be Learned from the Last Illness of Napoleon III.," on "The Chemistry of Calculus," on "The Action of "Digitalis," "The Statistics of Rheumatism," "The Treatment of Diabetes," "Leprosy in the West Indies," "The Rôle of Iron in the Blood and in Food," "The Structure and Regeneration of the Nerves," and on "Glycogen and Glycogeny," on "Archebiosis," on "The Relations of Phthisis to Tubercle," on "The Influence of Age and Length of Residence on Mortality among Europeans in India," and on "The Treatment of Symptoms." We have often had to comment on the action and non-action of the General Medical Council; on the progress made or not made in carrying out the Conjoint Examination Scheme, and on education movements, and in this connexion have written on "The Future of the English Universities," on "The Matriculation Examination of the University of London," on "Preliminary Education," and on "The Commission on Scientific Instruction at Oxford and Cambridge." And, of course, we have had on various occasions to devote not a little time and space to the Medical Women Question.

By means of our Hospital Reports we have given useful and interesting cases, and supplied examples of the medical and surgical practice of the day in our metropolitan and provincial hospitals and infirmaries. By the "Topics of the Day" and the weekly notes our readers have been kept informed of everything of special interest to them professionally and socially; while our Notes from Abroad have told them week by week what topics have come most to the surface with our Continental brethren. The Therapeutic Memoranda and the notices of new inventions and of articles of diet have, we are glad to think, been found useful; and it has given us much pleasure to be enabled to continue giving Mr. J. F. Clarke's most interesting "Autobiographical Recollections."

We will mention only a few more valuable articles that we have from time to time given, such as the notes "On the Surgical Instruments at the International Exhibition"; Dr. R. H. Bakewell's "Experience on board an Emigrant Ship"; Professor Laségue's article "On Hysterical Anorexia"; the "Notes on Foreign Hospitals and Schools of Medicine"; and the meeting of the German Association for the Advancement of Natural Science and Medicine; the Hunterian Oration of Mr. Hancock; Mr. Prescott Hewett's address to the Clinical Society, and Mr. Bryant's to the Hunterian; Dr. Richardson's paper "On Fibrinous Deposits in the Heart"; Professor John Curnow's very remarkable lecture "On Individualism"; an able and interesting article "On the Doctors in 'Middlemarch'"; and the articles "On Workers in Textile Fabrics," "On Yarkand as seen by a Physician," "On the State of Hindu Medicine," and "On Snakes."

We desire to express our warm thanks to all who have so kindly and ably contributed to the value and success of the journal, and to the large number who, as our accompanying advertisements show, have promised us aid and contributions in the ensuing year; and to them and all of our brethren, at home and abroad, engaged in peaceful pursuits or at the seat of war, we wish health and prosperity, "A Merry Christmas and a Happy New Year."

THE PHYSIOLOGY OF VISION.

VII.—The Sensations of Light and Colour.

We have already discussed the peculiar structure of the retina as a nervous structure, and now desire to deal with it as an organ of sensation. We have also pointed out that in every part save the yellow spot the rods and cones, which are the true sentient structures, have interposed, between them and the light, layers which are more or less opaque. Hence it is that in this yellow spot alone is the function of vision perfect; and we, in fact, make up for its small size by the movements of the eyeballs, intended to bring every point of an object in focus for this yellow spot. Other portions of the retina save the optic papilla have the power of being stimulated by light-waves, but in no part is vision so accurate as in the yellow spot.

But the question arises—Is light the only stimulus to which the optic nerve responds? To that the answer is plainly, No; for any violent stimulus, as a blow on the eye or an electric shock, sufficient to affect the nerve or its periphery, will give rise to the same kind of sensation. It is not, therefore, specificity in the stimulant, but specificity in the organ to which the effect of the stimulation is conveyed, which is implied by the sensation of light. And it is only because the retina is deep sunk in the orbit that it is not more frequently stimulated by other agencies than light. This is true of other organs of sense than that of vision, for the faintest electric shock produced by such a simple arrangement as that of two different metals, as zinc and copper, will give rise to a marked taste if brought in contact with the tongue; and it is not always easy to separate the effects of a pungent irritating body from those of a scent, as far as smell is concerned. Anything, therefore, which irritates a special nerve, whether at its periphery or in its course, will be appreciated by its centre, as taste, smell, sound, or light, as the case may be.

It is, however, in discussing the subject of colour that some of the most interesting facts relating to the retina are brought out. Newton was the first, by means of the analysing effects of the prism, to show that white light is not simple, but is compounded of the various coloured rays, which constitute the solar spectrum. The most important of these are three—viz., red, green, and violet,—with yellow intervening between red and green, and blue between green and violet. These colours are produced by waves in the luminiferous ether of varying length, the longest giving rise to the red rays, the shortest to the violet; but, as already pointed out, there are other rays in the solar spectrum not appreciated by the eye. Thus, there are longer waves than the red, and shorter than the violet, but these give rise to no impression on the retina, and hence are not luminous. But the long rays beyond the red are heat-rays, and the short rays beyond the violet are chemical rays. These heat-rays are appreciated by the general surface of the body, but the very short ones are not. We have a good example of the non-luminous heat-rays in the heat which is given off from a blackened stove where no fire is visible, but the heat is readily felt. Such a fact shows the propriety of separating, as is now generally done, the sense of contact—*i.e.*, touch—from the

sense of temperature produced by these invisible heat-rays, apparently appreciated by the same sentient surface.

It is a well-known fact that in preparing pigments a mixture of blue and yellow makes green; but it is a fact only comparatively recently discovered that blue and yellow rays of light do not give green but white light. But white light may be composed in various other ways. If we throw on a screen rays of light which are red and bluish-green, we produce white light; so, if we throw in the same way yellowish-green and violet rays on a screen, again we get white; but the two whites, though undistinguishable to the eye, are characterised by totally different properties,—for whilst the first white would have a stronger heating effect, the second would have a much more marked effect on a sensitive silvered plate, inasmuch as this white contains many more chemical rays than the other. In this respect the eye is inferior in delicacy to the ear, which can, from the volume of sound produced by an orchestra, pick out the tone and note of each particular instrument.

Associated with this is the interesting subject of colour-blindness. Those who suffer from this defect almost invariably are blind to the rays at one end of the spectrum only, and that is the red end. On their retina red rays produce no effect, and hence a surface illuminated by them only seems black. Many stories are told of individuals who suffered from this defect. Nevertheless, the very defect helps us to a theory as to the mode of stimulation of the optic nerve by light-giving rays. In all probability we have at least three kinds of rods and cones—one set which are affected by red rays, another by green, and a third by violet. When all of these or certain of them are stimulated at once, the sensation of white light is produced; but if those sentient of red only are alone stimulated, then the colour red is produced; but in red-colour-blind people no such rods and cones exist.

THE WEEK.

TOPICS OF THE DAY.

Rawdon Macnamara, F.R.C.S.I., M.D. (*honoris causâ*) Univ. Dub., Professor of Materia Medica, and ex-President of the Royal College of Surgeons in Ireland, Surgeon to the Meath Hospital, has been appointed the representative of the Royal College of Surgeons in Ireland upon the General Medical Council of Education and Registration of the United Kingdom.

The Government transport *Sprite*, which left the Thames on Sunday, the 21st instant, for Cape Coast Castle, took out the ten additional army medical officers considered necessary to meet the exigencies of the service on the Gold Coast. These gentlemen were—Surgeons G. B. Stewart, J. Watson, A. Minto, J. Maturin, K. Macaw, G. Andrew, J. Williamson, C. B. Jennings, T. Faris, and T. Oughton. Some idea of the strong European staff necessary to be provided to meet the casualties caused by the climate of the Gold Coast may be arrived at when it is stated that out of forty officers who left England on Sir Garnet Wolseley's staff, thirty have already been more or less prostrated by sickness, and this during a period which is looked upon as the healthy season. There is, we believe, a well-founded rumour that the Admiralty has decided to grant double pay to medical officers of the Royal Navy doing duty on shore, or on board the vessels stationed off the Coast, during the continuance of the present war.

ROYAL COLLEGE OF SURGEONS, IRELAND.

A meeting of the Council, Fellows, and Licentiates of the College was held in the Albert Hall, Stephen's-green, on the afternoon of Saturday, the 20th inst., for the purpose of conferring the Honorary Fellowship of the College upon the Rev. Samuel Haughton, M.D., Fellow of Trinity College, Dublin. Among those present were—the President, Vice-President, and Secretary of the College, many members of the Council, and of the Court of Examiners. The President, in conferring the Honorary Fellowship, alluded in complimentary terms to the high distinction Dr. Haughton had won for himself in the scientific world, and gracefully expressed the pleasure it gave him and his brethren to bestow the Fellowship of the College upon so worthy a recipient. The new Honorary Fellow having returned thanks, the diploma of Licentiateship was granted to the following candidates, who had been successful at the recent quarterly examinations:—G. D. Burke, Arthur Butler, John H. Courtenay, J. B. Emerson, Thomas Enright, J. R. Gentleman, A. T. H. Kerr, F. Langan, S. T. Lewis, Osborne Limirick, Henry Longford, C. E. M'Namara, Joseph M'Namara, Rawdon M'Namara, Charles Morrow, E. J. Murtagh, S. H. Newell, F. O'Flaherty, Alfred Patterson, J. H. Poett, R. Rainsford, L. W. Rawson, A. G. Russell, H. M. Scott, R. Stone, Agmon B. Vesey.

THE CONJOINT EXAMINING SCHEME FOR IRELAND.

We are in a position to state that the Committee of Reference, consisting of two delegates from each of the following bodies—viz., the University of Dublin, the King and Queen's College of Physicians, the Royal College of Surgeons, and the Apothecaries' Hall of Ireland—are at present meeting once or twice a week, with a view of perfecting the details of the scheme arranging the question of remuneration of the examiners, and settling the number of, and time for, the professional and arts examinations to be held under the Conjoint Examining Board. The University of Dublin has already appointed ten examiners—seven in professional subjects, and three in arts—as members of the Board.

THE MEDICAL OFFICERS OF THE SOUTH DUBLIN UNION.

The dispensary medical officers of the South Dublin Union are about to address an application for an increase of salary to the Board of Guardians of that union. Seeing that these gentlemen receive each £25 a year less than the physicians to the workhouse, that they conscientiously discharge to the best of their ability the onerous duties devolving upon them as agents of curative medicine in the slums and alleys of a large city, and that many of them in addition voluntarily act as local health officers in their several districts without fee or reward, it is to be hoped that the board of guardians will accede to an application couched in moderate and truthful terms. We willingly extract two sentences from a document accompanying the application, with a copy of which we have been favoured:—

"We trust that you will remember the continued risk we run from exposure to contagion in its most fatal forms, but too constantly present in this city; for it is upon us, dispensary physicians, and our families that this risk falls far more heavily than upon any other class of medical men, surrounded, as we are in our daily course of duty, by the depressing influence of overcrowding and other evils to be met with in the tenements of the humbler classes.

"The effects of such exposure is but too surely felt by us, as seen in the frequent occurrence of debility, illness, and even fatal results; the former but too often oblige us to relinquish any other means by which we may be seeking to supplement our scanty salaries, and the latter compel the families of your medical officers to seek that assistance from the benevolent which the parent was unable to provide during life.

FISSURES IN ANO TREATED WITH IODOFORM.

Dr. Francesco Parona (*Giornale Italiano delle Mal. Ven. e della Pelle*, October) gives his experience of iodoform in fissures of the anus, and strongly recommends it. He believes it acts in great measure as a local anæsthetic, "which allays the spasm of the sphincter during defæcation, while it favours cicatrisation by neutralising the irritating effects of

fæcal matters which may remain on the ulcerated surface." It has also a direct healing action. Dr. Parona uses the iodoform as an ointment (one part to three of lard), and applies it on a small cylinder of charpie, of a size requiring but little force for its introduction. The charpie has the advantage that its filaments adapt themselves readily to the slight irregularities of the anal mucous membrane. The dressing is changed twice a day, and replaced after each motion, and in the majority of cases the pain and spasm caused by the fissure cease in a few days, and the patient is well in a relatively short time. Of four cases, of which details are given, the longest time was twenty days, while one of the patients had been ill four months previous to the treatment.

CALCUTTA MEDICAL INSTITUTIONS.

The report on the Calcutta medical institutions for the year 1872, by J. Campbell Brown, C.B., Inspector-General of Hospitals, Indian Medical Department, Calcutta, states—"Of the 20,805 patients treated in the various hospitals, 2761 died, the mortality being thus at the rate of 132 per 1000. The chief diseases treated were fever, dysentery, cholera, diarrhœa, and small-pox, and it is curious to observe, in relation to the supply of pure water lately furnished by the Calcutta Municipality, that fever, dysentery, cholera, and diarrhœa all gave more admissions in 1872 than in 1871. In 1871 fevers gave 4251 admissions, against 5003 in 1872; dysentery, 980, against 1184; cholera, 800, against 1142; diarrhœa, 509, against 625. These facts must be annoying to those who see in pure water the panacea for all those diseases."

FROM ABROAD.—DR. JULES SIMON ON THE ABUSE OF WARM BATHS FOR YOUNG INFANTS.

Dr. Jules Simon delivered recently at the Hôpital des Enfants Malades an interesting lecture (reported in the *Gazette des Hôpitaux*, December 2) "On the Abuse of Warm Baths for Young Infants." He says that he has been much struck, both in his private and hospital practice, by the mischief produced by the practice, now so general, of administering daily warm baths to young infants, mothers and nurses not being content with the washing necessary for cleanliness, but keeping the infants in the bath for from five to ten minutes. At first all seems well; the child sleeps more, and sucks less often, and its docility and good condition are matters of congratulation. After a while, however, it becomes pale, and its limbs are soft—in a word, it is enfeebled. And how can it be otherwise? for the infant kept in a bath for five or ten minutes is in much the same position as an adult would be who had been kept in one for three-quarters or a whole hour; and where is the adult in Paris who could stand this with impunity? Whether the fact of the absorption of water be demonstrable or not, it is certain that the epithelial cells, engorged by fluid at the time in these repeated and prolonged baths, furnish to the capillaries a source of future absorption, the surface also being impregnated with heat and moisture. With the skin thus predisposed, the extremities of the surface of the child's body are at the same time most injudiciously exposed—following, as the lecturer says *is* (but should have said *was once*) the English fashion—to the inclemencies of the weather. These frail beings are expected to endure causes of fatigue and exhaustion which we could not tolerate ourselves; for in these northern climates there is not an adult who would submit to such a hygiene with impunity.

It is not intended to decry the reasonable employment of warm baths as a therapeutical agent in young infants. In nervous infants and in those who are constipated and the subjects of severe colic, they are of service; but baths in our climate must only be employed according to indications, and cannot, as in warm climates, be made an immoderate use of without evil results. Not only do they then become a source of enfeeblement, but they not infrequently give rise to cutaneous inflammations, from the fact that the infants, so far from being provided with the reconstituents they stand in need of, are placed in the position of scrofulous subjects attacked by eczema, which emollient baths only aggravate. M. Simon has frequently observed that infants in good health, subjected to these daily baths, become attacked, in spite of them, with intertrigo at the root of the thighs. The duration of the baths is consequently increased, and the disease spreads farther and farther for weeks or months. The baths are suppressed, and astringent lotions substituted, and the inflammation subsides in a relatively very short time.

There are, indeed, infants who remain lively and robust, and to whom these baths do not seem to do any harm; but for the Parisian population this is quite exceptional. From the nursling to the adult, the Parisians are mostly pale and anæmic, requiring much oftener corroboratives than antiphlogistics. In the country there is more power, and the infants, whose appearance there is excellent, will bear warm baths better; but still the bath should be regarded as an active debilitating agent, and not a mere means of cleanliness, and it is very questionable whether a daily warm-bath of ten minutes can be given with impunity to a child at the breast, even in the country. M. Simon also disapproves of medicated baths for children. Thus, in infantile syphilis, not only are the sublimate baths inefficacious, but they exaggerate the susceptibility to cold to which these little patients are so liable. Sometimes, too, the cutaneous manifestations are ameliorated while the disease is still making rapid progress. The skin is, in fact, a bad channel of introduction for all therapeutical agents ununited with fatty bodies; and in the immense majority of cases the sublimate baths, in place of giving tone to the syphilitic infant, enfeeble it, and favour the progress of the disease.

"To sum up what I have said, I consider the daily use of warm baths for young infants a very bad practice, and I interdict them in cutaneous inflammations. In both cases, whether in a hygienic or practical point of view, washing and lotions are far preferable. So, too, the sublimate baths, so much vaunted in infantile syphilis, are far less useful than mercurial frictions and Van Swieten's liquor. Warm-baths should not be prescribed in our climate except as a soothing remedy; and the way they have been abused, especially in Paris, should cause their proscription unless formally indicated. I am not now treating of their indications, my object being a more limited one—that of pointing out the inconvenience and danger of their repeated and prolonged employment."

REVIEWS.

1. *A Manual of the Practice of Surgery.* By W. Fairlie Clarke, M.A. and M.B. Oxon., F.R.C.S., Assistant-Surgeon to the Charing-cross Hospital. Second edition, revised, enlarged, and illustrated by 144 engravings. London: Henry Renshaw, 356, Strand. 1874. Pp. 402.
2. *A Manual of the Operations of Surgery, for the Use of Senior Students, House-Surgeons, and Junior Practitioners.* By Joseph Bell, F.R.C.S. Edin., Lecturer on Surgery, Surgeon to the Royal Infirmary and to the Eye Infirmary, and late Demonstrator of Anatomy in the University of Edinburgh. Third Edition, revised, enlarged, and illustrated. Edinburgh; Maclachlan and Stewart. London: Robert Hardwicke. 1874.
3. *The Student's Guide to Surgical Anatomy: being a description of the most important Surgical Regions of the Human Body, and intended as an Introduction to Operative Surgery.* By Edward Bellamy, F.R.C.S., Associate of King's College, London, Senior Assistant-Surgeon to the Charing-cross Hospital, Surgeon to the Royal Infirmary for Children, Waterloo-road, and Teacher of Operative Surgery in the Medical School of Charing-cross Hospital. London: J. and A. Churchill, New Burlington-street. 1873.

These three manuals are to a great extent supplementary of

one another, and they supply in a piecemeal manner much of all that knowledge which is required to make a competent practical surgeon. We fail, however, in seeing any advantage which small manuals of the practice of surgery and of surgical operations possess for house-surgeons and practitioners over such works as Erichsen and Bryant, for example, in which full descriptive accounts of diseases and injuries and their pathology are given side by side with directions as to what is best to do in different kinds of cases.

Indeed, we would go further, and say that it is vastly more important—and it would be well if all young surgeons felt it to be imperative—that comprehensive treatises should be adopted as guides to practice: works which, as well as being accurate and judicial, are critical and explanatory, rather than those which, to be concise, are authoritative and dogmatic, and abound in tutorial, but not reasoned-out preferences.

It is most undesirable that instruction upon great and intricate subjects—such as surgery, which in its nature and consequences is of momentous importance—should be supplied in a cut-and-dry sort of way; or that it should be dealt out as an exercise for the memory rather than for the reasoning intelligence of the instructed.

It is not the hard rock of dogmatism so much as the bread of lucid exposition that is required. But a small foolscap octavo volume upon a great practical subject must necessarily abound in dogma, and cannot be expositive.

But let it not be supposed, however, that we condemn the substance of the handbooks before us. On the contrary, we commend these manuals so far as they go; while Mr. Bellamy's work on surgical anatomy extends, we think, in area quite as far as it could or ought to go, and in detail, if anything, it errs on the side of fulness and even diffuseness.

Now to add a few words upon each work separately. The merits of Mr. Clarke's manual have evidently been appreciated, as it has now reached the second edition. To this edition has been added the supplement to the first—viz., the little work on "Bandages and Splints"; and the book, as it is now brought out, is improved by the addition of several illustrations—many of which have been copied from sketches by the author himself,—and also by a formulary of receipts and prescriptions, to which frequent reference is made in the text.

The contents are divided into five parts—on (1) Surgical Diseases; (2) Surgical Injuries; (3) Constitutional Effects of Surgical Diseases and Injuries; (4) Diseases and Injuries of Various Parts—Tissues and Organs; and (5) Operations.

It would be obviously unfair to complain of the arrangement of a book intended merely as a pocket guide for young practitioners when reference to any subject is made easy by a good index. But at first sight it strikes us with surprise that surgical diseases are dispensed with in forty-six pages, half of which treat of tumours, and nearly all the rest of inflammation, scrofula, and tuberculosis. No mention is made in Part 1 of venereal diseases, and we look in vain for surgical fever, erysipelas, and pyæmia. These latter diseases, with tetanus and hysteria, are included under Part 3, but we confess to strong misgivings that a very wrong impression is likely to be conveyed by grouping such formidable and fatal diseases as these under the heading of "constitutional effects" of diseases and injuries. Even collapse, as the author himself states, may be produced, independently of any disease or injury, through a sudden mental impression; moreover, some reference ought to be made to the distinction between collapse with hæmorrhage and collapse without hæmorrhage. In the latter case it is open to a doubt whether the injunction, "while the collapse continues, bleeding should on no account be practised," is invariably a sound one.

The amount of space allotted to the various subjects is not in all cases proportionate to their importance. For instance, in Part 4 it will be noticed that paracentesis abdominis occupies nearly as many lines as "ovarian disease," including ovariotomy, not much less than "penetrating wounds of the abdomen," and about half the space of "malignant tumours of the breast." Again, two pages and a quarter are devoted to bubo, and about three pages to the wide subject of secondary syphilis; while ulceration of the great toe receives nearly as much attention as all the varieties of club-foot and their treatment. We are pleased, however, to find that twenty-four pages are given up to diseases and injuries of the eye, in which most of the affections of this organ are alluded to with more or less brevity. It is gratifying to find that the essentials of the surgery of the eye are not altogether omitted from a manual on general surgery.

The get-up of the book is excellent, the illustrations are as clear and telling as they are useful, and the manner and style of the author are good. We have no doubt that the second edition will find even more favour than the first.

Mr. Bell has already on more than one occasion been complimented upon his Manual of Surgical Operations, while the teachers and the students of operative surgery have shown in a very practical manner what their estimation of the book is, as it has now reached the third edition. As is well known to those familiar with the former editions, the manual is chiefly intended to direct students in practising operations upon the dead subject. It supplies, too, a well-tried and systematic arrangement of the course of instruction on the cadaver, and is, therefore, useful to the demonstrator as well as to his class. As a ready aid to the practitioners in the Services, in the colonies, or in the country, who, being thrown upon their own unassisted resources, must themselves occasionally perform important operations, we do not, for the reasons we have stated, consider it has any peculiar merit.

The aim of the author has clearly been to retain the original size and character of his work; and, without pretending to originality, without completeness of detail or variety of method, and while many omissions are self-evident, Mr. Bell's book is, as it ever has been, a methodical and trusty guide and an accurate and intelligible treatise.

Mr. Bellamy's Guide to Surgical Anatomy is a work dedicated to an anatomist by a teacher of anatomy. It will occupy a useful place amongst surgical text-books, as it presents in a compact form those portions and that kind of anatomy which students ought to know when going up for their pass examinations. Although nothing strictly relevant to the subject can be added in a volume on surgical anatomy which is not contained in works of anatomy in general use, still such a volume is valuable to men in the midst of their surgical studies, to whom it would be useless to commend a perusal of Quain and Sharpey, Ellis, Holden, or Hilles.

A treatise on surgical anatomy is, too, and ought to be, a very different thing from one on operative surgery. Surgical anatomy is the foundation-stone of operative surgery, and a knowledge of it ought to be acquired before operations on the dead body are commenced. The one is the science upon which the art is based; the other, the art based upon that science. The one recognises and registers phenomena; the other has an object to gain, and applies means for its accomplishment. The one deals in facts, and is an assemblage of truths; the other deals in precepts, and is an assemblage of directions for action. The one speaks in the indicative mood, and says, "This is the situation of the femoral artery, and these are its relations;" the other speaks in the imperative mood, and says, "Do this, and avoid that, in order to tie the femoral artery." The one has a wider application than the other, is requisite for a correct diagnosis, and often renders as much assistance to the surgeon where an operation is not, as where it is demanded. Hitherto there has been no handbook by any English teacher on surgical, or, as Mr. Bellamy terms it, "applied anatomy," although Mr. Galton has supplied the English student with an excellent translation of Professor Roser's work on the subject. Mr. Bellamy's book, though divided up in the same general manner as Professor Roser's, differs from it in its more detailed arrangement and treatment. The anatomical descriptions are, as might be expected from the author's experience as a teacher of anatomy, reliable and good. For a work on applied anatomy, however, they every now and then impress one a little too much from the dissecting-room rather than from the bedside or operating-theatre point of view; while the directions given for the dissection of parts and regions are not necessary for the ends of surgical anatomy, and are likely to weary and harass the reader. In places the author's thoughts have been too concentrated upon the matter to allow him to pay sufficient attention to the manner of his writing, in consequence of which the sentences occasionally strike harsh and dissonant, and sometimes their meaning is even obscure. On the whole, however, the book is a very creditable performance, and we cordially congratulate Mr. Bellamy upon having produced it.

Letts's Medical Diary for the Year 1874.

Letts's Diaries, 1874. London: Letts, Son, and Co.

Of the general excellence of Letts's Diaries it is scarcely necessary for us to speak—it is acknowledged on all hands; and the issue for 1874 is no whit behind its predecessors. The

"Medical Diary" will prove a very valuable companion to the busy practitioner. It contains a well-arranged visiting-list for every day in the year; a diary for meetings of societies, and other engagements, including midwifery, 280 days from the date being calculated in a parallel column; scales of professional fees; information on English and foreign baths and mineral waters; a table of antidotes for poisons; information as to the administration of chloroform; therapeutic equivalents; the hypodermic injection of remedies; the chemical relations of the urine; English and metrical weights and measures, etc. A more useful pocket-book for a medical practitioner is not to be found. It can be obtained in different bindings, varying with the price. We can cordially recommend it.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 9.

Dr. C. J. B. WILLIAMS, F.R.S., President, in the Chair.

DR. JOHN HARLEY related the particulars of four cases of Disorders of Muscular Movement illustrating the Uses of Conium, which he demonstrated on the patients at the meeting. He said: At the present time an unusually large proportion of my patients are afflicted with nervous disorders, and as several of them are taking full doses of hemlock, I have availed myself of the opportunity of calling the attention of the Society to the uses, both medicinal and surgical, of this invaluable plant. I propose to demonstrate the action of the medicine, and with this view I will at once give three or four of the patients their customary dose, in order that the Fellows may witness the effects towards the close of the meeting. 1. The first patient, W. N., aged 44, is the subject of spasmodic wry-neck, of a chronic and severe nature. The right arm is almost equally affected, and while the head is plucked round to the right, and the chin tilted upwards, the arm is drawn over the chest to the other side of the body. He has been under my care for the last month in St. Thomas's Hospital, and during this time has taken from three to seven ounces of the succus conii of the British Pharmacopœia daily; he is at present taking three ounces and a half of the juice—the quantity which I now give him. 2. The second case is a similar one, but the spasm has not existed for more than fifteen weeks, and it is confined to the muscles of the neck. He too, is a strong, middle-aged, and otherwise healthy man. He has been under my care six weeks, and during this time has taken from five to seven ounces of the juice daily. He will now take his customary dose of three ounces and a half. 3. The third patient, a healthy young man, aged 19, has been long incapacitated for work by spasm of the muscles of the right upper arm. I have only recently given him conium in full doses. He will now take three ounces of the juice. 4. The fourth case is that of a little girl, aged 4½ years. Up to the time she came under my care she was the subject of epilepsy and complete hemiplegia of the right side. She has taken a paralysing dose of hemlock twice a day almost every day for the last three months. The juice I have given is that which I have used for the last year. It is, for juice, an efficient preparation, and one-sixth of the quantity which I have given those men is sufficient to produce moderate cicutism in a woman or a weakly man. I need not observe that the doses which I have administered to these patients are large, nor that the disorders under which they labour require strong treatment. In such cases there was from the first an almost or altogether uncontrollable irritation of the motor centres, an irritation which has now long since degenerated into a vicious habit—the muscles of one side exercising a withering tyranny over those of the other. To relieve such affections the remedy must be somewhat proportionate to the disease. If our patient is overcome by convulsion, we must overcome the convulsion by paralysing, within the limits of safety, the motor centres. If we do not adopt this principle of treatment and conquer the spasm, we may be sure it will maintain the ascendency. I have assured myself of one remarkable and most encouraging fact—namely, that while hemlock is from day to day, from week to week, and from month to month, quieting and restraining the turbulent centres of motion, it is at the same time invigorating them; and that while it holds spasm of one set of muscles in check, the corresponding muscles of the other side, which have perhaps become weakened and atrophied, rapidly improve in nutrition and power. This is most notable in children, and the little patient (Case 4) whom we have just had before us is a good example of it. The voluntary motor system is daily soothed to rest by the conium, as the intellectual portion of the brain may be soothed by opium to sleep, and when it awakes it is refreshed, not for unhealthy, but for healthy action. Here we recognise a most beneficent action—an intelligibly curative effect. The little girl is making a speedy recovery. Three months ago her mother carried her about in her arms; she could not walk, and the right arm hung useless by the side, and for the previous two months she had from five to nine convulsive seizures with loss of consciousness every day. From the day she came to me to the present time I have daily induced cicutism. The fits ceased at once, and there has not been a single return. She now walks alone, and is able to use the arm and raise it to her head. The cases of spasmodic wry-neck have benefited greatly; indeed, ever since I have induced strong cicutism daily in the patients the spasm has been, in the one case (the second) wholly arrested; and in the other almost abolished, and the use of the right arm has been restored. The other case (spasm of the arm) as yet has derived no benefit, but he has had efficient doses of hemlock only one week. Such are the indications for and results of medicinal treatment in disorder of muscular movement. I would now very briefly direct your attention to the surgical uses of hemlock. If you examine the patients at the end of this meeting you will find complete relaxation of the whole muscular system, and the muscles of the head and face are apparently affected to a greater degree than those of the rest of the body. The orbicularis is incapable of resistance; the movements of the eyeball are very sluggish, and there is more or less complete ptosis. The muscles of mastication and deglutition are nearly paralysed. Speech is slow, and effected with exertion; the voice is gruff, from relaxation of the laryngeal muscles. Withal, the heart and breathing are normal, sensation and intelligence are perfect, and the mind is calm. The surgeon will infer from these facts the value of conium in trismus, in spasm of the orbicularis and of the gullet, and in dislocations of joints, where the action of powerful muscles resists the efforts of the surgeon. To the ophthalmic surgeon conium is ready to become a valuable assistant. It at once relieves, as by magic, that powerful spasm of the orbicularis in keratitis which is caused by photophobia; and it is savage to talk of division of this muscle as a preliminary to incisions of the eyeball. There is one operation in which it will prove a great boon; that is, the removal of artificial substances from the gullet. Accidents are occasionally happening with false teeth: it is a merciless and dangerous operation to attempt the removal of such bodies from the stomach or œsophagus without first removing the spasm which their presence causes, and at the same time relaxing the tube to facilitate their extraction. I will not enlarge upon this topic; when you see the effects on the muscular system you will readily make your own inferences. I will, however, ask you to bear in mind one important fact—namely, that hemlock is totally destitute of anæsthesial properties, and that patients under its influence are able to help you by their efforts, and to guide you by their sensations. Those who are unfamiliar with the action of hemlock will probably think that there is danger in using it in the way I have done to-night. I can say positively that there is none. The effects of hemlock are remarkably uniform. The dose required is always proportionate to the motor activity of the individual. Relaxation of the orbicularis muscle may be used as an indication of the degree of cicutism. This indication may be safely reached by giving, a day or two prior to the operation, two or three increasing doses of the medicine. The succus conii varies considerably in power; that which I have used is perhaps a little stronger than the average, but I have at the present time four patients who are taking more than two ounces, six one ounce and a half, and more than a dozen one ounce as a single dose. And yet the succus is the only efficient preparation in the Pharmacopœia. I have long ago shown how a much more powerful medicine may be obtained.

Mr. B. CARTER asked Dr. Harley if he had any experience of these remedies in the condition called nystagmus, where there was a constant to-and-fro lateral and slight rolling movement of the eyeballs. This was supposed to depend on early defect of vision, so that the muscles never had time to become properly fixed so as to allow of distinct vision in one position.

Section of the orbicularis had been long discontinued; spasm could be relieved by a slight incision.

Dr. O'Connor asked if the first or second year's leaves had been used.

Mr. T. Smith asked what cases the remedy had been used in.

Dr. Harley said conia acted exactly like the succus, but was not so suitable for exhibition. He had used conium most largely in epilepsy and chorea, especially in chorea dependent on irritation of the corpora striata, and in the irritable condition of teething children. It was useless in paralysis agitans, save in the first stage. The eyeball was almost fixed. He could not tell what plant was used, but the annual was nearly as powerful as the biennial.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, December 4.

E. J. Tilt, M.D., President, in the Chair.

The following gentlemen were elected Fellows of the Society:—James Johnson Bailey, L.P.B.S. (Stockport), W. A. Concanon, L.K.Q.C.P.I., and Robert William Parker, M.R.C.S.

Dr. G. Murray exhibited an Intra-uterine Pessary hinged to a vaginal portion shaped like Hodge's ring pessary.

Dr. Wynn Williams exhibited a Shield for Supporting a Vulcanised Stem Pessary, which he used in the treatment of anteflexions. It has a pouch or socket in its lower part sufficiently large for the button of the stem to fit into. After introducing the stem by means of the stilette, the shield is passed over the handle of the stilette through a hole in the centre of the pouch, and is thus guided to the button of the stem, which readily falls into its place and is there retained.

Dr. Chambers exhibited his Divaricating Vulcanite Intra-uterine Stem, which he said was light, well retained, and answered all the purposes for which it was required most satisfactorily.

Dr. Tapson related a case of Intra-uterine Tumour. The author having found great difficulty in removing an intra-uterine growth by the ordinary écraseur, and others also failing, he at length effected his purpose in the following way:—Through two canulæ were introduced pliable cutting wires, which were passed high up into the uterine cavity. One canula being made a fixed point, the other was passed round the tumour, encircling it in the loop thus formed. The canulæ were then withdrawn, and the wires externally connected with the écraseur, and thus the tumour was cut through at its base, and the mass removed.

Dr. Potter believed that Dr. Frederick Bird, who had been consulted in this case, would at no distant date send a short communication to the Society describing more perfectly the instrument which had been used.

A case of Extra-uterine Pregnancy was communicated by Dr. MacCullum, of Montreal. The author of the paper was called on by the husband of a lady who appeared to be suffering from a severe attack of indigestion. She was then in her fourth month of pregnancy. He prescribed for her, and made a visit upon a patient some distance from home. On his return in three hours he found an urgent message to visit the lady, and on his arrival found her dead. She had suffered from severe vomiting, abdominal pain, and great faintness; her features became blanched, her countenance changed, and she told them she was dying. She had died about twenty minutes before his arrival. Upon examination the next day, an immense effusion of blood was found in the peritoneal cavity. The fœtus was discovered lying in the abdomen, and connected by a funis with an imperfectly developed placenta. The sac was formed by the structures of the Fallopian tube, near the centre of which the ovum had apparently been arrested. The ovary of the same side contained a corpus luteum. The uterus was increased in size, somewhat flaccid, and its inner surface was covered with a well-marked decidua.

The author also related a second case, which he had diagnosed as a case of Extra-uterine Pregnancy during the second month of gestation. The patient recovered, and, becoming again pregnant, was delivered at full term seventeen months afterwards.

Dr. Edis thought the best treatment in these cases, when there was evidence of collapse from internal hæmorrhage, was the application of cold to the abdomen with pressure, stimulants being only given if absolutely requisite to avoid a fatal termination, the employment of opium being rather indicated. He had found this treatment successful, although the patient was moribund when first seen.

Dr. Aveling said, as the subject of extra-uterine pregnancy was before the Society, he would like to take the opportunity of asking of any Fellows who had met with cases of the abdominal kind in which the fœtus had arrived at maturity, whether in such cases the ordinary uterine pains occurring during labour were observed.

Mr. Scott believed that in the first case mentioned by the author of the paper death had resulted from rupture of the sac, caused by the effort of vomiting—an accident which he believed to be always imminent in these cases from the extreme tenuity of some part or other of the sac. In answer to Dr. Aveling, he begged to refer him to a case which he had read before the Society, in which pains came on at term, subsided for some weeks, and then recurred with such intensity as to necessitate an operation.

Dr. Phillips also, in answer to the same question, stated that he had seen a case of abdominal pregnancy in which labour pains came on at term, and milk appeared in the breasts.

Dr. C. H. F. Routh read a paper, "On the Use of the Intra-uterine Stem in Uterine Diseases." The author, after premising that the most opposite opinions were held by learned men of different schools as to the usefulness of intra-uterine stems at all, pointed out that this arose from sufficient precautions not being taken before they were used; and that it was not sufficiently clearly laid down in what special uterine diseases they should be employed; and thirdly, in the quality of the instrument to be selected. Where proper care was taken to meet these three contingencies the use of intra-uterine stems was both safe and advantageous. I. Preliminary Treatment: All inflammatory and congestive symptoms should be first combated. Local blood-letting, by leeching, scarification, or it may be by the hysterotome; in cases complicated with general induration, potassa fusa; in cases of fundal endometritis, in addition, blisters to the abdomen. In milder examples, glycerine stupes applied for a week or so to the cervix uteri, etc., besides ordinary dietetic means and occasional laxatives. 2. In some cases it was necessary, in addition, to enlarge the cervical canal by tents. The author showed that some of the accidents following the use of tents were due to the neglect of precautionary measures preceding their use; also to the tents not having been properly disinfected; also to straight tents being forced up into straight uteri, in which cases flexed tents should be used. The author explained that some sponge-tents were injurious in this way, and that from too much pressure in their preparation their expansive power was much reduced. 3. The enlargement of the canal was sometimes best effected by the hysterotome, after which he introduced a small disinfected sea-tangle tent, covered with glycerinised and partly iodised cotton, into the outer part of the opening made, and kept it *in situ* by cotton plugs. This treatment was rarely followed by accidents. 4. His experience was entirely opposed to forcible and immediate dilatation by instruments. II. The author next proceeded to state the diseases in which the intra-uterine stem should be employed: 1. In cases of membranous cervix. One unsuccessful case was detailed as having led him to use the stem more heroically, and a second successful, in which this was done, was given in confirmation. 2. In cases of amenorrhœa not due to anæmia, but to a stoppage from some other accidental cause. The presence of a tent in utero provoked a catamenial flow. The advantages of a simple self-retaining stem over the stem made of copper and zinc were dilated upon, and a case given to illustrate the opinion. 3. In cases of dysmenorrhœa two varieties of this form of disease were given. In the first mechanical obstruction existed, and in the second the neuralgic element was most marked. Both had been cured by the elastic caoutchouc stem. 4. In cases of uterine flexion. A case of retroflexion was given, which was cured by the elastic stem, within which a spiral-coiled wire had been placed. The author recommended the use of internal stems, more particularly where Hodge pessaries had failed or could not be borne; where there was synchronously rectal disease, and where the flexions were very acute, with much fundal pain. III. The author then laid down what practice indicated as necessary conditions in the formation of an intra-uterine stem: 1. They should allow an omnilateral movement of the uterus. 2. They should not be longer than two inches, save in exceptional cases, in order that they may not touch the fundus uteri. 3. They should be bicornate

superiorly, so as to be retained in utero. 4. Their diameters should not be too small. 5. They should be light, and not easily corroded. IV. He then proceeded to show that the instruments already used were capable of division into seven groups: 1. Those which fixed the uterus like Dr. Simpson's original instrument. 2. Ordinary cylindrical stems with a disc, and which had been made of almost every known substance. These were chiefly disadvantageous inasmuch as they fell out, and prevented the resiliency of the uterus on itself. 3. Thoso with a vaginal support, either by a diaphragm or a Hodge. Like the last, they prevented the elasticity of the uterus on itself, but did not fall out. 4. Divaricating stems, as originally instituted by Graham Weir. These remained *in situ*, but they all prevented the elasticity of the uterus upon itself. 5. Coiled wire stems, which allowed for this uterine elasticity, but needed a support inferiorly. 6. Caoutchouc stems, as invented by Dr. Greenhalgh, and subsequently modified by others. 7. A modification of the fifth and sixth varieties combined, the caoutchouc stem having a thin coiled wire within. This last he had first used, and found very effective in some cases. Owing to the cornu superiorly a vaginal support could be frequently dispensed with.

Dr. Aveling said perhaps an appropriate opening to the discussion would be to call attention to a fact not mentioned by the author of the paper—viz., that intra-uterine stems were used in the seventeenth century. Henry van Roonhuyse, after dilating the cervix with gentian or sponge-tents, introduced a tent of silver, ivory, or horn after the fashion of a screw, thicker at one end than the other, and hollow. This, he said, might be carried without inconvenience. This practice was adopted in England by James Cook in 1647.

Dr. Barnes said he was convinced that intra-uterine stems were in properly selected cases of the greatest use. He had frequently employed the galvanic pessary with satisfactory results in cases of amenorrhœa, the catamenial discharge appearing and the nervous symptoms passing away. In consequence of the zinc portion becoming rough, he advised the removal and cleansing of the instrument once a fortnight. In cases of dysmenorrhœa he had after incising the os externum used Dr. Chambers' stem with advantage, pregnancy having frequently followed the removal of the dysmenorrhœal condition.

Dr. Heywood Smith supported Dr. Routh in his method of reducing uterine congestion by depletion before dilating the cervix uteri. In dividing the cervix he preferred the use of a nearly straight knife, and the introduction of sponge-tents after incision he thought dangerous. He waited until the edges of the incision healed before introducing any tent.

Dr. Squire remarked that if all the treatment described be really required merely with the object of introducing a stem, surely a prior question arises whether that operation should not be delayed until relief had been obtained by means less severe than those detailed in the paper.

Dr. T. Chambers said he had not found it necessary to adopt the prolonged preliminary treatment urged by Dr. Routh. He thought all dislocations should be reduced at once, and this method of treatment had in his hands proved most satisfactory. He thought it dangerous to introduce a stem in the consulting-room or out-door department of a hospital, and then allow the patient to go home. She should be kept in bed after its introduction at least a week.

Dr. Wynn Williams agreed with the last speaker that rest for several days was necessary after the introduction of the stem. Where much difficulty existed in introducing it, the stem should be made to assume the curve of the flexed uterus. He thought the precautionary measures proposed by the author should be carried out when any diseased condition existed.

Dr. Edis considered the employment of intra-uterine stems to be attended by much risk, not only to health, but also to life, and that although he had occasionally employed them, he avoided their use whenever it was possible. They should be employed with extreme caution and only after preparatory treatment.

Dr. Tilt, whilst admitting the value of stems, stated that he found it necessary to use them only in a limited number of cases. He was surprised that no speaker except Dr. Edis had taken into account the serious consequences that had occasionally followed the use of stem pessaries. He believed they not unfrequently caused or augmented uterine or peri-uterine inflammation.

Dr. Routh said, in answer to Dr. Squire, that if preliminary treatment cured his cases he never thought of applying the stem; and in answer to Dr. Tilt, he begged to say that he did not use the stem in *every* case, but only in those in which the ordinary measures failed.

OBITUARY.

HENRY WILLIAM FULLER, M.D., F.R.C.P.,

Was the son of Mr. W. Fuller, of Piccadilly, one of the leading general practitioners of the time, and "Visiting Apothecary to St. George's Hospital." Henry William Fuller entered as a student at St. George's Hospital, and afterwards studied at Cambridge, where he took the M.D. degree in 1851. He was elected a Fellow of the College of Physicians of London in 1852. He was early in life, by the influence of his father and friends, elected Assistant-Physician to St. George's Hospital, subsequently became Physician, and at the time of his death was Senior Physician. He was a painstaking and careful physician, and a courteous and intelligent gentleman. Without striking brilliancy of talent, he was throughout life a hard worker and a large contributor to professional literature. He was author of works on various diseases and subjects of practical professional import—viz., "On Rheumatism, Rheumatic Gout, and Sciatica," "On Diseases of the Heart and Great Vessels," "On Diseases of the Lungs and Air-Passages," "Tracheotomy in Croup," "Action of Belladonna, and on certain Causes which Modify its Action," etc. These works are carefully written, and give evidence of the conscientious manner in which he studied disease both at the bedside and in the writings of others. He was a fellow and member of various societies, and consulting-physician to several institutions. He died after a few days' illness from pyæmia, originating in abscess of the lung, in his fifty-sixth year. He will be deeply regretted by a large number of professional friends in London and the provinces.

GEORGE BURT, F.R.C.S.,

Was a native of Suffolk. He became a student at the then united hospitals of St. Thomas's and Guy's, under Cooper, Cline, and other distinguished men of the early part of the present century. He passed the College of Surgeons in 1810, and soon after commenced practice in Norfolk. He did not long remain there, and removed to Colchester, where he practised for a short time. He then came to London, where he spent the rest of his life. He resided in several places, but chiefly in Bridge-street, Blackfriars. He admired London very much, and rarely left it even for a short holiday—indeed, during his long career in the metropolis of at least half a century he has been known to leave it on pleasure three times only, and each for a very short period. He became a very diligent attendant at the Skin Hospital, then in Bridge-street, where he sat for many hours together assisting the late Mr. Startin, and frequently acting for him. He was afterwards appointed Surgeon to the Hospital, in which he took the greatest interest. He was a devoted lover of his profession, and had scarcely any pleasure or recreation out of it, and he followed up his duties at the Hospital to the very last, until his failing health (for he suffered for years with prostatic and vesical disease) compelled him to desist. He was a good and skilful practitioner, a kind-hearted and honourable man. He had one son, who was a private pupil of the late Mr. B. Cooper, and shortly after becoming a member of the College he died from blood-poisoning.

Mr. Burt through life never partook of stimulants, but was a great lover of tea, which he maintained always agreed with him. He was a member for many years of the Medical Society, which held its meetings in Bolt-court, but from his advaneed age he has outlived all his contemporaries.

JOHN SKAIFE, L.R.C.P. Edin., M.R.C.S.,

Died on the 12th inst. at his native place, Easington, Yorkshire, whither he had gone for the benefit of his health. Mr. Skaife formerly practised at Myddelton-street, Clerkenwell, and subsequently at 12, Northampton-square, where he carried on a considerable practice. He had been ailing from consumption for some time, but had been seriously ill for the past six months. He retired from practiee in May last. Deceased was forty years old.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, December 18:—

Crowther, Arthur Bingham, Hobart Town, Tasmania.
Dodson, Andrew, Sheinton, Shrewsbury.
Hamerton, George Albert, Gloucester-road, Peckham.
Harsant, William Henry, Epsom.
Hawkes, Anthony Mann, Doughty-street.
Hunt, Robert Edmund, Gort, Ireland.
Nicholson, Arthur, Newark-on-Trent.
Riding, Edwin, Liverpool.
Russell, Francis John Roberts, West Ham.
White, Ernest William, Norwich.

The following gentleman also on the same day passed his primary professional examination:—

Hughes, William Lewis, London Hospital.

The following gentleman passed on the 11th inst.:—

Carter, Frederick Heales, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

DAVIDSON, DAVID CHARLES, L.R.C.P. and L.R.C.S. Edin.—House-Surgeon to the Dorset County Hospital, Dorchester, *vice* Mr. Hollis, resigned.

GOEDICKE, F. W. E. R., L.F.P.S. Glasg., L.S.A.—Medical Officer of Health for the Parish of East Ham and Little Ilford.

STEWART, JAMES, B.A., L.R.C.P. Edin., L.R.C.S.I.—Second Assistant Medical Officer of the Kent County Asylum, Maidstone, *vice* David Hughes, M.R.C.S.E., resigned.

VINCENT, H. B., M.R.C.S., L.S.A.—House-Surgeon to the North Lonsdale Hospital, Barrow-in-Furness, *vice* J. Settle, resigned.

WOOD, T. OUTTERSON, L.R.C.P. Edin., M.R.C.S.E.—Third Assistant Medical Officer of the Kent County Asylum, Maidstone.

BIRTHS.

HACKNEY.—On December 20, at The Laurels, Warbleton, Hurst Green, Sussex, the wife of Alfred H. Hackney, M.R.C.S., of a son.

KNIGHT.—On December 18, at Shorleycroft, Keswick, the wife of Alexander A. H. Knight, M.D., of a son.

SCOTT.—On December 16, at 16, Murray-street, Camden-square, the wife of David Scott, M.D., of a son.

TEEVAN.—On December 16, at 10, Portman-square, the wife of William Frederick Teevan, F.R.C.S., of a daughter.

DEATHS.

BRIGHT, ELIZA, widow of the late Richard Bright, M.D., F.R.C.P., F.R.S., Physician-Extraordinary to the Queen, at 8, Southwick-crescent, Hyde-park, on December 18, aged 72.

FULLER, WILLIAM, M.D., F.R.C.P., Senior Physician to St. George's Hospital, at 13, Manchester-square, on December 18, in his 53rd year.

GROVE, EMMA, wife of John Grove, M.D., at Hampton, Middlesex, on December 20.

PLUMBE, ROBERT, late Surgeon on Madras Establishment, at his residence, 11, Leonard-place, Kensington, on December 19, aged 70.

TURNER, THOMAS, F.R.C.S., at his residence, 77, Mosley-street, Manchester, on December 17, in the 81st year of his age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

CITY OF LONDON LUNATIC ASYLUM, STONE, DARTFORD, KENT.—Assistant Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Committee of Visitors, under cover to Henry F. Youle, Clerk to the Committee, Guildhall, London, on or before January 15, 1874.

COTON-HILL INSTITUTION FOR THE INSANE.—Assistant Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Dr. Hewson, Coton-hill, Stafford.

GENERAL HOSPITAL, NOTTINGHAM.—Physician. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before March 10, 1874.

GERMAN HOSPITAL, DALSTON.—Honorary Medical Officer to the Eastern Dispensary. Candidates must be natives of Germany and be duly qualified. Applications, with testimonials, to Dr. Walbaum, Hon. Secretary, on or before December 29.

HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.—Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to the Honorary Secretary, on or before January 15, 1874.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, DUBLIN.—King's Professorship of Medicine. Candidates must be duly qualified. Applications, with testimonials, to Dr. G. Magee Finny, Registrar of the College of Physicians, and to the Rev. Dr. Carson, Registrar of Trinity College, Dublin, on or before February 1, 1874.

QUEEN ADELAIDE'S DISPENSARY, POLLARD-ROW, BETHNAL-GREEN-ROAD.—House-Surgeon. Applications, with testimonials, to the Rev. Thomas Peckston, 260, Cambridge-road, E., on or before January 2, 1874.

RADCLIFFE INFIRMARY, OXFORD.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before January 10, 1874.

ROYAL LONDON OPHTHALMIC HOSPITAL.—Assistant House-Surgeon. Candidates must possess a knowledge of diseases of the eye. Applications, with testimonials, to the Secretary, on or before January 1, 1874.

ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Assistant-Secretary, on or before January 12, 1874.

ST. GEORGE'S (HANOVER-SQUARE) PROVIDENT DISPENSARY, 59, MOUNT-STREET, GROSVENOR-SQUARE, W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to the Secretary, on or before December 29.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before December 28.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY AND DISPENSARY.—Senior House-Surgeon. Candidates must be doubly qualified. Applications, with testimonials, to the Medical Board, on or before January 1, 1874.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WESTMINSTER HOSPITAL.—Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Each candidate must attend (with his testimonials) the House Committee on February 10, 1874.

MR. DAVID SKINNER, M.R.C.S. Eng., late Medical Officer for District No. 5 of the Hollingbourn Union, Kent, has obtained a superannuation allowance of £30 per annum.

THE Rathkeale Board of Guardians have increased the salary of Dr. McCoy, Medical Officer of the Rathkeale Dispensary District, from £100 to £120 per annum.

THE LATE FOG.—The following notes of cases of accident admitted at the London Hospital during the late fog reached us too late for insertion last week:—*Case* 1: J. C., aged 62, whilst going to his work at four o'clock on the morning of December 10, lost his way in consequence of the dense fog, and "fell into a pit," where he lay for some time in an insensible condition. On admission he was perfectly sensible, and found to have a severe laceration extending through the left cheek and laying bare the facial artery for an inch and a half, but with no wound of the vessel. *Case* 2: J. H., aged 45, was admitted about 11 p.m. on the night of December 11, with a fracture of the second rib of the right side near its sternal end, and also fracture of the right scapula, about one inch and a half of the inferior angle being broken off; fracture of ribs beneath it; also emphysema of the same side. He stated that he was a shipkeeper, and went on board a ship lying in the river at seven o'clock in the evening, there being a dense fog at the time, when a dog flew at him, and, to get out of the dog's way, he unfortunately stepped back and fell into the ship's hold, a distance of twenty-five feet, his back coming in contact with some casks at the bottom of the hold. He was alone on board the ship, and remained where he fell for two hours, when he was found by another man, and brought to the Hospital. *Case* 3: G. S., aged 54, a "fitter," was in the engine-room of his ship, which was lying in the river, when, in consequence of the fog at midday on December 12, he fell into the hold, a distance of sixteen feet, alighting on his left shoulder. On admission he was found to have about an inch of the acromial end of the left clavicle broken off, and fracture of the fourth and fifth ribs of the same side.

THE return of deaths by the Sanitary Commissioner of the Punjaub for the week ending October 18 last states that—"The improvement in the public health noticed in last week's return has continued in the week under review. The total number of deaths has decreased in a large number of districts, and in some cases the decrease is very considerable. In a few there is a slight increase, but in the case of the latter the death-rate had not been unusually high before. Siálkot, Lahore, and Hoshiárpur continue very unhealthy, though there is a decrease of mortality in all three. The total deaths in Rewári have again fallen. In last week's return the number was 84; this week the number is just one-half, or only 42. The rapid decline of the epidemic will be seen from the following figures, which represent the total deaths in each of the last five weeks, viz., 140, 139, 99, 84, and 42. Delhi continues extremely unhealthy, though the total deaths have decreased from 185 to 151. In Faridábád, also, there is improvement, though the death-rate is enormous—viz., 195 per mille. The death-rates of this town for the last five weeks have been as follows:—228, 273, 176, 260, and 195 per mille. Excessive sickness continues in Bahadargarh, in the Rohtak district. This town has had a pestilential death-rate for some weeks. There is no improvement yet perceptible in Panipat, the death-rate is 101 per mille, as compared with 88 per mille for the previous week.

The total deaths have fallen in Jálandhar from 45 to 25, and in Tandah and Urmar from 35 to 27. Amritsar continues very unhealthy. There were only two deaths registered under the head of cholera; both of them occurred in the little village of Fírozpur in the Gurgaon district. Fifty-three deaths were registered under the head of small-pox; they occurred in thirteen different districts. Ten small-pox deaths were registered in Hazára, the highest number in any one district.

THE monthly report of deaths in the eight principal towns of Scotland for the month of November last states that the deaths of 2352 persons were registered, of whom 1184 were males and 1168 females. Allowing for increase of population, this number is 320 under the November average of the last ten years. A comparison of the deaths recorded in the eight towns shows that during November the annual rate of mortality was 20 deaths per 1000 persons in Edinburgh and in Dundee, 22 in Leith, 23 in Perth, 24 in Aberdeen, 26 in Glasgow, 37 in Paisley, and 43 in Greenock. Of the 2352 deaths, 961, or 41 per cent., were of children under five years of age. In Perth, 12 per cent. of the persons who died were under five years of age; in Edinburgh, 32; in Aberdeen, 35; in Greenock and in Paisley, 38; in Glasgow and in Dundee, 45; and in Leith, 58 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 574 persons, constituting 24 per cent. of the whole mortality. This rate was again exceeded in Paisley from the prevalence of scarlatina, and in Greenock from that of small-pox and scarlatina. Scarlatina was again the most fatal epidemic, having caused 213 deaths, or 9·0 per cent. of the whole mortality, being the same as during the previous month; but while the deaths from this disease slightly decreased in Glasgow, Aberdeen, and Greenock, those in Paisley increased. Small-pox was the next most fatal epidemic, and still continues on the increase, 83 deaths having been caused by that disease. Of these, 24 occurred in Glasgow and 54 in Greenock, constituting 2·2 and 23·6 per cent. of the deaths respectively in these towns. Fever caused 82 deaths, of which 36 were tabulated as typhus, 40 as enteric, 2 as relapsing, 2 as simple continued, and 2 as infantile remittent fever. Hooping-cough caused 38 deaths; croup, 38; diphtheria, 31; diarrhœa, 28; measles, 22; metria, 12; dysentery, 2; and cholera, 1. Fifty-one deaths were attributed to apoplexy, 46 to paralysis, 113 to heart diseases, 34 to hydrocephalus, and 91 to premature birth debility. The deaths from inflammatory affections of the respiratory organs (not including consumption, hooping-cough, or croup) amounted to 541, or 23·0 per cent. of the whole mortality. Those from consumption alone numbered 194, or 8·2 per cent.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. J. R. Phillips, Kanyaka.—Enclosure received.

Mr. J. E. Gross, Gibraltar.—Enclosure received.

Janson.—The note on the "Action of Pure Water upon Various Metals," by M. Chevreul, is in the *Comptes-Rendus* for November 17.

S. H. Y.—We believe that the Admiralty have decided upon granting double pay to all the medical officers belonging to the Royal Navy while attached to the forces under Sir Garnet Wolseley.

THE GOLD COAST.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to send you a note of some accounts of the Gold Coast which I picked up accidently lately:—"Cruickshank's Eighteen Years on the Gold Coast, 2 vols., 1853"; "Narrative of a Visit to Coomassie, by Capt. Winiette, late Lieut.-Governor of Cape Coast Castle"; *United Service Magazine*, June, 1849, p. 263, etc. Hoping these memoranda may be of some present interest, I am, &c., M. BLACK.

2, George-square, Edinburgh, December 20.

CASE OF SPASMODIC ASTHMA, ILLUSTRATING THE GOOD EFFECT OF CAMPHOR AND OPIUM WHEN GIVEN IN COMBINATION.

By A. CLARENCE FOSTER.

The following case may be deemed not unworthy of perusal, as it affords, apart from its general features, an interesting therapeutic incident not without some practical value:—

Miss L., aged 25, of regular habits and of average general health, was seized on the 30th ult. with slight fever, accompanied by a dry cough, which, however, was neither frequent nor severe.

She was put under mild antiphlogistic treatment, including small doses of tartar emetic, and went on favourably till the 3rd inst., when a most distressing attack of spasmodic asthma came on, lasting twelve hours. It set in at 11 a.m. and continued till 11 p.m., the patient sitting up in bed during the whole time, with the shoulders raised, and the head and body bent forward—any attempt to lean back making it impossible to breathe. The respirations during the fit were 90 per minute, with a pulse at 130. She was ordered while the paroxysm continued an ounce of gin every hour, alternately with a mixture containing full doses of carbonate of ammonia and ether. These remedies were given regularly to the end of the fit, but they had no perceptible influence in relieving it. At 11 p.m. the respiration became quite easy, the dyspnœa passing off without any expectoration, and the patient complaining of nothing but a feeling of exhaustion. The chest, when the paroxysm was over, sounded well on percussion. The circulation was tranquil, and the temperature not increased. Next day, about the same hour, she had another attack, continuing till night, and so the symptoms went on repeating themselves for a week, the patient having during this time frequent counter-irritants to the chest and back, and taking a great variety of antispasmodics, without obtaining the slightest relief; and as she had slept little from the beginning, a dose of chloral hydrate was now given, but with no better effect. She was then ordered half-grain doses of opium at short intervals, and although she took five grains in a few hours, it failed to procure either sleep or mitigation of the dyspnœa. Camphor, in two-grain doses, was now tried, with a like result, when, on the 12th inst., as soon as the fit came on, a powder was prescribed, containing one grain of opium and two of camphor, to be taken every two hours. After the first powder the breathing was much relieved, and when four had been taken it became perfectly easy. Two or three more, however, were administered at long intervals, and the patient remained, and now remains, free from any further attack.

The dyspnœa, under the influence of the powders, passed off gradually, and not somewhat suddenly as before, showing clearly that the shortening of the paroxysm and the prevention of its return were due to the action of the medicine.

It is an interesting circumstance that, although neither opium nor camphor taken alone had the slightest beneficial effect, yet when given together the result was to procure almost immediate relief.

Leeds, November 29.

COMMUNICATIONS have been received from—

Messrs. LETTS, SON, and Co., London; Dr. HENRY LEWIS, Folkestone; Mr. M. BLACK, Edinburgh; Mr. H. W. SAUNDERS, London; Mr. F. A. MAHOMED, London; Mr. W. C. BLAKER, Robertsbridge; Dr. J. W. MOORE, Dublin; Dr. PEACOCK, London; Mr. J. CHIATTO, London; Mr. J. R. PHILLIPS, Kanyaka; Mr. J. E. GROSS, Gibraltar; Dr. GALABIN, London.

APPOINTMENTS FOR THE WEEK.

December 27. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On the Motion and Sensation of Sound" (Juvenile Lectures).

29. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

30. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On the Motion and Sensation of Sound" (Juvenile Lectures).

31. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

January 1, 1874. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On the Motion and Sensation of Sound" (Juvenile Lectures).

2. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of Council.

EXPECTED OPERATIONS.

ROYAL FREE HOSPITAL.—The following Operation will be performed on Saturday (this day) at 2 p.m.:—

By Mr. Gant—Colotomy for Rectal Stricture.
