When there is only one imperfectly divided valve, there is probably always some obstruction to the flow of blood from the ventricle, though the gradually increasing power of the muscular walls may so completely compensate for the narrowness of the opening that no symptoms of the defect may arise. The condition is, however, a constant source of irritation, and the valves may thus become increasingly thick and rigid, till at length, the obstruction being no longer capable of being overcome, or the power of the ventricle being prostrated under some general depressing influence, or the muscular structure undergoing interstitial changes, and so becoming incapable of active contraction, the symptoms of aortic obstruction develope themselves. In other cases the symptoms arise during the progress of an attack of rheumatic fever from the occurrence of endocarditis of the defective valves, which under such circumstances are specially liable to become the seat of inflammation, and so the original defect is aggravated. A remarkable example of this kind, in which there were only two valves, one much larger than the other, with indications of imperfect division of the larger valve into three rudimentary segments, recently occurred in the Hospital, and has been exhibited by myself at the Pathological Society. In this case there could be no doubt that the aortic valvular disease originated in malformation; but the probable origin of the valvular disease in defective formation of the valves may be inferred in many other cases. Indeed, the condition of the valves described is often seen in combination with other obvious malformations of the heart, and occurs not unfrequently in very young children, and occasionally in infants that have never breathed. In other cases the condition in a very aggravated form is found in persons who die after comparatively short illness and have previously been entirely free from indications of any serious cardiac defect. I have seen several cases of this kind, in which a man has died after only a very short attack of illness, and in which after death very aggravated disease, which could obviously not have arisen in a short time, has been found; and in such cases the congenital origin of the disease may, I think, fairly be inferred.

2. Injuries of the aortic valves may be immediate or gradual. The valve may be torn, one of the angles being separated from its attachment to the wall of the artery, or the free fold may be lacerated, or the valve may be torn from the fibrous zone. The valve may also be gradually stretched so that the curtain hangs down at a lower level than natural. The former accidents generally occur while the patient is using some violent exertion; the latter condition ensues upon long-continued strain from hard work extending over several years. In either case the first effect is to occasion incompetency, but subsequently the valves become thickened and hardened, so as to be also sources of obstruction. It is, probable, also, that in some cases in which the valves become incompetent from injury the fibrous zone which bounds the orifice may become tonically contracted, so that the capacity of the orifice is diminished and the incompetency lessened; or there may be depositions of lymph on the edges of the torn valves and partial thrombosis, so as to reduce the space through which the blood can regurgitate.

3. Defects in the efficient action of the valvular apparatus may also result from alterations in the capacity of the orifice. This must be regarded as a tube of the depth of the valves, and either the outlet or inlet of the tube may be altered in capacity. In cases of dilatation of the ascending portion of the aorta the outlet of the orifice is generally expanded; and so the valves, which ought to come in contact over a considerable space when they fall back, overlap to a less and less extent, till at length they touch only at their edges. The edge then readily becomes everted, and so regurgitation occurs. On the other hand, with great dilatation of the ventricle the inlet of the orifice is often expanded, and in this case the tendency is for the sinus of the valve to become deepened, and then for the fold to give way at the most dependent point, so also allowing of regurgitation.

4. Lastly, the valves may be the seat of inflammation either as the primary source of disease or superinduced upon one or other of the conditions previously described. Thus, vegetations may form on the edges of the valves; or the surfaces may be thickened, the thickening either occupying the crescentic edge over which the valves in their healthy state come in contact when expanded, or the surface of the segments which are exposed to the ventricle under the same circumstances. In such cases the tendency is for the segments to be shorter and the sinuses shallower than natural, so that in addition to the obstruction caused by the thickened valves they become incompetent. Sometimes the obstruction thus occasioned is excessive; the valves become hardened and studded with cretaceous deposit, and the capacity of the orifice is very greatly reduced: instead of being, on the average, 35·6 Paris lines (80·1 mm. 3·14 E.I.) in men, and 34 (76·5 mm. 3·01 E.I.) in women, I have known it to measure only 24 (54 mm. and 2·13 E.I.), and even 18 Paris lines (40·5 mm. 1·59 E.I.); and in one very remarkable case, in which the obstruction probably originated in congenital malformation, there being only two segments, the aperture was a mere slit ten lines in length (22·5 mm. ·88 E.I.), and the valves were so extremely thickened and indurated as to be scarcely capable of separation.

In these cases of extreme obstruction there is often a tendency for the blood to burrow underneath the valves, so as to form a passage leading from the ventricle towards the commencement of the aorta, and such passage occasionally opens into the aorta, so that the blood flows into the artery during the systole and regurgitates into the ventricle during the diastole. Several cases of this kind have at different times fallen under my notice; you will find a preparation illustrating the condition in the Museum, which was described in the *Pathological Transactions* by Dr. Bristowe, and I have several specimens in my own collection at the Victoria-park Hospital.

Whether the disease of the aortic valves occasions obstruction or regurgitation, or both these defects, and whatever be the immediate cause upon which the disease depends, the left ventricle undergoes remarkable increase of capacity and strength, and thus the heart is larger and heavier than natural. If there be obstruction, the tendency is especially to increased thickness of the walls of the ventricle, the increased width being most marked at the base and diminishing towards the apex, so that the organ has a peculiarly pointed form. If, on the other hand, there be incompetency, whether as the primary disease or dependent upon previous obstruction, the special tendency is for the ventricle to be dilated; the cavity becomes very large, and is rounded at the apex, and the walls, though increased in thickness, have the increase more equally distributed over the parietes. In both these conditions, though the changes are the most marked in the left ventricle and auricle, the right side also becomes sooner or later involved, and in some cases the increase in the size and weight of the heart is very remarkable. I have found this organ to range in weight, in cases of aortic valvular obstruction, in males from

14 to 21 ounces avoirdupois, and in females from 13 to 18½ ounces; and in aortic regurgitation from 14 to 34 ounces in men, and from 16 to 23 ounces in women—this being a very striking increase of weight, for, as you will recollect I told you, the ordinary weight of the healthy heart is in men from 9 to 11 ounces, and in women from 8 to 10 ounces.

Mitral Valvular Disease.

Mitral valvular disease may originate in various ways.

1. The idea was first advanced by Mr. Burns, and has been supported by Dr. Farre, that mitral valvular contraction is sometimes congenital; but though it is probable that some of the very marked cases of contraction to which the term "button-hole" mitral has been given may be congenital defects, it is not often that malformation can be confidently assigned as the cause of the disease. One case, however, of the kind is included in the table, which occurred in a female of sixteen, in whom the foramen ovale was unclosed; and it is possible that some others, in which the patients had not had any other cardiac disease, and had been ailing all their lives, may equally have been of intra-uterine origin.

2. Injury has also in some few cases been a cause of mitral disease, the fold being torn through or the tendinous cords ruptured.

3. Probably, however, the largest proportion of cases originate in inflammatory changes; the folds of the valves may be thickened, the two curtains may be blended together, or the attached fold may become adherent to the lining membrane of the ventricle, and the edges and auricular surface of the valves may be studded with vegetations or larger or smaller deposits of fibrine, so as to be sources of obstruction to the flow of blood from the auricle into the ventricle. The valves also may become hard and unyielding, so as not to admit of closure, or the tendinous cords may give way so as to allow a portion of the fold to flap back with the systole; and in either case the blood will regurgitate from the ventricle into the auricle.

4. The orifice also may be dilated while the rest of the organ is unaltered, so that the valves are no longer capable of closing it; or the walls of the left ventricle may become dilated from overstrain, atrophy, or interstitial change, and incompetency may be occasioned by the imperfect adjustment of the valves so resulting. The simple dilatation of the orifice is, however, rare, though a case of the kind was in the wards during the course of last winter. We occasionally also meet with cases which present all the evidences of mitral regurgitation without the valves or orifice being diseased, and which can alone be explained on the assumption that the valves were not perfectly adjusted so as to close the orifice.

The changes which take place in the heart in cases of mitral valvular disease are scarcely less striking than those which occur in aortic valvular disease. In cases of mitral contraction in young subjects the folds of the valves become greatly expanded and are protruded forwards into the ventricle so as to fill a large portion of its cavity, the right auricle becomes greatly enlarged and its walls increased in thickness, and the lining membrane is thick and opaque and often rough. Thrombosis also not unfrequently occurs in the appendix of the auricle, and more rarely in the sinus, constituting the so-called aneurism of the auricle. Of the former condition I have a very good specimen at the Victoria-park Hospital; and of the latter there is also one in our own museum, which was described by Dr. Elliotson in his Lumleian Lectures. In cases of mitral constriction the right ventricle becomes large and its walls very thick and resisting, and the right auricle is dilated; the left ventricle being, however, not generally much altered in capacity or power. In cases of mitral regurgitation, on the other hand, and especially when of long duration, the left ventricle as well as the auricle and right cavities are dilated, and the whole organ becomes very wide and its apex blunted. But as in both cases the stress of the disease falls chiefly on the right side, the increase in the weight of the heart is less marked than in cases of aortic valvular disease. I have, however, weighed hearts thus diseased in males ranging from 14 ounces to 17 ounces in weight, and in females from 13 ounces to 18 ounces 8 drachms.

The degree of contraction of the mitral orifice is also sometimes very remarkable; often it is only a mere slit or a small oval aperture, and I have found it to have only a circumference of 18 (40·5 mm. 1·59 E.I.), 12 (27 mm. 1·06 E.I.), and 11 Paris lines (24·78 mm. ·96 E.I.), the natural circumference being 45·2 Paris lines (101·7 mm. 4 E.I.) in men, and 45 Paris lines (181·25 mm. 3·99 E.I.) in women.

It is scarcely necessary to dwell upon the cases of combined aortic and mitral valvular disease, except to remark that as regards the size of the heart these affections occupy also an intermediate position between the two separate forms of disease—the weight being less than in aortic and greater than in mitral disease. Thus, I have weighed organs which ranged from 14 ounces 8 drachms to 21 ounces 8 drachms in males, and from 7 ounces 8 drachms to 23 ounces in females.

I have already stated that the cases of aggravated pulmonic valvular disease, and of combined mitral and tricuspid, and of aortic, mitral, and tricuspid disease are probably always congenital.

ORIGINAL COMMUNICATIONS.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,
Resident Medical Officer to the London Fever Hospital.

No. X.

(*For Photo-lithographic Plate vide "Medical Times and Gazette," August* 9, 1873.)

Aneurism of Ascending and Transverse Aorta: Effect of Drugs—Abdominal Aneurism: Effect of Compression—Aneurism simulated by Endarteritis—Summary of Sphygmographic Evidence.

Aneurisms occurring in the course of the vessels going to the upper extremity formed the subject of the last communication, and their effect on the pulse-wave, the aorta not being involved, was found to be very great; while in those where the sac comprised part of the aorta, the difference between the two radial pulses was either extremely small or not to be distinguished. In the present paper aneurisms of the aorta itself will be discussed, and, though the results may be found in some cases disappointing, in others the testimony will prove of the highest value.

The first six tracings in Pl. viii. were obtained from a patient with aneurism of the ascending part of the arch. They are introduced to show how the effects of different drugs may be watched, and also to distinguish between the pulsation of an aneurismal tumour and that of the heart. T. S., a man aged 56, was admitted into Guy's under Dr. Wilks on June 24, 1873, with a pulsating tumour partially eroding the sternum and costal cartilages of the right side. He had all the symptoms of aneurism of the ascending part of the arch well marked. No doubt was entertained about the diagnosis. After remaining in the hospital for some months he left, his condition remaining unchanged.

Fig. 1, Pl. viii., represents his pulse under ordinary conditions. There was no difference to be detected between that of either side. The form of pulse is identical with that which accompanies hypertrophy of the heart and atheroma of the aorta, both of which were probably present: the tidal wave is prolonged, the pressure employed considerable, but no indications of aneurism are given. This is accounted for by two reasons—first, that the aneurism occurring previous to the point of origin of the innominate, both sides would be equally affected; secondly, aneurisms of the aorta, as previously remarked, frequently do not alter the character of the pulse, for no diminution of blood passing down either of the subclavians occurs, nor is there any diverticulum into which the blood flows before reaching the radial.

Fig. 2, Pl. viii., represents the pulse of the same patient after taking veratria for six days. He had been kept perfectly quiescent in bed, and this drug was exhibited, on account of its so-called depressant action on the vascular system, with the view of putting the patient in the most favourable condition for coagulation taking place in the sac. The very opposite effect is seen by the tracing to have been produced; the action of the heart has become more powerful and excited, the size of the pulse-wave being much greater, and the pressure employed also has been increased.

Fig. 3, Pl. viii., was obtained after the veratria had been discontinued for one day. The pulse has already visibly changed in its character: it is slower and softer, one ounce of pressure being all that is now required, instead of four ounces as on the

previous day. In one day more the pulse had returned to its usual condition.

Fig. 4, Pl. viii., shows the effect of digitalis administered in Mxx. doses of the tincture three times a day for seven days. The pulse is increased in size, and not retarded; neither of the drugs appear to have produced their usual physiological effect on this patient; the tracings, however, are only inserted to illustrate how accurately the effect of a drug on the vascular system may be gauged and demonstrated to others; and in no class of disease is it so important to be able to do so as in the one under consideration.

Figs. 5 and 6, Pl. viii., may be compared; they are tracings from two different forms of pulsation occurring in his chest-wall—Fig. 5 being produced by the tumour, Fig. 6 by the heart's apex. It is extremely interesting to notice the difference between them. In the former there is the single arterial movement, the sudden expansion, and the gradual and continuous collapse; in the latter the sustained contraction of the hypertrophied ventricle is demonstrated, the commencement and termination of the contraction being equally sudden.

Figs. 7 and 8, Pl. viii., are tracings of very great interest. In this case a double aneurism of the aorta was diagnosed by the sphygmograph. The pulse of the right side (Fig. 7) is decidedly aneurismal, the percussion being very slight—it only requiring one ounce of pressure, the up-stroke and apex seen in the tracing having been obtained with the greatest difficulty, while the tidal wave is prolonged and the dicrotic much diminished. On these grounds aneurism or dilatation of the ascending part of the arch before the origin of the innominate was diagnosed. On the left side (Fig. 8) the pulse has altered and become still more aneurismal in its character, percussion being much diminished and the tidal wave more prolonged, so that a square summit to the tracings is produced. On these grounds it was stated that another aneurism probably existed beyond the origin of the innominate, and in such a position as to interfere with the passage of blood down the left subclavian. A similar diagnosis was arrived at with some difficulty from physical signs by Dr. Wilks, and at the post-mortem was found perfectly correct; the ascending part of the arch being dilated to seven inches in circumference, and exactly opposite the origin of the left subclavian, behind and below it, was situate another aneurism pressing upon the trachea and touching the left side of the œsophagus. There was also a third aneurism two inches below the left subclavian. Here, then, is a case where the aorta alone was implicated, and yet an alteration was produced in the pulse of this side.

The next case illustrated is more obscure, the result not having transpired:—S. J., aged 46, a fish porter, was admitted under Dr. Wilks, June 7, 1873: a healthy-looking man, with good family history; had never had symptoms of constitutional syphilis; accustomed to carry heavy loads. He appeared in perfectly good health, appetite good, and bodily functions all regular; his only complaint was of partial aphonia, slight cough and expectoration, and a little pain on the left side of the neck, where there are some indurated glands. When he speaks, his voice is rough and hoarse; he makes no noise while breathing; there is no dyspnœa. His larynx appeared healthy when examined by the laryngoscope. Good resonance and normal respiratory murmur all over the chest, with the exception of slight occasional rhonchus. At the base of heart a systolic and diastolic bruit can be heard; the latter is transmitted down the sternum. The systolic bruit is harsh and rough, and can be heard between the scapulæ on a level with the third dorsal vertebræ. The pulsation of the aorta can be easily felt through the upper third of the sternum. The diagnosis was extremely obscure till the tracings of the pulse on either side were obtained by the sphygmograph, when they were found to differ greatly.

Fig. 9, Pl. viii., represents the pulse of the right side; it indicates especially an hypertrophied heart, and probably bad vessels. The pressure used was much greater than normal—namely, five ounces and a half; the percussion-wave is exaggerated; and the tidal sustained.

Fig. 10, Pl. viii., was obtained from the left side. The same pressure was used; it is, however, very much smaller than the pulse of the right side. The percussion, tidal, and dicrotic waves are all diminished, especially the first two. There is a tendency to rounding of the tops, and the pulse by comparison appears decidedly aneurismal. On these tracings a diagnosis of aneurism of the aorta between the origin of the innominate and left subclavian arteries was diagnosed. The man left the hospital two or three weeks after his admission, his condition being unchanged.

The next four tracings in the plate were obtained from J. D., a man under the care of Dr. Moxon and Mr. Durham, suffering from abdominal aneurism, whose case is fully reported in the volume of the Medico-Chirurgical *Transactions* for 1872, where the tracings also are published. Suffice it to say, that an aneurism of the abdominal aorta was ascertained to exist by post-mortem examination.

Fig. 11, Pl. viii., shows a perfectly normal, firm pulse, obtained with a pressure of three ounces from his right radial; while Fig. 12, Pl. viii., was obtained with a similar pressure from the left radial—*i.e.*, the one approximate to the aneurism. The waves are all more distinct and separated in this tracing. Why they should be so it is difficult to apprehend. One can only conclude that the proximity to the aneurism conduced to the result. Some difference has been found to exist in the pulse of the two radials in more than one instance of abdominal aneurism, though by no means in all. The difference is not sufficiently constant to found any rule or guide to diagnosis.

Figs. 13 and 14, Pl. viii., were obtained from the same patient while under chloroform, preparatory to compression of the abdominal aorta. Fig. 13, before compression was applied, is similar to the corresponding tracing in Fig. 11, except that one ounce more pressure was now employed; but immediately compression was commenced the pulse underwent an instantaneous and remarkable change: it became extremely dicrotic, as represented in Fig. 14. So marked and instantaneous was the alteration in its character, that by watching the lever of the instrument, while the back was turned to the operator, it was easy to tell the moment the artery was subject to pressure, and whether or not it was completely under control. This change was caused by the increased tension produced in the arterial system, or rather that part supplying the head, neck, and upper extremities, by the additional amount of blood contained in these vessels, while the supply to the lower half of the body was cut off. This brought the elastic coat of the aorta more fully into play, it being more distended and in turn contracting with greater vigour. It has been suggested that the stimulus of the pressure on the vaso-motor nerves altered in some way the condition of the blood-vessels, and so produced this result; but the effect was too instantaneous to be accounted for in this manner. Moreover, an exactly similar phenomenon to the one under consideration can be produced experimentally in a schema of the circulation by compression of the part representing the abdominal aorta.

The last two tracings are placed in the plate as examples of errors that may be made by the sphygmograph in the diagnosis of aneurism. E. F. was admitted into Guy's under the care of Dr. Moxon, November, 1871. His symptoms very closely simulated those of aneurism of the left subclavian involving the aorta, the principal being a rough systolic bruit heard in the aorta and transmitted along the left subclavian, severe but not constant pain down the left arm, and attacks of angina pectoris; there was, however, no pulsating tumour to be felt. The pulse-tracings in the two radials were found to differ, that in the left being the smaller. Fig. 15, Pl. viii., represents the pulse in the right, and is perfectly normal in appearance; while Fig. 16, Pl. viii., represents that of the left radial, and possesses aneurismal characters; the upstroke is distinctly sloping, and the percussion, tidal, and dicrotic waves are all diminished. This, taken with his other symptoms, led to a somewhat confident diagnosis of aneurism of the subclavian involving the aorta being made, in which, however, Dr. Moxon never agreed, he regarding the case as one purely of angina. The patient, after remaining in the hospital for some months, went out, and died suddenly the next day. A post-mortem was obtained, when ulceration and partial blocking of the coronary arteries were found, while the left subclavian was considerably diminished in calibre by endarteritis, producing great thickening of its walls, and diminishing its sectional area by fully one-half. There were patches of recent atheromatous inflammation of the aorta, but its elasticity was not perceptibly diminished.

From these tracings it will be seen that it is impossible to distinguish by the sphygmograph alone between diminution of the pulse from blocking of an artery by endarteritis and that produced by aneurism; but the presence or absence of a tumour will generally afford ground for a diagnosis, the other symptoms being similar. The presence of a tumour can generally be ascertained, and, if none can be discovered, endarteritis must be remembered as a probable alternative. Lastly,

in cases where tumour actually exists, and the diagnosis lies between a tumour *external* to the artery and aneurism, the sphygmograph will often distinguish between them; for while in aneurism, as we have seen, the secondary waves of the pulse—especially the percussion—are all diminished, and the upstroke becomes sloping, in cases of tumours external to the artery, pressing upon it and diminishing the pulse-wave, the upstroke is never sloping, it always remains vertical, while the percussion-wave remains well marked, sometimes more in proportion to the tidal than before; the dicrotic is diminished and sometimes annihilated. These results can be easily verified experimentally by partially compressing the brachial and obtaining tracings under these circumstances.

Finally, after reviewing the evidence afforded by the sphygmograph in cases of aneurism, we may sum up as follows:—

If the aneurism is one of an artery going to the upper extremity, and the aorta be not involved, valuable evidence will be given.

If the aneurism is one of a similar artery involving the aorta, frequently no difference can be detected in the pulsation of the radials.

If the aneurism be one of the aorta itself, and situated in the ascending part of the arch, no difference in the pulse of either side can be detected.

If of the transverse part of the arch, the pulse may or may not give evidence of its existence.

But in all cases the sphygmograph is useful in watching the effect produced by the treatment on the arterial system generally.

(*To be continued.*)

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, &c., &c.

(*Continued from page* 171.)

THERE is one phenomenon which, according to my experience, is constantly present after death from snake-bite—viz., rigor mortis. This has been referred to, I think, by Dr. Weir Mitchell, as tending to negative the idea that rigor mortis is due to coagulation of the fibrine in the muscles, seeing that it occurs in perfection in those cases in which the blood-fibrine is apparently completely destroyed.

Of what importance is this loss of coagulating power of the blood? Are we to take any notice of the altered colour of the arterial blood?

If we regard, with the great Harvey, the blood as "both author and preserver of the body, the primogenial matter and vital spark, the first to live and the last to die, the immediate seat of the vegetative faculty of the animal, and every other part of the body subordinate or posthumous to the blood," we cannot be indifferent to such great changes as almost invariably occur after snake-poisoning.

Both the colour of the blood and its coagulating power depend largely, according to modern research, upon the cruorine and globuline of the blood. We can conceive that anything hindering or diverting the oxygen-carrying property of the red corpuscles would be baneful to animal life—as would equally any substance coming between the fibrinogen and globuline of the corpuscles. May not even the fibrinogen be dissipated into other forms?

In suggesting these questions I do so more with the view of attracting the thoughts of others than with the hope of approaching to any satisfactory answer to them myself.

It has always been considered that a free supply of oxygen not only heightens the scarlet colour of the blood, but at the same time renders this fluid more coagulable. With a free supply of oxygen also all the animal faculties are exalted. If with malicious deadly intent we sought physiologically for any power which should by its presence divert the oxygen from its normal carrier, and dissolve the colloids (fibrinogen) of the blood, we should, I think, examine the secretions of the various glands throughout the animal kingdom. Knowing the power of the salivary glands to convert almost instantaneously starch (a colloid) into sugar (a crystalloid), we should, to limit our work, in the first place experiment with these, and having hit upon a venomous serpent, and injected the contents of his parotids, we should see accomplished all that we had sought for—diminished energy in our victim, purple cruorine circulating in the place of scarlet; partial, then general torpor, and death; and accompanying all this, and increasing in inverse ratio to the signs of life, destruction of the fibrinogen of the blood.

We are apt to forget how rapid are the processes passing within us, that one minute after the introduction of this poison into the veins is sufficient for its distribution throughout the body. We need not wonder when Dr. Weir Mitchell tells us that he has seen the whole blood of a dog rendered permanently fluid within eighteen minutes.

There is one very remarkable difference between the effects of the poison of our Australian snakes and that of the rattlesnake. Although the physical condition of the blood after death is alike in both cases, yet the following from Dr. Weir Mitchell, so far as putrefaction is concerned, does not, that I know of, apply to hoplocephalus curtus or other Australian snakes:—"The venom of the crotalus, like that of other snakes, is a septic or putrefacient poison of astounding energy. The rapid decomposition of the blood, and of the tissues locally acted upon by the venom, leaves no doubt upon the matter, and makes it apparent that an incipient putrefaction of this nature may so affect the blood as to destroy its power to clot, and perhaps also to nourish the tissues through which it is urged." I have even thought that here a preservative power was imparted to the body of the bitten animal. I have read occasionally of cases the very opposite, but will mention one case of death in the human being, where the body the day after death was singularly sweet, and when exhumed, as it was a month or so afterwards, was still not at all offensive. That it is as Dr. Weir Mitchell says, with rattlesnake poison, I have myself, through his having kindly supplied me with some, fully confirmed.

But there are certain symptoms of snake-poisoning that are so constant in India, America, and here, and so prominent, and yet withal varying with the species of animal bitten, as to require more than a passing notice. I allude to those referable to complications of the nervous system. The great difficulty to decide is to know whether they are to be referred to influences primarily acting on the nerve-tissue or to secondary results due to the first deterioration of the blood by the action of the poison. Dr. Weir Mitchell has well stated the difficulty of arriving at any conclusion in his excellent treatise above referred to. It is quite possible that an altered blood circulating through the brain and spinal cord and sympathetic ganglia might produce all the symptoms to which I am alluding—viz., coma, convulsions, and contractions of the smaller arteries leading to the capillaries. On the other hand, it is equally possible for the poison to act primarily on the nervous centre to which, in the course of circulation, it becomes applied. If we could get rid of the known effects upon the corpuscular elements of the blood, and the great fact of the marvellously short time—less than a minute—for all the blood in the body to make its circulation, and likewise of the other known fact of the rapid and persistent action of such germinal particles as ptyaline and pepsine, to which I will add the germinal matter of the serpent's poison, then we should probably decide in favour of the direct action of the poison on the nervous tissue. But we cannot do this. Rather than occupy time unsatisfactorily, I will relate what, in Victoria, the symptoms implying affections of the nervous system are.

Man is characterised from the lower animals by the great development of the intellectual faculties. These we know may be in abeyance and yet life continue. Consequently the deepest coma may not be so serious a symptom as paralysis of the spinal system and base of the brain.

A very common course of events after snake-poisoning in man is first vomiting (most probably reflex from the brain), then dilated pupils, followed by lethargy and coma. A less frequent course is vomiting, dilated fixed pupils, consciousness slightly or not at all affected, and a few muscular spasms, chiefly about the neck, and trismus. Now, the appearance of the man with the first set of symptoms is to everybody alarming. The second set of symptoms, coming on more slowly, excite little or no alarm. And yet I think they are more frequently followed by a fatal result. Some cases, presently to be detailed, are in this regard worthy the reader's attention.

Dogs, when bitten, usually become convulsed in a few minutes, and, recovering from this, vomit and stagger about, and finally lie down and die with the consciousness unaffected to the last. Some are never convulsed, vomit, lie down, and die.

Birds die rapidly; but they are so differently organised to man that they form improper subjects for comparison. The

almost universal contraction of the small arteries, producing coldness, sleep, and dilation, and more or less stagnation in the venous system, may be referred to paralysis of the spinal system of nerves, or, as suggested by Dr. Day, of Geelong, to irritation of the sympathetic system. The widely dilated pupil admits, also, of either explanation—viz., paralysis of the centre for the third nerve, or irritation of the sympathetic filaments of the ciliary ganglion. This state of itself, if not counteracted, would in the end induce death as surely as external cold does, and it demands from us additional attention, as that to which all the so-called stimulating treatment is applicable, and above all the simple uncomplicated treatment I have recommended.

Treatment.—In the beginning of our Australian summer, 1868, about the end of October, I for the third time recommenced a yearly series of experiments on the treatment of snake-poisoning. I had hitherto completely failed in obtaining any beneficial results. I did not direct my mind to the discovery of any so-called antidote, but to a mode of treatment that might help us, if possible, towards a better *rationale* of the treatment of other blood affections; for, however difficult the subject of snake-poisoning might be, I considered it the simplest problem given to us to solve. Here there is no mystery. One animal bites another, which sooner or later dies. Let all the resulting conditions be fully examined, and the *modus operandi* of the virus might yet be discerned. A whole lifetime might be necessary for the work and the ramifications to which it would give rise, but yet the results to the world would more than repay the trouble and expense of the inquiry.

Without much hope of success, I then (October, 1868) reconsidered all that had been written on the subject and observed by myself. I was induced to think that perhaps ammonia had the greatest claim to be considered useful in snake-poisoning. I had hazarded the hypothesis of the germinal matter of the snake appropriating to itself the inspired oxygen, or at least diverting it from the cruorine of the blood corpuscles; whereby we obtained an explanation of the lessening of all the vital phenomena, the absence of fibrine after death, and in its place millions of nucleated and maculated leucocytes, be they simply altered white corpuscles or new cells. Of their existence there was not then, nor is there now, the least doubt, nor of their still increasing or presenting themselves in greater abundance in the blood of the bitten animal many hours after death.

I may mention that I had, when opportunity offered, busied myself greatly with examining the blood of patients dead from pyæmia, fever, puerperal fever, and leucocythæmia, but never found appearances like those after death from snake-bite. In leucocythæmia we should expect the nearest resemblances if the maculated cells were simply altered white corpuscles. But I failed to discover them; and Dr. McGillivray, a known microscopist and surgeon in Victoria, after having carefully examined the blood of patients dying of leucocythæmia, and recorded the totally fluid character of the blood and the enormously increased quantity of white corpuscles, proceeds to say—"I ought to mention that the cells in leucocythæmia are quite different from the large, uncleated, maculated cells found in the blood of animals killed by snake-poison, for an opportunity of examining which (in a dog) I am indebted to Professor Halford. The specimen I examined agreed in all respects with his description. The maculated cells appear very different from the ordinary white corpuscles and the cells of leucocythæmia, and are probably of a different nature."

Subsequently Dr. Stuart, of Sandhurst, examined the blood of a man who had died within two hours after the bite of an Australian snake. He wrote me as follows:—"I found the maculated corpuscles even more marked than you delineate them, and send on a portion of the blood to you as a confirmation of your explanation of the action of the poison." Unfortunately, the weather being then intensely hot, by the time the blood arrived in Melbourne its corpuscular elements were all broken up. It was perfectly fluid, and of a dirty light plum colour, exactly like what I had before so often seen, but find it impossible to describe.

Being then (in October, 1868) possessed of certain facts, and thinking upon the probable value of ammonia, I received from England a letter from Staff-Surgeon Lewin, in which was the following paragraph:—"I see you used ammonia in D——'s case, but if your theory about the living germs in the blood using up its oxygen be correct, the indication of treatment is to use any deoxygenated volatile agent in enormous doses, so as to deoxygenate the blood as completely as possible, and for that purpose ammonia in its most concentrated form seems most suitable. Doubtless stimulants (hydrocarbons) are also useful, but I think it very desirable that ammonia should have a fair trial, and it might easily be tried on dogs. My idea is that the fluids of the body should be rapidly saturated with the substance. It might be given internally in large doses, and also be smelt and breathed so far as spasm of the glottis allows. Its success would be an excellent negative proof of the correctness of your microscopical observations. . . . . I hope you will try the ammonia treatment on dogs. It must be given in large doses. The animal must be deluged with it." I am glad I have preserved this letter; the suggestions it contains are now highly interesting. I did try to deluge dogs with ammonia, but discovered no means of effecting it till I hazarded its injection into the veins.

The results of my first experiments were that in all stages of snake-poisoning dogs were improved by it—in many the symptoms were instantly stopped, and if they returned were again checked by another injection. I then felt bound to suggest a similar treatment in the case of men being bitten. A very few days only elapsed before a serious case occurred at Buckworth, Victoria. Dr. Dempster was bold enough to inject the man, who forthwith rose up from his previous comatose and threatening condition and speedily recovered. From this time (November 11, 1868) commenced a new era in the treatment of snake-bite in Victoria.

But, before proceeding with the detail of cases, it will be as well to consider what may be the action of ammonia when thus injected into the human body. In no other way can such an immense quantity of ammonia be introduced into the blood. By this process both the stomach and the lungs are avoided. A back way is sought to enter the citadel of life—the heart. The forts stationed at the glottis and along the stomach and alimentary canal are attacked in the rear, and whatever the snake has added to the blood is speedily pursued, and probably, if too much time have not been lost, overtaken by the ammonia.

That the ammonia exerts no influence upon the constituents of the snake-poison itself is nearly certain; for, long ago, Dr. Weir Mitchell had shown that when it is thoroughly well mixed with the strongest liquor ammoniæ and injected beneath the skin of a dog, death follows as certainly as if it had been unmixed. This I found to be the case also with the poison of our snakes. But that it does counteract the effects of the poison when injected into the circulation is seen by the resulting animation almost immediately following. If we suppose that the coma and general paralysis are due to deficient oxygenation, then the removal of these conditions should depend upon the re-establishment of the chemical processes of alternate oxidation and deoxidation. How ammonia can bring this about, except by arresting the molecular changes going on in the blood, it is difficult to say. Indeed, we know next to nothing of the molecular changes taking place in living organs. Who can trace the functions of ammonia in the sap of plants?—and yet it stands in as important a relation to plants, and subsequently to animals, as heat itself. It is the source of all the nitrogenous elements of both. Very much the same idea as originally presented by me of the action of snake-poison is enunciated by Dr. Broadbent(a) when speaking of the action of prussic acid. He remarks that in death from the latter poison there is no paralysis of the muscles of respiration, and yet there is apparently everywhere deficient oxidation; and he further adopts the hypothesis that "nascent carbon and hydrogen set free in the nervous structure to exercise their affinity for oxygen, would seize it and anticipate the normal oxidation." In 1867 I pointed out that there was no obstacle to the entrance of air in snake-poisoning—that the mystery was what became of the oxygen. I imagined that probably the snake-poison diverted it from its ordinary carriers, the blood corpuscles, and that instead of heat we had molecular motion induced for the aggregation of molecules and the growth and development of leucocytes. I know not whether we may assume that ammonia might be broken up in the animal organism into its constituent nitrogen and hydrogen; if it could be, we are still not in a position to say what might be its *rôle* of action in the course of recovery from snake-poisoning, since we have no ultimate analysis of the poison itself.

But we can now leave these considerations for others of the more obvious and mechanical effects of the injection of liquor ammoniæ into the veins.

The most remarkable, because unlooked for, effect is the conversion of feeble rapid heart-beats into slow powerful beats,

(a) *Journal of Anatomy and Physiology*, Nov., 1868.

which keep up for some time. Attendant upon this is a freer circulation through the peripheral vessels. This is followed by returning warmth to the body, normal colour to the surface, and more or less consciousness.

Now, these are most important facts for us to consider, and I shall treat of them as carefully as I am able. It may be remembered that I referred to the contracted state of the smaller arteries in snake-poisoning, whereby the capillary systems were poorly fed and the veins stagnating and full. This state, if persistent, must end in coma and death; but by the injection of ammonia it is at once removed. How is this brought about? I was pleased to excess in finding soon after my own observations of these facts some physiological explanation of this remarkable and, as I have said before, unlooked-for process. No one would certainly have expected the number of the heart's pulsations per minute to be reduced by throwing liquor ammoniæ into the veins or even into the heart itself; but MM. Cyon and Ludwig have shown that there arise in the interior of the heart certain nervous filaments which converge to one or two branches which pass to the pneumogastric and thence to the medulla oblongata. Stimulation of the central end of the cut nerve is followed by dilatation of all the arteries of the body. Stimulation of the peripheral end of the cut nerve produces no effect either upon the heart itself or upon the coats of the arteries. The reflected impression was traced from the cord along the splanchnic nerve to the arteries.

Now, with these facts before us, what may be the action of ammonia upon the inner surface of the ventricles? The stimulus is probably conveyed by this branch of the pneumogastric (called, from its reducing the number of pulsations, "*le nerf depresseur du cœur*") to the spinal canal, and thence to the arteries, which dilate. The heart, feeling the relief to the peripheral circulation, has no need to pulsate so rapidly, but takes on a steady and forcible rhythm, which it maintains for a long time.

(*To be continued.*)

ON

CONSTIPATION SIMULATING DIARRHŒA.(a)

By DAVID NELSON, M.D. Edin.,

Formerly Physician to the Queen's Hospital, and Professor of Clinical Medicine; afterwards Professor of the Principles and Practice of Medicine in the Queen's College.

(*Continued from page* 201.)

As examples for practical illustration, I may now cite a few cases briefly, and confining myself to these particular symptoms. For instance:

Case 1.—Some time ago I was called into the country to see a lady who had been suffering for a long time with continual recurrences of this so-called diarrhœa, which had ended in vomiting also. After examination into the matter I came to the conclusion that there was obstruction, and accordingly advised evacuation. Of this the patient herself seemed very doubtful indeed, remarking that she had been purged six times that very morning while dressing. From this state of her mind, and also feeling that the obstruction might be of such a nature that the use of purgatives by the mouth caused pain, I merely prescribed an antacid sedative for the stomach—namely, potassa, calumba, and hydrocyanic acid,—and got her to acquiesce in the employment of injections. On the next visit I found a range of vessels, each containing an extraordinary quantity of hard fæcal matter, intermixed with chalk. After this ocular demonstration she was content to follow up the proposed line of treatment, and got well, taking care afterwards to compare the daily proportions between increment and excrement.

Case 2.—In like manner another elderly lady, after suffering from severe habitual constipation, for which she used from time to time to take strong purgatives, with the effect of irritating the membrane, at length was overtaken with this apparent diarrhœa, ending in a like irritability of the stomach, with rejection of all food, intermittent pulse, and a sense of sinking, as if about to faint and die. In this instance, what appeared like hard tumours were to be felt in the ascending and transverse colon, the latter pressing on the aorta, to judge from the heavy motion and sound. Here, in like manner, there was a difficulty in making the patient agree with the view taken of her case. In fact, she said that she felt convinced nothing of the kind could be in her, from the frequent motions, the food having been taken in such small quantities, and even then rejected. There was also an additional difficulty in the way, from her daughter and granddaughter telling me that she had a long-rooted aversion to such things as injections and the like. However, I persuaded her to submit, though, on the next visit, she rather triumphantly said, "I was right, doctor; nothing but the injections themselves have come away, though the relaxation is better." The sickness had also stopped through the use of the sedative with ice. I could perceive, however, a little advance of the masses, was as positive as she was, especially from this change in their position, and succeeded in getting her to persevere. After four or five days the daughter said, on my entering the house, "They have come." And certainly there they were; a great number of tough, solid masses of very irregular shape, and varying in bulk from the size of a golf-ball to that of a larger or smaller walnut. After that she progressed as well as her age and other ailments would permit, and is now alive.

Case 3.—An elderly innkeeper, very stout, and with a large abdomen, had in like manner been troubled with what he thought was habitual diarrhœa, accompanied with indigestion, flatulence, and frequent pain in the epigastrium and elsewhere. The motions, when these attacks came on, were many in the day, though often no more than a drachm or two—these coming away sometimes when he thought he was merely going to discharge a little flatus. At length the settled vomiting made him seek more help in the matter, and after treatment similar to that already described he got over his ailments, and continues well. Other cases quite like the above need not be entered into.

Case 4.—An old gentleman, who had generally been costive, and afflicted with dyspepsia during the greater part of his life, at last was taken with this sort of diarrhœa, which he stopped by astringents, and by-and-by, being seized with constant retching and vomiting and severe abdominal pain, his daughter, who kept him by keeping a ladies' school there, desired me to see him. I found great distension and flatulence, and a tympanitic ring on superficially tapping the abdomen, but at the same time, on deep pressure and deep percussion, which gave acute pain, the dulness of the colon and a sort of unyielding fulness about it were discernible. He shrunk and pulled a sudden breath at every stroke of the fingers. The vomiting was allayed by the sedative and ice, and blue pill and colocynth, given by the mouth, aided by injections. The result was decisive, and amongst other matters there was the escape of a curious mass of vegetable origin, like broken almonds, walnuts, and the like, intermixed amongst other things with a quantity of grape-seeds. When the old gentleman's attention was directed to this, he remarked, "Now, that shows how long some things may lie in the bowels!" and proceeded to state that several weeks before, while dining with an old schoolfellow, his friend began to joke him over the dessert about the daintiness of his eating and drinking, saying that it was no wonder he was always ailing, as he picked out this and rejected that during his dinner, and now did the same thing at dessert. Referring to some popular book on medicine which declared that people might be too refined in their diet, and so lead to constipation, he added that he ate all things as they came, skins of fruit, walnuts and chestnuts, grapes with their skins, seeds, and all, concluding with—"You know that I am never ill, my bowels are like clockwork for regularity; and I would advise you to do the same." He did so with the above result. He was then about seventy, but lived some years longer.

Case 5.—I was hurriedly called to see a lady, the vehicle coming to the door for me. I found her lying prostrate and cold, and suffering intense agony over the abdomen, particularly at the right side and also at the right collar-bone. She could not cry out, but muttered and breathed hard and fast, shivering the while. She had again and again been troubled with vomiting, and also frequent small ineffectual motions, which she took to be diarrhœa. When these agonies formerly came to a crisis chloroform would be employed, but still they would return. From the features of the case I considered that gall-stones were the cause, and accordingly, obtaining tincture of opium, I myself witnessed and watched the exhibition of repeated doses thereof to the extent of twenty or thirty drops at a time, until 220 were taken, with relief to the one symptom of pain, but without

(a) Read before the Midland Medical Society, Birmingham.

any sleep or stupor, only a sensation of comparative ease, with return of heat to the extremities and surface, and a warm moisture. After this, as she complained of a heavy bearing-down, I examined per vaginam, and found no enlargement of the womb, as she supposed, but a vast mass in the rectum, which I proposed should be forthwith removed. Accordingly, prescribing an aperient, I told the nurse to proceed with injections. After a time the nurse called on me to say that she could not penetrate, and that all came back again without properly entering the gut. I advised that she should first move the ivory pipe backwards and forwards through the mass, and then employ the long tube. This was done with success. A very large and hard, but now broken up, lump was first discharged, almost white, like old ivory, followed by much more of a similar kind, and many gall-stones amongst it. These were white in the centre, but coated with pale yellow on the outside, very like Indian corn, and flattened on the sides. The patient got well, and kept well afterwards, by due attention to diet and exercise, and the use of nitro-muriatic acid baths, along with the daily employment of Spanish soap to the extent of thirty or forty grains or more.

Case 6.—Another female suffered in quite a similar way, and was relieved by similar treatment, followed up by the mineral acid baths and the Spanish soap. The gall-stones in this case were in much greater number, but smaller, and of a greyish-white colour.

Case 7.—An old man of 78 consulted me a short time ago about retchings, violent occasional pains in the abdomen, with disturbance of the bowels, and a settled, heavy, continuous pain to the right of and across the stomach. There was dulness there, and there was a shrinking under pressure or percussion. Suspecting hardened fæces, I proceeded upon the suspicion. Although the milder aperients acted regularly through many days, no masses came away; yet the patient said he felt that something was slowly moving on, and that the settled weight and pain were passing from right to left, as along the track of the colon, while flatus would rattle across there instead of being so often ejected by the gullet. Having old, tender piles, he dreaded any strong action, but ultimately reported it had come at last,—that he had never had such an effort or suffered more pain in his life than in passing the hard mass, but that now he felt well in every respect.

Case 8.—Another elderly lady had had the like symptoms of dyspepsia, with vomitings and alternations of protracted constipation with frequent petty purgings. She lived in one of a terrace of houses which were all her own property, and there she sat and brooded from day to day, scarcely ever going out or taking exercise. On account of her constant dyspepsia she had at length taken to almost nothing but a milk diet, with small additions of brandy. Paroxysms of agonising pain supervened, always relieved for the time being by opium, but only to return. When I expressed an opinion of loaded intestines, the patient herself, like others, urged the very little she had taken for months, and also pointed to the sinking in of the abdomen as a physical proof of non-accumulation. However, the course of treatment was resorted to, and after some perseverance, using aconite and belladonna for the pains instead of opium, there at last came away a great number of large, round, white, and hard masses, more like big balls of putty that had been drying for some time than any fæcal matter. When her husband applied a stick to them, and found them so difficult of penetration, as compared with what he expected, he said, "Well, without having witnessed this I could hardly have believed it, considering her babylike diet and her going so often to the closet." I must here observe that, with all its blandness and apparent innocence, a milk diet, with its tendency to a great accumulation of casein, is very apt to produce a constipation of this kind, and the purer the milk the more likely is it to lead to this result. I have noticed this again and again. One gentleman, who attended a case of scirrhus of the pylorus with me, in which the patient had been taking milk, felt sure one day that the person had violated his rules, and had been swallowing toasted cheese. Now, the vomit, I must admit, did look and smell exactly like some Welsh rabbit, but it was the cheese of the milk turned rancid. Goat's or ass's milk is more fitted for the purpose in view, but I think should always be watered, and the tougher particles prevented from agglomerating by being boiled up with arrowroot or flour, or other material of that kind.

Case 9.—A gentleman, between 60 and 70, who died a few years ago, had been troubled with alternations of constipation and diarrhœa—as usual, not much attended to by himself except under pressure of present symptoms. He was a large, fat, and powerful man, but latterly had a pale lemon-like hue about him. At length the pain, constipation, and vomiting became extreme, and he wished me to see him. On the visit I detected a large, hard, and tender mass to the left of and a little below the navel. From the peculiar hue of the countenance, I suspected a malignant tumour. Sedatives, mild aperients, and injections were in this case vain. The gentleman who attended with me (Mr. Burdett) found, after a few days, fæcal matter in the urine, which I also saw. The body was not examined, but, doubtless, whatever was the chief disease, perforation had occurred, so as to admit of this rather unusual phenomenon.

Case 10.—Another case, the previous progress of which I did not personally observe, because I was called to see it only shortly before death, yet doubtless had been somewhat similar to those just described. The patient herself and family stated that she had long suffered from indigestion and relaxation of the bowels, so that, on journeying by rail with her grandchild to visit its mother in Birmingham, she previously took an astringent and sedative draught to avoid inconvenience while in the train. On arriving at the station, however, she was seized with violent pains and sickness, and was forthwith driven to her daughter's house, near Bath-row. Here, as is the wont, brandy was first tried; but as she got worse, Surgeon-Major Yates was sent for, and afterwards myself. Here the tenderness was near the ileo-cæcal valve. Leeches, I think, were applied, and afterwards a blister, while she took sedative draughts and had mild injections. These injections brought almost nothing away, and she gradually sank and died, with all the symptoms of acute peritonitis. An examination was made, which revealed the usual effusions from the inflammation, and at the lower part of the ascending colon there were found not very large, but very hard and adherent lumps closely impacted, and which there can be little doubt had had much to do with the induction of the peritonitis.

I shall not farther task your patience by any additional cases, but I think they tend to show the importance of a careful and early diagnosis in all such *ordinary* ailments, as they are called. It also becomes evident that, as there may be many complications, it behoves us in adopting the evacuative process to begin and advance with caution and circumspection, and to avoid especially commencing with powerful agents by the mouth lest we might do more harm than good, particularly if scirrhus, induration, or other organic physical obstacle be in the way. But employing at first only mild aperients and mild injections, we thus cautiously and safely feel our way towards the use of calomel, colocynth, or scammony, or the injection of the oil of turpentine. The possible induction of intussusception is an awkward danger staring us in the face, but mild liquid injections are rather a safeguard against that; nor should we here forget that case in which a poor man's life was saved by Mr. Richard Griffin, of Weymouth, if I mistake not, by the simple injection of common air by an ordinary pair of bellows. That gentleman, who had continued to hold a parochial appointment, not from any necessity, but from a resolve to protect the poor against certain so-called guardians, was summoned several years ago by a brother parochial surgeon into the midst of a distant heath in such a case where intussusception had supervened. As there were none of the ordinary appliances at hand, his ingenuity availed itself of this pair of bellows, when he unloosed and distended the intestines with complete success. His liberal patrons considered five guineas a most exorbitant charge for only blowing a pair of bellows, and refused to pay. Under these circumstances he had to appeal to the Poor-law Board, who, of course, ordered immediate payment. Such are the occasional annoyances in medical practice, when, not considering the importance of the result, but only the apparently simple means, such people will begrudge fees earned, as they think, only by looking at a patient, or giving some seemingly commonplace directions, or writing a few words upon a scrap of paper, or using this common pair of bellows. Not that I can personally complain, but at the same time such a case as the above is very far from being at all singular.

TYPHOID fever has appeared among some of the people living in the Chatham Dockyard. Two women have died and three men are in hospital.

A FINE of £5 each and costs was inflicted on Tuesday by the magistrate of the Southwark Police-court on three milkmen for adding water to their milk.

THORACIC ANEURISM: CONSOLIDATION OF THE TUMOUR UNDER TREATMENT.

By FREDERICK IRVING DE LISLE, L.R.C.P.,
Medical Officer of the St. Peter Port Hospital, Guernsey.

So much has been said by many able writers on the treatment of aneurism, and so many apparently excellent theoretical reasons for adopting remedial measnres opposed in many important particulars to that which I am abont to advocate, that it is with some diffidence that I approach the subject. But, as many anthorities are still holding different views as to the manner in which aneurism should be treated—some being so bold as to assert that this disease is incurable, and that reported cases of cure were in the first place errors of diagnosis; others that starving the patient and snbjecting him to small bleedings is indicated; whilst a third party maintain that the consolidation of the tumour by coagulation (the end that all who treat aneurism have in view) is best obtained by placing the patient on a generous diet, and by the administration of large doses of iodide of potassium, both advising rest. Others, again, are in favour, where it is practicable, of surgical operations, as tying the subclavian and carotid arteries for aneurism of the innominate; and surgical appliances, as Liston's clamp, in aneurism of the abdominal aerta.

In the above remarks I have left aneurisms of the extremities out of consideration. I do not think that I can do better than refer those who disbelieve in the cure of aneurism to a very interesting report of an innominate aneurism, the cure of which was proved by post-mortem examination, and reported in your columns by Dr. McNalty, May 31, 1873, p. 569. This report, I may add, I read with much interest, for at the time the case that I shall presently subjoin was nnder treatment.

Low diet seems to me peculiarly objectionable, and the assertion that under its influence less blood is made is, I consider, open to question. For it is chiefly in quality, rather than in quantity, that the blood is altered, and the proportionate amount of fibrine in the blood is lessened, thus making it less coagulable. Starving also increases the number, although it lessens the force, of the heart's contractions.

Frequent bleeding in small quantities has in my opinion more to recommend it than low diet; for, as is well known, venesection increases the proportionate amount of fibrine, but, on the other hand, it has also a tendency to render the heart's action irregular, and this might disturb the clot that was forming, and retard instead of hastening the cure.

Full and generous diet combined with rest, keeping the patient entirely in a recumbent position, avoiding everything, as alcoholic drinks, that will in any way accelerate the heart's action, seems to me the most philosophical, where operative procedure is determined against or impracticable. The administration of iodide of potassium is, I think, generally unnecessary when there is no reason to suspect syphilis, for, except in certain diatheses, the blood coagulates readily if placed under proper conditions.

The galvano-puncture—recommended first, I think, by Ciniselli—although it has much to recommend it, is not unattended with danger, nor is the clot as hard and durable as might be desired.

Samuel L., aged 38, farmer, applied to me on May 22 with the following history and symptoms:—

In August last whilst exerting himself in his fields more than usnal, he felt a "crack" in the upper part and right side of his chest, which was followed by faintness and nausea; for some days after he was unable to work, owing to a feeling of weakness and palpitation of the heart on the slightest exertion, but he did not think it necessary to apply for medical advice. Soon after this, about a fortnight, he noticed that his voice got weaker, and in a short time he was unable to speak above a whisper. About two months ago he commenced to have difficulty in swallowing, and this steadily increased. Patient's father met with an immediately fatal accident three weeks ago: this caused a great shock to his system, and he believes that the difficulty in swallowing has increased more quickly since then. He has several times since the strain felt a numbness in the right arm, extending to the tips of the fingers, rendering them quite "foolish." Last evening the difficulty in swallowing was greater than ever, and he was only able to get small qnantities of liquid food to pass the obstruction. This morning all foed was completely arrested and rejected. Patient points to the depression in the neck at the upper part of the sternum as the spot where the difficulty takes place. He has lost flesh considerably lately.

On examination, patient has a peculiar yellow appearance, conveying an idea of malignant disease. There is a small pulsating tumour projecting above the clavicle on the right side, communicating a peculiar thrill to the touch, and a blowing sound to the ear through the medium of the stethoscope. Heart sounds normal, but the second sound is strikingly loud, having a pecnliar twang like the springing of tant catgut. The right clavicle is raised and more arched than the left, and the fingers of the right hand are slightly clubbed. Pulse on the right side is harder and more wiry than on the left. Patient asserts that he has never suffered from any venereal disease. His mother is alive and healthy, aged 65. He has several brothers younger than himself; has lost two by accident, bnt none from disease. Neither himself nor any of his brothers have ever been very strong men. One brother suffers from palpitation of the heart.(a)

Ordered to remain entirely in bed and in the recumbent position, and to take small quantities of liqnid food from an invalid's cup frequently. ℞. Tinct. digitalis, tinct. hyoscyam. āā ℥v., to be taken every four hours.

May 23.—Has been able to swallow since he has been in the recumbent position. Yesterday evening, being tired of remaining in bed, he got up, dressed, and came downstairs and laid on the green bed;(b) after leaving that and going upstairs to his bedroom, he found that he could not swallow. The power of swallowing returned this morning. To take eggs beaten up, milk, and beef-tea; to remain in the recumbent position and to continue the mixture.

24th.—Patient is able to swallow liquid food without difficulty. The tumour is not now visible, but the pulsation is felt just below the level of the clavicle. Thrill distinctly heard through the medium of the stethoscope. Continue as yesterday.

26th.—Patient has no difficulty now in swallowing. He has taken without inconvenience eggs beaten up, beef-tea, milk, and thin cornflour. The sound transmitted to the ear over the site of the tumour is slightly rougher and not so loud as previously. The second sound of the heart is still abnormally loud, but it has lost the peculiar twang that it had when first examined. The tongue is covered with a thick fur, and the breath is very offensive. The bowels have not been moved for some days. Allowed to eat small pieces of crumb of bread buttered, and eggs very soft boiled. Continue the mixture, and ordered an injection of warm soap and water.

27th.—Was able to eat the food ordered yesterday without difficulty. The injection was not administered, as he had some griping pains, and the friends thought that the bowels were going to be moved spontaneously. Ordered to have the injection to-night. Continue the mixture. Allowed to sit for an hour in an easy chair and to eat meat or fish.

30th.—Tumour still pulsates to the touch, but much less than when first observed, and has a hard crustaceous feel. Has not felt numbness in the right arm or tingling in the fingers since he commenced the treatment. Cough has entirely ceased, and the voice is getting stronger.

June 4.—Pulse on the right side is greatly smaller than on the left. The tumour communicates a scarcely perceptible pulsation to the touch, but there is still a whiz communicated to the ear by the stethoscope, but it is accompanied by a crackling sonnd. Omit the mixture.

8th.—The tumour feels more solid, and pulsation cannot be distinguished, but a slight thrill may be felt. When the stethoscope is applied blood is still heard passing through the tumour, the walls of which appear to be thick and the column of blood passing through it small. Exactly over the tumour the beat of a small vessel can be distinguished, which was not previously demonstrable. Pulse in right wrist considerably smaller than in left.

12th.—Tumour feels quite solid; the beat of the vessel over the tumour is stronger, and the vessel feels larger than previously. A slight thrill is heard when the stethoscope is placed over the tumour, but whether it proceeds from the tumour or the vessel in such close contact with it, I am unable to state with certainty, but my impression is that it proceeds

(a) This man fell down a cliff 100 feet high on June 26, and died three weeks after from the effects of the injuries received. Whilst he was under my care I frequently examined his heart carefully, but was never able to detect a bruit. No post-mortem examination was allowed.

(b) A large square-shaped sort of couch, stuffed with green ferns and usually covered with baize. It is to be found in the kitchens of nearly all our farm-houses.

from the vessel. Right pulse is still smaller than the left, but their beats are more equalised than I have before felt them. Allowed to walk about quietly in his garden twice a day for twenty minutes at a time.

16th.—Tumour feels quite solid. The vessel has increased in size since my last visit, and the force of the pulsatiou is greater. Right and left pulses almost eqnal. Felt considerable palpitation of the heart for the first two days, when he commenced to walk, but did not feel it at all to-day, and very little yesterday. To coutinne as before, but allowed to increase his walks if he does not find it bring on palpitation.

25th.—The vessel over the tumour has increased to the size of a goose-quill. The tumour remains quite hard. Right and left pulses are equal. Patient has had no returu of the palpitation. Allowed to go ont in his fields and superintend the work, but on no account to exert himself.

I have seen this patient several times since that date, and have always taken the opportunity of examining him. The tumour remains quite solid, and he is to all intents cured.

This was what may be termed a desperate case. Here was a patient in danger of starvation, and it was evident that, unless prompt measures were taken to reduce the size of the aneurismal tumour that was pressing on the œsophagus, death would be the result, although life might be prolonged by means of nutritious enemata. As was showu by this case, the patieut may sometimes be relieved, and that quickly, without recourse being had to operations at once difficult and dangerous. When I first saw the case I was on the point of proposing the distal operation to him, but ou reflection I determined to try palliative measures for a day or so, and improvement taking place under their exhibition led me to persevere.

It is well in private practice to avoid operative measures as much as possible, as patients have great dread of the surgeon's knife; and here in the country parishes of Guerusey we have a difficulty to encounter from which I fear practitioners in other country places are not exempt. Our country people always think that a surgeou should be able to perform any operation without the slightest assistance, and on proposing a consultation I have often been met with the following blunt reply, which is much more forcible in the native *patois*:—"Oh, sir! if you are uot clever enough I will fetch another doctor." Not long ago a well-to-do farmer cousulted me for malignant disease of the testicle. I pointed out to him the necessity for au operation, and he acquiesced, but asked if I should require another doctor with me. I told him that I certainly should, aud stated the reason wherefore. We then agreed as to whom the other surgeon should be, and appointed a day for operating; but the following day his wife called on me, and said that unless I was willing to perform the operation aloue her husbaud had decided not to have it done at all.

Now, it strikes me that in many cases of aneurism of the abdominal aorta the effect of rest and good feeding might be noticed previous to the application of Listou's clamp. It is true that the cure would be more tardily effected by the former method, but it would have the recommendation of being safer, for, as has been shown by the sphygmograph, the application of the clamp to the abdominal aorta produces iucreased arterial tension in the upper part of the body—a thing to be avoided with diseased arteries; for when one artery has an aneurism, the probability is that the other vessels are not in a sound condition.

Auscultation of the Chest in Diseases of the Brain.—At a recent meeting of the New York Academy of Medicine, Dr. Brown-Séquard made some remarks on "The Importance of Frequent Anscultation and Percussion of the Chest in Cases of Organic Diseases of the Brain." He cited cases occurring iu animals and man, showing that injuries to the brain will produce emphysema, pneumonia, and diseases of the liver, stomach, and kidney. Pneumonia is oftener produced when the injury is on the right side of the brain. He referred to 188 cases of tubercle, compiled from various sources, in which the origin of the disease was traced to inflammation of the brain, showing it to be not of accidental occurrence. His conclusions were that in animals which have received brain injury inflammation of the lungs may follow. The injury in this manner causes death. In man the same effect is shown by actual experiment. The life of man may be saved, after injury to the brain, by early auscultation and percussion.—*New York Medical Record*, July 1.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

THREE CASES OF OVARIOTOMY.

(Under the care of Mr. HULKE.)

Case 1.—*Large Multilocular Ovarian Tumour—Rupture of Cyst—Ovariotomy—Recovery.*

Ann N., aged 52, admitted in the middle of August with an abdominal tumonr, was transferred on the 27th of that month to the surgical ward. Her belly, globularly distended, measured from the ensiform cartilage to pnbis tweuty-three inches, and its girth at the umbilicus was forty-two inches and a half, being one inch and a half more than it had measured at the same level ten days previously. The whole of the lower part of the front of the belly was dull on percussiou; the upper limit of the dulness was an oblique line, reaching higher on the right than on the left side, and crossing the median line rather nearer to the navel than to the ensiform cartilage. Above and to the right of the navel was a large, hard mass, while below the navel in the raphé was a distinct creaking, when, with the hand placed flat upon the belly, an attempt was made to move the abdominal walls upon the underlying mass. Throughout this dull area, except where the hard, solid masses were felt, a deep, rather indistinct wave across the tnmour could be elicited. Three days later, over the whole frout of the tumour percnssion brought out a snperficial wave, which could not only be felt but was also visible; and when the finger-tip was quickly and firmly pressed ou the belly, a thin overlying stratum of fluid was displaced before reaching the more deeply-placed tumour. This led to the supposition that ascites was now superadded to an ovarian cyst. She had also procidentia uteri, with prolapsus vesicæ and much difficulty in micturition. Her breathing was embarrassed, so that she was unable to lie down in bed. Her appetite had failed. She was very emaciated and feeble, and a fatal termination was evidently near.

Takiug into account the ascertained presence of large solid masses, which would necessitate a relatively long incision, the presumed existence of adhesions suggested by the creaking, and the extreme weakness of the patient, Mr. Hulke did not feel warrauted in urging her to submit to ovariotomy, nor justified in refusing her the chance it alone offered, if, with a full understanding of the attendant risk, she elected to have it done. She chose it, and, with the concurrence and assistance of Dr. Davis, the tumour was removed on the 28th. On opening the peritoneal cavity a large quantity of brownish bloody fluid gushed out, very unlike the usual straw-coloured fluid of ascites, and evidently cystic. When the opening had been enlarged enough to allow the hand to be passed into the belly, a large transverse rent was found in the principal cyst, above the level of the navel. Through this the bloody fluid free in the peritoneal cavity had evidently escaped, and the supervention of the usual physical signs of ascites three days previously marked the time when this rent took place. Notwithstanding this there were not any marks of recent peritonitis present. An adhesion of the great omentum, iucluding several very distended veins, to the spot where the creaking had been felt, was tied with silkworm gut, aud severed; the ends of the thread were cut off close. A large solid tuber filling the pelvis was the cause of the extrusion of the uterus and bladder. The pedicle was sufficiently long to permit the use of a clamp without any drag on the womb. She made an uninterrupted recovery. The only medicine taken was a single half-grain of morphia in a suppository placed in the vagina directly after the operation. During the first twenty-four hours she was nourished entirely with beef-tea aud milk enemata. Ou the second day these were given at longer intervals, and she began to take food by the mouth.

At Christmas she called to show herself, and was then so stout and strong as hardly to be recognised at first sight.

Case 2.—*Proliferous Ovarian Cyst—Ovariotomy—Recovery.*

M. T., aged nearly 50, was transferred, December 27, 1872, from the medical to the surgical wards with an abdominal tumour of rather more than two years' growth. First noticed in the left flank, it now formed a large globular swelling, distending

her whole belly, and pressing the intestines away from the front into the loins. At its most prominent part, around the navel, it distinctly fluctuated; but above the pubes and in the left flank were hard, inelastic solid masses. Manipulation was slightly painful, and for the last three weeks she had felt a soreness in the right inguinal region. The tumour, as a whole, seemed to be movable—it could be swayed about. The uterus was pulled up and to the left. It seemed to be movable independently of the tumour; its cavity was not enlarged. The bladder was irritable. The girth at the navel was forty-three inches and a half. She felt very helpless, and was disabled by the bulk and weight of her belly. She had had eight children. Catamenia had ceased four years, but four months ago she again had a slight bloody flow, which had since occasionally recurred. Her thoracic organs were healthy, and no kidney disease was discoverable.

January 2.—The tumour was removed. It proved to be a compound proliferous cyst. The pedicle was sufficiently long to allow a clamp to be put on without much dragging on the uterus.

During the first thirty-six hours no food was given by the mouth. She occasionally sucked a small bit of ice, and had from time to time an enema of two ounces of strong beef-tea.

On the second evening her pulse had reached 116 beats per minute, and her temperature had risen to 102·6. From this the feverishness declined. During the first week the temperature ranged between 99° and 100°, and then averaged 98·6° F.

On the third day her urine became slightly bloody; she complained of pain in the loins, and her skin was dry and harsh. These symptoms were relieved by sweating her freely with an extra blanket and raising the temperature of the room. The hæmaturia was followed by considerable deposit of lithates, which quickly disappeared after a few five-grain doses of carbonate of lithia.

At the end of the month she was considered convalescent; but the lower angle of the wound containing the pedicle—a very fleshy one—did not quite cicatrise till a fortnight later.

Case 3.—*Compound Ovarian Cyst of Rapid Growth—Ovariotomy—Death.*

—, aged 21, a *petite blonde*, married three years, miscarried at the end of the first year in the fifth month, and was confined at the seventh month in November, 1872, of her second child. Before and during the second pregnancy she had not been aware of any unusual condition of her belly, but after the birth of the child the belly remained full, and on getting up her attention was attracted by a sort of splashing inside her as of water. For this she was admitted, January 7, into the Middlesex Hospital under the care of Dr. Liveing, and the swelling proving ovarian and not ascitic, she was transferred to Mr. Hulke. The navel was flat. On rising without assistance from the bed, the musculi recti abdominales were projected in relief on the front of the tumour as a rod, and not separated as in ascites. Her belly was greatly distended, the girth at the navel being thirty-six inches, and it was everywhere dull on percussion, except for about two inches below the sternum, and in the extreme flanks. This dulness was continuous with that of the liver, and it extended downwards quite to Poupart's ligament and the pubes. Over its whole area fluctuation and thrill were distinct, except on the right side, where, about three inches to the right of the navel, and two inches from the rib-cartilages, was a solid mass about seven inches in diameter. With the exception of slightly prolonged expiratory murmur below the collar-bones, nothing abnormal was found in the chest; it expanded well, and was normally resonant. The urine was free from albumen, and its specific gravity was 1020. Micturition of late frequent. Her hands and feet were usually purplish and cold, and her face always a little flushed. Skin moist and cool. She had latterly lost flesh, and found herself much inconvenienced by the bulk of her belly, occasionally saying her life was a burden.

She was one of seven children, of which two died in childhood, and two sisters and two brothers survived. Her mother and one sister are dropsical—from the patient's account probably anasarcous. At the end of January the girth at the navel was one inch and a half more, and the distance from the pubic symphysis to sternum had increased two inches. Taking into account the patient's constitution, her family history, the quick growth of the tumour, and its concurrence with pregnancy (which has been found to favour the formation of adhesions) ovariotomy could not be regarded without much apprehension of an unfavourable result, but it was her only chance. A menstrual period having ceased on February 23, five days later (on the 28th), at 9 a.m., the tumour was removed. It consisted of three principal cysts, the largest of which contained a dirty straw-coloured viscid fluid, the second a perfectly colourless water-like serum, and the third a colloid mass too thick to pass through the trocar. A strong broad vascular adhesion to the abdominal wall in front of the descending colon was transfixed, and tied in two pieces with fishing gut and severed without bleeding. The pedicle was very broad and thin, long enough to be clamped without dragging. The patient, who took ether, was sick after the abdominal incision, and before the cysts were tapped, which caused a few minutes' delay. As in the other cases, ice only was given by mouth during twenty-four hours, and enemata of beef-tea were administered. She dozed occasionally through the day, after having tr. opii ℥x. in two of the enemata. At 9 o'clock p.m. her pulse was 112, and temperature 101·2°. The belly was flat, not tender when touched, but she had had two or three coughing fits and complained of phlegm, which she could not get up, being unable to cough freely, as this made her belly painful. Slight rhonchus was heard over the front of both lungs, but the lungs expanded freely and plenty of air entered them. Sinapisms and afterwards a large linseed poultice were applied. At half past eleven o'clock she vomited, the first time since the operation, and after this she passed a restless night harassed by thirst, and towards morning by a pain in her left shoulder.

Next morning (March 1), at 8 a.m., her temperature had fallen to 100·8°, but her pulse had risen to 134 beats, Her cheeks, before the operation usually slightly flushed, were pale, and her features expressed great oppression. The belly was quite flat, not at all tender when pressed, except along the line of the incision; she said she had not any pain in it, but only in her chest and shoulder. In the chest nothing more than an occasional rhonchus was heard. At noon the pulse was 134, and the temperature 100·3°; but the sense of oppression, which she referred entirely to the chest, had much increased. At 5 p.m. the resident medical officer detected a loud friction-sound over the heart, which certainly was not previously present. The frequency of the pulse had risen to 148 beats, and the temperature was 101·4° F. Sickness now became troublesome. Eight leeches were put on over the heart, calomel and opium were given by mouth every second hour, and mercurial ointment rubbed into the arms and thighs. The strength now rapidly failed. Small quantities of iced champagne were given from time to time, but the sickness increased. At 8 p.m. the belly was still flat, free from tenderness and pain, but in the course of the night it became swollen.

At 7 a.m. on the 2nd she was pulseless, cold, cyanosed, and she died shortly after, or about forty-eight hours after the operation.

At the post-mortem examination, made next day by the Registrar, the wound was found to be already united. There was a small quantity of turbid serum in the peritoneal cavity. The whole parietal and visceral peritoneum was injected; it had not generally lost its polish, but parts, particularly in the neighbourhood of the incision, had a thin coat of fresh exudation, and near the wound also were many small subserous hæmorrhagic spots. The bronchi were injected, and the bases of the lungs congested and atheromatous. The pericardial sac contained a little serum. In the subserous tissue under the pericardium, on the left side of the heart, were numerous minute grey pearly beads (miliary tubercles?), and the endocardium of the left ventricle exhibited several red injected patches; it was also rough from a coating of soft fresh exudation, particularly on the mitral and aortic valves. The right ventricle contained a tough, fibrinous, adherent clot, which extended into the pulmonary artery.

German Professors and Students during the late War.—In a work published by a German student at Leipzic, biographical notices are given of 248 students and 4 professors who fell in action—the University of Leipzic suffering the greatest loss, 63 members in all. Out of the 13,765 German students matriculating in the summer term of 1870, 4510 went through the campaign, about 3500 of whom were in the ranks, and 1000 attached to the ambulances. Out of 1505 university professors, 15 were under arms, 253 devoted themselves to the care of the sick and wounded, and 120 worked for the national cause by tongue and pen.—*Philadelphia Medical Times*, 1873, No. 81.

SATURDAY, AUGUST 30, 1873.

THE COMMISSION ON SCIENTIFIC INSTRUCTION AT OXFORD AND CAMBRIDGE.

The subject of the relation of the older English universities to natural science is one of high interest and importance to the profession of medicine. For centuries medicine as a profession has received but a comparatively small share of the advantages which an education at Oxford or Cambridge affords, although these advantages have been lavishly showered on divinity and law. The main reason for this inequality has been that the studies which have been encouraged in the universities have been those which are fundamental for the theologian or jurist, whilst those which lie at the foundation of the art and science of the physician or surgeon have been until lately completely, and are still comparatively, ignored. The neglect of natural science in the Universities of Oxford and Cambridge is only one clause of the indictment which educational reformers bring against the government and management of those venerable seats of learning; but it is perhaps the most important one. We have so recently discussed the subject of university reform that we should not have again recurred to it had it not been for the appearance of the very important report of the Royal Commission on Scientific Instruction and the Advancement of Science in the two Universities, which has just been published.

The Commission which has produced this report is not to be confounded with another Royal Commission which is collect ingevidence as to the financial condition of the universities and colleges and the amount of funds available for enlarged plans of educational usefulness. The Science Commission is presided over by the Duke of Devonshire, the Chancellor of the University of Cambridge, and amongst its members are Stokes, Sharpey, Huxley, Sir John Lubbock, and Mr. B. Samuelson—names which have sufficient weight to insure a careful consideration for the conclusions at which they have arrived. The evidence which the Commissioners have collected they have arranged and considered under six heads:—1. The courses of study and the examinations. 2. The professoriate. 3. The scientific institutions within the universities. 4. The colleges. 5. The relation of the universities to technical education, and to education for scientific professions. 6. The duty of the universities and the colleges with regard to the advancement of science.

Different thinkers will form different estimates as to the proportion which general literature should bear to direct scientific pursuits in the education of a young man who is intended for a scientific profession, or who has determined to devote his life to the cultivation of any branch of natural science. It is a question which we shall not attempt now to discuss. We would only observe that the Commissioners evidently regard the examinations which every student has to pass before obtaining his bachelor's degree—examinations known at Oxford as Responsions and Moderations—as an obstacle in the way of scientific progress which might well be removed. They would not indeed sweep away all tests and proofs of liberal education, but, by placing these outside the threshold, they would leave the student of science free on entering the university to pursue the special objects which he has in view. They recommend that on leaving school each boy should pass an examination in literature and the general branches of learning equivalent to the German *abiturienten examen;* that this should be his passport to the university, where, from the first moment of his entering, he would be free "to devote his whole time and energy to his scientific studies." The "leaving examination" would be arranged, and, we presume, superintended by the universities and the public schools. The idea is really that of the preliminary examinations which stand at the entrance of the legal and medical professions, and of the matriculation examination of the University of London. The Commissioners would indeed permit a boy who fails to pass the leaving examination to enter the University on condition that he passes at some later period of his course an equivalent examination. But they recommend that a leaving examination should become the general rule of all great schools, and they believe it would be as beneficial for boys who are not intended for a university as for those who are to continue their education there. They also recommend that "those parts of science which are suitable to form part of the education of boys should be fully recognised in it. But natural science is not taught at schools, and probably one reason is that the universities hold out no inducements to schools to teach it. Out of 107 scholarships at Oxford six only are for proficiency in natural science. An increase of natural science scholarships would be an incentive to schools to teach and to boys to learn, and such increase the Commissioners hold to be imperative. They recommend that there should be not only College Scholarships but University Scholarships for Science, comparable to those which already exist for classical and mathematical attainments.

Within the universities themselves they recommend a large increase of the scientific professoriate. They compare the list of professors at Oxford and Cambridge with the list of professors at the University of Berlin, and the comparison is certainly not in favour of the former. Whatever be the ultimate arrangement of the Science Faculty in the University of Oxford, they recommend the immediate establishment of two professorships in Physics, two additional in Chemistry, five independent professorships in Biology (exclusive of those assigned to the Faculty of Medicine), and two chairs of Mathematics and Mathematical Physics, and a chair of Applied Mechanics and Engineering. These professorships would be of the first order, with proportionate emolument; but in addition the Commissioners recommend the appointment of a considerable staff of adjoint professors or readers, demonstrators and assistants, and a commensurate increase in accommodation—laboratories, lecture-rooms, with the necessary apparatus and appliances. The whole Faculty of Science

they would place under a single administrative body in each university, in which every department of science should be represented, and which should have large but definite duties imposed upon it—financial and educational. For this body they propose the title "University Council of Science."

With regard to the duties of professors, the Commissioners hold them to be double—first, the duty of teaching; secondly, that of advancing science. They will not allow that the duty of original research should excuse a man from lecturing, nor, on the other hand, that the labour of lecturing should entitle a professor in a great university to spend the remainder of his time in learned leisure. Some of the witnesses examined by the Commission have suggested that the duties of lecturing and teaching required from the professors are so onerous that they leave no time for original research, and they have recommended that the professorial statutes as to the number of lectures should be relaxed. We are glad to notice that the Commissioners refuse to countenance this suggestion. They urge very properly that the university duties of a professor only last six months, and "that he has thus the invaluable privilege of being master of his time for fully one-half of the year. It is therefore only reasonable that during the university terms he should devote a fair proportion of his time to the work of teaching." In this those who know Oxford and Cambridge best will fully concur. If our old universities are not only to maintain their reputation for excellence in classical literature and in mathematics, but are to vie with the German universities as the great scientific centres of the country, giving each year an impulse to experimental philosophy which shall be felt throughout the civilised world, a new spirit of activity and life must take the place of their dignified but somewhat indolent routine. Undoubtedly they are "seats of learning," for learning has been nowhere more sedentary. The idea of progress in sound knowledge, which was the idea which actuated the founders of those grand mediæval cloisters and colleges, has been well-nigh forgotten, and the enormous revenues which the intelligence and piety of former ages have made available for the increase of the sum of all human attainments have been mainly spent in keeping alive a knowledge of a literature which centuries ago yielded all of which it was capable. The Commissioners fully recognise that the functions of a great national university are not merely to teach and to examine, but to advance all parts of human knowledge and culture, and we welcome the appearance of their report as the harbinger of a new era of intellectual progress and activity in the great universities of England.

MEDICAL USES OF ELECTRICITY.—No. I.

But a very few years ago a paper on the employment of electricity in medicine would, in England, have subjected its writer to more than a suspicion of serious flirtation, if not of alliance, with that unholy thing—quackery. On the Continent, indeed, in France and Germany, physicians of the highest standing—such as Duchenne de Boulogne, "the Father of Electro-therapeutics," Du Bois Raymond, Trousseau, Remak, Benedikt Eulenberg, and Ziemssen,—have for many years been working zealously at the subject, and by their numerous and valuable publications have made the medical uses of electricity largely and widely known. But in England the belief in its therapeutical value and powers has been of very slow growth, and it is only very lately that the profession at large has begun to take any real or widely spread interest in the matter. Their attention has, however, at last been fully aroused by the labours of Reynolds, Anstie, Radcliffe, Althaus, Buzzard, Tibbits, and other physicians; and there appears to be not a little danger lest their zeal in the use of the power placed in their hands should outstrip their knowledge of the subject, and lest, therefore, some abuse of electricity in medicine should lead to a depreciation of its value or a dread of its use. Cases could, we fear, already be quoted in which very serious mischief has been produced by the use of faradisation ignorantly and improperly employed. There is, indeed, no lack of works to teach the proper uses and the proper limits of the employment of the various forms of electricity, medically and surgically; but many of these are in a foreign language, and are therefore sealed books to the mass of the profession, and some, while in the English language, are too lengthy to be of much use to busy practitioners, and probably but seldom fall in the way of the majority of them. It is thus not easy for medical men generally to get at all a full or exact knowledge of what electricity can do in medicine, or in what cases and how it may be safely employed; while at the same time the occasional papers on its uses and the cases illustrating its power for good, published in the periodical medical press—especially in the *Practitioner*—are strongly incentive to the employment of it. Perhaps it may be said, also, that the less a man really knows about it the more is he apt (on the *omne ignotum pro magnifico* principle) to expect from it, and the more likely is he to employ it rashly and inopportunely. We may, indeed, hope and expect that the excellent "Lectures on the Clinical Uses of Electricity," by Dr. Russell Reynolds, and Dr. Tibbits' admirable "Handbook of Medical Electricity," will do very much to impart the desired knowledge to the profession at large. But it appears to us that we may do something towards supplying this needed information by the publication of a few short plain papers on the use of electricity in diagnosis and in treatment.

We do not propose to attempt to go fully into our subject; any such attempt would carry us far beyond our intended limits; but we hope to give such an account of what has been thoroughly tried and proved in the employment of electricity, that the practitioner may know well when he may safely use it, what he may expect from it, and how far he may safely and usefully go in the use of it.

We do not intend to give any description of the instruments to be used—we must credit our readers with some knowledge of these; but it is as well to premise that we shall use the word electrisation in its general sense, as including—

Franklinism—i.e., Friction, or Static Electricity: the electricity evolved by the friction of glass or amber. *Voltaism—i.e.*, Voltaic, Galvanic, Dynamic, Contact or Current Electricity, the "Constant Current," the "Battery Current": the electricity evolved by chemical action; and *Faradism*—the Induced Current, Electro-Magnetism, or, as it is so often called, the Interrupted Current: "the currents of momentary duration discovered by Faraday to be generated or induced in a coil of copper-wire by the action upon it, under certain conditions, of a permanent magnet, or of a voltaic current."

We will once for all acknowledge that we are largely indebted for what we have to say to the various English authors already mentioned of works on medical electricity. We shall draw freely on their writings and on the various papers that have appeared on our subject in the *Practitioner*, but we shall not as a rule name again the works or the writers from whom we have gained much of the information contained in these papers.

We will now proceed to give two or three general directions for the employment of electrical treatment.

Be careful not to frighten the patient with the apparatus used or the mode of using it. Children may easily be seriously alarmed by what the operator has by daily use become perfectly familiar with; and even "children of a larger growth" are often extremely nervous at the idea of electrical treatment. The consequences of the alarm so caused may be very serious, and would very probably be placed to the credit of the electricity, and so may bring discredit on the treatment employed.

The operator should always be careful to know exactly the

strength of the current he is about to employ. Dr. Tibbits gives a good rule on this point—"In either diagnostic or therapeutic electrisation the operator should never use electricity upon a patient without first testing it upon his own hand, and, if about to apply to the face, upon his own face." In all our machines the strength of the current, either voltaic or faradic, may vary from day to day, and attention to this rule is the only sure means of testing the current to be used.

When acting on muscles the treatment must not be prolonged so as to tire the muscles or the patient; if the application of the battery-current, "or of any form of electricity, is followed by weariness in the limb, giddiness in the head, pain in the head, a feeling of faintness, of sickness, or a nondescript sense of discomfort about the epigastrium, do not go on with electricity at all; cease altogether for a time." And do not apply to muscles a current of such strength as causes pain: the force of the current should be just enough to excite contraction, but contraction without pain; if it is painful it may do mischief. A muscle pained is a muscle hurt.

RESEARCHES IN THE PHYSIOLOGY AND PATHOLOGY OF THE BRAIN.

Ever since there has been a science there has been a science of mind, and mind has for the most part been relegated to the brain, whilst moral and emotional sensations have been referred to such out-of-the-way organs as the liver, spleen, and stomach. It is only recently that there has been any serious attempt on the part of philosophers—as they used to be called—on the one hand, and of men of science on the other, to deal with the organs whence thought and art are in whatever way evolved—*i.e.*, the brain; and it is still more lately that they have tried to localise in a scientific way either sensory or motor impulses. Nevertheless, in recent days important advances have been made. First we were able to recognise that in some way the cerebral hemispheres had the most important part to play in intellectual function. Gull and Spurzheim, to whom is due a certain credit for having first directed attention to this point, mixed up their truth with all kinds of absurd fallacies. It was not difficult to make out that the cerebellum in some way controlled movement, but how and in what way was by no means easy to prove, nor has it been proved to this day. So, too, it was not difficult to find out the important part played by the medulla oblongata, though even now it is difficult to say what are its exact functions. Enough has, however, been done to show that it exercises most important influences over circulation and respiration directly, and over several of the other functions of the body indirectly. But when we approach the study of the cerebral hemispheres we must not forget that in man the cerebral ganglia—the mass of the hemispheres—so greatly overlap and overcap the other important parts of the brain that these are lost in their substance; whereas in some of the lower animals, especially fishes, we encounter successively, from before backwards, olfactory lobes, cerebral lobes, optic lobes, cerebellum, and medulla oblongata. We have, however, been able to make out that what we call in man the cerebrum has at its base two great ganglionic masses—the corpora striata and the optic thalami,—which are in intimate connexion with the brain proper (cerebral hemispheres), and which again in turn communicate more or less directly with the spinal cord and peripheric distribution of the nerves. Now, if there is anything proved in cerebral physiology it is surely this: that the so-called optic thalami are the centres of reception from without—in other words, of sensation, and that the corpora striata are the centres of motility, whether reflex—directly or indirectly—or coming straight from the cerebrum. At all events, these two great masses of grey matter are interposed between the grey matter of the hemispheres and the conducting rods thereof, the white and grey matter of the cord; and whereas irritation of the one may produce signs of pain, irritation of the other always produces motion, perhaps in the form of convulsion. But the question arose, "How can we manage to irritate (say) the corpus striatum without injuring other parts of the brain to such an extent as seriously to interfere with any exact inference from the result of the experiment?"—and this has been heretofore an insurmountable difficulty. It was discovered that for some reason or other the nerve substance constituting the brain and spinal cord was not capable of irritation by direct stimulation, especially by electricity. However, two German observers—Fritsch and Hitzig—made the attempt to determine function by injecting chromic acid through a fine trocar into the substance of the brain. This of course killed a certain portion of the brain substance, the extent being marked by the change of colour, and the results were noted. In this way they obtained certain facts of great importance, especially as regards the localisation of certain functions. The same line of research was subsequently taken up by Dr. Ferrier, of King's College, who, however, found that by induced electricity he could obtain much better results than by any other method. His researches are published in the current (third) volume of the "West Riding Lunatic Asylum Report,"—for by the kindness of Dr. Crichton Browne, the Superintendent of the Asylum, Dr. Ferrier was able to carry on his experiments there. Moreover they serve notably to confirm the conclusions of Dr. Hughlings-Jackson, whose interesting reports and lectures on cerebral diseases are now appearing in our columns.

The following are Dr. Ferrier's conclusions. Imperfect as he admits they are, nevertheless they are most worthy of examination, and we commend them to the attention of the profession. He says:—

"1. The anterior portions of the cerebral hemispheres are the chief centres of voluntary motion and the active outward manifestation of intelligence.

"2. The individual convolutions are separate and distinct centres; and in certain definite groups of convolutions (to some extent indicated by the researches of Fritsch and Hitzig), and in corresponding regions of non-convoluted brains, are localised the centres for the various movements of the eyelids, the face, the mouth and tongue, the ear, the neck, the hand, foot, and tail. Striking differences corresponding with the habits of the animal are to be found in the differentiation of the centres. Thus the centres for the tail in dogs, the paw in cats, and the lips and mouth in rabbits, are highly differentiated and pronounced.

"3. The action of the hemisphere is in general crossed; but certain movements of the mouth, tongue, and neck are bilaterally co-ordinated from each cerebral hemisphere.

"4. The proximate causes of the different epilepsies are, as Dr. Hughlings-Jackson supposes, 'discharging lesions of the different centres in the cerebral hemispheres.' The affection may be limited artificially to one muscle or group of muscles, or may be made to involve all the muscles presented in the cerebral hemispheres, with foaming at the mouth, biting of the tongue, and loss of consciousness. When induced artificially in animals, the affection as a rule first invades the muscles most in voluntary use, in striking harmony with the clinical observations of Dr. Hughlings-Jackson.

"5. Chorea is of the same nature as epilepsy, dependent on momentary and successive discharging lesions of the individual cerebral centres. In this respect Dr. Hughlings-Jackson's views are again experimentally confirmed.

"6. The corpora striata have crossed action and are centres for the muscles of the opposite side of the body. Powerful irritation of one causes rigid pleurosthotonus, the flexors predominating over the extensors.

"7. The optic thalamus, fornix, hippocampus major, and convolutions grouped around it, have no motor signification, and are probably connected with sensation.

"8. The optic lobes or corpora quadrigemina, besides being concerned with vision and the movements of the iris, are centres for the extensor muscles of the head, trunk, and legs. Irritation of these centres causes rigid opisthotonus and trismus.

"9. The cerebellum is the co-ordinating centre for the muscles of the eyeball. Each separate lobule (in rabbits) is a distinct centre for special alterations of the optic axes.

"10. On the integrity of these centres depends the maintenance of the equilibrium of the body.

"11. Nystagmus, or oscillation of the eyeballs, is an epileptiform affection of the cerebellar oculo-motorial centres.

"12. These results explain many hitherto obscure symptoms of cerebral disease, and enable us to localise with greater certainty many forms of cerebral lesion."

THE WEEK.

TOPICS OF THE DAY.

In a letter from their secretary (Mr. D. Maconochie), which has been published in the *Times* and widely circulated, the Dairy Reform Company, of Orchard-street, Portman-square, acknowledge with some appearance of reservation that a very large number of the cases in the recent typhoid epidemic at the West-end have been due to their milk. It is a pity that a large part of Mr. Maconochie's letter should have been devoted to proving the possibility of the outbreak having been produced by other causes than the Company's milk. He says but little satisfactorily to account for the fact that the Company in the first instance virtually declined to stop their milk supply when warned by the joint letter of Sir William Jenner and Dr. Murchison. A more satisfactory part of the statement is that the Company have determined to institute a weekly medical inspection of the farms whence their milk is obtained, and of the persons employed on them, whilst the cattle are to be also regularly inspected by competent veterinarians.

The sewage and disease controversy is dying out with the typhoid outbreak which gave rise to it. Mr. Hope, who writes to the *Times* in defence of sewage irrigation, recommends a thorough scientific examination by Government of all animal and vegetable produce on sewage farms, to be continued over a sufficiently long period; and he enforces his proposition by the fact that the inquests of last year proved that between ninety and one hundred people died in London from starvation.

At Hammersmith, a gardener, George Hunt, has been committed to take his trial on a charge of murder by administering poisonous mushrooms to a woman, who died from the effects. The papers have lately contained numerous cases of accidental poisoning. A number of children at Blackburn have been made very ill, and one has died, from eating arseniate of soda; and the child of a herb doctor at Plumstead has died from swallowing strong acetic acid, administered by his mother in mistake for a "harmless solution of aconite" which was kept on the kitchen chimney-piece.

The death-rate of London seems to be increasing. During the week ending Saturday, August 23, the deaths exceeded by 23 the average number of the corresponding week in the last ten years; but zymotic diseases are diminishing. There were 482 deaths from the seven principal diseases of the zymotic class, against 585 and 538 in the two preceding weeks. The deaths from these seven diseases exceeded, however, by 28 the corrected average. This was due to excessive fatality from diarrhœa. Deaths from diarrhœa, which had been in the two previous weeks 470 and 405, declined to 362, being 127 in excess of the corrected average. Sixteen deaths were referred to simple cholera—eleven were of children under five years of age. The deaths from fever were thirty-two—one was certified as typhus, twenty-seven as enteric or typhoid, and four as simple continued fever.

SANITARY PRECAUTIONS IN THE PORT OF LONDON.

Meetings are almost daily held by the Port of London Committee of the Corporation for the purpose of taking immediate steps for the prevention of an outbreak of cholera or other epidemic disease in London. The Danish emigrants who have been kept under observation during the last fortnight as "suspected" of cholera were, with three or four exceptions, furnished with a clean bill of health on Thursday week by the port medical officers. The entire party, consisting of seventy-four men, women, and children, were discharged on Saturday last, and were placed on board a steamer for Plymouth, whence they will embark for New Zealand. It is only due to the port sanitary authority to add that in the first few weeks of its existence it has possibly saved the metropolis from an epidemic of cholera.

THE AUTUMN MANŒUVRES.

(*From our Special Correspondent.*)

The man who chose Dartmoor as a site for this year's Manœuvres must be enjoying the satisfaction of having made as complete and disastrous a blunder as a commander can usually achieve in time of peace. A high plateau of bog, dotted with rocky eminences called Tors—"a filthy compound of stones and squish," as some indignant warriors called it,—which takes toll from every cloud that issues from the Atlantic, was not the place which would have occurred to any but a cocked-hatted mind as a fit site for camps of instruction. As everyone knows who has seen much of war, continued wet is the soldier's worst enemy. Heat and cold can be faced with impunity, but everything collapses before long-continued rain. The result of the watery campaign which has just elapsed has not been so damaging to the men as might have been expected, and this is probably due to the moderate temperatures which prevailed, as well as to the careful elimination of all men whose health was doubtful before the skeleton battalions were sent into the field. But the expenditure in horseflesh must have been serious. It was pitiable to see the poor brutes standing in the wind with no covering at all, night after night, drenched to the very last hair on their skins. The amount of sickness among the regulars is indicated by the fact that about 2 per cent. had to be sent away to Plymouth and other places according to the statements of the regular medical officers; probably the number will be found to have exceeded that figure when the totals have been added up. The volunteers have enjoyed good health, and have sent away a few men only for minor ailments. If a man is not likely to be able to march within two or three days, it is not usually worth while to retain him at the camp. The First Provisional Battalion, composed as in former years of the Inns of Court, Oxford, Cambridge, Artists, and other corps, complained bitterly, and with good reason, of being placed on a foul-smelling piece of ground at Ringmoor, on which a battalion (the 49th Middlesex) manifestly uncleanly in its habits had been encamped a fortnight before; and this merely to save some staff officer the trouble of marking out another camp. Fortunately nothing worse than vomiting and diarrhœa was caused by it. There were only three changes of camp, and only two or three field-days; the time and labour expended were mostly thrown away; and everyone went home with a hope that business might never again bring him to Dartmoor.

We have been surprised to see this week, by the report of the *Times* correspondent attached to the forces encamped on Cannock Chase, that there has been a dearth of medicines in one of the field hospitals there. It has hitherto been the custom at these Autumn Manœuvres to appoint a principal medical officer endowed with full powers to demand whatsoever he considered necessary in the shape of medicines, surgical instruments, etc., and who has therefore been held responsible that no complaints of the present description should arise. In this instance it appears that the gentleman who was nominated

principal medical officer became sick just before the troops arrived at their destination, and his duties were taken over by a successor who could scarcely have had time to make himself acquainted with the plans of his predecessor. To this circumstance, we believe, the deficiency in question must be traced; and as the requisite medicines themselves were actually in the camp, if not in the field hospital itself, the want of medical stores could only have been temporary. Moreover, each regiment and battery of artillery carries with it to the Manœuvres a small article of equipment called a "field companion." This is strapped over the shoulders of an orderly, and contains a carefully selected and closely packed store of most things likely to be needed in the emergencies of active service—a few medicines, some pills and powders for diarrhœa, etc., lint, bandages, tourniquets, scissors, and the like. It will thus be seen that, with healthy troops just marched out of their barracks for exercise, everything that could be supposed to be required was available for each corps on the ground. We have no doubt that probably before the account was printed the missing medicine-chests were unearthed and placed in the field hospital ready for all emergencies. Anyway we are inclined to think that this grievance was more imaginary than real.

POISONING BY LUCIFER MATCHES.

An inquiry was held last week by Mr. S. Lowe, the coroner for Lincoln, touching the death of an infant who had been poisoned by sucking lucifer matches. It appeared from the evidence that the deceased on Saturday night with another child got hold of a box of matches and sucked the phosphorus from forty of them. Severe symptoms came on two hours afterwards. Nothing was done, however, until eleven o'clock, when Dr. Harrison was sent for, but all his efforts were unavailing, and the child died on Sunday morning. Dr. Harrison said that on Saturday night, about eleven o'clock, he was requested to see deceased. He found the child cold and pulseless. The mother told him that about four o'clock she found the child playing with a box of lucifer matches, and that it had sucked the ends off some of them. About six o'clock sickness commenced, and continued up to the time he was sent for. He examined the remnants of the matches, and counted forty-two that had been sucked. When he first saw the child it was in a state of collapse, and he thought it would die very soon, but after some time it improved. About five o'clock in the morning a severe pain in the stomach came on, and the child died shortly after. The child was one year and nine months old. A post-mortem examination was made by Dr. Lowe and himself on Sunday night. The stomach was remarkably pale, with the exception of one small patch. The kidneys were congested. There were no other post-mortem appearances of any consequence. The mouth was closed; the lips and gums were pale and blanched. There was no luminosity about the stomach, no odour of phosphorus or garlic, and no vapour. One portion of the vomit smelt like the phosphorus on the ends of the matches. He agreed with Dr. Lowe's written report, which stated that he had examined the stomach after he had dried it, and it burned with a pale phosphorescent light. He had no doubt that death was caused by the phosphorus. One match contained one-fifth part of a grain of pure phosphorus, so that the whole amount taken by the child would be eight grains. One grain was certain to kill, and even less than one-half a grain has been known to be fatal. Dr. Harrison, continuing his remarks said it was very unusual for death to occur so rapidly as in this case—viz., in thirteen hours. Phosphorus was considered an irritant poison, but in this case the blood seemed to have been poisoned. There was no sulphur on the matches, which are called gas matches, and manufactured by Bellerby and Sons, York. There was no disease whatever about the child. The jury returned a verdict that the child was poisoned by phosphorus inadvertently taken by itself.

THE ASHANTEE WAR.

The first batch of invalids resulting from the "little war" forced upon us by the King of Ashantee have just reached this country in the *Himalaya*, and have been transferred to Haslar Hospital. They appear to have suffered severely from the malarious climate of Cape Coast, the small contingent of Marine Artillery and Light Infantry sent from England at the outbreak of the war contributing no less than three officers and eighty-five non-commissioned officers and men to the numbers just arrived. The head-quarters of the 2nd West India Regiment were only disembarked at Cape Coast on July 11 last; but although, from the nature of their constant duties in the tropics, they might have been expected to be somewhat acclimatised, they speedily began to suffer from the prevailing forms of fever and dysentery. Many of the officers were attacked; the colonel of the regiment has come home in the *Himalaya* invalided, and the adjutant died a few days before the news left. No operations of any importance have yet taken place on either side. The Ashantees are still reported to be in close proximity to Cape Coast Castle, and no fears are entertained for the safety of that place or for Elmina. Meanwhile there is a dreary wait, without any other alternative, before our troops, and, it is to be feared, a further melancholy list of deaths and invaliding in perspective. The recent appointment of Colonel Sir Garnet Wolseley (who has for some time held a post on the staff at head-quarters) to the command of the troops on the Coast would argue that the Government were about to send out more reinforcements; but if such be the case it is to be hoped, as the settlement is reported not in danger, that no more men will be sent from this country or elsewhere until such time as they can actually be placed in the field to operate against the enemy. Active duty is in itself a preventive of disease; and in the long run more lives would be saved by a prompt and vigorous setting down of the Ashantees for good and all than by pursuing a policy of dribbling up small detachments to the seat of fighting, and tying the hands of the officer in command by refusing him the means of following up to the end such successes as he may gain. There is little honour and much loss of life to be anticipated from our collision with the King of Ashantee, and we can only pray for an early and lasting deliverance.

UNWHOLESOME FOOD FOR INFANTS.

A medical gentleman drew attention, at an inquest recently held by Dr. Hardwicke, touching the death of two children, to the fact that some of the so-called infant food which was extensively advertised, and in consequence used by young and inexperienced mothers, was adulterated with articles which were not of a glutinous nature, and therefore unfit for children. The coroner remarked that if a person using these prepared foods would send samples to the officials appointed by the parish, they would be analysed, and in cases of adulteration the sellers would be prosecuted, and a great check be given to the sale of such stuffs. This is a matter which should have the attention of our analysts and of the authorities whose duty it is to enforce the provisions of the Adulteration Act. It is to be hoped that the hint given by Dr. Hardwicke will be acted upon. It is impossible that any form of adulteration of any kind of food can be attended with worse results than that of the food of infants.

BISHOPS STORTFORD AGAIN.

Some time since we called attention to a disgraceful custom which prevailed at Bishops Stortford with respect to retaining heaps of manure and other offensive collections for an unjusti-

fiable time in the streets of this town. The Board of Health, fortified, we regret to say, by the opinions of several medical gentlemen, ignored a recommendation for the frequent removal of the dangerous nuisances in question. It is gratifying to state that one of the first orders of the lately appointed Medical Officer of Health is confirmatory of our views on the subject—that the collections of manure and contents of dust-bins, etc., should be removed daily. The inhabitants of Bishops Stortford may congratulate themselves on having obtained the services of a gentleman who has given evidence that he can carry out necessary reforms uninfluenced by local interests or prejudices.

DUTCH MEDICAL SERVICE.

The *Scotsman's* London correspondent states that the Government of the Netherlands has announced its willingness to employ British surgeons on the following conditions:—The applicant must lodge with the chief of the medical staff of the Netherlands army at the Hague his name and address, along with satisfactory certificates as to character. He must be under thirty-five years of age. He must be able to speak either Dutch or French or German well enough to be able to pass a short *vivâ voce* examination. His engagement will be for five years, and may be prolonged. Successful candidates will take rank with first lieutenants on the staff. The pay will be 2250 guilders (about £185) per annum, with prospects of promotion. The Netherlands Government will grant a first-class passage to the seat of war, and a premium of 4000 guilders (about £330). The Batavian Republic has never forfeited the character given to it by Dugald Dalgetty, according to whom "its behaviour on pay-day might be an example to Europe." Besides, the attractions of the Dutch Indies to the scientific surgeon (especially if he be a naturalist) are at once rich and unique.

HEALTH OF SYDNEY.

The rate of mortality here (writes the New South Wales correspondent of the *Times* from Sydney on June 14 last) is highly favourable, being at the rate of 18 deaths annually to every 1000 persons living. Comparing the mortality of Sydney and suburbs with that of towns in the mother country, the result is much in our favour. In Sydney there are 48 persons to the acre and a mean death-rate of 23·8 per 1000; in the suburbs the rate is 14 per 1000. The towns in the United Kingdom having 34 persons per acre show a mean rate of 25 per 1000. There are in London 42·5 persons per acre and a mean mortality of 22·1 per 1000. Liverpool, Manchester, and Glasgow are the only cities more densely peopled than Sydney. The mean summer mortality is 23·8 per 1000 in the city of Sydney and 14 in the suburbs, against 25 in the towns of the United Kingdom. A good deal of attention is now being paid to water-supply, drainage, sewerage, and the removal of garbage, and the provision of city breathing-places, so that the rate of mortality will probably be lower than it is. The population is increasing rapidly.

HEALTH OF SCOTLAND.

The quarterly return ending June 30, 1873, of the deaths registered in Scotland, states that—

"In Scotland 19,931 deaths were registered during the quarter ending June 30, being in the annual proportion of 232 deaths in every ten thousand persons of the estimated population, or 2·32 per cent. The mean death-rate of the quarter during the ten previous years was 223 deaths in every ten thousand persons, or 2·23 per cent., so that the mortality of the past quarter has been high. In the five registration groups of districts into which Scotland is now divided, the death-rate was highest in the crowded town, and lowest in the sparsely inhabited insular-rural districts. Thus, for every ten thousand persons in each of these groups of districts, there occurred 272 deaths in the principal towns, 279 in the large towns, 228 in the small towns, 183 in the mainland-rural, and 164 in the insular-rural districts. Of the eight principal towns, the mortality was lowest in Leith and Edinburgh, highest in Greenock and Glasgow. Thus, for every ten thousand persons in each of these eight towns, there occurred during the quarter in the proportion of 213 deaths in Leith, 229 in Edinburgh, 240 in Dundee, 243 in Aberdeen, 269 in Perth, 293 in Paisley, 308 in Glasgow, and 316 in Greenock; 6762 of the deaths were registered during April, 6959 during May, and 6210 during June—being at the rate of 225 deaths daily during April, 225 daily during May, 207 daily during June. The diseases in the eight principal towns show that the zymotic, or epidemic and contagious, class of diseases has been on the increase, for while only 437 deaths therefrom occurred in April, 474 occurred in May, and 483 in June. The tubercular class of diseases proved most fatal in May—441 deaths having occurred in April, 479 in June, but 499 in May. Diseases of the brain and nervous system also proved most fatal in May, and were least fatal in June. Thus, 261 deaths therefrom occurred in May, 255 deaths in April, but only 248 in June. Diseases of the heart, on the other hand, were least fatal during May, for only 121 deaths therefrom occurred in May, but 133 in June, and 155 in April. The deaths from diseases of the respiratory organs decreased with the advance of the season, numbering 561 in April, 555 in May, and 441 in June. Kidney and urinary diseases were most fatal in May; but diseases of the uterus and childbirth were least fatal during that month; 124 deaths from debility and premature birth occurred in April, 123 deaths in May, and 132 in June. The deaths from old age, without marked disease, were 122 in April, 129 in May, and 94 in June. Of the individual diseases, small-pox seems to be on the decrease, 23 deaths therefrom having occurred in April, 17 in May, and only 13 in June. Measles, on the other hand, has been on the increase from January till the end of May, for 118 deaths therefrom occurred in April, 160 in May, and 150 in June. Scarlatina has been on the increase, the deaths therefrom having increased from 24 in April to 45 in June. Hooping-cough, on the other hand, has declined from 76 deaths in April to 55 in June. Typhus fever has rather increased, rising from 25 deaths in April to 30 in June. Enteric fever was most fatal in May, 36 deaths having occurred during that month, but only 33 in April, and 30 in June. Consumption was most fatal in May, when 351 died from it, 311 in April, and 322 in June. The deaths from bronchitis diminished with the advance of the season, 389 deaths therefrom having occurred in April, 366 in May, and 299 in June."

FROM ABROAD.—DR. HAMMOND ON ATHETOSIS—EFFECTS OF SENNA ON THE URINE—INFANT MORTALITY IN FRANCE.

In a paper recently read at the "Medical Library and Journal Association of New York," Dr. Hammond gave an account of the affection which he terms "athetosis." He observes (*Medical Record*, July 1) that there are several diseases one of the chief characteristics of which is involuntary movement while consciousness remains intact; but the present form had never been discriminated prior to the publication of his "Treatise on Diseases of the Nervous System," wherein two cases of athetosis are given. Since then various cases have been recorded, and it is now generally regarded as entitled to its separate pathological status. The name is derived from *αθετος* (without fixed position), and is specially applied to designate the chief phenomenon of the disease—the inability to keep the fingers and toes from continued motion. The movements are not disorderly as in hysteria and chorea, nor so tremulous as in paralysis agitans and the various forms of sclerosis hitherto described. They are regular, and are to some extent under the control of the will—that is, by a strong effort of volition the patient can for a short time prevent them; but they soon reassert themselves, notwithstanding the most strenuous endeavours to keep the muscles quiet; even during sleep the movements continue. The movements are not simple oscillations such as are present in paralysis agitans and sclerosis, but are slow as if performed with deliberation. The thumb

and little finger are more affected than the other fingers; and owing to the constant exercise, the muscles of the forearm become greatly enlarged, like those of an athlete. Pain is very generally complained of in the contracting muscles, and in one case caused very great distress. The sensibility of the skin over the affected parts is lessened, and a feeling of numbness prevails more or less extensively over the side of the body corresponding to the disordered motility. In all other parts it is normal. In two of the cases observed the athetosis was preceded by epileptiform paroxysms.

Of the six cases known to Dr. Hammond, two have occurred in women, and three of the subjects were intemperate. In none of the cases has treatment been of material benefit, but death has not as yet ensued in any case. In each of the cases there has been a steady advance in the severity of the peculiar symptoms, but the general strength of the patient has not been materially impaired.

If attention be paid to the situation and character of the movements, there can be no difficulty ordinarily in making a correct diagnosis, but Dr. Hammond recapitulates the main features of the affections likely to be confounded with athetosis. Thus, in *diffused cerebral sclerosis*, the muscular contractions are tonic and permanent, the affection, too, almost invariably beginning in infancy, and leading to atrophy or arrest of development of some part of the brain. In *multiple cerebral sclerosis*, tremor is a principal symptom, but this differs essentially from the apparently deliberate and obviously regular movements of athetosis. Besides, the hypertrophy of muscle, so characteristic of this, is never a consequence of tremor. Another marked phenomenon of sclerosis, festination, is absent in athetosis. In *multiple cerebro-spinal sclerosis*, the involuntary movements which appear after paralysis are only manifested when voluntary movements are made, and there is usually festination. *Chorea* is generally a disease of childhood. The involuntary movements are irregular, and cease during sleep, while those of athetosis continue. There is neither pain nor disturbed sensation, and the disease is generally curable. In *paralysis agitans* there is tremor, and not entire muscular contraction, unaccompanied by pain or anæsthesia. There are often intermissions in the day, and usually during sleep. There is no tendency to the tonic contractions which seem to ensue later in the course of athetosis.

Of the pathology of the affection nothing yet is known, as no post-mortem has yet been made. Physiology would seem to indicate the corpus striatum and perhaps the optic thalamus as the seat of the morbid process, which probably consists in sclerosis, the result of slow inflammation. No treatment has arrested the onward march of the disease, though galvanism has perhaps exerted a slight controlling power.

At the last meeting of the Paris Therapeutical Society, Professor Gubler drew attention to a curious property in senna of colouring the urine in a peculiar manner. The urine of persons who have taken senna becomes of an intense yellow colour with a green reflection, just like the urine in jaundice; but nitric acid shows that bile has nothing to do with this colouring. If a fragment of caustic potass be let fall to the bottom of a tube containing urine charged with senna, a magnificent purple colour is produced; but nothing of the sort takes place under the influence of potass in icteric urine. This colouring has been observed in all the patients who have taken senna whose urine has been examined—even where only half an ounce of the infusion or a black draught of the Codex has been administered. Urine loaded with senna is incapable of assuming the variable rose colour under the influence of nitric acid which normal urine always assumes. Infusion of senna itself treated with caustic potass assumes to a certain extent the purple colour. But the phenomenon is here far less marked, and M. Gubler believes that in this case a process goes on similar to that which occurs in relation to asparagus, turpentine, copaiba, etc.—a certain amount of oxidation taking place in the economy for the production of the peculiar odour of asparagus or the violet odour. With rhubarb M. Gubler produced a much less intense colour than with senna; but he suspects that the phenomenon in both cases is due to the chrysophanic acid, which is common to both the substances. After the absorption of the senna, the colouring of the urine may persist even to the next day. M. Gubler observed that for the detection of bile in the urine he always employs nitric acid, which he thinks is far preferable to iodine. He referred also to a peculiar colour of the urine often met with in severe disease, furnishing a *feuilles mortes* colour which may be easily mistaken for biliary colouring. The colour is really due to the superposition of a blue colour on the yellow; and at his clinic M. Gubler has often shown this blue colouring, which he has named provisionally "urinary *indigose*." On isolating it by ether, he renders the liquid clear by bringing to its upper part a ring of a beautiful blue colour.

In relation to the Bill brought into the French National Assembly by Dr. Theophile Roussel, having for its object the diminution of infantile mortality, M. Lagneau publishes (*Gaz. Hebd.*, August 8) an interesting analysis of the population returns, showing that the mortality of infants is considerably greater in the department of the Seine, and probably in other large centres of population, than is generally supposed.

In estimating this mortality, we can not only compare the number of living and dead, but also the number of children born alive who survive at given ages—the difference between the births and survivals showing the mortality at such ages. While for entire France the loss of children below the age of five during the eleven years 1855-65 amounted to from 29·65 to 31·07 per cent., in the department of the Seine it attained far higher proportions. Thus, of 54,520 children born in 1856 there only survived 26,798 at the census of 1861, furnishing a deficit of 27,722, or 50·84 per cent. of deaths during the first five years of existence. Of the 66,016 children born in 1867, there survived at the census of 1872 only 31,670, being a deficit of 34,346, or 52·02 per cent. of deaths during the first five years. After some calculations for which we have not space, showing the proportions of the children who died in the department, and of those who died in other departments to which they had been sent to be nursed, M. Lagneau terminates with the following conclusion :—

"The preceding deductions appear sufficient to show that death, which in France in general takes off about a third (30·29 per cent.) of the children below five years of age, removes more than one-half (51·43 per cent.) of those who are natives of the department of the Seine, these dying in this department or in other departments to which they are sent to nurse in a number approximating to that of those who are kept at home with their parents."

STATE OF HINDU MEDICINE.

The almost neglected (and daily apparently becoming more so) state of Hindu medicine has raised the advocacy in its behalf of the *Grant College Students' Journal*, a monthly paper of medical news published at Bombay. Its last issue for the month of July contains an article entitled "A Word in behalf of Hindu Medicine." The subject is one of importance. It is highly probable beneficial results to the science of medicine would follow an energetic attempt to develope the resources and the indigenous materials of the medical art of that vast country. We therefore lay before our readers the following remarks of the writer of the article in question, as they are well worthy being reproduced in our pages. He says :—

"We know not of any systematic attempt ever being made in the discovery of the medical department of Oriental know-

ledge. A few persons have attempted to give the outlines of Hindu medicine, comprising therein the surgical and anatomical portions of the art, and some few have made original researches as regards the diseases, and the botanical, zoological, and geological resources of India, in order to the enrichment of science in general. But we again repeat that no systematic attempt has yet been made in developing the resources and the indigenous materials of the medical art of this vast country. We say indigenous materials of medical art, because there are still extant many original works of great note on the art in this land; and, moreover, there may be found (although we are not sure) ample materials already ready worked to hand in the transactions of the several branches of the R. A. Society established in the Presidency towns. But the real want is not of works or materials, but of men eager to engage themselves in the undertaking. Our present educational system, although it breeds up generations of men able to take part in social, moral, and political concerns of this country yet has almost failed, up to the present time, in giving a sufficiently scientific turn to the thoughts of the people. Under such a state of things, however, it is a matter of great consolation to find that our University has encouraged the study of ancient languages such as Sanscrit, Latin, and others. We think more than a dozen Sanscrit scholars can now, if they choose, take themselves to the translating of the several indigenous scientific works either into English or into one of the widely spoken vernaculars of the country. For our part, however, we would never like to see any fact, howsoever consecrated by its antiquity, and which would not stand the test of experiment, enter into the system of the really useful and tried principles of medicine. But the current of opinion regarding the value of Hindu medicine runs, at present, in a direction which augurs anything but favourably for its future development. It is much to be regretted that the attainments of the people of this country in Western science and literature, instead of making them eager to verify and test the results so laboriously arrived at by their ancestors, have made them to impugn all the ancient doctrines without distinction as trash and unworthy of the trouble of experimentation. But it would be well for these off-hand critics to pause for awhile before they can take such a bold step and 'to stand on the old road until they find a better one.' In behalf of Hindu medicine we must put in our voice, and advise the people to issue a writ of *habeas corpus* in favour of the good old Sushruta, Charak, and Vãgbhat, and to give them a fair trial before consigning them to eternal banishment and filling up their places by new and untried friends. Now, to effect a complete regeneration of the whole of Hindu medicine, and to effect its thorough amalgamation with its brother of the West, are works which will require a great deal of time, men, and money. In the first instance a collection should be made of the native medical books that may be extant; secondly, they should be collated and re-edited. This part of the work would be far easier to accomplish now than it would be after a lapse of a score of years, when the few good teachers and practitioners of native medicine that now exist would be defunct, and the technicalities of the art would remain unexpounded. It should also be remembered that no new followers elect nowadays to enlist themselves in the Hindu medical corps, as the art is falling day by day into undeserved disrepute, and threatens in the course of time to become altogether obsolete. It is better, therefore, that the people, and the graduates of medicine in particular, should make the best of this time of harvest.

"We should also propose that chairs for readers in Hindu medicine should be established in the several Presidency colleges. We do not see why this should not be so. In many civilised countries of Europe chairs have been established for teaching oriental languages, and in the Presidency College, Calcutta, a new professorship has been created for agricultural chemistry with a grant of 5000r. to secure the necessary materials and implements of the art. At St. Petersburg a chair has been devoted (we hear) to demonology. These several instances will show the reasonableness and utility of our request for a Hindu medicine chair. We are quite sure that if the people and government do set about the work in good earnest, their labours will be amply rewarded. Apart from the additions which the medical science in general would receive to its several departments, we are certain innumerable new and specific drugs and preparations would come into our possession, which will induce men to put more faith in the medical art, and make the present mode of treatment more certain, practical, and useful. At all events, a grain of gold in a bushel of chaff is worth the trouble of finding it out. We propose to take an early opportunity of laying before our readers a faithful translation of Sushrutam and other Hindu authors on medicine."

CLINICAL REMINISCENCES.—No. II.

By PEYTON BLAKISTON, M.A., M.D., F.R.C.P., F.R.S.

Intestinal Obstruction.

Obstructions taking place in different parts of the intestinal canal are of frequent occurrence; and, arising as they do from various causes, they occasionally assume a peculiar form and excite great interest.

There is generally a marked difference in the symptoms arising from obstruction in the small and in the large intestines; although when it takes place near their union at the ileo-cæcal valve it is difficult to diagnosticate its exact position. Usually, however, the urgency of the vomiting and the rapidity with which exhaustion is produced sufficiently separate obstruction of the small from that of the large intestines, which latter is sometimes prolonged to a period of thirty or even thirty-three days, during the greater part of which time little or no vomiting takes place.

Small Intestines.

When obstruction takes place at the origin of the intestinal canal—the pyloric orifice of the stomach,—it is usually, but not always, occasioned by carcinoma.

Two remarkable cases have fallen under my notice in which it arose from a different cause—one that of a gentleman, the other that of a lady, both middle-aged, and both previously in fair health. The symptoms and progress of the affection were so exactly similar in both cases that a description of one will suffice for both. About an ounce of Burnett's disinfecting fluid (chloride of zinc) had been swallowed in mistake for fluid magnesia. The urgency of the symptoms arising from a destruction of a portion of the mucous membrane of the stomach had been mitigated and relieved by suitable soothing treatment during some three or four weeks, and the patients were progressing favourably, and complaining of little or no pain or discomfort after taking food, when periodical vomiting came on, the stomach becoming much distended before each act of vomiting—the symptoms thus gradually assuming the same character as those which occur in carcinomatous narrowing of the pyloric orifice of the stomach, and the patients eventually dying seven or eight weeks after the accident from inanition.

A post-mortem examination revealed the same appearances in both cases. The effects of the irritating poison on the mucous membrane of the stomach were chiefly seen on the great curvature, but the ulcers may be said to have in a great measure healed over. The pyloric orifice, however, was nearly blocked up by thickening of the sub-mucous tissue, thus presenting somewhat of the same appearance as in carcinoma.

A case of carcinoma pylori once came under my notice in which the progress and termination of the case were most unusual. A man about 42 years of age had been suffering for some time with all the symptoms of a carcinomatous affection of the stomach, including frequent and copious vomiting of fluid containing dark brown shreds resembling tobacco, when the vomiting gradually ceased, the action of the bowels became regular, and the patient regained so much strength that he was able to walk four or five miles daily. One day he was suddenly seized with vomiting of semi-solid stercoraceous matter, and speedily sank.

On examination of the body, extensive carcinomatous disease was discovered in the stomach, involving not only the pyloric orifice, but a large portion of the great curvature. The pyloric opening had been enlarged by ulceration, which had destroyed much of the morbid growth around it, so that it had a diameter of an inch or more. The great curvature adhered to the transverse colon, and communicated with it by a large opening, through which the contents of the colon had passed into the stomach.

I know not whether the pyloric orifice was enlarged in a similar manner in two other cases wherein an amendment took place, and life was prolonged for six or seven years afterwards. As there was not a post-mortem examination in either case, the matter must remain in doubt.

Whilst on this subject I may mention that I have found great relief afforded, when there have been sharp lancinating pains, by the subcutaneous injection of a few drops of a strong solution of morphia in the left hypochondriac region—a remedy which is perfectly heroic in cases of genuine sciatica, as shown in a paper of mine published some years ago in this journal.

Two or three cases of carcinoma of the duodenum occurred in my practice, but they did not present any feature requiring notice. In one case, however, obstruction of the duodenum was produced from without. A middle-aged man was affected with medullary sarcoma of the testicle, which, as is often the case, crept along the chain of glands skirting the abdominal veins, and expanded into a large tumour at the upper part of the abdomen. This tumour pressed the duodenum upwards, and became adherent to it for some inches, thus producing intestinal obstruction, attended with much the same symptoms as in carcinoma pylori, except that there was no evidence of ulceration. After death it was found that the intestines were free from all disease.

As is well known, obstruction of the small intestine more frequently arises from hernia than from any other cause, but such cases have only accidentally come under my notice, as in the following instance:—About thirty-five years ago an old man came under my care, as a patient of the Birmingham Dispensary, suffering from bronchitis. Suddenly there appeared symptoms of obstruction of the small intestine. He was therefore carefully examined to ascertain whether there was a hernia. None, however, could be discovered, but a small hard knob of the size of a pea was found close to the right side of the arch of the pubis. Now, it happened that some years before, when dissecting in the Ecole de Mars at Paris, I had seen a curious specimen of hernia, which was caused by a portion of the small intestine having passed through a slit in Gimbernat's ligament, and having been retained there, formed a tumour about the size of a pea. This specimen being in pickle, I had examined it repeatedly whilst Mr. Thompson, an English medical student, was making a drawing of it. It struck me as possible that the same occurrence might have taken place in this case, as no other source of obstruction could be discovered. I therefore sought the assistance of my surgical colleague, Mr. George Elkington, and subsequently that of the senior surgeon, Mr. Baynham. Both of them thought the small lump was a gland, but at my urgent solicitation they agreed to cut down upon it. They did so, and it proved to be a hernia caused by a portion of the small intestine having passed through a slit in Gimbernat's ligament, exactly similar to the one I had seen in Paris. The patient made a complete recovery.

In the following case, too, an unusual state of things was revealed. A schoolboy, aged 15, feeling unwell, was placed under the care of the medical attendant of the school, who gave him some medicine which purged him violently. Soon afterwards he complained of severe pain in his right flank, urgent vomiting set in, and there was no action of the bowels. Seen in consultation he was found to be in a state of extreme prostration. His countenance was hippocratic and covered with a profuse cold sweat; his pulse 140, small, wiry, and feeble. On examining him I found a scrotal hernia on the right side, which he said had been there for a long time. A consulting surgeon was then called in. He thought the hernia was omental, and was not the cause of the obstruction in the bowels. Still we thought it right to tell the parents of the lad that it was possible that the hernia might be the cause of the obstruction, and to put it to them whether it should be cut down upon to ascertain whether such was the case or not. They wished it, and accordingly the hernia was explored, and found to be omental, as the surgeon had surmised, and in no way connected with the intestine. Consequently no relief was obtained, and the patient died about six hours afterwards. A lump of excessively indurated fæcal matter, about the size of a pea, was found impacted in the appendix vermiformis, which, as well as some portion of the neighbouring ileum, was highly inflamed and embedded in pus.

I take this opportunity of stating that I have witnessed several instances in which great injury has been induced by the administration of strong drastic purges in cases of intestinal irritation and obstruction.

Years ago I often heard obstruction attributed to intussusception, but I myself never saw a case of this kind which was not accompanied by inflammation of the ileum at its juncture with the cæcum, unless, indeed, the following case might be considered one:—An aged female was suffering from obstruction, and the symptoms were sufficiently urgent to render it probable that it lay somewhere in the small intestines, but not high up. No traces of hernia were discoverable. Small doses of opium were administered, and salt and water thrown up per anum. I am afraid to state the quantity injected before she complained of inability to retain more; but it was enormous. On its being allowed to escape it brought with it a large quantity of fæces without any scybala, and relief, followed by speedy restoration to good health, resulted.

Large Intestines.

Many cases of obstruction of the large intestines have come under my notice arising from various causes, amongst which the most frequent have been an accumulation of foreign bodies, as fruit-stones, etc., carcinomatous narrowing, chiefly at the commencement of the descending colon or the sigmoid flexure, and once in the rectum. Some cases, however, occurred in which none of these causes of obstruction were present.

A lady, aged 34, after her confinement, suffered from obscure pains in the abdomen, and the bowels ceased to act, the abdomen being at the same considerably distended. There were, however, no symptoms of peritonitis or effusion within the abdominal cavity. Enemata passed up a considerable distance and in large quantity came back slightly tinged with fæcal matter; but no relief was obtained, and she gradually sank in a typhoid state. On examination, the ascending and transverse colon was found greatly distended and perfectly flaccid, the injected state of its vessels giving traces of inflammatory action, but no pus was found. The obstruction seemed to have been caused by the loss of muscular power in the coats of the intestine.

The following curious case was that of a policeman, aged 32, whose bowels had been confined for some days, and who, on suffering from severe griping pains, applied for admission to the Birmingham General Hospital. He derived comfort from small doses of gum opii; but copious enemata failed to bring down any fæcal matter. After a few days a round swelling was seen to come up from behind the pubis, looking like a distended bladder. My colleague Mr. Hodgson being called in, passed a catheter into the bladder; but only a small quantity of urine was drawn off, and the size of the tumour was in no degree diminished. It was therefore evident that the swelling was caused by distension of some portion of the colon, probably the cæcum. But where was the obstruction that caused the distension, and what was its nature, we knew not. It continued to increase till it reached the size of a small child's head, and fluctuation was perceived by the finger passed up the rectum. I proposed to Mr. Hodgson to puncture the swelling with a trocar; and to prevent effusion into the abdominal cavity I had a curved grooved needle made with a movable handle, which, after being threaded, could have been passed into the swelling, and having by its groove revealed the nature of the contents of the sac, could have been pushed on, and its point having been turned backwards towards the outer surface of the abdomen near where it had entered, could have been brought out, by which means the sac could have been fastened to the abdominal wall; it could then have been pierced, and its contents evacuated by means of a large trocar. Mr. Hodgson thought the operation would have been attended with too much risk, and declined to perform it. The patient died after about thirty days of obstruction. On examination of the body it was found that a mass of small intestine had passed over into the right flank, and had bound down the ascending colon over the internal psoas muscle. Had the operation been performed, it is probable that, after the evacuation of the sac, the intestine would have righted itself and the patient would have recovered, as there were no strong adhesions.

Another case occurred, in which I think recovery might have resulted from the performance of an operation. A girl, aged 16, became a patient of the Birmingham Dispensary, suffering from obstinate constipation evidently resulting from obstruction in the large intestines. On introducing the finger per anum a stricture was discovered just within reach. I could myself see no reason why a blunt-pointed bistoury should not have been introduced and the stricture cut through—as the sphincter is divided in cases of fissure of the anus,—but my colleagues declined to perform the operation, and the patient died. The stricture was found to be of a simple fibrous character.

The late Mr. Jukes published the case of a woman who was under my care suffering from obstruction of the large

intestine, and on whom he performed Amussat's operation, opening the colon in the loin, and forming an artificial anus. The patient survived the operation sixteen days, I think, dying of peritoneal inflammation of a low character extending from the wound. The obstruction was found at the sigmoid flexure, and was caused by a carcinomatous growth.

For some time previous to this occurrence, Amussat's operation had been much discussed, and we were in constant habit of injecting bodies per anum in the hospital dead-house, and performing the operation on them. Subsequently two of our pupils, when engaged in practice, I believe performed the operation successfully; but I do not remember their names, nor the particulars of the operations.

About twenty-three years ago, a case occurred which interested me very much. The wife of a medical man, about 38 years of age, had symptoms of obstruction of the large intestine. She was in rather a delicate state of health, and her countenance had a leaden, earthy appearance, particularly under the eyes. It was found that she had a largish hard tumour attached to the back of the uterus, if not incorporated with it. As the case progressed the convolutions of the intestines were strongly marked, and the course of the distended transverse colon could be distinctly traced, the distention terminating abruptly at its left extremity, where the descending portion commenced. After a time, however, these markings were obliterated by more general distension of the abdomen. The seat of the obstruction was considered to be at the commencement of the descending colon, and its character as well as that of the uterine tumour to be carcinomatous. The late Dr. E. and Mr. C. H. J. being friends of her husband, came down and met us in consultation. Dr. E. was of opinion that the obstruction was caused by pressure of the uterine tumour on the rectum, on which I requested Mr. J. to pass the colon tube if possible, and to inject warm water. He passed it with ease, and more than a quart of water was thrown up. It was thus proved that the obstruction lay above the rectum. Dr. E. then proposed that a drop of croton oil should be given every hour, and was of opinion that the stricture and tumour were both of a fibrinous nature. To this I strongly objected, as being calculated to give much pain, and to cause irritation, if not inflammation, of the intestine, and thereby greatly increase the discomfort of the patient, without offering the slightest chance of the obstruction being removed by it. I only agreed to one dose being given, under the distinct understanding that should it produce serious discomfort it should not be repeated, but that I should revert to my previous treatment by opium and warm enemata. The patient gradually sank, having lived about twenty-eight days from the time when the bowels first ceased to act.

The whole of the back of the uterus was found to have become converted into a large carcinomatous mass projecting backwards. A tumour of similar character, about the size of a pullet's egg, was found in the left ovary, and there was carcinomatous stricture of the colon at the commencement of its descending portion, an opening being left through which a crow-quill could hardly pass.

Five or six cases of obstruction of the large intestines terminated in complete recovery, the obstruction having been caused in some cases by a collection of fruit stones, and in others by that of numerous large and hard scybala impacted in the caput coli, and even in the rectum. In all cases the line of treatment was the same. At the onset a purgative was sometimes given; but, failing to act, was never repeated. When vomiting was urgent ice was given when it could be obtained, and throughout the illness small doses of gum opii were administered with such frequency as the symptoms called for. At the same time enemata of warm water or gruel were thrown up in such quantities as the bowel could receive. When it was found practicable to introduce the colon tube it was always employed, but sometimes it was found impossible to pass the promontory of the sacrum. The tube was larger and less flexible than those in general use some years ago, in order to prevent its doubling up in the rectum when its progress was opposed by the projection of the sacrum. Its extremity also was made large and rounded in order that it might not hitch in the folds of the mucous membrane of the bowel. It was slightly curved to assist the operator in his endeavour to pass it into the sigmoid flexure by a semicircular sweep, such as is employed in passing a catheter. But it was often a matter of no small difficulty, and required great dexterity, to pass it well into the colon. I would strongly advise all young practitioners to take every opportunity of practising its introduction, in order to be ready in time of need.

Here I may perhaps be allowed to say a word about the treatment of certain forms of constipation which sometimes terminate in obstruction—such, for instance, as arise from want of tone in the muscular coats of the intestines, occurring in persons of sedentary habits or suffering from debility arising from various causes. In such cases I have seen great improvement produced by the employment of pills containing one grain each of quinine and capsicum, and two grains of the myrrh and aloes pill, the latter ingredient being gradually diminished as the bowels regained their tone. Combined with this treatment, enemata of *cold* salt and water were thrown up when the pills failed to produce the desired effect, but no stronger aperient was ever given. When the patient was subject to piles, myrrh and the watery extract of aloes were substituted for the myrrh and aloes pill.

By this line of treatment the *vis medicatrix naturæ* was allowed fair play. The patients may have died from the effects of an incurable disease, but their end was never hastened by ill-advised attempts of the medical attendant to arrest the progress of the disease.

ON A FORM OF

PARALYSIS AFFECTING THE FOREARM

COMMONLY SUPPOSED TO BE RHEUMATIC.

THE June number of the *Archives Générales de Médecine* for this year contains a paper by Dr. F. Panas, one of the Surgeons of the Lariboisière Hospital, originally read by him to the Academy of Medicine at Paris as long ago as November 21, 1871. With the exception of a few scattered cases, chiefly of paresis of the ocular and facial muscles, English medical literature contains very little on the subject of local paralyses. In our own columns, in the number for March 26, 1864, there is a clinical lecture by Mr. (now Sir) James Paget, giving a number of interesting cases, chiefly traumatic. We therefore gladly abstract the following article from our French contemporary:—

Dr. Panas states that for nearly six years he has been led to doubt the rheumatic origin of the paralysis which generally receives the name of "rheumatic paralysis of the radial nerve." He uses the word "radial" in such a way as to show that he means, not only the branch we usually term "radial," but also the trunk of the musculo-spiral. Facts have forced him at last to conclude that, so far from being allied to or caused by rheumatism, this lesion is due to temporary compression of the nerve. One constant fact is the limitation of the paralysis to one invariable point of the nerve-trunk, between the place where the filaments of the triceps and those of the long supinator muscle emerge. Thus the former muscle always escapes being paralysed, whilst the latter is always attacked simultaneously with the other muscles of the forearm supplied by the radial nerve. Surely the effect of cold cannot explain this. Is it not far more probable that we have here, so to speak, a physiological experiment which results in a mechanical lesion in one invariable part of the nerve, between the bend of the elbow and the point where the nerve curves from behind, in front of the outer border of the humerus? The second fact which excites attention is that this paralysis almost always follows decubitus. This also would make us suspect pressure, and leads us to examine the relations of the nerve in the dead subject. The first portion of the nerve (musculo-spiral) is in the axilla, and lower down it is deeply placed beneath the triceps muscle in the musculo-spiral groove of the humerus, and thus escapes all compression from without. And the same may be said of its internal cutaneous branch. But at the outer border of the humerus it winds round the outer border of the bone, in order to come forward and to descend in the interspace between the supinator longus and the brachialis anticus. From its point of reflection to the bend of the elbow the nerve measures some nine or ten centimètres long (three and a half to four inches nearly), and is actually contained in a fibrous sheath, which is inelastic and does not admit of extension, formed by the aponeuroses of the two muscles respectively. This sheath and its superficial position expose it in this situation to more compression than anywhere else.

The external (musculo-) cutaneous nerve is also equally exposed to compression in this situation, and does not escape it.

On questioning the patients the mechanism of the paralysis is found to be essentially uniform, though it presents the trifling difference that in some cases the pressure is partly effected by the resistance of the plane on which the patient has slept—it may be a bed, a table, a bench, the ground, or the back of a chair; whilst in other cases he uses his arm as a pillow, in which case the head effects the pressure. In the former case the arm is between the trunk and the plane of resistance; in the second case between this and the head of the patient. Therefore, anatomically, all the fibres ought to be affected, except those supplied to the triceps and those of its internal cutaneous branch. And so they are. All the extensor muscles of the hand and fingers—the long and short supinators, the two radial extensors (extensor carpi radialis longior and brevior), the long abductor of the thumb (extensor ossis metacarpi pollicis), and the anconeus—are deprived of voluntary motion, whilst electric contractility and mechanical action remain intact, and both muscular and cutaneous sensibility are also retained or only feebly blunted. They are, however, not infrequently perverted. Thus sensibility to electric currents is often greatly intensified, and the patients complain of feelings "like ants stinging them," or of "pins and needles." But the triceps muscle invariably escapes, whilst the supinator longus is always paralysed. M. Duchenne, of Boulogne, founds on this a differential diagnosis between lead-palsy and the radial paralysis of which we speak, for in lead-paralysis the long supinator escapes. As regards electric contractility, we know that this (as regards faradisation) may be lost from cold, and preserved in traumatic cases—*e.g.*, Bell's or spontaneous facial paralysis,—where, Dr. Duchenne says, the fascial muscles do not respond when faradised. They do respond to a continuous current, but so do muscles in many other kinds of paralysis. But it is quite possible that facial paralysis may be traumatic in many cases.

The following instances of the preservation of electric contractility (as tested by faradisation) deserve mention in this respect. 1. An adult who had symptoms of fractured base of the skull, followed by left facial paralysis—the muscles of the paralysed side responded well to the currents. 2. A patient, aged 45, had a woman fall from a height on to his shoulder—this was followed by paralysis of the deltoid, and of the supinator longus. In this case also the faradised muscles acted well. 3. A lad, aged 17, was obliged to rest the weight of his body on his two arms whilst his hands held on to a rail at a theatre. In this constrained position he was forced to remain for some time. His left arm was completely paralysed, but Dr. Duchenne found the electric contractility intact. 4. A carter, aged 22, had a bite on the arm from a horse at the level of the depression for the head of the radius. After the inflammation thus set up had subsided, there was paralysis of all the muscles supplied by the radial nerve, except the supinator longus and the extensor carpi radialis longior, but electric contractility was not lost. 5. A man, aged 30, broke his leg and sustained other injuries. All the radial muscles as well as the triceps were paralysed, but acted when faradised. 6. A cook's assistant, aged 44, had paresis of all the muscles of the left arm supplied by the radial nerve, from the pressure of the pad of a crutch with only one stem, on which he was forced to lean very heavily when his foot slipped. The reason he used crutches was that he suffered from arthritis of the knee. In all these cases, which are, as will be seen, traumatic, electric contractility was unimpaired. And so it is in the class of cases to which M. Panas now invites our attention. He says that an explanation of the preservation of this contractility may perhaps be found in the fact that the actual time of pressure is not very prolonged. But the paralysis itself always comes on after a very heavy sleep (either from drunkenness or great fatigue). It comes on whilst they are warm in bed. He gives the following amongst other cases illustrative of his views:—A carpenter, aged 41, who had had neither rheumatism nor syphilis, got drunk at Fontainebleau, and lay down on the grass with his head on his hand; he worked at his trade in Paris till 4 p.m. next day, when he found the radial muscles paralysed. He was not seen by the author till eight days after. Cured by galvanism. A convict, aged 29; a founder, aged 35, much given to drink; another male patient, aged 28, also after drinking heavily. These and other cases all got well comparatively quickly after galvanism.

M. Panas draws the following conclusions:—1. This radial paralysis is due to slight and temporary compression. 2. This compression is on the superficial portion of the nerve, where it rests on the plane of the humerus. 3. The weight of the body or of the head is the compressing force or agent. 4. There is always a prolonged decubitus; and 5th, profound sleep. 6. There is either drunkenness or very great fatigue before the sleep. 7. The onset of the paralysis is sometimes gradual. 8. Out of more than thirty cases collected by him only one seemed referable to cold. 9. The anatomy, pathology, and etiology all concur to make this a mechanical or traumatic paralysis. 10. Cold and rheumatism fail to explain it. This form of paralysis is pretty well known to both physicians and surgeons in England, as it is not very uncommon in the out-patient rooms of our large hospitals. We do not know that anyone except M. Panas has made so large a collection of cases or has examined them so carefully, but we believe the affection has long been considered as due to pressure, and that the remark is often made that it chiefly occurs in the intemperate or in those who sleep very heavily. The cases given by this distinguished French surgeon are for the most part in somewhat younger patients than those which have been seen by ourselves.

REVIEWS.

The Microscopic Structure and Mode of Formation of Urinary Calculi. By H. Vandyke Carter, M.D. London: J. and A. Churchill. 1873. Pp. 51.

Dr. Carter has in this work commenced the investigation of a subject but little known to pathologists, and has arrived, we think, at some very important and valuable conclusions respecting it. During a prolonged stay in India he has availed himself of the opportunities which surgical practice in that country affords for investigating microscopically a large number of calculi. Eighty specimens have been submitted to examination; 6 per cent. of these were from the female bladder, 15 per cent. were urethral or renal from the male, and 79 per cent. were extracted from the male bladder by lithotomy. One-half of the latter group were taken from children under ten years of age, and only nine were from patients over forty. From Dr. Carter's observations he regards it as evident that urinary calculi are not mere precipitates or aggregations of ordinary crystalline and amorphous deposits, held together by means of mucus: an animal basis is an essential component of urinary calculi. Both the crystalline and submorphous ingredients possess a substratum, evident on removal of the mineral parts, which is of firm consistence, more or less translucent, colourless, structureless, and obviously of organic origin. This material underlies "the compact layers of uric acid, the more brittle ones of both kinds of phosphates, as well as all urate formations beyond the granular, and some of those of the calcic oxalate." This animal matter has not been found to exist alone; it is probably not always identically the same. Its fullest development seems to attend urate globules and laminæ whose structure is exactly retained in their organic basis until destroyed by reagents. This organic matter presents a finely granular striated or fibrillated appearance. One of Dr. Carter's main results is that some of the more characteristic ingredients of calculi are present in forms "peculiar to a group of structures which, though immediately of physical origin, yet seem to hold a position intermediate between the pure mineral and the organic. For these he proposes the name "submorphous," in contradistinction to "amorphous." Such are globules, dumb-bells, spheroids, laminæ, etc. He also finds that the nuclei or first-formed ingredients of calculi are often due to accumulation or unusual formation of globular urates; not seldom is the oxalate in submorphous forms the first material laid down; but that comparatively seldom do crystals of uric acid compose the nucleus of a calculus. A mere aggregation of ordinary urinary deposits is not sufficient to account for the appearance or the growth of a stone. Neither is a stone of spontaneous origin the result of accident, for the nucleus was always found to be solid, and not composed of inspissated mucus.

Our space will not permit us to notice the author's discussion of the mode of formation of calculi. But it is to be regretted that his acquaintance with the intimate structure of calculi has not increased his confidence in the various modes proposed for their dispersion. "A portion of compact laminar structure from a stone composed of uric acid

or urates, when treated under the microscope with potassic solution, is certainly seen to clear after a time more or less completely; but there remains behind a membranous matrix, often firm in consistence, which resists solution, and in the mass would not only impede the action of the alkali, but, unless removed, would, it is probable, become a nidus for subsequent deposit." Neither does the electric current, short of producing electrolysis, seem more promising, for, according to Bridgman and Ord, a weak galvanic current favours the production of submorphous forms, and the magnetic current causes the crystals of calcium oxalate formed in a colloid to assume a much larger size than common. We strongly recommend this very interesting volume to our readers. It is beautifully illustrated with plates of the microscopic appearances of calculi. Dr. Carter has added one more to the list of valuable books which our medical brethren have found energy and time to write under the suns of India.

The Spectroscope and its Application. By J. Norman Lockyer, F.R.S. London: Macmillan. 1873. Pp. 117.

This little work is a reproduction of three lectures delivered by the author at the Society of Arts in 1869. The first lecture gives an account of the means and method of spectroscopic research. The prism and its effect on light, the use of the slit, Fraunhofer lines, combination of prisms, and the construction of spectroscopes, with the method of measuring spectra, are amongst the subjects of this lecture. In the second lecture the spectra of different substances, the detective power of spectrum analysis, the use of the spectroscope in arts and manufactures, and its application to the heavenly bodies are passed under review. In the third the author treats of the absorption of light, the practical application of the phenomena of absorption, the absorption spectra of various substances, the lines of the solar spectrum, the absorbing power of gases and vapours, and the nature of the sun's atmosphere and spots, solar prominences, the spectra of other stars, and the future of the spectroscope. One of the most interesting matters in the book is the account given of solar cyclones. By careful observation of the shifting of the hydrogen line a storm has been watched moving across the sun at something like the rate of 100 miles a second. The indications which the spectroscope gives us of the enormous forces at work in the sun and the stars, the light it has thrown upon the composition of the sun's atmosphere, the nature of variable stars, the constitution of nebulæ, are undoubtedly the greatest marvels of modern science. Mr. Lockyer's book is admirably adapted as an introduction to spectroscopic study.

GENERAL CORRESPONDENCE.

PURPURA HÆMORRHAGICA.

Letter from Dr. Lavies.

[To the Editor of the Medical Times and Gazette.]

Sir,—You may possibly consider the following case worth publication:—M. S., aged 60, committed to prison for felony in January last, was in good health up to the beginning of the present month, when she complained of languor and asked for and obtained a change of diet. On the 16th inst. my attention was called to a bruised appearance of her eyes and nose. I asked to see her arms and legs, and found them covered with purple spots, with bruises about the joints. She was at once placed in our invalid ward, and at ten o'clock in the evening, on being visited by a warder, she expressed herself very comfortable—quite well—and in no pain. In the morning at seven she was found dead—a small quantity of vomited blood by her side. The post-mortem examination revealed a purpuric condition throughout the alimentary canal, with considerable blood-extravasation about the stomach, spleen, kidneys, etc., the peritoneal surface of the intestines being covered with marks similar to those on the skin; the heart containing a small quantity of fluid blood in each ventricle. A good deal of blood had escaped into the stomach, some of which was vomited, and there can be little doubt she died of syncope.

Two interesting questions appear to me to arise out of this case, bearing on the history and pathology of purpura, about which I do not think very much is known—first, may strong mental impressions be concerned in producing such blood-changes as had evidently taken place in this case? and secondly, had prison diet anything to do with it? In answer to the latter question, the diet is certainly not luxurious—it consists of bread, gruel, Indian meal pudding, meat, soup, potatoes, onions, carrots, rice, cheese; but there is no limitation set on my instructions for necessary change, and I have never seen a case of purpura since I have been in the habit of visiting the prison, now more than thirty years. To assist in answering the former question I would observe that the prisoner appears to have been a woman of deep feeling and impressionable mind, and that about a week before her attack she had received some very touching letters from her relatives, which seemed, observers report, to have affected her very acutely.

I apologise for troubling you. I am not in the habit of publishing, and I only do so in this case in the hope of contributing some facts in reference to a disease the etiology of which is confessedly somewhat obscure.

I am, &c., J. S. Lavies, M.D.

11, Warwick-square, Belgravia, S.W., August 25.

WHAT IS THE ACTUAL CAUTERY?

Letter from Mr. G. J. S. Camden.

[To the Editor of the Medical Times and Gazette.]

Sir,—I see in Dr. Fayrer's work on the "Thanatophidia of India" that the actual cautery was used unsuccessfully (which in another place he calls a *red-hot* iron). This is not what I was always taught and had seen as actual cautery. I consulted "Cooper's Surgical Dictionary," edited by Lane. There it is called an iron in a state of incandescence, which is, according to Maunder, incipient white heat. Professor Symes in his lectures calls it a red-hot iron. I also made many inquiries of medical friends, and all spoke of it as a red-hot iron. Having twice assisted in using and once used actual cautery, I hope I know something on the subject. When actual cautery is to be used the iron must be heated till it is really of a white heat, and looks almost as white as white paper. If then applied it destroys the part instantaneously, giving no pain; but it must be removed quickly on the heat decreasing, and then another iron applied. Several irons are required for use, and a fierce fire kept up by bellows, till your object is attained; but if a red-hot iron only is used, the agony is intense, as we all know who have touched it. The first time I saw it used on a girl of fourteen years no pain was given, to my great astonishment; the second time on an elderly person (both for fungus in the upper maxillary bone), her screeching was fearful, till I told the operator his irons were not half hot enough. He then requested me to heat them properly, which being done, not a murmur was heard. The irons were being used only red-hot. The last time was opening four or five sinuses in a favourite horse's shoulder. He never flinched, and scarcely seemed aware of what was being done. The only thing he noticed—for he never moved—was the hissing made by the destruction of the skin. Actual cautery is painless.

I am, &c., G. J. S. Camden, M.R.C.S.

London, August 22.

P.S.—For India I would suggest using—to obtain the white heat for actual cautery—a large spirit blow-pipe similar to those made many years since to boil water on your table in a minute; the iron to be held on a piece of pumice-stone.

OBITUARY.

EDWARD VAUGHAN AUSTIN, M.R.C.S.,

Of Oakfield, Reigate, was found dead on the 14th inst. in Reigate-park. The deceased left his house on the Saturday previous, and attended a patient in Southpark. He left there to return home, but was never seen alive afterwards. On the following Thursday evening his body was found lying in the fern-brakes within forty yards of the pathway. A valuable gold watch and other property were found upon him. Mr. Steele, jun., who examined the body, was of opinion that death resulted from a fit. Mr. Austin had been subject to fits of late. He was 63 years old, and was secretary to the Surrey Archæological Society, and a member of several learned societies.

CHARLES A. HEMINGWAY, M.R.C.S.,

Has just died, rather suddenly, at his residence in Leeds-road, Dewsbury. The deceased was engaged in his duties until a

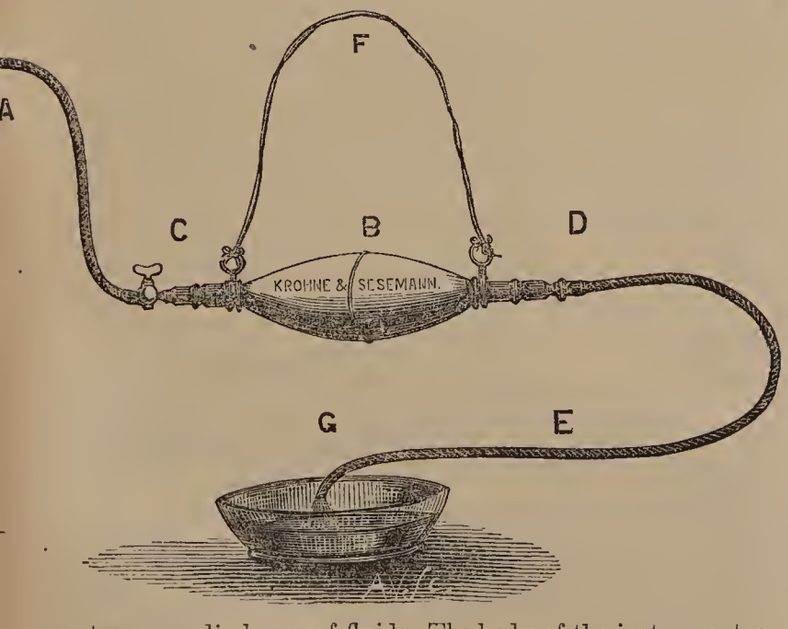
few hours before his death. He had been unwell and in a low state of mind for some weeks. Mr. Hemingway was the certifying surgeon under the Factories Act for the district. He took much interest in the Mechanics' Institute, of which he was president. He was the author of the following works:—"On the Reduction of Compound Fracture with Protrusion of Bone by the Use of the Lever"; "A Popular Lecture upon the Brain, Heart, and Lungs." He was also the inventor of cased splints for the treatment of fractures.

NEW INVENTIONS.

NEW INSTRUMENTS FOR THE TREATMENT OF EMPYEMA IN CHILDREN.

At the January meeting of the Obstetrical Society, Dr. Bathurst Woodman showed two instruments for the treatment of empyema in children, intended to be worn after paracentesis thoracis (suggested to him by Dr. Playfair's apparatus,—see *Obstetrical Transactions*, vol. xiv., p. 4). The first was a glass tube bent into a form resembling a double U. To this two elastic tubes were adapted, one at each end, furnished with clips such as chemists use in volumetric analysis. One elastic tube is to be introduced into the pleural cavity, the glass tube to be filled with disinfecting fluid, and the whole suspended by a tape from the child's neck. The second elastic tube holds sufficient fluid to render it unnecessary to empty the apparatus more than once in twenty-four hours. The whole can be made for three or four shillings.

The second apparatus, which is also made by Messrs. Krohne and Sesemann, 8, Duke-street, Manchester-square, and 241, Whitechapel-road, is very light. It can be used to exhaust the pleural cavity of pus or other fluids present there; or, by reversing the syringe, to inject disinfectants or pure water at a temperature of 98° to 100° Fahr. into the pleural cavity. The apparatus is air-tight, can be made to hold enough disinfecting fluid to prevent unpleasant smell, and need not be emptied more than once a day. It consists of an elastic tube A, furnished with a stopcock C, which is turned so as to shut off air when the syringe is reversed or removed to cleanse it. This is the tube introduced into the chest after paracentesis. A few holes may be made in the sides of the chest-end for an inch or so of its length to facilitate the



entrance or discharge of fluids. The body of the instrument, B, consists of a Higginson's syringe, which is reversible, so as to admit of being used as a force-pump for the injection of fluids, as above mentioned; or as a suction-pump for their withdrawal. To this by means of an adapter a second elastic tube, E, can be attached, so as to let the fluids run into, or to draw disinfectants out of, the basin G.

The figure does not show clearly the adapters at each end, and the letter D, which denotes one of them, is misplaced. A tape, F, is attached, to suspend the whole from the child's neck (in a little bag if preferred), so as to be always ready for use. A little disinfecting fluid can be kept in B; on the body of the syringe there is an arrow to show the direction of the current. If suitable nozzles are adapted, it is a good instrument for transfusion of blood.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Aug. 21:

Day, Edmund Overman, Hemel Hempstead.
Rodwell, Thomas Henry Bate, Loddon, Norwich.
Smith, Thomas William Toone, Austrey, Warwick.
Watson, Charles Russell, Sydney, N.S.W.

The following gentlemen also on the same day passed their primary professional examination:—

Crétin, Eugène, St. Bartholomew's Hospital.
Mason, Samuel Butler, London Hospital.

BIRTHS.

ADAMS.—On August 18, at Barnes, Surrey, the wife of James Adams, M.D., of a daughter.

CLARKE.—On August 17, the wife of W. Fairlie Clarke, M.A., M.B., F.R.C.S., of Mansfield-street, Cavendish-square, of a son.

DALY.—On August 26, at 101, Queen's-road, Dalston, the wife of Frederick H. Daly, M.D., of a daughter.

SELOUS.—On July 19, at Unao, the wife of Major E. Selous, of a son.

TAYLOR.—On August 23, at Bocking, the wife of Thomas Taylor, M.R.C.S., of a daughter.

WISE.—On August 23, at Haddon Lodge, Shooter's-hill, S.E. (the residence of her father, Wm. Jackson, Esq.), the wife of Wm. C. Wise, M.D., of a daughter.

MARRIAGES.

BARLOW—FROOM.—On August 23, at St. Mary's (Bolton's), West Brompton, Stephen Babington, second son of the late George Hilars Barlow, M.D., Senior Physician to Guy's Hospital, to Lolo Undine Anne Teevan, only child of William Froom, Esq., late of Charlwood-park, Surrey, and grandniece of the late Rear Admiral (of the Red) Anselm John Griffiths.

EDWARDS—PAYNE.—On August 21, at Birdbrook, Essex, Frank Edwards, L.R.C.P., L.S.A., of Furneaux Pelham, Herts, eldest son of Thomas Edwards, Esq., of Wixoe Park, Suffolk, to Alice, eldest daughter of Henry Payne, Esq., of The Moat, Birdbrook.

LAW—BELL.—On August 20, at St. John's Episcopal Church, Edinburgh, Alfred Robert Law, M.D., M.R.C.S., of Richmond, Surrey, to Charlotte Elizabeth, elder daughter of William Bell, Esq., of 6, Melville-street, Edinburgh.

STAYNER—MCCULLOCH.—On August 7, at St. John's Episcopal Church, Dumfries, Frederic Henry Stayner, Esq., son of the late Thomas Allen Stayner, Postmaster-General of British North America, to Harriet, daughter of James Murray McCulloch, M.D., of Dumfries.

WRIGHT—HODGSON.—On August 20, at Brathay Church, Ambleside, Strethill Harry Wright, M.D., F.R.C.P., Superintendent of the Barony Parish Hospital and Asylum, Barnhill, Glasgow, eldest son of Thomas Strethill Wright, M.D., F.R.C.P., to Elizabeth, youngest daughter of the late Rev. William Hodgson, M.A., Rector of Clifton, Westmoreland, and formerly Principal of Moore College, Liverpool, New South Wales.

DEATHS.

BUCHANAN, WILLIE, son of George Buchanan, M.D., at 24, Nottingham-place, W., on August 24, aged 4 months.

DIGBY, FREDERICK, M.R.C.S. Eng., L.S.A., at Cheltenham, on August 20, aged 37.

HAYLES, GEORGE, M.R.C.S. Eng., L.S.A., at Alresford, Hants, on August 23, aged 72.

JAMESON, WILLIAM, M.D., native of Edinburgh, Caballero of Spain, late Professor of Botany and Chemistry in the University of Quito, and Director of the Mint of Ecuador, at Quito, Ecuador, on June 23.

STEVENSON, HELEN EMSLIE, wife of James Stevenson, M.D., at 411, Edgware-road, on August 22.

TRAILL, ROWLAND JOHN, M.D., at Collaroy, New South Wales, from paralysis, on August 16, aged 58.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ARDWICK AND ANCOATS NEW DISPENSARY AND HOSPITAL, MANCHESTER.—Senior House-Surgeon. Applications, with testimonials, to the Rev. W. Hutton, Honorary Secretary, 57, Higher Ardwick, Manchester, on or before August 30.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

BRIGHTON AND HOVE LYING-IN INSTITUTION.—House-Surgeon. Candidates must be M.R.C.S. of Great Britain or Ireland, and L.R.C.P. or L.S.A. Lond. Applications, with testimonials, to the Chairman of the Committee of Management, 76, West-street, Brighton, on or before September 3.

BRISTOL DISPENSARY.—Medical Officer. Candidates must possess a diploma in Surgery from the Royal College of Surgeons of London, Edinburgh, or Dublin, or from the Faculty of Physicians and Surgeons of Glasgow. Applications, with testimonials, to the Secretary, on or before September 6.

BURTON INFIRMARY AND DISPENSARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Honorary Secretary, J. C. Grinling, Esq., Burton-on-Trent, on or before September 1.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to John Binks, Esq., Honorary Secretary, Wakefield.

East Suffolk Hospital, Ipswich.—House-Surgeon and Secretary. Candidates must be unmarried, and M.R.C.S.England L.S.A., or L.R.C.P. Applications, with testimonials, to the Secretary, on or before September 2.

Evelina Hospital for Sick Children, Southwark-bridge-road, S.E.—Registrar. Particulars may be obtained from the Hospital.

General Hospital, Birmingham.—Resident Registrar and Pathologist. Candidates must be duly qualified. Applications, with testimonials, to the House-Governor and Secretary, on or before September 6.

Inverary (Parish of).—Medical Officer. Applications, with testimouials, to A. Henderson, Esq., Town Clerk, Town Clerk's Office, Inverary, on or before August 30.

Inverness District Asylum.—Assistant Medical Officer. Candidates must be duly qualified aud registered. Applications, with testimonials, to Dr. Aitken, Medical Superintendent, on or before September 15.

Liverpool Northern Hospital.—House-Surgeon. Candidates must possess both a medical and surgical qualification. Applications, with testimonials, to the Chairman of the Committee, on or before Sept. 8.

Manchester Royal Infirmary.—Physician's Assistant. Candidates must possess medical and surgical qualifications. Applications, with testimonials, to the Chairman of the Weekly Board, on or before Sept. 6.

Manchester Royal Infirmary, Dispensary, and Lunatic Hospital.—Honorary Assistant-Physician. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Board, on or before August 30.

Metropolitan Free Hospital, Devonshire-square, City.—Honorary Assistant-Physician. Applications, with testimonials, to the Committee of Management, on or before September 2.

Newcastle-upon-Tyne Borough Lunatic Asylum.—Assistaut Medical Officer. Candidates must be registered. Applications, with testimonials, to John Atkinson, Clerk to the Committee of Visitors, on or before August 30.

Provident Surgical Appliance Society, 25, Bartholomew-close.—Assistant-Surgeon. Applications, with testimonials, to the Secretary, on or before September 10.

Royal Free Hospital, Gray's-inn-road.—Junior House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to the Secretary, on or before September 10.

St. Mary's Hospital and Dispensary for Women and Children, Quay-street, Manchester.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, Joseph Barber, 14, John Dalton-street, Manchester, on or before September 12.

St. Thomas's Hospital.—Resident Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Applications, with testimonials, to the Treasurer.

Skipton and Settle Union, Yorkshire.—Medical Officer of Health. Candidates must be legally qualified medical practitioners, and registered. Applications, with testimonials (three copies of each), to Thomas Brown, Esq , solicitor, Skipton, on or before September 5.

Ripon Dispensary and House of Recovery.—Resident House-Surgeon and Dispenser. Candidates must be unmarried, and duly qualified Applications, with testimonials, to the Honorary Secretaries, on or before August 30.

Wantage Union.—Medical Officer. Candidates must be duly qualified, Applications, with testimonials, to Edward Ormond, Clerk of the Union. Wantage, on or before September 8.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Belford Union.—Mr. Aylmer E. Hayes has resigned the East District; area 12,704; population 2869; salary £25 per annum.

Caiston Union.—Mr. Joseph Aston has resigned the Waddingham District; area 11,178; population 2073; salary £35 per annum.

Cheltenham Union.—The Third District is vacant; salary £30 per annum.

APPOINTMENTS.

Bideford Union.—John Thompson, M.D., M.R.C.S. Eng., L.S.A., to the Workhouse. Edgar Cox, M.R.C.S. Eng., L.S.A., to the Bideford District.

Bramley Union.—John Sloan, B.M. and M.C. Univ. Glas., to the Bramley District.

Doncaster Union.—Charles H. Lister, M.R.C.S. Eng., L.S.A., to the Doncaster East District.

St. Thomas's Union.—Wm. J. Williams, M.D., M.R.C.S. Eng., L.S.A., to the Heavitree District.

Sussex.—Francis V. Paxton, M.D., as Analyst for the Western Division of the County.

Wareham and Purbeck Union.—Joseph Fall, M.R.C.S. Eng., to the Winfrith District.

The library of the Obstetrical Society will be closed from September 1 to September 13, both days inclusive.

St. Bartholomew's Hospital and College.—Prizes, etc., awarded, Session 1872-73.—Senior Scholarships in Medicine, Surgery, Materia Medica, and Therapeutics: 1 (£50), A. F. Stevens; 2 (£25), C. S. W. Cobbold. Senior Scholarships in Anatomy, Physiology, and Chemistry: 1 (£50), E. Crétin; 2 (£25), G. H. Hames and F. H. Spooner-Jeaffreson. Exhibition: £20 yearly for two years, H. F. Chapman. Junior Scholarship: 1 (£50), W. A. Shoolbred; 2 (£30), F. S. Eve; 3 (£20), C. W. M. Moullin. Kirkes Medal: H. J. Ilott, C. S. W. Cobbold, equal. Wix Prize: J. C. Verco; 2nd Prize, H. M. Barker. Hichens Prize: C. S. W. Cobbold. Practical Anatomy—Foster Prize: G. H. Hames and J. Ranking; 3. F. H. Spooner; 4. W. H. Briggs; 5. H. G. Cumming; 6. F. Watts; 7. W. Kebbell; 8. F. H. Carter; 9. J. Spark; 10. J. K. Barton. Treasurer's Prize: F. S. Edwards. Examiners' Prize: F. S. Eve; 3. T. J. Verrall; 4. A. Upton; 5. F. E. Woodward; 6. A. G. Williams; 7. J. H. Simpson; 8. W. A. Shoolbred; 9. W. R. Pearless; 19. L. B. Calcott.

Army Medical Service.—The following is a list of gentlemen who competed successfully for appointments as Surgeons in H.M.'s Army Medical Service, at the examination held at the London University on August 11 :—

Order of Merit.	Names.	Marks.	Order of Merit.	Names.	Marks.
1.	Langridge, G. J.	2318	7.	Thomsett, R. G.	1900
2.	Fowler, B. W.	2219	8.	McQuaid, P. J.	1868
3.	Webb, W. E.	2145	9.	Tobin, J. J.	1685
4.	Gubbins, W. L.	2090	11.	Spencer, F. H.	1660
5.	Wood, O. G.	2005	10.	Ring, J.	1640
6.	Mapleton, R. W.	1905			

Indian Medical Service.—The following is a list of the candidates for her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House on August 11, 1873. Fourteen candidates competed for eleven appointments; thirteen were reported qualified.

Order of Merit.	Name.	Marks.	Order of Merit.	Name.	Marks.
1.	A. J. Willcocks	2195	7.	H. K. McKay	1825
2.	J. Moloney	2076	8.	J. J. H. Wilkins	1715
3.	F. R. Swaine	1980	9.	M.L.Bartholomensz	1390
4.	C. W. S. Deakin	1922	10.	P. Thompson	1310
5.	H. Allison	1920	11.	R. C. Ross	1245
6.	J. G. Collis	1891			

Mr. Charles Johnson, grocer, of 141, Kent-street, Southwark, has been fined £5 and costs for selling adulterated mustard. Dr. Muter, the analyst, examined the mustard and found it to contain flour and turmeric. The defendant urged the magistrate to reduce the fine, inasmuch as the mustard was bought by him in the condition in which he sold it; but the magistrate declined, stating there was little justice shown to the public if such cases were lightly passed over.

Composition and Quality of the Metropolitan Waters in July, 1873.—The following are the returns (by Dr. Letheby) of the Association of Medical Officers of Health :—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	18·33	0·068	0·147	0·002	14·6	3·2
West Middlesex	18·20	0·016	0·147	0·000	14·3	3·2
Southwark & Vauxhall	18·53	0·056	0·166	0·001	14·8	3·2
Chelsea	18·52	0·069	0·145	0·001	15·0	3·3
Lambeth	18·80	0·072	0·147	0·002	15·0	3·3
Other Companies.						
Kent	28·04	0·008	0·243	0·000	20·8	6·0
New River	17·83	0·024	0·147	0·000	14·0	3·0
East London	18·39	0·028	0·154	0·001	14·3	3·5

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in those of the Grand Junction and the Lambeth Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 120,204,176 gallons; and the number of houses supplied was 503,832. This is at the rate of 33·8 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 30·5 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Amicus.—Received, with thanks.

Gus.—June 17, 1858.

Cray.—Dr. Bell Pettigrew, F.R.S., has been appointed Lecturer on Physiology at the School of Medicine, Surgeons' Hall, Edinburgh.

Veto.—Sir Isaac Newton was elected President of the Royal Society on the retirement of Lord Somers from that office in 1703.

Credulous.—The kings of England had from very ancient times pretended to a power of curing scrofula by touching those who were afflicted by that malady. It is well known that Dr. Samuel Johnson was, when a child, touched for the scrofula by Queen Anne. The princes of the House of Brunswick relinquished the practice.

Cirus.— "Death his dart
Shook, but delayed to strike."—*Milton.*

A Doctor's Log.—No. I.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As we lay all the day in the bay of Biscay oh! the black angry billows rolling mountains high, washing over the decks; not a sail visible, the dreary monotony of water, water everywhere, somewhat broken by the flitting seagulls—Where do they live? Are they never tired? Do they sleep on these white-crested waves, possibly our beds also this stormy night? Poor ladies, women, and children lie prostrate, especially one golden-haired bride. Most of the passengers are sea-sick; a few appearing at dinner notice the anxious face of the courteous captain, hear the howling wind, feel the terrible tossing, vibration, rolling, and apparently shuddering quiver of the *Serapis* buffeted by the cruel treacherous ocean, and naturally every thought turns wistfully to those at home, to parents, relations, wives, or children. Useless to go to bed; the swinging lights in the saloon, where the water bursts in occasionally, are dismally cheerful. An old sheet of paper and a stumpy pencil handy, the old inclination to scribble comes on as a resource, trusting to the indulgence of your readers for jerky incoherence. Before leaving England for India, gratuitous advisers gave all sorts of hints, not a few being miserable Job's comforters: "Smith, we give you six months; the next cholera season will be brisk, specially attacking old fat new-comers." Others suggested—"Live well; keep a good house; go in for sport; don't drink beer or spirits, stick to claret. Take out lots of flannel clothes, boots, harness, saddlery, a good helmet, the best filter, an express rifle, books, microscope, surgical instruments, specially an aspirator; see that your luggage is strongly packed and corded, the best of bullock-trunks lined with tin." The bachelor advises a wife, to be supplied by return of post by the *Matrimonial News!* The married man says—"Keep your wife and children at home. If this, that, and the other cannot stand climate, what chance has a fragile woman or a delicate boy?" Amidst all the worries of settling accounts, paying long-forgotten bills, ordering uniform white clothing, many little things were never thought of. An assistant-surgeon is allowed 18 cwt., or 90 cubic feet, enabling him to take out chest of drawers (if in strong cases), bed, valise, portmanteaus, tub, books, box; or if married, packages containing table linen, glass, crockery, and cutlery. In the cabin two small bullock-trunks only are allowed, but there is a baggage-room accessible during the voyage; the remainder goes down into the hold. You must keep your eye if possible on every article until on board; the labels should be printed and spread in all directions, besides each box should have some particular mark, say a white zigzag or a red bull's eye, to distinguish readily amidst heaps of others. Your heavy baggage being down the hold, only to be got at on reaching final destination 1000 miles up country of India, it is a matter of considerable personal consequence to have the necessaries packed in small available compass. Many readers of the *Medical Times and Gazette* have to travel, and these hints may be of service therefor. In the cabin, in the two portmanteaus have pajamas, shirts (specially flannel), socks, under-clothing, towels, soap, a good travelling-bag, old uniform, one suit of old plain clothes, strong seasoned boots, Scotch cap, slippers, goloshes, dressing-gown, stationery, string; a number of small leather bags to hang from pegs in the cabin, or else a good hold-all; also certain books—"Tanner's Index of Diseases," a small surgical manual, "Meadows's Midwifery," and the "Prescriber's Companion." Bottles containing toilet vinegar, *eau-de-Cologne*, or lime-juice and glycerine, are simple luxuries, but very valuable during sea-sickness, especially to help unfortunate ladies whose stock soon runs out. Chlorodyne is a necessary not supplied in the ship. Take rugs, pea-coat, field-glasses, and a waterproof sheet, all easily rolled and strapped. Excepting a watch, which need not be wound up, or at all events corrected, pack up all rings, pins, jewellery, and knick-knacks in the heavy baggage. Even then bear in mind the numerous thefts in India; and, if there is a chance of returning to England, leave your valuables there. In the way of money, about £20 in gold at the very least should be carefully secreted or carried about with you; also about the same amount in notes if tolerably flush of cash, which very few assistant-surgeons are. Do not forget to take out a good lamp, one or two suits of thin flannel serge, besides a small quantity of white clothing.

We are three in a cabin under the saloon—very dark; no water comes in; the rolling bearable; one man over another in a kind of dinner-waggon, the third in a hunk at right angles. (How fat ladies clamber up and down, in and out of the top shelf appears a mystery.) Very cold; the rugs handy just now. Uniform worn all day, including mess dress at dinner, excepting in the Red Sea, when white clothing. All these vessels magnificent, ours the best—6211 tons, 3945 horse power, a crew of 250, about 1600 souls on board, including shoals of women and children. A neat commodious hospital for the troops, plenty of light and space, twenty comfortable swinging cots; also eight similar cots in the women's hospital, and a small place for the crew. The women's quarters are satisfactory, the nursery convenient. Women and children truly are *impedimenta*, either ill, in the way, wanting food or something, or a light at irregular hours, else transgressing the rules. On some trips they smuggle in children with eruptive fevers, get off vaccination, or, concealing pregnancy, are delivered before the ship is in blue water, causing endless inconvenience. Still, these things are unavoidable, and one cannot help noticing how much happier married people are, in spite of discomfort. Respecting men, syphilis, bubocs, gonorrhœa, contusions, eruptions, rapidly develope, the greatest care being taken to exclude the embarkation of weeds, useless soldiers, or epileptics. For sea-sickness, brandy, lime-juice, chloral, bromides, chloroform, chlorodyne, bismuth, charcoal, coffee, tea, champagne, opium, carbolic acid, do no good—indeed, chewing a hard navy biscuit is as good a prescription as any. Ladies suffer frightfully, yet seldom about. Men are miserable creatures, requiring any amount of force to get them out of their stuffy cabins on deck. So far, beyond contusions and prostration of sea-sickness, nothing of professional interest to record; but we have not shaken down yet. What with recent embarkation, the storm, and general cheap condition of the passengers, all are on the same level—even the sheep, horses, and dogs look miserable. A library, cards, the prospect of living like fighting-cocks, of visiting Malta and hearing some opera, of theatricals on board, when "Richard will be himself again," afford comfort, and we hope for a calm sea and a prosperous voyage. A considerable amount of scuffling about baths in the morning appears the only tangible grievance so far. The soldiers and sailors are very chummy; the former, intensely nautical, easily strain themselves hauling ropes. The sea air induces considerable iodism amongst the children—old eruptions reindnced. On the other hand, acute cases become very tractable. Although mothers lose milk and are generally wretched, the infants rally wonderfully—one or two cases of tabes rather troublesome, the constipation obstinate, vomiting incessant, and a tendency to convulsions induced by debility—roughing it, as well as the fright of the storm. For children who refuse all nourishment, the old remedy of bottled stout in teaspoonful doses settles the stomach, induces appetite, and restores vitality far better than brandy and port. In the way of food for infants, concentrated milk and ship biscuit very valuable even in severe illness. The reader will please understand that after severe trial during the hurricane, the good ship *Serapis* now "ploughs azure furrows in a sapphire sea" at the rate of eleven knots an hour, having passed from cold, rain, and fogs into the realms of glorious summer. At one time we notice the rugged Spanish coast on the left hand, and the dark African shore on the right, and observing occasional towers, sometimes red and white houses, unrelieved by trees or gardens. The lapis lazuli look of the sea and sky, the languid, soft, sensuous atmosphere, the patches of emerald green contrasting with yellow sand, the bold rocks, and the velvety appearance of lofty mountains, as, emerging from Trafalgar Bay, we pass grand old Gib., all worthy of observation. Algiers from a distance of ten miles has the appearance of a thriving watering place—any number of houses and villas dotted about, even on the highest hills. Next, the snow-capped mountains become more perpendicular, apparently sloping down to the water, with deep valleys here and there. For amusement the soldiers play all-fours, Don Pedro, "25," or cribbage on deck, and of an evening do Christy Minstrels. Then do the six brides take a wonderful interest in astronomy, plunging porpoises, also the phosphorescent waves as explained by sentimental husbands, several of whom, unshaven, resemble broken-down burglars. It was a pleasant change one fine day to sail close to several rose-tinted rocky islands, one called Galata visible for thirty miles, apparently uninhabited even by birds. On Sunday evening, the chaplain being sick, the captain performed service, reading a sermon on "storms" admirably and impressively, each listener fully conscious of the terrible weight of responsibility both of life and property the preacher bravely undertook. Lately dancing on the deck by the light of lanterns has been instituted, the Flick-Flock galop, Babil and Bijou waltzes are admirably played by our amateur quadrille band; the air so mild that neither hats nor opera cloaks are required; and the carriages are ordered at ten o'clock. All this is pleasant excepting that the Mediterranean air appears very treacherous—for instance, this morning the sick-list of women and children affected with diarrhœa, bronchitis, neuralgia, dyspepsia, erythema, boils, catarrhal ophthalmia, febricula, malarial complications, contradicted the poetical twaddle about the renewal of life in the sunny south. Two women are suffering from chronic rheumatism, one inclines to erysipelas, and a creole, with a history of brain fever, entertains delusions of suffering from syphilis, induced by demoniac or else magnetic influence. Beef-tea, wine, scruple doses of bromide of potassium, followed by a scruple of chloral at night tried, the chances being that a crop of boils unavoidably will be induced. Before reaching final destination near the Himalayas, I hope to be able to record interesting cases, notes, and observations whilst passing through the Suez Canal, the Red Sea, the Bay of Bengal, and on the road up country. This evening we hope to reach Malta, about 2200 miles from

Charing-cross.

The Army Medical Deparment.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The new Warrant for the Army Medical Department seems to have caused about as much dissatisfaction in India as at home, and perhaps you may find room some day for the following remarks if you consider them worth printing. The loss of 2s. 6d. a day after fifteen years' service if not promoted, the question of forage, etc., etc., I shall not in this paper again touch on: they have been so fully discussed by nearly everyone who has written upon the subject. I should like to make a few remarks on such points as have not been written on much or at all hitherto during the period which has elapsed since the publication of the Warrant. It seems to me that in the general scope of the Warrant it either goes a deal too far or not far enough. The real regimental system has been destroyed, but in its place we do not find that a regular corps completely distinct from regiments has been established. There is no such thing as putting hospitals entirely under medical officers, making them, in fact, as separate from regiments as one regiment is from another. We don't find that a man, in future, who is sick will be removed to a hospital where he will be as much severed from his regiment and as completely removed from all regimental control as if he were transferred to a distinct department. Not a bit of it—whether such a change would be for good or evil. As far as I can make out, the authorities, or whoever the framers of the Warrant are, have simply abolished the real regimental system of medical men being gazetted to regiments, and have in its stead substituted a bastard regimental system of attached men. This plan may simplify and equalise the roster for home and foreign service; but in other respects will in all probability, I suspect, be found to combine most of the evils of both a staff and a regimental medical service. In what way can the position, social and otherwise, of an attached differ from a gazetted regimental man except for the worse? It may be slightly cheaper; the saving will be hardly earned to him. You have only to consider for a moment that this system of attached men has been applied for years to a large portion of the army medical officers—constituting the Army Medical Staff, Assistant and Staff Surgeons, and Staff Surgeons-Major,—and so little did they appreciate it that regimental gazetted appointments commanded a money value in the market. Supposing that the regimental system is at an end, might I solicit your influence to obtain for us in future some security against constant shifting from station to station in the shape of fixed appointments to stations for definite periods of years, in lieu of that security of tenure which the regimental system gave us. One hears, certainly, of regiments being moved pretty frequently nowadays from station to station, but still I don't believe that regiments, as a rule, have been moved so frequently as many staff medical men, particularly in India. These moves fall very heavily, especially on married men. A staff medical man is sent to a station—say he takes a house and furnishes it, and buys a horse to enable him to perform his duties; or perhaps he combines the due performance of his duties with enabling his wife to go out in the evening—when perhaps she, poor woman, is far too wearied and oppressed with the heat to walk,—he buys a trap. Well! he has just made a few friends, his wife is just getting

into a little society, when down comes a telegraphic or other message: medical officer wanted at some place—say 500 miles off; a brigade order quickly follows that our staff friend is to proceed at once. Furniture, horse, trap, etc., have all to be sold for what they will bring, and off he and his wife start for their new station. He has to pay his wife's railway expenses himself, as Government only allow his (and some servants, I think). And at their new station they have no certainty of remaining. They may remain a month or six months, or any time of their Indian service. No one knows how long or how short their stay may be. They may move at any time, and any furniture, horses, etc., may have at a few hours' notice to be sold as before. You may imagine how this tells on the income of an Assistant-Surgeon! And now to contrast the combatant and medical service of the future. I should be inclined to give the advice of *Punch* to those about to marry—"Don't"—to all parents thinking of educating a son for medicine with the view of his entering the army. They had far better send him in as a combatant. Say the boy is eighteen. Nothing has now to be paid on the purchase of commissions, and by going into the combatant ranks he will be gaining pay and counting promotion and service at once; while if the same boy be sent to a medical school or college, four or five years (during which he gains no money) will have to be spent in obtaining an expensive education, simply to enable him to enter a service where he will probably be thought less of than his combatant brother, and who will in addition have a home in a regiment, and have counted four or five or even more years of service. No, I don't think that the medical service as it is can compete against the combatant.

And now, Sir, if I have not trespassed too much on your space, might I suggest, as a plan of obtaining medical men for the army, that Government should offer inducements to young men to enter for short service, and let them go on its completion with a bonus. A great many first-rate young medical men just after they pass cannot get into practice on account of youth, etc., and they are hampered very likely by the want of money. A thousand pounds, or even say five hundred, after five or six years' service would enable them to start, or at least be of great use to them. They might buy with it a share in a practice, perhaps. The army is too poor a calling ultimately for many with sanguine dispositions – they must enter it as a profession for life; and after twenty years' service it is too late to begin private practice generally. But let Government offer a bonus of say £500 to £1000 to all likely to leave the army after five, six, or even ten years' service, and I believe many first-rate young medical men would be induced to enter it.

I am, &c.,

An Army Medical Officer.

APPOINTMENTS FOR THE WEEK.

August 30. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

September 1. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

2. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

3. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

4. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

5. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Medical Society of London, 8 p.m. Meeting of Council.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·68 in. The highest was 30·04 in. on Sunday morning, and the lowest 29·45 in. on Tuesday morning.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURES

DELIVERED IN THE ROYAL INFIRMARY, EDINBURGH,

By T. GRAINGER STEWART, M.D., F.R.C.P., F.R.S.E.,
Physician to the Royal Infirmary.

III.—ON A CASE OF CIRRHOSIS OF THE KIDNEY.

Gentlemen,—The case to which I propose to direct your attention to-day is one with which those of you who have attended in my wards during the past eight months are well acquainted.

Samuel A., aged 50, a shoemaker, married, resident in Edinburgh, was first admitted to Ward VII., November 25, 1872, and examined the following day. He complained of general debility, from which he had suffered for four weeks. The only illness which he remembered having was subacute rheumatism, which lasted only a short time and did not recur. In the beginning of November he had severe epistaxis, and from that time was anæmic and feeble. Habits as to food stated to be favourable, but it was ascertained that he had been so intemperate that neither his wife nor children could live with him.

On admission he was pale, pasty-looking; his temperature was normal; the alimentary system was normal. The patient was obliged to get up three or four times in the night to make water. His urine was of normal quantity, pale straw colour, specific gravity 1017, reaction acid; it contained no albumen, sugar, nor bile.

On February 15 of the present year he was readmitted, complaining of dyspnœa, dropsy, and general weakness. After leaving the hospital he returned to work, but on account of increasing debility had to give it up. He was obliged to rise five or six times every night to make water. On February 8 he had noticed that his legs and feet were beginning to swell.

On admission, his face was somewhat swollen, his alimentary system was natural, there was no pain nor uneasiness in the heart or great vessels, form and appearance of præcordia were natural. The cardiac impulse was feeble; the superficial dulness was extended to the left side, and measured two inches and three-quarters, deep dulness seven inches; auscultation, first sound sharper than natural, second sound accentuated at the base; pulse 96, regular, but feeble. There was some dulness towards the bases posteriorly, and in the dull parts the expiration was prolonged, character vesicular but faint, the accompaniments crepitation, vocal resonance not increased; breathing 30 per minute, cough frequent, attended by copious glairy mucous sputum. There was some œdema, specially of the legs. Urine about forty ounces daily, of pale straw colour, acid reaction, specific gravity 1015; contained a considerable amount of albumen, and a few hyaline and finely granular tube-casts. The diagnosis established was cirrhosis of the kidney with an intercurrent inflammatory attack, and œdema of the lungs. Under treatment, by means of chloric ether, carbonate of ammonia, and digitalis, with poultices to the chest, the patient gradually improved, the dropsy disappeared, the albumen diminished, and the quantity of urine rose on some occasions to seventy ounces, the specific gravity being about 1013.

On March 14 the patient had so far recovered that he was able to leave the house.

On May 3 he was again admitted, complaining of dyspnœa, dropsy, and general weakness. Since leaving the Infirmary he had not been able to work. The cardiac impulse was faintly felt in the mamillary line between the sixth and seventh ribs; the superficial dulness was three inches, the deep eight. There was no cardiac murmur; the pulse 108, regular and full; the arteries tortuous. There was a relative increase of the white corpuscles of the blood, thirty to forty being seen in the field at once. There was no enlargement of spleen or lymphatic glands. Towards the bases of both lungs posteriorly there was some dulness on percussion, and crepitation with inspiration. The respirations thirty-two per minute; cough troublesome, sputum mummulated, frothy, muco-purulent. There was slight œdema of the feet. He had to rise four or five times during the night to micturate; the daily quantity was about fifteen ounces, sp. gr. 1015, colour pale amber, reaction acid, deposit hyaline and finely granular tube-casts; it contained distinct trace of albumen.

The diagnosis of cirrhosis of the kidney established during his previous illness was now confirmed, but it was evident there was less of the inflammatory affection and of the pulmonary œdema than previously, while the heart had become decidedly more hypertrophied. He was ordered iron with digitalis, and a cough mixture containing chloric ether, tincture of henbane, syrup of squills, and infusion of senega. On May 11, the symptoms continuing the same as on admission, the urine was 20 ozs., and contained 139 grs. of urea. On the 12th the urine was 18 ozs., the urea 129·6 grs. On the 14th the urine was 20 ozs., the urea 124·8 grs. On the 15th, 30 ozs., the urea 207·8 grs. On the 16th, 30 ozs., the urea 245·76 grs. On the 17th the urine was 30 ozs., the urea 273·6 grs. Up to the 14th the bowels were loose; but afterwards, when this symptom had improved, the urea was more abundant.

On the 24th the patient appeared seriously worse; his face was flushed, particularly in the middle of each cheek; there was an irregularity and feebleness of pulse, and the superficial dulness of heart had increased to four inches, while the patient had ceased to be anxious about his condition, and declared himself considerably better. I remarked at the time how grave I considered these symptoms, and suggested as an explanation of the rapid increase of cardiac dulness that effusion might be taking place into the pericardium.

On the 26th it seemed as if a fatal result were impending; but in this we were agreeably disappointed, for a distinct rally took place, the breathing became easier, and the superficial dulness of heart diminished; but dropsy soon recurred both in the subcutaneous tissues and the lungs, the superficial cardiac dulness increased to five inches, the pulmonary symptoms became more severe, and the patient died on June 9.

Autopsy.—The body was slightly œdematous; the pericardium contained about an ounce of fluid; the heart was enlarged, particularly the left ventricle (it weighed 1 lb. 7 oz.), the valves were competent, there were small patches of atheroma on different parts of the endocardium, the musculi papillares, and still more the columnæ carneæ, were somewhat atrophied, but the walls, as a whole, were greatly thickened. The aorta was atheromatous, as were also many of the smaller arteries. The left lung was very œdematous; the right was in a state of solid œdema, and throughout its substance there were limited pneumonic patches. The liver was of natural size, its connective tissue slightly increased. The stroma of the spleen was firmer than natural, and its capsule thickened and adherent to neighbouring viscera. The kidneys were somewhat below the natural size; their capsules did not strip off easily, their surface was slightly granular, the cortical was relatively diminished and dense in structure, the cones were natural, the pelves and ureters somewhat dilated, and the bladder hypertrophied (in connexion with old stricture). On microscopic examination many of the small arteries were found hypertrophied and their walls considerably thickened—the thickening being almost entirely due to increase of the middle coat; the Malpighian bodies presented no waxy reaction, and the capsules of some were thickened. The tubules of the cones were for the most part natural—some of those in the cortical substance contained traces of inflammatory exudation, but many were healthy; towards the surface, however, they were more scanty, and in some parts quite obliterated; but there was nowhere to any extent the appearance with which you are familiar—of tubules blocked up with exudation and in process of atrophy. The stroma was very much increased towards the surface, and to a less extent in more internal parts. The brain was natural; there was some atheroma of the branches of the middle cerebral artery. On microscopic examination of the small vessels and capillaries it was found that the internal coat appeared natural, while the middle was greatly thickened with undoubted increase of the muscular elements. The external coat was in many of the vessels more distinct than natural; in some it presented a fine fibrillary wavy appearance, but there was no evidence of any material having been effused around the vessels. There were in connexion with the vessels numerous minute aneurisms.

The diagnosis which we established in this case was cirrhosis of the kidney, with hypertrophy of heart, degeneration of vessels, and œdema of lungs. It was confirmed at the post-mortem in every particular. Let me now explain the grounds for the diagnosis.

The presence of albumen and tube-casts in the urine showed that Bright's disease existed. The degree of dropsy during

his second and third periods of residence in the Infirmary showed that some degree of inflammation of the tubules was present. But it was evident throughout that this was not all, but that behind this trivial affection there was important chronic disease. The circumstances which proved this were—1st. The obvious chronic ill-health of the patient. 2nd. The anæmia of a kind frequently seen in Bright's disease. Doubtless it was in part due to the severe epistaxis; but, apart from this, it was obvious that there was some cause of a more chronic kind in operation. Be sure in practice to test the urine of every patient who presents the peculiar anæmic appearance which you saw in this case. 3rd. The epistaxis itself was a symptom often attending upon cirrhosis. It was, prior to the first admission, very severe in this case, but it and other hæmorrhages are not uncommon in the more advanced stages of cirrhosis. The hæmorrhage may be from the uterus, the kidneys, or the mouth, but is most frequently from the nose, and it also should lead to examination of the urine. 4th. The condition of the conjunctiva, the brightness due to œdema, was well marked, and constitutes in many cases a very suggestive symptom. 5th. The state of the heart, the distinct hypertrophy of the left ventricle, without apparent cause either in orifices, in valves, or in vessels, is in itself an important symptom. 6th. The œdema of the lungs on two occasions nearly proving fatal, and ultimately killing the patient. 7th. The most conclusive proof of all was the diminution of urea.

Now, it must be remembered that this group of symptoms may be associated with other forms of renal disease, or rather with one other form—viz., the very chronic inflammatory,—for in this too there are chronic ill-health, anæmia, sometimes hæmorrhages, the bright eye, the hypertrophied heart, the œdema of the lungs, and the diminution of the urea. But the history suffices to distinguish such cases. If the disease be inflammatory and originate in the tubules it is always attended by marked dropsy, at least in every case which is severe enough to become chronic, and it never has that singularly insidious commencement which we observe in cirrhosis. Those of you who were attending in my wards during the past winter session may remember that during the first residence of this patient in the Infirmary I expressed the opinion that he was probably suffering from cirrhosis, even when no albumen was present. I did so on account of his general condition, the urinary trouble, and in particular of the state of his heart.

Had the case been inflammatory there could have been no doubt about the matter, for the albumen would have been distinct and constantly present; besides, there would have been either dropsy present or a history of it.

If anyone were inclined to inquire why, on the other hand, we excluded a diagnosis of waxy degeneration, I would reply that there never was here the early polyuria so characteristic of waxy, and that the peculiar group of symptoms just described rarely, or I may say never, occurs in that disease.

I wish you to notice also certain other features of our patient's case. He suffered from dyspepsia, frequently was sick after eating, and had alternately attacks of constipation and diarrhœa. These symptoms complicate all the forms of Bright's disease in the more advanced stages, and their management is of great importance to the patient. It must therefore be your care by regulation of diet and attention to the state of the alimentary tract to ward off attacks of the kind. You will often find the condition when once established very difficult of cure. There seems good ground to believe that, as in our patient the amount of urea passed by the kidneys waxed and waned according to the severity of the diarrhœa, the intestine afforded a channel for its removal. I mention this to impress upon you the advantage which must accrue if free purgation be established in cases in which the kidneys cannot be roused to action. Notice, again, the condition of the eyes. In many cases there is well-marked albuminuric retinitis; in our patient there was no such change. Had it existed it would have constituted an important evidence; but I think you will find that when it attends upon cirrhosis the renal disease is usually in an advanced stage. It is no uncommon thing for patients to have kidney disease diagnosed by the oculist when no prominent symptom of Bright's disease had existed. It does not follow, however, that the disease is not far advanced, for the advance of the disease is often very insidious. With regard to nervous symptoms, you will observe that there was nothing characteristic in this case; there was neither the acute uræmia nor the chronic uræmia terminating fatally, nor the suddenly occurring and again disappearing convulsions which we occasionally meet with in this form; neither was there the headache so often complained of, nor the mania, nor the acute delirium from which some patients suffer, but there was on one or two occasions during the night some delirium. You remember the case of a cabman who has this disease, and who has latterly gone to his home in the Highlands, and you have not forgotten how often I directed your attention to the peculiar delirium from which he suffered during the night, and which appeared to depend simply on Bright's disease.

What was the sequence of events in this case? The death was undoubtedly due to the affection of the lungs; what was its cause? The impurity of the blood increases the tendency to stasis and dropsy, so that very slight causes, such as exposure to cold, may suffice to induce congestive or even inflammatory changes. In our patient there were some patches of the lungs actually pneumonic, although these were too deeply seated to be diagnosed during life. Why was the heart hypertrophied? There was no disease of orifices, or of valves, or of larger vessels which could account for it; we very carefully examined the minute arteries: the internal coat was natural, the middle was thickened with well-marked increase of the muscular elements, while the external was certainly more distinct than natural, although there was nowhere evidence of a distinct hyaline fibroid material such as Sir William Gull and Dr. Sutton have described. In the absence of such a change no one would, I think, maintain that the state of the small vessels accounted for the hypertrophy, unless one who held Dr. Johnson's theory—that the heart grows in order to overcome the stopcock action of the small arteries. We are profoundly indebted to Dr. Johnson for the observation that the middle coats of the arteries do become hypertrophied, whether the theory he has advanced be correct or not. But while I ascribe these changes to the renal lesion, I beg you to notice that I do not consider that simply a local disease. It is a special local manifestation of that tendency to increased growth of connective tissue with atrophy of essential elements of parts which constitutes one of the most important morbid processes occurring in the body.

The treatment in this case was directed mainly to the relief of symptoms, and on the first two periods of his residence in the Infirmary was very successful; but against the combination which was present at the end we could accomplish nothing.

ORIGINAL COMMUNICATIONS.

CASE OF HYDROA.

VOMITING AFTER FOOD—VOMITING OF BLOOD—LEFT-SIDE PAIN—ERUPTION ON LEFT SIDE OF CHEST PRESENTING THE CHARACTERS OF HYDROA—SAME IN LEFT AXILLA—ADMINISTRATION OF ARSENIC—CESSATION OF ERUPTION—IMPROVEMENT IN GENERAL CONDITION.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

T. G., FEMALE, aged 22, admitted November 11, 1872. Has been ailing two years. Frequently has vomited blood, sometimes two or three times a week. Once there was an interval of two months. Thinks she may have brought up a teacupfull at once; the blood was sometimes clotted. If she eats the least bit of meat she is sick directly; if she takes anything but fluid she feels pain in the epigastrium. Had jaundice twice four or five years ago. Bowels regular. Tongue moist. No catamenia last two months; the flow was scanty previously. Has pain in left side, not worse after food. On left side of chest there is a pretty copious eruption of scattered red papules; a few have become scabbed and quasi-pustular. This eruption has come and gone, off and on, for last two years. Lower dorsal spines are tender. She is able to walk now, but has been unable after a long confinement to bed. Spoon diet, milk; extract. cannibis indica, gr. ss., tannini gr. ij. in pil. ter die.

November 13.—No sickness at all since admission. Pulse 87; temperature 96·8°. Ung. hydr. ammon. chlor. dil. ad eruptionem.

28th.—Has tried fish, but it caused sickness, and she has had to return to pudding and liquids. Has had much left-side pain, but is pretty cheerful; gets about. The eruption on left

side has increased; there are many red papules tending to become pustular, and the dark-red quasi-pustules before present have become larger. They show a blackish scabbed central depression, a considerable thickening of the cutis, and a margin which seems to be formed by a ring of small vesicles.

Ordered on 30th—Hyd. cum cretâ, pulv. Doveri, āā gr. ijss. in pil. ter die.

December 5.—Eruption attended with much burning. There are four large patches from size of a threepenny to size of a sixpenny-piece, circular, with considerably indurated bases, and marginal rings of whitish vesicles on a red area more or less marked and extensive. The other spots are much smaller, but show a like tendency to spread and become depressed and scabbed in centre.

7th.—In left axilla there are six or eight papular elevations looking much as if they would form vesicles; the rest of the eruption is in much the same state. Much pain in the eruption at night. Liq. potassæ arsenitis ℥iij., aq. ʒij., ter die. Poultice.

9th.—The eruption in the axilla has increased; several of the vesicles have become confluent, and the skin in the patch they form is notably thickened.

11th.—Eruption increasing in axilla; one elevation has now got a central dark scab, and a complete white ring around, formed by epidermis raised by effusion of sero-purulent fluid. Another spot has also a similar whity spreading raised margin with a central depression. Other spots are commencing as red dots or papules. Several of the old spots are drying up, and the scab can be detached, leaving a pretty healthy surface below covered with a very thin epidermis. Eyelids are rather sore (? from arsenic). Poultice is comfortable.

16th.—Eruption is very much better; on the side most of the spots have lost their scabs, and present a depressed whity centre, and a slightly raised red margin; those in the axilla also are drying up. Pt. cum mist. ʒj. ter die.

23rd.—Doing well; no sickness; the eruption has ceased, and almost all the scabs have come off. She remained in the hospital until January 15, having no recurrence of the eruption, and no sickness as long as she kept to pudding, eggs, and the like. She was very active and helpful in the wards.

Remarks.—The stomach disorder in this case is suggestive of ulcer, yet I hardly think that one of the ordinary lesions of this kind existed. The hæmorrhage was unlike that of ulcer, in occurring too frequently and in too small quantities, and in being, as I suspect, rather blood-stained mucous fluid than true blood. Probably there occurred on the gastric mucous surface some process analogous to that which we witnessed on the cutaneous surface; and this may have given rise to the occasional hæmorrhage, of which, however, there was very little while she was in the hospital. The stomach symptoms appeared to be rather referable to neurotic disorder than to ordinary inflammation. Some inflammation no doubt there was, but determined by nerve disorder. The eruption was very peculiar. I had never seen the like before, and had no name to give it till Dr. Cheadle pronounced it hydroa. It passed through the following phases:—(1) Red papular spots; (2) the same, with vesiculo-pustules developed at their apices; (3) the elevation and induration of the spot increasing, the central part became depressed and covered with a more or less dark scab, while the vesicle-forming process spread excentrically, producing a distinct whitish ring, enclosing the scabbed area, and itself surrounded by a zone of redness; (4) the vesicle-forming process ceased, the scab became detached, and the affected spot was left with only a whitish centre and a slightly raised red margin. These characters of the eruption closely correspond with those given in M. Bazin's case, quoted in the excellent report given in the *British Medical Journal*, 1870, vol. i., p. 491. The reporter remarks that hydroa is a vesicating form of erythema papulatum *seu* multiforme, the latter term including a variety of appearances which have moved dermatologists to bestow on them the names of E. circinnatum, E. iris, E. tuberculatum, E. gyratum, E. annulose, E. papulatum. In one particular my case conforms not to the rule laid down by Hebra with regard to specific erythema—viz., that it shall occur symmetrically, and shall never exempt the dorsal surface of the hands or feet. It was one-sided, and did not affect the hands or feet. Nevertheless, being guided by Bazin, I must reckon it a genuine instance of hydroa, which it resembles further in its recurring tendency and in its spontaneous disappearance. Certainly it was not eczema, or pemphigus, or lichen, or psoriasis. Ecthyma it somewhat resembled in the inflammatory tumefaction of the spots, but differed from it in the scantiness and superficiality of the exudation and in its peculiar annular arrangement. Herpes seems to me the form of skin eruption to which it has most affinity, and I should propose to apply to it the term herpes centrifugus, which is much more descriptive of the phenomena than hydroa, as the latter leads one necessarily to think of a profuse watery discharge. But whatever name we apply to it, the main point for us to try to seize is its true pathological significance. What was its cause—of what kind of disorder in the system was it the result and evidence? Not, I believe, of syphilis, though I inclined to regard it so at one time. It was not in the least benefited by mercurial treatment, and it was not associated with any other syphilitic symptom. In two of the cases given in the report above quoted there was some question of the syphilitic character of the eruption. Neither can I look upon it as having any connexion with scrofula, such as lupus is usually thought to hold. I should ascribe it to the existence of what our French *confrères* call a "*diathèse herpétique*," by which I understand a tendency to various skin disorders and to various neuroses, the former having their *raison d'être* in vaso-motor nerve paralysis. Asthma and bronchial irritation are sometimes associated with eczema, as in a case I saw recently. In the one we have been discussing the internal disorder had its seat in the gastric mucous membrane, and not in the bronchial.

SNAKE-POISONING IN INDIA.

Communicated by J. FAYRER, C.S.I., M.D., F.R.C.P.

The following experiments with snake poison were recently performed in India by Mr. Richards,(a) and by the Committee (appointed by Government), of which Dr. Ewart is president and Mr. Richards and Dr. Mackenzie are members, in compliance with suggestions made by Dr. Brunton and myself.

The result is so far encouraging, for life was prolonged for many hours; and with improved apparatus for carrying on artificial respiration it is possible that even more satisfactory results may be anticipated. But it is still to be feared that in severe cases of cobra poisoning, when the quantity of virus inoculated has been large, the injury done to the nerve apparatus may prove so severe that resumption of its functions, even after elimination of the poison has taken place, is improbable. Meanwhile, to have prolonged life for many hours is of the utmost importance; for if there be a hope of recovery by elimination of the virus, life being thus supported, time is given for that process to go on. That it does so appears to be shown by the experiments.

In less severe cases, artificial respiration may, when aided by therapeutic agents, administered on general principles, be able to save life in bites that otherwise would have proved fatal. It is satisfactory to know that the subject will receive full and careful consideration from the present Committee, and that the real value of some of the various modes of treatment that have been proposed will be again tested.

Mr. Richards, who is a most indefatigable labourer, and to whom I am indebted for valuable aid as well as original observations, records some interesting facts in reference to the action of the virus in certain quantities, and also his own experience of artificial respiration, the use of strychnine, and the intravenous injection of liquor ammoniæ. One of his experiments shows that not only may life be supported for many hours—more than twenty-four in that case—but that the poison is eliminated by the kidneys.

The investigation of the subject in all its aspects is now being carefully continued in India by the Committee appointed by Government at my suggestion, whilst in London the nature of the physiological action of the virus is under investigation by Dr. Brunton and myself; and there is reason to hope that at all events some facts of importance will be noted and added to those already recorded.

The experiments recorded by Mr. Richards confirm what has been often observed, that very severe symptoms caused by snake-poison may be recovered from without any aid at all, and afford additional proof of the necessity for caution in accepting recoveries generally as the result of the action of

(a) The date of Mr. Richards' experiments is not noted, but they were performed during the first half of 1873, and previous to those by the Committee of which he is a member.

remedies. Such recoveries, which are frequent, account for the reputed success of the new antidotes that are continually being advocated, no doubt with as good faith as with little reason.

Though animals to all appearance dead from intense cobra poisoning, whose respiration had ceased, after passing into a state of complete unconsciousness, have been kept alive for many hours by artificial respiration, the result of the investigations on the physiological action of the virus do not perhaps so far offer very hopeful prospect of complete recovery in such cases. But, as in the case of other active poisons, however deadly, there must be a quantity which, though dangerous in the extreme, is not of necessity absolutely fatal, so it is in snake-poison; and in such cases, which must be numerous, and in which without aid death would most probably occur, we may hope that rational measures may be the means of saving life that would otherwise be lost.

Meanwhile, let the search for antidotes be prosecuted by those who see reason for hoping that such exist—agents that may have the power not only of neutralising the virus when in the blood, but of restoring the normal condition of the nerve apparatus which there is too much reason to fear has been seriously injured.

The result of artificial respiration has been so far satisfactory that it has kept up organic life for many hours and thus given time for elimination of the poison. It remains to be seen yet whether, if such elimination occur, the nerve apparatus is still capable of resuming its functions. If it be so, we may expect the best results from artificial respiration; if not, at least we may anticipate useful aid (when combined with other remedies) in the treatment of those who have not received the poison in its most intense form.

Artificial respiration is a remedy so easily practised that it has at all events the advantage of simplicity and general applicability, for there could be no difficulty, if it really prove efficacious, in teaching even the Indian peasant to practise the Sylvester mode.

With reference to the physiological action of the cobra virus it would be premature to say more at present, while the subject is under investigation, than that it apparently produces its lethal effects by acting on the cerebro-spinal system generally. The nerve-centres and nerve distribution both are liable to suffer, and arrest of the respiration by paralysis of its muscular apparatus is the most frequent mode in which death is caused. The cerebral ganglia are also sooner or later affected, and in some cases the virus appears to act directly on the heart, arresting its action tetanically in systole. This it would appear is most likely to occur when the poison is carried directly to the heart by injection into a vein. The muscular fibre is also, beyond doubt, in some instances affected.

The first part of a paper on this subject by Dr. Lauder Brunton and myself, published in the *Proceedings of the Royal Society*, discusses this subject in detail; it is therefore unnecessary to repeat it here.

First Instalment of a Report of the Committee appointed by the Government of India to investigate the Treatment of Snake-poisoning by Artificial Respiration or other measures, suggested by Drs. Fayrer and Dr. Lauder Brunton. President: Dr. J. Ewart, Professor of Physiology at, and Surgeon to, the General Hospital, Calcutta. Members: Dr. Mackenzie, B.M.S.; Vincent Richards, Esq., Civil Surgeon, Balasore.

Experiment No. 1.—A middling-sized dog was bitten on the abdomen by a cobra at 7.30 a.m. (July 1, 1873); as the bite was considered a doubtful one, the dog was again bitten by another cobra. 7.59 a.m.: Extremely restless, and passed urine. 8.10 a.m.: The breathing is hurried, and there are twitchings at the corners of the mouth. 8.12 a.m.: Universal convulsions. 8.15 a.m.: Commenced artificial respiration. The dog to all appearance was dead; the heart was beating irregularly, but soon began to beat regularly. 9.15 a.m.: The heart is beating rapidly, but without force; lachrymation. No response to the galvanic current. 9.40 a.m.: Heart beating well; temperature 101·2°. 11.15 a.m.: Ditto. The bellows slipped out of the trachea through the carelessness of the man blowing it. 1 p.m.: Heart beating well. Passed fæces after giving two enemas of hot water. Pupils dilate on the application of the galvanic current. 2.30 p.m.: Heart beating well. Pupils dilate, and the animal passes urine on the application of the galvanic current. 6.30 p.m.: Heart beating well. 8.10 p.m.: Ditto. 10 p.m.: Heart at first beating feebly, but afterwards more vigorously. The lungs were not being properly inflated, and the nozzle of the bellows was found to be partially closed by mucus. 11.30 p.m.: Heart beating vigorously. Midnight: Heart beating feebly; lungs imperfectly inflated; cleared the nozzle of the bellows. July 2nd, 12.30 a.m.: Heart beating feebly. Body cold. 1.5 a.m.: Heart ceased to beat; sixteen hours and fifty minutes since artificial respiration was commenced. The blood was found coagulated.

Remarks.—This experiment is by no means a fair test, as not only was the dog bitten twice by two fresh cobras (though there was some doubt about the bite of the first one) but the appliances, at once commenced, at present are of the roughest kind. We had also little assistance. Dr. O'Brien very kindly rendered us considerable assistance in making observations. Mr. Assistant Apothecary Wilson also assisted. The trachea was opened very late in the above case, there being at first no intention on our part of performing artificial respiration.

Experiment No. 2.—July 9th.—A large dog was bitten in the abdomen by a cobra at 8.55 a.m. 9.20 a.m.: Staggering about. 9.25 a.m.: Convulsions. 9.27 a.m.: Commenced artificial respiration. There was some difficulty at first, the apparatus being new and imperfect. 9.35 a.m.: Heart beating slowly; animal is apparently sensible. 9.40 a.m.: The artificial respiration is 44 to a minute; pulse also 44. 10.3 a.m.: There had been considerable contractility of the muscles, but there is now little response to the galvanic current, except of the iris, which alternately expands and contracts. 10.30 a.m.: The same. Irides scarcely so active. Temperature 101·3°; heart beating 112, forcibly but irregularly; respirations 40. Lachrymation has gone on continuously. 11.10 a.m.: The femoral pulse is going on very steadily and well. 11.15 a.m.: Temperature 100·8°; respirations 36; heart beating 100, strong but very irregular. It was beating much more regularly when I first felt it. Irides still act by galvanism. 11.40 a.m.: Changed the bellows, as the air escapes from the one we were using. 12 noon: Irides still act. Respirations 44; heart 160, strong; temperature 100·6°. Applied heat under the dog. 12.30 p.m.: Heart beating very strongly and regularly, 140; temperature 100·7°; respirations 44; irides still act. 1.15 p.m.: Respirations 32; heart 184, pretty strongly; temperature 102·3°. Only one iris (the right one) acts on the application of galvanism. 1.40 p.m.: Both irides act. 2.30 p.m.: Transfused about three ounces of blood, with warm water, ammonia, and chlorate of potash, into the left femoral vein. There was a marked improvement in the action of the heart, which had been beating feebly and irregularly. We now opened the thorax, and observed the beating of the heart and inflation of the lungs. The arteries bled freely when cut, the blood spurting out in regular jets. 3.30 p.m.: The heart began to fail considerably. Injected about three ounces of warm water and fifteen grains of chlorate of potash into the right femoral vein. The animal passed fæces and urine, and the heart almost immediately ceased to beat.

Remarks.—Artificial respiration was faulty; death occurred six hours and three minutes after artificial respiration was commenced. The blood coagulated, but there was also a good deal of fluid blood. This would be expected after the injection of the ammonia and chlorate of potash. We were kindly assisted in the above experiment by Dr. Laurie.

Experiment No. 3.—July 10.—A large dog was bitten on the abdomen by a cobra at 8 a.m. 8.14 a.m.: Restless. 8.20 a.m.: Is whining, and is greatly distressed. 8.40 a.m.: Convulsed. 8.45 a.m.: Commenced artificial respiration. The pupils, which were fully dilated, contracted, and convulsions ceased. The animal appears sensible. 9 a.m.: Heart beating sixty-eight per minute. Occasional slight convulsions; there has been universal convulsion; lachrymation and blinking of the lids. 9.30 a.m.: Heart beating forcibly, 136; respirations 40; temperature 101·1°. Universal convulsion; irides contract; lachrymation; applied heat. 10.15 a.m.: Respirations 40; heart beating so rapidly as to render it impossible to count the beats; tremor of the hind quarters; irides act on the application of the galvanic current; temperature 101·8°. Salivation has been going on since the commencement of artificial respiration. 11.5 a.m.: Respirations 44; heart 180, not very strongly; temperature 102°. No response whatever to the galvanic current. 12.5 p.m.: Respirations 40; heart 160, not very strongly; temperature 103·1°. The only response to the galvanic current is the passage of urine. This occurred again at 12.30 p.m. The pupils have been dilated since the irides ceased to act. 12.50 p.m.: Respirations 46. Pupils are

now contracted, and the irides respond to galvanism. Heart beating regularly and pretty strongly, 168; temperature 103·1°. The mucous membrane of the mouth and the tongue have both recovered their natural colour to a great extent. 1.30 p.m.: Irides act by galvanism. Passed water in a pretty good stream. Respirations 44; heart beating extremely rapidly; temperature 140·5°. 2.15 p.m.: Respirations 44; temperature 105·15°; heart beating very rapidly. The only response to the galvanic current was micturition. 3.15 p.m.: Respirations 44; heart acting too rapidly to count the beats. Pupils contracted, but they dilated on the application of galvanism. Temperature 106·4°. The tube had become twisted, and so interfered with the inflation of the lungs. Changed the bellows at 4 p.m., as the air was escaping, but the air escapes from the one we are now using. 4.15 p.m.: Heart beating feebly and rapidly; irides act, but very slightly; respirations 36; temperature 106·3°. 5.12 p.m.: Heart ceased to beat, seven hours and twenty-seven minutes after the artificial respiration was commenced. Temperature when the heart ceased to beat 107·8°.

Experiment No. 4.—July 12: A large dog was bitten on the left hind leg by a cobra at 7.15 a.m. 7.30: Respiration much hurried—100, and sometimes more; pulse slow, 80; temperature normal, 103°. 7.45 a.m.: Respiration not so hurried, 180; pulse slower, 60; temperature falling, 102·3°. 7.50 a.m.: Appears much distressed, and is salivated. 7.58 a.m.: Convulsed. 7.59 a.m.: Commenced artificial respiration. Convulsions at once ceased, but returned on the interruption of the respiration. The pupils, from being widely dilated, became contracted. The animal appears sensible. 8.7 a.m.: Pulse 160, respirations 40, pupils natural, temperature 102°; blinking of the lids; applied heat. 8.24 a.m.: Convulsive movements of the hind quarters. 8.47 a.m.: The same. 8.50 a.m.: Ditto. 9 a.m: Pulse beating rapidly, 176; respirations 32; pupils natural; temperature 101·4° (has been gradually falling from the commencement); dilatation of the pupils only in response to the galvanic current. 10 a.m.: Heart beating 140, respirations 40; temperature now rising 102·6°. The pupils dilated, and urine was passed on the application of the galvanic current. Lachrymation and salivation going on continually. 10.30 a.m.: Respirations 32, pulse (femoral) 176, temperature normal, 103°. Passed urine, and the pupils dilated on the application of galvanism. 11 a.m.: Respirations 32, temperature 103·2°, pulse very rapid, about 200. Pupils dilate on applying the galvanic current. 12 noon: Pulse 160, respirations 32. Passed urine, and the pupils dilate on the application of galvanism. Temperature 103·4°. 1 p.m.: Pulse 160, good; respirations 44; temperature 103·2°. The same effect on the application of galvanism. 2 p.m.: Pulse 176, pretty strong and regular; respirations 40; temperature the same, 103·2°. The same effects on the application of galvanism. 4 p.m.: Pulse 160, regular, but weaker; very slight action of the iris on the application of galvanism; urine is passed; temperature 105°. 5 p.m.: Pulse 176, very weak; respirations 36; temperature 104·2°. 6 p.m.: Pulse 166, very weak; respirations 42; temperature 104°. 7 p.m.: Pulse 160, stronger; respirations 42; temperature, 103·5°. 8 p.m.: Pulse 176, pretty strong; respirations 42; temperature 103·7°. 9 p.m.: Respirations 32, temperature 103·7°, pulse too quick to count; irides dilate by galvanism. 10.10 p.m.: Pulse good, 128; respirations 32; temperature 104·5°. Micturition and dilatation of the pupils on the application of galvanism. 11 p.m.: Pulse pretty good, 160; respirations 36; temperature 104°. Pupils dilate on the application of galvanism. Midnight: Pulse 160, pretty good; respirations 36; temperature 105°. Micturition only on the application of galvanism. July 13th, 1.5 a.m.: Heart ceased to beat; temperature 105·2°. The heart had gradually become weaker, and suddenly ceased to beat seventeen hours and six minutes after the commencement of artificial respiration. Inflation of the lungs was not complete, as we found them much congested. The blood was fluid, but very soon coagulated. We are indebted to Dr. O'Brien for assistance in this case.

Experiment No. 5.—A large dog was bitten on the thigh by a cobra at 6.50 a.m. Temperature was then 103°. 7 a.m.: Passed a stool. Temperature now 103·8°. 7.10 a.m.: Temperature 103·6°. 7.55 a.m.: Convulsed. Temperature 105°. 8 a.m.: Commenced artificial respiration. 8.3 a.m.: Temperature 100·1° (!). 8.5 a.m.: Slight convulsive movements. 8.12 a.m.: Respirations 36; pulse over 200, pretty regular; temperature 103°. 8.42 a.m.: Universal convulsions in response to the galvanic current. 9.12 a.m.: Temperature 103·8°; respirations 36. Heart beating very quickly but not very strongly. 10 a.m.: Temperature 101·8°; respirations 40; pulse 160, not very strong. Action of the iris and micturition in response to the galvanic current. 11 a.m.: Temperature 102·8°; respirations 36; pulse 176, pretty strong. Slight action of the iris and micturition in response to the galvanic current. Noon: temperature 104·4°; respirations 40; pulse 180, weak. The irides do not act, but there is micturition on applying galvanism. 1 p.m.: Temperature 103·6°; respirations 36; pulse 140, weak. Pupils dilate, and water is passed on the application of galvanism. 2 p.m.: Had passed fæces. Temperature 105·2°; respirations 36; heart beating too rapidly to count—no reflex action whatever. 3 p.m.: Had passed a stool. Temperature 105·4°. The femoral could not be felt, and the heart was scarcely beating. 3.20 p.m.: Heart ceased to beat seven hours and twenty minutes after the commencement of artificial respiration.

Remarks.—The lungs were found congested, showing that artificial respiration was not complete. This is the fault of the men blowing the bellows. The blood coagulated after death.

GLEANINGS IN WAR SANITATION

FROM N. PIROGOFF'S "BESICHTIGUNG DER MILITAIR-SANITÄTS-ANSTALTEN IN DEUTSCHLAND, LOTHRINGEN, UND ELSASS."

By NATHANIEL ALCOCK, L.K.Q.C.P., A.M.D.

(*Continued from page* 174.)

THE fourth and most practical question proposed by Dr. Pirogoff to himself is, "What success attended during the past war the so-called conservative and expectant treatment in general, and especially of those wounds which according to former belief demanded an immediate removal of the injured limb?"

Taking the parts of the body *seriatim*, Dr. Pirogoff considers the results of wounds of each compared with those of the same wounds when treated according to former notions.

Antiphlogistic treatment, as understood heretofore—bloodletting, leeching, etc.—has been by common consent abandoned, and is not employed even in those penetrating head wounds with injury of the skull, which seem most to demand it; trepanning, too, is but seldom resorted to—nevertheless, the fate of the head wounded cannot be said to be much improved. In penetrating chest wounds, however, when treated on the expectant plan, a remarkable proportion of recoveries ensued, and the successful result was noticeably affected by the escape or implication of the ribs. In the majority of instances the bullet, probably by reason of its form, its rapid revolution, and its narrow circumference, passed through an intercostal space, leaving the bones uninjured, and the healing of the lung fistula which subsequently formed was doubtless much facilitated by the comparatively pure air of the German hospitals; on the other hand, when the wound was accompanied by a broken rib the result was mostly fatal.

In penetrating wounds of the abdomen no improvement has been attained; therefore, while in chest wounds only has any advance been made, penetration of the chest or abdomen continues to be as hopeless as before.

In a wound from a mitrailleuse projectile the sole peculiarity seemed to be a greater similarity between the opening of entrance and that of exit than is the case when an ordinary bullet has passed through.

The number of instances in which Chassepot wounds healed without suppuration was very remarkable, being in a great measure attributable to the wholesome condition of the hospitals, but also to the abandonment of surgical interference. In simple gunshot wounds the conservative and expectant treatment was adopted, to the exclusion of all incisions, and even of cold or warm applications, and was thus carried to almost an extreme of simplicity. Sponges have been happily replaced by irrigation, and salves and cerates have given way to solutions of carbolic acid. It is well to remember that decomposing coagula and serum in a wound contribute to its infection, either by the independent formation of microzymes or by their introduction from without, and that, consequently, gunshot wounds, unsuited as they are for being hermetically sealed, present still a difficult problem to be solved. With this view, two methods recently proposed deserve attention—

Guérin's apparatus and Lister's carbolised lime bandage. The former consists of an indiarubber bag tied round the limb above the wound, and terminating below in a tube which leads to a vacuum globe; into this all pus is conducted without contact with the air. But the appliance is far too elaborate for use in time of war. The English method attempts the occlusion of the wound by a mixture of oil, carbolic acid, and chalk, but runs the risk of pus-collections forming underneath, and does not seem to have merited the praises bestowed upon it by the journals.

It was proposed by Professor Burow that wounds should be left completely stripped, but this deprives them of the benefits of equable pressure and support, and would be but a retrograde mode of surgery, while its sole advantage would be the prevention of pus-accumulations in the part.

There is, then, at present no more practical means than the laying of a drainage-tube along the bottom of the wound and keeping up constant irrigation; for this purpose one end of the tube is attached to the irrigation syphon, and the other leads into a utensil, the lotion-stream being composed of one part of carbolic acid in eighty parts of water. All pus is thus continually drawn off and the cavity is disinfected. Further, the edges may be united by wire sutures, and the whole enclosed in a fenestrated plaster-of-Paris bandage.

Some of the dressings used by the Germans demand attention, and of these machine-made charpie, a light and permeable description of gauze, and the oil-paper substitute for oil-silk are the most efficacious; also the parchment water-bags, which could retain water for a week, and by constant evaporation cool the surface with which they came in contact.

English machine-combed tow, derived from the worn-out ropes of ships, was found to be, in consequence of being imbued with tar, advantageously disinfectant.

Dr. Pirogoff now passes to the consideration of the very important subject of conservative surgery, and says that to appreciate the progress made in this direction one must revert to the teachings of Bouchet, Larrey, and Dupuytren, by whom amputations were divided into primary, intermediary, and secondary, and by whom, also, it was inculcated that lapse of time before operating cost more lives than it saved limbs. These doctrines, however, though held by some authorities to this day, have been for the most part dissipated by the three following causes:—The introduction of statistics into surgery; the use of the immovable bandage (plaster of Paris) in compound fractures; and by the adoption of operations which supersede removal of the limb. In 1841-42, Malgaigne showed by figures that the mortality in the Paris hospitals after primary and after secondary amputations of the lower extremity was about equal, being in either case between 65 and 78 per cent. It appeared, however, from these calculations, that the removal of limbs for organic disease in bones and joints, as caries, etc., was less fatal than primary and secondary amputations for external injuries. In the year previous attention had been drawn to Seutin's immovable paste bandage, and some few surgeons accordingly determined on trying it in such compound fractures as would have, in conformity with previous notions, demanded immediate removal of the limb. At the same time excision of injured bones and joints began to gain acceptance. Yet the tenets of 100 years, which had been put in practice during the bloodiest wars, could not be easily subverted; and therefore did Dr. Pirogoff, even in 1847, follow without hesitation the doctrines which he had inherited, and carried them with him when sent to the Caucasian war for the purpose of investigating the value of anæsthesia on the battle-field.

He amputated as heretofore in compound fractures, and obtained a consequent death-rate of 20 per cent. in the upper extremity, and 72 per cent. in thigh amputations. Owing to the novelty of ether vapour, he suspected that it exercised some toxic influence on the wounded, and this surmise was also supported by the occurrence of eight deaths from septicæmia, but further observation of 600 different operations under ether and chloroform proved that the mortality was not thereby affected.

Seeing, then, the fatality of thigh amputations, Dr. Pirogoff after the Caucasian expedition, 1849, wrote as follows:—"The conservative method of treatment might be attempted with some hope of success, even on the battle-field." And to these timid utterances against established practice he was still further prompted by having found in the Caucasian hospitals ten cases of bad compound thigh fracture which had done well, not only without operation, but without treatment of any kind. He was also convinced that the application of a permanent paste bandage would render the transport of such wounded possible. Later on, in the first Holstein wars, Stromeyer and Langenbeck carried out the conservative method of resection on a very large scale. Nevertheless, had not Dr. Pirogoff brought the plaster-of-Paris bandage into notice in 1850, this conservative method would never have reached its present utility. From experience of the value of this bandage, Dr. Pirogoff was, when the Crimean war began, prepared with its assistance boldly to have recourse to the conservative method of resection on the field, and would have derived a fuller measure of success had it not been for the unsanitary condition of the hospitals, the scantiness of materials for preparing the bandages, and ignorance of the efficacy of drainage-irrigation as a means of preventing retention of matter in the interior of wounds. As an evidence of how indispensable the plaster-of-Paris bandage is in conservative surgery, it may be mentioned that from being unacquainted therewith neither did the allies in the Crimea, the French in the Italian campaign, 1859, nor the French in Strasburg perform many successful resections; whereas the Germans, on the other hand, though not applying it on the battle-field, used the plaster-of-Paris bandage very generally throughout their hospitals; and for this reason in the Holstein, the Austrian, and more especially in the last war, this conservative method was put in practice by them to an unequalled extent. The hindrance to the application of this method lay in excessive contusion and laceration of the soft parts surrounding the broken bone, with or without injury of the main vessels and nerves, in comminution or extensive fissuring of the bone, with opening of the canal and laceration of the marrow, and in the impossibility of transporting those so wounded.

During the late war, Dr. Pirogoff neither saw nor heard of any of those injuries which were heretofore ascribed to the windage of large projectiles, and in which without the skin being broken the deeper structures of the limb were reduced to a complete pulp. Such cases, when they occurred, were clearly the result of contact with spent shot; nor were any instances of contusions with immense ecchymosis, also formerly attributed to spent shot, anywhere to be met with.

As to the effects of present bullets on bones, there was no positive evidence that they fissured or comminuted the large bones more often than their predecessors. It was even observable that compound fractures were not usually enlarged by incision for the removal of splinters; and this is well, since the measures taken in the Crimean war for their extraction secured but little success.

Finally, the transport of the wounded was not so difficult as was hitherto supposed; not only were very many with compound fracture conveyed to great distances in fixed bandages, but some also who travelled without any bandage whatever received no harm. From which it appears, either that the three circumstances which used to prevent the saving of limbs—torn bloodvessels, comminuted bones, and inability for removal—have been less frequent in the late war, or have lost much of their previous significance.

Most surprising, however, was the result of conservative treatment in compound thigh fractures, and this was made still more apparent by comparison with the statistics of thigh amputation, corroborating what Dr. Pirogoff had written years before—"that all military surgeons would agree in this to apply in a more extended degree the conservative mode of treatment to gunshot wounds of the thigh, since they would have before their eyes the 90 to 95 per cent. death-rate in primary thigh amputations as well with us (Russians) as with the French in the Crimea." Again, in the German hospitals more than thirty cases of recovery from gunshot fractures of the upper and middle thigh were met with, whereas of thigh amputation only twenty-one survivors were found, and in none of these had the operation been performed in the upper third.

No one could have anticipated the extraordinary success which attended the treatment of knee-joint wounds. About forty cases were counted which had not only healed satisfactorily, but even retained some mobility, and that notwithstanding the permanent impaction of the bullet in the joint and the transport of the patient without dressing. As in breast wounds, so in these, the size, shape, and action of the Chassepot bullet seem to exercise some influence, since in most instances the bones were not fractured, "whereas with us in Sebastopol the reverse was generally the case, and almost all our knee-wounded died, whether amputation was performed or not." Another circumstance lately remarked in connexion

with these wounds was, that when a happy result followed the direction of the entrance of the bullet was from before backwards, and not from side to side. Considerable inflammatory swelling ensued in some, in others union without suppuration; but in no case were antiphlogistic remedies employed.

To return to thigh fractures, there is one circumstance which deserves especial notice, and may in some measure account for the absence of bone-splintering—viz., that in many cases the bullet track had no direct connexion with the seat of fracture: in no other way can the frequent healing of these wounds without the extrusion of splinters and sequestra be explained. In the treatment of these fractures the three means which play a chief part are—first, the immovable bandage; second, the inclined plane, or a special bed; and third, the continuous extension of the injured limb.

Claiming the priority of invention of the plaster-of-Paris or immovable bandage, Dr. Pirogoff lays down the fundamental advantages of the appliances as follows:—That it exercises a uniform circular pressure throughout the entire length of the limb, thereby paralysing the attached muscles; that it secures immobility to the broken fragments; and that it keeps up continuous extension to a certain extent when put on and allowed to harden while the limb is being extended. The firm unyielding capsule formed by this bandage when it embraces the joints above and below the wound prevents the further approximation or riding of the broken ends, and keeps the limb on a constant stretch. Finally, the fenestra in the bandage must be so arranged that the fixity of the bandage will not be lessened. If it be too small or too far removed from the site of the wound, pus will collect beneath; if too large the bandage loses strength, and the limb ceases to be immovable. This fenestra may be made either during the application of the bandage or later. The former method requires most skill, and seems to have been quite unknown to the German surgeons, who, after resection of the elbow-joint, are in the habit of placing the arm in an Esmarch splint and fixing it therein with a plaster-of-Paris bandage; but this is not the true immovable bandage, nor does it admit of the patient getting up or going about, whereas when applied according to Dr. Pirogoff's directions, it allows him during convalescence to walk about in the open air. The process is as follows:—A drainage-tube is drawn through the wound, which is either covered with charpie or united by sutures, a roller of flannel, cotton, or other rough texture is applied over the entire limb, and on this plaster-of-Paris paste is smeared; a large piece of wire-gauze is then taken, an aperture corresponding to the size and position of the wound cut out, and with the remainder the limb is closely enveloped; plaster-of-Paris paste is again laid on; and finally the whole is fixed by one or more layers of "pasted" bandage, additional turns being given in the vicinity of the fenestra if extra strength be required. When the material has fully hardened, the fenestra is opened through the "pasted" bandage by means of a strong scalpel. The flexible wire-gauze accommodates itself to all inequalities of the surface, and so a perfectly equable case is formed, which allows neither spring nor breakage in the bandage. Should still greater substance be desired, the further introduction between the wire-gauze and outer bandage of splints of lime-tree bark soaked in the paste will attain the object. In the application of the bandage to thigh or hip-joint fractures the wire-gauze renders most important service, making a girder for the pelvis or a trouser for the injured limb, as far, if necessary, as the sole of the foot. When the fenestra has been opened it is indispensable that the pus should have free exit by suitable drainage, and that none be allowed to insinuate itself between the wound and the bandage. Should such interspace exist, it must be effectually closed with cement, and for this purpose a solution of resin in sulphuric ether is most satisfactory.

The plaster-of-Paris bandage may be put on either at the bandage places preparatory to transport, or subsequently in the hospitals for the purpose of treatment—in the former case without a fenestra, providing the distance to be accomplished is not too great, and that the appliance can be removed on arrival. In the latter case the question arises, How soon ought the bandage to be applied? and this is not easy to answer.

For one unaccustomed to its use, it is in general better, when the inflammatory swelling has come on, to wait a little. Dr. Pirogoff, however, does not delay under any circumstances; but if there be much swelling he slits the bandage, when set, in its whole length, and so converts it into a case, out of which the limb can be taken to be cleansed or to be treated in any way required; and should suppuration or abscesses occur, the inner surface of this splint can be from time to time brushed with carbolised plaster-of-Paris paste, while the necessary drainage-irrigation system can also be arranged in connexion with the wound; but when the swelling has subsided, and fixity of the limb becomes the chief indication, the ordinary plaster-of-Paris bandage must be substituted. As a lighter kind of bandage for use at the conclusion of the treatment, when suppuration has ceased and the wound healed, a flannel roller is to be applied, its outside smeared with a mixture of one pound boiled starch, and one and a half to two beer-glasses of plaster of Paris,—pasteboard splints saturated with the same are laid along the limb, and the whole covered with several layers of linen bandage also soaked in this. When dry it is split up, separated from the limb, varnished, its edges bound and strings attached at intervals. This forms a durable and elastic support which will last for months.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

FOUR CASES OF TYPHOID FEVER IN ST. THOMAS'S HOSPITAL, APPARENTLY DUE TO MILK.

[Reported by George H. Evans, Resident Assistant-Physician.]

Case 1.—Frances S., aged 19, under-nurse, from Henrietta-street, Cavendish-square, admitted June 16, 1873. She is servant in a family where there are five children and two nurses. Three of the children and the other nurse have been taken ill at intervals during the last two months, the first case having occurred in the week after Easter, and have been said to have been suffering from typhoid fever. She has been ill about two weeks with headache, pain in the back, loss of appetite, thirst, occasional delirium at night; no diarrhœa till day of admission, on which morning she has had a dose of castor oil, and diarrhœa since. The nurses and children have been supplied with special "nursery milk" from the same company which supplies the rest of the family. None of the rest of the family have partaken of the nursery milk; none have been ill. She has passed through a typical attack of typhoid fever, followed by a distinct relapse when convalescent, from which she has now recovered.

Case 2.—Jane W., aged 26, nurse, from Marylebone-road, admitted August 4, 1873. The whole family were supplied with milk from the company. The eldest daughter, aged 18, a son aged 5, and a child aged 2 have all had slight attacks of what has been said to be typhoid fever. This patient was taken ill about July 25 with pain in the head and abdomen; has slept badly; took to bed on July 29; has had diarrhœa during the last week. She is now convalescent from a mild but definite attack of typhoid fever.

Case 3.—Sarah K., aged 20, kitchen-maid, from Grosvenor-street, admitted August 13, 1873. The family in which she is in service are supplied with milk by the company. There are no children; no one else has been ill in the house. She was taken ill about the end of July with giddiness, headache, pain in the back and abdomen, and occasional diarrhœa. She has had up to the last few days distinct rose-coloured spots, and is now convalescing from a mild attack of typhoid fever.

Case 4.—Rebecca L., aged 26, kitchen-maid, from Great Cumberland-place, admitted August 15, 1873. The circumstances of this case are very similar to those of Case 3—viz., family without children supplied with milk by the company, the kitchen-maid alone being attacked. Her illness commenced early in August. On the 6th she first applied to the doctor, complaining of headache, sickness, aching in limbs, and feeling generally ill. She did no work from that time, but did not take to bed till sent to the Hospital. She has had a copious eruption of rose-coloured spots, but the attack has been a mild one. It appears that both this patient and the previous one were the only persons in their respective houses who were in the habit of drinking milk by itself in any quantity.

LEEDS GENERAL INFIRMARY.

AN OUTBREAK OF SEPTICÆMIA.

The history of isolated epidemics is always interesting, and we have come across few more so than that of the terrible pyæmic, or rather septicæmic, outbreak which occurred in the General Infirmary at Leeds in the year 1864, and for the details of which we are indebted to Mr. Jessop. Every case, or nearly so, operated on during a certain three weeks died from a low form of purulent peritonitis, so insidious that in many cases it was only discovered after death. The surgeons ceased operating as far as possible; a committee of medical officers investigated the sanitary condition of the Hospital, and found, amongst other defects, that many patients were using straw mattresses ten or more years old, some of which were rotten—converted into a kind of manure by the percolation of discharges and moisture. All sanitary improvements that could be devised were made, and we believe they have not had another case of this form of septicæmia. Such facts with regard to pyæmia, erysipelas, and phagedæna of hospitals are instructive, and suggest the question—"How far in well-arranged, well-cared-for wards are such diseases communicated to patients by the beds or mattresses on which they lie?"

In his communication Mr. Jessop says—The old terms purulent and "putrid" infection are well adapted to convey the meaning which I have been accustomed to attach to pyæmia and septicæmia respectively—the former characterised by collections of pus in the substance of internal organs, the latter by diffuse inflammations of surfaces, serous, synovial, venous, lymphatic, cutaneous. The two are not, I believe, wholly distinct pathological conditions. I have found them occasionally associated in the same individual, and have not unfrequently observed their simultaneous appearance in the wards.

Rigors, followed by profuse sweating, repeated more or less frequently, and accompanied each time by a rapid rise of four or five degrees of heat, not to be accounted for by any local inflammation, are the most reliable amongst the early symptoms of pyæmia. In septicæmia the rigors are less marked, sometimes entirely absent; there are no profuse sweatings, and the rise in temperature, though always sufficient to give a dry, pungent feel to the touch, is not invariably so high when measured by the thermometer. In many of the worst cases mentioned in the accompanying table, the patients, having been apparently well previously, suddenly began to vomit, the skin became hot, the secretions stopped, the tongue quickly dried, and the pulse was characterised by rapidity and feebleness. The local signs were often trivial, sometimes, even in cases where subsequent post-mortem inspection revealed the most advanced serous inflammations, altogether wanting. Then came what I can only describe as "rapid sinking."

I have an impression—it is only an impression—that the dark, lanky-haired, long eyelashed, thick muddy-complexioned, strumous subject is more liable to pyæmia after an accident or operation than others.

Severe injuries of the lower limbs, amputations, primary and for disease, have furnished an overwhelming proportion of the cases of pyæmia which have fallen under my observation. Exceptions to this rule have, for the most part, occurred during epidemics, and several will be found on reference to the table.

Once I have seen pyæmia kill after an operation for fistula in ano. I remember an old man dying of pyæmia after Chopart's amputation for disease, in whose urine an abundance of sugar was found to be a constant element; but as no examination had been made until after the pyæmic symptoms had manifested themselves, I am unable to say whether or no sugar had existed before amputation. If an operation be performed on a person whose kidneys are much damaged, as in calculous diseases, old urethral strictures, prostatic enlargements, in the various forms of Bright's disease, or even in an advanced fatty degeneration, pyæmia or septicæmia are almost certain to follow in one or other of their varieties. The habitual sot frequently succumbs after an operation to septicæmia. On the other hand, I have frequently observed men who have been reputed heavy drinkers to make rapid recoveries after even severe operations, but these have generally proved to be the occasional drinkers, not the regular soakers.

As I have already said, severe injuries of the lower limbs and amputations have furnished a considerable number of the examples of pyæmia which I have met with. I have not, however, seen any reason to attribute a greater share in its production to the bones than to any other tissue. I have seen a death from pyæmia consequent upon a primary Chopart, and also after a primary amputation at the shoulder-joint, in neither of which was there any section through bone.

Tabular Statement of Thirty-five Cases of Erysipelatous Diseases which occurred in the Leeds General Infirmary during the latter months of 1864.

No.	Sex.	Age.	Nature of case; when admitted.	Nature of pyæmic attack.	Date of seizure.	Result.	Post-mortem appearances.	Duration of attack.
1..	F (ward nurse)	35	Chronic ulcer of leg	Erysipelas of foot, leg, and thigh; formation of abscesses	Sept. 6, 1864	Recovered	—	—
2..	M	30	Strumous hernia, testis; protrusion shaved off, and edges of skin brought together. Sept. 22, 1864	Phagedæna of wound; erysipelas of scrotum, abdomen, head, and face	Sept. 26, 1864	Recovered	—	—
3..	M	40	Crushed foot	Hospital gangrene; lymphatics of leg and thigh acutely inflamed	Sept. 29, 1864	Recovered with secondary amputation	—	—
4..	F (ward nurse)	42	None	Erysipelas of head, face, chest, and upper extremities	Oct. 5, 1864	Died Oct. 13	—	9 days
5..	F	17	Bronchocele; tracheotomy	Erysipelas of trunk, head, face, upper extremities; pleurisy, with effusion	Oct. 6, 1864	Recovered Nov. 13	—	39 days
6..	M	50	Tumour in orbit; removal of entire contents. Oct. 6	Pyæmic inflammation of joints; pneumonia	Oct. 10, 1864	Died Dec. 13	Both knees, one elbow, and one wrist contained purulent synovia, and showed signs of commencing disintegration; right lung grey hepatisation; and pleura contained turbid serum	65 days
7..	F	Middle aged	Hygroma of bursa patellæ; removal on Oct. 20	Diffuse peritonitis	Oct. 24, 1864	Died Oct. 27	The peritoneum was universally inflamed, and coated with a layer of creamy lymph	3 days

No.	Sex.	Age.	Nature of case; when admitted.	Nature of pyæmic attack.	Date of seizure.	Result.	Post-mortem appearances.	Duration of attack.
8..	M	53	Fractured ribs on both sides; lung penetrated; scalp wound. Oct. 26	Erysipelas of head and face; immense and rapidly spreading carbuncle of back	Oct. 31, 1864	Died Nov. 13	—	13 days
9..	F	45	Carbuncle on back; incisions. Oct. 29	Phagedæna	Nov. 2, 1864	Recovered Dec. 5	—	33 days
10..	M	56	Simple fracture of leg. Oct. 24	Erysipelas of head and face	Nov. 3, 1864	Recovered Dec. 3	—	30 days
11..	F	Middle aged	Chronic glaucoma; Hancock's division of ciliary region. Nov. 3	Rapid sinking; no diagnosis formed during life	Nov. 4, 1864	Died Nov. 8	Peritoneum universally inflamed and thickly coated with creamy lymph	4 days
12..	M	70	Simple fracture of patella	Vomiting; rapid sinking	Nov. 4, 1864	Died Nov. 6	Exactly like the preceding case	2 days
13..	M	—	Smash of leg; amputation below knee. Nov. 4	Diffuse cellular inflammation of stump and thigh; double pleurisy	Nov. 7, 1864	Died Dec. 10	Stump and thigh sloughy and largely infiltrated with pus; both pleuræ contained turbid fluid and soft adhesions	33 days
14..	M	30	Compound fracture of patella; joint opened. Oct. 22	Diffused cellular inflammation of whole limb; general pyæmia	Nov. 9, 1864	Died Dec. 25	Entire limb sloughy and infiltrated with pus; purulent deposits in lungs	46 days
15..	M	—	General anasarca and ascites, from which he was convalescent	Erysipelas of head, face, and neck; diffuse peritonitis	Nov. 10, 1864	Died Nov. 17	Purulent peritonitis	7 days
16..	M	—	Hernia, testis	Erysipelas of scrotum, abdomen, and thighs; diffuse peritonitis	Nov. 14, 1864	Died Dec. 18	Purulent peritonitis; pelvic and femoral veins filled with purulent clots	34 days
17..	M	29	Syphilitic ulcer of leg	Phagedæna	Nov. 18, 1864	Sent home immediately	—	—
18..	M	50	Acute Bright's disease, 3 weeks	Erysipelas of neck and throat; diffuse peritonitis	Nov. 20, 1864	Died Nov. 23	Purulent peritonitis	3 days
19..	M(a)	45	Scalp wound. Nov. 1	Erysipelas of head and face; many joints inflamed	Nov. 25, 1864	Recovered Dec. 10	—	15 days
20..	F	—	Ovarian tumour, with ascites; paracentesis. Nov. 24	Erysipelas of abdomen; diffuse peritonitis	Nov. 30, 1864	Died Dec. 5	General peritonitis; abdomen contained opaque serum, and much shreddy lymph	5 days
21..	M(b)	29	Caries of malleolus; gouging. Nov. 26	Erysipelas of foot and leg	Nov. 30, 1864	Recovered	—	—
22..	M	66	Enlarged prostate	Diffuse peritonitis	Dec. 1, 1864	Died Dec. 5	Purulent peritonitis	4 days
23..	F	Middle aged	Sinus resulting from chronic mammary abscess; laid open. Nov. 24	Erysipelas of breast; diffuse peritonitis	Dec. 2, 1864	Died Dec. 4	Intense general peritonitis; universal coating of lymph	2 days
24..	M	—	Suppurating bursa over olecranon; incision. Dec. 1	Erysipelas of arm; pleuro-pneumonia; suppuration of knee-joint, and diffused suppuration of thigh	Dec. 5, 1864	Died	—	—
25..	M	—	Spontaneous anæmia	Small carbuncle on neck; erysipelas of neck, head, and face	Dec. 10, 1864	Died	—	—
26..	M	—	Fatty tumour of neck; excision. Dec. 1	Erysipelas of head, face, neck, and back	Dec. 10, 1864	Recovered	—	—
27..	M	63	Intracapsular fracture of neck of femur	Erysipelas of leg; diffuse peritonitis	Dec. 13, 1864	Died Dec. 18	—	5 days
28..	M	—	Compound fracture of arm; excision of elbow. Dec. 12	Diffuse cellular inflammation of arm; general peritonitis	Dec. 13, 1864	Died Dec. 20	—	7 days

(a) This patient's son was attacked by erysipelas at home the day after he had visited his father at the Infirmary.
(b) Same case as No. 29. (c) See Case 21.

The majority of the cases of pyæmia have arisen sporadically, and have apparently had no immediate connexion with other disorders. Occasionally, however, erysipelas and other diseases of a like type have been present in the hospital during the presence of pyæmia. Notably there occurred, a few months ago, three cases of pyæmia, two of which were under my care, and are referred to again below, during an epidemic of phagedæna. (See also Cases 6 and 14 in the tabular statement.)

In the worst forms of acute pyæmia I cannot say that I have seen any good effect derived from treatment. The slighter forms are not unfrequently recovered from. The measure which has undoubtedly yielded the best results, and which alone, in my judgment, deserves the name of remedy, is the placing of the patient in a gentle but continuous current of fresh air. Good support, regulated both in quality and quantity by the patient's capability of digestion, is also requisite.

Two cases have recently arisen in my wards—the only two I have had during my two years' connexion with the new Hospital,—at a time when there seemed to be a disposition in this part of the country for wounds to assume an unhealthy character, as was evidenced by a severe outbreak of phagedæna in almost every ward in which wounds were collected, and by the simultaneous admission from the surrounding and even distant districts of unhealthy phagedænic sores.

The first of the two occurred in a youth who was suffering from acute necrosis of the right humerus. After the usual succession of rigors and sweating, the left hip and right knee-joints became painful and swollen. The second was in a man beyond middle age, who had been cut externally for strictured urethra, and in this case also the local manifestation was in one knee.

I make special mention of these cases because of the excellent effect produced on emptying the joints by means of the pneumatic aspirator. In the former case an ounce and a half of pus was removed from the hip-joint, and two ounces of purulent synovia from the knee, and in the latter, an ounce and a half of purulent synovia was taken from the knee. In each the recovery was rapid and complete, both as to the general and local affection.

In the Old Leeds Infirmary pyæmia may be said to have been endemic. The cases were by no means rare. This was due in a great measure, if not entirely, to the crowding together in an old ill-constructed building of a very large number of severe injuries and operations of magnitude. In our new Hospital pyæmia is almost unknown. I have a strong conviction that with thorough ventilation, the spreading out of cases over a sufficient space, and the observance of cleanliness, pyæmia will become a rare affection. In order to avoid it I carry out these views to the best of my ability, and hitherto, with the exceptions above mentioned—due unquestionably to the presence in the wards of many offensive sores,—my efforts have been completely successful.

Statistics of Small-pox in the German Empire.—According to the statistical account published by the German Chancery, the number of cases of small-pox that occurred in the various States composing the German Empire from 1860 to 1870-71 amounted to 232,824, of which 28,539 terminated fatally. In 208,793 of the cases it is stated whether vaccination was performed or not—viz., unvaccinated 27,793, vaccinated 181,000. There were also 6015 revaccinations. Of the non-vaccinated 8894 died, or 32 per cent., of the vaccinated 17,260, or 9·5 per cent., and of the revaccinated 445, or 7·4 per cent.—*Berlin. Klin. Woch.*, August 11.

Removal of Pigmentary Stains after Venereal Eruptions.—M. Langlebert wishes to make known a simple means of effecting the removal of the pigmentary spots which syphilitic eruptions, and especially ecthyma, leave behind. Of a deep yellow, sometimes almost black, they are very lasting, those of the legs sometimes persisting for years, to the great annoyance of the patients. The various applications hitherto employed being of little avail, M. Langlebert having remarked that blisters which had been kept open only for a few days leave, especially in individuals of a dark complexion, white traces that are well-nigh indelible, applied in an old case of syphilitic ecthyma small blisters over the syphilitic patches, and maintained suppuration for a week by means of blistering ointment. The success was complete, and has induced him to recommend the adoption of the practice.—*Gaz. des Hôp.*, Aug. 2.

SATURDAY, SEPTEMBER 6, 1873.

THE DAIRY REFORM COMPANY AND THE OUTBREAK OF ENTERIC FEVER.

The Dairy Reform Company furnishes a telling instance of the truth of the adage that "it is not in mortals to command success." There is every reason to believe that in an age of dishonest trading this Company has conducted its business honestly, that it has endeavoured to supply its customers with the best milk, and that it has, in truth, sold a milk in which the chemist could detect no fault—a milk unadulterated with water or any other fraudulent addition. The milk was obtained from cows fed on pastures not irrigated with sewage, in a generally healthy and productive part of the country. In fact, every recognised requisite for a good milk supply—healthy cattle, good pastures, and honesty of purpose and practice—was provided in the dealings of this unlucky Company, and yet they stand convicted of having spread disease, death, and misery amongst a very large number of innocent people—their customers—in one of the healthiest parts of one of the healthiest cities in Christendom.

Up to a certain point there is no doubt that the Dairy Reform Company are simply to be pitied. Up to August 4 they were the innocent authors of an enormous and wide-spread evil—an evil which, apart from all commercial considerations, would by none, probably, be more poignantly regretted than by the directors of the Company themselves. But from and after the date of August 4 the relations of the Company to their customers were placed on a different footing, and their conduct demands, and undoubtedly will receive, an impartial investigation from the guardians of the public health. On that day the Company received a letter from Dr. Whitmore, the Medical Officer of Health for St. Marylebone, from which the following is a quotation:—

"Without presuming to express any opinion as to the cause of this outbreak, I nevertheless feel that the occurrence of so many cases of the disease amongst children and others who habitually drink your milk is, to say the least, a remarkable coincidence; and, as Medical Officer of Health of this parish, I feel it my duty to suggest for your serious consideration the

necessity of your at once ceasing to supply the public with milk obtained from your present sources, and until it can be shown that the outbreak has its origin in other causes."

This letter was delivered on August 4. We will at present say nothing with regard to other warnings addressed to the Company. The simple and sufficiently remarkable fact is that after receiving this communication the Company do not appear to have instituted any skilled inquiry as to any sources of contamination which might be present at their dairy farms until August 12—eight days afterwards; and up to the following day they continued to distribute their deadly poison amongst their customers. Such a disregard of official medical advice and apparent indifference as to consequences can certainly only with difficulty be justified.

But the charge against the Company does not rest here. On August 7 Dr. Whitmore again wrote to the directors of the Company in the following terms:—

"Since the date of my letter addressed to your manager, Mr. Maconochie, suggesting to him the necessity of suspending for a time the sale of your milk, several other cases of typhoid fever have been brought to my notice, all of which have occurred in families who obtain their milk supply from your establishment. Under these circumstances I feel that my official position as Medical Officer of Health of this important parish imposes upon me the very responsible duty of calling upon you at once to discontinue any further supply of milk to the public from your present source until such time as the true cause of the outbreak can be ascertained. I must also take leave to say that should you think proper to disregard this notice, and should the investigation which I am now pursuing prove that the present outbreak of fever in that district is in any way attributable to the milk, the responsibility of any future ill-consequences that may occur will be yours.

To this letter Dr. Whitmore received an answer that the directors were prepared to obey his orders "provided that the Vestry will undertake to compensate us weekly or monthly for all the loss or injury which we may sustain in loss of custom or reputation"!—certainly the first time in the history of commerce, we should think, that a vendor has required to be recompensed for not being permitted to sell food that was suspected to be poisonous to human beings! But these were not the only or even the most important warnings the Company received. On Monday, August 11, the following letter was delivered to the directors by Dr. Murchison. It was written on the preceding Saturday, August 9:—

"Sir,—Within the last week we have been called to see a large number of cases of enteric fever, and many others well authenticated have been brought to our notice which have commenced in the West-end of London, mostly since the middle of last month. These cases cannot be traced to any defective drainage or to polluted water, and they are not restricted to localities supplied by one water company. The one condition in common has been the use of milk supplied by your dairy, and in several families there have been special circumstances corroborating the opinion that the milk has been the medium of conveying the poison. This evidence is so strong that we deem it to be our duty to call your attention to the matter, in the hope that you will suspend the issue of milk from your dairy until the cause of the outbreak has been thoroughly investigated. The facts we refer to have been communicated to Mr. J. N. Radcliffe, the Medical Inspector of the Privy Council, who has been deputed to inquire into the matter. (Signed) "William Jenner, M.D.
"C. Murchison, M.D.

"P.S.—Of thirty-seven families in which it has come to our knowledge that typhoid fever has occurred, thirty-five are supplied with milk from your dairy.—C. M."

To this appeal, signed by perhaps the two greatest authorities on the subject of enteric fever, the directors answer in a long letter, dated August 11, in which they recite a list of reasons for differing from Sir William Jenner and Dr. Murchison in the opinion they had formed as to the cause of the fever, but which contains the following:—

"The Company is under contracts for £12,000 worth of milk, and if we were to discontinue selling the milk in London we must of course have it destroyed in the country, as we could not make the poisoned milk into cheese or butter. The Company also have premises in several parts of London, some of them on long leases, and adapted for their own purposes at a very large capital outlay, none of which would be of the slightest use to any other business, and they are under obligations to pay rent, etc., amounting to £650 a year."

In another paragraph they speak of the loss to the individual members of the Company.

Now, it is at least greatly to be regretted that the directors of a public commercial company of high character, and established we have no doubt on principles of honour, should have committed the very grave mistake of even hinting a pecuniary reason for not instantly stopping the issue of a food which they were warned by the highest authorities was spreading death and disease amongst their customers. We would give the directors full credit for all they have done for improving the milk supply of the metropolis; we allow that to them the reasons against assigning to their milk the fever outbreak may have appeared good and sufficient; but we cannot allow that they are fitted to be judges in the matter. *Qui s'excuse s'accuse*, and the letter which we publish from the Secretary of the Company, Mr. Maconochie, is of that character; but whatever may be said by the Secretary in mitigation, the fact remains that for eight days after they had been warned by a public medical officer the directors continued to circulate their fever-spreading milk, without instituting any skilled inquiry as to its possibility of contamination; and they virtually acknowledged in their answer to Dr. Whitmore's second letter, quoted above, that they were influenced by pecuniary motives in the course they pursued.

MEDICAL USES OF ELECTRICITY.—No. II.

Electricity as a Help in Diagnosis.

In diagnosis assistance can be obtained from electricity in cases in which there is altered muscular contractility, or altered muscular or cutaneous sensitiveness, or both of these conditions. We have used the word sensitiveness, because much confusion is often made in the use of the terms "electric irritability" and "electric contractility," and it should be remembered that these do not mean the same thing, though they are often employed interchangeably, as the irritability of a muscle is evidenced by its contraction. "Irritability" of a muscle truly used signifies susceptibility of a muscle to the action of electricity, or of any other irritant or excitant; "contractility," its capacity of action, or the amount of force with which it contracts. Let a current of electricity be applied to the arms of a patient in whom one arm (say the left) is paralysed, while the right is healthy, and the muscles of the latter are found to act with much greater force, much more vigorously, than those of the left. This does not of itself prove that the "muscular irritability" of the muscles of the right arm is greater than those of the left, but that they are stronger, and therefore act with greater power. To test truly the "irritability," the sensitiveness or excitability of a muscle, find out the lowest power that will excite it to contract. Take, for instance, a case of hemiplegia; apply the rheophores of a faradic instrument to one of the muscles of the healthy side, and find the lowest power to which the muscle answers; then apply the rheophores to the same points of the corresponding muscle on the opposite or diseased side, and notice whether or no it contracts: if it does, lower the power of the current; if it still excites contraction the irritability of the muscle is increased; or *vice versâ*, according to the result. If the voltaic current is used to test with, one electrode should be kept stationary, and the current interrupted by repeatedly raising and reapplying the other, or by gliding it over the muscle. And it must be remembered that great

care must be taken to apply the current in an exactly similar manner on both sides—the electrodes or rheophores must be applied to identical parts of the muscle. When using the voltaic current particularly care must be taken to pass it in the same direction in both limbs. A centrifugal current—that is, a current passing from a positive electrode downwards to a negative electrode applied farther from the centre than the positive electrode—is called a "direct" or descending current; and a current which passes in the reverse direction is an "indirect" or ascending current. Now, healthy nerve and muscle are more sensitive to a descending than to an ascending current; therefore, care must be taken not to reverse the current when testing "irritability."

In hemiplegia it will most likely be found that the irritability of the muscles to either a voltaic or a faradic current is normal; there is no disease of the muscular tissue. Let the current then be passed along the motor nerves of a muscle, and if this responds to the excitation, it is proved further that the conducting power of the motor nerves has not been injured, and that the spinal cord is not diseased or destroyed at the part whence those nerves are given off; there is not "spinal paralysis"; the mischief then is cerebral. It may be, however, that the irritability is lessened somewhat, even in hemiplegia, from disuse, and in such case a few applications of faradism will suffice to restore it. When the case is of such standing that rigidity has come on, the irritability will probably be found to be increased; and this points to some irritative lesion, as increased vascularity of the brain or hæmorrhage into its substance.

It will be gathered from what has been said, then, that one of the diagnostic uses of electricity is to determine, in a case of loss of voluntary power in a muscle or in a limb, whether this depends on something that cuts the muscle or muscles off from the influence of the spinal cord, or on something which, though it does not deprive them of that influence, does paralyse them to the will. In cerebral disease, *per se*, there is no diminution of the electro-contractility of the paralysed muscle; there may be, as we have before explained, an increase of it.

In spinal disease so situated that it affects the cord above that portion of it which gives off the nerves bdistriuted to the paralysed muscles, the electro-contractility of the affected muscles is not necessarily diminished.

But the electro-contractility of the paralysed muscles is lessened or destroyed when that portion of the spinal cord supplying the nerves to the affected muscles has been destroyed or injured.

In traumatic paralysis the same effect is produced—*i.e.*, when the motor nerve of a muscle has been cut through, or is pressed upon by an exostosis, or is in some other way cut off from the influence of the spinal cord, the electro-contractility of the muscle is destroyed or diminished.

In the last two classes of cases there is true "spinal paralysis"—the "spinal paralysis" of Marshall Hall,—the affected muscle or muscles being functionally shut off from the spinal cord.

In simple "*cerebral paralysis*," then, the electro-contractility of the muscles is normal; in "*spinal paralysis*" it is diminished or destroyed, and the degree of loss bears a direct proportion to the amount of interference between the muscles and the spinal cord, or the amount of mischief in the cord itself. This rule undoubtedly holds good in the great majority of cases of cerebral paralysis, but not in all; and Dr. Althaus has stated that in one hundred cases he found the sensitiveness or excitability in some cases diminished and the muscles flaccid, in some increased (cases of early rigidity and irritative lesion), and in others normal.

In *hysterical paralysis* the electro-contractility is as a rule normal, though "electro-sensibility" may be lowered or lost—that is, the patient may scarcely or not at all feel the contraction of the muscles, even though the electric current excites them to powerful action. If, however, the paralysis has continued for some time, and the muscles have become flabby and soft, there will be found some lessening of their excitability as well as of their strength; but a few applications of the current will remove this condition.

Again, electricity may be of great and valuable service in distinguishing between real and feigned disease. In railway accident cases, for instance, it is not rarely asserted that persons feign or "put on" symptoms—that they sham paralysis of a limb, for example; and there is no doubt whatever that this is sometimes done; or, persons who have been in a railway accident may be frightened into the belief that they are more seriously injured than they really are, and the idea that a limb has been paralysed may render it powerless when it is not really paralysed by disease: and in both these classes of cases electricity may be of essential service. Test the muscular irritability of both sides with the faradic current, and if there is a marked difference in the response of the muscles on the two sides it is certain that there is more the matter than can be either feigned or fancied. Cases have been published in which a patient has been accused of, and had been believed by medical men to be, feigning paralysis of a limb, but when the electric test was tried it at once proved that the paralysis was real. A faradic current that excited vigorous action in the healthy limb had not the slightest effect on the muscles of the other limb—a differentiation that it was utterly impossible for the patient to produce; no exertion of the will can prevent a healthy muscle from contracting under a strong electric current.

In some kinds of paralysis it is found that the muscular irritability to the electric current is greatly diminished or lost if either faradism or the rapidly interrupted voltaic current be applied; but to a slowly interrupted voltaic current the affected muscles not only do act, but show a greater degree of irritability than the healthy muscles do. And reaction of this sort is only found in peripheral paralysis. It is therefore of great service in diagnosing peripheral from central disease, as, for example, in distinguishing between paralysis of the facial nerve and facial hemiplegia. It will also help to decide in a case of paralysis of the extensor muscles of the fingers and wrist whether this is caused by lead or by a rheumatic affection of the radial nerve. In the latter the reaction is normal, but in lead palsy the reaction to the faradic current is lessened or lost, while to the slowly interrupted voltaic current it is increased. In some cases of the "essential" paralysis of children—cases caused by the local application of cold and not dependent on special disease—the same reaction is found.

It is doubtful whether any real aid to diagnosis is to be obtained from modification of the electric sensibility of either the skin, the muscles, the trunks of the nerves, or of the nervous system generally.

THE ASHANTEE WAR.

It is satisfactory to be able to state that the views persistently advocated by us since the outbreak of the war on the Gold Coast have been endorsed by the authorities, and it is no longer a secret that at the termination of the rainy season active operations on a sensible scale will be undertaken to crush the petty enemy who has had the effrontery to place himself in opposition to the British arms. Sir Garnet Wolseley, accompanied by a numerous staff, will shortly leave this country for the seat of war, and, after a careful survey of the situation and necessities, will transmit requisitions to the authorities for all that he may consider necessary in the shape of men and stores. The troops selected will leave England so as to arrive on the coast exactly at the moment they are required. There will thus be no longer delay in such a pestiferous climate than is absolutely

required to carry out the details which will already have been laid down, and, having chastised the invaders, the expeditionary regiments will immediately return home. This promptitude of action will be the means of saving many lives; and, although rumour asserts that the war will be carried so far into the Ashantee kingdom as to destroy the capital of Coomassie itself, situate about 130 miles from the coast, we venture to predict that, in proportion to the strength employed on this service, the death-rate will be smaller than that now occurring during the continuance of the defensive attitude which we have been constrained to adopt by the overwhelming incursion which has been organised on our almost defenceless settlement.

Stores of all descriptions are being hurriedly forwarded to Cape Coast Castle, and scarcely a week passes without some vessel being despatched with supplies from this country. The Government would appear at last to have recognised the importance of dealing with this matter once and for all. Since the beginning of the present century we have been in a chronic state of enmity with the Kings of Ashantee, and when we have been successful (which has not always been the case) the results achieved have been so small as to leave the prestige of our great power far from satisfactorily established in the savage mind. Taking England's last "little war" against the King of Abyssinia and his capital of Magdala as a specimen, it will at once be seen that, however trifling, whatever *is* to be done is worth doing well, and that thoroughness of action pays best in the long run. The employment of natives to assist us, in the shape of an organised body such as the Houssa force, may be all very well to preserve peace when once its necessity to the enemy has been enforced, but it is an established fact that the blacks will contend much more stoutly against their own colour than against whites, and we sincerely hope that Sir Garnet Wolseley will not be induced to restrict his demand for our own soldiers by depending too much upon what *may* be accomplished by the bands which Captains Glover and Thompson are about to organise.

We hear on good authority that a vessel will be appointed as a hospital ship for the reception of the wounded and invalids; this, if placed off Cape Coast Castle, will obviate the necessity of treating the sick on shore, and, to those who are acquainted with the deadly effects of the climate, it will at once show that the heads of the Medical Department are earnestly endeavouring, by every means in their power, to mitigate the evils of this deadly campaign. Other vessels should be appointed to transport all men who are capable of removal, as soon as possible, to this country; and the importance of carrying out such an arrangement will doubtless not be overlooked.

If, as is the opinion of many, the present war might have been avoided by retaining a sufficient force upon the coast, instead of inviting attack by exhibiting our comparative weakness, we trust the Government will now atone for its past shortcomings, and with every confidence in the known experience of those who at present direct the affairs of the Medical Department, we look forward to a result as satisfactory and lasting as that which followed our march to the capital of Abyssinia.

THE WEEK.

TOPICS OF THE DAY.

Sir A. Grant, the Principal of the University of Edinburgh, has thought it necessary to publish in the *Times* newspaper a defence of that University in reference to its treatment of the lady medical students. He commences by saying that he acknowledges and regrets "the hardship and difficulty of the position in which the ladies referred to have been placed; but this is owing to the state of the law of the land as interpreted by the Court of Session, and not to any discreditable transactions on the part of the University." After stating the facts of the long history of the attempt of Miss Jex Blake and her companions to effect and maintain a footing in the University, Sir A. Grant concludes:—

"I sincerely sympathise in the earnest appeal made by Miss Jex Blake—in the very able letter which forms the subject of your article—to the Legislature to take up the consideration of the medical education of women. It is a subject well worthy the attention of the Legislature, and one which can only be properly dealt with, as a general social subject, by the Legislature. Whether or not a university is a suitable institution for the medical instruction and examination of women is a wide question, on which I will not venture to enter. But, however this be decided, all other universities of the United Kingdom must share in the decision of the University of Edinburgh, and this University will loyally bear her part in carrying out whatever Parliament may ordain as expedient. In the meantime, under considerable obloquy, she can at all events claim to have contributed something in the way of experience to the elucidation of the question."

Now, it appears to us that Sir A. Grant has conferred little benefit on the University of which he is Principal, or on the cause of the women medical students, by the publication of his letter. Here to excuse is to accuse, and the Principal's letter is throughout an apology. The real apology, we think, ought to be made by those who ran the risk of injuring an ancient University and renowned school of medicine by permitting, in the first instance, the admission of women. Once admitted to the University, the mischief was done, and it would be difficult to persuade the sympathisers with the lady-student cause that they have not been hardly dealt with. Sir A. Grant's letter, however, contains the admission that the disturbances amongst the students arose in consequence of the women students "having joined a mixed class in anatomy under an extra-academical lecturer," a proceeding which very properly and naturally, we should think, "outraged the feelings or prejudices of the students." The University Court had had the decency, it will be remembered, to refuse to hold mixed classes. In Thursday's *Times* Miss Jex Blake replies at length, giving her view of the facts of the case.

The death-rate of London in the week ending August 30 fell to eight below the average numbers in the corresponding week of the last ten years. The total number of deaths was 1477. The deaths from the different forms of fever were 38, from diarrhœa 277. Diarrhœa is declining in fatality. The deaths from this cause in the previous week were 362.

A case of supposed Asiatic cholera in Shoreditch, Newcastle-under-Lyne, turns out to have been a sporadic one. The man is said to be recovering. A schooner arrived at Wick from Dantzic on Tuesday, and the captain reported that he had a case of cholera on board. The vessel was removed to St. Clair's Bay. The man who was ill is recovering; and, should no fresh case occur, after disinfection the vessel will be allowed to come into the harbour.

The Medical Director-General of the Navy reports upon the condition of the invalids who have recently arrived at Portsmouth from the West Coast of Africa on board H.M.S. *Himalaya*, that the troops left England 110 strong, and reached Cape Coast Castle in time to take part, under Colonel Festing, R.M.A., in the action at Elmina. Fever, however, soon broke out, and, with the exception of about twenty men who have remained behind with their chief, all were invalided and shipped on board H.M.S. *Himalaya* for England, but eleven died on the passage, and sixty were on arrival sent to Haslar Hospital for treatment.

AMBULANCES FOR MILITARY HOSPITALS.

We were rather surprised to read, in the *Times* of last week, a letter from a correspondent at Plymouth, complaining—with

seeming good cause—of the defective arrangements existing at Stoke Hospital for the removal of sick and wounded men. From the account given, it would appear that a private of the Army Service Corps fell out of a train whilst in motion about twelve miles from Plymouth; he was picked up by a passing train, and being found to be much injured, was promptly taken back. The authorities at the military hospital were at once communicated with on the subject of providing an ambulance for his removal, but on arriving at Plymouth, the medical officer of the volunteers—who had humanely accompanied him—found nothing waiting but a light cart with bare boards, in which he very properly refused to allow the injured man to be placed. A fatigue party, with a stretcher, was after a long delay procured, and by this means the man at length reached Stoke Hospital. It is, moreover, stated by the same correspondent that the local press had already commented on the manner in which the invalids arriving at Plymouth from Dartmoor during the Autumn Manœuvres were received by the hospital authorities. This is a state of things which clearly should not be allowed to exist. If—as was stated by the driver of the light cart—the hospital had no more appropriate conveyance at hand, we may fairly ask whose fault it is that one of our largest military hospitals is left unprovided with so necessary an article of equipment as an ambulance for the removal of the sick and wounded. Plymouth is a large garrison town with several detached barracks, the sick of all regiments and detachments quartered there being treated in the hospital at Stoke, and it seems preposterous to imagine that the want of such a conveyance can really exist. Should this, however, prove to have been the case, we can only trust that the publicity now given to such an awkward fact will be the means of rousing someone, either at head-quarters or at Plymouth, to a sense of doing (even if tardily) their duty.

DISEASE OF THE HEART FROM OVER-EXERTION.

There are few more interesting subjects in cardiac pathology than the so-called "spontaneous" enlargement of the heart. Many authors have gone so far as to deny *in toto* the occurrence of uncomplicated hypertrophy or dilatation of the heart or of one of its ventricles; but their position has now for some time been untenable, as was especially pointed out by Dr. Quain in his recent lectures on "Diseases of the Muscular Walls of the Heart." We have now before us a contribution of no less than nineteen cases of the kind, observed by Fräntzel in soldiers who had taken part in the Franco-Prussian war (Virchow's *Archiv*, 1873, vol. lvii., p. 215, and *Centralblatt*, 1873, No. 35). These patients were perfectly healthy at the commencement of the campaign, and began to suffer from cardiac symptoms for the first time during the course of the war. When they came under treatment at the end of the campaign they were found to be labouring under enlargement of the heart, without discoverable disease in any other part of the vascular system, in the lungs, or in the kidneys. Of the cases enumerated the left ventricle alone was hypertrophied and dilated in ten, the right ventricle alone in two, and both ventricles in three; and in two other cases dilatation alone of the one ventricle or of the other was found. Fräntzel accounts for the cardiac enlargement by the extreme fatigue and muscular exertion which the men underwent for months in the field. The increased pulmonary activity induced by the obstruction to the expansion of the thorax under the uniform raised the tension in the pulmonary artery, and caused dilatation with hypertrophy of the right ventricle; and in the same way a corresponding enlargement of the left ventricle was brought about by the severe muscular exertion generally, as well as by the contraction of the peripheral arteries during the cold of winter. The occurrence of simple dilatation is accounted for by the extreme severity of the exertion in some cases, and by the proportionately less resistant power of the cardiac tissue in others, who were badly nourished under the circumstances of privation in which their disease commenced.

THE INNERVATION OF THE INTESTINES.

Within the last few years very much has been done and written by Nasse, Schiff, Mayer, and V. Basch, and others, upon the movements of the stomach and intestines, as well as upon the nervous supply of their arteries, and the relation of the vascular condition to the vermicular movements of the alimentary canal. The latest experiments on this subject are those of Hougkeest van Braam, who followed Sanders' method of opening the abdominal cavity under a solution of common salt at the temperature of the blood (Pflüger's *Archiv*, 1873, vol. vi., No. 266, and *Centralblatt*, 1873, No. 29). The following results at which he has arrived are decided and satisfactory. The vagus is the motor nerve of the stomach, but not of the small intestine, and movements of the latter after irritation of the vagus are due to the escape of the masses from the stomach into the intestine. Neither has the vagus any influence on the movements of the colon or uterus. The splanchnics are at once the inhibitory nerves of the intestine and stomach and the vaso-motor nerves of the intestine, and it is for this reason that the gastric movements are less readily induced by irritation of the vagus if the splanchnics remain uncut. The author does not decide whether the inhibitory action of the splanchnics exists independently of their vaso-motor action or is merely a consequence of it. That the latter is more probably the case is shown by the circumstance that the movements of the intestines are in great measure dependent on the condition and amount of the blood in the intestinal vessels. Local irritation does not spread normally or induce peristaltic movements. Anti-peristaltic movements do not occur normally; yet the entrance of fæcal masses into a portion of the intestine induces a movement therein which may extend peristaltically beyond.

IRREGULAR PRACTITIONERS AND THEIR VICTIMS.

A verdict of manslaughter was returned at an inquest held on Saturday last, at Barnstaple, on the body of Mrs. Elizabeth Yeo, who had died suddenly, against a chemist named Goss, of Bramton. It appeared from the evidence that the deceased, while suffering from malignant cancer, was under the treatment of the accused, who first gave her some ointment and lotion for outward application. Her system had absorbed large quantities of impure sulphate of zinc. As stated by Dr. Thompson, of Bideford, zinc applied to an absorbent surface for a long time would be highly dangerous. The deceased had used the lotion for two months before her death. A coroner's warrant was issued for the apprehension of Goss.

HOSPITAL MANAGEMENT IN SYDNEY.

A Royal Commission for inquiry into the working of public charities in Sydney is now sitting, and startling disclosures have been made as to the management of the Sydney Hospital and other kindred institutions. The evidence of patients and nurses in the Hospital tends to prove the existence of very gross negligence on the part of the authorities.

UNHEALTHY DWELLINGS.

Dr. Whitmore, in his report on the sanitary condition of the Marylebone district, states—"The one great obstacle to the sanitary improvement of the destitute poor is the structurally defective condition of the dwellings in which they are compelled to live. No material reduction in the present death-rate can be expected until all ruinous and dilapidated houses in the parish are pulled down, and healthy commodious ones erected in their stead."

FEVERS IN WOLVERHAMPTON.

The spread of typhoid and typhus fevers at Wolverhampton is causing considerable anxiety amongst the inhabitants. During the past week there have been several deaths from these diseases, and the death-rate is seriously high amongst young children.

HEALTH OF MARYLEBONE.

There were only 164 cases of medical outdoor relief in Marylebone parish during the week ending the 23rd ult., as against 226 in the corresponding week of last year.

FROM ABROAD.—THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE—THE GERMAN COMMISSION ON CHOLERA.

The second meeting of the French Association for the Advancement of Science has just been held, with full success, at Lyons. M. Ducros, the now celebrated Préfet of the Rhône, seated on the right hand of the President, welcomed the members "in the name of the great city of which he had the difficult honour of being the representative." The President, M. De Quatrefages, in his address, observed that the Association was to be congratulated that amidst the changes in municipalities and préfets it had been alike welcomed by all, belonging, in fact, as it did, to no party. Amidst the present confusion that prevails in France, let it then plant its standard "Science and our Country," and rally around it all lovers of truth. Slow indeed had been the progress of science, and its appreciation, even within the last hundred years. How changed are matters now, "when science seems, like a magic tree, visibly growing, adding without cessation bough to bough, branch to branch. Reflect a moment, and without exaggeration or metaphor you will see that it is impossible to comprehend the actual condition of our scientific acquisitions without admitting that a more or less important discovery is made almost every day, perhaps every hour." The present age can only in energy be compared in science with what the period of the revival of learning was for letters. It is also remarkable for its practical applications of science; and this, so far from being deprecated, is but another feature of progress: new and diversified problems are for ever being set, the solution of which calls forth renewed efforts of pure science. It is in the great centres of industry, where applications reign supreme, that science, without which these cannot be, receives surest recognition. Strange as it may seem, it is amongst the lettered class that science least receives its due, determined as it would seem to defend foot by foot a domain which was once all its own. While duly valuing all that great writers have done for us, and the cultivation of languages whence our own is derived, we should take care that our children are initiated at an early period into the knowledge of scientific facts, ideas, and methods; for if science is popularised with so much difficulty, if it is too often treated with indifference by those who owe it most, and if recruits are so much wanted to carry on its work, the fault has chiefly arisen from a system of instruction in which literature alone is present, and in which science takes no part. The impressions of childhood are not to be effaced; and what respect can the scholar acquire for that which he sees treated as an importunate accessory? Manhood reached, what interest can be felt in that which has never been learnt; and what is to be expected of what is not even known? This is why governments have taken so little account of men engaged in studying nature and her forces; and yet on emergencies they have to be eagerly sought, as witness the great and numerous services they rendered during the siege of Paris. Under more peaceful circumstances they are sought for as indispensable as jurors in international exhibitions. These once passed away, the governments, instead of retaining their *savants* as advisers, allow them to disperse until new emergencies arise; but "the day will come when every great administration will have its 'consulting committee' essentially composed of men of science; and be sure that then many errors will be avoided, and many forces now lost will be utilised." But in order that such an institution should arise and flourish, the necessity of this intervention of science must be generally apprehended and accepted; and it is with this view that the French Association opens its doors to all comers.

"But let us not dissimulate the fact that we shall require perseverance. It is not in a few years that habits are transformed, and French habits are but little favourable to our operations. Generations have succeeded each other, living in indifference with regard to what we are seeking favour for, and do not be surprised if their descendants resemble them. They will oppose to us that force of inertia which too often wears out the boldest courage and the most noble ardour. They perhaps will even add some raillery and disdain. Let us despise these arms of ignorance and indolence, and appeal from them to time. Persevere! and with our country as our object, science as a means, the past as a lesson, and the future as a hope, let us forget nothing and labour on."

The section of the Medical Sciences, which seems to form a more prominent feature than the similar section in our British Association, elected Professor Claude Bernard as its president. M. Ollier read a paper on the Surgical Means for Increasing the Growth of Bones, founded on a series of experiments and clinical observations. He finds that where there has been arrest of growth of the long bones, impeding progression or causing deformity, he can induce increase of growth by producing a superficial exfoliation of bone by means of caustics. In an instance in which, after an arrest of growth of the radius had been followed by deformity of the hand consequent on the continued growth of the ulna, this was rectified by the removal and crushing of the cartilage of the latter. M. Gayet, of Lyons, gave an account of his experiments on Regeneration of the Crystalline Lens, whence he concluded that what has hitherto been regarded as regeneration of the lens was really but the complement of the development of the primary crystalline, which had been extracted at an age when the animal had not attained full growth. This accords with the results of clinical observation, no reproduction of the lens having ever been met with. M. Gayet also described a modification he has introduced of Graefe's Operation for Cataract. M. Foltz, of Lyons, read a memoir on the Homology of the Thumb with the two last toes. M. Diday electrified the audience with his Physiological Theory of Love, which in the brief account we have seen of it is not intelligible. M. Chauveau gave to the section what he termed a demonstration of the Transmission of Tuberculosis by the Digestive Organs. He observed that his numerous observations enabled him to state that if the healthy young of animals susceptible of tuberculosis were fed with food with which the matter of tubercle was mixed they would all exhibit tuberculosis in various organs. In anticipation of this meeting he had purchased some healthy calves, and, having had them fed as described, on slaughtering them the sixtieth day after the first ingestion the lymphatic system was found extensively tuberculised, while caseous deposits existed in the lungs. M. Delore read a paper on the "Sudden Rectification of In-Knee." This deformity, which is a common result of rickets and scrofula, which prevail so extensively at Lyons, M. Delore states is principally due to exaggeration of the natural curvature of the femur and tibia, accompanied by great depression of the internal tuberosity. In 350 cases he has rectified it by forcible pressure under chloroform, continued until the periosteum is detached and the epiphysis is separated, as announced by a cracking sound. The position is maintained by a starch bandage, and in a month the cure is complete. No accident has occurred, but the operation should not be performed after the fifteenth year or on weak subjects. Dr. Blane, of our Indian Medical Service, drew the attention of

the section to the question of the Propagation of Cholera, which, he said, all his investigations led him to attribute to potable water, and that the purity of this constituted the sole prophylactic. As a disinfectant he prefers chloride of aluminium, which he not only adds to the excrements, but administers by the mouth and with ice in enemata.

The Federal Council of the German Empire has appointed the following distinguished persons as a new Cholera Commission:—Generalarzt Dr. Böger and Professor Hirsch as representing Prussia; Professor von Pettenköfer for Bavaria; Medicinalrath Dr. Günther for Saxony; and Obermedicinalrath Dr. Volz for Baden—Professor Pettenköfer to preside. Its object is to pursue an exhaustive inquiry into the history and mode of propagation of cholera, undertake investigations as to the cholera germ or poison, and examine into all the local and individual circumstances that may influence the course of the disease and its practical treatment. The results of the labours of the Commission are to be published in an exhaustive treatise illustrated by plans and maps. It is evident, at all events, that much old ground is destined to be trodden over again, many theories are to be revcutilated, and that a portly tome will be compiled. But shall we be any nearer to the preventiou of the scourge which, when it arrives, always, under all forms of treatment, exacts its terrible penalty of a 50 per cent. mortality?

ON MUSCULAR IRRITABILITY AFTER SYSTEMIC DEATH.

(Croonian Lecture.)

By BENJAMIN WARD RICHARDSON, M.D., F.R.S.

[Abstract.]

The lecturer commenced by referring to the labours of Dr. Croone, the physician with whose name this lecture is connected. Croone was distinguished as one of the founders and as first Registrar of the Royal Society, and his scientific work included important contributious to the subject of muscular motion. Immediately preceding Croone, Nicholas Stenon, of Copenhagen (first an anatomist and afterwards Bishop of Heliopolis, a man whom Haller has described as *vir industrius, candidus, innocuus et magnus inventor*, and whom the Grand Duke of Tuscauy buried in the tomb of his Royal house), had made kuown the fact that the contractile portiou of muscle is resident in the carneous or fleshy part of the muscle, as distinguished from the fibrous part. This discovery, seized by Croone, led him to observe that the fleshy part of muscle is made up of fibres, and that each fibre possesses a distinct power of contraction; so that, to use his own words, "the force of the whole muscle is but an aggregation of each particular fibre."

Upon this observation, perfeetly original at the time it was announced, Crooue advaneed an hypothesis as to the cause of muscular motion. He showed that for muscular contraction it was necessary that the arteries should supply blood to the fleshy muscular fibres—that the blood should pervade the fibres—that iu its course, forced on by the stroke of the heart, it should mix with another liquor within the muscles, aud diffuse into the minute vesicles of which each muscular fibre is ultimately composed. To complete the mechanism for motion, he held that the nervous filaments which ramify into each muscle supply a refined fluid, much more active than the muscular fluid, by which the activity of the muscle is called into play.

The leeturer uext briefly traced the various hypotheses that have beeu advanced to explain muscular motion since the time when Croone made his original observations, the purport of the argument being that, although great advances have been made in the study of structure, and one very great advance in the study of functions—viz., by Haller in his separation of the respective forces of nerve and muscle—the precise question of the cause of muscular motion remains much in the same doubt as Croone left it.

Respecting the various theories and hypotheses since the time of Crooue, the author had nothing to say iu detail; the object of his lecture was to put forward certain facts he had learned on the phenomenon of muscular irritability after systemic death—that muscular irritability which remains sometimes for a brief, at other times for a long period after all the outward manifestations of life have ceased, aud when, to the common apprehension, the animal tissues are dead. He included in the same study certain examples in which muscular irritability has for a time ceased, but has become redeveloped under new conditions. He thus included the study of those states which favour the continuance of irritability or which destroy it, and those couditions which suspend but do not destroy it. By this method of research the author thinks we may proceed backwards towards living irritability, and may determine upon what that depends with more facility than by experimenting on the phenomena of irritability in the living animal. He imagines that if he knew nothing of the construction of a watch, or why for a certain time a watch maintains its motion, and if he had nobody to teach him these things, he might be better able to arrive at the fact he wanted by trying to set the motionless watch into motion than by interfering with it while it is iu motion.

The record of experimental endeavour carried out with the design above explained included a review of the work of twenty-five years. The subjects brought under consideration were arranged as follows:—

(1.) The effect of cold on muscular irritability after systemic death.

(2.) The effect of motor forces, mechanical, calorific, electrical.

(3.) The effect of abstracting and supplying blood.

(4.) The effect of certain chemical agents, inorganic and organic.

Effect of Cold.

Previous to the time of John Hunter it was supposed that cold was the most effective agent for destroying muscular irritability, and to this day the impression is commonly maintained; so that the sensatiou of cold in a motionless animal is accepted as the surest evidence of death. Hunter was the first to show by direct experiment that this was au error, aud that cold suspends irritability without destroying it. The original experiment of Hunter illustrative of this position was here described. The effects of cold employed in various ways iu the author's experimental researehes were now detailed systematically. The effect of cold in suspending the muscular irritability of fish, reptiles, and frogs was first described. On all these animals it was shown that cold could be made to suspend without destroying the muscular irritability for a long period of time, and that in fish (carp, on which the author had made the greatest number of experiments) the restoration of irritability could be perfected to the extent of the restoration of the living function.

Passing to warm-blooded animals, the author showed that in every animal that has been deprived of life without the occurrence of mechanical injury there is a period in the process of cooling wheu general muscular irritability may be made manifest. He demonstrates this fact by the simple experiment of throwing a current of water heated to 115° Fahr. over the arterial system of the recently dead auimal. If the surrounding temperature be high at the time of this experiment the operation should be performed within a few minutes after death; but if the temperature be below freezing-point, it may be delayed for a long period. In one experiment the author reproduced active muscular contraction in an animal that had lain dead and exposed to cold 6° below freezing-poiut for a period of three hours. In this case the muscles generally remained irritable for seven minutes after the injection of the heated water, while in the muscles of the limbs, by repeating the injection at intervals, the irritability was maintained for two hours.

The author drew a comparison between these experimental results and the phenomena of muscular irritability that have been observed in the humau subject after death by cholera. A short description of the muscular movements occurring sometimes after death from cholera was introduced. The movements were not conscious, nor were they promoted by electrical excitation; but the flexors and extensors belonging to each part in which there is movement are alternately contracted and relaxed as if from some iuternal influenee. The same observations apply to the phenomena of contraction and relaxation in the muscles of animals that have been held in abeyance by cold and have been called into action by the injeetion of heated fluids.

The influence of cold in suspending without destroying muscular irritability was further evidenced by the experiment of subjecting some young animals to death by the process of drowning them in ice-cold water. It was shown that in the kitten the muscular irritability may be restored to the complete re-establishment of life after a period of two hours of apparent systemic death, although the muscles when the animal is first removed from the water may give no response to the galvanic current. This same continuance of irritability after apparent systemic death by drowning in ice-cold water has been observed in the human subject, not in so determinate, but in an approximated degree. An instance was adduced in which a youth who had been deeply immersed for twelve minutes in ice-cold water retained muscular irritability so perfectly that he recovered, regained consciousness, and lived for a period of seven hours.

Commenting on the method of irritability, the author showed that a certain period of time is required before the irritability is raised from a mere passive condition, in which it responds only to external stimuli, into the condition necessary for independent active contractility. The change of condition from the passive to the active state, when it occurs, is so sudden as to seem instantaneous at first, then it is slowly repeated. This rule holds good in respect to voluntary muscles and involuntary. It is specially true in regard to the heart, which organ, the author states, may perform its office under two distinct degrees of tension and pressure—a low tension, in which the organ itself is reduced in size and moves almost insensibly; and a full tension, in which it is of larger size and moves with a sufficient power to impel the blood so as to overcome the arterial elasticity and the capillary resistance.

Another fact bearing on this subject is, that in rapid decline of muscular irritability the muscles most concerned in the support of the organic functions—namely, the heart and the muscles of respiration—are the last to yield up their spontaneous power; but when they have lost their power, they are the last to regain it. To this rule there is one exception—viz., in the muscular fibre of the right auricle of the heart.

The author then explained that the degree of cold which suspends irritability is fixed within certain measures of degree, from 38° to 28° Fahr. being the most favourable degrees of cold. Above a temperature of 38° Fahr. the muscles in a little time pass into permanent rigidity—*rigor mortis*. Below 28° the muscles, if the effect of the cold be extended to their whole structure, pass into some new molecular condition from which they do not return into active life; at least, they do not by means of any process of recovery with which we are at present conversant.

Effect of Motor Forces.

Cold, by the inertia it induces, suspends, under certain conditions, but does not destroy, muscular irritability. The motor forces, on the contrary, quicken the irritability for a brief period, and then completely destroy it. A method may perhaps be discovered for overcoming the effects of these forces, but at present it is not known. The mode in which all the motor forces act in arresting irritability is by the induction of a contractile state, which, once established, remains permanent. It should be remarked however, that the forces respectively named mechanical, calorific, electrical, act with different degrees of intensity, perhaps because we cannot as yet apply them, in this particular research, with equal measures of intensity. The author here related his experiments on the effect of the different forces upon the right auricle of the heart, and reported as the result of his observations that, while all the forces act ultimately alike in producing permanent contraction, the mechanical excitation is much slower than the calorific; while electrical excitation appears to hold an intermediate place, as if it were a combination of mere mechanical motion with an increased temperature. Electrical tension may nevertheless be increased so as to rival heat in its immediate effect on contraction.

The author here traced out the results of a series of short sharp irritations of muscle with a needle-point, and compared them with the effect of a blow, showing that in each case rigidity follows, but is much slower in development when it is excited by the needle.

The influence of heat in destroying irritability, by its power of producing permanent contraction, was described from experiments bearing on the relation of temperature to the muscular contraction of different animals—frogs, pigeons, and rabbits. It was shown that a relative rise in temperature in each class, a rise averaging 12° in Fahr. scale, from the natural temperature of the animal, is efficient for producing permanent rigidity, the cause of the ultimate rigidity being coagulation of the coagulable muscular fluid.

The effect of electrical excitation is in the same direction, but is varied according to the mode in which the excitation is performed. Discharge from the Leyden jar produces contraction, which is permanent or intermittent in accordance with the mass of the muscle and the intensity of the discharge. This fact was elucidated by reference to a series of experiments with a Leyden battery, placed in cascade, and the effect produced by the discharge from ninety-six feet of surface upon animals of different sizes and weights, from sheep down to pigeons, as well as on sections of the bodies of the same animals immediately after death. The experimental facts demonstrated that with an efficient discharge the whole muscular system of a small animal could be fixed instantly in the rigidity of death, and that the precise position of the animal at the period immediately preceding death was retained with such perfection, so sudden was the change, that nothing but physical examination by the hand could bring to the mind the fact that the animal had passed from life into death.

But the same shock passed through a sheep weighing 54 lbs. produced only a temporary contraction of muscle, and required several repetitions before the rigidity was rendered permanent.

By employing discharges of lower tension it was found that muscles, or special tracts of muscles, in the same animal immediately after its death, could be made rigid quickly or slowly by variation of the intensity of the discharge.

The effect of the intermittent electro-magnetic current was next brought forward, and was shown to resemble closely that of the simple electrical discharge from the Leyden phial. Intensified, it induces instant and permanent contraction; and if it be repeated, even with but sufficient force as to call forth feeble contraction, it destroys the irritability, *cæteris paribus*, more quickly than if the muscle had been left at rest.

Parenthetically, the lecturer dwelt here on the common practice, after sudden death, of endeavouring to excite the action of the enfeebled heart by passing through it an electrical current. Some practitioners, said the author, have gone so far as to introduce a needle into the heart itself, and to make the needle act as one of the conductors from a battery. Such experimentalists, before they undertake this operation on the human subject, should at least observe the effect of the agency they are employing on the exposed heart of an inferior animal recently and suddenly killed by drowning or by a narcotic vapour. They would learn then with what infinite facility the muscular irritability of the heart, in all its parts, is excited for a moment only, to be permanently destroyed. They would learn that if blood be not passing through the muscular structure concurrently with the exciting agent, they could not more effectually arrest function than by the very method they have adopted to sustain it.

The influence of the continuous current on muscular irritability was introduced by the author, together with a special reference to the first experiments of Aldini on the bodies of malefactors who had been recently executed; and it was shown from Aldini's most noted experiment how largely the phenomena of motion he induced in a dead man, and the recital of which caused so much sensation in the year 1803, were due, not to the galvanism, but to the circumstance that the dead body had been exposed for the hour after death, and before the experiments commenced, to the action of cold two degrees below freezing-point. On the whole the continuous current acts on muscular fibre after the manner of heat. If the muscle recently dead be exposed to cold, the current, when sufficient, restores for a limited period the irritability, and finally destroys it by inducing persistent contraction; if the muscle recently dead be left at its natural temperature, the current simply shortens the period of irritability by quickening contraction.

Abstraction and Supply of Blood.

Under this head the author first considered the effect of abstraction of blood from the living muscular fibre. He showed that when the flow of blood was very rapid there was invariably a given period of muscular excitation. In sheep killed in the slaughterhouse he found that this muscular excitement occurred at the time when the proportion of blood removed from the animal was equivalent to about the 320th part of the weight of the animal. The increased irritability passes rapidly into general convulsion without consciousness,

and, as a rule, ceases for a time with a temporary cessation of further loss of blood. After this the irritability remains if the bleeding be arrested altogether, and can be called into action by any external stimulus, although it is rarely spontaneously manifested when the vessels are left divided and open. After an interval of one or two minutes there is a recurrence of loss of blood, followed by a muscular excitement which marks the moment of systemic death. The breathing and circulation cease, but the voluntary muscles retain their irritability for several minutes, until they undergo permanent contraction—indeed, they retain their irritability under the influence of cold, and lose it under the influence of mechanical motion, heat, or electricity, as markedly as when death has been produced without abstraction of blood.

The fact of the two stages of exalted muscular irritability during abstraction of blood is important, as indicating the two different tensions of muscle to which reference has already been made. The first convulsive action, convulsion of syncope, marks a definite period, when the tension of the heart, and therewith of the whole vascular system, is reduced to a degree of action well defined and attended with definite phenomena. In this stage the force of the heart is sufficient to move the unconscious muscles, and gradually, if blood be resupplied, to lift them again into the condition for the sudden development of active conscious life. The second excitement—convulsion of death—indicates the period when the passive or lower tension of the muscular power ceases.

A distinction was here drawn by the author between the muscular condition present during syncope and during death. Syncope, it was urged, means the continued action of the heart at a low tension, from which it can be suddenly raised into full tension with restoration of the powers of life; death means the cessation of the lowest tension at which the heart can effectively work.

It was shown that in all the cases of restored animation after apparent death the condition of the heart was that of a muscle acting under the lower degree of tension. In this intermediate stage, between syncope and death, the most striking results were obtainable; but beyond this stage the methods so successful during it were practically useless for restoration.

The experiments of the author for re-establishing artificial respiration, together with artificial circulation, and of these combined with electrical excitation of the nervous centres, were next referred to; but as they had already formed the subject of a paper read before the Society, they were but briefly dwelt upon. If, continued the author, the question be asked, why, at a certain stage of hæmorrhage, there is development of muscular excitability, the answer is not difficult. The phenomenon is probably due to an irregularity in the distribution of power between the muscular organ and the nervous centre with which it is connected: the effect is due, that is to say, to a continued nervous irritation applied to the muscle after the resistance of the muscle is impaired, while the cessation of the motion is due to the nervous exhaustion that succeeds. In this first series of changes the voluntary muscles and the voluntary centres are involved; but the loss of blood continuing, the same series of changes affect in turn and in like order the involuntary muscles and their nervous centres. The result of this is the second convulsion, indicating death, after which there is no further motion except that which belongs to particular parts; there is no central motion, that is to say, supplying all parts as from a prime source of power, and sustaining all parts from a prime direction of the motion supplied.

The author described in this place a number of experimental attempts to preserve blood for the purposes of transfusion. He had endeavoured to preserve by slow desiccation of blood; but had found that when blood was submitted to evaporation, however slowly, an albuminous pellicle formed on the upper surface, exactly as casein forms on milk, and this prevented the perfection of the process. Recently he had been more successful by evaporating blood to which saline substances had been added; he could not, at the same time, pronounce what he considered a satisfactory termination of this line of experimental inquiry.

Effect of some Chemical Agents.

In this portion of his lecture the author detailed a series of experimental researches with various chemical substances, organic, inorganic, and intermediate, which tend to prolong the period of muscular irritability by diffusion through the tissues of animals recently dead. The substances which suspend irritability act in two ways. Some, like chloride of sodium and other soluble saline substances, act merely by holding the coagulable fluid of the muscular tissue in a continued state of fluidity; others seem to have a different action, and to hold the nervous function also in suspense. The nitrite of amyl and other members of the nitrite series belong to this last-named class of agents, and some of the cyanogen bodies exert a similar influence. In experiments with nitrite of amyl on cold-blooded animals (frogs), the author had suspended muscular irritability for a period of nine days, and had then seen it restored to the extent even of restoration of life. In one instance this restoration took place after the commencement of decomposition in the web of the foot of the animal. In warm-blooded animals a series of suspensions had been effected by nitrites and also by cyanogens, not for so long a period, but for periods of hours, in one instance extending to ten hours.

Under the head "Action on Nervous Matter" the author included, finally, a description of certain experiments he had made to determine the direct effects of some agents upon the nervous matter. In the whole series of his inquiries no fact had impressed him more forcibly than this, that the muscular irritability, in so far as it belongs to the muscle, may be sustained for hours after the nervous excitation which calls it into spontaneous action has ceased. Hereupon he infers that after death the nervous matter undergoes a change of condition which, in result, is identical with that change in muscle which we call "rigor mortis." There is evidence, moreover, from some rare cases, that the final inertia of nervous matter may be suspended and revived, so that all the muscles may be reanimated. This point was elucidated by reference to the phenomena that had recently been observed by Mr. Wasdale Watson, of Newport, Monmouthshire, on a double monster, photographs of which were placed before the Society. In this instance two children were born so attached that the separation of them was impossible. Both lived equally for three hours after birth, and then one died, and remained dead for three hours, while the other lived. At the end of the time named the dead child recommenced to breathe, and showed other signs of restored muscular power; then it sank into a second death, but at intervals of about four hours moved again; at length, twenty-three hours after its first apparent death, during a fit of crying of the living child, it recovered sufficient power to breathe and even to cry, and manifested evidence of life in all its muscles, except the heart, for twenty minutes, when it had a severe convulsion which stopped all further motion.

In this instance the author believed that the retention of muscular irritability had depended upon the retention in the nervous organism of the conditions necessary for exciting motion.

He proceeded to describe his researches as to the possibility of suspending nervous changes incident to death, so as to retain the conditions requisite for the communication of nervous impulse to muscular fibre.

Summary.

1. There are three degrees of muscular irritability—the active efficient, passive efficient, negative inefficient. The muscle after death may be suspended in any of these conditions for action; but, as a rule, it is the last condition only that is maintained long after death.

2. Muscular irritability may be suspended or stopped altogether under three different conditions, having reference to its connexion with nervous activity:—(*a*) The nervous and muscular activities may be suspended equally, on which there may follow spontaneous return of motion. (*b*) The muscular irritability may outlive the nervous function, on which the phenomenon of irritability may be induced by the application of the motor forces, but there is no return of spontaneous irritability—*i.e.*, of irritability belonging to the animal as an independent agent. (*c*) The nervous function may outlive the muscular irritability, under which circumstances irritability is invariably stopped by the production of persistent contractility of the muscular fibre.

3. Nervous activity exciting muscular action is identical with all the motor forces and particular to none. It is equivalent to mechanical, calorific, or electrical force, and equally susceptible of manifestation through either.

4. Muscular irritability after death is possible under conditions which, so far, are thus known. Cold, in certain defined degrees, suspends without destroying it. The motor forces strike it into rest. Blood sustains it or stops it according to the balance of power existing between the muscular and nervous systems. Some chemical agents suspend it independently, others suspend it together and equally with

suspension of the nervous function. When suspension is equal there may be spontaneous return; when it is unequal there is no return.

In conclusion, the author said there had been six great advances in physiological medicine—viz., the introduction of the art of anatomy, the discovery of the circulation of the blood, the discovery of the chemical process of respiration and nutrition, the discovery of the ultimate structure of animal bodies, the discovery of osmosis and of the crystalloidal and colloidal conditions of animal matter, and the discovery of methods for the general and local extinction of pain. The next grand advance has for its design the discovery of the precise relationships of nervous to muscular structure in the living and in the dead conditions. That established, the phenomena of muscular movement, its suspension or its destruction, will be understood like every other physical fact that lies this side of ultimate fact—that is to say, that lies, as this clearly does, within the range of experimental inquiry.

ON HYSTERICAL ANOREXIA.(a)

By Dr. LASÉGUE,

Professor of Clinical Medicine in the Faculty of Medicine of Paris
Physician to La Pitié Hospital.

In my opinion we shall never succeed in composing the history of hysterical affections but by the separate study of each symptomatic group. After this preliminary analytical labour, we may collect the fragments, and from them reproduce the whole disease. Regarded in its entirety, hysteria has too many individual phenomena and hazardous incidents to allow of the particular being found in the general.

This procedure, very questionable when applied to diseases limited as to time, as to space and localisations, and as to the modality of phenomena, here finds its legitimate employment. I have already endeavoured to characterise cough and temporary catalepsy of a hysterical nature; and others have devoted valuable monographs to hemiplegia, transitory or permanent contractions, anæsthesia, etc. On the present occasion I wish to treat of a symptomatic complexus too often observed to be a mere exceptional occurrence, and which possesses the further advantage of enabling us to penetrate into the intimacy of the mental dispositions of hysterical subjects.

The disturbances of the digestive organs which supervene during the course of hysteria are numerous. They consist in repeated and sometimes almost incoercible vomiting, in gastric pains, hæmatemeses, in constipations, or diarrhœas, which are singular, whether by their evolution or by some of their characters. Among the more serious symptoms, vomiting of blood has chiefly attracted the attention of physicians. Gastralgias—purely subjective phenomena—are ill understood, and disturbances of the intestinal canal give rise to much uncertainty.

Attention has been paid in preference to the curious perversions of appetite, examples of which superabound in almost innumerable varieties. While relating singular cases of strange appetite, the true condition of the patients has not been investigated; and the whole is reduced to the profitless notion that hysterical patients are liable to the most out-of-the-way disorders of the digestive functions. Nevertheless, it would not be impossible to attempt a classification of this description of anomalies; but although I have had the opportunity of observing a great number of these, I do not intend to speak of them here, even incidentally.

The object of this memoir is to make known one of the forms of hysteria of the gastric centre which is of sufficient frequency for its description not to be, as too readily happens, the artificial generalisation of a particular case, and constant enough in its symptoms to allow of physicians who have met with it controlling the accuracy of the description, and to prevent those who have yet to meet with it in their practice being taken unawares. The term "anorexia" might have been replaced by "hysterical inanition," which would better represent the most characteristic of the accidents; but I have preferred the former term, without otherwise defending it, precisely because it refers to a phenomenology which is less superficial, more delicate, and also more medical.

Of the different stages of which digestion consists, the best analysed by patients, and the least easily investigated by the physician, is the appetite for food. If the term "anorexia" is generally adopted to represent a pathological condition, it has no physiological correspondent, and the word "orexia" does not exist in our language. The consequence is that we are defective in expressions for the degrees or varieties of inappetence—the poverty of our vocabulary corresponding to the insufficiency of our knowledge.

In certain cases there is suppression of appetite, without the patient exhibiting aught else than regret at the absence of a stimulus for taking food. Repugnance is not present, and frequently the proverb *l'appetit vient en mangeant* receives its justification. Under other conditions, the patient has a more or less decided repugnance for certain aliments, while in other cases any alimentary substance whatever excites disgust. However general the inappetence may be, it always has its graduated scale, so that aliments are not indiscriminately rejected with the same insistance.

On the other hand, there are affections, whether of the stomach or of the central nervous system, whether localised or diathetic, which are accompanied by an illusory sense of appetite, occurring at unequal or quasi-regular intervals. In certain hysterical and in certain diabetic patients these false appetites become exacting and imperious. Almost always such patients, in obedience to a theoretical hypothesis, entertain the idea that their uneasiness is due to inanition, and that it may be overcome by the aid of nutriment, however reduced in quantity this may be. Experience shows us that two drops of laudanum succeed better in appeasing this imaginary hunger than does the ingestion of aliments.

Exactly opposed to this exaggeration is the diminished appetite and the conviction that food will prove injurious, the patient here, as in the former case, acting in conformity to an instinctive hypothesis. When she is docile, and desirous of being delivered from her fears, she makes the effort, and acquires the conviction either that her health is improved under the employment of alimentation, even though it does cause suffering, or that her apprehensions have been ill-founded. When indocile, and anxious before all things to avoid pain, which, although hypothetical, is dreaded in advance, she persists in her abstinence from food. This is the case with the hysterical patients whose history I shall now endeavour to depict. Cases which persist for years are not suitable for narration, and I believe that it will be better, in place of particular facts, that I should present a somewhat diagramatic sketch of the disease.

A young girl, between fifteen and twenty years of age, suffers from some emotion which she avows or conceals. Generally it relates to some real or imaginary marriage project, to a violence done to some sympathy, or to some more or less conscient desire. At other times, only conjectures can be offered concerning the occasional cause, whether that the girl has an interest in adopting the mutism so common in the hysterical, or that the primary cause really escapes her.

At first, she feels uneasiness after food, vague sensations of fulness, suffering, and gastralgia *post-prandium*, or rather coming on from the commencement of the repast. Neither she nor those about her attach any importance to this. The same sensations are repeated during several days, but if they are slight they are tenacious. The patient thinks to herself that the best remedy for this indefinite and painful uneasiness will be to diminish her food. Up to this point there is nothing remarkable in her case, for almost every sufferer from gastralgia has submitted to this temptation, until he has become assured that such relative inanition is not only profitless but aggravates his suffering. With the hysterical things take another course. Gradually she reduces her food, furnishing pretexts sometimes in a headache, sometimes in temporary distaste, and sometimes in the fear of a recurrence of pain after eating. At the end of some weeks there is no longer a supposed temporary repugnance, but a refusal of food that may be indefinitely prolonged. The disease is now declared, and so surely will it pursue its course that it becomes easy to prognosticate the future. Woe to the physician who, misunderstanding the peril, treats as a fancy without object or duration an obstinacy which he hopes to vanquish by medicines, friendly advice, or by the still more defective resource, intimidation. With hysterical subjects a first medical fault is never reparable. Ever on the watch for the judgments concerning themselves, especially such as are approved by the family, they never pardon; and considering that hostilities have been commenced against them, they attribute to themselves the right of employing these with implacable tenacity. At this initial period, the only

(a) *Archives Générales de Médecine*, April, 1873.

prudent eourse to pursue is to observe, to keep silent, and to remember that when voluntary inanition dates from several weeks it has become a pathologieal condition, having a long course to run.

It is neeessary, in order to appreciate at their value the various elements which concur in the development of the disease, to submit each of these to a minute analysis. The gastric pain, which is, or appears to be, the point of departure of the accidents, requires especially that we should dwell upon it. It varies in intensity from a confused sense of pressure to a kind of stomachal cramp, accompanied by fainting, pallor, sweats, or even shivering. There is neither vomiting nor any real desire to vomit even in extreme eases, the patient only asserting that a degree beyond would induce this. In mere appearanee these painful paroxysms in nowise differ from those which are so frequently met with in all affections of the digestive organs. Food induces them, and they do not oeeur except after meals. If this were really so, we should want any distinctive signs, and should be reduced to adding gastralgia to the already too long list of localised hysterical neuroses.

But the painful sensation persists more or less during the intervals of the repasts, being sometimes insignificant, sometimes more eonsiderable, and now and then so attenuated in degree that the patient complains of a general uneasiness without being able to indicate a fixed point. Whatever may be its form, seat, or degree, is this painful sensation due to a stomachal lesion, or is it not only the reflex impression of a perversion of the central nervous system? I cannot believe that the solution ean rest doubtful from the moment that the question is put. At the commencement of a great number of cerebro-spinal diseases we meet with præeordial suffering, a sense of epigastric pressure, or contractions, which also attend even transitory emotions. All of us have felt this kind of uneasiness while referring it to the definite moral cause that has given rise to it; but supposing an individual suddenly seized with this epigastric constriction, without any obvious eause, the uneasiness becomes such as to give rise to anxiety. The patient seeks from whence so strange an impression can arise, and it is often in such a seareh that the *délire des persecutés* eommences. Supposing that the cephalic affeetion does not lead to such serious consequenees, the first and most natural hypothesis that occurs to the patient is that he is suffering from disease of the stomach. All præeordial anxiety, with apprehension and the semi-vertigo it entails, becomes exaggerated by food, which forms an additional reason for attributing it to gastric irritation.

The characteristics of this gastralgia from reflex causes are not impossible of discernment, the circumstances under which they may exist being by no means of rare occurrence. It is distinguished from painful irritation of the stomach because it is not exactly localised, and is accompanied by an entirely special inquietude; it is sudden, the way not having been prepared for it by gradually increasing indigestions; it is not followed by dyspeptic accidents; the intestinal functions remain unimpaired save by habitual constipation, which is easily overcome; the nature of the food taken exercises no influence on the paroxysms; and the character of the pain, when it really exists, bears no analogy to the gastric suffering determined by a lesion, however superficial.

From the moment that the nature of this *malaise* has been ascertained, important progress has been made in the establishment of the diagnosis. I cannot too strongly insist on these splanchnic neuroses, and on their relations to certain cerebral conditions.

The hysterieal subject, after some indecision of but short duration, does not hesitate to affirm that her only chance of relief lies in an abstinence from food; and, in fact, the remedies appropriate to other gastralgias are here absolutely inefficacious, however zealously both physician and patient may employ them. The repugnance for food continues slowly progressive. Meal after meal is discontinued, one of these, whether breakfast or dinner, alone being alimentary; and almost always some article of diet is successively suppressed, whether this be bread, meat, or certain vegetables—sometimes one alimentary substance being replaced by another, for which an exclusive predilection may be manifested for weeks together. Things may be thus prolonged during weeks or months without the general health seeming to be unfavourably influenced, the tongue being clean and moist and thirst entirely absent. The persevering constipation readily yields to mild laxatives, the abdomen is not retracted, and sleep continues more or less regular. There is no emaciation, although the amount of nutriment scarcely amounts to a tenth of that habitually required by the patient. The power of resistance of the general health in the hysterieal is too well known for astonishment being excited at seeing them support without injury a systematic inanition to which robust women could not be exposed with impunity. Moreover, this diminution of aliment is made not suddenly, but by degrees, so that the economy more easily habituates itself to the decrease. Another ascertained fact is, that so far from muscular power being diminished, this abstinence tends to increase the aptitude for movement. The patient feels more light and active, rides on horseback, receives and pays visits, and is able to pursue a fatiguing life in the world without perceiving the lassitude she would at other times have complained of. There are no visible signs of chlorosis or anæmia, or, at least, inanition cannot be accused of having induced them, for most of the patients were already in a chloro-anæmic condition.

If the situation has undergone no change as regards the anorexia and refusal of food, the mental condition of the patient is brought out more prominently, while the dispositions of those surrounding her undergo modification as the disease becomes prolonged. If the physician had promised rapid amendment, or if he has suspected a bad disposition on the part of his patient, he has long since lost all moral authority. Nevertheless, the patient only exceptionally resists the administration of medicines. Just as she is invincible in regard to food, she shows herself docile even for the least attractive remedies. I have seen one chewing morsels of rhubarb whom no consideration would have induced to taste a cutlet. The most active gastric stimuli, purgatives whether mild or drastic, mineral waters, produce no effect, good or bad. The same may be said of diffusible stimuli, fetid gums, valerian, hydro-therapeutics, douches at different temperatures, as also of tonics, preparations of iron, cutaneous derivatives, etc. Laxatives alone are of use by removing constipation, none of the other agents even producing a diminution of the anorexia. When after several months the family, the doctor, and the friends perceive the persistent inutility of all these attempts, anxiety and with it moral treatment commences; and it is now that is developed that mental perversion, which by itself is almost characteristic, and which justifies the name which I have proposed for want of a better—hysterieal anorexia.

The family has but two methods at its service which it always exhausts—entreaties and menaces,—and which both serve as a touchstone. The delicacies of the table are multiplied in the hope of stimulating the appetite; but the more the solicitude increases, the more the appetite diminishes. The patient disdainfully tastes the new viands, and after having thus shown her willingness, holds herself absolved from any obligation to do more. She is besought, as a favour, and as a sovereign proof of affection, to consent to add even an additional mouthful to what she has taken; but this excess of insistance begets an exeess of resistanee. For it is a well known law conformable to the experience of all that the best way to double the obstinacy of the hysterical is to allow the supposition, explicitly or implicitly expressed, to transpire that if they would they could dominate their morbid impulses. A single concession would transfer them from the position of patients to that of capricious children; and to this concession, in part from instinct and in part from obstinacy, they will never consent.

(*To be continued.*)

REVIEWS.

The Science and Art of Nursing the Sick. By Æneas Munro, M.D. Glasgow: J. Maclehose. 1873.

This is an attempt to supply a hitherto marked deficiency in the literature of this subject. The author claims to have had special opportunities, and has evidently taken no small pains to produce a work that should form a useful practical guide to the sick-room. Its scope is somewhat ambitious, dealing not only with the duties of an ordinary nurse, but entering minutely into the question of diet, sketching briefly many points of minor surgery, and giving full instructions for monthly nursing.

A suggestion thrown out in the earlier portion of the work "that it would be advisable to organise a staff of district visiting nurses, similar to or combined with the district Bible-

woman, as now employed by some of our churches," is a very good one; "such an organisation might prove of incalculable benefit in showing the people how to clean their homes *properly*, how to cook their food *well*, and many other things of a similar nature." He justly observes that "the Church in this respect has shot ahead of our profession."

There is much in this work that the young practitioner will be glad to learn. It is just the book to place in the hands of any intelligent woman intending to qualify as nurse, and if more heads of households were familiar with its teachings, it would save them much anxiety and the doctor much unnecessary trouble.

The chapter on sick-diet is well worth perusing, and, together with the appendix on "Invalid Cookery Receipts," will doubtless prove of great service to many an invalid whose friends have taken the trouble to study them.

The chapter on "Nursing during Pregnancy and in the Lying-in Room" would almost better have formed a separate treatise; for though it is essential that a monthly nurse should understand the details of a sick-room, still it is not requisite, nor desirable, that an ordinary nurse should combine the duties of the lying-in room with her other acquirements—the two should be perfectly separate and distinct. The subject is well and exhaustively treated, and is evidently written by one who thoroughly understands the practical details.

The work itself reflects great credit on the author, and deserves a large circulation. It is printed on toned paper, in a bold clear type, that, in the quiet hours of watching, might easily be read without distress.

Leçons Cliniques sur les Maladies des Femmes. Par T. Gallard, Médecin de l'Hôpital de la Pitié. Paris: J. B. Baillière. 1873. Pp. 792; 94 figures.

Clinical Lectures on the Diseases of Women. By Dr. Gallard. London: Baillière, Tindall, and Cox.

The author in his preface tells us that the work does not purport to be a systematic treatise on the subject, but simply, as its title suggests, clinical lectures, which were delivered from time to time to his class at the above-mentioned Hospital. He prefers rather to describe accurately a few subjects than to sketch merely a great number, and has endeavoured to show that a study of these diseases offers no more difficulty or obscurity to the general practitioner than that of any other organ in the economy. He says:—

"I shall be happy if the readers of this book arrive at the same conviction and acquire the same confidence in themselves; for I desire nothing so much as to succeed in popularising this part of science, in rendering it so simple and accessible to all that we shall be able at length to see this speciality disappear from the practice of medicine, from those who pretend to monopolise in a small number of privileged hands all that belongs to the treatment of diseases of women."

The first 144 pages are occupied with preliminary details as regards the normal anatomy of the female organs, methods of examining, use of speculum, sound, etc.; a clear understanding of this necessarily important study being much facilitated by several illustrations of the various instruments employed. Then follow some well-written chapters on metritis, the author dividing this subject into the simple acute parenchymatous, the internal or acute mucous (metritis hæmorrhagica), and the chronic metritis.

The space devoted to the first of these, more especially in reference to treatment, is not so great as one would have expected, considering that acute metritis is the precursor of the chronic form, to which the author devotes over 200 pages. He illustrates his views by clinical cases—a method which will approve itself as eminently useful to the busy practitioner. Menorrhagia he considers as the principal, if not the only symptom that can be regarded as pathognomonic of acute internal metritis, and advises the intra-uterine injection of tinct. fer. perchl., etc., only when the acute symptoms are subsiding and merging into the chronic form. He speaks very favourably of digitalis in this condition, and regards it as the most useful agent in restraining the hæmorrhage and relieving the inflammation.

The chapter on chronic metritis enters fully into the symptoms, diagnosis, and treatment of this troublesome affection. The author discusses the relative merits of bleeding, tartarised antimony, mercury, iodine, hyoscyamus, arsenic, ergot, digitalis, alkalies, and abstinence; and under the local medication, leeches, baths, injections, tampons, caustics, actual cautery, blisters, electricity, etc.; and then enters upon the hygienic management, hydrotherapie, regimen, and, in fact, everything that has been or is supposed to influence the course of this disorder.

The chapter on hypertrophic elongation of the cervix uteri comprises the symptoms, diagnosis, and treatment of this rare condition, M. Huguier's conoidal amputation of the neck being the only mode described. The description of fibroid tumours of the uterus applies more to polypi, or, at any rate, intra-uterine, and not intra-mural, fibroids, removal by the écraseur or the scissors being the methods recommended. He quotes M. Nélaton as advocating the removal of intra-mural growths by free incision and enucleation, but states that he has never met with one favourable for such an operation. Although he professes to disbelieve in the absorption or disappearance of these growths by any remedies we can employ, he yet advises the administration of alkalies, iodine, etc., with this object in cases not deemed proper for operation.

The subject of cancer is treated at length. He considers the occurrence of metrorrhagia as one of the most important symptoms in the differential diagnosis between chronic metritis and cancer in the early stage, it being a constant symptom in the latter and exceptional in the former, occurring suddenly without any assignable cause, and often very profuse.

In considering the etiology of cancer, he regards it as the result of a particular predisposition—of a morbid state anterior even to its formation—a diathesis, in fact. He thinks it impossible that chronic metritis can degenerate into cancer.

Although advocating removal of the cervix, he does not consider Récamier's plan of removal of the whole of the uterus justifiable.

He devotes two chapters to the subject of hæmatocele, and agrees with Velpeau—only to puncture in case of absolute necessity.

The volume closes with a consideration of ovaritis—marriage being recommended as a remedy when leeches, scarification, and other measures have been resorted to in vain.

Besides a table of contents, there is a very good index, which facilitates reference and makes the volume very complete.

The practitioner will find the subjects enumerated discussed in a practical and simple manner; and, although he will not find anything more than our recent text-books give, still it is an honest record of careful thought and observation, and will well repay perusal. If the author be as good at other subjects as he shows himself to be in this, he, for one, has justified his opening remarks.

GENERAL CORRESPONDENCE.

THE FLUID MEASURE OF THE BRITISH PHARMACOPŒIA.

Letter from Dr. Lewis Shapter.

[To the Editor of the Medical Times and Gazette.]

Sir,—According to the accepted method of interpreting the fluid measure of the British Pharmacopœia, one fluid ounce is very generally assumed to have its equivalent in two tablespoon of fluid, two fluid drachms in one dessertspoonful, and one fluid drachm in one teaspoonful. It is only necessary, however, to test the spoons in common use in order to demonstrate the fallacy of such a comparison, and to point to the necessity for the revision of a system which, as at present understood, can only tend to inaccuracy of observation. Will you permit me, therefore, to direct attention to the results of such simple experiments which appear to prove, as accurately as the circumstances of the case will admit, that one tablespoon contains one fluid ounce (an eight-ounce bottle being equal to either ten, nine, or barely eight tablespoonfuls, according to the spoon used), one dessertspoon contains four fluid drachms (with scarcely any variation), one teaspoon contains two fluid drachms (with slight variation); or, in other words, our supposed doses are being in many cases simply doubled from a misinterpretation of figures in common use. The effect of such a misunderstanding—which, I believe, will be almost universally admitted—must necessarily be to produce an erroneous knowledge not only of the doses, but also of the special uses of drugs; so that, to insure requisite and essential accuracy, it seems impossible to overrate the importance of an alteration in the present system; for even if these facts are known, and acted upon by some, yet this very circumstance

can only tend to an increased want of uniformity in practice, and more unreliable methods of observation. Without entering, then, into detail regarding the obvious errors that may arise under the existing method of interpretation, I would only add that these remarks are supported by the variations, practically observed, regarding the efficacy of the same prescribed doses in different cases—such variations being probably due, upon the one hand, to the use of graduated glasses, and, on the other, to the adoption of the spoon-measure.

In conclusion, it remains for consideration whether the present standard of comparison (even if revised) is sufficiently reliable to be continued, or whether another method, not subject to variation, can be placed in its stead. Many of the eight-ounce bottles are certainly accurately graduated into eight parts, so that one ounce is taken, or two dessertspoonfuls, but not two tablespoonfuls. This graduation of bottles is, however, by no means universal, and for the most part does not extend, in the case of eight-ounce bottles, to sixteen parts, and in the case of six-ounce bottles to twelve parts. The dessertspoon is not in such common use as to supplant the tablespoon; and the teaspoon (so frequently employed for children), unless we are content to adopt the equivalent measure of two drachms, must be entirely discarded from use. As therefore we are so soon to have an appendix to the British Pharmacopœia, if it is not too small a matter, might I venture the suggestion that it would tend to the advancement of therapeutics if some definite statement were added to it, not only for our own instruction, but also for the special guidance of those whose business it is correctly to interpret our prescriptions.

I am, &c., Lewis Shapter, B.A., M.B. Cantab.

Exeter, September 1.

PURPURA HÆMORRHAGICA.

Letter from Dr. T. Inman.

[To the Editor of the Medical Times and Gazette.]

Sir,—Whilst at the Liverpool Royal Infirmary, I had under my care (at the same time) two very bad cases of this disease—both in young women. One was a servant in good place, well fed, and comfortable. Without any warning symptom she awoke one morning, and found blood coming from her mouth, eyes, and nose. When I saw her the face seemed as if it had been bruised to a jelly by violence. There were apparently severe contusions on the body, and blood was flowing from every cavity of the body except the ears. The urine seemed more like blood than the ordinary fluid.

Within a few days the second patient was admitted, and in precisely the same condition as the first. The closest inquiry could not elicit the existence of premonitory signs, nor of any cause whatever for the occurrence of the complaint, which, as in the first instance, came on suddenly in the night.

The treatment was terebinthinate in both cases; and the diet milk, with a small modicum of spirits and beef-tea. The first patient recovered slowly, and was well in about six weeks; the second died suddenly about the tenth day after seizure.

I am, &c.,

Clifton, August 31. Thomas Inman, M.D. Lond.

THE DAIRY REFORM COMPANY AND TYPHOID.

Letter from Mr. D. Maconochie.

[To the Editor of the Medical Times and Gazette.]

Sir,—It is so difficult for critics, after an event, to place themselves exactly in the position of those who were actors in it and to realise the ignorance of subsequent developments which those actors laboured under at the time, that we are not surprised that our position and action have been to a certain extent, and by some writers, misunderstood. We therefore, Sir, ask your permission to make a very brief statement in your columns, believing that the whole subject is so important to the medical profession that they will not consider us presumptuous, as laymen, in addressing you.

First, Sir, we have always been under the impression that no case of typhoid poisoning through milk had ever occurred, unless in presence either of proof or of the gravest suspicion of adulteration. The idea that there was any real danger of milk which was unadulterated being nevertheless poisoned, had, we readily confess, never occurred to us. Of the immense medical value of genuine milk we had the highest opinion, and when we started business in 1867 we frequently sent in tenders to hospitals and workhouses. Our tenders were always high, for unadulterated milk is an expensive article, and we found to our disappointment that the subject was, with a very few exceptions, treated with the greatest apathy and lukewarmness. This naturally tended still further to throw us off our guard as to sanitary precautions, and we confined our attention to preventing adulteration, to seeing that the milk was properly cooled, the cows properly fed, and to fighting our natural enemies—the perquisite-loving cooks. To give some idea of our system and organisation, we enclose for your inspection a copy of our rules, and the engagement form which all our *employés* sign.

Under this condition of things, we received Dr. Whitmore's statement, that circumstances seemed to point to our milk as producing typhoid, with such absolute incredulity that one of our directors (Mr. Hope) was not even informed of it until the second day. But when we then found that Dr. Whitmore was under the belief that the whole, or the major part, of our milk came from a sewage farm, we regarded the whole thing as arising from a misconception, inasmuch as we derived no part of our supply from any such source.

When persons once start with an apparently justified scepticism of this nature, nothing is more difficult than to surmount it; for what does it involve? That a theory started upon a datum, among others, which was erroneous, should nevertheless prove correct for another reason.

Again, as was very natural, Dr. Whitmore was himself far from satisfied at first that it was the milk, and in his first letter used the following words:—"Without presuming to express any opinion as to the cause of this outbreak." If *he* was doubtful, why should *we* have been certain?—especially as, in the words of our letter to the *Times*, "As often happens, in a moment of anxiety and pressure, the medical gentlemen who first communicated with us each thought that the facts in full detail had been put before us by one of the others. The result was that we remained in ignorance of most of them, and learned them from the columns of the medical journals, for the first time, *after* we had cut off the suspected supply."

But, Sir, we are prepared to go further, and to question the policy on public grounds of stopping any business and throwing out of work a couple of hundred of people on suspicion, however strong; for even one mistake would raise a host of coarse, bitter, and ignorant enemies, of the very class which already gives so much trouble to medical officers.

However, the precautions we are now taking are such as have never before been carried out for the protection of any article of food. They are briefly as follows:—

1. That the sanitary condition of each farm shall be from time to time inspected and reported upon by a medical officer from London.

2. That the local medical men shall report to us weekly on the health of the individuals, and on a single case of infectious disease arising shall immediately stop the milk.

3. That the local veterinary surgeons shall report to us weekly on the health of the cows, having similar power to stop the milk.

4. That all our *employés* in London shall be medically inspected weekly, the London medical man having full power to close all or any of our establishments if he sees fit, without reference to us.

5. That our milk shall be watched and analysed from time to time by two eminent chemists, who have power to enter our premises at all hours, and take what samples they please.

6. Finally, as a satisfaction to themselves, we have sent orders of admission to our premises to the Medical Officer of Health of every district where we have any customers.

If any of your readers can suggest any weak point in our armour, we will take immediate steps to remedy it.

In conclusion, Sir, we beg to say that though circumstances made us appear at first as if antagonistic to the medical authorities, this only arose from the double misunderstanding which we have explained above. What we have always desired to be is a useful and reliable instrument in the hands of the physicians of London.

I am, &c., D. Maconochie, Secretary.

Dairy Reform Co. (Limited), Orchard-st., W., Aug. 28.

Dr. Moore, of Rajpootana, has been awarded the Government prize for the best manual of Indian family medicine.

OBITUARY.

ROBERT BOWER, M.R.C.S.E., L.S.A.

Mr. Bower died at Southport, in Lancashire, on August 24. He had retired from practice for many years, owing to a paralytic seizure. The writer of this paper became acquainted with Mr. Bower at school and studied with him in London. He was considered the best anatomist in Mr. Grainger's school, then a celebrated anatomical school in the Borough, and his success at the College was looked upon as certain. Judge then our surprise and mortification when he left the College a rejected man. Half a dozen hands were held out to welcome him, but to our congratulations he anwered in a faltering voice, "I am rejected." "Rejected!" we all said at once: "Impossible!" and then came the question, "By whom?" "Sir William Blizard." "Upon what question?" "Upon amputation in traumatic gangrene." Away we posted to Mr. Richard Grainger's in the Borough with our bad news. Upon being satisfied that we were not joking, he pulled out his watch and said, "We cannot reach the College before the Court rises, or I would have accompanied you and appealed to Sir Astley Cooper, and asked him whether he would allow one of his best pupils to be rejected on a subject which he had publicly taught and practised in Guy's Hospital." On Mr. Bower waiting upon Sir Astley Cooper the following morning, he said, "Give me Sir William's questions and your answers." To the first and second questions satisfactory answers were given, but the third was fatal to his passing. They were as follows:—1st. How would you treat a case of compound fracture of the forearm? 2nd. But suppose mortification took place, what would you do? 3rd. In case the mortification continued to advance up the limb what would you do then? "I would amputate." "Amputate!" said Sir William; "what, before the line of demarcation had formed?" "Yes, Sir William, in traumatic, but not in idiopathic gangrene." Sir William then said, "I should advise you to study surgery three months longer." Having heard Mr. Bower's statement, Sir Astley said, "As I was in the room, why did you not appeal to me? Your answer was quite right. You have seen me practise it in Guy's. Baron Larrey was the first surgeon to ignore the line of demarcation in traumatic gangrene after the battle of Waterloo. I am very sorry for you. You might have a special examination granted you on petition, but I advise you to wait the three months." Mr. Bower again presented himself at the Christmas examination of 1823 and had a mere formal examination given him. In after years Mr. Richard Grainger alluded to Mr. Bower's rejection when giving evidence before a committee of the House of Commons on some subject connected with our profession. Mr. Bower settled down in Rochdale, where he held a small but highly respectable practice, which he never seemed desirous of extending, probably from the circumstance of his never marrying.

JOHN W. MOORE MILLER, M.D., Inspector-General of Hospitals,

Died at Southsea a few days since. He had received the silver war medal with four clasps for his services at the Pyrenees, Neville, Nivc, and Orthes, and was also engaged in the campaign of 1815. He contributed several articles on "Public Health" and "Drainage" to local periodicals, and "Case of Arrested Development of Bladder and Urethra with Operation for Relief."

GEORGE FABIAN EVANS, M.D., F.R.C.P.,

Died on the 30th instant after an illness of some months, aged 76 years. He was Senior Consulting-Physician to the Birmingham General Hospital, and a practitioner well known in the midland counties. He was a Fellow of the Royal Medical and Chirurgical Society of London.

The papaya tree and its juice are used, says the *Morning Post*, in India to make meat tender. The juice or a solution of it undoubtedly softens, digests, or dissolves meat, albumen, and gluten. Assistant-Surgeon Gopal Chunder Roy has written an interesting paper on this subject in the *Calcutta Journal of Medicine*. He compares the action to that of a ferment, and suggests the administration of a few grains of the dried juice after meals in cases of indigestion depending on a deficient secretion of gastric juice. His experiments were conducted at Netley, under Dr. Parkes.

MEDICAL NEWS.

Royal College of Surgeons.—At the last half-yearly Examination in Arts, etc., for the diplomas of Fellowship and Membership of the College, there were ninety-five candidates for the first-named distinction. Of this number seventy-one passed, and eighteen, having obtained a sufficient number of marks for the Membership, will have to be re-examined in the extra subjects in which they failed. Only six were altogether rejected. The following gentlemen passed for the Fellowship, viz.:—

Messrs. A. R. Anderson, W. C. S. Bennett, A. L. Bowen, R. J. Bryden, F. W. Buée, G. C. R. Bull, J. E. Bullock, R. D. Cameron, W. H. Carrington, F. E. Cockell, F. O. Combe, W. L. Chubb, W. Cock, W. H. Copley, C. Crossley, A. S. Currie, E. W. Dease, F. S. Edwards, W. J. V. Harle, W. Falla, F. W. Giles, F. C. Gayton, J. R. Guy, G. H. Hames, G. F. Harris, C. Gross, H. C. Goold, H. Hine, F. Hickman, R. Hunt, C. Howard, J. H. Kyan, J. W. Jerome, J. C. Keer, H. Le Cronier, J. R. Leeson, J. F. M'Crea, V. Matthews, W. H. Mason, A. S. Morton, E. J. Morley, B. J. Newmarsh, W. J. C. Nourse, T. C. Nugent, W. H. Packer, C. J. R. Owen, A. F. Parker, C. N. Pearson, J. K. Pickford, A. O. H. Phillips, T. G. Prosser, E. A. Praeger, E. L. Robinson, J. H. Simpson, F. H. Spooner, R. C. Stewart, A. J. Sturmer, C. H. Tamplin, G. H. W. Thomas, G. G. Tatham, S. J. Thomson, H. W. G. Triggs, H. H. Tidswell, W. H. P. Thorn, A. Vores, T. J. Verrall, W. J. Walsham, C. E. Walker, W. P. Whitcombe, A. T. O. White, H. R. Whitehead.

For the Membership there were 238 candidates, of which number 181 passed and fifty-seven were rejected. The following were successful, viz.:—

Messrs. J. C. Ady, R. P. Allen, J. Alexander, S. Angear, H. T. Baxter, W. E. Ankliff, J. H. Bennett, N. Bentham, A. Blackmore, W. Beecham, E. Berdoe, F. Browne, H. T. W. Blakeney, D. R. Bowen, R. B. Bothamley, J. H. Breach, E. J. Booth, J. Buckle, C. Bradford, J. F. Brown, J. T. Butterworth, F. Casson, T. W. J. Allen, H. Charles, J. T. Brett, J. Cæsar, T. J. Cadett, F. J. Bennett, H. M. Chapman, P. E. Campbell, W. Chalmers, J. G. Clark, H. E. Davies, J. B. Coumbe, T. W. Colbourn, E. Creighton, E. S. Dalton, H. C. Crew, M. A. Chilton, S. R. Corder, J. L. Denson, R. Dempster, A. S. Dawson, A. Dobson, W. Dunstan, C. Donkin, W. E. Dixon, E. H. Dumbleton, D. C. Embleton, C. H. Downes, E. H. Dyer, T. F. Ensor, H. Ewbank, A. Fawcett, D. Evans, G. Ellis, W. T. H. von Beverhondt, C. J. Fooks, L. B. Eskell, S. B. Fairley, A. G. B. Gipps, J. S. Fallon, A. Fowham, G. A. Farrer, W. Fligg, G. J. W. Flower, W. H. Gaze, W. H. Goodchild, S. J. Gabriel, J. Greenwood, C. R. Graham, T. H. Greame, H. P. Gilbert, H. D. Halliday, G. C. Gaudin, T. Hammond, H. F. Hann, A. A. Hart, J. H. Heritage, J. R. Hewitt, T. L. Hall, J. M. L. Davies, J. T. Hinton, H. Hancock, J. W. Hodgson, H. Harris, W. H. Hiddingh, J. D. Hayward, J. A. Howard, J. T. James, W. Huey, V. A. Jaynes, T. G. Jenkins, W. V. V. Chapman, H. Goodchild, E. E. Jewers, F. P. Jervis, C. A. Lane, A. B. Lipscomb, H. Leak, G. A. Macdonald, W. G. V. Macfarlane, E. D. Maddick, F. W. D. MacGaeken, J. T. J. Morrison, F. W. Mott, H. C. Nance, W. J. Murray, A. R. T. O'Regan, S. F. Newton, W. P. Palmer, R. R. Norton, W. J. Parry, W. T. Parker, A. L. Perkins, W. A. Phillipps, W. W. Pitman, W. O. Piper, W. S. Porter, A. Pratt, J. J. Powell, T. E. G. Prideaux, C. O. Richardson, J. W. L. Russell, J. Rose, A. Shipton, E. W. Pryce, E. S. Russ, T. Sayer, F. Schneider, C. T. K. Shaw, S. G. Sharpe, W. Shaw, J. T. Smith, O. B. Shelswell, T. W. Shepherd, J. A. L. Stephen, F. C. Strutt, F. Smith, J. F. Tabb, W. E. Good, J. H. Thompson, W. B. Stebbing, F. W. Storry, F. H. Smith, A. E. Webb, J. W. L. Ware, W. H. Wheeler, F. A. Trevan, M. J. Verdon, C. J. Williams, T. W. Wakem, C. Wood, W. P. Smith, T. Wilmot, S. W. Woollett, H. Williams, W. L. Yates, W. H. F. Young, W. J. B. Odhams, A. C. Otway, L. W. K. Phillips, J. H. Pettinger, W. Llewellyn, F. A. Leigh, A. P. Cooper, G. N. Stathers, H. Howerd, M. Davies, D. G. Allen, S. W. Coombs, G. Rice, W. J. Jolliffe, G. Fitz Thomas, C. J. Lathbury, F. W. Brookes, C. B. Carter, W. J. Garbutt, F. E. Huxley, W. H. Brown, G. H. Coates, C. J. Fox, R. M. Rogers-Harrison, J. W. Lethbridge, E. A. Rich, J. Scott, E. B. Smith, J. R. Whittingham, F. Wilde, E. J. Loader, J. D. Llewellyn.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Aug. 28:

Foreman, Joseph, Wigan.
Hardwicke, Edward Arthur, Rotherham.
Hibberd, Henry Jukes, Westbourne-place, Harrow-road.
Jackson, William, Leamington.
Keyworth, George Hawson, Wellingley, near Rotherham.
Lakin, Charles, Leicester.
Lambert, John, Farsley, near Leeds.
Tomes, Arthur, Coughton, Warwickshire.

The following gentlemen also on the same day passed their primary professional examination:—

Caddy, Henry, Guy's Hospital.
Elcum, Donald, Guy's Hospital.
Simmonds, William Allason, Guy's Hospital.
Turtle, James Henry, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Bennett, Charles John, M.R.C.S. Eng.—Medical Officer of Health for the Chapel-en-le-Frith, Glossop, and Hayfield Rural, and Glossop and Fairfield Urban Sanitary Districts.

Harris, Michael, M.B. Lond.—Demonstrator of Anatomy at the Liverpool Royal Infirmary School of Medicine.

HODGES, FRANK HENRY, M.R.C.S.E., L.S.A., L.R.C.P. Edin.—House-Surgeon and Apothecary to the Leicestershire Infirmary and Fever House.

STRANGE, WILLIAM, M.D., L.R.C.P., L.R.C.S.—Medical Officer of Health for the Rural and Urban Sanitary Districts of Worcester.

NAVAL APPOINTMENTS.

ADMIRALTY.—J. G. Wall and J. W. Scott, Surgeons to the *Repulse*, additional for disposal; W. F. Spencer, M.D., and W. H. Boland, Surgeons to the *Royal Alfred*, additional for disposal; Francis R. M. Loftie, Surgeon, additional to the *Duncan;* Ahmuty Irwin, Staff-Surgeon to the *Rattlesnake*, additional for service in the *Simoom;* Dr. George B. Beale, Staff-Surgeon to the *Fisguard*, additioual for temporary service; Thomas L. Homer, Surgeon to the *Impregnable;* James Donovan, Surgeon to the *Ganges*, additional for service in the *Liberty;* Alfred C. Delmege, M.D., Surgeon to the Royal Marine Artillery Division; J. K. Conway, M.D., Surgeon to the Cape of Good Hope Hospital; Robert Turner, Surgeon to the *Indus*.

BIRTHS.

ARMSTRONG.—On August 25, at Plymouth, the wife of Surgeon-Major Armstrong, 16th Regiment, of a daughter.

BOGLE.—On August 30, at 12, Inverleith-terrace, Edinburgh, the wife of Dr. A. L. Bogle, Surgeon-Major H.M. Bengal Medical Service (retired), of a daughter.

CARMICHAEL.—On August 31, at The Woodlands, Burton-on-Trent, the wife of W. Carmichael, M.D., L.R.C.P., R.N., Staff Surgeon 2nd Class, of a son.

CAWLEY.—On May 25, at Glenelg, Adelaide, South Australia, the wife of Dr. Thomas Cawley, F.R.C.S. Edin., M.R.C.S. Eng., formerly of the Yarmouth and Guy's Hospitals, of a daughter.

CRIBB.—On August 24, at Bishops Stortford, Herts, the wife of Henry Cribb, L.R.C.P. Lond., of a son.

KIRKMAN.—On September 1, at Barming-heath, Maidstone, the wife of William P. Kirkman, M.D., of a daughter.

MURRAY.—On August 29, at Tenbury, Worcestershire, the wife of W. Berkeley Murray, M.D., of a daughter.

ORTON.—On August 27, at 30, Lower Phillimore-place, Kensington, the wife of George Hunt Orton, M.B. Lond., of a son.

WARD.—On August 27, at Northbourne, Chobham, Surrey, the wife of S. M. Ward, M.B., M.A., M.R.C.S. Eng., of a daughter.

MARRIAGES.

BARNARD—LUCAS.—On September 2, at St. Mark's, Kensington, Frederick James Barnard, Esq., formerly of St. John's College, Cambridge, barrister-at-law, Middle Temple, only son of James Barnard, Esq., of Beaumont Villa, Northampton, to Elizabeth Alicia Jane (Lizzie), eldest daughter of the late Dr. Bennett Lucas, F.R.C.S., and of Mrs. Bennett Lucas, of 48, Arundel-gardens, Kensington-park, W.

BAUGAY—JACKSON.—On August 20, at St. Martin's-in-the-Fields, Richard Baugay, M.D., to Margaret Jackson, both of Cheadle, Cheshire.

BELLRINGER—TANNER.—On August 27, at Painswick Church, Thomas Bellringer, Esq., solicitor, Liverpool, to Martha (Patty) youngest surviving daughter of the late Robert Tanner, M.R.C.S., of Castle Godwyn, Painswick, Gloucestershire.

BERGEN—PIPER.—On September 3, at the parish church, Darlington, A. H. V. Von Bergen, Esq., Middleton, St. George, to Ada Maria, elder daughter of S. E. Piper, Esq., F.R.C.S., Orwell House, Darlington.

CAMPBELL—WHYLOCK.—On September 3, at St. Ann's, Lewes, Sussex, John Gore Campbell, Captain 104th Fusiliers, second son of Lieutenant-Colonel J. Campbell, late 60th Rifles, to Florence, eldest daughter of W. Sandom Whylock, M.D., M.R.C.S. Eng., Staff Surgeon-Major, late of the 38th (1st Staffordshire) Regiment.

GREEN—MoWILLIAM.—On September 1, at St. Michael's, East Teignmouth, the Rev. R. Eling Green, B.A., to Isabelle Jean, third daughter of the late James Ormiston McWilliam, C.B., F.R.S., F.R.C.P., M.D., R.N., Medical Inspector of H.M. Customs, London.

HARVEY—POTTER.—On September 2, at St. Botolph's Church, Aldgate, City, George Harvey, M.D., to Julia Agnes, second daughter of Wm. Potter, Esq., Tower-hill, London.

HARVEY—TURNBULL.—On August 27, at St. Mary's Church, Cheltenham, Edward Harvey, Esq., Captain Royal Engineers, to Rose Marion Monckton, daughter of Francis Turnbull, M.D., Surgeon-Major Retired List, Bengal Army.

HAYDON—WARREN.—On August 27, at St. John's, Frognal, Hampstead, Flaxman Haydon, of 55, Basinghall-street, eldest son of S. J. B. Haydon, sculptor, to Fanny, youngest daughter of Charles Holman Warren, M.D., late of Milverton, Somerset.

SANDERS—SPRINGETT.—On August 27, at St. Peter's Church, Brafferton, Richard Careless Sanders, M.R.C.S. Eng., L.S.A., Surgeon Indian Army, to Margaret Cramer, third daughter of the Rev. Robert Springett, vicar of Brafferton.

SAUNDERS—GRIER.—On August 27, at Clifton, Lawrence Saunders, M.D., of Cambridge-terrace, Stapleton-road, Bristol, to Ellen, only daughter of Thomas Grier, Esq., of Cheltenham.

SMITH—GRIMKE.—On August 26, at the Cathedral, Manchester, Herbert Clementi Smith, M.A., Precentor and Minor Canon of the Cathedral, to Ruth Drayton, eldest daughter of Thomas Drayton Grimke, M.D., of Hilton-park, Prestwich.

STEWART—FRASER.—On August 26, at Stirling, William Stewart, M.D., Surgeon 21st Royal North British Fusiliers, to Agnes, second daughter of P. S. Fraser, Esq., J.P., D.L., Edinburgh.

WHYTEHEAD—DUNN.—On September 2, at the parish church, Doncaster, John Burnard Whytehead, of Chatham House, Rothwell, Yorkshire, to Caroline, fourth daughter of George Dunn, M.D., J.P., of The Priory.

DEATHS.

CARROLL, HONOR HEWITT, youngest daughter of the late Rev. John Darwall, of St. John's, Deritend, Birmingham, and widow of J. W. Carroll, M.D., of Calcutta, at York, on August 14, aged 72.

EVANS, GEORGE FABIAN, M.D., at his residence, Birmingham, on August 31, in the 68th year of his age.

FALLS, EDMUND BURKE, Naval Cadet of H.M.S. *Britannia*, and youngest son of W. Stewart Falls, M.D., accidentally drowned at Bournemouth, on the eve of joining his ship, on August 27, aged 13.

HEENAN, ROBERT, C.E., Superintending Engineer Indus Valley State Railway, son of the late John Heenan, M.D., of Parsonstown, Ireland, at Mooltan, Punjaub, on July 26.

HUISH, HENRY, M.D., L.R.C.S., Surgeon-Major (half-pay) 3rd Hussars, at 4, Lipson-terrace, Plymouth, on August 31.

LOWRY, J. R. C., M.B., Indian Medical Staff, son of James Carry Lowry, Esq., Q.C., of Rockdale, county Tyrone, at Kulladghee, Bombay Presidency, on July 19.

MILLER, JOHN, M.D. Edin., Inspector-general of Army Hospitals (retired), at 3, Eastern-parade, Southsea, on August 29.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRKENHEAD BOROUGH HOSPITAL.—House-Surgeon. Candidates must be duly qualified in medicine and surgery, and registered. Applications, with testimonials, to the Chairman of the Weekly Board, on or before September 15.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

BRISTOL DISPENSARY.—Medical Officer. Candidates must possess a diploma in Surgery from the Royal College of Surgeons of London, Edinburgh, or Dublin, or from the Faculty of Physicians and Surgeons of Glasgow. Applications, with testimonials, to the Secretary, on or before September 6.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to John Binks, Esq., Honorary Secretary, Wakefield.

EASTERN DISPENSARY, BATH.—Resident Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Francis Savage, Esq., Hon. Secretary, 10, Beaufort-buildings East, Bath, on or before September 24.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Registrar. Particulars may be obtained from the Hospital.

GENERAL HOSPITAL, BIRMINGHAM.—Resident Registrar and Pathologist. Candidates must be duly qualified. Applications, with testimonials, to the House-Governor and Secretary, on or before September 6.

INVERNESS DISTRICT ASYLUM.—Assistant Medical Officer. Candidates must be duly qualified and registered. Applications, with testimonials, to Dr. Aitken, Medical Superintendent, on or before September 15.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Candidates must possess both a medical and surgical qualification. Applications, with testimonials, to the Chairman of the Committee, on or before Sept. 8.

MANCHESTER ROYAL INFIRMARY.—Pathological Registrar. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Board, on or before September 20.

MANCHESTER ROYAL INFIRMARY.—Physician's Assistant. Candidates must possess medical and surgical qualifications. Applications, with testimonials, to the Chairman of the Weekly Board, on or before Sept. 6.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Medical Officers. Candidates must be duly qualified. Applications, with testimouials, to P. Goldschmidt, Esq., Chairman of the Board, 100, Albert-square, Manchester, on or before October 15.

PROVIDENT SURGICAL APPLIANCE SOCIETY, 25, BARTHOLOMEW-CLOSE.—Assistant-Surgeon. Applications, with testimonials, to the Secretary, on or before September 10.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Junior House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to the Secretary, on or before September 10.

ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, QUAY-STREET, MANCHESTER.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, Joseph Barber, 14, John Dalton-street, Manchester, on or before September 12.

ST. THOMAS'S HOSPITAL.—Resident Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Applications, with testimonials, to the Treasurer.

STAFFORDSHIRE GENERAL INFIRMARY.—Assistant to the House-Surgeon. Applications, with testimonials, to the Secretary on or before Sept. 12.

WANTAGE UNION.—Medical Officer. Candidates must be duly qualified, Applications, with testimonials, to Edward Ormond, Clerk of the Union. Wantage, on or before September 8.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Glendale Union.—Mr. J. K. Thornton has resigned the Ford District; area 11,727; population 2072; salary £10 per annum.

APPOINTMENTS.

Aston Union.—Henry F. Marshall, M.B. Univ. Lond., M.R.C.S. Eng., L.S.A., to the Deritend District.

Christchurch Union.—William Watmouth, M.R.C.S. Eng., L.S.A., to the Eastern District.

Halifax Union.—James E. Crowther, L.S.A., to the Stainland District.

Louth Union.—John D. Wrangham, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Hainton District.

Petworth Union.—William Morris, M.R.C.S. Eng., L.S.A., to the Second District and the Workhouse.

Prescot Union.—Germain King, L.R.C.P. Lond., M.R.C.S. Eng., to the Lower Widnes District.

St. George-in-the-East Parish.—William R. Horniblow, M.D. Edin., M.R.C.S. Eng., L.S.A., to the North District.

South Shields Union.—George F. Henry, L.R.C.P. Edin., L.R.C.S. Edin., to the Westoe District.

Dr. Edwards, the Medical Officer, reported to the Newcastle Town Council on Tuesday last that there was a case of undoubted Asiatic cholera in the town, but the patient was slowly recovering.

The British Medical Benevolent Fund has received £100 in donations from Miss Caroline Brown for 1873.

The late Mr. John Stuart Mill, by his will, leaves a sum of £3000 to any university in the United Kingdom which first opens its degrees to women. He also leaves £3000 to endow scholarships for female students only.

Health of the Punjaub.—The Sanitary Commissioner of the Punjaub, in his weekly report ending June 21 last, states that there has been a considerable decline in the number of deaths at Delhi; the deaths from all causes have fallen from 154 to 136, and the small-pox deaths from 30 to 11, The death-rate is still very excessive, being 64 per mille. Amritsar continues very unhealthy, though there is a slight decline in the deaths from small-pox, which have fallen from 18 to 15. The death-rate of Siálkot is very excessive. Five deaths are registered there under the head of small-pox, but it is probable that other deaths really due to small-pox are registered under other heads. There is a considerable increase in the number of deaths registered at Jálandhar in the last few weeks. The mortality from small-pox has, as was expected, begun to decline throughout the province; the deaths from this disease have fallen from 893 to 731. Three deaths were registered under the head of cholera in three different districts. There is no reason to believe that they were due to true Asiatic cholera. The annual vaccination report of the Civil Surgeon to the Amritsar Municipal Committee, dated April 15 last, shows that during the four months and six days of the cold weather, when vaccine operations were in progress, 6747 children were vaccinated, against 2000 in the previous year. The present epidemic in the city is the result of the neglect of former years, and it is to be hoped it will be the last. There can be little doubt that the present epidemic would have been much more fatal but for the efforts of the Municipal Committee during the late cold weather to spread vaccination. The epidemic has been light at Amritsar as compared with the experience of other cities.

Marini's Anatomical Preparations.—Among the most curious things at the Vienna Exhibition are the anatomical preparations of Dr. Marini, of Naples, showing how various parts may be preserved for years in an extraordinary manner. The freshness which a portion of, or a whole, subject may exhibit is astonishing. For example, a foot prepared at Paris in 1864, and bearing Professor Sappey's voucher, remained quite unaltered; and on making an incision into it the subjacent parts looked as fresh as those of a person just dead. The fatty tissue presents its ordinary aspect, and the tendons have their pearly lustre. The tissues, moreover, retain their transpareney, and, viewed in the dark before a light, their different layers and the position of the bones are distinguishable. By one of his processes Dr. Marini produces what he calls the "coriaceous" condition, in which the tissues are hard and without transpareney, but on being placed in water recover all their freshness. A portion of such a preparation made in 1863, exhibited before the jury, had all the appearance of being part of a recent corpse. It will be remembered that at the Paris Exhibition of 1867 M. Brunetti obtained the grand prize for his preparations made by the agency of tannic acid; but these, although exhibiting the natural forms, were dry and hard. At present M. Marini keeps his procedure a secret. Another ingenious procedure is only employed for embalming and what he calls petrifaction. By this means Thalberg has been preserved in a "fresh" state for the adornment of his widow's drawing-room. That property of electricity has been utilised by which it transports certain salts, molecule by molecule, to one of the poles, and eliminates others, so that the tissues to their ultimate cellular terminations become penetrated with insoluble salts, while the general form is preserved. Signor Daffito, a former préfet of Naples, was recently so embalmed, and as it is a long process, Dr. Marini, in order not to have to go to the cemetery every day while it was going on, attached a small electrical bell, which sounded as long as the electrical current continued, desiring the keeper of the cemetery to let him know when it ceased ringing. The popular imagination became aroused, and it was asserted that the devil in person was ringing the confessional bell in the ears of the defunct préfet—he having died without extreme unction, and having had only civil burial."—*Lyon Méd.*

Hired Nursing the Best.—Dr. Weir Mitchell writes: "What you want in the sick-room is a calm, steady discipline, existing but unfelt—the patient, cool control which a stranger is far more apt to exercise than a relative. In a word, just as the doctor feels it unwise to attend alone his own dear ones in grave illness, for like but lesser reasons, the best nurse is a stranger,—one who is naturally free from worry and irritation, who is unmoved by traditions of love, and who, acting purely and simply from sense of duty, takes that care of her own health which is essential to make her nursing perfect. Such an attendant is willing to take her share of sleep and fresh air, and so remain cool and tranquil under all circumstances and in all exigencies, making far more light the task of the doctor, and able from experience of illness to note changes and call for aid at needed times. Such help excludes from the sick-room that host of little annoyances for doctor and patient which I may call fuss. Most doctors will agree with me that, save in the case of infants, when the mother cannot and should not be displaced, the best nursing is paid nursing, and the worst very often that which comes from the family."—*Philadelphia Medical Times*, 1873, No. 80.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

F. Edgar.—The letter is not suited to our columns, but if you like to send an advertisement in the usual way we will hand it to our publishers for their consideration.

Rahere.—The old students' dinner will take place as usual in the Grand Hall of St. Bartholomew's on Wednesday evening, October 1.

Bibliopole.—Both the libraries you mention are closed for the month of September.

W. C. F.—Next week.

Huntington need have no scruple under the circumstances stated of enforcing the agreement.

Herbert G. should apply to the Hospital Board.

Foot and Mouth Disease and Milk.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—There being at the present time such a discussion on the question of the effect of milk from cattle being fed on sewage grass, I beg to relate the following:—At the end of 1872, during the prevalence of the foot and mouth disease in North Wales, a farmer I am acquainted with had his cattle ill from it. Being afraid to sell his milk or butter as usual, but obliged to milk the cows, the milk was thrown away, and his family were obliged to purchase for their own use. After a few days, however, his wife thought the milk appeared very good, and began to use it and make butter from it for their own use. She speaks of the milk and butter as good or better than usual. The family consists of the farmer, wife, and nine or ten children (varying in age from two to seventeen years), two female servants, and three or four lads and men who worked on the farm—none of whom were rendered ill by the use of the said milk. I should have hesitated to use the milk myself—but facts are stubborn things.

London, August 30. I am, &c., G. J. S. Camden, M.R.C.S.

Blex.—The University of Prague has refused admission to the Russian women-students who left Switzerland a short time ago.

Ciro.—Dr. Charles Augustus Vandermonde; left in manuscript papers relating to the state of Medicine in China, partly derived from the notes and observations of his father. He died on May 28, 1762.

A Successful Candidate.—Having passed the preliminary examination, you can enter on your hospital studies in October next. The Students' Number of the *Medical Times and Gazette*, which will be published on the 13th inst., will give you the desired information.

A Double Monster in the Eleventh Century.—Roger of Wendover, in his "Flowers of History," under the date 1062, gives an example of two women more closely united than the "Two-headed Nightingale" exhibited in London three years ago:—

"There was an extraordinary birth on the confines of the lesser Brittanny and Normandy. For in one, or rather in two, women there were two heads and four arms, and everything else double down to the navel; but below there were two legs, two feet, and everything else single. The one laughed, ate, and talked; the other wept, fasted, and kept silence. What they ate with two mouths was expelled at one orifice. At last one of them died, and the other survived: the living bore the dead for nearly three years, till at length she died also from the oppression and stench of the corpse." (Bohn's edition, 1849, vol. i.)

Imposture.—"The Alchemist," by Ben Jonson.

> "The doctor—the smoky-bearded—he
> Will close you so much gold in a bolt's head,
> And in a turn convey in the stead another,
> With sublimed mercury that shall mount in the heat,
> And all fly in fumo."

"The Alchemist" was written against a sect of impostors common in the days of Queen Elizabeth.

B. S.—The lettuce was considered as producing sleep and recovery from intoxication; it was in consequence of this belief that this salad was served up after meals. Thus Martial tells us—

"Claudere quæ cœnas Lactuca solebat avorum,
Dic mihi cur nostras inchoat illa dapes."

Metaphysics.—

"Am I but what I seem, mere flesh and blood?
A branching channel and a mazy flood?
The purple stream that through my vessels glides,
Dull and unconscious, flows like common tides.
The pipes, through which the circling juices stray,
Are not that thinking I, no more than they.
This frame, compacted with transcendent skill,
Of moving joints, obedient to my will,
Nurs'd from the fruitful globe, like yonder tree,
Waxes and wastes. I call it *mine*, not *me!*
New matter still the mould'ring mass sustains;
The mansion chang'd, the tenant still remains,
And, from the fleeting stream repair'd by food,
Distinct as is the swimmer from the flood."

A Doctor's Log.—No. II.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As the vessel daily required seventy tons of coal, a supply was taken in, permitting twenty-four hours' stay at Malta. So, chartering a boat, next an inside car, a hurried visit paid to the lions—including St. John's Church (the celebrated silver gates); the Palace with its marble steps, armoury, and ball-room; the wondrous tapestry, and the relics of the knights; the dried monks, with grinning skulls, shaggy beards, and shrivelled mummy hands—Valetta resembling a star-fish resting on the Mediterranean. The eye, soon wearied of grim forts, batteries, barracks, hospitals, of yellow houses, searches in vain for trees or green fields—anything to relieve the painful glare. At a terrific pace rattling along the City of Stairs, we notice images of saints in various corners of the clean streets; magnificent bow-windowed houses, elegantly designed; trumpery shops, advertising lace, jewellery, coral, sponges, and flowers; handsome well-dressed men; ugly women in black hoods; sleek priests, loathsome beggars, and—most welcome sight—the *fac-simile* of London policeman 192 X; well-drilled soldiers salute with lightning rapidity; officers in smart uniforms, else in plain clothes fit for Rotten-row; officers' wives—neat and nice English ladies all over—flit by. In vain endeavouring to diagnose the faculty either on foot or pill-box-broughamed, observe fine fat aristocratic chemists with waxed moustachios, more resembling heavy cavalry colonels than lean or starved apothecaries. Time not permitting to visit the suburbs, the civil, military, and especially the magnificent naval hospital, or to make inquiries respecting the drainage combination with drinking-water, the amount of typhoid fever, malaria, diphtheria, ophthalmia, granular lids—in fact, the old-established ailments, varied with occasional cholera and suicidal tendencies,—we are told that, hot and dusty in summer, it is muddy and cold in winter; the blazing sun, the damp south-east wind, the heavy dew, the scanty rainfall, the soft spongy sandstone, the scanty vegetation, the island—twenty miles by twelve, and sixty in circumference—over-populated by a puny, half-starved race, are amongst the prominent points leading to the opinion that, unless emigration is encouraged or the barren rock covered with more soil, Malta will ever continue liable to epidemics. To Sir Henry Storks the credit is due of one phase of sanitary legislation as effectual, if not more so in its way, than vaccination. There a few public gardens, with orange groves and lovely purple flowers, also fields about the length and width of this ship (surrounded with stone walls), are welcome oases. The chief productions are corn, cotton, vegetables, fruits; the water, derived from springs, received into aqueducts; the rain-supply stored in tanks; and the drainage has an excellent incline into the sea, which may account for the fine eels, mullet, and lobsters. The opera house is a magnificent building, partially to be accounted for by the amount of rock, the facilities for working and carriage, the cheapness of labour, and the innate artistic taste of the inhabitants. The performance, too, very creditable: an orchestra of forty, some of the singers good—all painstaking; but if little people, with a small company and wretched scenery, ambitiously attempt the "Prophète," the stroke is more bold than commendable. The boxes well filled, the governor enshrined in the centre of the house—and as he enters the band strikes up the National Anthem!—a few people in the stalls, the pit empty, and in the gallery a solitary policeman was sucking oranges. The opera is *the* thing at Malta (a stall costing about £5, if not less, for the season), subscribers generally going on foot—many of the dukes, marquises, and counts living economically. The artillery mess externally has a palatial front, also a fine staircase, lofty rooms with painted ceilings—in fact, the military are everything. I could find out nothing about doctors, but to the best of my belief they are wonderfully clever and painstaking, on fees far smaller than their parochial brethren at home. The history is singularly interesting, associated with the shipwreck of St. Paul, the supposed burial-place of Hannibal, the exploits of the Knights of St. John, and of Count Roger, who *claimed* to be King of Sicily, and, in spite of the Pope, was crowned, without any tattoo question. In 1800, when the unfortunate Maltese were ruled cruelly by the French, the English fleet blockaded the island, and for two years privation and pestilence decimated the garrison, who lived on rats, dogs, cats, and mules, obtained at exorbitant prices. But it was not until 1814 that all previous treaties were ignored, and the Maltese most gladly accepted the British flag and protection. Somehow it was a relief to get out of the harbour to continue the voyage; and, on comparing notes, so many complained of feeling below par—the old Indians very short in temper, several bachelors with "heads" on, whilst the *mal de mer* again attacked those susceptible. A patient whose kidneys had been damaged by Canadian cold years before, suffered all the agonies and inconvenience of diuresis, with insatiable thirst, restless nights, dyspepsia, depression, and lumbar pain. With a history of scarlet and rheumatic fever, and having had good things in his days, the prognosis unfavourable, the tremendous strain of flogging the tired horse to death cannot be ignored, and the mile-posts point out to the sufferer how rapidly he is travelling towards Bright's disease, dropsy, coma, phthisis, or gradual exhaustion. After all, what can be done in middle age beyond general support, taking off pressure at one point to tax doubly the other organs, already overworked, besides attention to the skin? As the *Serapis* steamed along, hotly pursued by another vessel anxious to be the first in the Suez Canal (*en passant*, it is startling to record that the dues to be paid will amount to £2500), the sick-list of women—about six in hospital and to-day probably about twenty attending—afforded materials for note-taking not very comfortably, with the ship rolling, the spray dashing in at the ports, the children squalling, the women grumbling, and the sailors singing or shouting whilst swabbing the decks. A professional "life on the ocean wave" differs vastly from the luxurious comfort of the library and consulting-room in Brook-street. Supposing a weakly infant, brought up by hand, suffering from bronchitis and diarrhœa, whilst the mother gives the history, tells the tale of restless nights, of the tossing, the sea-sickness, the inability to procure cow's milk or suitable food. Neighbours charitably would wet-nurse if their own infants were well, or the supply sufficient. The ship's rations are very good, yet here of no service. The steward has three kinds of milk—Anglo-Swiss, Aylesbury, or Irish. What more can be done? We notice with alarm the depressed fontanelles, the earthy look and smell, the feeble respiration, and the coated tongue; investigatiug a few salient symptoms, whilst the ship gives a lurch, upsetting nurse, patient, physician, and prescription—the stethoscope in one direction, the case-book in another, probably a seasick victim included in the catastrophe oft repeated. Then the weary song of the hot night, restless and disturbed, specially by the noise made by other invalids. The allowance of beer is half a pint per woman, but as nursing mothers at sea require more, an extra supply, on representation, has been granted—indeed, everything that could be done under the circumstances has been done, every suggestion liberally, promptly, carried out—Liebig, arrowroot, stimulants all available, the medical officer writing out a case to explain just cause—besides checking expenditure. The women and children carefully examined, vacciuated, weeded, prior to embarkation; the difficulty to be entirely clear of variola, scarlet fever, typhus, measles, hooping-cough, can never be sufficiently estimated. The period of incubation no man can define; on this point, if books and notes were available, some startling instances might be given, just as curious as the instantaneous blaze of an eruptive fever when a child with a trifling cold has been vaccinated in an infected neighbourhood. Not counting ladies, there are in round numbers about 300 women and children on board, the followiug rules having been framed for their guidance:—At 6.30 a.m., all bedding to be rolled up. 7 a.m.: Breakfast. 7.30 a.m.: Quarters vacated until 11 a.m.; scrubbers at work weather permitting. 12 noon: Dinner. 1.30 p.m.: Quarters vacated until 3 p.m.; swabbers clear up and sweep the place out. 4.30 p.m.: Supper. Sunset: All women and children to go below. 8 p.m.: All in bed; swabbers clear up. 8.30 p.m.: Rounds. Thursday all bedding and boxes on deck (weather permitting), the bunks and quarters scrubbed with soap. No wet clothes to be hung in the wash-house or quarters, and all slops at once to be thrown overboard. Sentries prevent auy man entering except husbands and scrubbers. Women and children of dirty habits will be reported; extreme cleanliness must be preserved about the lavatories, and at the same time there must be no waste of water. Having been round these quarters morn, noon, and night as a matter of duty, in addition to that of pleasure, to criticise the arrangements, one cannot help thinking what a fine thing discipline is. Supposing these women had all their own way, what an amount of mortality and pestilence would be generated and communicated to the troops who cost the country so much, and whose health on landing in India is of such paramount importance! As it is, taking and keeping young children on deck for so many hours has objections in the way of diarrhœa, bronchitis, croup, hooping-cough, and convulsions; also in the way of severe neuralgia, menorrhagia, and tonsillitis, affecting mothers; the complaints, however, in many instances frivolous, not to say under the circumstances unreasonable. On a sea voyage, menstruation goes all wrong, uterine displacements encouraged by vomiting, digestion goes to ruin from the amount of chlorodyne taken. Women will not stump up and down the deck for exercise; the sea air adds a craving appetite to dyspepsia, the best treatment consisting of impromptu dances. The ladies take one side of the deck, the soldiers' wives another; the fiddles strike up galops and waltzes, and thus the demons of malaise, depression, muddy complexion, and morning headaches are expelled. "I love dancing," said a matter-of-fact count to a lovely, fascinating, and conversational partner who deserved a more gallant remark; "it *do* make me perspire." By good luck, Dr. Doyle, R.N., has "Trousseau" on board, where it is recorded that in 1854 a troop-ship proceeding to the Crimea put back to Plymouth, variola having broken out. Cleansed, fumigated, she started again, the disease after fifteen days at sea reappearing. On the next voyage, although every sanitary precaution had been adopted, a similar outbreak again occurred. In other books, also, are wonderful narratives to show that yellow fever for a length of time has been conveyed in the coals. All these lessons urge upon those concerned the careful examination of troops before embarkation, the most rigid precautions during the voyage; and as regards landing and marching in a new country, possibly more anon. Respecting the men, so far, nothiug to record—the bread, biscuit, soup, puddings, rice, preserved meat, potatoes, tea, beer, all satisfactory; and as at the canteen no intoxicating liquors are sold, no drunkenness, scarcely any crime. The sailors, hard-working, contented, and happy, differ from soldiers in being too proud to appear at hospital unless seriously ill. One man is stated to have fallen overboard, fracturing his wrist and losing his cap, yet in extreme peril, Jack first swims for his cap, next for his life, even when hauled on board saying nothing about his hand. What a contrast is the bright, active, dare-devil, honest sailor up in the rigging to the same man drunk and squandering his pay on shore at Portsmouth! Leaving Malta on a Thursday morning, on the following Monday the entrance to the Suez Caual is reached at Port Saïd, consisting of a breakwater, a lighthouse, a harbour, and a curious town—a cross between Aldershot and Charlton Fair—huts and houses, shops and gay stalls in the sand. Egyptian soldiers, Arabs in dressing gowns and surplices—many blind on one side or pitted with variola, scraggy women squatting in the market veiled up to the eyes, half-naked boys, with mules, camels, and dogs are met with. Passing by Dr. Salem, physician and surgeon—advice gratis from nine to one—with a fine array of drugs in the background, hotels, warehouses, and photographic pictures (exiles from Holywell-street), the visitor will only be too glad to take a return boat to the vessel, which in the present case looked magnificent—a kind of floating crystal palace. There are numerous vessels in the harbour, besides enormous dredging-machines, which are constantly at work up and down the canal—the most interesting achievement for centuries: about 86 miles long, 120 feet wide, 30 feet deep, the channel marked out by buoys, the water blue, the banks, at first about six feet, shelving outwards; and beyond the telegraphic posts, an occasional camel or a congregation of red-legged flamingoes, we see nothing but the broad expanse of the dry dreary desert and the bright blue sky overhead. A ship in front runs aground, and we just manage to pass her by triumphantly, shortly after to meet the same misfortune; but the tug, the arrangement of sail, besides the shifting of weight, overcome the difficulty. It is curious to notice myriads of little fish in the eddy swell and return of the stream, for the instant helpless and flopping in the moist sand. There is a pleasant breeze, the thermometer 70° Fahr. Everyone, impressed with the solitary grandeur,

remains on deck, even neglecting meals. But the sick-list is vexing: one little child, dry nursed, has succumbed to diarrhœa with bronchitis, and to-night, when we anchor, a simple solitary grave will be dug in the Egyptian sand. Others are very ill, having caught cold or else malarious fever at Malta, which, although transient to adult men, becomes serious to childreu or nursing mothers. The banks of the canal gradually inclining upwards about thirty feet, after a time the progress resembles that of a railway train through a chalk-cutting, occasionally relieved by a small hut or a signal station. The baby spoken of just now, put into a coffin wrapped rouud with a union jack, was taken on shore in the steam pinnace, aud, the funeral party scrambling up the embankment (sinking deeply at every step), gradually reached the burrow dug in the drifting sand, where, by a lantern's light, the clergyman in his surplice read the burial service over the poor little innocent—a scene singularly impressive; and as the moon photographed the hull, masts, rigging, and ropes of the *Serapis* on the banks of the canal, the solemn awful silence of the vast desert, the bright stars overhead, and the soft balmy air of Egypt, every trivial thought changed into scrious reflection. The next day, passing Ismailia and Lake Timsat, noticing houses and ships, we increase speed to nine knots, and drawing twenty feet of water, the Bitter Lake, dotted with posts and marked with a light-house, is traversed. The general effect and colour of the water resembling the Mediterranean, scanty vegetation and lofty mountains of sand, a great expanse like glass, dotted with a tug here and a dredging machine there, and an occasional vessel. To-day, cases of ophthalmia, trifling as yet, children with diarrhœa, men with syphilis, gonorrhœa, skin eruptions, boils, and trifling ulcers, present themselves. The atmosphere very pleasant, uot the least salt. The bath-water, contrary to expectation, without the slightest tendency to produce smarting. Neither bird, beast, nor fish seen. Last night in the cabins a little stuffy—so it would be in an enormous man-of-war anchored in the Regent's Canal. Distance, 2200 miles to Malta, 1000 thence to Port Saïd, and 86 on to Suez; total, 3286 miles from London. Thermometer 94° Fahr.—on deck near the sweet water canal, in sight of the railway and large houses, docks, hotels, hospital, churches, etc., below the mountains—in fact, SUEZ.

COMMUNICATIONS have beeu received from—

MR. IRVING DE LISLE; Mr. JOHN ST. S. WILDERS; Mr. R. H. LEACH; Dr. SHAPTER; Dr. F. R. WILSON; Mr. J. CHATTO; Dr. HANDFIELD JONES; Dr. T. GRAINGER STEWART; Mr. CAMDEN; Dr. INMAN; Dr. BRUCE; Mr. J. H. THOMAS; Mr. MACONOCHIE; Dr. FAYRER; Dr. G. H. EVANS.

BOOKS RECEIVED—

Thorpe's Quantitative Chemical Analysis—Du Traitement des Rétrécissements de L'Urèthre par la Dilatation Progressive, par T. B. Curtis, M.D.—Liddle's Report on the Sanitary Condition of the Whitechapel District of the Board of Works—Munro on the Science and Art of Nursing the Sick—Posthumous Works of Napoleon III. in Exile, collected and arranged by Count la Chappelle—History of the American Ambulance established in Paris during the Siege of 1870-71, by Thomas W. Evans, M.D., D.D.S., Ph.D.—Ross's Report on the Sanitary Condition of St. Giles's District—Annual Report of the Manchester and Salford Sanitary Association—Fox on the Nature of Zymotic Diseases.

PERIODICALS AND NEWSPAPERS RECEIVED—

APPOINTMENTS FOR THE WEEK.

September 6. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

8. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

9. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West Loudon, 3 p.m.

10. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; Loudon, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

11. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

12. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, August 30, 1873.

BIRTHS.

Births of Boys, 1096; Girls, 1061; Total, 2160.
Average of 10 corresponding years 1863-72, 2017·0.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·63 in. The highest was 29·78 in. on Wednesday morning, and the lowest 29·32 in. on Thursday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION will be opened on WEDNESDAY, OCTOBER 1st, with an Introductory Address, at 4 p.m., by Professor Edgar Sheppard, M.D.

LECTURERS.

Anatomy, Descriptive and Surgical—Prof. John Curnow, M.D.
Physiology— } Prof. W. Rutherford, M.D.
Practical Physiology— } Demonstrator: Urban Pritchard, M.D.
Chemistry— } Prof. C. L. Bloxam, F.C.S.
Practical Chemistry— } Demonstrator: W. N. Hartley, F.C.S.
Medicine, Principles and Practice of—Prof. George Johnson, M.D.
Surgery, Principles and Practice of—Prof. John Wood, F.R.S.
Clinical Surgery—Prof. Sir William Fergusson, Bart., F.R.S.
Hygiene—Prof. W. A. Guy, M.B., F.R.S.
Botany—Prof. Robert Bentley, F.L.S.
Materia Medica and Therapeutics—Prof. A. B. Garrod, M.D., F.R.S.
Obstetric Medicine and the Diseases of Women and Children—Prof. W. Playfair, M.D.
Forensic Medicine—Prof. D. Ferrier, M.A., M.D.
Comparative Anatomy—Prof. T. Rymer Jones, F.R.S.
Pathological Anatomy—Prof. L. S. Beale, M.B., F.R.S.
Dental Surgery—Prof. Samuel Cartwright, F.R.C.S.
Ophthalmology—Prof. J. Soelberg Wells, M.D., F.R.C.S.
Practical Surgery—Prof. John Wood, F.R.S.
Psychological Medicine—Prof. Edgar Sheppard, M.D.
Dean of the Faculty—Prof. Bentley, F.L.S.
Medical Tutor—Evan B. Baxter, M.D.

KING'S COLLEGE HOSPITAL.

CLINICAL LECTURES are given five times a week by the Physicians and Surgeons. Clinical Instruction is also given in Diseases of the Throat and in Skin Diseases.

Physicians—Dr. G. Johnson, Dr. L. S. Beale, Dr. A. B. Garrod, Dr. Duffin.
Assistant-Physicians—Dr. Yeo, Dr. Kelly.
Physician for Diseases of Women and Children—Dr. W. Playfair.
Assistant Obstetric Physician—Dr. T. C. Hayes.
Surgeons—Sir W. Fergusson, Bart.; John Wood, F.R.C.S.; H. Smith, F.R.C.S.
Surgeon-Dentist—S. Cartwright, F.R.C.S.
Ophthalmic Surgeon—J. Soelberg Wells, M.D., F.R.C.S.
Assistant-Surgeon—H. Royes Bell, F.R.C.S.
Pathological Registrar—C. Kelly, M.D.
Sambrooke Registrars—R. Birch, M.R.C.S.; W. Rose, M.R.C.S.
Administrator of Chloroform—Charles Moss, M.R.C.S.
Vaccinator—W. Dunu, Esq.

An Ophthalmic Department and a Ward for Children are attached to the Hospital.

The Physician's Assistant, Physician-Accoucheur's Assistant, and House-Surgeon, as also their assistants, clinical clerks, and dressers, are selected by examination from among the Students, without extra fees.

SCHOLARSHIPS, REGISTRARSHIPS, AND PRIZES.

WARNEFORN SCHOLARSHIPS.—Students entering the Medical Department of this College in October, 1873, will have the exclusive privilege of contending for two Scholarships of £25 each for three years. These Scholarships are given for proficiency in Divinity, Classics, Mathematics, History, and English. The subjects may be ascertained by applying to the Secretary.

Five Medical Scholarships are awarded at the close of each Winter Session for proficiency in professional subjects—viz., one of £40 for two years, one of £30 for one year, and three of £20 for one year.

A Warneford Scholarship of £25 for two years is also annually awarded for proficiency in Divinity and Hospital Practice.

SAMBROOKE REGISTRARSHIPS.—Two of £50, tenable for two years, are annually awarded to matriculated Students of this department.

DANIELL SCHOLARSHIP.—One of £20, for two years, given for proficiency in Chemistry, is open to Students of the Medical Department.

Endowed Prizes, of the value of £25, £15, £10, and £4 4s. each, and College Prizes of the value of £60 are annually awarded.

For further information apply personally, or by letter marked outside "Prospectus," to J. W. Cunningham, Esq., Secretary.

Sheffield School of Medicine.—

SESSIONS of 1873-4.—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st, when the Introductory Lecture will be delivered by Henry Jackson, Esq., Fellow and Assistant-Tutor, Trinity College, Cambridge, in the Anatomical Theatre at 4 p.m.

LIST OF LECTURES.

Anatomy, Descriptive and Surgical—Mr. Skinner and (Vacant).
Demonstrations of Anatomy—Mr. Clark, Mr. E. Skinner, Mr. T. H. Morton.
Physiology—Mr. Thos. Leeds and Mr. S. Morton.
Principles and Practice of Medicine—Dr. Frank-Smith.
Principles and Practice of Surgery—Mr. W. F. Favell and Mr. Parker, F.R.C.S.; Mr. A. Jackson.
Chemistry—Mr. Allen.
Dental Mechanics—Mr. G. Mosely.
Clinical Medicine—Dr. Bartolomé, Dr. Law, and Dr. Frank-Smith.
Clinical Surgery—Mr. Barber, Mr. W. F. Favell, and Mr. Parker, F.R.C.S.
Practical Surgery—Mr. Hallam.
Practical Physiology—Dr. Thomas.

SUMMER SESSION, commencing MAY 1st, 1874.

Midwifery and Diseases of Women—Dr. Hime.
Materia Medica and Therapeutics—Dr. Young.
Medical Jurisprudence and Toxicology—Mr. Baker and Mr. Harrison.
Botany—Mr. Birks.
Comparative Anatomy—Mr. W. Jackson.
Practical Chemistry—Mr. Allen.
Dental Surgery—Dr. Merryweather.
Demonstrations of Pathology and Microscopy—Mr. Hallam (at the Infirmary).
Demonstrations of Operative Surgery—Mr. Favell and Mr. Parker, F.R.C.S.
Diseases of the Eye—Mr. Clarke.

Perpetual fee for attendance on all the Lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42.

Prospectuses and all further information may be obtained upon application to the Hon. Secretary,

ARTHUR JACKSON, St. James's-row, Sheffield.

St. Thomas's Hospital,

ALBERT-EMBANKMENT, WESTMINSTER-BRIDGE, S.E.—The MEDICAL SESSION for 1873 and 1874 will commence on WEDNESDAY, the 1st OCTOBER, 1873, on which occasion an Inaugural Address will be delivered by Dr. J. Harley, at Two o'clock.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

PRIZES AND APPOINTMENTS FOR THE SESSION.

The Wm. Tite Scholarship, founded by the late Sir Wm. Tite, C.B., M.P., F.R.S., the proceeds of £1000 Consols, tenable for three years, was awarded last Session.

First Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, and £5.

Second Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, £5; the Dresserships and the Clinical and Obstetric Clerkships.

Third Year's Students—Winter Prizes, £20, £15, and £10; Mr. George Vaughan's Cheselden Medal; the Treasurer's Gold Medal; the Grainger Testimonial Prize; the two House-Physiciauships; the two House-Surgeoncies; the Resident Accoucheurships. Two Medical Registrarships, at a salary of £40 each, are awarded to third and fourth years' Students, according to merit.

The Solly Medal, with a Prize of 10 Guineas, will be awarded at the end of the Session to a Student of the third, fourth, fifth, or sixth years, for the best Report of Surgical Cases.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.
Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.
Physicians—Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison.
Obstetric Physician—Dr. Barnes.
Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.
Ophthalmic Surgeon—Mr. Liebreich.
Assistant-Physicians—Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne.
Assistant Obstetric Physician—Dr. Gervis.
Assistant-Surgeons—Mr. F. Mason, Mr. Hy. Arnott, Mr. W. W. Wagstaffe.
Dental Surgeon—Mr. J. W. Elliott.
Resident Assistant-Physician—Dr. Evans.
Resident Assistant-Surgeon—Mr.
Apothecary—Mr. R. W. Jones.

Medicine—Dr. Peacock and Dr. Murchison. Surgery—Mr. Sydney Jones and Mr. MacCormac. General Pathology—Dr. Bristowe. Physiology and Practical Physiology—Dr. Ord and Dr. John Harley. Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe. Anatomy in the Dissecting-room—Anatomical Lecturers, Mr. Rainey and Dr. R. W. Reid. Practical and Manipulative Surgery—Mr. Croft. Chemistry and Practical Chemistry—Dr. A. J. Bernays. Midwifery—Dr. Barnes. Physics and Natural Philosophy—Dr. Stone. Materia Medica—Dr. Clapton. Forensic Medicine and Hygiene—Dr. Stone and Dr. Gervis. Comparative Anatomy—Mr. C. Stewart. Ophthalmic Surgery—Mr. Liebreich. Botany—Mr. A. W. Bennett. Dental Surgery—Mr. J. W. Elliott. Demonstrations Morbid Anatomy—Dr. Payne. Mental Diseases—Dr. Wm. Rhys Williams.

T. B. PEACOCK, M.D., Dean.
R. G. WHITFIELD, Medical Secretary.

For entrance or prospectuses, and for information relating to Prizes and all other matters, apply to Mr. Whitfield, Medical Secretary, St. Thomas's Hospital, S.E.

Middlesex Hospital College.—The

WINTER SESSION, 1873-74, will open on OCTOBER 1st with an Introductory Address, at 3 o'clock, by Mr. Henry Morris, M.A., F.R.C.S.

The Medical College attached to the Hospital provides the most complete means for the education of Students who are preparing for the Examinations of the University of London, the Colleges of Physicians and Surgeons, and the Society of Apothecaries.

Some members of the staff receive Students as boarders.

MIDDLESEX HOSPITAL ENTRANCE SCHOLARSHIPS.—Two Entrance Scholarships, of the annual value of £25 and £20 respectively, each tenable for two years, are awarded at the commencement of the Winter Session. For the College prospectus, containing information as to fees, Entrance and other Scholarships, Clinical Appointments, residence of Students, &c., apply to the Dean.

JOHN MURRAY, M.D., Dean.

Liverpool Royal Infirmary School of

MEDICINE.—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st. The Introductory Address will be delivered by Dr. Caton at 3 p.m.

The New Buildings, including a Museum, a complete series of Chemical Laboratories, a Physiological Laboratory, and an additional Dissecting-room, are now completed.

HOSPITAL PRACTICE.—ROYAL INFIRMARY.

Physicians—Dr. Turnbull, Dr. A. T. H. Waters, Dr. Glynn.
Surgeons—Mr. Stubbs, Mr. Bickersteth, Mr. Hakes.
Assistant-Surgeon—Mr. Reginald Harrison.

LECTURES.—WINTER SESSION.

Principles and Practice of Medicine—A. T. H. Waters, M.D., F.R.C.P.
Principles and Practice of Surgery—Reginald Harrison, F.R.C.S.
Physiology—Richard Caton, M.D.
Anatomy—W. Mitchell Banks, F.R.C.S.
Pathology—Alexander Davidson, M.A., M.D.
Ophthalmology—T. Shadford Walker, M.R.C.S.
Chemistry—J. Campbell Brown, D.Sc. Lond.
Anatomical Demonstrations—Michael Harris, M.B.
Histological Demonstrations—Rushton Parker, M.B., B.S., F.R.C.S.

The School of Medicine adjoins the Royal Infirmary and Lock Hospital, and is situated in the immediate neighbourhood of the Eye and Ear Infirmary, the Lying-in Hospital, and the Dispensary for Skin Diseases, where excellent opportunities are afforded for the practical study of these specialties.

A prospectus of the School and further information may be obtained from the Registrar, Mr. Reginald Harrison, 51, Rodney-street, Liverpool.

RULES AND REGULATIONS

OF THE

EXAMINING MEDICAL BODIES IN ENGLAND.

SESSION 1873-74.

EXTRACTS FROM THE REGULATIONS OF THE GENERAL MEDICAL COUNCIL ON THE SUBJECTS OF REGISTRATION OF MEDICAL STUDENTS AND PRELIMINARY EXAMINATIONS.

REGISTRATION OF MEDICAL STUDENTS.

The following regulations have been adopted by the General Medical Council in reference to the registration of students of Medicine:—

1. Every medical student shall be registered in the manner prescribed by the General Medical Council.

2. No medical student shall be registered until he has passed a preliminary examination, as required by the General Medical Council.

3. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration.

4. The registration of medical students shall be placed under the charge of the Branch Registrars.

5. Each of the Branch Registrars shall keep a register of medical students according to the subjoined form:—

Form for the Registration of Medical Students.

Date of Registration.	Name.	Preliminary Examination and Date.	Place of Medical Study.

6. Every person desirous of being registered as a medical student shall apply to the Branch Registrar of the division of the United Kingdom in which he is residing, according to the annexed form, which may be had on application to the several qualifying bodies, medical schools, and hospitals; and shall produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination, as required by the General Medical Council, and a statement of his place of medical study.

7. The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration.

8. Each of the Branch Registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he his Registrar, a sufficient number of blank forms of application for the registration of medical students.

9. The several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory.

10. A copy of the Register of Medical Students, prepared by each of the Branch Registrars, shall be transmitted, on or before December 31 in each year, to the Registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Acts, and through the Branch Registrars to the several medical schools and hospitals.

11. The several qualifying bodies are recommended not to admit, after October, 1870, to the final examination for a qualification under the Medical Acts, any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least four years previously.

In the case of candidates from other than schools of the United Kingdom the Branch Councils shall have power to admit exceptions to this recommendation.

PRELIMINARY EXAMINATION IN ARTS RECOGNISED BY THE GENERAL MEDICAL COUNCIL.

"That testimonials of proficiency granted by the national educational bodies, according to the subjoined list, may be accepted, the Council reserving the right to add to or take from the list." (A degree in Arts of any university of the United Kingdom, or of the colonies, or of such other universities as may be specially recognised from time to time by the Medical Council, is considered a sufficient testimonial of proficiency.)

LIST OF EXAMINING BODIES WHOSE EXAMINATIONS FULFIL THE CONDITIONS OF THE MEDICAL COUNCIL AS REGARDS PRELIMINARY EDUCATION.

I. Universities of the United Kingdom: Oxford: Examination for a Degree in Arts; Responsions; Moderations; Local Examinations (Senior), certificate to include Latin and Mathematics. Cambridge: Examination for a Degree in Arts; Previous Examination; Local Examination (Senior), certificate to include Latin and Mathematics. Durham: Examination for a Degree in Arts; Examination for students in their second and first years; Registration Examination for Medical Students; Local Examinations (Senior), certificate to include Latin and Mathematics. London: Examination for a Degree in Arts; Matriculation Examination. Aberdeen, Edinburgh, Glasgow, St. Andrews: Examination for a Degree in Arts; Preliminary Examination for Graduation in Medicine or Surgery. Edinburgh: Examination of (Senior) Candidates for Honorary Certificates under the Local Examinations of the University of Edinburgh. Dublin: Examination for a Degree in Arts; Entrance Examination. Queen's University (Ireland): Examination for a Degree in Arts; Entrance Examination; Examination for the Diploma of Licentiate in Arts; Previous Examination for B.A. Degree.

II. Other bodies named in Schedule (A) to the Medical Act.—Royal College of Surgeons of England: Examination conducted under the superintendence of the College of Surgeons, by the Board of Examiners of the Royal College of Preceptors. The Society of Apothecaries of London: Examination in Arts. Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh: Preliminary Examination in General Education, conducted by a board appointed by these two Colleges combined. Faculty of Physicians and Surgeons of Glasgow: Preliminary Examination in General Literature. Royal College of Surgeons in Ireland: Preliminary Examination, certificate to include Mathematics. Apothecaries' Hall of Ireland: Preliminary Examination in General Education.

III. Examining Bodies in the United Kingdom, not included in Schedule (A) to the Medical Act.—Royal College of Preceptors: Examination for a first-class certificate.

IV.—Colonial and Foreign Universities and Colleges.—Universities of Calcutta, Madras, and Bombay: Entrance Examination, certificate to include Latin. M'Gill College, Montreal: Matriculation Examination. University of Toronto; King's College, Toronto; Queen's College, Kingston; and Victoria College, Upper Canada: Matriculation Examination. King's College, Nova Scotia: Matriculation Examination; Responsions. Dalhousie College and University, Halifax, Nova Scotia: Matriculation Examination. University of Fredericton, New Brunswick: Matriculation Examination. University of Melbourne: Matriculation Examination, certificate to include all the subjects required by the General Medical Council. University of Sydney: Matriculation Examination. Codrington College, Barbadoes: 1. English certificate for students of two years' standing, specifying the subjects of examination; 2. Latin certificate, or "Testamur." Tasmanian Council of Education: Examination for the degree of Associate of Arts, certificate to include Latin and Mathematics. Christ's College, Canterbury, New Zealand: Voluntary Examinations, certificate to include all the subjects required by the General Medical Council. The Examiners for Commissions in the Military and Naval Services of the United Kingdom: Certificate to include all the subjects required by the General Medical Council. Cape of Good Hope: Third class certificate in Literature and Science, granted by the Board of Public Examiners. South Australia, South Australian Institute, Adelaide: Preliminary General Examination.

FORM OF APPLICATION FOR REGISTRATION AS A MEDICAL STUDENT.

I hereby apply to be registered as a student in Medicine, in conformity with the Regulations of the General Council of Medical Education and

Registration of the United Kingdom, for which purpose I submit the following particulars :—

Name of Applicant. (To be written in words at length.)		Preliminary Examination.	Date of Preliminary Examination.	Place of Medical Study.
Surname.	Christian Name.			

Applicant's Signature,

Address,

Date of Application,

To the Registrar of the Branch Council for

N.B.—The above form of application, duly and legibly filled up, must be forwarded to the Registrar, post free, and be accompanied by a certificate of the applicant's having passed a preliminary examination as required by the General Medical Council, and a statement of his place of medical study. The certificate of examination must testify that the student has been examined in—1. English Language, including grammar and composition; 2. Arithmetic, including vulgar and decimal fractions; Algebra, including simple equations; 3. Geometry—first two books of Euclid; 4. Latin, including translation and grammar. And in one of the following optional subjects—Greek; French; German; Natural Philosophy, including mechanics, hydrostatics, and pneumatics.

UNIVERSITY OF OXFORD.

DEGREES IN MEDICINE.

Every student in Medicine is required to pass all the examinations for the degree of B.M., and to reckon the time of his medical study from the final examination for Arts.

1. Candidates for the degree of B.M. are required to pass two examinations, each of which is held yearly in full Michaelmas Term, usually at the end of November, due notice being given, in the usual manner, by the Regius Professor of Medicine. Each examination is conducted by the Regius Professor of Medicine and three persons who have been admitted to Regency either as Masters of Arts or as Doctors, and who are nominated yearly by the Vice-Chancellor, subject to the approval of Convocation. Each examination is conducted partly in writing, partly *vivâ voce*, and part of each is practical. The subjects of the first examination are Human Anatomy and Physiology, Comparative Anatomy and Physiology to a certain extent, and those parts of Mechanical Philosophy, Botany, and Chemistry which illustrate Medicine. The subjects of the second examination are the Theory and Practice of Medicine (including Diseases of Women and Children), the Materia Medica, Therapeutics, Pathology, the Principles of Surgery and Midwifery, Medical Jurisprudence, and General Hygiene. Every candidate at this second examination is to be examined in two of the ancient authors, Hippocrates, Aretæus, Galen, and Celsus, or in one of those four, and in some modern author approved by the Regius Professor.(a) His knowledge of disease also is tested at the bedside, and he is required to make observations with the microscope or any other aids to diagnosis with respect to patients submitted to him.

Before a candidate is admitted to the first of these two examinations, he must have spent two years in professional studies after having passed the examinations required for the degree of B.A., unless he was placed in the first or second class in the School of Natural Science, in which case, if he receive from the public examiners a special certificate of his attainments in Mechanical Philosophy, Chemistry, or Botany, he may be admitted to this examination at once, and need not then be examined again in any science specified in such certificate. Instruction in Natural Science is carried on at the University Museum, where there is practical instruction in Physics, Chemistry, and Anatomy and Physiology, together with courses of lectures by the professors in those and other subjects.(b) Large collections illustrate the several subjects; there is a pathological series, including the collection of Schröder van der Kolk, in the medical department, where there is also a medical laboratory. The Radcliffe Library, containing nearly 20,000 scientific volumes, is open daily to all students from ten till four, and on certain evenings during term. Before a candidate is admitted to the second examination, he must have completed sixteen terms from the date of the same *testamur* and two years from the date of his *testamur* in the first medical examination, and must deliver to the Regius Professor satisfactory certificates of his attendance at some first-class hospital. Everyone attending to be a candidate at either examination is required to give the Professor notice of his intention a fortnight at least before the week in which the examination is to be held.

No one from another University can be incorporated as a Graduate in Medicine without passing these two examinations.

2. A Bachelor of Medicine wishing to proceed to the degree of Doctor is required to read publicly within the precincts of the Schools, in the presence of the Regius Professor, a dissertation composed by himself on some medical subject approved by the Professor, and to deliver to him a copy of it.

(a) Such as Morgagni, Sydenham, Boerhaave.

(b) Regius Professor of Medicine, H. W. Acland, M.D., LL.D., F.R.S.; Professor of Geometry, H. J. S. Smith, M.A., F.R.S.; Professor of Natural Philosophy, Rev. B. Price, M.A., F.R.S.; Professor of Experimental Physics, R. B. Clifton, M.A., F.R.S.; Professor of Chemistry, W. Odling, M.A.; Linacre Professor of Physiology, G. Rolleston, M.D., F.R.S.; Professor of Zoology, J. O. Westwood, M.A., F.L.S.; Professor of Geology, J. Phillips, D.C.L., F.R.S.; Professor of Mineralogy, N. S. Maskelyne, M.A., F.R.S.; Lee's Reader in Anatomy, J. B. Thompson, B.A.; Demonstrator in Anatomy, Charles Robertson, Esq.; Demonstrator of Chemistry, T. H. G. Wyndham, M.A.; Professor of Botany at the Physic Gardens, M. Lawson, M.A., Magdalen College; Lecturer in Natural Science at Magdalen College, E. Chapman, M.A.; Lee's Reader in Chemistry at Christ Church, A. G. V. Harcourt, M.A., F.R.S.; Lee's Reader in Physics, A. W. Reinold, M.A.

UNIVERSITY OF CAMBRIDGE.

REGULATIONS FOR DEGREES IN MEDICINE AND SURGERY.

Degree of Bachelor of Medicine.—Before a student can become a Bachelor of Medicine he must have resided nine terms (three academical years).

Five years of medical study are required, of which time six terms (two academical years) shall be spent in the University after the student has passed the previous examination. In the case of those who have graduated with honours as Bachelor of Arts, four years of medical study are deemed sufficient, and four terms only of medical study in the University are required.

The previous examination in Classics and Mathematics may be passed in the first or the second term of residence. In addition to the previous examination, the student is required to pass an examination in Algebra at the same time or in some subsequent term.

There are three examinations for M.B.

The first examination is in—1. Mechanics and Hydrostatics; 2. Chemistry, with Heat and Electricity; 3. Botany. Before presenting himself for it the student must have attended lectures on Chemistry, including manipulations, and on Botany. (Students who have obtained honours in any tripos or passed the general examination for B.A. are not required to be examined in Mechanics and Hydrostatics; and those who have passed the special examination in Botany for B.A. are not required to be again examined in that subject.)

Students who have obtained honours in the Natural Science Tripos and have passed satisfactorily in Chemistry, with Heat and Electricity, and Botany, are exempted from this first examination.

The second examination is in—1. Elements of Comparative Anatomy; 2. Human Anatomy and Physiology; 3. Pharmacology. The student must have completed two years of medical study, the time of medical study required to be spent in the University being included in these two years; and must also produce certificates of attendance on lectures on the Elements of Comparative Anatomy, Human Anatomy and Physiology, Materia Medica and Pharmacy, and Pathology; one year's hospital practice, and one season's dissections.

Students who have obtained honours in the Natural Sciences Tripos, and have passed with credit the examinations in Chemistry, Botany, or Comparative Anatomy, are not required to be again examined in those subjects.

The third examination is in—1. Pathology and Practice of Physic (two papers); 2. Clinical Medicine (in the wards of the Hospital); 3. Medical Jurisprudence. The candidate must have completed the course of medical study, and must produce certificates of attendance on one course of lectures on each of the following subjects:—Principles and Practice of Physic, Clinical Medicine, Clinical Surgery, Medical Jurisprudence, and Midwifery; and of having attended hospital practice

during three years, and of having been clinical clerk for six months at a recognised hospital, or of having had special charge of hospital, dispensary, or union patients under a qualified medical practitioner.

After the third examination an Act has to be kept, which consists in reading an original thesis, followed by a *vivâ voce* examination on the subject of the thesis, as well as on other subjects of the Faculty.

The Degree of Doctor of Medicine may be taken three years after M.B. An Act has to be kept, with *vivâ voce* examination, and an essay has to be written extempore. A Master of Arts of four years' standing can proceed direct to M.D., provided he produces the same certificates and passes the same examinations as for M.B.

Degree of Master in Surgery.—The candidate must have passed all the examinations for the degree of M.B., and must produce certificates of having attended a second course of lectures on Human Anatomy, one course of lectures on the Principles and Practice of Surgery, one year's clinical surgical lectures, ten cases of midwifery, a second season of dissections, three years' surgical practice of a recognised hospital, and of having been House-Surgeon or Dresser for six months. The subjects of the examination are—1. Surgical Anatomy; 2. Pathology and the Principles and Practice of Surgery; 3. Clinical Surgery; and 4. Midwifery.

The examinations are partly in writing and partly *vivâ voce* in the dissecting-room and in the hospital. They take place in the Michaelmas and Easter Terms, an interval of two days being allowed to intervene between the first and second examinations for M.B.

All the subjects required for the first and second examinations may be fully studied, and the necessary certificates obtained, in the medical school of the University. The attendance at the Hospital and lectures in Cambridge is also recognised by the University of London, and by the College of Surgeons and the Society of Apothecaries.

UNIVERSITY OF LONDON.

BACHELOR OF MEDICINE.

Every candidate for the degree of Bachelor of Medicine shall be required—

1. To have passed the matriculation examination, or to have taken a degree in Arts in either of the Universities of Sydney, Melbourne, or Calcutta (provided, in the last case, that Latin has been one of the subjects in which he has passed).

2. To have passed the preliminary scientific examination.

3. To have been engaged in his professional studies during four years subsequently to matriculation or graduation in Arts, at one or more of the medical institutions or schools recognised by this University; one year, at least, of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom.

4. To pass two examinations in Medicine.

PRELIMINARY SCIENTIFIC (M.B) EXAMINATION.(a)

The preliminary scientific examination shall take place once in each year, and shall commence on the third Monday in July.

[Candidates for the degree of M.B. are strongly recommended by the Senate to pass the preliminary scientific examination before commencing their regular medical studies; and to devote a preliminary year to preparation for it according to the following programme:—*Winter Session:* Mechanical and Natural Philosophy, Chemistry (especially Inorganic), Zoology. *Summer Session:* Practical Chemistry (Inorganic), Botany.]

No candidate shall be admitted to this examination until he shall have completed his seventeenth year, and shall have either passed the matriculation examination(b) or taken a degree in Arts in either of the Universities of Sydney, Melbourne, or Calcutta (provided, in the last case, that Latin has been one of the subjects in which he has passed); nor unless he have given notice of his intention to the Registrar at least *fourteen days* before the commencement of the examination.

The fee for this examination shall be £5.

Candidates shall be examined in the following subjects of the First B.Sc. examination(c):—Mechanical and Natural Philosophy, Inorganic Chemistry, Botany and Vegetable Physiology, Zoology.

EXAMINATION FOR HONOURS.

Any candidate who has passed the preliminary scientific (M.B.) examination in all its subjects may be examined at the honours examination next following the preliminary scientific (M.B.) examination at which he has passed, in (1) Experimental Physics, (2) Chemistry, (3) Botany, and (4) Zoology; unless he have previously obtained an exhibition in either of these subjects at the first B.Sc. examination, in which case he shall not be admissible to the examination for honours in that subject.

If, in the opinion of the examiners, any candidate of not more than twenty-two years of age at the commencement of the pass examination, who shall have passed either the first B.Sc. examination or the preliminary scientific (M.B.) examination, shall possess sufficient merit, the candidate who shall distinguish himself the most of all the candidates who shall have passed either of the said examinations, and who were not more than twenty-two years of age at the commencement of the pass examination, in Experimental Physics;(d) the candidate who shall have distinguished himself the most of all the candidates who have passed either of the said examinations, and who were not more than twenty-two years of age at the commencement of the pass examination, in Chemistry; the candidate who shall distinguish himself the most of all the candidates who shall have passed either of the said examinations, and who were not more than twenty-two years of age at the commencement of the pass examination, in Botany; and the candidate who shall distinguish himself the most of all the candidates who shall have passed either of the said examinations, and who were not more than twenty-two years of age at the commencement of the pass examination, in Zoology,—shall each receive an exhibition of forty pounds per annum for the next two years, payable in quarterly instalments (it being intended that one exhibition only shall be given in each case among all the candidates, although some of such candidates may have passed the first B.Sc. examination, and others the preliminary scientific (M.B.) examination); provided that on receiving each instalment he shall declare his intention of presenting himself either at the second B.Sc. examination within two academical years(e) from the time of his passing the first B.Sc. examination, or at the first M.B. examination within three academical years from the time of his passing the preliminary scientific (M.B.) examination, as the case may be.

Under the same circumstances the first and second candidates for honours in Experimental Physics shall each receive a Neil Arnott Bronze Medal.

FIRST M.B. EXAMINATION.

The first M.B. examination shall take place once in each year, and shall commence on the last Monday in July.

No candidate shall be admitted to this examination unless he have passed the preliminary scientific examination at least one year previously,(f) and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the matriculation examination, or taken a degree in Arts in one of the before-named universities, been a student during two years at one or more of the medical institutions or schools recognised by this University; and of having attended a course of lectures on each of three of the subjects in the following list:—Descriptive and Surgical Anatomy, General Anatomy and Physiology,

(a) Candidates who matriculated previously to January, 1861, will not be required to pass the preliminary scientific (M.B.) examination in any other subjects than Chemistry and Botany; and they will be allowed to pass the preliminary scientific examination and the first M.B. examination in the same year if they so prefer.

(b) A certificate of age must be produced by every candidate who passed the matriculation examination in the preceding January or June.

(c) Candidates who shall pass in all the subjects of the preliminary scientific (M.B.) examination, and also *at the same time* in the Mathematics of the first B.Sc. examination, shall be considered as having passed both the preliminary scientific examination and also the first B.Sc. examination, without being required to pay an additional fee; and candidates who shall pass in all the subjects of the preliminary scientific (M.B.) examination, and who shall have *previously* passed the first B.A. examination, shall be admissible to the second B.Sc. examination.

(d) The Exhibition in Experimental Physics having been provided by the liberal endowment of Dr. Arnott, will be entitled "The Neil Arnott Exhibition."

(e) By the term "academical year" is ordinarily meant the period intervening between any examination and an examination of a higher grade in the following year, which period may be either *more* or *less* than a calendar year. Thus the interval between the *first* examinations in Arts, Science, and Medicine, and the *second* examinations of the next year in those Faculties respectively, is about sixteen months; whilst the interval between the second B.A. examination and the M.A. examination of the next year, or between the second B.Sc. examination and the D.Sc. examination of the next year, is less than eight months. Nevertheless, each of these intervals is counted as an "academical year." Candidates who had attained the age of 21 years before January 1, 1860, are admissible to the successive examinations for degrees in Science without the intervals between them prescribed by the Regulations. Candidates who have been admitted to the first B.Sc. examination within six months after passing the matriculation examination will be required to give evidence of having completed their 18th year.

(f) *See* footnote (a).

**

Comparative Anatomy, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the matriculation examination, or taken a degree in Arts, dissected during two winter sessions. 4. Of having, subsequently to having passed the matriculation examination, or taken a degree in Arts, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry; in applying tests for discovering the adulteration of articles of the Materia Medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, etc. 5. Of having attended to practical pharmacy, and of having acquired a practical knowledge of the preparation of medicines.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the commencement of the examination.

The fee for this examination shall be £5.

Candidates shall be examined in the following subjects:—Anatomy, Physiology,(g) Materia Medica and Pharmaceutical Chemistry, Organic Chemistry.

EXAMINATION FOR HONOURS.

Any candidate who has been placed in the first division at the first M.B. examination may be examined at the Honours examination next following the first M.B. examination at which he has passed, for honours in (1) Anatomy, (2) Physiology, Histology, and Comparative Anatomy, and (3) Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry. If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy, the candidate who shall distinguish himself the most in Physiology, Histology, and Comparative Anatomy, and the candidate who shall distinguish himself the most in Materia Medica, Pharmaceutical Chemistry, and Organic Chemistry, shall each receive an exhibition of £40 per annum for the next two years, payable in quarterly instalments; provided that on re-receiving each instalment he shall declare his intention of presenting himself at the second M.B. examination within three academical years(h) from the time of his passing the first M.B. examination. Under the same circumstances, the first and second candidates in each of the preceding subjects shall each receive a gold medal of the value of £5.

SECOND M.B. EXAMINATION.(i)

The second M.B. examination shall take place once in each year, and shall commence on the first Monday in November. No candidate shall be admitted to this examination within two academical years(k) of the time of his passing the first examination, nor unless he have produced certificates to the following effect:—1. Of having passed the first M.B. examination. 2. Of having, subsequently to having passed the first M.B. examination, attended a course of lectures on each of two of the subjects comprehended in the list previously given,(l) and for which the candidate had not presented certificates at the first M.B. examination. 3. Of having conducted at least twenty labours. (Certificates on this subject will be received from any legally qualified practitioner in Medicine.) 4. Of having attended the surgical practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the medical practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. N.B.—The student's attendance on the surgical and on the medical hospital practice specified in Regulations 4 and 5 may commence at any date after his passing the preliminary scientific examination, and may be comprised either within the same year or within different years; provided that in every case his attendance on surgical and medical hospital practice be continued for at least eighteen months subsequently to his passing the first M.B. examination. Attendance during three months in the wards of a lunatic asylum recognised by the University, with clinical instruction, may be substituted for a like period of attendance on medical hospital practice.(m) 6. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients in a hospital, infirmary, dispensary, or parochial union, during six months. 7. Of having acquired proficiency in vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate shall also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

The fee for this examination shall be £5.

Candidates shall be examined in the following subjects:—General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations shall include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. N.B.—Candidates will be expected to write prescriptions in Latin, without abbreviations. The Senate desire it to be understood that Bachelors of Medicine of the University of London have no right as such to assume the title of Doctor of Medicine.

EXAMINATION FOR HONOURS.

Any candidate who has been placed in the first division at the second M.B. examination may be examined at the honours examination next following the second M.B. examination at which he has passed, for honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine shall receive £50 per annum for the next two years, with the style of University Scholar in Medicine.

Under the same circumstances, the candidate who shall distinguish himself the most in Obstetric Medicine shall receive £30 per annum for the next two years, with the style of University Scholar in Obstetric Medicine.

Under the same circumstances, the candidate who shall distinguish himself the most in Forensic Medicine shall receive £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine.

Under the same circumstances, the first and second candidates in each of the preceding subjects shall each receive a gold medal of the value of £5.

BACHELOR OF SURGERY.

The examination for the degree of Bachelor of Surgery shall take place once in each year, and shall commence on the Tuesday following the fourth Monday in November.

No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having passed the second examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

The fee for this examination shall be £5.

The examinations comprise Surgical Anatomy and Surgical Operations, by printed papers. Examination, and report on cases, of surgical patients; performance of surgical operations upon the dead subject; application of surgical apparatus; *vivâ voce* interrogation.

EXAMINATION FOR HONOURS.

Any candidate who has been placed in the first division at the B.S. examination may be examined at the honours examination next following the B.S. examination at which he has passed, for honours in Surgery.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most shall receive fifty pounds per annum for the next two years, with the style of University Scholar in Surgery.

Under the same circumstances, the first and second can-

(g) Any candidate shall be allowed, if he so prefer, to postpone his examination in Physiology from the first M.B. examination at which he presents himself for examination in the remaining subjects until the first M.B. examination in the next or any subsequent year; but such candidate shall not be admitted to compete for honours on either occasion; and he shall not be admitted as a candidate at the second M.B. examination until after the lapse of at least twelve months from the time of his passing the examination in Physiology.

(h) *See* foot note (e).

(i) Any candidate for the second M.B. examination who has passed the first M.B. examination under the former regulations will be required to have also passed the examination in Physiology at some previous first M.B. examination carried on under the present regulations, at which examination he shall not be allowed to compete for honours.

(k) *See* footnote (e).

(l) *See* First M.B. Examination, Clause 2.

(m) The Senate regard it as highly desirable that candidates for the degree of M.B. should practically acquaint themselves with the different forms of insanity by attendance in a lunatic asylum.

didates shall each receive a gold medal of the value of five pounds.

MASTER IN SURGERY.

The examination for the degree of Master in Surgery shall take place once in each year, and shall commence on the fourth Monday in November.

No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery(n) in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University—*a*. To clinical or practical surgery during two years in a hospital or medical institution recognised by this University; *b*. Or to clinical or practical surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; *c*. Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on clinical or practical surgery, or two years of practice, will be dispensed with in the case of those candidates who, at the B.S. examination, have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

The fee for the degree of Master in Surgery shall be £5.

The examination shall be conducted by means of printed papers and *viva voce* interrogation, and includes Logic and Moral Philosophy. Any candidate who has taken the degree either of B.A., B.Sc., or M.D. in this University is exempted from this part of the examination; and any candidate who has passed the second M.B. examination may at any subsequent M.S. examination present himself for Logic and Moral Philosophy alone, if he so prefer; thereby gaining exemption, if he should pass, from examination in that subject when he presents himself to be examined for the degree of Master in Surgery. Surgery, including a commentary on a case in Surgery by printed papers; Surgical Anatomy, by printed papers; Surgery, by printed papers. Examination, and report on cases, of surgical patients in the wards of a hospital. Dissection of a surgical region or performance of surgical operations; *viva voce* interrogation.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Surgery at the examination for the degree of Master in Surgery shall receive a gold medal of the value of £20.

DOCTOR OF MEDICINE.

The examination for the degree of Doctor of Medicine shall take place once in each year, and shall commence on the fourth Monday in November. No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having passed the second examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University—*a*. To clinical or practical Medicine during two years in a hospital or medical institution recognised by this University. *b*. Or to clinical or practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. *c*. Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on clinical or practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the second M.B. examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

These certificates shall be transmitted to the Registrar at least *fourteen days* before the examination begins.

The fee for the degree of Doctor of Medicine shall be £5.(o)

The examination shall be conducted by means of printed papers and *viva voce* interrogation, and includes Logic and Moral Philosophy. Any candidate who has taken the degree either of B.A., B.Sc., or M.S. in this University, is exempted from this part of the examination; and any candidate who has passed the second M.B. examination may at any subsequent M.D. examination present himself for Logic and Moral Philosophy alone, if he so prefer; thereby gaining exemption, if he should pass, from examination in that subject when he presents himself to be examined for the degree of Doctor of Medicine.

Medicine, including a commentary on a case in Medicine or Obstetric Medicine, at the option of the candidate, by printed papers. Medicine, by printed papers. Examination and report on cases, of medical patients in the wards of a hospital. *Viva voce* interrogation and demonstration from specimens and preparations.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine at the examination for the degree of Doctor of Medicine shall receive a gold medal of the value of £20.

REGULATIONS RELATING TO CANDIDATES WHO COMMENCED THEIR MEDICAL STUDIES IN OR BEFORE JANUARY, 1839.

Bachelor of Medicine.—Candidates who commenced their professional studies in or before January, 1839, shall be required to pass the preliminary scientific examination in Chemistry and Botany only, and shall be admitted to the first examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during two years in their professional studies. 2. Of having attended a course of lectures on each of four of the subjects comprehended in the list previously given.(p) 3. Of having dissected during nine months. 4. Of having attended to practical Pharmacy during a sufficient length of time to enable them to acquire a practical knowledge in the preparation of medicines.

Candidates who commenced their professional studies in or before January, 1839, shall be admitted to the second examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during four years in their professional studies. 2. Of having passed the first M.B. examination. 3. Of having attended a course of lectures on each of two of the subjects comprehended in the list previously given.(q) 4. Of having dissected during twelve months. 5. Of having attended to practical Pharmacy during a sufficient length of time to enable them to acquire a practical knowledge in the preparation of medicines. 6. Of having conducted at least six labours. 7. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months. 8. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months. 9. Of moral character from a teacher in the last school or institution at which they have studied, so far as the teacher's opportunity of knowledge has extended.

Candidates who have not taken a degree in Arts or passed the matriculation examination in this University, will be required to translate a portion of Celsus *de Re Medicâ*.

REGULATIONS RELATING TO PRACTITIONERS IN MEDICINE OR SURGERY DESIROUS OF OBTAINING DEGREES IN MEDICINE.(r)

Bachelor and Doctor of Medicine.—Bachelor of Medicine.—Candidates shall be admitted to the two examinations for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been admitted prior to the year 1840 members of one of the legally constituted bodies in the United Kingdom for licensing practitioners in Medicine or Surgery; or of having served previously to 1840 as Surgeons or Assistant-Surgeons in her Majesty's Army, Ordnance, or Navy, or in the service of the Honourable the East India Company. 2. Of having received a part of their education at a recognised institution or school, as required by the charter of the University. 3. Of moral character, signed by two persons of respectability.

Candidates who have not taken a degree in Arts, or passed the Matriculation examination in this University, will be required to translate a portion of Celsus *de Re Medicâ*.

Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession shall be admitted to the examination for this degree on producing certificates to the following effect:—1. Of having been engaged during five years in the practice of their profession. 2. Of

(n) Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates, the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

(o) This fee will continue to be £10 to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of £5 at the preliminary scientific examination.

(p) *See* First M.B. Examination, Clause 2.

(q) *See* First M.B. Examination, Clause 2.

(r) All these regulations are applicable exclusively to practitioners who obtained their licences or commissions prior to 1840.

having taken the degree of Bachelor of Medicine in this University.

Candidates who have not taken a degree in Arts, or passed the matriculation examination in this University, will be required to translate a portion of Celsus *de Re Medicâ*.

Examinations in 1873-74.—The following are the dates at which the several remaining medical examinations for the year 1873-74 will commence:—Matriculation: Monday, January 12, 1874. Bachelor of Medicine: Second M.B., Monday, November 3. Bachelor of Surgery: Tuesday, November 25. Master in Surgery: Monday, November 24. Doctor of Medicine: Monday, November 24.

UNIVERSITY OF DURHAM.

For Registration.—No one shall be held to be a student in Medicine who has not been registered in a register kept for that purpose. No one shall be so registered unless he has passed one of the preliminary examinations recommended by the General Medical Council. Every registered student shall receive from the Registrar a certificate of his registration, for which he shall pay the sum of five shillings. The registration examination shall be directed to the rudiments of Religion, Literature and Science, and shall be conducted by two or more examiners nominated by the Warden. The registration examination shall be held twice a year—viz., shortly before the winter session, and shortly before the summer session, of the College of Medicine, Newcastle-upon-Tyne. The registration examination will begin at Durham on Tuesday, September 16, 1873, and on April 14 and September 15, 1874, at 9 a.m. each day. Applications to be made to Arthur Beanlands, Esq., Durham, at least one month before the day of examination, to whom also each candidate must, at the same time, send the examination fee, £1, and a certificate of character, and specify the optional subject in which he wishes to be examined.

Subjects of Examination for September 16, 1873.—Necessary Subjects:—The History contained in the Acts of the Apostles; English Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Euclid, Books I. and II.; Latin Grammar, with Virgil, Æncid, Lib. I. and II.; and one of the following optional subjects:—Greek Grammar, with Xenophon's Memorabilia; French Grammar with Voltaire's Charles XII.; German Grammar, with Goethe's Dichtung und Wahrheit, Book I.; Elementary Questions in Mechanics, Hydrostatics, and Pneumatics.

Subjects of Examination for April 14 *and September* 15, 1874.—Necessary Subjects:—The History contained in the Acts of the Apostles; English Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Euclid, Books I. and II.; Latin Grammar, with—in April, Cæsar, De Bello Gallico, Lib. I. and II.; in September, Virgil, Æneid, Lib. I. and II.; and one of the following subjects:—Greek Grammar with Xenophon's Memorabilia; French Grammar, with Voltaire's Charles XII.; German Grammar, with Goethe's Dichtung und Wahrheit, Book I.; Elementary Questions in Mechanics, Hydrostatics, and Pneumatics. The following examinations are also accepted as qualifications for registration:—1. Durham senior examination of persons not Members of the University. For this, candidates are required to satisfy the examiners in Latin, Algebra (including Simple Equations), Euclid (Books I. and II.); and one of the four following subjects:—(1) Greek, (2) French, (3) German, (4) Mechanics, Hydrostatics, and Pneumatics. 2. Durham examinations for students in Arts in their first year.

The next senior examinations of persons not Members of the University will commence at Durham, on Monday, June 8, 1874, at two o'clock.

For Licences and Degrees.—Candidates for the degrees of M.C., M.B., and M.D., in the University of Durham, are required to reside for three terms, as students in Arts, at the University, either in Durham or in Newcastle.

For the Licence in Surgery.—The regulations are the same as those for the licence in Medicine, except that the final examination is directed more particularly to Surgery, and may or may not be passed at the same time as the final examination for the licence in Medicine.

For the Licence in Medicine.—A candidate must produce certificates of registration as a student in Medicine, of having, after registration, spent four years in medical study at one or more of the schools recognised by the licensing bodies named in Schedule (A) of the Medical Act, 1858, one of the said four years being spent at the University College of Medicine, Newcastle-on-Tyne, of good moral conduct, and of having attained the age of 21 years. There are two examinations; one after the second winter session, the other after the fourth winter session, of medical study. The first is directed to Anatomy, Physiology, and Chemistry; the second to the other branches of medical education, and more particularly to the Practice of Medicine.

For the Degree of Master in Surgery.—A candidate must be a Licentiate in Surgery, and also a Licentiate in Medicine, of the University, and of the standing of eighteen terms (six years) at least from the date of his registration at Durham, and of three terms at least from the date of his admission to the licence in Surgery. He must be a Bachelor of Arts, or have passed the final examination for B.A., or one equivalent thereto, and must have kept one year's residence in Arts, either at Durham in the University, or at Newcastle-upon-Tyne in the Durham University College of Medicine. The examination for this degree is directed chiefly to the Practice of Surgery.

For the Degree of Bachelor of Medicine.—A candidate must be of the standing of one year at least as a Licentiate in Medicine, and of six years at least from the date of his matriculation. He must either be a Bachelor of Arts or have kept one year's residence in Arts, either at Durham in the University, or at Newcastle-upon-Tyne in the Durham University College of Medicine, and have passed the final examination for the degree of B.A., or an equivalent thereto. The examination for this degree is directed chiefly to the Practice of Medicine.

For the Degree of Doctor in Medicine.—A candidate must be of the standing of one year at least as a Bachelor in Medicine of the University of Durham, and of the standing of seven years from the date of his matriculation at Durham, and must perform such exercises as the Warden and Senate require.

The examinations for the licences and degrees in Medicine and Surgery are conducted in Newcastle. Those for the licences: 1. By printed papers of questions. 2. Practically in Anatomy, Physiology, Chemistry, Materia Medica, Pharmacy, Surgery, Medicine, Midwifery, and Medical Jurisprudence. 3. *Vivâ voce* on all the subjects. The examinations are held, except in special cases, yearly in the month of June, at the close of the Easter Term, and are open to Members of the University. The next examination will begin on Monday, June 8, 1874, at 9 a.m. The licences and degrees are conferred in Convocation at Durham. The examiners are appointed yearly by the Warden of the University, and approved by Convocation.

Expenses at Durham.—The average annual cost of residence at University College may be estimated at £80 to £85; at Bishop Hatfield's Hall, at £65 to £70. Students may also, with the consent of the authorities, reside in a private house or lodging (approved by the authorities) without becoming members of any college or hall. The University fees payable by such students will amount to about £20 per annum.

Fees for Examination and Degrees: For senior middle class examination, £1; for examination at the end of first year, £1; for registration examination, £1; for registration, 5s.; for a certificate in Chemistry, 10s.; for each public examination in Medicine or in Surgery, £1; for a licence in Medicine, £3; for a licence in Surgery, £3; for a degree of Master in Surgery, £6; for a degree of Bachelor in Medicine, £6; for a degree of Doctor in Medicine, £6.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

BY-LAWS RELATING TO MEMBERS.

1. The Members of the College, present and future, shall be alone eligible to the Fellowship. They shall have the use of the Library and Museum, subject to the regulations relating thereto, and shall be admitted to all lectures, and shall enjoy such further privileges as may from time to time be defined by the by-laws; but they shall not be entitled to any share in the government, or to attend or vote at general meetings, of the Corporation. 2. All persons who have been admitted, before February 16, 1859, Licentiates of the College, shall be entitled to be admitted Members of the College, provided that they have, since their admission as Licentiates, obeyed the by-laws, and do accept such Membership, and engage henceforth to obey the by-laws of the College. 3. Any extra-Licentiate who shall have produced testimonials as to character satisfactory to the Censors, and shall have assured the said Censors that he is not engaged in the practice of pharmacy, and who shall comply with such other regulations as are required

by the by-laws of the said Corporation, may be proposed to the College to be admitted a Member of the College. 4. Any person who shall have satisfied the College touching his acquirements in general Science and Literature, and his knowledge of Medicine, Surgery, and Midwifery, and who shall comply with the by-laws and regulations of the College, may be proposed to the College to be admitted a Member of the College. 5. Every candidate for the membership of the College, under the last by-law, who shall have commenced his professional studies after September, 1861, shall satisfy the Censors' Board that previously to the commencement of his professional studies he has obtained a degree in Arts from some university of the United Kingdom or of the colonies, or from some other university specially recognised by the Medical Council; or that he has passed examinations equivalent to those required for a degree in Arts. All other candidates for Membership shall be examined on the subjects of general education by the President and Censors of the College. 6. Every candidate for Membership shall furnish proof that he has attained the age of twenty-five years. 7. Every candidate shall produce a testimonial from a Fellow or Member of the College, satisfactory to the Censors' Board, to the effect that, as regards moral character and conduct, he is a fit and proper person to be admitted a Member of the College. 8. Every candidate (*except such as shall be admissible under the provisions of Sections* 15 *and* 16) shall produce proof of his having been engaged in professional studies during a period of five years, of which four years at least shall have been passed at a medical school or schools recognised by the College. 9. Every candidate (*except such as shall be admissible under the provisions of Sections* 15 *and* 16) shall produce evidence, satisfactory to the Censors' Board, of his having studied the following subjects:—Anatomy (with Dissections), during two winter sessions(a); Physiology, during two winter sessions; Chemistry, during six months; Practical Chemistry, during three months; Materia Medica, during three months; Practical Pharmacy, during three months (by Practical Pharmacy is meant instruction in the laboratory of a registered medical practitioner, or of a member of the Pharmaceutical Society of Great Britain, or of a public hospital or dispensary recognised by the College); Botany, during three months (this course of lectures may be attended prior to the commencement of professional studies, and any candidate producing satisfactory evidence that Botany formed one of the subjects of his preliminary examination will be exempt from attendance on this course); Morbid Anatomy, during six months (this includes attendance and instruction in the post-mortem-room during the period of clinical study); Principles and Practice of Medicine, during two winter sessions (it is required that the principles of public health should be comprised in this course of lectures, or in the course of lectures on Forensic Medicine: the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Principles and Practice of Surgery, during *two winter sessions* (the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Clinical Medicine, during *three winter sessions and three summer sessions*(b) (the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Clinical Surgery, during *two winter sessions and two summer sessions* (the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school: by Clinical Medicine and Clinical Surgery are meant special study and instruction at the bedside, with lectures on cases); Midwifery and the Diseases peculiar to Women, during three months (certificates must also be produced of attendance on not less than twenty labours, and of instruction and proficiency in vaccination); Forensic Medicine, during three months; of having attended diligently during three winter sessions and three summer sessions the Medical Practice, *and during three winter sessions and two summer sessions the Surgical Practice*, of an hospital containing at least 100 beds; of having been engaged during six months in the clinical study of Diseases peculiar to Women; and of having served the office of clinical clerk in the medical wards during at least six months. [The requirements printed in italics apply to candidates who commenced their professional education in the United Kingdom on or after October 1, 1867; and to candidates who commenced their professional education at a recognised foreign or colonial school on or after October 1, 1868.] 10. Every candidate who has prosecuted his studies abroad, whether in part or to the full extent required by the preceding by-law (*except such as shall be admissible under the provisions of Section* 16), shall, nevertheless, bring proof of his having attended during at least twelve months the medical practice of an hospital in the United Kingdom containing at least 100 beds. 11. If the Censors' Board doubt the sufficiency of the certificates and testimonials produced by any candidate, or his fitness, in any respect, for admission to examination, they may submit the case to a general meeting of the Fellows. 12. No candidate shall be admitted to examination who is engaged in trade; or who dispenses medicine, or makes any engagement with a chemist, or any other person, for the supply of medicines; or who practises Medicine or Surgery in partnership, by deed or otherwise, so long as that partnership continues. 13. No candidate shall be admitted to examination who refuses to make known, when required by the President and Censors, the nature and composition of any remedy he uses. 14. Every candidate (except in cases specially exempted under Sections 15 and 16) shall give proof of his acquirements by written answers to questions placed before him, and shall be examined *viva voce* at three separate examinations, and shall be approved by the President and Censors, or by the major part of them. 15. Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a university in the United Kingdom wherein the courses of study and the examinations to be undergone by the students previously to graduation shall have been adjudged by the Censors' Board to be entirely satisfactory, shall be exempt (if the Censors shall think fit) from all or any parts of the examinations hereinbefore described, except such as relate to the third or pass examination; the nature and extent of which examination shall, in the case of each candidate, be determined by the Censors' Board. Every candidate for the Membership will, however, be required to translate into English a passage from a Latin author, and he will have the opportunity of showing a knowledge of Greek, or of one or more of the modern European languages. 16. If any candidate who has attained the age of forty years shall produce testimonials not merely satisfactory as to his moral character and conduct and his general and professional acquirements, but further showing that he has improved the art or extended the science of Medicine, or has at least distinguished himself highly as a medical practitioner, the Censors' Board, having well weighed and considered these testimonials, may, if they see fit, submit them to the Fellows at a general meeting, and it shall be determined by the votes of the Fellows present, or of the majority of them, taken by ballot, whether the candidate shall be admitted to examination, which shall, in every such case, be as full and complete as the Censors may deem sufficient. 17. Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule (A) to the Medical Act, and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the primary examination.(c) 18. Any candidate who shall have obtained a degree in Surgery, at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and the Principles and Practice of Surgery. 19. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery.

The fee to be paid for admission as a Member of the College shall be thirty guineas.

BY-LAWS AND REGULATIONS RELATING TO THE EXAMINATION FOR THE MEMBERSHIP.

Every candidate for the Membership of the College (except such as shall be admissible under the provisions of Sections 15 and 16 of the by-laws) will be required to pass the following examinations:—

The first examination, on Anatomy and Physiology, will be conducted on successive days, as follows:—On Monday: Evening, from 7 to 10, by written questions. On Tuesday: Evening, commencing at 7 o'clock, *vivâ voce*, on dissections and preparations.

(a) The winter session comprises a period of six months.

(b) The winter session comprises a period of six months, and the summer session a period of three months.

(c) *See* Regulations relating to the examinations.

The second examination will be conducted as follows:—On Monday: Evening, from 7 to 10, by written questions on Surgical Anatomy, and on the Principles and Practice of Surgery. On Tuesday: Morning—The candidate's practical knowledge will be tested, either at the College or in the surgical wards of an hospital; Afternoon, from 1 to 4, on Materia Medica, and on Chemistry in its applications to Pathology, Pharmacy, and Toxicology. *This Examination will be conducted by written questions and partly in a practical manner.* Evening, commencing at 7 o'clock, by written questions on Midwifery, and the Diseases peculiar to Women. On Thursday, commencing at 7 p.m., examination *viva voce*.

The third or pass examination will be conducted on successive days, as follows:—On Thursday, from 2 to 6, by written questions on Medical Anatomy, and on the Principles of Medicine. On Friday, from 2 to 6, by written questions on the Practice of Medicine, including the Principles of Public Health and on Psychological Medicine. On Saturday or Monday, the candidate's practical knowledge will be tested, either at the College or in the medical wards of an hospital. On Tuesday, examination, *viva voce*. On Wednesday, examination, *viva voce*.

1873.—Third or Pass Examination:—On Thursday, October 23.

1874.—On Thursdays, January 22, April 23, July 23, October 22. The first and second examinations are generally held at the commencement of the same months.

Candidates will not be admitted to the first examination until after the termination of the second winter session of professional study at a recognised medical school, nor to the second examination until after the termination of four years of professional study, nor to the third or pass examination until after the completion of the required course of professional study.

Every candidate must give fourteen days' notice, in writing, to the Registrar of the College, of his intention to present himself for examination, at the same time transmitting the following certificates:—*For the Primary Examination.*—Evidence of having passed an Arts examination; and, in the case of those who shall have commenced professional studies after 1861, evidence of having previously obtained a degree in Arts from some university of the United Kingdom or of the colonies, or from some other university specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a degree in Arts; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised medical school: all other candidates for membership shall be examined on the subjects of general education by the President and Censors of the College. *For the Second Examination.*—Evidence of having completed four years of professional study; of having attained the age of twenty-one years; of instruction and proficiency in the practice of vaccination; and of having attended not less than twenty labours, and of having discharged the duties of clinical clerk, and performed the duties of dresser, for periods of not less than three months. *For the Pass Examination.*—Proof of having attained the age of twenty-five years; a testimonial from a Fellow or Member of the College; evidence of having completed the required course of professional study.

BY-LAWS RELATING TO LICENTIATES.

The College will, under its Charter, grant licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery (which licences are not to extend to make the Licentiates Members of the Corporation), to persons who shall conform to the following by-laws.

Every candidate for the College licence (except when otherwise provided by the by-laws) is required to produce satisfactory evidence to the following effect:—1. Of having attained the age of 21 years. 2. Of moral character. 3. Of having passed, before the commencement of professional study, an examination in the subjects of general education recognised by the College. 4. Of having been registered as a medical student in the manner prescribed by the General Medical Council. ["After October, 1870, every candidate (not exempted from registration) is required to have been registered at least four years previously."] 5. Of having been engaged in professional studies during four years, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—*a*. Attending the practice of a hospital or other institution recognised by the College for that purpose. *b*. Receiving instruction as the pupil of a legally qualified practitioner holding any public appointment which affords opportunities, satisfactory to the examiners, of imparting a practical knowledge of Medicine, Surgery, or Midwifery. *c*. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced *before* the candidate shall have passed an examination in the subjects of general education will not be recognised by the College. 6. *Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals,* of having discharged the duties of clinical clerk at a recognised hospital for a period of not less than three months; of having performed the duties of dresser at a recognised hospital for a period of not less than three months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. 7. Of having studied the following subjects:—Anatomy (with dissections) during two winter sessions; (d) Physiology during two winter sessions; Chemistry during six months; Practical Chemistry during three months; Materia Medica during three months; Practical Pharmacy during three months (by Practical Pharmacy is meant instruction in the laboratory of a registered medical practitioner, or of a member of the Pharmaceutical Society of Great Britain, or of a public hospital or dispensary recognised by the College); Botany during three months (this course of lectures may be attended prior to the commencement of professional studies; and any candidate producing satisfactory evidence that Botany formed one of the subjects of his preliminary examination will be exempt from attendance on this course); Morbid Anatomy during six months (this includes attendance and instruction in the post-mortem room during the period of clinical study); Principles and Practice of Medicine during two winter sessions (it is required that the principles of public health should be comprised in this course of lectures, or in the course of lectures on Forensic Medicine: the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Principles and Practice of Surgery, during *two winter sessions* (e) (the attendance on these lectures must not commence earlier than the second winter session at a recognised medical school); Clinical Medicine, during *two winter sessions and two summer sessions* (e), (the attendance on these lectures must not commence until after the first winter session at a recognised medical school); Clinical Surgery, during *two winter sessions and two summer sessions* (e), (the attendance on these lectures must not commence until after the first winter session at a recognised medical school; by Clinical Medicine and Clinical Surgery are meant special study and instruction at the bedside, with lectures on cases); Midwifery and the Diseases peculiar to Women, during three months (certificates must also be produced of attendance on not less than twenty labours, and of instruction and proficiency in vaccination); Forensic Medicine, during three months. 8. Of having passed the professional examinations.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule (A) to the Medical Act, and recognised by the College as requiring a course of study and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination. (f) Any candidate who shall have obtained a degree in Medicine at a university recognised by the College, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory

(d) The winter session comprises a period of six months, and the summer session a period of three months.

(e) The requirements printed in italics apply to candidates who commenced their professional education in the United Kingdom on or after October 1, 1867; and to candidates who commenced their professional education at a recognised foreign or colonial school on or after October 1, 1868.

(f) *See* Regulations relating to the examinations.

to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

Any candidate, being a "registered medical practitioner," whose qualification or qualifications shall have been obtained before the first day of January, 1861, having been with the consent of the College admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render in his case unnecessary.

Licentiates of this College shall not compound or dispense medicines except for patients under their own care.

BY-LAWS AND REGULATIONS RELATING TO THE EXAMINATION FOR THE LICENCE.

Every candidate for the College licence, before he is admitted to examination, will be required to sign a declaration, stating that he has not been rejected within three months by any of the Examining Boards included in Schedule (A) to the Medical Act.

The first examination, on Anatomy and Physiology, will be conducted on successive days as follows:—On the first day: Evening, from 7 to 10, by written questions. On the second day: Evening, commencing at 7 o'clock, *viva voce*, on dissections and preparations. The second, or pass examination, will be conducted on successive days, as follows:—On the first day: Evening, from 7 to 10, by written questions on Surgical Anatomy, and on the Principles and Practice of Surgery. On the second day: Morning—The candidates practical knowledge will be tested, either at the College or in the surgical wards of an hospital. Afternoon, from 1 to 4, on Materia Medica, and on Chemistry in its applications to Pathology, Pharmacy, and Toxicology.(g) This examination will be conducted partly by written questions and partly in a practical manner. Evening, commencing at 7 o'clock, by written questions on Midwifery and the Diseases peculiar to Women. On the third day: Evening, from 7 to 10, by written questions on Medical Anatomy, and on the Principles and Practice of Medicine, including the Principles of Public Health. On the fourth day: Morning—The candidate's practical knowledge will be tested, either at the College or in the medical wards of an hospital. Evening, commencing at 7 o'clock, *viva voce*, on the Principles and Practice of Medicine, Surgery, and Midwifery.

Candidates will not be admitted to the first examination until after the termination of the second winter session of professional study at a recognised medical school; nor to the second, or pass examination, until after the termination of four years of professional study.

The College does not admit to the pass examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least four years.

Any candidate who shall be rejected at the first examination, will not be re-admitted to examination until after the lapse of three months, and will be required to produce a certificate of the performance of dissections, or other professional study satisfactory to the examiners, during that time.

Any candidate who shall be rejected at the second or pass examination, will not be re-admitted to examination until after the lapse of six months, and will be required to produce a certificate of attendance on the practice of a recognised hospital, and also of attendance on clinical lectures, or other professional study satisfactory to the examiners, during that time.

Every candidate intending to present himself for examination, is required to give fourteen days' notice in writing to the Registrar of the College, at the same time transmitting the following certificates:—For the First Examination: Evidence of having passed an Arts examination, of having been duly registered as a medical student, and of having completed the second winter session of professional study at a recognised medical school. For the Second, or Pass Examination: Evidence of having completed four years of professional study, of having attained the age of 21 years, of instruction and proficiency in the practice of vaccination, of having attended not less than twenty labours, and of having discharged the duties of clinical clerk, and performed the duties of dresser, for periods of not less than three months. A testimonial of moral character is required of every candidate.

Blank forms of the required certificates of attendance on hospital practice and on lectures may be obtained on application at the College.(h)

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule (A) to the Medical Act and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the first examination.

Any candidate who shall have obtained a degree in Medicine at a university recognised by the College, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination.

Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

Any "registered medical practitioner" whose qualification or qualifications shall have been obtained before the first day of January, 1861, having been, with the consent of the College, admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render in his case unnecessary.(i)

The fee for the College licence is fifteen guineas,(k) of which five guineas are to be paid on admission to the first examination, which fee will not be returned to any candidate rejected at this examination, but will be allowed in the fee for the licence, and he will be admitted to one subsequent first examination without the payment of an additional fee.

Any candidate who shall be rejected at the second or pass examination will have the fee paid on admission to this examination returned to him, less three guineas.

(g) Candidates who shall have passed the first examination for the licence at this College before October 1, 1867, are exempted from re-examination on Materia Medica, and on Chemistry in its application to Pharmacy.

Examinations of candidates for the College licence will take place, commencing as follows:—For the first examination on the first Mondays in the months of October and December, 1873, and February, April, July, October, and December, 1874; and for the second, or pass examination, on the second Mondays in the same months.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RELATING TO THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF FELLOW.

SECTION I.—*Preliminary Examination.*—I. Candidates will be required to produce one or other of the following certificates or *testamurs*, viz.:—1. Of Graduation in Arts at a University recognised for this purpose. The following are the Universities at present recognised, viz.:—Oxford, Cambridge, Dublin, London, Durham, Queen's University in Ireland, Edinburgh, Glasgow, Aberdeen, and St. Andrews; Calcutta, Madras, and Bombay; Canada, M'Gill College, Montreal, and Queen's College, Kingston. A certificate or *testamur* of graduation in Arts at a Foreign University, on the special recommendation of the Court of Examiners, approved by the Council. 2. Of having passed such examinations in Arts as shall from time to time be required for graduation in Medicine by a University recognised for this purpose. The following are the Universities at present recognised, viz.:—Oxford, Cambridge, Dublin, London, and Durham. (N.B. In the case of the University of London, the certificate of having passed the Matriculation examination must contain evidence that the candidate passed in Greek and in French or German, in addition to the several compulsory subjects comprised in the examination.) II. Candidates who shall not be able to produce one or other of the foregoing certificates will be required to pass an examination

(h) Hours of attendance, from 11 a.m. to 4 p.m.; Saturdays, from 11 a.m. to 2 p.m.

(i) Forms of application may be obtained of the Registrar of the College.

(k) The fee must be paid three days prior to the day on which the examination commences.

in English, Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of the Council of the College.

The following are the subjects of the examination referred to in the foregoing paragraph for December, 1873, and until further notice, viz. :—

Part I. Compulsory Subjects.—1. Reading aloud a passage from some English author. 2. Writing from dictation. 3. English Grammar. 4. Writing a short English composition; such as a description of a place, an account of some useful or natural product, or the like. 5. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple and compound, of vulgar fractions, and of decimals. 6. Questions on the Geography of Europe, and particularly of the British Isles. 7. Questions on the outlines of English History—that is, the succession of the Sovereigns and the leading events of each reign. 8. Mathematics. Euclid, Books I. and II. or the subjects thereof. Algebra to simple equations inclusive. 9. Translation of a passage from the second book of Cæsar's Commentaries "De Bello Gallico." 10. Translation of a passage from the first book of the Anabasis of Xenophon. 11. Translation of a passage from X. B. Saintine's "Picciola"; or, at the option of the candidate, translation of a passage from Schiller's "Wilhelm Tell."

Part II. Optional Subjects.—Papers will also be set on the following subjects; and each candidate will be required to offer himself for examination on one subject, at his option :— 1. Translation of a passage in French or German, as the case may be, from the before-mentioned works. Besides these translations into English, the candidate will be required to answer questions on the grammar of each subject, whether compulsory or selected. 2. Mechanics. The questions will be chiefly of an elementary character. 3. Chemistry. The questions will be on the elementary facts of Chemistry. 4. Botany and Zoology. The questions will be on the classification of plants and animals. The quality of the handwriting and spelling will be taken into account. N.B. Each candidate (who has not already paid the amount) is required to pay a fee of £2 on the morning of the first day of the examination, prior to his admission thereto. The next examination will be held on or about the third Tuesday or Wednesday in December. The exact dates of the examinations will be duly advertised when fixed in the journals; and candidates are required to send in the prescribed forms of application not less than three weeks before the commencement of the examination.

Note.—*Candidates who passed, prior to the 1st of January, 1870, an examination recognised as equivalent to the preliminary examination for the diploma of Member, will be required in order to qualify for the Fellowship to pass in Algebra, Greek, and French or German, included in Part I., and in one, at their option, of the four subjects included in Part II. of the foregoing examination, and those who passed, subsequently to the 1st of January, 1870, an examination equivalent to that required for the Membership, will have to pass in all the aforesaid subjects excepting Algebra, when the certificate shall contain evidence that this last subject was included in the first-named examination.*

Special Notice.—In the case of candidates, natives of India, the certificates of having passed the matriculation examinations of the Universities of Calcutta, Madras, and Bombay, will be recognised as equivalent to the foregoing preliminary examination, provided that they contain evidence that, in addition to the compulsory subjects thereof, the candidate passed in Latin, and, in lieu of Greek, in one of the Eastern languages comprised in the lists of subjects issued from time to time by the respective Universities.

Section II.—*Professional Education.*—I. Except in the cases and instances hereinafter provided for to the contrary, every candidate for admission to the first or anatomical and physiological examination for the Fellowship is required to produce the following certificates, viz. :—1. Of having passed the preliminary examination appointed by the Council, or such other examination as the Council may from time to time determine to be equivalent thereto. 2. Of having studied Practical Pharmacy during three months. 3. Of having attended lectures on Anatomy during two winter sessions at a recognised school or schools. 4. Of having performed dissections at a recognised school or schools during three winter sessions. 5. Of having attended lectures on General Anatomy and Physiology during one winter session at a recognised school. 6. Of having attended a practical course of General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class, at a recognised school. *Note A.*—By the practical course referred to in Clause 6, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, etc.; but it is not hereby intended that the learners shall perform vivisections. 7. Of having attended one course of lectures on Comparative Anatomy, one course of lectures on Chemistry, and a three months' course of Practical Chemistry (with manipulations) in its application to medical study, at a recognised school or schools. *Note B.*—The course of lectures on Chemistry included in Clause 7 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination. *Note C.*—The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

II. Except in the cases and instances hereinafter provided for to the contrary, every candidate before his admission to the second professional examination is required to produce the following certificates, viz. :—1. Of being twenty-five years of age. 2. Of having been engaged for six years in the acquirement of professional knowledge in hospitals or schools of Anatomy, Surgery, and Medicine recognised by the Council of the College for that purpose; or if the candidate be already a Member of the College, he shall produce certificates of having been engaged for two years in the acquirement of professional knowledge in recognised hospitals and schools, in addition to the certificates required for the diploma of Member. 3. Of having attended lectures on Surgery during one winter session at a recognised school. 4. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding clause No. 3, at a recognised school. *Note D.*—The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to Surgery, on the living person, or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effect of diseases and accidents on the living person or on the dead body; the use of surgical apparatus; the examination of diseased structures, as illustrated in the contents of a museum of morbid anatomy and otherwise. 5. Of having attended, at one or more recognised school or schools, one course of lectures on each of the following subjects, viz. :—Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours), Pathological Anatomy during not less than three months. *Note E.*—The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course. 6. Of having performed operations on the dead body under the superintendence of a recognised teacher. 7. Of instruction and proficiency in the practice of vaccination. *Note F.*—In the case of candidates who commence their professional education on or after October 1, 1868, the certificate of instruction in vaccination will only be received from recognised vaccine stations, or from recognised vaccine departments in medical schools or hospitals, or other public institutions, where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (eight or ten on an average weekly) as may be found, after due inquiry, to be sufficient for this purpose at each place. 8. Of having attended the surgical practice of a recognised hospital or hospitals during four winter and four summer sessions, and the medical practice of a recognised hospital or hospitals during one winter and one summer session. 9. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months. *Note G.*—It is intended that the candidate should receive the instruction required by Clause 9 at an early period of his attendance at the hospital. 10. Of having attended clinical lectures on Surgery during two winter and two summer sessions, and clinical lectures on Medicine during one winter and one summer session at one or more recognised hospital or hospitals. 11. Of having attended, during three winter and two summer sessions, demonstrations in the post-mortem rooms of a recognised hospital. 12. Of having served the office of

House-Surgeon or Dresser, for not less than six months, in a recognised hospital.

Notice.—*The alterations in the Regulations, which are applicable to candidates who commenced their professional studies on or after October* 1, 1870, *are contained in Clauses* 3, 5, *and* 6, *paragraph I., in Clauses* 3, 4, 5, 9, 10, *and* 11, *paragraph II., and in notes A, B, C, D, E, and G, paragraphs I. and II. of Section II.*

III. In the case of a candidate who shall have taken by examination the degree of Bachelor or Master of Arts in any university in the United Kingdom recognised by the Council for this purpose, it shall be sufficient for him to produce a certificate or certificates that he has been engaged for five years (instead of six years) in the acquirement of professional knowledge in hospitals or schools of Anatomy, Surgery, and Medicine recognised by the Council of the College for that purpose.

IV. Any Member of the College shall, after the expiration of eight years from the date of his diploma, be entitled to be admitted to the professional examination for the Fellowship upon the production of a certificate, signed by three Fellows, that he has been for eight years in the practice of the profession of Surgery, and that he is a fit and proper person to be admitted a Fellow if upon examination he shall be found qualified.

Section III.—*Professional Examinations.*—1. The examinations are held twice in the year, in the months of May and November, and at such other times as the Council may appoint. 2. The examinations occupy not less than two days, either successive or at such intervals as the Court of Examiners may appoint. 3. The first examination, on Anatomy and Physiology, is partly written and partly *viva voce* on the recently dissected subject and on prepared parts of the human body. The second examination, on Pathology, Therapeutics, and the Principles and Practice of Surgery and Medicine,(a) is partly written, partly *viva voce*, and partly on the practical use of surgical apparatus, and includes the examination of patients, and operations on the dead body. 4. Prior to his admission to the first or anatomical and physiological examination, the candidate is required to pay—*a.* A fee of five guineas, to be allowed on the fee for the diploma of Fellow, but to be retained in case of rejection. 5. Prior to his admission to the second professional examination, the candidate is required to pay—*a.* (b) A fee of five guineas (if a Member) over and above all charges for stamps, to be retained in case of rejection. *b.* (b) A fee of twenty-five guineas (if not a Member) over and above all charges for stamps, of which five guineas will be retained in case of rejection. 6. A candidate whose qualifications shall be found insufficient on his anatomical and physiological examination shall be referred, and shall not be allowed to present himself for re-examination until after the expiration of six months from the date of his reference. 7. A candidate whose qualifications shall be found insufficient upon his pathological and surgical examination shall be referred, and shall not be allowed to present himself for re-examination until after the expiration of one year from the date of his reference, unless the Court of Examiners shall otherwise determine.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF MEMBER OF THIS COLLEGE.

I. *Preliminary General Education and Examination.*—(1.) Candidates who commenced their professional education on or after January 1, 1861, will be required to produce one or other of the following certificates:—1. Of graduation in Arts at a university recognised for this purpose. The following are the universities at present recognised, viz.:—Oxford, Cambridge, Dublin, London, Durham, Queen's University in Ireland, Edinburgh, Glasgow, Aberdeen, and St. Andrews, Calcutta, Madras, and Bombay; Canada—M'Gill College, Montreal, and Queen's College, Kingston. 2. Of having passed an examination for matriculation, or such other examination as shall, in either case, from time to time be sanctioned by the Council of this College, at a university in the United Kingdom, or at a colonial or foreign university recognised by the Council of this College. The following are the examinations at present recognised under this Clause (No. 2), viz.:—Oxford.—Responsions or Moderations. Middle-Class Examinations, Senior, the certificates to include Latin and Mathematics. Cambridge.—Previous Examination. Middle-Class Examinations, Senior, the certificates to include Latin and Mathematics. Dublin.—Entrance Examination. London.—Matriculation Examination. Durham.—Examination of students in Arts in their second and first years. Middle-Class Examinations, Senior, the certificates to include Latin and Mathematics. Registration Examination for medical students. Queen's University in Ireland.—Two years' Arts course for diploma of Licentiate in Arts. Preliminary Examinations at end of B.A. course. Middle-Class Examinations, the certificates to include Latin and Mathematics. Matriculation Examinations. Edinburgh, Aberdeen, Glasgow, and St. Andrews.—Preliminary or Extra Professional Examinations for graduation in Medicine. Calcutta, Madras, and Bombay.—Matriculation Examinations. Canada—Queen's College, Kingston.—Matriculation Examination, Preliminary Examination of students in Medicine; M'Gill College, Montreal; University College, Toronto; Victoria College, Toronto; University of Laval, Quebec.—Matriculation Examinations. Nova Scotia—King's College, Windsor.—Matriculation Examination. Responsions. New Brunswick; Fredericton.—Matriculation Examination. Dalhousie College and University, Halifax.—Matriculation Examination. Australia—Melbourne.—Matriculation Examination, with a certificate that the student has passed an Examination in Latin. Sydney; Matriculation Examination. New York—Bellevue Hospital Medical College.—Matriculation Examination. 3. Of having passed the preliminary examination for the Fellowship of this College. 4. Of having passed the preliminary examinations of the Royal Colleges of Surgeons of Ireland and of Edinburgh, or of the Faculty of Physicians and Surgeons of Glasgow. 5. Of having passed the Examination in Arts of the Society of Apothecaries of London, or of the Apothecaries' Hall of Ireland. 6. Of having passed the first-class examination of the Royal College of Preceptors. 7. Of having obtained the *testamur* of the Codrington College, Barbadoes. 8. Of having obtained the degree of Associate of Arts granted by the Tasmanian Council of Education, with a certificate that the student has been examined in Latin and Mathematics. 9. Of having passed the voluntary examinations of Christ's College, Canterbury, New Zealand, the certificate to include all the subjects required from time to time in the preliminary examination of the College. (2.) Candidates who shall not be able to produce one or other of the foregoing certificates will be required to pass an examination, in English, Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of this College.

The following are the subjects of the examination referred to in the foregoing paragraph for December, 1873, and until further notice, viz.: Part (1.)—Compulsory subjects:—1. Reading aloud a passage from some English author. 2. Writing from dictation. 3. English Grammar. 4. Writing a short English composition; such as a description of a place, an account of some useful or natural product, or the like. 5. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple and compound, of vulgar fractions, and of decimals. 6. Questions on the Geography of Europe, and particularly of the British Isles. 7. Questions on the outlines of English History, that is, the succession of the sovereigns and the leading events of each reign. 8. Mathematics: Euclid, Books I. and II., or the subjects thereof; Algebra to simple equations inclusive. 9. Translation of a passage from the second book of Cæsar's Commentaries, "De Bello Gallico." Part (2.)—Optional Subjects:—Papers will also be set on the following six subjects, and each candidate will be required to offer himself for examination on one subject at least, at his option; but no candidate will be allowed to offer himself for examination on more than four subjects:—1. Translation of a passage from the first book of the Anabasis of Xenophon. 2. Translation of a passage from X. B. Saintine's "Picciola." 3. Translation of a passage from Schiller's "Wilhelm Tell." Besides these translations into English, the candidate will be required to answer questions on the grammar of each subject, whether compulsory or

(a) Candidates can claim exemption from examination in Medicine under the following conditions, viz.:—1. The production by the candidate of a degree, diploma, or licence in Medicine entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in Medicine of a colonial or foreign university approved by the Council of the College. 2. A declaration by the candidate, prior to his admission to the final examination for the Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same. N.B.—A candidate who has passed an examination in Medicine for the Membership will not be required to pass any further examination in Medicine for the Fellowship.

(b) The sum of £2 paid on the Preliminary Examination will be allowed against these amounts.

optional. 4. Mechanics. The questions will be chiefly of an elementary character. 5. Chemistry. The questions will be on the elementary facts of chemistry. 6. Botany and Zoology. The questions will be on the classification of plants and animals. The quality of the handwriting and the spelling will be taken into account. N.B.—Each candidate (who has not already paid the amount) is required to pay a fee of £2 on the morning of the first day of the examination prior to his admission thereto. The next examination will be held on or about the third Tuesday or Wednesday in December. The exact dates of the examination will be duly advertised when fixed in the medical journals. Candidates are required to send in the prescribed forms of application not less than three weeks before the commencement of the examination.

Note.—A candidate in order to qualify for the Fellowship is required, in addition to the subjects included in Part (1), to pass in Greek and in French or German, and in one at his option of the remaining subjects in Part (2).

II. *Professional Education.*—(1.) Professional studies prior to the date at which the candidate shall have passed an examination in general knowledge in conformity with the regulation in the preceding section are not recognised.

(2.) The following will be considered as the commencement of professional education:—1. Attendance on the practice of a hospital or other public institution recognised by this College for that purpose. 2. Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. 3. Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College. *The commencement of professional study, otherwise than by attendance on lectures in recognised medical schools, or by attendance on the practice of recognised hospitals, will not be admitted until a certificate thereof shall be furnished to the Secretary for registration at the College, by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the hospital or other institution to the practice of which he shall have entered, and will, consequently, date only from the reception of such certificate by the Secretary; the certificate to be accompanied by proof of having passed the necessary preliminary examination in general knowledge.*

(3.) Candidates will be required to produce the following certificates, viz.: 1. Of being twenty-one years of age. 2. Of having been engaged, subsequently to the date of passing the preliminary examination, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. 3. Of having attended lectures on Anatomy during two winter sessions. 4. Of having performed Dissections during not less than two winter sessions. 5. Of having attended lectures on General Anatomy and Physiology during one winter session. 6. Of having attended a practical course of General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class. *Note A.*—By the practical course referred to in Clause 6, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, etc.; but it is not hereby intended that the learners shall perform vivisections. 7. Of having attended lectures on Surgery during one winter session. 8. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 7. *Note B.*—The course of Practical Surgery referred to in Clause 8 is intended to embrace instruction in which each pupil shall be exercised in practical details such as in the application of anatomical facts to Surgery, on the living person or on the dead body. The methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents, on the living person or on the dead body. The performance, where practicable, of the operations of Surgery on the dead body. The use of surgical apparatus. The examination of diseased structures, as illustrated in the contents of a museum of morbid anatomy and otherwise. 9. Of having attended one course of lectures on each of the following subjects, viz.: Chemistry, Materia Medica, Medicine, Forensic Medicine; Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours); Pathological Anatomy during not less than three months. *Note C.*—The course of lectures on Chemistry included in Clause 9 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination. 10. Of having studied Practical Pharmacy during three months. 11. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study. 12. Of instruction and proficiency in the practice of vaccination. *Note D.*—In the case of candidates who commenced their professional education on or after the 1st of October, 1868, the certificate of instruction in vaccination will only be received from recognised vaccine stations, or from recognised vaccine departments in medical schools or hospitals, or other public institutions, where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (eight or ten on an average weekly) as may be found, after due inquiry, to be sufficient for this purpose at each place. *Note E.*—The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course. 13. Of having attended, at a recognised hospital or hospitals, the practice of Surgery during three winter(c) and two summer(d) sessions. 14. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months. *Note F.*—It is intended that the candidate should receive the instruction required by Clause 14 at an early period of his attendance at the hospital. 15. Of having, subsequently to the first winter session of attendance on surgical hospital practice, attended, at a recognised hospital or hospitals, clinical lectures on Surgery during two winter and two summer sessions. 16. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of practical surgery. 17. Of having attended during the whole period of attendance on surgical hospital practice (see Clause 13) demonstrations in the post-mortem rooms of a recognised hospital. 18. Of having attended, at a recognised hospital or hospitals, the practice of Medicine, and clinical lectures on Medicine, during one winter and one summer session.

Notice.—*Clauses* 6, 8, 11, 14, *and* 17, *and Notes A, B, C, E, and F, together with the courses of lectures on Forensic Medicine and Pathological Anatomy mentioned in Clause* 9, *are applicable to candidates who commenced their professional education on or after the 1st of October*, 1870. N.B.—Blank forms of the required certificates may be obtained on application to the Secretary, and all necessary certificates will be retained at the College.

III.—1. Certificates will not be received on more than one branch of science from one and the same lecturer; but anatomy and dissections will be considered as one branch of science.

2. Certificates will not be recognised from any hospital in the United Kingdom unless the surgeons thereto be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any school of anatomy and physiology or midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom; nor from any school of surgery, unless the teachers in such school be members of one of the legally constituted Colleges of Surgeons in the United Kingdom.

3. No metropolitan hospital will be recognised by this College which contains less than 150, and no provincial or colonial hospital which contains less than 100 patients.

4. The recognition of colonial hospitals and schools is governed by the same regulations with respect to number of patients and to courses of lectures as apply to the recognition of provincial hospitals and schools in England.

5. Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations

(c) The winter session comprises a period of six months, and, in England, commences on October 1, and terminates on March 31.

(d) The summer session comprises a period of three months, and, in England, commences on May 1 and terminates on July 31.

of this College; and in such cases clinical lectures will not be necessary, but a certificate of having acted as a dresser for a period of at least six months will be required.

6. Certificates will not be received from candidates who have studied in London, unless they shall have registered at the College their cards of admission to attendance on lectures and hospital practice within fifteen days from the commencement of the session; nor from candidates who have studied in the provincial schools in England, unless their names shall be duly returned from their respective schools. N.B.—At their first registration in October, candidates will be required to produce a certificate of having passed one or other of the preliminary examinations in general knowledge recognised by this College.

7. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

8. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom, and graduates in Surgery of any university recognised for this purpose by this College, will be admitted to examination on producing their diploma, licence, or degree, together with proof of being 21 years of age, a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

9. Graduates in Medicine of any legally constituted college or university recognised for this purpose by this College, will be admitted to examination on producing, together with their diploma or degree, proof of being 21 years of age, a certificate of instruction and proficiency in the practice of vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

IV. *Professional Examination.*—This examination is divided into two parts. 1. The first or primary examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. 2. The second or pass examination, on Surgical Anatomy and the Principles and Practice of Surgery and Medicine,(e) is partly written, partly oral, and partly on the practical use of surgical apparatus, and the practical examination of patients. 3. The primary examinations are held in the months of January, April, May, July, and November, and the pass examinations generally in the ensuing week respectively. 4. Candidates will not be admitted to the primary examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the pass or surgical examination until after the termination of the fourth year of their professional education. 5. The fee of £5 5s., paid prior to the primary examination, and allowed on the whole fee of £22(f) payable for the diploma, is retained; and after any two consecutive failures at the primary examination, the candidate is required to pay an *additional* fee of £5 5s. prior to being again admitted to that examination, which *additional* fee is also retained. 6. Five guineas, part of the sum of £16 15s., the balance of the whole fee due for the diploma and paid prior to the pass examination, is retained; and after any two consecutive failures at the pass examination, the candidate is required to pay an *additional* fee of £5 5s. prior to being again admitted to the said pass examination, which *additional* fee is also retained. 7. A candidate having entered his name for either the primary or pass examination, who shall fail to attend the meeting of the Court for which he shall have received a card, will not be allowed to present himself for examination within the period of three months from the date at which he shall have so failed to attend. 8. A candidate referred on the primary examination is required, prior to his admission to re-examination, to produce a certificate of the performance of dissections during not less than three months, subsequently to the date of his reference. 9. A candidate referred on the pass examination is required, prior to his admission to re-examination, to produce a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on Clinical Surgery, subsequently to the date of his reference.

(e) Candidates can claim exemption from examination in Medicine under the following conditions, viz.:—1. The production by the candidate of a degree, diploma, or licence in Medicine entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in Medicine of a Colonial or foreign university approved by the Council of the College. 2. A declaration by the candidate, prior to his admission to the final examination for Membership or Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

QUALIFICATION IN MIDWIFERY.

REGULATIONS RESPECTING THE PROFESSIONAL EDUCATION OF CANDIDATES FOR THIS CERTIFICATE.

1. Persons who were Fellows or Members of the College prior to the first day of January, 1853, will be admitted to examination for the certificate of qualification in Midwifery upon producing their diploma.

2. Persons having become Members of the College subsequently to the first day of January, 1853, will be admitted to examination on producing their diploma, together with a certificate or certificates of having attended twenty labours.

3. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom, and Graduates in Surgery of any University recognised for this purpose by this College, will also be admitted to examination on producing, together with their diploma, licence, or degree, proof of being 21 years of age—of having been occupied at least four entire years in the acquirement of professional knowledge—of having attended one course of lectures on Midwifery—and of having attended not less than twenty labours.

4. Graduates in Medicine of any legally constituted college or university recognised for this purpose by this College, will also be admitted to examination on producing, together with their diploma or degree, proof of being 21 years of age—of having been occupied at least four entire years in the acquirement of professional knowledge—of having completed, at recognised schools, the Anatomical and Surgical education required of candidates for the diploma of Member of the College—of having attended one course of lectures on Midwifery—and of having attended not less than twenty labours.

5. Persons having commenced their professional education, either by attendance on hospital practice or on lectures on Anatomy, prior to the first day of January, 1853, will be admitted to examination on producing the several certificates of professional education required for admission to examination for the diploma of Member of this College at the period when such persons shall respectively have, in such manner, commenced their professional education.

6. Persons having commenced their professional education, either by attendance on hospital practice or on lectures on Anatomy, after the 31st day of December, 1852, will be admitted to examination on producing certificates of being 21 years of age—of having been engaged during at least four entire years in the acquirement of professional knowledge—of having completed at recognised schools the professional education required of candidates for the diploma of Member of this College—of having attended one course of lectures on Midwifery and the Diseases of Women and Children—and of having personally conducted thirty labours.

Note.—All candidates who shall commence their professional education on or after October 1, 1866, will, in addition to the certificates enumerated in the foregoing clauses, be required to produce a certificate of having, prior to such commencement, passed a preliminary examination in general knowledge recognised by this College.

N.B.—The fee for the certificate is as follows, viz.:—1. Persons who were Fellows or Members of this College prior to January 1, 1853, two guineas. 2. Persons admitted Fellows or Members of this College subsequently to January 1, 1853, three guineas. 3, 4. Persons producing any other diploma or certificate or degree which may be considered by the Council to afford satisfactory proof of sufficient surgical and medical education, three guineas. 5, 6. All other persons, ten guineas.

The examinations are held in the months of February, May, August, and December.

REGULATIONS RELATING TO THE DIPLOMA IN DENTAL SURGERY.

Education.—Candidates are required to produce the following certificates:—

1. Of being twenty-one years of age.

2. Of having been engaged during four years in the acquirement of professional knowledge.

3. Of having attended, at a school or schools recognised by this College, not less than one of each of the following courses of lectures, delivered by lecturers recognised by this College—namely, Anatomy, Physiology, Surgery, Medicine, Chemistry, and Materia Medica.

4. Of having attended a second winter course of lectures on Anatomy, or a course of not less than twenty lectures on the Anatomy of the Head and Neck, delivered by lecturers recognised by this College.

5. Of having performed Dissections at a recognised school during not less than nine months.

(f) This sum of £22 is exclusive of the fee of £2 paid for the preliminar examination.

6. Of having completed a course of Chemical Manipulation, under the superintendence of a teacher or lecturer recognised by this College.

7. Of having attended, at a recognised hospital or hospitals in the United Kingdom, the practice of Surgery and clinical lectures on Surgery during two winter sessions.

8. Of having attended, at a recognised school, two courses of lectures upon each of the following subjects—viz., Dental Anatomy and Physiology (Human and Comparative), Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy, by lecturers recognised by this College.

9. Of having been engaged, during a period of not less than three years, in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a competent practitioner.

10. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of Dental Surgery during the period of two years.

N.B.—The students of the London schools are required to register the above certificates at this College; and special returns will be required from the provincial schools.

Examination.—The examination is partly written and partly oral.

The written examination comprises General Anatomy and Physiology, and General Pathology and Surgery, with especial reference to the practice of the Dental Profession.

The oral practical examination comprises the several subjects included in the curriculum of professional education, and is conducted by the use of preparations, casts, drawings, etc.

Members of the College, in the written examination, will only have to answer those questions set by the section of the Board consisting of persons skilled in Dental Surgery; and in the oral examination will be examined only by that section.

A candidate whose qualifications shall be found insufficient will be referred back to his studies, and will not be admitted to re-examination within the period of six months, unless the Board shall otherwise determine.

Examinations will be held in January and June.

The fee for the diploma is ten guineas, over and above any stamp duty.

Note.—A ticket of admission to the museum, to the library, and to the College lectures will be presented to each candidate on his obtaining the diploma.

SOCIETY OF APOTHECARIES (ENGLAND).

Every candidate for a certificate of qualification to practise as an apothecary will be required to produce testimonials—1. Of having passed a preliminary examination in Arts, as a test of general education. (This examination must be passed before the commencement of professional studies, which is defined by the Medical Council to be "the time of commencing studies at a medical school.") 2. Of having served an apprenticeship or pupilage of not less than five years to a practitioner qualified by the Act of 1815. (This period may include the time spent in attending lectures and hospital practice.) 3. Of having attained the full age of 21 years, of which satisfactory evidence will be required. 4. Of good moral conduct. 5. Of having pursued a course of medical study in conformity with the regulations of the Court.

Course of Study.—Every candidate whose attendance on lectures shall have commenced on and after October 1, 1863, must attend the following lectures and medical practice during not less than three winter and two summer sessions (each winter session to consist of not less than six months, and to commence not sooner than the first nor later than the 15th of October; and each summer session to extend from May 1 to July 31):—

First Year.—Winter Session: Chemistry; Anatomy and Physiology; Dissections. Summer Session: Botany; Materia Medica and Therapeutics; Practical Chemistry.

Second Year.—Winter Session: Anatomy and Physiology, including dissections and demonstrations; Principles and Practice of Medicine; Clinical Medical Practice. Summer Session: Midwifery and Diseases of Women and Children, and Vaccination; Forensic Medicine and Toxicology; Clinical Medical Practice.

Third Year.—Winter Session: Principles and Practice of Medicine; Clinical Medical Lectures; Morbid Anatomy; Clinical Medical Practice.

N.B.—All medical students presenting themselves for the second examination shall produce evidence of having served the office of clinical clerk at a recognised hospital during the period of six weeks at least; and also shall produce evidence that they have been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

No certificates of lectures or of anatomical instruction delivered in private to particular students, apart from the ordinary classes of recognised public medical schools, can be received by the Court of Examiners.

All students are required *personally* to register the several tickets of admission to lectures and medical practice within the first fifteen days of the months of October and May.

Examination in Arts.—Examinations will be held at the Hall of the Society on Friday and Saturday, January 30 and 31, April 24 and 25, September 25 and 26. Candidates will be examined in the following branches, and no candidate will be approved unless he show a competent knowledge of each branch of the examination:—1. The English language; 2. The Latin language; 3. Mathematics; 4. One of the following subjects at the option of the candidate:—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Natural Philosophy. Candidates applying to be admitted to any examination must pay the fee (one guinea) at least one week before the examination, and must sign their names in the Candidates' Book between 11 a.m. and 3 p.m. o'clock, not later than the previous Thursday. If a candidate fail to pass the examination, the fee will not be returned to him, but he will be admissible to either or both of the two next following examinations in Arts without the payment of an additional fee, upon giving the usual notice, and signing the Candidates' Book.

Syllabus of Subjects for Examination, 1874.—I. The English Language: The leading features of its history; its structure and grammar; English composition. [The books recommended for study in this subject are Adams's "Elements of the English Language" and Trench's "English, Past and Present."] II. The Latin Language: January examination—Cicero: Philippic, I. April examination—Horace: Satires, Book I. September examination—Virgil: Æneid, Book I. Re-translation of easy sentences. Grammatical questions will be introduced into the Latin paper, and each candidate will be expected to give satisfactory answers to these. III. Mathematics: The ordinary rules of arithmetic; vulgar and decimal fractions; addition, subtraction, multiplication, and division of algebraical quantities; simple equations; the first two Books of Euclid. IV. (*a*) Greek: Xenophon, Anahasis, Books I. and II.; grammatical questions. (*b*) French: Molière, "Le Misanthrope"; translation from English into French; grammatical questions. (*c*) German: Schiller's "Wilhelm Tell"; translation of short sentences from English into German; grammatical questions. (*d*) Natural Philosophy: Mechanics; hydrostatics and pneumatics. [The book recommended for study in this subject is Snowball's "Cambridge Course of Elementary Natural Philosophy."]

Certificates in Arts granted by any of the bodies whose certificate is recognised by the Medical Council will be accepted from candidates who present themselves at the professional examination at the Hall as equivalent to their having passed this examination.

Professional Examinations.—The Court of Examiners meet in the Hall every Thursday, where candidates are required to attend at 4.30 p.m. Every person intending to offer himself for examination must give notice in writing to the Clerk of the Society on or before the Monday previous to the day of examination, and must at the same time deposit all the required testimonials and the fee at the office of the Beadle, where attendance is given every day, except Sunday, from 10 to 4 o'clock; Saturdays, 10 to 2.

The examination of candidates is divided into two parts, and is conducted partly in writing and partly *viva voce*.

The written examination will take place on Wednesdays, and the viva voce *examination on Thursdays.*

Those students *only* who have to undergo the writing will have to attend on Wednesday, at half-past 4 p.m.

The first examination, which may be passed after the second winter session, embraces the following subjects:—The British Pharmacopœia; Latin of Physicians' Prescriptions; Anatomy and Physiology; General and Practical Chemistry; Botany; and Materia Medica.

Second or pass examination, after the third winter session (the five years' pupilage being completed):—Principles and Practice of Medicine; Pathology; Therapeutics; Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology.

All graduates in Medicine of British universities will be admitted to a practical examination in Medicine and Midwifery only.

Licentiates of the Royal College of Physicians, London; of the Royal College of Physicians, Edinburgh; of the Royal Colleges of Physicians and Surgeons, Edinburgh; of the King and Queen's College of Physicians, Ireland; of the Faculty of Physicians and Surgeons, Glasgow; and of the Apothecaries' Hall of Dublin, will be admitted to a *viva voce* examination in Medicine, Midwifery, Forensic Medicine, and Toxicology.

Members of the Royal College of Surgeons, England; Licentiates of the Royal College of Surgeons, Edinburgh; and Licentiates of the Royal College of Surgeons, Ireland, possessing a surgical qualification only, will be admitted to a first and second examination on one evening. The first or *viva voce* examination will include the subjects of Physicians' Prescriptions, Visceral Anatomy, Physiology, Chemistry, Materia Medica, Botany, and Pharmacy; the second, which is partly written and partly *viva voce*, will include the subjects of Practice of Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicological Chemistry.

Any candidate who has passed his first examination for the licence of the Royal College of Physicians, London; the licence of the King and Queen's College of Physicians, Ireland; the joint licence of the Royal College of Physicians and Surgeons, Edinburgh, or for the single licence of the College of Physicians, Edinburgh; the licence of the Faculty of Physicians and Surgeons, Glasgow; the first professional examination for the degree of M.B., or Master in Surgery, in the Universities of Oxford, Cambridge, or London; or the second part of the professional examination for the degree of M.B., or Master in Surgery, in the Universities of Edinburgh, Aberdeen, St. Andrews, and Glasgow; or the first examination for the medical and surgical degrees in the Irish Universities; or the first examination for the licence of the Apothecaries' Company, Dublin, will be admitted to a single examination in Materia Medica, Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicology, part of which examination will be conducted in writing.

The examination of candidates for certificates of qualification to act as Assistant in compounding and dispensing medicines, is as follows:—In translating physicians' prescriptions, in the British Pharmacopœia, in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Medical Botany.

By the 22nd section of the Act of Parliament, no rejected candidate for the licence can be re-examined until the expiration of six months from his former examination. A candidate rejected on his first professional examination can be admitted to re-examination after the expiration of three months. No rejected candidate as an Assistant can be re-examined until the expiration of three months.

Fees.—For a certificate of qualification to practise, six guineas, the half to be paid at the first examination; for an Assistant's certificate, two guineas.

Students' Prizes.—The Society of Apothecaries annually offer two prizes for proficiency in the knowledge of Botany, and also two prizes for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most in the examination; and of a silver medal and a book to the candidate who does so in the next degree.

The examination in Botany will be held at the Hall of the Society on the second Wednesday in June, at 10 a.m., and will be conducted by printed papers and *vivâ voce* questions.

The examinations in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Society on the third Wednesday, and on the following Friday, in October, from ten in the forenoon to one in the afternoon of each day; by printed papers on the Wednesday, and by *vivâ voce* questions on the Friday.

The Society's Botanic Garden at Chelsea is open daily (except Sunday) from ten till five o'clock p.m., and on Saturdays from ten till two o'clock. Tickets of admission may be had on application at the Beadle's office, Apothecaries' Hall, Blackfriars, E.C.

ARMY MEDICAL DEPARTMENT,

WHITEHALL-YARD.

QUALIFICATIONS OF CANDIDATES FOR COMMISSIONS IN THE ARMY MEDICAL SERVICE, WITH A SUMMARY OF THE RULES BY WHICH THE PAY, PROMOTION, AND RETIREMENT OF MEDICAL OFFICERS ARE REGULATED AND DETERMINED.

1. Every candidate desirous of presenting himself for admission to the Army Medical Service must be unmarried, and not under 21 nor over 28 years of age. He must produce a certificate from the District Registrar, in which the date of birth is stated; or if this cannot be obtained, an affidavit from one of the parents or other near relative who can attest the date of birth will be accepted. He must also produce a certificate of moral character from the parochial minister, if possible.

2. The candidate must make a declaration that his parents are of unmixed European blood, and that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a Medical Officer in any climate. His physical fitness will be determined by a Board of Medical Officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed. The Board must also certify that he is free from organic or other disease, and from constitutional weakness or other disability likely to unfit him for military service in any climate.

3. The candidate must possess two diplomas or licences, one to practise Medicine, and the other Surgery in Great Britain or Ireland, and must be registered under the Medical Act in force at the time of his appointment.

4. Certificates of registration, character, and age must accompany the declaration when filled up and returned.

5. Candidates will be examined by the Examining Board in the following compulsory subjects, and the highest number of marks attainable will be distributed as follows:—*a.* Anatomy and Physiology, 1000 marks; *b.* Surgery, 1000; *c.* Medicine, including Therapeutics, the Diseases of Women and Children, 1000; *d.* Chemistry and Pharmacy, and a practical knowledge of drugs, 100. N.B. The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of each candidate for the Army Medical Service will be determined by the result of the examinations in these subjects only. Examinations will also be held in the following voluntary subjects, for which the maximun number of marks will be—French and German (150 each), 300 marks; Natural Sciences, 300. The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German. The Natural Sciences will include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to Materia Medica. The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences.

6. After passing this examination, every candidate will be required to attend one entire course of practical instruction at the Army Medical School on:—(1) Hygiene; (2) Clinical and Military Medicine; (3) Clinical and Military Surgery; (4) Pathology of Diseases and Injuries incident to Military Service.

7. At its conclusion the candidate will be required to pass an examination on the subjects taught in the school. If he give satisfactory evidence of being qualified for the practical duties of an Army Medical Officer, he will be eligible for a commission as Surgeon.

8. During the period of his residence at the Army Medical School each candidate will receive an allowance of 5s. per diem with quarters, or 7s. per diem without quarters, to cover all cost of maintenance; and he will be required to provide himself with uniform (viz., the Regulation undress uniform of a Surgeon, but without the sword).

9. All candidates will be required to conform to such rules of discipline as the Senate may from time to time enact.

The daily rates of pay of Medical Officers of the Army are as follows:—Pay daily: Director-General special; Surgeon-General £2, after twenty-five years' service £2 5s., after thirty years' service £2 7s., after thirty-five years' service £2 10s.; Deputy Surgeon-General £1 10s., after twenty-five years' service £1 12s., after thirty years' service £1 15s., after thirty-five years' service £1 17s.; Surgeon-Major 17s. 6d., after fifteen years' service £1, after twenty years' service £1 4s., after twenty-five years' service £1 7s.; Surgeon, on appointment 10s., after five years' service 12s. 6d., after ten years' service 15s. Charge pay: The principal Medical Officer of an army in the field, of 10,000 men and upwards, £1 daily; of 5000 men and upwards, 15s. daily; of less than 5000, 10s. daily. Or, the principal Medical Officer of a colony where the number of commissioned officers and enlisted men is 1500 and upwards, 5s. daily.

A Surgeon must pass such examination as the Secretary of State for War may require before he can be promoted to the rank of Surgeon-Major.

Medical officers shall have a right to retire on half-pay after twenty years' service; medical officers of the rank of Surgeon-Major, or Surgeon, shall be placed on the retired list at the age of 55, and all Surgeons-General and Deputy Surgeons-General at the age of 65 years.

A medical officer placed on half-pay by reduction of establishment, or on the report of a medical board, in conse-

quence of wounds or ill-health caused in and by discharge of his duties, or on account of age (under Rule 11), shall be entitled to half-pay at the following daily rates:—Surgeon-General, after thirty years' service, £1 17s. 6d.; after twenty-five years' service, £1 13s. 6d.; after twenty years' service, £1 10s. Deputy Surgeon-General, after thirty years' service, £1 5s. 6d.; after twenty-five years' service, £1 2s. 6d.; after twenty years' service, £1 1s. Surgeon-Major, after twenty-five years' service, £1; after twenty years' service, 16s. 6d.; after fifteen years' service, 13s. 6d.; after ten years' service, 11s. Surgeons, after ten years' service, 10s.; after five years' service, 8s.; under five years' service, 6s.

The rate of half-pay awarded to officers retiring for their own convenience after twenty years' service on full-pay shall not exceed one-half of their full-pay at the time of retirement.

ARMY MEDICAL SCHOOL.

President of the Senate.—Sir T. Galbraith Logan, K.C.B., M.D., Director-General of the Army Medical Department.

Members of the Senate.—Sir Ranald Martin, C.B., Physician to the Indian Council; Surgeon-General T. G. Balfour, M.D., Principal Medical Officer Royal Victoria Hospital; Surgeon-General T. Longmore, C.B., Professor of Military Surgery; Surgeon-General W.C. Maclean, Professor of Military Medicine; William Aitkin, M.D., Professor of Pathology; E. A. Parkes, M.D., F.R.S., Professor of Military Hygiene.

Assistant Professors.—Surgeon-Majors T. H. Porter, W. H. Webb, and F. S. B. F. De Chaumont, M.D.; and Surgeon F. H. Welch.

Candidates for Commissions in the Army and in the Queen's Indian Service proceed to Netley after passing the examination in London. At Netley they attend the medical and surgical practice of the Royal Victoria Hospital, and learn the system and arrangements of military hospitals. During four months they attend the lectures given by the professors and assistant-professors, and go through a course of practical instruction in the hygienic laboratory and microscopical room.

NAVAL MEDICAL DEPARTMENT, ADMIRALTY.

QUALIFICATIONS AND EXAMINATION OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL SERVICE OF THE ROYAL NAVY.

The Lords Commissioners of the Admiralty are pleased to direct that the following regulations, relative to the examination of candidates for the appointment of Surgeon in the Royal Navy, shall in future be adopted:—

1. Every candidate desirous of presenting himself for admission to the Naval Medical Service must be not under 21 nor over 28 years of age. He must produce a certificate from the District Registrar, in which the date of birth is stated; or, if this cannot be obtained, an affidavit from one of the parents or other near relative, who can attest the date of birth, will be accepted. He must also produce a certificate of moral character.

2. The candidate must make a declaration that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate.(a) He must also attest his readiness to engage for general service, and to proceed on foreign service when required to do so.

3. The candidate must be registered under the Medical Act of 1858, as licensed to practise Medicine and Surgery in Great Britain or Ireland, and he must have performed the capital and minor operations of Surgery under a recognised teacher.

4. Certificates of registration, character, and age must accompany the schedule when filled up and returned.

5. Candidates will be examined by the Examining Board in the following subjects:—Anatomy and Physiology; Surgery; Medicine, including Therapeutics, the Diseases of Women and Children; Chemistry and Pharmacy, and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.) The eligibility of each candidate for the Naval Medical Service will be determined by the result of the examinations in these subjects only.

(a) His physical fitness will be determined by a Board of Medical Officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. Every candidate must also be free from organic disease of other organs, and from constitutional weakness or other disability likely to unfit him for naval service in any climate.

Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to Materia Medica; also in French and German; and the number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of these branches of science.

6. After passing this examination, every candidate will be required to attend one entire course of practical instruction in the Medical School at Netley, on—(1) Hygiene; (2) Clinical and Naval and Military Medicine; (3) Clinical and Naval and Military Surgery; (4) Pathology of Diseases and Injuries incidental to Naval and Military Service.

7. At its conclusion, the candidate will be required to pass an examination on the subjects taught in the School. If he give satisfactory evidence of being qualified for the practical duties of a Naval Medical Officer, he will be eligible for a commission as Surgeon.

8. During the period of his residence at the Netley Medical School, each candidate will receive an allowance of 5s. per diem with quarters, or 7s. per diem without quarters, to cover all cost of maintenance; and he will be required to provide himself with uniform—viz., the regulation undress uniform of a Surgeon, but without the sword.

The full- and half-pay of Naval Medical Officers is in accordance with the following scale:—Full-pay: Inspector-General of Hospitals and Fleets—On promotion or under twenty-five years' service, £2 5s.; ditto or above twenty-five years' service, £2 6s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £2 10s. Deputy Inspector-General of Hospitals and Fleets—On promotion or under twenty-two years' service, £1 11s.; ditto or above twenty-two years' service, £1 12s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 18s. Staff Surgeon—On promotion or under twenty years' service, £1 3s.; ditto or above twenty years' service, £1 4s.; and for each additional year of service 1s. a day more until the maximum is reached—namely £1 10s. Staff Surgeon 2nd Class—On promotion or under fourteen years' service, 18s.; ditto or under seventeen years' service, £1; and for each additional year of service 1s. a day more until the maximum is reached—namely £1 2s. Surgeon—Under five years' service,(b) 11s.; under eight years' service, 12s. 6d.; under eleven years' service, 14s.; under fourteen years' service, provided he passed his examination for Staff Surgeon 2nd Class while under ten years' service, 15s. 6d.; above fourteen years' service, ditto, 17s. Half-pay: Surgeon—Under five years' service, 6s.; under eight years' service, 8s.; under eleven years' service, 10s.; above eleven years' service, provided he passed his examination for Surgeon while under ten years' service, 11s. Staff Surgeon 2nd Class—On promotion or under fourteen years' service, 11s.; ditto or under seventeen years' service, 13s.; ditto or above seventeen years' service, 14s. Staff Surgeon—On promotion or under twenty years' service, 16s.; ditto or above twenty years' service, 16s. 6d.; and for each additional year of service 6d. a day more until the maximum is reached—namely, 18s. 6d. Deputy Inspector-General of Hospitals and Fleets—On promotion or under twenty-two years' service, £1 1s.; ditto or above twenty-two years' service, £1 2s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 7s. Inspector-General of Hospitals and Fleets—On promotion or under twenty-five years' service, £1 11s.; ditto or above twenty-five years' service, £1 12s.; and for each additional year of service 1s. a day more until the maximum is reached—namely, £1 18s.

RULES AND REGULATIONS OF THE EXAMINING MEDICAL BODIES IN SCOTLAND.

UNIVERSITY OF EDINBURGH.

The Session 1873-74 will be publicly opened on Monday, November 3, with an address by the Principal.

GRADUATION IN MEDICINE—STATUTES OF THE UNIVERSITY OF EDINBURGH RELATIVE TO GRADUATION IN MEDICINE AND SURGERY.

Three medical degrees are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

I. The preliminary branches of extra-professional education are—English, Latin, Arithmetic, the elements of Mathematics, and the elements of Mechanics; and the proficiency of students in these branches is ascertained by examination prior to the commencement of their medical study.

II. No candidate is admitted to a professional examination who has not passed a satisfactory examination on at least two

(b) Except during session at Netley. *See* Regulations.

of the following subjects (in addition to the subjects mentioned above):—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy; and the examination on these latter subjects also takes place before the candidate has entered on his medical curriculum.

III. A degree in Arts (not being an honorary degree) in any one of the universities of England, Scotland, or Ireland, or in any colonial or foreign university, specially recognised for this purpose by the University Court, exempts from all preliminary examination; and an examination in Arts by any corporate body whose examination has been recognised as qualifying for entrance on medical study by resolution of the General Medical Council of the United Kingdom, provided the said examination by the said corporate body shall be also approved by the University Court, shall exempt from preliminary examination in Arts, on all subjects comprised in the said examination of the said corporate body.

IV. No one is admitted to the degree of Bachelor of Medicine or Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session for each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course, and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.

V. Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—

1. That he has studied each of the following departments of medical science—viz., Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children (two courses of Midwifery of three months each being reckoned equivalent to a six months' course, provided different departments of Obstetric Medicine be taught in each of the courses), General Pathology (or, in schools where there is no such course, a three months' course of lectures on Morbid Anatomy, together with a supplemental course of Practice of Medicine, or Clinical Medicine), during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures above prescribed; Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery, courses of the same duration as those of not less than one hundred lectures above prescribed, or two courses of three months, lectures being given at least twice a week; Medical Jurisprudence, Botany, Natural History, including Zoology, during courses including not less than fifty lectures.(a *and* b)

2. That he has attended for at least two years the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons.

3. That he has been engaged for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of an hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain.

4. That he has attended for at least six months, by apprenticeship or otherwise, the out-practice of an hospital, or the practice of a dispensary, physician, surgeon, or member of the London or Dublin Society of Apothecaries.(b)

VI. The studies of candidates for the degrees of Bachelor of Medicine and Master in Surgery are subject to the following regulations:—

1. One of the four years of medical and surgical study required by Section IV. must be in the University of Edinburgh.

2. Another of such four years of medical and surgical study must be either in the University of Edinburgh or in some other university entitled to give the degree of Doctor of Medicine.

3. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such four years, and to that extent shall be held equivalent to one year's attendance on courses of lectures as above prescribed.

4. One year's attendance on the lectures of teachers of Medicine in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or of such teachers of Medicine in Edinburgh, or elsewhere, as shall from time to time be recognised by the University Court, may be reckoned as one of such four years, and to that extent shall be held as attendance on courses of lectures, as above prescribed.

5. Candidates may, to the extent of four of the departments of medical study required by Section V., Sub-section 1, attend, in such year or years of their medical and surgical studies as may be most convenient to them, the lectures of the teachers of Medicine specified in the foregoing Sub-section 4.

6. All candidates, not students of the University, availing themselves of the permission to attend the lectures of extra-academical teachers in Edinburgh, must at the commencement of each year of such attendance enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the matriculation fee paid by students of the University, and having, in respect of such payment, a right to the use of the library of the University.

7. The fee for attendance on the lectures of an extra-academical teacher in Edinburgh, with a view to graduation, must be of the same amount as that exigible by medical professors in the University.(c)

8. No teacher is recognised who is at the same time a teacher of more than one of the prescribed branches of study, except in those cases where professors in the University are at liberty to teach two branches.

VII. Every candidate must deliver, before March 31 of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—

1. A declaration in his own handwriting that he has completed his 21st year,(d) and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master.

2. A statement of his studies, as well in literature and philosophy as in Medicine, accompanied with proper certificates.

VIII. Each candidate is examined, both in writing and *viva voce*—first, on Chemistry, Botany, and Natural History; secondly, on Anatomy, Institutes of Medicine, Materia Medica,(e) and Pathology; thirdly, on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; fourthly, Clinically on Medicine and on Surgery in an hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, and Natural History are conducted, as far as possible, by demonstrations of objects placed before the candidates.

IX. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of their second year, may be admitted to examination at that time.(f)

X. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

XI. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

XII. Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

XIII. If any candidate at these examinations be found unqualified, he cannot be again admitted to examination unless he has studied, during another year, two of the prescribed subjects, either in the University or in some other school of Medicine.

XIV., XV., XVI. * * * * *

XVII. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of

(a) Certificates of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the parts dissected, and the carefulness with which the dissections have been made. Students are recommended not to appear for an examination in Anatomy, with a view to a degree, until they have dissected the human body at least once.

(b) The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine. *See* Note as to vaccination, appended to Section XX.

(c) The fee must be paid at the commencement of the course.

(d) Or that he will have done so on or before the day of graduation.

(e) Including Practical Pharmacy.

(f) Students who commence their medical studies in May may appear for this examination on the second October after the commencement of their studies, provided they have complete certificates for two qualifying summer sessions, and one qualifying winter session, two courses having been attended during each of the three sessions.

Medicine, and is of the age of 24 years, and has been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on an hospital, or in the Military or Naval Medical Services, or in medical and surgical practice.(g) Provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a Graduate in Arts of one of the Universities of England, Scotland, or Ireland, or of such other Universities as are above specified, or unless he shall, before or at the time of his obtaining the degree of Bachelor of Medicine, or within three years thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects,—namely, French, German, Higher Mathematics, and Natural Philosophy. And provided also that the candidate for the degree of Doctor of Medicine shall, on or before the 31st day of March in the year in which he proposes to graduate, submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degree of Bachelor of Medicine, which he may have made a subject of study after having received the degree.(h)

XVIII. The medical examiners for all candidates for graduation in Medicine are the Professors in the Faculty of Medicine, and, in addition, three persons appointed annually by the University Court.

XIX. The provisions of these statutes came into operation on the 4th of February, 1861.

XX. Persons who began their medical studies before the 4th of February, 1861, are entitled to graduate under the system in force before or after that date, according as they may comply with the regulations in force in the University before or after that date.

Note.—In conformity with the desire expressed by the Privy Council, it has been resolved that any candidate for a degree in Medicine must produce, at his final examination, a certificate from a dispensary or other public institution where vaccination is practised, attesting that he has been practically instructed in the operation, and is acquainted with the appearances which follow its performance.

Notice to Candidates for Graduation in Medicine.—Candidates who commenced their medical studies by attendance on qualifying classes before February 4, 1861, are entitled to appear for examination for the degree of Doctor of Medicine, after four years' study, on completing their twenty-first year, and without having taken the degree of Bachelor of Medicine. They are also exempted from the preliminary examinations mentioned in Sections I. and II., and require only to undergo an examination in Latin. They are also exempted from attendance on Practical Chemistry and Practical Midwifery, and require only three months of Clinical Surgery, and eighteen months of hospital attendance.

An *Annus Medicus* is constituted by at least two winter courses of one hundred lectures each, or by one such course, and two summer courses of fifty lectures each, all being duly certified.

Four *Anni Medici* are required for Graduates in Medicine. Two at least of these years must be passed at a university which grants degrees in Medicine, one of the two being at Edinburgh.

One or two of the *Anni Medici* may be taken at qualified extra-academical schools, in the manner stated in the succeeding paragraph:

In University College, in King's College, in the hospital schools of London, in the extra-academical School of Edinburgh, in the School of the College of Surgeons of Dublin, and in certain medical schools where at least two lecturers have been qualified by the University Court, a candidate may make *two Anni Medici*—one of which must be constituted by hospital attendance and Practical Anatomy, and the other by at least two courses of one hundred lectures, or one such course, and two courses of fifty lectures. The classes at these schools only qualify to the extent of four, and one of the four must be Practical Anatomy.

In provincial schools where there are no lecturers qualified by the University Court, a candidate can make *one Annus Medicus only*, and this is constituted by attendance on a qualified hospital, along with a course of Practical Anatomy.

The Edinburgh extra-academical classes only qualify if the fee paid at the commencement of the session is the same as that paid to the professors in the University.

All classes must be taken at a university, except *four* selected by the candidate. The classes so selected must be qualifying courses, as regards the subjects and extent.

Three months' courses of Materia Medica, Pathology, and Midwifery do not qualify. For each of these subjects *one* course of one hundred lectures is required.

No teacher is qualified who lectures on more than one of the required subjects, as specified in Section VI., 8.

Every candidate for a degree in Medicine must be a matriculated student of the University for the year in which he appears for examination or graduation.

The dates of the examinations for 1873-74 have been fixed as follows; and candidates for each of them are required to assemble in the upper Library Hall a quarter of an hour before the time fixed for examination:—Preliminary examination in Arts, October 14 and 15, 1873; March 17 and 18, 1874, at 10.30 a.m. each day. First professional examination, October 24 and 25, 1873; April 1 and 2, 1874, at 11 o'clock each day. Second professional examination, April 9 and 10, 1874, at 12 o'clock each day. Final professional examination, June, 1874, at 12 o'clock. Graduation, August 1, at 10 o'clock.

The names of candidates for the foregoing examinations must be given in, and the fees paid, etc., as follows:—For the final examination in June, 1874, on or before May 24; for graduation on August 1, on or before July 15; for second professional examination in April, 1874, on or before March 28; for preliminary examination in October, 1873, on or before October 4; for preliminary examination in March, 1874, on or before March 7; for first professional examination in October, 1873, on or before October 11; for first professional examination in April, 1874, on or before March 21; theses for M.D. on or before April 30, 1874. Specimens of the examination papers for 1872-73 are given in the Calendar.

The preliminary examinations in Arts accepted by the General Council are recognised *pro tanto*—that is to say, they exempt from examination in Arts on the subjects comprised in them, in so far as the examinations are of the same extent as those required by this University. Any subjects required by the statutes, and not included in these examinations, or not carried out to the requisite extent, must be passed at the University. In all cases candidates must produce certificates of having passed such examinations, with an official notice of the subjects in which they have passed.

The fees for the examinations must be deposited with the Registrar at least ten days before the day of examination. The fees are—For the preliminary examination, each non-matriculated student pays a fee of 10s. (candidates who paid the fee in March may obtain admission to the examination in October without further payment); for the degree of M.B., three Examinations, £5 5s. each, £15 15s.; for the degree of C.M., £5 5s. additional; for the degree of M.D., £5 5s. additional to that for M.B., exclusive of £10 Government stamp. The graduation fees must all be paid on or before July 15 in the year in which candidates propose to graduate.

Note.—Total fees and stamp for graduating as M.D. only, by Regulations, for students who commenced their medical education before February, 1861, £25.

Candidates, settled for a period of years in foreign parts, who have complied with all the regulations for the degree of M.D. (under the new statutes), but who cannot appear personally to receive the degree, may, on satisfying the Senatus to that effect by production of sufficient official testimonials, have the degree conferred on them in absence.

Students are recommended to commence their medical studies by attending a summer session.

MEDICAL DEGREES.—PRELIMINARY EXAMINATION IN ARTS.

PROGRAMME FOR 1873-74.

I. In conformity with Section I. of the Statutes (see p. 3), examinations on the preliminary branches of extra-professional education will take place on Tuesday and Wednesday, October 14 and 15, 1873, and on Tuesday and Wednesday, March 17 and 18, 1874, at 10.30 o'clock a.m. Examination on Tuesdays.—English, Arithmetic, Mechanics, Greek, Higher Mathematics, and German. Examination on Wednesdays.—Latin, Elements of Mathematics, Natural Philosophy, French, Logic, and Moral Philosophy. 1. English.—The Examination will include (1) Writing a passage of English from dictation; (2) English Composition, with the correction of sentences of bad English; (3) Questions in English Grammar, with analyses of sentences, and the derivation and definition of some common English words; (4) General questions in History and Geography. 2. Latin.—"Livy," Book ix., an easy passage from a Latin prose author, and a single passage of English (translated from a Latin author) to be retranslated into Latin, the more difficult Latin words being given. 3. Arithmetic.—The common rules, including Vulgar and Decimal Fractions. 4. Elements of Mathematics.—Euclid, Books i. ii., and iii., and the ordinary rules of Algebra, including Simple Equations. A knowledge of Euclid alone will not be sufficient. 5. Elements of Mechanics.—Elementary Mechanics and Hydrostatics. (*See* "Tomlinson's Rudimentary Mechanics," Weale's series.

II. At the same dates examinations will take place in conformity with Section II. of the same Statutes, which enacts that no candidate shall be admitted to a professional examination who has not passed a satisfactory examination on at least *two* of the following subjects (in addition to the subjects mentioned above):—1. Greek.—Xenophon, "Memorabilia," Book i. 2. French.—Molière, "Le Fourberies de Scapin." 3. German.—Schiller's "Thirty Years' War," Book i. 4. Higher Mathematics.—Euclid, Books i. to vi.—Algebra, Trigonometry, and Conic Sections. 5. Natural Philosophy.—Text-book recommended—Balfour Stewart's "Elementary Physics." 6. Logic.—Jevon's "Elementary Lessons in Logic." 7. Moral Philosophy.—Professor Calderwood's "Handbook." The working of the questions in Arithmetic, Mathematics, Mechanics, and Natural Philosophy, as well as the answers, must be exhibited. As regards Latin, Greek, French, and German, mere translation is not sufficient. Candidates must answer questions in grammar, and must be prepared to translate a passage of English into these languages.

In Section XVII. of the said Statutes it is enacted that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts, or unless he shall, before or at the time of his obtaining the degree of Bachelor of Medicine, or within three years thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. Two of these must be Greek and Logic or Moral Philosophy, and the *third* may be any one of the following subjects—namely, French, German, Higher Mathematics, Natural Philosophy.

Examinations of the same extent, and on the same subjects, at other British Universities granting the degree of M.D. will exempt from these Preliminary Examinations. Certificates of having passed such examinations must be produced, with an official notice of the subjects on which the candidate has passed an examination.

Students who come under the old statutes, in consequence of having commenced their medical curriculum by attendance on classes before February 4, 1861, will be examined in Latin on Wednesday, October 22, 1873, and Wednesday, March 18, 1874, at 10.30 a.m. For nature of examination, see Section I. of this programme.

(g) Certificates for at least two years' practice must be produced on or before July 15 of the year in which the candidate proposes to graduate.

(h) The candidate must lodge his thesis with the Dean on or before April 30 of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in practical Medicine, Surgery, Midwifery, or some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

UNIVERSITY OF ABERDEEN.

The regulations for granting medical degrees are framed in conformity with an Ordinance of the Universities (Scotland) Commissioners, dated March 16, 1861, and approved by her Majesty in Council.

The following are the degrees in Medicine granted by this University—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.).

The preliminary examination and professional curriculum, and examination for the degrees of M.B., C.M., and M.D. being in conformity with the Ordinances of the Scotch Universities Commissioners, are nearly the same as those of the Universities of Edinburgh, Glasgow, and St. Andrews.

The studies of candidates for the degrees of Bachelor of Medicine and Master in Surgery are subject to these regulations:—

One at least of the four years of medical and surgical study must be in the University of Aberdeen.

Another of such four years must be either in this University or in some other University entitled to give the degree of Doctor of Medicine.

FEES FOR GRADUATION.

1. Each candidate for the degree of M.B. shall pay a fee of £5 5s. in respect of each of the three professional examinations.

2. If the candidate desires to be admitted to the degree of Bachelor of Medicine only, he shall not, on admission thereto, be required to pay any further fee in addition to the £15 15s. so paid by him; but if he desires to be admitted to the degree of Master in Surgery also, he shall, on being admitted to such degree, pay a further fee of £5 5s.

3. And every candidate for the degree of Doctor of Medicine shall pay, in addition to the fees paid by him for the degree of Bachelor of Medicine, a fee of £5 5s., exclusive of any stamp duty which may for the time be exigible.

EXEMPTION FROM THE FOREGOING REGULATIONS.

Students who shall have begun their medical studies before the first Tuesday of November, 1861, are entitled to appear for examination for the degree of M.D. after four years study, one of which must have been at the University of Aberdeen.

Further information may be obtained from the Dean of the Medical Faculty, Professor Macrobin, M.D.

UNIVERSITY OF ST. ANDREWS.

The regulations for granting medical degrees are framed in conformity with an ordinance of the Universities (Scotland) Commissioners; they therefore generally correspond with those of the Universities of Edinburgh, Aberdeen, and Glasgow.

The degrees in Medicine granted by the University of St. Andrews are those of Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.)

The preliminary examination and professional curriculum and examinations for these degrees are generally the same as those of the Universities of Edinburgh, Aberdeen, and Glasgow. The following regulations, however, for candidates for the degrees of Bachelor of Medicine and Master in Surgery present some difference:—

No one shall be received as a candidate for the degree of Bachelor of Medicine or Master in Surgery unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities and colleges, viz.:—The University of St. Andrews; the University of Glasgow; the University of Aberdeen; the University of Edinburgh; the University of Oxford; the University of Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the School of the College of Surgeons in Dublin, or under such private teachers of Medicine as may from time to time receive recognition from the University Court.

Attendance on the lectures of any private teacher in Edinburgh, Glasgow, or Aberdeen shall not be reckoned for graduation in St. Andrews if the fee for such lectures be of less amount than is charged for the like course of lectures in the University of Edinburgh, of Glasgow, or of Aberdeen, according as the teacher lectures in Edinburgh, Glasgow, or Aberdeen.

FEES FOR GRADUATION.

For the degree of Bachelor of Medicine five guineas in respect of each of the three divisions of the examination on professional subjects; and if the candidate desires to be admitted to the degree of Bachelor of Medicine only, he shall not, on admission thereto, be required to pay any further fee in addition to the fifteen guineas so paid by him; but if he desires to be admitted to the degree of Master in Surgery also, he shall, on being admitted to such degree, pay a further fee of five guineas; and every candidate for the degree of Doctor of Medicine, who has previously obtained the degree of Bachelor of Medicine, shall pay, in addition to the fees paid by him as a candidate for the degree of Bachelor of Medicine, a fee of five guineas, exclusive of any stamp duty which may for the time be exigible.

N.B.—The degree of Doctor of Medicine may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years, whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the Medical Examiners of the sufficiency of his professional knowledge; provided always, that degrees shall not be conferred under this section to a greater number than ten in any one year. Fee £52 10s.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted, viz.:—Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). [The preliminary examination, curriculum, and professional examinations for these degrees, being in conformity with the ordinance of the Scottish Universities Commissioners, are the same as for the Universities of Edinburgh, St. Andrews, and Aberdeen.]

Of the four years constituting the curriculum, one at least shall have been passed in the University of Glasgow, and another either in that university or in some other university entitled to give degrees in Medicine.

The fees for the degrees are as follows:—For the degree of M.B. (for each of three examinations, £5 5s.), £15 15s.; for that of C.M. (in addition to the fee for M.B.), £5 5s.; for the degree of M.D. (in addition to the fee for M.B.), £5 5s.; and the Government stamp for the diploma, etc., £10 3s.

The preliminary examinations of medical students in branches of general education take place at the beginning and at the end of the winter session.

The regulations under which the above degrees are granted, and the notices of the subjects of examination, will be obtained by application to the Registrar of the University.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

ABSTRACT OF REGULATIONS FOR THE LICENCE.

No one can obtain the licence of the College until he has completed the age of 21 years.

Every applicant for the licence must produce evidence that he has been engaged in the study of Medicine during a period of at least four years subsequently to his registration as a medical student, which period shall include attendance during not less than four winter sessions, or three winter and two summer sessions, at a recognised medical school.

The applicant must produce certificates that he has attended the following courses at a university, or at some medical school recognised by the college:—Anatomy, one course, six months; Practical Anatomy, six months; Chemistry, one course, six months; Practical Chemistry, three months; Materia Medica and Pharmacy, one course, three months; Physiology or Institutes of Medicine, one course, three months; Practice of Medicine, one course, six months; Clinical Medicine, six months; Principles and Practice of Surgery, one course, six months; Clinical Surgery, three months; Midwifery, one course, three months; Medical Jurisprudence, one course, three months; Pathological Anatomy, one course, three months; or General Pathology, one course, three months; Practical Pharmacy, three months.

The applicant must also produce evidence of having attended the practice of a public hospital (containing not fewer than eighty beds) during a period of not less than twenty-four months, twelve of which must have been spent in attendance on the medical wards. He must also have attended for six months the practice of a public dispensary, or have acted for six months as a clinical clerk or dresser in a hospital, or have been engaged for six months as visiting assistant to a registered practitioner.

The applicant must also have attended at least six cases of labour under the superintendence of a qualified medical practitioner, and must produce a certificate to that effect.

The applicant will also be required to produce a certificate that he has studied vaccination under a competent and recognised teacher, and that he is thoroughly informed in every necessary part of the subject.

Every applicant for the licence must have passed the preliminary examination in Literature and Science, and have had his name inscribed in the Register of Medical Students, instituted by the General Medical Council, previous to the commencement of his medical studies.

The examination will embrace the following subjects:—1. English: Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations. 3. Geometry: First two Books of Euclid. 4. Latin: Translation into English, Cicero de Senectute et de Amicitia, *or* Horatii Carmina, Lib. II. et III.—Parsing: Translation from English into Latin, the Latin words being supplied. 5. One of the following subjects, at the option of the candidate:—1. Greek: Herodotus' History, Book I., and Homer's Iliad, Book II. 2. French: Voltaire's "Henriade." 3. German: Schiller's "Wilhelm Tell." 4. Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics.

The professional examination will be divided into two parts, according to the following arrangements of subjects:—(1) Anatomy, Physiology, Chemistry; (2) Materia Medica and Pharmacy, Pathology, and Pathological Anatomy, Practice of Medicine, Midwifery, Medical Jurisprudence, Clinical Medicine, including the examination of patients, as well as of various morbid products. No candidate will be admitted to the first examination until he has completed two, or to the second until he has completed four, years of professional study. The examinations will be conducted partly *viva voce*, partly by written papers.

The following will be the periods of examination up to October, 1874:—(1.) Preliminary examinations in Literature and Science—Tuesday and Wednesday, October 21 and 22, 1873; Tuesday and Wednesday, April 21 and 22, 1874; Saturday and Monday, July 25 and 27, 1874. (2.) First professional examinations—Wednesday, October 15, 1873; Wednesday, January 21, 1874; Wednesday, April 22, 1874; Wednesday, July 29, 1874; Wednesday, October 14, 1874. (3.) Second professional examinations will be held on the Thursdays and Fridays following the first professional, and will occupy both days.

The fee payable by a Licentiate is ten guineas. In the event of a candidate being unsuccessful at his examination, the sum of two guineas will be retained to defray expenses.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

REGULATIONS TO BE OBSERVED BY CANDIDATES FOR THE DIPLOMA.

These are the same as those given below for the conjoined qualification in Medicine and Surgery conferred by the Colleges of Physicians and Surgeons, with the following exceptions in professional education:—

No third course of Medicine and no course of Pathological Anatomy are required.

A certificate of three months' instruction in Pathological Anatomy at the post-mortem room of a recognised hospital will be required from candidates commencing professional study after October 1, 1861.

The regulations for the preliminary examination in general education generally correspond with those to be observed by candidates for the joint qualification of the Royal Colleges of Physicians and Surgeons, Edinburgh.

PROFESSIONAL EXAMINATIONS FOR THE DIPLOMA OF THE COLLEGE.

The regulations are generally the same as those for the professional examinations for the joint diploma of the two Colleges, with the following exceptions:—

The sum of £4 must be paid to the Treasurer of the College for the first examination, not latter than 10 a.m. of the day preceding it. The sum will be considered as paid to account of the entire fee of £10 payable for the diploma.

In the case of a candidate being unsuccessful at this examination, £2 will be returned to him, the remaining £2 being retained to meet the expenses of the examination.

The second examination embraces Surgery and Surgical Anatomy, also Medicine, Midwifery, Materia Medica, and Medical Jurisprudence; and shall not take place before the termination of the winter session of the last year of study. In the case of candidates who began their course of study after September 16, 1866, it will not take place till four years after the examination in general education. Applications for examination must be made to the Secretary not later than the Tuesday previous to the day of the examination. Every candidate must produce to the Secretary—1. Satisfactory evidence of his having attained the age of twenty-one years, and of having been duly registered; 2. Certificates of having attended the prescribed classes, together with the certificates enumerated; 3. The certificate of his having passed the first professional examination; and 4. A tabular statement (for which a printed form will be furnished by the officer) exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, and dispensaries attended during each session of his studies. If he have been an apprentice he must also insert the name of his master, the date of his indenture, and the length of time for which he was bound. This statement, accurately filled up, must be attested by his signature, and will be preserved by the College as a record.

If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

The remaining fee payable to the College (being £6), together with the receipt for the fee paid for the first professional examination, must be lodged not later than 10 a.m. of the day preceding the examination day, in the hands of the Treasurer, who will certify this upon the Secretary's letter. The sum of £4 will be returned to unsuccessful candidates.

Periods of examination for the year 1873-74:—I. Preliminary Examinations in General Education: On Tuesday and Wednesday, October 21 and 22, 1873; on Tuesday and Wednesday, April 21 and 22, 1874; on Saturday and Monday, July 25 and 27, 1874. II. First Professional Examinations: On Tuesday, October 28, 1873; on Tuesday, January 27, 1874; on Tuesday, April 7, 1874; on Tuesday, April 28, 1874; on Tuesday, July 28, 1874. III. Second Professional Examinations: These will take place immediately after the conclusion of the first professional examinations, at each of the above-mentioned periods.

THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.

The Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain the diplomas of both Colleges.

The general principle of this joint examination is, that it shall be conducted by a Board, in which each body is represented in those branches which are common to both Medicine and Surgery; but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery.

The object of the joint examination is to give to students facilities for obtaining from two separate bodies, and at less expense, a qualification in Medicine and a qualification in Surgery.

Students passing that examination successfully will be enabled to register two qualifications under the Medical Act—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh.

The arrangement for thus conferring a double qualification by the co-operation of the two Colleges is in conformity with Section XIX. of the Medical Act, and received the special sanction of the General Council of Medical Education and Registration, at a meeting held on August 7, 1859.

SCHOOLS OF MEDICINE.

1. Every candidate must have followed his course of study in a *University*, or in an *established School of Medicine*, as defined below, or in a *Provincial School* specially recognised by the Colleges of Physicians and Surgeons of that division of the United Kingdom in which it is situate.

2. Under the title *established School of Medicine* are comprehended the medical schools of those cities of Great Britain and Ireland in which diplomas in Medicine and Surgery are granted, and such colonial and foreign schools as are similarly circumstanced in the countries in which they exist.

PROFESSIONAL EDUCATION.

1. Candidates commencing professional study after September 16, 1866, must have been engaged during four years after the examination in general education, in professional study, which shall include not less than four winter sessions, or three

winter and two summer sessions' attendance at a recognised medical school.(a)

2. The candidate must produce certificates of having attended the following separate and distinct courses of lectures:—

Anatomy, two courses,(b) six months each; Practical Anatomy, twelve months. Or, in the option of the candidate, Anatomy, one course, six months; Practical Anatomy, eighteen months. Chemistry, one course, six months. Practical or Analytical Chemistry, one course, three months. Materia Medica, one course, three months. Physiology, not less than fifty lectures.(c) Practice of Medicine, one course, six months. Clinical Medicine, six months.(d) Medicine—a third course, which may either be Practice of Medicine or Clinical Medicine, at the option of the student, one course, six months.(d) Principles and Practice of Surgery, one course, six months. Clinical Surgery, one course, six months.(d) Surgery—a third course, which may either be Principles and Practice of Surgery or Clinical Surgery, at the option of the student, one course, six months.(d) Midwifery and the Diseases of Women and Children, one course, three months. Medical Jurisprudence, one course, three months. Pathological Anatomy, one course, three months.(e) The six months' courses delivered in Scotland must consist of not fewer than one hundred lectures, with the exception of Clinical Medicine and Clinical Surgery. The three months' courses must consist of not fewer than fifty lectures.

3. The candidate must also produce the following certificates:—(*a.*) Of having attended six cases of labour under the superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b.*) Of having attended for three months instruction in Practical Pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or a chemist and druggist recognised by either College, on special application, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients. (*c.*) Of having attended for twenty-four months a public general hospital containing, on an average, at least eighty patients. (*d.*) Of having attended for six months the practice of a public dispensary specially recognised by either College; or of having been engaged for six months as visiting assistant to a registered practitioner. (*e.*) Of having been instructed in vaccination. The certificate to be signed by the teacher, who must be a registered practitioner.(f)

4. The following order of study is recommended as a guide to the student, though not enjoined:—First year: Anatomy, Practical Anatomy, Chemistry, Practical or Analytical Chemistry, Hospital. Second year: Anatomy, Practical Anatomy, Physiology, Surgery, Materia Medica (the last either in this or the third year), Hospital. Third year: Practice of Medicine, Clinical Surgery, Practical Anatomy, Practical Pharmacy, Clinical Medicine, Pathological Anatomy, Hospital. Fourth year: Surgery or Clinical Surgery, Midwifery and the Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Hospital.

5. It is strongly recommended to students to avail themselves of any opportunities which they may possess of attending lectures on Ophthalmic and Mental Diseases, also on Natural History and Comparative Anatomy; and of obtaining practical instruction in the use of the microscope, in addition to the courses of instruction which are absolutely required.

PRELIMINARY EXAMINATION IN GENERAL EDUCATION.

1. All students who intend becoming candidates for the diplomas of the Colleges must have passed the complete examination in general education, and have had their names inscribed in the Register of Medical Students instituted by the General Medical Council, at the commencement of their professional studies.

2. The following will be the preliminary examination in general education for the double qualification in Medicine and in Surgery conferred conjointly by the Royal Colleges of Physicians and Surgeons, and also for the separate diploma of each College, for 1873-74:—1. English Language, including Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions. 3. Algebra, including Simple Equations. 4. Geometry: First Two Books of Euclid. 5. Latin: Translation from one of the two following books at the option of the candidate—viz., Cicero de Senectute et de Amicitia, or Horatii Carmina, Lib. II. et III.; and of an easy passage from a book not prescribed; Exercises in Parsing, and in rendering English correctly into Latin, the Latin words being supplied. 6. One of the following subjects at the option of the candidate:—(1.) Greek: Herodotus' History, Book I., and Homer's Iliad, Book II. (2.) French: Voltaire's "Henriade." (3.) German: Schiller's "Wilhelm Tell." (4.) Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics. N.B.—In Greek, French, and German, parsing of words from the passages given to be translated will be required; also translation of short sentences from English into their respective languages.

3. Testimonials of proficiency granted by certain educational bodies will be accepted as sufficient evidence of general education, and will exempt from the preliminary examination.

4. The preliminary examinations shall take place at stated periods, and shall be conducted by a special board of examiners in Arts, to be chosen from time to time by the Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh.

5. Students who intend to undergo the preliminary examination shall give in their names, addresses, and places of birth to the officer of either College, not later than three days before the day of examination, and shall pay a fee of 10s., not to be returned in case of rejection, but will be admissible to re-examination at a future period without paying another fee.

6. Candidates, the commencement of whose professional studies was prior to September 17, 1866, may pass the preliminary examination in general education at any of the periods previous to the first professional examination, but are recommended to do so at the earliest possible period. Candidates under this regulation who have not passed a preliminary examination in general education will be admitted to a special examination in general education previously to their first professional examination. For this they shall pay a fee of £1.

PROFESSIONAL EXAMINATION.

1. Candidates for the double qualifications shall be subjected to two professional examinations, to be conducted at separate times, partly in writing and partly orally.

2. Opportunities for both examinations will be presented six times in each year. On each of these occasions the candidates shall assemble for the purpose of writing answers to the questions proposed. The oral examinations will be conducted on the days immediately succeeding.

3. Unsuccessful candidates at either the first or second examination shall be remitted to their studies for a period to be determined by the judgment of the examiners, but not in any case less than three months.

4. The first examination shall embrace Anatomy, Physiology, and Chemistry, and shall take place not sooner than the end of the second winter session.

5. Candidates who desire to pass the first professional examination must apply to the Inspector of Certificates on or before the Saturday preceding the day of examination, (g) and must produce certificates of attendance in regard to all those of the required courses of lectures which have reference to the subjects of that examination. They must also produce a certificate of having passed the preliminary examination.

6. The sum of £6 must be paid to the Inspector of Certificates for this examination, not later than 10 a.m. of the day preceding it. This sum will be considered as paid to account of the entire fee of £16 payable for the two diplomas.

7. In the case of a candidate being unsuccessful at this

(a) Candidates commencing study prior to the above date will be admitted to examination after four winter sessions', or three winter and two summer sessions' attendance on classes at a regular medical school.

(b) The two courses must not be attended in the same session.

(c) In those schools of England and Ireland in which two separate courses of lectures are delivered at separate hours—one on Anatomy, the other on Anatomy and Physiology—the former of these courses will be received as a course of Anatomy, and the other as a course of Physiology.

(d) Two courses of Clinical Medicine, of three months each, if not simultaneous, will be held equivalent to one course of six months. They must be attended during the period of attendance at the hospital where they are delivered. The same rules will apply to Clinical Surgery.

(e) A certificate of attendance on the post-mortem examinations at a general hospital will be accepted in lieu of this course.

(f) By a Regulation of the Privy Council, of date December 1, 1859, no one can be appointed as a contractor for vaccination under the English Poor-law who does not produce a certificate of proficiency in vaccination from a person authorised by the Privy Council to grant the same.

(g) Candidates at a distance are requested to send their certificates much earlier, so as to give sufficient time for the exchange of one or two explanatory letters; as much disappointment has been occasioned by the discovery of defects in their course of study when it was too late to rectify them by the production of documents.

examination, £4 will be returned to him; the remaining £2 being retained to meet the expense of examination.

8. The second examination shall embrace Medicine, Surgery and Surgical Anatomy, Midwifery, Pathological Anatomy, Materia Medica and Pharmacy, and Medical Jurisprudence; and shall not take place before the termination of the winter session of the last year of study. In the case of candidates who began their course of study after September 16, 1866, it will not take place till four years after the examination on general education.

9. Applications for examinations must be made to the Inspector of Certificates not later than the Tuesday previous to the day of examination.(g)

10. Every candidate must produce to the Inspector—1st. Satisfactory evidence of his having attained the age of 21 years; 2nd. A certificate of his having passed the preliminary examination, unless this certificate have already been seen by the Inspector of the Colleges; 3rd. A certificate of his registration in the books of the General Medical Council; 4th. A certificate of his having passed the first professional examination; 5th. The certificates of his classes, and the other certificates required; and 6th. A tabular statement (for which a printed form will be furnished by the Inspector), exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, and dispensaries attended during each session of his studies. The tabular statement accurately filled up must be attested by his signature, and will be preserved by the Colleges as a record.

11. The fee payable for this examination, which shall be £10, must be lodged with the Inspector not later than 10 a.m. of the day preceding the examination day.

12. On the production of the above documents, and after receiving the fees, the Inspector shall give the candidate a letter authorising the examiners to take him on trial.

13. In case of a candidate being unsuccessful at the second examination, £8 will be returned to him; the remaining £2 being retained to meet the expense of the examination.

14. Candidates who have passed the first professional examination in Anatomy, Physiology, and Chemistry, at any of the licensing boards recognised by the Medical Act, will be admissible to the second professional examination, on producing certificates of the whole course of study prescribed, and of having passed their preliminary and first professional examinations. If any of the three subjects of the first examination have been omitted, such candidates will have to undergo an examination on the omitted subjects; and none of the subjects will be omitted at the second examination, even if some of them should have formed part of the first examination by another board. The fee payable by such candidates is £16, and unsuccessful candidates will receive back £14.

15. In addition to the written and oral examinations, all candidates shall be subjected to a practical clinical examination in Medicine and Surgery, which shall include the examination of patients, physical diagnosis, the use of the microscope, surgical appliances, bandages, etc.

16. Candidates desirous of special examinations on other days than those fixed by the regulations, must prepare a case to be submitted for the consideration of the authorities of the College with evidence to show why it was and is impossible for them to avail themselves of the ordinary examinations past and future. They must *at the same time* produce certificates of the whole of the prescribed course of study and of the preliminary examination, and state the earliest and the latest days within which they can present themselves. It is very desirable that all such candidates, and especially those who are at a distance from Edinburgh, should present their applications as long beforehand as possible.

The fees for special examinations are as follows:—£28 for first and second examinations, of which £22 will be returned to candidates remitted on the first examination, and £10 to candidates successful in the first, but unsuccessful in the second examination. £25 for second examination, when the candidate has passed the first under the conditions of Section 14. Of this £16 will be returned to the candidate if unsuccessful. £19 for second examination, when the candidate has passed the first before the examiners of the Colleges. Of this £10 will be returned to the candidate if unsuccessful.

17. No candidate shall be admissible to examination who has been rejected by any other licensing board within the three months preceding his examination.

(g) See note (g) on previous page.

I. *Preliminary Examinations in General Education.*—On Tuesday and Wednesday, October 21 and 22, 1873; on Tuesday and Wednesday, April 21 and 22, 1874; on Saturday and Monday, July 25 and 27, 1874.

II. *First Professional Examinations.*—On Tuesday, November 4, 1873; on Tuesday, February 3, 1874; on Tuesday, April 14, 1874; on Tuesday, May 5, 1874; on Tuesday, July 21, 1874; on Tuesday, August 4, 1874.

III. *Second Professional Examinations.*—These will take place immediately after the conclusion of the first professional examination, at each of the above-mentioned periods.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

ABSTRACT OF REGULATIONS FOR THE LICENCE, 1873-74.

Course of Study.—(1.) Anatomy, two courses, six months each. (2.) Practical Anatomy, twelve months. (3.) Chemistry, one course, six months. (4.) Practical or Analytical Chemistry, one course, three months. (5.) Physiology, not less than fifty lectures. (6.) Practice of Medicine, one course, six months. (7.) Clinical Medicine, one course, six months. (8.) Principles and Practice of Surgery, one course, six months. (9.) Clinical Surgery, one course, six months. (10.) In addition to the above courses of Surgery and Clinical Surgery, one six months' course of either of these at the option of the student; Materia Medica, one course, three months. (11.) Midwifery and the Diseases of Women and Children, one course, three months. (12.) Medical Jurisprudence, one course, three months. (13.) Practical Midwifery, attendance on at least six cases of labour. (14.) Pathological Anatomy, three months' instruction in the post-mortem room of a recognised hospital. (15.) Practical Pharmacy, three months' practical instruction. (16.) Hospital and Dispensary Practice, twenty-four months' attendance on the practice of a public general hospital containing on the average at least eighty patients.

A certificate of proficiency in vaccination, from a vaccine institution recognised by the Faculty, will be required of every candidate. Candidates (not exempted from registration) must have been engaged in professional study during four years from the date of registration, which shall include not less than four winter sessions' or three winter and two summer sessions' attendance at a recognised medical school.

Candidates are subjected to two professional examinations. The first examination embraces Anatomy, Physiology, and Chemistry, and cannot be undergone before the end of the second winter session of study.

The second examination embraces Surgery and Surgical Anatomy, Medicine, Materia Medica, Midwifery, and Medical Jurisprudence, and cannot be undergone before the termination of the full period of study.

Intending candidates for the second examination must produce evidence—1st, of being 21 years of age; and 2nd, of having passed the first examination. They will also present to the Secretary for inspection their class and hospital certificates, and write out a tabulated statement of their whole course of study, for which the Secretary, on application, will supply candidates with printed forms.

The fee for the diploma is £10—£4 for the first, and £6 for the second examination.

Candidates who possess a qualification to practise, or who have passed the examination in Anatomy, Physiology, and Chemistry before any of the licensing boards, will be admitted to the second examination on producing evidence of having attended the full curriculum, and paying the fee of £10.

DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain two separate licences—one in Medicine and one in Surgery.

The fee for the two diplomas granted conjointly is £16—£6 for the first, and £10 for the second examination.

The first examination for the double qualification will be held in the Faculty Hall, Glasgow, on October 2, 1873, January 15, April 2, May 7, and July 23, 1874, and on each occasion it will be continued on the succeeding day. The second examination will be held, the written part on each the above days, and the oral part on the succeeding day. Applications to be admitted, either to the first or second examination, must be made to the Secretary of the Faculty not later than the Monday preceding the examination.

PRELIMINARY EXAMINATIONS CONDUCTED BY THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, SESSION 1873-74.

1. Preliminuary examinatious in general literature, in accordance with the regulations of the General Medical Council, will be held in the Faculty Hall during the session 1873-74, on the following days, commencing at 11 o'clock, viz.:—Friday, October 17, aud Friday, October 31, 1873; Friday, April 24, aud Friday, July 24, 1874; aud on each occasion the examination will be continued on the succeeding day.

The examination will embrace the following subjects:—1. English language. 2. Latin. 3. Arithmetic; Algebra. 4. Geometry. 5. One of the following subjects at the optiou of the candidate:—(1.) Natural Philosophy — Mechanics, Hydrostatics, and Pneumatics. (2.) Greek. (3.) French. (4.) German.

The fee for the examination and certificate is 10s., payable to the Secretary previous to the examination.

FACULTY OF MEDICINE IN IRELAND.

UNIVERSITIES, COLLEGES, COURSES OF STUDY, DEGREES, AND LICENCES TO PRACTISE.

The following bodies grant one or more degrees or licences to practise Medicine or Surgery, and provide courses of instruction in the Medical Sciences:—The University of Dublin grants the degrees of M.B. or Bachelor of Medicine; M.D. or Doctor of Medicine; aud M.Ch. or Master of Surgery; also licences in Medicine (L.M.) and Surgery (L.S.). In connexion with the University, Trinity College gives a diploma in State Medicine, after examination, to Doctors of Medicine of Dublin, Oxford, or Cambridge. The Queen's University in Ireland, with its Provincial Colleges at Belfast, Cork, and Galway: This University confers the degrees of M.D. and M.Ch. The King and Queen's College of Physicians in Ireland grants a licence and a Fellowship. This institution, in connexion with the Medical Faculty of the University of Dublin, constitutes the School of Physic in Ireland. The Royal College of Surgeons in Ireland grants letters testimonial qualifying to practise Surgery as a Licentiate, and also confers a Fellowship. Fellows and Licentiates of the Colleges of Physicians and Surgeons may obtain from their respective colleges a diploma in Midwifery. The Rotundo and Coombe Lying-in Hospitals grant diplomas in Midwifery, which are, however, not recognised under the Medical Act. The Governor and Company of the Apothecaries' Hall of Ireland also confer a diploma.

The medical session in Ireland commences about the first week in November.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC.

The School of Physic in the University of Dublin is under the joint control of the Board of Trinity College and of the President and Fellows of the College of Physicians.

MATRICULATION.

All students of the School of Physic must be matriculated by the Senior Lecturer of Trinity College, for which a fee of 5s. is payable. No student can be admitted for the winter courses after November 25.

DEGREES AND LICENCES IN MEDICINE AND SURGERY.

The Act 21 and 22 Vic., c. 99, recognises, as qualifications for medical and surgical practitioners, the degrees and licences in Medicine and Surgery granted by the University. The degrees are—1. Bachelor of Medicine. 2. Doctor of Medicine. 3. Master in Surgery.

UNIVERSITY DEGREES.

1. *Bachelor in Medicine.*—A candidate for the degree of Bachelor in Medicine must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B.A., or at any subsequent commencement, provided the requisite medical education shall have been completed. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on the following courses of lectures, viz.:—Courses of five months' duration (November to April)—Anatomy, Practical Anatomy (with Dissections), Surgery, Chemistry, Practice of Medicine, Midwifery. Courses of three months' duration (April to July)—Botany, Practical Chemistry, Medical Jurisprudence, Materia Medica and Pharmacy, Institutes of Medicine.

Hospital Attendance.—1. Nine months' attendance on the clinical lectures of Sir Patrick Dun's Hospital. 2. Nine months' additional attendance on the clinical lectures of any hospital recognised by the Board. 3. Instruction in practical midwifery, including not less than six deliveries. 4. Certificate of personal attendance on fever cases, stating name and date of each case.

Any of the above-named six or three months' courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows (and three of them, at the discretion of the candidate, may be attended in the University of Edinburgh), provided the candidate have kept an *Annus Medicus* in the School of Physic.

The Schools recognised are:—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Dr. Steevens' Hospital. 4. The St. Peter-street School. 5. The School of the Catholic University.

An *Annus Medicus*, or a year's attendance, in the School of Physic may be kept in three ways:—1. By attending at least two, or not more than three, of the foregoing courses which are of six months' duration. 2. By attending one course of six months' and two of three months' duration. 3. By nine months' attendance on Sir Patrick Dun's Hospital and clinical lectures; together with one course of six months', or, in lieu thereof, two courses of three months' duration.

The fees for nine mouths' attendance at Sir Patrick Dun's Hospital is £12 12s. The fees for each course of lectures is £3 3s. The fee for the *Liceat ad Examinandum* is £5. The fee for the degree of M.B. is £11.

2. *Doctor in Medicine.*—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

3. *Master in Surgery.*—The degree of Master in Surgery can only be obtained by students who are Bachelors of Arts, and who have completed the professional curriculum and passed the examinations required. The curriculum extends over a period of four years, and comprises attendance upon the following courses of lectures:—viz., Anatomy, one course; Demonstrations, three courses; Dissections, three courses; Theory and Practice of Surgery, two courses; Practice of Medicine, one course; Chemistry, one course; Materia Medica, one course; Midwifery, one course; Practical Chemistry, one course; Botany, one course; Medical Jurisprudence, one course. After the year 1874, the Mastership in Surgery will be conferred upon those candidates only who are of Masters in Arts standing.

Hospital Attendance.—Three sessions, each of nine consecutive months' duration, in any recognised hospital, together with attendance on the clinical lectures on Medicine and Surgery there delivered. Any of the above-named courses may be attended at any of the medical schools of Dublin recognised by the Board, provided the candidate has kept an *Annus Medicus* in the School of Physic. The following hospitals are recognised by the Board:—1, Sir Patrick's Dun's School of Physic Hospital; 2, Meath Hospital; 3, Richmond, Whitworth, and Hardwicke Hospitals; 4, Dr. Steevens' Hospital; 5, Jervis-street Infirmary; 6, City of Dublin Hospital; 7, Mercer's Hospital; 8, St. Vincent's Hospital; 9, Adelaide Hospital; 10, Mater Misericordiæ Hospital. Of the courses of lectures, which are of five months' duration, not more than three can be attended during any one session. Candidates will also be required to perform surgical operations on the dead subject. Candidates for the degree of Master in Surgery, who have already passed the examination for the degree of Bachelor of Medicine, will be examined in Anatomy and Surgery only. Fee for the *Liceat ad Examinandum*, £5. Fee for the degree of M.Ch., £11.

UNIVERSITY LICENCES.

Candidates for the licences in Medicine or Surgery must be matriculated in Medicine, and must have completed four years in medical studies. Candidates for the licences in Medicine or Surgery must pass the following examination in Arts, unless they be students in the Senior Freshman or some higher class:—Homer's Iliad, Books I., II., (omitting catalogue of ships), III.; Lucian's Dialogues (Walker's edition); Xenophon's Anabasis, Books I., II., III.; Virgil, Æneid, Books I., II., III.; Sallust; Horace, Satires; Latin Prose Composition; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra to the end of Simple Equations; Euclid,

Books, I., II., III. Students who have passed the foregoing examination will be required to pay the admission fee of £15.

1. *Licentiate in Medicine.*—The medical course and examination necessary for the licence in Medicine is the same as for the degree of M.B., with the exception that any general hospital approved by the Board of Trinity College may be substituted for Sir Patrick Dun's. Candidates who are already Licentiates in Surgery of the Royal College of Surgeons in Ireland, or Members of the College of Surgeons of England, on passing the foregoing Arts examination, will be admitted to examination for the licence in Medicine. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in Medicine, £5.

2. *Licentiate in Surgery.*—The surgical course and examination necessary for the licence in Surgery are the same as for the degree of Master in Surgery. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in Surgery, £5.

Total Expenses of obtaining the Degrees of Bachelor in Medicine and Master in Surgery.—I. Lectures: 1. Anatomy (one course), £3 3s. 2. Practical Anatomy (three courses), £9 9s. 3. Dissections (three courses), £15 15s. 4. Surgery (two courses), £4 4s. 5. Practice of Medicine, £3 3s. 6. Chemistry (two courses), £4 4s. 7. Materia Medica and Pharmacy, £3 3s. 8. Midwifery, £3 3s. 9. Botany. 10. Medical Jurisprudence, £3 3s. 11. Institutes of Medicine, £3 3s. Matriculation fee, 5s.—II. Hospitals: Sir P. Dun's (first year), £9 9s.; ditto (second year), £9 9s.; ditto (third year), £9 9s.; Practical Midwifery, £3 3s.; Ophthalmic Surgery, £2 2s.—III. Degrees: 1. *Liceat ad Examinandum in Medicinâ*, £5. 2. *Liceat ad Examinandum in Chirurgiâ*, £5. 3. M.B. degree, £11. 4. M.Ch. degree, £11.—Total Expenses: 1. Lectures, £52 15s. 2. Hospitals, £33 12s. 3. Degrees, £32. Total, £118 7s.—N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to £83 4s., should be added to the foregoing, making the total £281 11s.

THE QUEEN'S UNIVERSITY IN IRELAND,

Granting the degrees of Doctor in Medicine and Master in Surgery, and diplomas in Midwifery, includes three colleges—the Queen's Colleges of Belfast, Cork, and Galway—each of which possesses a Faculty of Medicine. The curriculum of medical study extends over a period of four years, and is divided into two periods of two years each. The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, Materia Medica, and Pharmacy. The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. At least two of the above courses of lectures must be attended in some one of the Queen's Colleges; the remainder may be taken, at the option of the candidate, in any university, college, or school recognised by the Senate of the Queen's University. Candidates are required before graduating to have also attended in one of the colleges of the Queen's University lectures on Experimental Physics and on one Modern Language, and to have passed the matriculation examination. They are further required to attend, during the first period, Practical Chemistry in a recognised laboratory, and the practice during six months of a recognised medico-chirurgical hospital, containing at least sixty beds, together with the clinical lectures delivered therein; and to attend, during the second period, a recognised midwifery hospital, with the clinical lectures therein delivered, for a period of three months; or a midwifery dispensary for the same period; or ten cases of labour, under the superintendence of the medical officer of any hospital or dispensary where cases of labour are treated: and eighteen months' practice of a recognised medico-chirurgical hospital containing at least sixty beds, and in which clinical instruction is delivered. There are two University examinations; one comprising the subjects of study in the first period, the other the subjects of the second period. The degree of Master in Surgery and the diploma in Midwifery are only conferred upon candidates who already hold the degree of Doctor in Medicine, and who have also passed a special examination in Surgery or Midwifery. The University examinations are held twice in each year—in June and September. Candidates who commenced their medical studies elsewhere are admitted to the first University examination before proceeding to college. Further information will be found in the "Queen's University Calendar," or may be obtained by application to the Secretary, Queen's University, Dublin Castle.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

Examinations for the licence in Medicine are statedly held on the second Tuesday and Wednesday in each month (except August and September).

The name of every candidate, together with his schedule and the documents hereafter mentioned, must first be submitted to the College at one of its meetings. These are held regularly on the first Friday in each month (except August and September).

CURRICULUM.

A candidate who has not, previous to entering his name, obtained any medical or surgical qualification recognised by the College, must produce—1. Evidence of having been engaged in the study of Medicine for four years. 2. A certificate of having passed the preliminary examination of one of the recognised licensing corporations before the termination of the second year of medical study. 3. Certificates of having studied, at a school or schools recognised by the College, the following subjects, viz.:—Practical Anatomy; Antomy and Physiology, or Institutes of Medicine; Botany; Chemistry; Practical Chemistry; Materia Medica; Practice of Medicine and Pathology; Surgery; Midwifery; Medical Jurisprudence. 4. Certificates of having attended a medico-chirurgical hospital in which regular courses of clinical lectures are delivered, together with clinical instruction, for twenty-seven months; or such hospital for eighteen months, with nine months' attendance on a medical hospital, and similar courses of clinical lectures and instruction. 5. A certificate of having attended practical midwifery for six months at a recognised lying-in hospital, or evidence satisfactory to the College in each individual case of having attended practical midwifery. 6. Certificates of character from two registered physicians or surgeons.

A candidate who has already obtained a medical or surgical qualification recognised by the College is only required to produce his diploma or certificate of registration, and the certificate of practical midwifery, and testimonials as to character.

EXAMINATION FOR THE LICENCE IN MEDICINE.

The examination consists of two parts. The subjects of the first part or previous examination are—Anatomy, Physiology, Botany, Chemistry. The subjects of the second part or final examination are—Materia Medica, Practice of Medicine, Medical Jurisprudence, Midwifery.

All candidates for the second or final examination (with the exception below specified)(a) are examined in the practice of Medicine at the bedside in one of the hospitals of Dublin.

Candidates qualified as follows are required to undergo the *second part* of the professional examination *only*, viz.:—1. Graduates in Medicine of a university in the United Kingdom, or of any foreign university approved by the College. 2. Fellows, Members, or Licentiates of the Royal College of Physicians of London or Edinburgh, who have been admitted upon examination. 3. Graduates or licentiates in Surgery. 4. Candidates who, having completed the curriculum above mentioned, have passed the previous examination of any of the licensing corporations in the United Kingdom.

DIPLOMA IN MIDWIFERY.

Candidates already qualified in Medicine or Surgery may apply for permission to be examined for the diploma in Midwifery. The certificates required to be lodged are the same as those required from *qualified* candidates for the licence to practise Medicine.

Fees.—Fee for the licence in Medicine, £15 15s. Fee for licence in Medicine and diploma in Midwifery (for which latter there is a separate examination), if taken out within an interval of a month, £16. Fee for the diploma in Midwifery, £3 3s.

Further information can be obtained from the Registrar, College of Physicians, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

I.—REGISTRATION OF PUPILS.

Every person requiring to be registered as a pupil on the

(a) Candidates who are physicians or surgeons of five years' standing are exempted from the clinical and written portions of the final examination.

College books shall, if the Council think fit, be so registered if he shall have laid before the Council a receipt showing that he has lodged, to the credit of the President and for the use of the College, in the Bank of Ireland, a registry fee of five guineas.

II.—QUALIFICATIONS OF CANDIDATES FOR LETTERS TESTIMONIAL.

Every registered pupil shall be admitted to an examination for letters testimonial if he shall have laid before the Council the following documents:—

a. A receipt showing that he has lodged a sum of twenty guineas in the Bank of Ireland to the credit of the President and for the use of the College.

b. A certificate that he has passed an examination as to his acquaintance with the Greek and Latin languages.

c. Certificates showing that he has been engaged in the study of his profession for not less than four years.

d. Certificates of attendance on an hospital recognised by the Council, where clinical instruction is given during three years.

e. Certificates of attendance on three courses of lectures on Anatomy and Physiology; three courses of lectures on the Theory and Practice of Surgery, and of the performance of three courses of dissections, accompanied by demonstrations; also, certificates of attendance on two courses of lectures on Chemistry, or one course of lectures on General and one on Practical Chemistry; one course of lectures on Materia Medica; one course of lectures on the Practice of Medicine; one course of lectures on Midwifery; one course of lectures on Medical Jurisprudence; and one course of lectures on Botany.

QUARTERLY EXAMINATION.

1. Examinations are held quarterly, on the second Tuesday in February, May, August, and November, at which candidates shall be divided into two classes—junior and senior.

2. The junior class shall produce certificates of having attended three courses of lectures on Anatomy and Physiology; three courses of lectures on Practical Anatomy, with dissections; two courses of lectures on Chemistry; one course of lectures on Materia Medica; one course of lectures on Botany; and one course of lectures on Forensic Medicine.

3. This class shall be examined in Anatomy, Physiology, and Materia Medica.

4. The fee for this examination shall be five guineas; not to be returned in case of rejection, but to be allowed in the fee for the second examination.

5. The senior class shall produce certificates of having attended three courses of lectures on the Theory and Practice of Surgery, one course of lectures on the Practice of Medicine, and one course of lectures on Midwifery; also certificates of attendance on a recognised hospital for three winter and three summer sessions.

6. This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of prescription.

7. Both these examinations shall be partly written and partly oral.

8. The fee for this examination shall be fifteen guineas.

Fees to be paid by Candidates for Letters Testimonial.

1. The candidate pays ten shillings for his preliminary examination.

2. Five guineas as registered pupil of the College.

3. Five guineas for the junior class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4. Fifteen guineas for the senior class examination—total £26 15s.

5. In addition to the foregoing, a fee of one guinea is to be paid to the Registrar on handing each licentiate his diploma.

6. Every candidate rejected at the quarterly examination shall be required to pay to the College the sum of two guineas on applying for re-examination, so as to recompense the College for the necessary expense.

III.—QUALIFICATIONS OF CANDIDATES FOR THE FELLOWSHIP.

Every registered pupil or licentiate shall be admitted to examination for the Fellowship if he shall have laid before the Council the following documents:—

a. A receipt showing that he has lodged in the Bank of Ireland, for the use of the College, if he be a licentiate, the sum of twenty guineas, or thirty-five in case he be a registered pupil, provided in either case he intends to reside beyond ten miles from Dublin. Should the candidate intend to reside in Dublin, or within ten miles thereof, he shall lodge, if he is a licentiate, thirty guineas; or, if he be a registered pupil, forty-five guineas. Fellows entering on the country list, who may subsequently settle as practitioners in Dublin, or within ten miles thereof, shall pay ten guineas to the College.

b. A certificate that he is 25 years of age.

c. A certificate that he is a Bachelor of Arts of some university, or that he has been examined in such manner as the Council may from time to time direct, with a view to ascertain that he has obtained a liberal preliminary education.

d. A certificate, signed by two or more Fellows of the College, of good general conduct during his professional education.

e. Certificates that he has been engaged in the acquisition of professional knowledge for a period of not less than six years, during three of which he must have studied in one or more of the schools or hospitals recognised by the Council. He may have studied for the other three years in any school or schools of the United Kingdom which shall be approved by the Council, or in any foreign school of repute. It is also required that the candidate shall have had opportunities of practical instruction as house-surgeon or dresser in a recognised hospital.

f. Certificates of attendance on the several courses of lectures required to be attended by candidates for letters testimonial, together with one course of lectures on Comparative Anatomy and one course on Natural Philosophy.

g. A thesis on some medical subject, or clinical reports, with observations, of six or more medical or surgical cases, taken by himself.

h. Candidates of the required age, who shall have taken the degree of Bachelor of Arts in a British or Irish university, and have complied with the foregoing regulations in other respects, will be admitted to examination at the end of five years of professional study, of which three years must have been passed in one or more of the recognised schools or hospitals.

i. Licentiates of the College, who may not be able to show that they have followed the course of study specified in the preceding regulations, may, at the expiration of ten years from the date of their diploma, be admitted to the examination required for the Fellowship, provided they produce such evidence as shall be satisfactory to the Council that they have conducted themselves honourably in the practice of their profession.

PRELIMINARY EXAMINATION, REGISTRATION, AND MATRICULATION.

Registered pupils are admitted to answer the preliminary examination at any period previous to the final examination for letters testimonial.

Students who are not registered pupils are also admitted to answer the preliminary examination at any period previous to the examination for letters testimonial, upon payment of a matriculation fee of ten shillings.

The following are the subjects upon which each candidate for the preliminary examination will be examined, viz.:—The English language, including grammar and composition. Arithmetic, including vulgar and decimal fractions. Algebra, including simple equations. Geometry, first two books of Euclid. Latin and Greek, including translations and grammar. In Greek—the Gospel of St. John, the Menippus of Lucian, or the First Book of Xenophon's Anabasis. In Latin—the First and Second Books of the Æneid of Virgil, the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are held quarterly, viz.:—On the third Wednesday in January, April, July, and October in each year. Fee, ten shillings.

Candidates are requested to enter their names, and pay the fee to the Registrar, at least three days previous to the day of examination.

THE APOTHECARIES' HALL OF IRELAND.

BY-LAWS AND REGULATIONS.

Every candidate for the licence to practise is required to undergo a preliminary and a professional education and examination.

THE PRELIMINARY EDUCATION AND EXAMINATION IN ARTS.

Compulsory.—1. English Grammar, Composition, Writing from Dictation, and the leading events of Roman and English History. 2. Arithmetic and Algebra, to Simple Equations. 3. Geometry: First Two Books of Euclid. 4. Latin: The Twenty-first Book of Livy or the first Three Books of the

Æneid of Virgil. 5. Greek: The first Two Books of the Anabasis of Xenophon or the Ninth Book of the Iliad of Homer. 6. French: Charles XII., or "Voyage en Orient" of Lamartine. 7. German: "Wilhelm Tell" or "Die Rauber" of Schiller. Candidates will be examined in French or German, as they may select.

Optional.—1. Natural Philosophy: Mechanics, Hydrostatics, and Pneumatics. 2. Natural History: The Classification, Elementary Structure, and General Physiology of Vegetables and Animals.

THE ARTS EXAMINATIONS

will be held at the Hall four times in the year—viz., the third Thursday in the months of January, April, July, and October, at the hour of 12 o'clock noon. It will be conducted by means of printed papers and by special examiners (Graduates in Arts of the University of Dublin), with assessors from the Court of the Hall. The answers to the papers will be required in writing.

Unsuccessful candidates will be remitted to their studies for a period of six months.

THE PROFESSIONAL EDUCATION AND EXAMINATIONS.

Every candidate for the licence to practise must produce certificates to the following effect:—

1. Of having passed an examination in Arts previously to entering on professional study.

2. Of being at least 21 years of age, and of good moral character.

3. Of apprenticeship to a qualified apothecary, or of having been engaged in practical pharmacy with an apothecary for a period of three years subsequent to having passed the examination in Arts.

4. Of having spent four years in professional study.

5. Of having attended the following courses, viz.:—Chemistry, during one winter session; Anatomy and Physiology, during two winter sessions; Demonstrations and Dissections, during two winter sessions; Botany and Natural History, during one summer session; Practical Chemistry (in a recognised laboratory), during three months; Materia Medica, during three months; Principles and Practice of Medicine and Therapeutics, during one winter session; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, during one winter session; Forensic Medicine, during one summer session; instruction in the practice of vaccination.

6. Of having attended, at a recognised hospital or hospitals, the practice of Medicine and clinical lectures on Medicine, during two winter and two summer sessions; also the practice of Surgery and clinical lectures on Surgery, during one winter and one summer session.

7. Of having performed the operation of vaccination successfully under a recognised vaccinator.

The Court of Examiners require lecturers and teachers to hold weekly class examinations.

The examination for the licence to practise is divided into two parts:—The first part comprehends Chemistry, Botany, Anatomy, Physiology, and Pharmacy; the second—Medicine Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

The professional examinations will be held quarterly, and will commence on the first and second Mondays in the months of January, April, July, and October.

Candidates for the licence must lodge their testimonials, and enrol their names and addresses, with the Clerk, at the Hall, in Dublin, a week prior to the day of examination.

ROYAL SCHOOL OF MINES (GOVERNMENTAL).—During the twenty-third session (1873-74), which will commence on October 1, courses of lectures and practical demonstrations will be given by the Professors. The fee for students desirous of becoming Associates is £30 in one sum on entrance, or two annual payments of £20, exclusive of the laboratories. Pupils are received in the chemical laboratory under the direction of Dr. Frankland, and in the metallurgical laboratory under the direction of Dr. Percy. These laboratories will be re-opened on October 1. By order of the Lords of the Committee of Council on Education, the instruction in Chemistry, Physics, Applied Mechanics, and Natural History will be given in the new buildings in the Exhibition-road, South Kensington.

THE HARTLEY INSTITUTION, SOUTHAMPTON.—Principal, C. G. Blackader, M.A., Trinity Coll., Cantab. In the department of preliminary medical education, which is recognised by the Royal Colleges of Surgeons and Physicians, students are prepared for the regular curriculum of the medical schools, one winter and two summer sessions thus passed counting towards the four years' professional study required of all candidates for a diploma. Students in this department also receive instruction in dressing, taking notes of cases, etc., at the Southampton Royal Infirmary. For further information address the Principal.

TO CORRESPONDENTS.

We beg to return our best thanks to the Registrars and Secretaries of the various Universities, Colleges, and Schools for their prompt replies to our Circular, and for the trouble they have taken in supplying the latest Regulations of the Institutions with which they are connected.

In order to confine the whole of this week's Number to information specially important to Students, we are compelled to defer answers to several Correspondents, together with all notices of passing events, until next week.

Medical Times and Gazette.

SATURDAY, SEPTEMBER 13, 1873.

TO STUDENTS.

THE saying, "All men think all men mortal but themselves," is a terse and happy expression of the difficulty and slowness with which immortal man recognises the mortality of his material and earthly part. In the pride of youth and strength and health, he does not *feel* that any part of him is mortal. He sees change and decay all around him, he may live in the daily and hourly sight of the churchyard; but he has had no personal knowledge of weakness and decay, and so in his lusty vitality and vigour, though he may theoretically acknowledge that man is mortal, he does not personally and practically feel that he himself is so. But let sickness or accident bring down his pride of strength and lower his sense of vitality, and then he *feels* and knows that he too may die. In a somewhat like way may we explain, perhaps, the difficulty a youth has in learning the value of time. His seniors may preach to him on the text, "*Ars longa, vita brevis est*," but he does not feel it; he believes he has ever plenty of time before him, and that to-morrow will be time enough for work. It is only education, properly so called, that will make him feel the paramount value of to-day. Education with others, the emulation so excited, and the experience gained in the little world of school, will make him practically recognise that, in order to fight successfully and well the battle of life, each and every day must be utilised, that each day must see "something attempted, and something done." To a youth who comes up to London to study Medicine, the four years that stretch out before him may seem a very eternity of time, and he can hardly be made to believe that they are all too short for what he has to do. But happily the Medical Students of the present day are a better trained and more educated race than were those of former years, and we may well expect that they will more readily and more truly appreciate the necessity of buckling well and at once to their work. It is therefore with better courage and heart that we attempt to give them a few words of advice as to how to work during their four years of studentship.

It would be a waste of words, we imagine, to say much about the choice of a Medical School. If Paterfamilias is in the profession, he most likely will send any son whom he may destine to a medical career to the school he himself was educated at; or the advice of any near or trusted relation who may be a medical man, or of the family medical adviser and friend, is sought on the subject. If, however, the choice is really to be made by a comparison of the Medical Schools with each other, we recommend attention to be paid to the strength of the tutorial as well as of the professional staff; and particularly that inquiry be made as to the care given to provide clinical teaching,—not merely clinical lecturing, but to the provision made for clinical teaching in the wards. Select the school that seems to be the most complete in all departments, so that it shall be the fault of the Student, not of the school, if

he is not able, by means of a well-ordered out-patients' department, clinical clerkships, surgical dresserships, and clinical instruction, to obtain a knowledge of the art and practice of his profession, as well as of the science thereof. And, other things being equal, we are inclined to prefer a large school to a small one. Many reasons might be adduced for such a preference, but we will mention here one only. For success in the medical profession, a knowledge of mankind is especially important and necessary—in all pursuits and callings a quick and accurate comprehension of differences of temper and temperament is important—and in none can the power of readily reading and understanding character, disposition, and temperament be of greater moment than in ours. And certainly a Student will have more opportunity of learning this lore, and of testing his skill in its application, at a large school than at a smaller one.

But suppose that the school has been selected, and that the Student stands on the threshold: let him well consider what he is about to undertake. He will for his own sake, for the sake of achieving success in his life's career, wish to use well his student years; but we would have him enter on his work with also a reverence for his chosen profession, and an earnest, thoughtful determination for its own sake to seek after a true and accurate knowledge of it. He cannot well think too highly of it, nor cherish too great a love and regard for it; for of all callings, dealing with things temporal, there is not one of greater importance to man's well-being and happiness,—to none other are more important issues committed.

We will credit every Student with intending honestly to strive to do his best, and, in order to carry out that intention, we would advise him to especially cultivate some virtues and modes of working. And first we would say, work methodically; follow an orderly course or way; be not like "the man who flutters about in blindness, like the bat, or is carried hither and thither, like the turtle sleeping on the wave, and fancying, because he moves, that he is in progress"; but pursue your studies according to a *method*—that is, "a *progressive transition* from one step in any course to another." And here you are fortunately not left entirely to your own judgment. A course or plan of study is laid down for you, and you *must* follow it more or less fully and exactly. Do so honestly and diligently. We do not say, confine yourself entirely to its limit and exact order, but fulfil it; and then, if you have energy and time left for studies outside of or complementary to it, you may with clear conscience and profit pursue them. But be not persuaded to despise or lightly regard the plan marked out for you. It has been found to work well for the great majority of students, and has been founded and built up on the experience of many generations of teachers and learners. Even in the matter of attendance on lecturers, follow the course marked out. A certain number of lectures you *must* attend; do not listen to those who, it may be, will tell you to attend as few as possible, that lectures are a mistake and a waste of time, that you will learn more from books, and so on. Use your books to supplement and explain the lectures. These are the pith and essence of what your books contain, and though all are not equally good, and some may be positively bad, yet attend them regularly and diligently. From the worst you may learn something, if determined to carry away all that can be gleaned from it, and out of your very attendance, if you attend rightly, you may extract great advantage. One of the worst habits you can fall into is the habit of careless, wandering attention, and it is very easily fallen into; while a habit of close, nice, intent attention is simply invaluable. Never, therefore, go to a lecture in order that your mere bodily presence at it may be noted for the gaining of your certificate; but in this, as in all things, whatever you do, do it with all your might; persist in giving real, steady, watchful attention throughout each lecture. You will thus gain a habit of giving your mind fully and closely to whatever you are about, and you will thus be doing your best to strengthen and improve, or to acquire, quickness and tenacity of memory—a gain of inestimable value and service, and one which will remain with you when the subjects by help of which you acquired it may have faded or passed away. And next we would say, be thorough in all that you do; no kind of work should be done in an easy, half-minded, perfunctory kind of way, but all work of every kind should be done in the best possible way—well, and thoroughly well. Persist in making your knowledge thorough in extent if you can, but at all events thorough in kind and degree. Cherish a reasonable and healthy scepticism—that is, distinguish between assertion and proof, and demand a why and a wherefore for all that you are called on to believe. Much will have to be accepted for the present "on authority," but accept all such things with reservation, with a determination, that is, to test and try them for yourself as the opportunity of so doing may offer.

Seek to make your knowledge of each subject you study full, exact, and ready. And to insure these aims you cannot do better than take for your guidance the Baconian doctrine that "reading makes a full man, writing an exact man, and speaking a ready man." Read and listen, that your knowledge may be full; write on the subjects you study, that it may be exact—not writing your information out from books, but from your own acquired and digested knowledge of a subject, write out such an account of it as will represent it clearly and usefully to another mind; and in order to assure yourself that your knowledge of a subject is ready, be willing to talk of it, and to speak on it, and gladly accept every good opportunity of being examined in it.

When from the lecture-theatre, the dissecting-rooms, the laboratory, and the study you come to the practical work of your profession—in the out-patient rooms and the wards—bring with you still method and thoroughness. Be content at first to observe others at work, and not too ready and eager to examine patients yourself; and when you do arrive at this, be not tempted by showiness and quickness of diagnosis; be on your guard against the formation of hasty and rapid conclusions, but try to have a clear reason for every opinion you form, so that you may be able to justify it to others. Seek eagerly and gladly accept the post of clinical clerk and dresser. These appointments will not merely give you the best opportunities for examining patients, but they will oblige you to do so; and your description of cases, your diagnosis, and proposed treatment will be open to the criticisms of your teachers and your fellow-students—the best stimulus possible to the doing your work well and thoroughly. You will thus gain an invaluable training in the art of examining patients—that is, in "the exercise of common observation, directed by method." What the method shall be, will be dictated probably by the physician or surgeon under whom you work; and it does not greatly matter, so long as it is thorough, taking in the whole ground. You may perhaps, by-and-by, alter it so as to make it suit more perfectly the bent of your own mind; but through it you will gain the habit of always examining each patient thoroughly—the best possible guard against errors in diagnosis through imperfect scrutiny and too hastily drawn conclusions. And do not think that it is enough to be diligent in case-taking; you may accumulate piles of carefully taken cases, and yet get comparatively small good from your labour. You must "read, mark, learn, and inwardly digest" them. "The slothful man," saith the proverb, "roasteth not that which he took in hunting; but the substance of a diligent man is precious." Do not, from indolence or other cause, fall into the like error of letting your recorded cases lie idle. They ought to be very precious. Classify, compare, and constantly ponder them. Next to the examination of living cases of

disease, the study of well-recorded cases ought to be most instructive. Strive constantly to make your own records as full, minute, and graphic pictures of disease as you can, in the fewest possible number of words.

One piece of advice we will here venture to give to our young friends the Students in reference to the treatment of disease: do not forget the last part of the axiom that it is your duty to study to cure disease "*cito, tuto, et jucunde.*" In hospital practice you may not have much opportunity of learning the niceties of dietetics or the niceties of medication; but these *are* of importance, and, in private practice, of great importance. Take every opportunity, then, of learning how to treat disease pleasantly; do not despise what may at first seem to you small things, but cultivate a knowledge of diet and of refinements in medication: seek to make your medicines, your drugging of your patients as elegant, as little nauseous, as little like medicines, as possible.

One thing more. Preventive medicine, the science of preserving health and preventing disease, the polity and practice of hygiene, are daily becoming more recognised and of greater importance in the eyes of the public and the Government. Under lately passed Acts of Parliament, sanitary boards and sanitary medical officers are being appointed all over the kingdom; and though at present the Local Government Board seems, in the working of these Acts, to be ruled by the idea that medical skill is needed only where disease is present, and not to prevent it, and that therefore it is sufficient to appoint amateurs as inspectors under the Acts, yet this state of things is not likely to be allowed to last. The time will come when the public will demand skilled advice in all health matters—central as well as local. Be ready for it. Many valuable health appointments are already open to medical men. Offices of still greater importance and value, under the Public Health Act, will be within their reach. Make yourselves acquainted with the science and practice of hygiene by every means in your power, so that you may be prepared to undertake sanitary appointments, great or small, with the confidence that belongs to skilled knowledge—not the confidence too often born of the ignorance of the amateur.

We have now said as much as space will let us say, and not a few wise and inspired sayings will occur to you as expressing in a few words nearly all that we have written. "Whatsoever thy hand findeth to do, do it with thy might," may well and profitably be taken as your motto; or, "Be strong; quit you like men." Work with a stout heart; and in all you do be honourable English gentlemen. We welcome you heartily to the profession of your choice, and bid you Godspeed.

CHANGES IN THE LONDON MEDICAL SCHOOLS.

The changes in the teaching staffs of the London Medical Schools during the year that has passed have not been so numerous as in some former years. Here and there we have lost by death a well-known name, but some of the chief changes have occurred, we are happy to say, not in consequence of the inexorable demands of the universal creditor, but through the well-earned retirement from the labour of teaching of some who, still in active life amongst us, will continue, we hope, for many years to adorn the profession for which they have long and honourably laboured.

Taking the Schools in alphabetical order, the following are the chief alterations in the staffs to be noted:—At St. Bartholomew's the death of Mr. Holmes Coote made a vacancy in the surgical staff, which was filled by the promotion of Mr. T. Smith to the rank of Surgeon, and the election of Mr. Marsh to an Assistant-Surgeoncy. Mr. Callender quits the chair of Descriptive Anatomy, and shares with Mr. Savory the Surgical chair; the Anatomical chair is now shared by Mr. T. Smith and Mr. Langton; and Mr. Marsh, Mr. Cumberbatch, and Mr. Furner superintend and conduct Anatomical Demonstrations and teach Operative Surgery. Dr. E. Klein delivers the histological part of the Physiological course; Dr. Claye Shaw gives a course of lectures on Mental Diseases; and Mr. Langton a course of demonstrations on Diseases of the Ear. Mr. T. Smith shares with the other Surgeons the teaching of Clinical Surgery.

At the Charing-cross Hospital and School, Mr. Cantlie is now the sole Demonstrator of Anatomy, and Mr. T. Bolas has been appointed Demonstrator of Practical Chemistry. Dr. J. M. Bruce has been elected Assistant-Physician to the Hospital, with a clinical lectureship on Diseases of Children; and Dr. E. Sparks, Physician to the Department of Skin Diseases. Mr. J. A. Bloxam has been elected an Assistant-Surgeon. Mr. Barwell shares with the other Surgeons the teaching of Clinical Surgery, and Mr. Heaton and Dr. G. V. Poore will deliver a course of lectures on Public Health. Lastly, Mr. A. H. Garrod is appointed Lecturer on Comparative Anatomy.

At St. George's Hospital and School, Mr. Ellis and Mr. Blake have been appointed Demonstrators of Anatomy; Dr. Cavafy succeeds Dr. W. Ogle in the chair of Physiology; and Mr. Herbert Watney has undertaken the teaching of Practical Physiology and Histology. Dr. R. J. Lee has been elected an Assistant Obstetrical Physician; Mr. Holmes will deliver lectures on Clinical Surgery; Mr. J. W. Haward will lecture on Morbid Anatomy, and Dr. Barclay on Hygiene. Dr. Whipham lectures on Botany.

At Guy's, Dr. Owen Rees retires from the chair of Medicine, which is now filled by Drs. Wilks and Habershon. Mr. Rendle and Mr. Lucas have been appointed Anatomical Demonstrators. Dr. Pye-Smith shares with Dr. Pavy the teaching of General Anatomy and Physiology. Dr. Owen Rees having also resigned the Physiciancy to the Hospital, has been succeeded by Dr. Moxon, and Dr. F. Taylor has been appointed Assistant-Physician. Mr. Durham has been promoted to a Surgeoncy, and Mr. Higgens has been appointed Assistant Ophthalmic Surgeon. Dr. Goodhart will teach with Dr. Fagge Pathology, and Dr. Moxon has undertaken the chair of Materia Medica; Mr. Durham teaches Operative Surgery; and Dr. F. Taylor shares with Dr. Fagge the department of Cutaneous Diseases.

At King's College, Dr. Curnow has succeeded the late Mr. Partridge in the chair of Anatomy; Dr. Hayes has been appointed Assistant Obstetric Physician to the Hospital; and Dr. Ferrier, Lecturer on Forensic Medicine. Dr. Duffin lectures on Diseases of the Skin.

At the London Hospital, Mr. Hutchinson has resigned his share of the chair of Surgery, which is now filled solely by Mr. Couper; Mr. H. A. Reeves has been appointed Demonstrator of Anatomy; and Mr. McCarthy shares with Dr. Woodman the teaching of Physiology and Histology.

At St. Mary's, Mr. B. Schlesinger has been appointed Assistant Anatomical Demonstrator.

At the Middlesex, Mr. Morris is now the sole occupant of the chair of Descriptive Anatomy; Mr. Hensman lectures on Botany and Comparative Anatomy, and Dr. King on Forensic Medicine. Mr. Turner has been appointed Assistant Dental Surgeon.

At St. Thomas's, Mr. Le Gros Clark has resigned his share of the chair of Surgery, which is now filled by Mr. S. Jones and Mr. MacCormac. He has also resigned his Surgeoncy at the Hospital; Mr. MacCormac has succeeded him. Mr. A. W. Bennett has been appointed to the chair of Botany.

At University College Hospital, Dr. W. R. Gowers has been appointed to an Assistant-Physiciancy, Mr. Marcus Beck to an Assistant-Surgeoncy, and Mr. J. F. Streatfield to an Ophthalmic Surgeoncy.

At the Westminster, Mr. Pearse and Mr. Cowell succeed Mr. Holthouse in the chair of Surgery; Mr. Davy takes the Anatomical chair. Dr. Anstie has succeeded Dr. Radcliffe as Physician to the Hospital, and Dr. Allchin has been appointed Assistant-Physician. The resignation of Mr. Holt left a vacancy in the Surgical staff, which has been filled by the appointment of Mr. Bond as Assistant-Surgeon, and the promotion of Mr. Cowell. Mr. E. M. Holmes has been appointed to the chair of Botany; Dr. Potter and Dr. Dupré teach Forensic Medicine; and Mr. Bond gives a course of lectures on Diseases of the Skin.

EDUCATIONAL VACCINATING STATIONS.

In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, the following arrangements are made:—

1. The vaccinating stations enumerated in the subjoined list are open, under certain specified conditions, for the purposes of teaching and examination.

2. The public vaccinators officiating at the stations are authorised to give the required certificates of proficiency in vaccination to persons whom they have sufficiently instructed therein; and

3. The public vaccinators, whose names in the subjoined list are printed in italic letters, are also authorised to give such certificates, after satisfactory examination, to persons whom they have not themselves instructed.

London.—Principal Station, Surrey Chapel, Blackfriars-road: *Mr. James Furness Marson*, who attends on Tuesday and Thursday, at 1 p.m. North-west Stations—Marylebone Institution, 15, Lower Seymour-street: Mr. William A. Sumner, on Monday, at 10 a.m.; Albion Hall, Grove-place, Lisson-grove: Mr. William A. Sumner, on Wednesday, at 10 a.m. West Station, 9, St. George's-road, Pimlico, S.W.: Dr. Edward Lowe Webb, on Thursday, at 10 a.m. East Station, Eastern Dispensary, Leman-street: Mr. Charles T. Blackman, on Wednesday, at 11 a.m. North Station, Tottenham-court Chapel, Tottenham-court-road: Mr. William Edwin Grindley Pearse, on Monday and Wednesday, at 1 p.m. South-west Station, 2, Regent-place, Horseferry-road: Mr. William Edwin Grindley Pearse, on Tuesday, at 2 p.m. Strand Station, Charing-cross Hospital: Mr. Robert William Dunn, on Monday, at 10 a.m.

Birmingham.—The School-rooms, 27, Old Meeting-street, on Monday; the rooms occupied by the Working Men's Mutual Improvement Society, in Barr-street, on Tuesday; St. Mark's School-rooms, St. Mark's-street, on Wednesday; and the Islington Assembly-rooms, 42, Broad-street, on Thursday: *Dr. Edmund Robinson*, at 11 o'clock on the days before-mentioned.

Bristol.—The Public Vaccination Station, Peter-street: *Dr. Henry A. P. Robertson*, on Wednesday, at 10 a.m.

Exeter.—Odd Fellows' Hall, Bamfyld-street: *Mr. Charles H. Roper*, on Thursday, at 3 p.m.

Leeds.—Heed-stroet: *Mr. Frederick Holmes*, on Tuesday, at 2.30 p.m.

Liverpool.—4, Oldham-street: *Mr. Arthur Browne Steele*, on Thursday, at 2 p.m.

Manchester.—159, Rochdale-road: *Mr. Ellis Southern Guest*, on Monday, at 2 p.m.

Newcastle-on-Tyne.—The Central Vaccination Station, 21, Nun-street, *Dr. Thomas C. Nesham*, on Thursday, at 3 p.m.

Sheffield.—The Public Vaccination Station, Townhead-street, *Mr. William Skinner*, on Tuesday, at 3 p.m.

Edinburgh.—The Royal Dispensary: *Dr. William Husband*, on Wednesday and Saturday, at 12.

Glasgow.—The Hall of the Faculty of Physicians and Surgeons; *Dr. Hugh Thomson*, on Monday, at 12. The Royal Infirmary: Dr. Robert Dunlop Tannahill, on Monday and Thursday, at 12.

At Downing College, Cambridge, every alternate year an election to a Fellowship takes place, the holder of which must be engaged in the active pursuit of the studies of Law or Medicine. These Fellowships are of the annual value of £200, and are tenable for twelve years. They are not, if practicable, vacated by marriage, and the Fellows are not required to reside. There are now two vacant Fellowships. Foundation Scholarships of £50 per annum (in some cases with rooms and commons) are offered annually for distinction in Natural Science, tenable until the B.A. degree, and in case of special merit for three years longer. Minor Scholarships of £40 per annum, tenable for two years, are offered each year for competition before entrance, and one or more of these is awarded for proficiency in Natural Science.

Wolverhampton and Staffordshire General Hospital.—Two hundred and ten beds. Attendance recognised by the Examining Boards. Pupils resident and non-resident. The Hospital contains large male and female accident wards, general medical and surgical wards, a children's ward, a ward for diseases of women, and a fever wing. The out-patient department, commodious and convenient, is semi-detached from the main building. Fees for Hospital Practice: One year, Ten Guineas; perpetual, Twenty Guineas. Physicians—Dr. Millington and Dr. Totherick. Surgeons—Mr. Vincent Jackson, Mr. J. O'Brien Kough, Mr. C. A. Newnham. House-Surgeon—Mr. Burton Ravenhill. Physicians' Assistant—Dr. Nankwell. Operations are performed in the theatre every Thursday morning, at eleven o'clock. The practice in the Hospital is very extensive, the number of cases treated being large and important. Practical instruction in Surgery to first-year students, and Dresserships for students after two years' professional education, both in accordance with the Royal College of Surgeons of England, may be obtained at this Hospital; also, Clinical Clerkships. For particulars apply at the Hospital to Vincent Jackson, Honorary Secretary of the Medical Committee. (See Advertisement.)

DAYS AND HOURS OF INTRODUCTORY LECTURES

TO BE DELIVERED AT THE DIFFERENT MEDICAL SCHOOLS.

IN THE METROPOLIS.

	Days and hours, p.m.	
St. Bartholomew's Hospital and Medical School	Oct. 1,	No Introductory Lecture announced.
Charing-cross Hospital and Medical Coll.	„ 1, 8	Mr. Bellamy.
St. George's Hospital Medical School	„ 1, 2	Mr. Brudenell Carter.
Guy's Hospital Medical School	„ 1, 2	Mr. James Hinton.
King's College Medical Department	„ 1, 4	Prof. Edgar Sheppard.
London Hospital Medical College	„ 1, 3	Dr. Prosser James.
St. Mary's Hospital Medical School	„ 1, 8	Dr. Shepherd.
Middlesex Hospital Medical School	„ 1, 3	Mr. Morris.
St. Thomas's Hospital Medical College	„ 1, 2	Dr. J. Harley.
University College Faculty of Medicine	„ 1, 3	Dr. F. F. Roberts.
Westminster Hospital Medical School	„ 1, 8	Mr. Cowell.

IN THE PROVINCES.

	Days and hours, p.m.	
Birmingham Queen's College	Oct. 1, 3	Professor Clay.
Birmingham General and Queen's Hospitals (Introductory Clinical Address)	„ 7, 3½	Dr. Bell Fletcher.
Leeds School of Medicine	„ 1, 4	Mr. T. Scattergood.
Liverpool Royal Infirmary School of Medicine	„ 1, 3	Dr. Caton.
Manchester Royal School of Medicine	„ 1, —	Professor Gamgee.
Newcastle-upon-Tyne Coll. of Medicine	„ 1, 2	Dr. Edwd. Charlton.
Sheffield School of Medicine	„ 1, 4	Mr. Henry Jackson.

The Winter Session of the Bristol Medical School will commence on October 1.

TABLE OF FEES CHARGED IN THE MEDICAL SCHOOLS OF ENGLAND

FOR ALL LECTURES AND HOSPITAL PRACTICE REQUIRED FOR THE LICENTIATE EXAMINATIONS OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE LONDON SOCIETY OF APOTHECARIES, AND FOR THE MEMBERSHIP EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

London.	£	s.	d.
St. Bartholomew's, £110 5s. (in three half-yearly instalments of £36 15s., £36 15s., and £36 15s.), or in one sum	105	0	0
Charing-cross, £80 17s. (in three yearly instalments of £34 13s., £31 10s., and £14 14s.); in the case of Matriculated Students (Matriculation fee, £2 2s.), payable in five instalments	74	3	0
St. George's Hospital, perpetual £105 (in yearly instalments of £42, £42, and £10 10s.)—(with the exception of Practical Chemistry)	94	10	0

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, BLOOMSBURY-SQUARE, LONDON.—SCHOOL OF PHARMACY.—SESSION 1873-74.—The session will commence on Wednesday, October 1, and extend to the end of July, 1874. Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood on Monday, Tuesday, and Wednesday mornings at nine o'clock, commencing on Monday, October 6. Also lectures on Botany and Materia Medica by Professor Bentley, on Friday and Saturday mornings at nine o'clock, commencing Friday, October 3. A course on Systematic Botany will be delivered at the Royal Botanic Gardens, Regent's-park, during the summer months. Laboratory: The suite of Laboratories for Practical Instruction in General and Pharmaceutical Chemistry will be opened on Wednesday, October 1, under the direction of Professor Attfield. The Laboratories are open from ten a.m. till five p.m. Students can enter at any period during the session.

THE ROYAL COLLEGE OF SCIENCE, established at the late Museum of Irish Industry, in St. Stephen's Green, is a branch of the Science and Art Department at South Kensington. A complete staff of Professors is connected with the institution, and courses of lectures are delivered on all scientific departments, to which the admission charge is moderate. The diploma of Associate is conferred at the end of a three years' course.

QUEEN'S COLLEGE, LIVERPOOL.—The session will commence on Monday, Oct. 6. The College is in connexion with the University of London, and its classes comprise the subjects required for the Matriculation, B.A., B.Sc., and Preliminary Scientific M.B. Examinations of that University. Instruction in Practical Chemistry is given in the College Laboratory by Professor Hamilton. Provincial examinations of the London University are held at Queen's College. Fees: Separate classes, £2 2s. to £3 3s. per session; Practical Chemistry, £5 5s.

ADDITIONAL INFORMATION RESPECTING THE METROPOLITAN SCHOOLS, ETC.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

This Hospital comprises a service of 710 beds, of which 676 are in the Hospital in Smithfield, and 34 are for convalescent patients at Lauderdale House, Highgate.

Whole fee for attendance on lectures and hospital practice 105 guineas, payable by instalments, or a single payment of 100 guineas. Payment in either of these ways cutitles to a perpetual ticket.

Four House-Physicians and four House-Surgeons are appointed annually, on the payment of a nominal fee, and are provided with rooms by the Hospital authorities. The Senior Midwifery Assistant is appointed for twelve months, and is eligible for re-election for a second twelvemonth. The Junior Midwifery Assistant is appointed for six months, and is provided with rooms by the Hospital authorities. The Ophthalmic House-Surgeon, also provided with rooms, is appointed for six months, and is eligible for re-election for a second term of six months. Diligent students are selected to hold these appointments, for which no fee is required.

The Clinical Clerks to the Physicians and to the Physician-Accoucheur, the Clerks to the Assistant-Physicians and Assistant-Surgeons, and the Dressers in the special departments, are chosen from the diligent students without payment of any extra fee. Sixteen Ward Dresserships are annually given to the students of the second year who pass the best examinations in the subjects of study of the first and second years, or who may be otherwise specially recommended. Other Ward Dresserships may be obtained by payment of the usual fees.

Courses of Practical Surgery and of Practical Physiology have been instituted in accordance with recent regulations of the Royal College of Surgeons.

Special Departments:—Diseases of the Skin (Dr. Duckworth, Friday, at 1.30), Diseases of the Eye (Mr. Power and Mr. Vernon, Tuesday, Thursday, and Saturday, at 1.30), Diseases of the Ear (Mr. Langton, Friday, at 2.30), Orthopædic Surgery (Mr. Willett, Friday, at 12.30), Deutal Surgery (Mr. Coleman, Friday, at 9 a.m.).

The following scholarships and prizes are awarded:—Open Scholarship in Science, founded 1873: subjects of examination—Physics, Chemistry, Botany, and Zoology. This Scholarship, of the value of £100, tenable for one year, will be competed for on September 25 and following days. Preliminary Scientific Exhibition, founded 1873: subjects of examination—Physics, Chemistry, Botany, and Zoology. This Exhibition, of the value of £50, is awarded in October. Lawrence Scholarship and Gold Medal, of the value of forty guineas, founded 1873, by the family of the late Sir W. Lawrence. Brackenbury Scholarship in Medicine, and Brackenbury Scholarship in Surgery, founded 1873, by the will of the late Miss Hannah Brackenbury, who left £2000 for this purpose. Senior Scholarship of the value of £50—Anatomy, Physiology, and Chemistry. Junior Scholarships of the value of £50, £30, and £20 are awarded after an examination in the subjects of study of the first year, at the end of the summer and winter sessions. The Jeaffreson Exhibition, of the value of £20, and tenable for two years, is awarded at the commencement of each winter session to the student who passes the best examination in the subjects of preliminary education. The Wix Prize is awarded for the best essay on the following subject—"The Healing Art, so far from tending to Materialism, confirms, by its Induction of Accumulated Evidence of Design, Man's Instincts of Natural Religion; and thus, on St. Paul's showing, prepares his mind for the reception of Revealed Religion." Hichens Prize: subject of examination—Bishop Butler's Analogy. Bentley Prize, for the best report of surgical cases occurring in the wards of the Hospital during the previous year. It is expected that the reports will comprise the histories, progress, treatment, and results of not less than twelve cases, with observations thereupon. Foster Prize: subject of examination—Practical Anatomy; senior. Treasurer's Prize: subject of examination—Practical Anatomy; junior. The Kirkes Gold Medal: subject of examination—Clinical Medicine.

An examination of all students of the first year is held at the close of the first winter and first summer sessions.

A College for resident students exists in connexion with the Hospital. Resident Warden, Mr. Morrant Baker, from whom students will obtain information respecting rooms in the College, or will be advised regarding residence out of the Hospital.

All communications to be addressed to the Warden of the College, St. Bartholomew's Hospital.

CHARING-CROSS HOSPITAL.

Gentleman are received—1st. As matriculated students, or those who enter for their entire medical education at the Charing-cross Hospital Medical College. 2ndly. As occasional students, or those who enter to one or more particular classes. Matriculated students have the privilege of filling the offices of Registrar, Pathological Assistant, Assistant-Demonstrator, Clinical Clerks, Dressers, Dentist's Assistant, Resident Medical Officer, Resident Surgical Officer, and Physician-Accoucheur's Assistant, and they alone are eligible to become candidates for the scholarships, medals, and various general class prizes.

The fee for the courses of lectures and hospital practice required by the University of London, the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries, to non-matriculated students, is £80 17s.; for the hospital practice alone, £31 10s. The fee to matriculated students for the full period of the lecturcs and hospital practice required by the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries, is £76 5s.; for the hospital practice alone, £31 10s. Composition fee for Dental Surgery, £42. The fee for matriculation is £2 2s., to be paid on entering. Payment of fees may be made in five instalments.

The offices of Medical and Surgical Registrar to the Hospital, and Pathological Registrar to the School, tenable for two or three years, for the efficient performance of the duties appertaining to which the Council award an annual stipend, is open to all matriculated students of the Hospital who have obtained their qualifications, as are also the offices of House-Physician, House-Surgeon, and Resident Physician-Accoucheur's Assistant.

Scholarships, Medals, and Prizes. — Scholarships: Two entrance scholarships of the value of £30 and £20 respectively, tenable for one year, will be awarded annually in October after a competitive examination in the following subjects:—Compulsory: English, Latin, Mathematics, French, or German. Optional (only one of which may be selected): Chemistry, Mechanics, German, or French. The Llewellyn Scholarship of £25 is open to all matriculated students who have just completed their second academical year. The Golding Scholarship of £15 a year is open to all matriculated students who have just completed their first academical year. The following medals are awarded anuually:—The gold medal for general proficiency; the governors' clinical silver medal; silver class medals, on all the subjects of the lectures; bronze class medals, on all the subjects of the lectures.

Free Scholarships.—Candidates for free scholarships are required to be sons of professional men of reduced circumstances and position, or of gentlemen in a corresponding station of society, and are to have had a classical education fitting them for the medical profession. They must have already commenced their medical studies, and, from unforeseen circumstances, be unable to complete their professional education without such assistance. They are to send in their applications and testimonials before September 1.

In addition to the ordinary classes, special classes have been established for practical instruction in Morbid Histology, by Dr. Bruce; Auscultation and Physical Diagnosis, by Dr. Green; Instruction and Supervision in Case-taking, by Dr. Powell; and Electro-Therapeutics, by Dr. Poore. The class of Practical Surgery is divided into three sections—viz., Operations, by Mr. Bellamy; Bandaging, by Mr. Fairlie Clarke; and Surgical Pathology, by Mr. Bloxam. By special arrangement the students of Charing-cross Hospital are admitted to the practice of the Royal Westminster Ophthalmic Hospital, which almost immediately adjoins it.

ST. GEORGE'S HOSPITAL.

Perpetual pupils pay at the time of entry a compounding fee of £105. They are admitted to the practice of the Physicians and Surgeons, to all the lectures (except Practical Chemistry), to compete for all prizes and exhibitions, to hold the appointments of House-Physician, House-Surgeon, Assistant House-Physiciau, Assistant House-Surgeon, Ophthalmic and Orthopædic Assistants, and Clinical Clerk and Dresser for two periods of three months each.

Gentlemen are admitted to the hospital practice and lectures required for the licence of the College of Physicians, for the diploma of Member of the College of Surgeons, and for the licence of the Society of Apothecaries (with the exception of Practical Chemistry), on payment of the following fees—viz., £42 for the first year of study, £42 for the second year of study, and £10 10s. for each succeeding year. By payment of these fees pupils are entitled to hold the office of Clinical Clerk and Dresser, and to become candidates for the offices of Medical and Surgical Registrars, and Demonstrator of Anatomy, to each of which offices a salary of £50 is attached. An Obstetric Assistant, with a salary of £100 and board and residence is annually elected from amongst those students who have obtained a legal qualification to practise. Pupils may also enter to the hospital practice and lectures separately.

The appointments of House-Physician and House-Surgeon are made every six months, are four in number, and are tenable for one year. These appointments are awarded after examination, and are given without fee or payment, each officer being lodged and boarded at the expense of the Governors of the Hospital. The whole of the patients are under the charge of these officers in the absence of the Physicians and Surgeons.

Exhibitions and Prizes.—"The William Brown Exhibitions," of £100 per annum, tenable for two years, and of £40 per annum, tenable for three years, are competed for by perpetual pupils who have recently obtained their diploma, or have nearly completed their studies. The examinations embrace all departments of practical knowledge. The Brackenbury prizes of £40 each in Medicine and Surgery are awarded annually after a competitive examination. The Treasurer's Clinical Prize of £10 10s., the gift of A. Shaw Stewart, Esq. Sir Charles Clarke's Prize for good conduct: The interest of £200 Consols, to be awarded annually to the student of the Hospital "who, by reason of his general good conduct during the preceding year, should be considered the most deserving." The Thompson Medal: A silver medal to be awarded annually for the best clinical report of medical and surgical cases observed in the Hospital during the preceding twelve months. Sir Benjamin Brodie's Clinical Prize in Surgery will be awarded to the perpetual pupil of the Hospital who shall have delivered to the Surgeons the best report of not more than twenty surgical cases which have occurred in the Hospital during the preceding twelve months. Dr. Acland's Clinical Prize in Medicine will be awarded to the perpetual pupil of the Hospital who shall produce the best report of not more than twenty medical cases which have occurred in the Hospital during the preceding twelve months. The Henry Charles Johnson Memorial Prize in Anatomy will be awarded to that pupil who shall, in the judgment of the Medical School Committee, exhibit the greatest proficiency in practical anatomy. General Proficiency Prizes: To pupils in their first year, £10 10s.; to pupils in their second year, £10 10s.; to pupils in their third year, £10 10s.

For further particulars apply to Dr. Wadham, Dean of the School.

GUY'S HOSPITAL.

This Hospital contains nearly 720 beds.

Voluntary Examinations are held at four periods of the students' course, as follows:—1st. At entrance, commencing on October 6, in Elementary Classics, Ancient and Modern History, and Mathematics. The candidate who most distinguished himself receives £25; the second candidate, £20; the third, £15. 2nd. At the end of the first sessional year, in all the subjects of that year—one sum of £30, another of £25, and a third of £10 10s. (presented by one of the Governors). 3rd. At the end of the second sessional year, in the subjects which form the course of study up to that time—£35 and £30. 4th. At the end of the third sessional year, in all the subjects of the curriculum—£40 and £35. Honorary certificates are also given to candidates who pass creditable examinations.

Special Examinations.—Two gold medals are given annually by the Treasurer to students who have completed their third, and not exceeded their fourth, year—the one for Clinical Medicine, the other for Clinical Surgery.

The fees for hospital practice and lectures are as follows:—For the first year, £40; for the second year, £40; and £20 for the third; and £10 for succeeding years of attendance. £105 entitles a student to a perpetual ticket. Materials used in practical courses are charged extra.

Students are selected according to merit for the following appointments:—House-Physicians, House-Surgeons, and Obstetric Residents (Senior and Junior), Surgeon's Dressers, Clinical Assistants, Dressers in the Eye Wards, Post-mortem Clerks, Obstetric Out-patient Clerks, Assistant-Physician's Clerks, Assistant-Surgeon's Dressers, Dressers in the Surgery, Dental Surgeon's Dressers, Aural Surgeon's Dressers, Medical Clinical Clerks, Surgical Clinical Clerks, Extern Obstetric Attendants, Assistant-Surgeon's Clerks, Clerks in the Electrifying-room.

The Registrars and the Demonstrators in Anatomy and Chemistry assist the pupils in their studies.

For further information apply to Mr. Stocker, Apothecary to the Hospital.

KING'S COLLEGE.

The fees, amounting to £100, may be paid either in one sum on matriculation or in three amounts at the commencement of each winter session. Students are, however, recommended to add £2 2s. for a second course of Chemistry, as well as the fee for attendance on the medical tutor's class for one year—viz., £3 3s. All resident students are required to attend the tutor (Dr. E. B. Baxter) during their first year.

Resident Medical Officers, Clinical Clerks, and Dressers are chosen by examination from matriculated students who are pupils of the Hospital.

Scholarships.—Warneford Scholarships: The sum of £200 is set apart annually for scholarships in the Medical Department—viz., "For the encouragement of the previous education of medical students," two scholarships of £25 per annum for three years; "For the encouragement of resident medical students," one scholarship of £25 per annum for two years. College Scholarships: The following are given every year to matriculated students of this department:—1. One of £40 for two years, open to students of the third and fourth year: 2. One of £30 for one year, open to students of the second year; 3. One of £20 for one year, open to students of the first year. Daniell Scholarship; £20, tenable for two years, is open to every student of the College who has worked in the laboratory for at least six months. Sambrooke Registrarships. Two of £50 every year.

Prizes.—Leathes Prizes: Bible and prayer-book to two matriculated medical students. Warneford Prizes: £40 is expended in the purchase of medals and books as prizes to two matriculated medical students. Class Prizes are awarded annually for proficiency in each subject of study; these consist of books of the value of £3. Two Medical Clinical Prizes, one of £3 for the winter session and the other of £2 for the summer session; and two Surgical Clinical Prizes of the same value are given for attendance at the Hospital. Todd Medical Clinical Prize: This prize was founded in memory of the late Dr. Todd. It consists of a bronze medal and books to the value of £4 4s. Tanner Prize: £10, for proficiency in the study of Obstetric Medicine.

Residence of Students.—A limited number may reside within the College.

For further information apply to Professor Bentley, Dean of the Medical Department.

ST. MARY'S HOSPITAL.

The Hospital contains 170 beds—68 medical, and 102 surgical. There are special departments for the Diseases of Women and Children, and for Diseases of the Eye, the Ear, the Skin, and the Throat.

A Medical Tutor assists the students daily in the practical portion of their studies in the wards, and in preparing for the final examinations. Special instruction is given to students preparing for the examinations of the University of London.

Appointments in the Hospital and School.—All these appointments are open to the pupils without additional fee, and are held in succession, so as to secure a complete system of clinical training. Five of these appointments exceed in value an equal number of scholarships of £50 each. All general students are required to perform the duties of Clinical Clerks and Dressers for a period of six months during the last two years of their curriculum. Students of the third year are appointed to assist the Physicians and Surgeons in charge of the out-patients. A Resident Registrarship within the Hospital has been created, with a salary of £100 a year and dispensary fees, tenable for one year *and open to re-election*, preference being given to past House-Surgeons and perpetual pupils. The Demonstrator of Anatomy is appointed annually, with a salary of £50 a year.

The Medical Tutor is also appointed annually, at a salary of £100 a year. The holders of both these appointments are eligible for re-election.

Scholarships, Prizes, etc.—Three scholarships in Natural Science, of the annual value of £40, tenable for three years, and an exhibition in Natural Science of £20, for one year. One of the scholarships and the exhibition are awarded by open competitive examination immediately before the commencement of the winter session. A scholarship in Anatomy, of the annual value of £20 (the holder of which is styled Assistant-Demonstrator, and assists in the teaching of Practical Anatomy), is offered for competition amongst those students who have completed their second winter session; and a scholarship in Pathology, of the value of £20 (the holder of which is styled Assistant-Curator), for those students who have completed their third winter session. Examinations for prizes are held at the termination of each session in the various classes for students of the first, second, and third year. Two Prosectors are appointed annually, who each receive a certificate and £5 for their services in the dissecting-room.

The entrance fee for general students may be paid in instalments by arrangement with the Dean of the School. Students who have kept the two years course at the University of Cambridge are admitted as perpetual pupils on payment of 55 guineas, and those who have kept a portion of the course elsewhere at a proportionate reduction. A fee of £1 1s. is required to be paid to the library and reading-room. Instruction in vaccination can be obtained; fee £1 1s.

Further information may be obtained from Dr. Cheadle, Dean of the School; or from Mr. Knott, the Registrar, at the Hospital.

THE LONDON HOSPITAL.

During the winter session lectures on Anatomy, Physiology, Chemistry, Pathology and Morbid Anatomy, Medicine, Surgery, and Dental Surgery will be given. Clinical lectures and clinical instruction will be regularly and systematically delivered on the cases occurring both in the clinical and in the ordinary medical and surgical wards. There will be clinical lectures on the cases in the wards for diseases of women, and clinical instruction in the obstetric out-patient rooms, as well as in the special departments for diseases of the eye, ear, and skin.

During the summer session, lectures on Midwifery and Diseases of Women, Materia Medica, Botany, Comparative Anatomy, Practical Histology and the Use of the Microscope, Pathology and Morbid Anatomy, Practical Chemistry, Forensic Medicine, Syphilis, Diseases of the Eye and Use of the Ophthalmoscope, Diseases of the Skin, Diseases of the Throat and Use of the Laryngoscope, will be given.

Clinical lectures and clinical instruction will be delivered, as in the winter session, in connexion with every branch of practice.

Table of Fees.—General fee for perpetual attendance on all the lectures, and for attendance on medical and surgical practice, qualifying for examination at most of the medical and surgical boards, £90; composition fee for gentlemen entering at or before the beginning of their second winter session, their first year having been spent elsewhere, £70; perpetual fee for lectures and hospital practice, £100; perpetual fee for lectures alone, £50; perpetual fee for hospital practice alone, £50. Extra Fees: Practical chemistry (for apparatus, etc.), £2 2s.; subscription to the library (compulsory), £1 1s. *Note.*—The general fee and the perpetual fee are payable in two instalments of £45 and £50 each respectively, at the commencement of each of the first two years of attendance. If preferred, the *perpetual* fee can be paid in three instalments—£45 at the commencement of each of the first two years of attendance, and £10 at the commencement of the third year. The composition fee is payable in two instalments of £35.

Scholarships and Prizes.—Seven scholarships will be offered for competition during the ensuing winter session. The two Buxton Scholarships will be awarded in October to the students who distinguish themselves most in the subjects appointed by the General Council of Medical Education and Registration as the subjects of the preliminary examinations. 1. A scholarship, value £30, to the student placed first in the examination. 2. A scholarship, value £20, to the student placed second in the examination. 3. A scholarship, value £20, will be awarded to the first year student who shall pass in April, 1874, the best examination in Human Anatomy. 4. A scholarship, value £25, will be awarded to the first year or second year student who shall pass at the end of the winter session the best examination in Anatomy, Physiology, and Chemistry. 5. A hospital scholarship, value £20, for proficiency and zeal in Clinical Medicine. 6. A hospital scholarship, value £20, for proficiency and zeal in Clinical Surgery. 7. A hospital scholarship, value £20, for proficiency and zeal in Obstetrics. The Duckworth-Nelson Prize, value £10, will be awarded by competition at the end of the winter session, 1874, and will be open to all students who have not completed their education. The subjects of examination will be Practical Medicine and Surgery. Money prizes, to the value of £60 per annum, are awarded by the House Committee to the most meritorious of the dressers in the out-patient rooms. The special conditions may be learnt on inquiry. The offices of Resident Medical Officer, Junior Resident Medical Officer, four Medical Assistants, Clinical Clerks, Resident Accoucheur, Maternity Pupils, four House-Surgeons, Surgical Dressing Pupils, two Medical Clinical Assistants, two Surgical Clinical Assistants, Medical Registrar, Surgical Registrar, Assistant-Dentist, Post-mortem Clerks, and two Prosectors of Anatomy, are open to the students.

Communications addressed to the Dean or Vice-Dean of the School, at the London Hospital Medical College, Turner-street, Mile-end, London, E., will receive immediate attention.

MIDDLESEX HOSPITAL.

This Hospital contains upwards of 300 beds, of which 185 are for surgical, and 120 for medical cases. There is a special department for cancer cases, affording accommodation for thirty-three in-patients, whose period of residence in the Hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients from diseases of the eye. There are special out-patient departments for diseases of the skin, the throat, the eye, and ear.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patient rooms. Classes, open to all the students, are held for practical instruction in the microscopic examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes books from the library of the school. Two entrance scholarships of the annual value of £25 and £20, tenable for two years, are offered for competition at the commencement of the winter session. Two Broderip Scholarships of the annual value of £30 and £20, tenable for two years, and two clinical prizes of six and four guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside and in the post-mortem room. The Governors' Prize of twenty guineas is awarded annually to the student who shall have most distinguished himself during his three years' curriculum. Class prizes are also given. The Clinical Clerkships and Dresserships are open to students free of charge, while the Clinical Clerk and Dresser of the Physician and Surgeon of the week dine at the board-room table free of expense. Six resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed reside and board in the Hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the medical school.

The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries is £90, which may be paid by instalments.

Dental students who intend to become Licentiates in Dental Surgery of the Royal College of Surgeons are admitted to attend the requisite courses of lectures and hospital practice on payment of a fee of forty guineas, either in one payment, or by instalments of twenty-five guineas on entrance, and fifteen guineas at the beginning of the second winter session.

ST. THOMAS'S HOSPITAL.

The admission fee to hospital practice and all the lectures is £40 for the first year, and a similar sum for the second, £20 for the third, and £10 for each succeeding year; or £105 at one payment for unlimited attendance. Special entries may be made to any course of lectures, or to the hospital practice.

There are special departments for diseases of the eye, diseases of women and children, vaccination, diseases of the skin, diseases of the teeth, and mental diseases.

Prizes and Appointments.—A scholarship has been founded by Sir W. Tite, M.P., F.R.S., the proceeds of £1000 Consols, tenable for three years, on proof of continued residence and good conduct. Preference, in case of equality between students, to be given to the son of a medical man, and more particularly of one who has been educated at St. Thomas's Hospital, or is in practice at Bath. This Scholarship was awarded at the end of last session. To the three most distinguished pupils for general proficiency, the following prizes are awarded:—First year's students—winter, £20, £15, £10; summer, £15, £10, £5. Second year—winter, £20, £15, £10; summer, £15, £10, £5. Clinical and obstetrical clerks and dressers are selected according to merit from among second year's students. The dressers and obstetric clerks are provided with rooms and commons during their period of attendance in the Hospital free of expense. Third year's students—winter, £20, £15, £10. The Cheselden Medal, founded by George Vaughan, Esq., is awarded in respect of a special examination in Surgery and Surgical Anatomy. The Solly Medal, with a prize of £10 10s., will be awarded at the end of the session to third, fourth, fifth, or sixth year's students, for the best report of surgical cases. The Treasurer's Gold Medal is given annually for general proficiency and good conduct. The Grainger Testimonial Prize, of the value of £20, will be awarded biennially to the third or fourth year's students for a physiological essay, to be illustrated by preparations.

The House-Physicians, the House-Surgeons, and Resident Accoucheur are chosen from gentlemen who have obtained their professional diplomas. All are provided with rooms and commons. The two offices of Medical Registrar and Surgical Registrar are from time to time filled from among gentlemen who have completed their studies in the school. Each Registrar, on completing his annual report to the satisfaction of the Physicians and Surgeons, receives a gratuity of £40.

For further information apply to Mr. Whitfield, Medical Secretary, St. Thomas's Hospital, London, S.E.

UNIVERSITY COLLEGE, LONDON.

The fees for lectures and hospital practice required by the Colleges of Physicians and Surgeons and the Society of Apothecaries during the student's entire course amount to £106 16s., which may be paid as follows:—First winter, £37 6s.; first summer, £11 11s. Second winter, £32 1s.; second summer, £7 7s. Third winter, £11 4s.; third summer, £7 7s.

Entrance Exhibitions.—Three Entrance Exhibitions, of the respective values of £32, £20, and £10 per annum, tenable for two years, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter's attendance in a medical school. The subjects of the examinations are—Classics, Elementary Mathematics, Natural Philosophy, and either French or German at the option of the candidate. The next examination will take place at the College on September 25 and 26. Notice of intention to compete, with a statement of the modern language in which the candidate wishes to be examined, must be left addressed to the Secretary, not later than 2 p.m. on Saturday, September 17, at the office of the College, where the Regulations may be obtained.

Scholarships and Exhibitions.—The Atkinson Morley Surgical Scholarship, of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the theory and practice of Surgery. The Sharpey Physiological Scholarship, of about £95 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: A prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy.

Medals and Prizes.—Dr. Fellowes' Clinical Medals, one gold and one silver, awarded at the end of the winter and of the summer session to pupils who have most distinguished themselves by reports and observations on the medical cases in the Hospital. The Liston Gold Medal is awarded at the end of the summer session to the pupil who has most distinguished himself by reports and observations on the surgical cases in the Hospital. The Alexander Bruce Gold Medal will be awarded for proficiency in Pathology and Surgery. The Cluff Memorial Prize is awarded every other year for proficiency in Anatomy, Physiology, and Chemistry.

Class Medals and Prizes.—Besides the above, gold and silver medals or other prizes are awarded in each class.

The appointment of Assistant-Curator to the Museum of Anatomy and Pathology, of Demonstrators of Anatomy, of Resident Medical Officer to the Hospital, and of Surgical Registrar—all of which have emoluments attached to them—are almost invariably conferred upon students of the College.

Offices in the Hospital tenable by Students.—Physicians' Assistants, House-Surgeons, Midwifery Assistants, Physicians' Clerks, Surgeons' Dressers, Ward Clerks, and Ophthalmic Surgeons' Assistants are selected from the pupils, without additional fees.

Further information and detailed prospectuses may be obtained at the office of University College, Gower-street, W.C.

WESTMINSTER HOSPITAL.

The entry fee to lectures and hospital practice required by the College of Physicians and Surgeons and the Society of Apothecaries may be paid in one sum of £78, which is perpetual, in two payments of £40 each, at the commencement of the first two years, or in four payments of 27, 14, 25, and 13 guineas respectively, at the commencement of the first four sessions.

In addition to the practice of the Hospital, which contains 191 beds, the general students of this school are admitted to the practice of the Royal Westminster Ophthalmic Hospital, and to that of the National Hospital for Epilepsy and Paralysis.

Prize Appointments.—A House-Physician, House-Surgeon, and Resident Obstetric Assistant are appointed annually, by examination, from amongst the senior students, without the payment of any fee. The Medical and Surgical Registrars, each of whom receives a salary of £40, are also appointed annually. The Assistant House-Surgeon and the Clinical Clerks and Dressers are open to the diligent students, as are also the posts of Physician's Assistant, Surgeon's Assistant, and Ophthalmic Assistant.

Prizes.—In addition to the appointments above enumerated, there are two entrance scholarships of £20 and £10, each tenable for two years, an exhibition in Anatomy and Physiology for first year's men, a scholarship of twenty guineas in Anatomy and Physiology for second year's men, a prize of the value of £20 for general proficiency, and two clinical prizes of the value of five guineas each. Certificates of honour are also awarded to the most meritorious students.

Full particulars as to courses of lectures and mode of instruction will be found in the annual prospectus of this School, and any further information may be obtained by personal application to Mr. Cowell, the Dean of the School, or the Secretary of the Hospital.

ENGLISH PROVINCIAL SCHOOLS AND HOSPITALS.

THE QUEEN'S COLLEGE, BIRMINGHAM.

Professors in the Medical Faculty.—Winter Courses: Medicine, Dr. Russell, Dr. Balthazar Foster. Surgery, Mr. Pemberton, Mr. Furneaux Jordan. Anatomy, Mr. Charles J. Bracey, M.B., Mr. W. Thomas, M.B. Physiology, Dr. Norris, Mr. T. H. Bartleet, M.B. Chemistry, Dr. Alfred Hill. Demonstrators of Anatomy, Dr. Robert Jolly, Mr. H. Campbell Pope. Summer Courses: Midwifery, Mr. John Clay, Dr. John Bassett. Diseases of Women and Children, Mr. Samuel Berry, Dr. R. C. R. Jordan. Forensic Medicine and Toxicology, Mr. Thomas Swain, Dr. Alfred Hill. Practical Chemistry, Mr. Anderson. Botany, Dr. William Hinds. Materia Medica and Therapeutics, Mr. J. St. S. Wilders, Dr. Edward Mackey. Ophthalmic Surgery, Mr. J. Vose Solomon. Dental Surgery, Mr. Thomas Howkins. Comparative Anatomy, Dr. Thomas Savage. Medical Tutor and Registrar, H. Campell Pope, M.R.C.S.

Resident Students.—Students may reside within the College, where they will be provided with rooms and board, and will be under the supervision of the Warden, Sub-Warden, and Resident Tutors. Resident students are expected to attend the College Chapel, unless specially exempted by the Warden.

Resident Tutors.—The Professor of Classics, the Professor of Mathematics, and the Medical Tutor.

Hospital Practice.—At the General and Queen's Hospitals.

Scholarships and Prizes.—The Sands Cox Prize.—A prize of

the value of £20 is given annually in the Medical department. The Warden's Prize, of the value of £5 5s., offered by the Rev. Canon Espin to the most proficient student of the first year. Class Prizes.—Medals and certificates of honour are awarded annually in each class after examination.

The composition fee for all the lectures required by the Examining Boards is fifty guineas, payable by two equal instalments. Fees for rooms and board of resident students £50 per annum.

THE GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.

These Hospitals are now amalgamated under the direction of a Clinical Board. Students are required to attend both Hospitals.

The General Hospital, Birmingham.—Physicians: Dr. Bell Fletcher, Dr. Russell, Dr. Wade, Dr. Foster. Surgeons: Mr. Alfred Baker, Mr. Oliver Pemberton, Mr. T. H. Bartleet, Mr. W. P. Goodall, Mr. Robert Jolly. Resident-Physician and Medical Tutor: Mr. Edwin Rickards, M.A., B.A. Oxon., F.R.C.S. Resident-Surgeon and Surgical Tutor: Mr. Bennett May. Registrar and Pathologist: (Vacant.)

The Queen's Hospital, Birmingham.—Physicians: Dr. Fleming, Dr. Johnston, Dr. Heslop, Dr. Sawyer. Surgeons: Mr. West, Mr. Gamgee, Mr. Furneaux Jordan, Mr. J. St. S. Wilders. Obstetric Surgeon: Mr. John Clay. Dental Surgeon: Mr. Charles Sims. Resident-Physician and Medical Tutor: Dr. Leeson. Resident-Surgeon and Surgical Tutor: Mr. Gilbert Smith.

The Lying-in Department is under the charge of Mr. John Clay, and the Dental under Mr. C. Sims.

Special instruction is given at the Hospitals in the use of the Microscope, Laryngoscope, and Ophthalmoscope, also in case-taking and the art of prescribing. Practical Pharmacy is taught in the dispensaries of the Hospitals.

Appointments.—At the General Hospital: Resident Medical Assistant, Resident Surgical Assistant, and two Resident Dressers, tenable for six months. At the Queen's Hospital: Resident Medical Assistant, Resident Surgical Assistant, and Resident Obstetric Assistant, tenable for six months.

Clinical Prizes.—The following prizes will be given annually: Senior Medical Prize, for 3rd or 4th year students—1st prize, £6 6s.; 2nd prize, £4 4s. Senior Surgical Prize, for 3rd or 4th year students—1st prize, £6 6s.; 2nd prize, £4 4s. Junior Medical Prize, for 2nd year students—1st prize, £5 5s.; 2nd prize, £3 3s. Junior Surgical Prize, for 2nd year students—1st prize, £5 5s.; 2nd prize, £3 3s. Midwifery Prize, £2 2s.

A special prize, value £4 4s., will be given for regularity of attendance and general good conduct.

Scale of Fees.—Fees for attendance for four years, £31 10s.: this payment may be made in two equal sums. One year's attendance, £15 15s.; six months' attendance, £10 10s.

Notice.—Further particulars may be obtained by application to the Rev. the Warden, at the College.

BRISTOL MEDICAL SCHOOL.

The winter session will commence on Wednesday, October 1, 1873. Medicine, Dr. Martyn and Dr. Fox. Surgery, Mr. Coe and Mr. Tibbits. General Anatomy and Physiology, Mr. Atchley and Dr. Spencer. Descriptive and Surgical Anatomy, Mr. Board and Mr. Dobson. Superintendence and Dissections, Messrs. Chute, Lawrence, and Elliott. Chemistry, Mr. Coomber.

The summer session will commence on May, 1, 1874. Midwifery and Diseases of Women, Dr. J. G. Swayne. Forensic Medicine, Mr. W. P. Keall. Materia Medica and Therapeutics, Dr. G. F. Burder. Botany, Mr. A. Leipner. Practical Chemistry, Mr. Coomber. Pathological Anatomy, Dr. Martyn and Dr. Fox. Comparative Anatomy, Mr. Atchley.

Fee for perpetual attendance on all the above courses, except Comparative Anatomy, £57 15s.

Competitive examinations are held amongst students of the first, second, and third years respectively; and prizes of money, instruments, and books are annually awarded.

Medical and Surgical Hospital Practice and Clinical Lectures are attended at the Royal Infirmary or at the General Hospital.

Further information may be obtained on application to the Honorary Secretary, Dr. G. F. Burder.

BRISTOL ROYAL INFIRMARY.

This Infirmary contains 242 beds. Physicians: Dr. Brittan, Dr. Fairbrother, Dr. Beddoe, Dr. Fox. Surgeons: Mr. Leonard, Mr. Clark, Mr. Tibbits, Mr. Steele, and Mr. Board. House-Surgeon: Dr. Shingleton Smith. Secretary: Wm. Trenerry.

Fees.—For one year, Surgeon's pupil, £12 12s.; Dresser (extra fee), £12 12s. For two years (at one payment), Surgeon's pupil, £21; Dresser (extra fee), £21. For three years (at one payment), Surgeon's pupil, £26 5s.; Dresser (extra fee), £26 5s. Dressers reside in the house in weekly rotation. Physician's pupil, for six months, £8; one year, £15; eighteen months, £20; perpetual, £25. Clinical Clerks are appointed without extra fee. A gold medal and other prizes are awarded annually.

BRISTOL GENERAL HOSPITAL.

The Hospital contains 140 beds. Physicians: Dr. Martyn Dr. Burder, Dr. Fripp. Surgeons: Mr. Coe, Mr. Lansdown, Mr. G. F. Atchley, Mr. N. C. Dobson. Physician-Accoucheur: Dr. Swayne. Two scholarships of £15 each are awarded annually. Also a scholarship, called the Sanders Scholarship, for the study of Medicine and Surgery, being the interest of £500 (to be given annually) bequeathed to the Hospital by the late J. N. Sanders, Esq.

Fees.—Medical or Surgical practice, for six months, £6; one year, £10; perpetual, £20. Extra fee for clinical clerk or dresser, £5 5s. for six months. Library fee, £1 1s. per annum. Dressers reside in the Hospital by rotation and free of expense.

Resident pupils (including board, lodging, and washing), £100 for the first year, £60 for each subsequent year; or for five years, with apprenticeship to the Hospital, £260.

Further information will be afforded by Lieut. H. Fox, Secretary to the Hospital.

CAMBRIDGE UNIVERSITY MEDICAL SCHOOL.

The winter session will commence on October 8. Winter Courses.—Anatomy: Professor Humphry and Dr. Wilson. Anatomy and Physiology: Professor Humphry. Practical Physiology: Dr. Michael Foster. Superintendence of Dissections: Dr. Wilson and Mr. Williams. Medicine: Professor Paget. Chemistry: Professor Liveing. Practical Chemistry: Professor Liveing and Mr. Hicks. Physics: Professor Maxwell. Zoology and Comparative Anatomy: Professor Newton. Demonstrator of Comparative Anatomy: Mr. Bridge. Materia Medica: Professor Fisher. Summer Courses.—Practical Physiology: Dr. Michael Foster. Osteology: Professor Humphry and Dr. Wilson. Practical Histology: Dr. Wilson and Mr. Yule. Chemistry and Practical Chemistry: Professor Liveing and Mr. Hicks. Comparative Anatomy, Dissections: Mr. Bridge. Pathology: Dr. Bradbury. Botany: Professor Babington.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

The Hospital contains 120 beds. Physicians: Dr. Paget, Dr. Latham, Dr. Bradbury. Surgeons: Mr. Lestourgeon, Dr. Humphry, Mr. Carver. Clinical lectures are given weekly by the Physicians and Surgeons, and practical instruction is given daily by the Resident Physician and the Resident Surgeon. Fees for attendance upon the practice (Medical and Surgical), £15 15s. for an unlimited period; £10 10s. for one year; £8 8s. for six months.

UNIVERSITY OF DURHAM.—COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

Winter Session, commencing October 1, 1873.—Physiology, Dr. Hume. Anatomy, Dr. Nesham, Dr. Armstrong, and Mr. Russell. Medicine, Dr. Charlton and Dr. Philipson. Surgery, Dr. Heath. Chemistry, Professor Marreco, M.A. Practical Physiology, Dr. Reoch. Mental Diseases, Dr. T. O. Wood.

Summer Session.—Midwifery, Dr. Gibson. Botany, Mr. H. E. Armstrong. Medical Jurisprudence, Dr. B. Bramwell. Materia Medica, Dr. Arnison. Therapeutics, Dr. Humble. Practical Chemistry, Professor Marreco, M.A. Operative Surgery, Dr. Heath. Pathological Anatomy, Dr. Gibb. Pharmacy, Mr. Proctor.

Fees for Lectures.—Composition fee for all the lectures qualifying for the Licence in Medicine and the Mastership

in Surgery of the University of Dublin, the Licence and Membership of the Royal College of Physicians, the Diploma of the College of Surgeons, and the Licence of the Apothecaries' Society, payable on entering to the first winter session, £52 10s. Perpetual ticket for Pharmacy curriculum, £12 12s. Separate courses of lectures, each £4 4s. The composition fee entitles the holder to attend the lectures on Botany, Chemistry, Materia Medica, and Pharmacy, and to use the Museum of Materia Medica in the library of the College.

Hospital Practice.—This can be attended at the Newcastle Infirmary, which contains 230 beds.

Fees for Hospital Practice.—Twelve months, £7 7s.; six months, £5 5s.; three months, £4 4s.; perpetual fee, £17 17s.; or, if paid by instalments, first year £7 7s., second year £6 6s., third year £5 5s. These fees also are payable in advance.

Medical Scholarships in the University of Durham.—Four scholarships, of £25 a year each, tenable each for four years. Dickinson Memorial Scholarship, £15, tenable for one year, for general proficiency. By a recent Act of Convocation, students may now proceed to the degrees of M.D. and C.M. of the University of Durham by keeping the necessary terms in Arts either at Durham or Newcastle. Four Resident Dressers, who also act as Physicians' Clinical Clerks, are chosen every six months from the senior students. Fee for six months' board and residence, £10 10s.

College Medals.—At the end of each session a silver medal and certificates of honour will be awarded in each of the required classes.

Further particulars may be obtained from Dr. Luke Armstrong, Registrar, or of Dr. Arnison, Secretary.

T. O. Wood, L.R.C.P., Medical Superintendent of the Dunston Lodge Lunatic Asylum, will deliver a course of lectures on Psychological Medicine, illustrated by cases in the Asylum, to students in their third and fourth years, during the latter half of the winter season. Due notice will be given of the time.

Medical Tutor and Demonstrator, J. Reoch, M.A., M.B., M.C., who will superintend and assist the students in their studies, and during the summer session will give a complete course of Practical Physiology.

LEEDS SCHOOL OF MEDICINE.

The winter session will commence on Wednesday, October 1, 1873. Anatomy, by Mr. James Seaton, Dr. Robert T. Land, and Mr. John A. Nunneley. Physiology, by Messrs. C. J. Wright and James Walker. Principles and Practice of Medicine, by Dr. John D. Heaton and Dr. T. C. Allbutt. Principles and Practice of Surgery, by Messrs. Clandins G. Wheelhouse, T. Pridgin Teale, and T. R. Jessop. Chemistry by Mr. Thomas Fairley. Materia Medica, by Dr. John E. Eddison. Midwifery, by Mr. W. Hall. Forensic Medicine, by Mr. Thomas Scattergood. Pathology, by Dr. Eddison. Botany, by Mr. Edward Atkinson. Comparative Anatomy, by Mr. C. G. Wheelhouse and Dr. T. C. Allbutt. Demonstrators of Anatomy, Messrs. Robert Parr Oglesby, Edmund Robinson, and J. A. F. McGill. Demonstrations in Operative Surgery, by Messrs. C. G. Wheelhouse, Pridgin Teale, and T. R. Jessop. Demonstrations of Skin Diseases are given at the Infirmary. Ophthalmoscopic Demonstrations, by the Surgeons of the Eye and Ear Department of the Infirmary. Total fees, entitling to all the lectures and hospital practice required by the licensing boards, £88 4s. These fees may be paid at once, or in two instalments at the commencement of the first and second years. Entrance fee to library and reading-room, £1 1s., to be paid by all students on entrance. Class prizes, two clinical prizes of £10 each, a Forensic Medicine Prize of £10, and two chemical scholarships are awarded to students. House-Surgeoncies, Clinical Clerkships, and Dresserships are open to the students.

Honorary Medical Officers of the Hospital.—Consulting Physician: Charles Chadwick, M.D. Consulting Surgeons: William Hey, F.R.C.S., and Samuel Hay, F.R.C.S. Physicians: John Deakin Heaton, M.D., T. Clifford Allbutt, M.D., and John Edwin Eddison, M.D. Surgeons: C. G. Wheelhouse, F.R.C.S.; T. Pridgin Teale, M.A., F.R.C.S.; T. R. Jessop, F.R.C.S.; and James Seaton, L.R.C.S.

Terms of Attendance upon the Hospital Practice.—The fees for attendance upon the medical practice alone, or upon the surgical practice alone, are as follows, being the same in each case:—One winter session, £7 7s.; one summer session, £6 6s.; twelve months, £12 12s.; eighteen months, £15 15s.; three years, £21. Applications for medical practice are to be made to Dr. Heaton, Claremont, between 9 and 10 a.m. Applications for surgical practice are to be made to Mr. T. Pridgin Teale, Cookridge-street, between 10 and 12 a.m.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

The introductory address will be delivered on October 1, 1873, at 3 p.m., by Dr. Richard Caton.

Hospital Practice, Royal Infirmary.—Physicians: Dr. Turnbull, Dr. Waters, Dr. Glynn. Surgeons: Mr. Stubbs, Mr. Bickersteth, Mr. Hakes. Assistant-Surgeon: Mr. Harrison. Pathologist: Mr. Banks. Dental Surgeon: Mr. Snape.

Terms for Hospital Attendance and Clinical Lectures:—For six months' medical practice, £5 5s.; one year, £6 6s. For six months' surgical practice, £6 6s.; one year, £8 8s.

Lectures, Winter Session.—Medicine, Dr. Waters. Surgery, Mr. Harrison. Physiology, Dr. Caton. Anatomy, Mr. W. M. Banks. Dissection, vacant. Pathology, Dr. Davidson. Chemistry, Dr. Brown. Practical Physiology, Rushton Parker, M.B.

Lectures, Summer Session.—Midwifery, Dr. Steel. Diseases of Children, Dr. Gee. Materia Medica, Dr. Nevins. Medical Jurisprudence, Dr. E. Whittle. Toxicology and Practical Chemistry, Dr. Brown. Botany, Dr. W. Carter. Comparative Anatomy and Zoology, Dr. Dickinson.

Exhibitions.—Four exhibitions (value £31 10s. each), consisting of six months' free board and residence in the Royal Infirmary.

The fee for all the lectures required by the Colleges of Surgeons and Physicians and the Apothecaries' Hall is forty-five guineas (exclusive of Practical Chemistry).

LIVERPOOL NORTHERN HOSPITAL.

The winter session will commence on Monday, October 2 Physicians: Dr. Davidson and Dr. Dickinson. Surgeons: Mr. Manifold and Mr. Lowndes. Dental Surgeon: Mr. Jame. Lloyd.

The Hospital contains 146 beds. Clinical clerkships and dresserships are open to all the students, without additional fee. Clinical prizes will be awarded at the termination of the winter session.

Fees for Hospital Practice and Clinical Lectures.—Perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately, on payment of half the above fees. The Hospital receives one resident pupil, fee 60 guineas per annum. Attendance on the practice of this Hospital qualifies for all the Examining Boards.

For further particulars apply to the House-Surgeon, Mr. Vasey.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

Two hundred beds. Clinical Lectures, with special instruction in the employment of medical and surgical instruments, in bandaging, and in minor surgery, are regularly given during winter and summer sessions. Accommodation for resident pupils. The lectures and practice are recognised by all the examining boards.

Fees for Practice and Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

For further particulars, apply to the House-Surgeons.

MANCHESTER ROYAL SCHOOL OF MEDICINE AND SURGERY (INCORPORATED WITH OWENS COLLEGE.)

The winter session will commence October 1.

Director of Medical Studies, Mr. G. Southam.

Lecturers.—Physiology, Mr. Smith. Practical Physiology and Histology, Dr. A. Gamgee. Descriptive Anatomy, Mr. Bradley. Practical Anatomy, Mr. T. Beswick Perrin. Comparative Anatomy and Botany, Mr. W. C. Williamson. Chemistry, Mr. Henry E. Roscoe, Ph.D. Medicine, Dr. Roberts and Dr. Morgan. Surgery, Mr. Southam and Mr. Lund. The Eye, Mr. Hunt. General Pathology, Dr. H. Simpson. Midwifery, Dr. Thorburn. Materia Medica, Mr. Somers. Forensic Medicine, Mr. Harrison. Hygiene, Dr. A. Ransome. Clinical Medicine, by the Physicians; and Clinical Surgery by the Surgeons to the Royal Infirmary.

Perpetual fee to the whole of the lectures required, except Practical Physiology, £42.

Hospital practice at the Royal Infirmary, where clinical lectures are regularly delivered by the Physicians and Surgeons of the institution; composition fee £42.

Three scholarships, of the value respectively of £20, £15, and £10; the Platt Physiological Scholarship of £50, tenable for two years; and the Dumville Surgical Prize, value £20, are offered for competition. Prizes are also awarded at the end of the session.

Further particulars may be obtained from Mr. Southam, Director of the School, and prospectuses may be obtained from the Registrar at the College, Oxford-street, or the School.

MANCHESTER ROYAL INFIRMARY AND DISPENSARY.—BARNES HOUSE OF RECOVERY, MONSALL.—BARNES CONVALESCENT HOME, CHEADLE.

The Manchester Royal Infirmary contains 296 beds; the Barnes House of Recovery, 92 beds; and the Convalescent Home, 35 beds. Consulting Physicians: Sir J. L. Bardsley, M.D., Drs. P. Wood, R. F. Ainsworth, and F. Renaud. Physicians: Drs. M. A. E. Wilkinson, T. H. Watts, H. Browne, W. Roberts, H. Simpson, and J. C. Morgan. Assistant-Physicians: D. J. Leech, M.B. Consulting-Surgeons: Messrs. T. Turner and J. Jordan. Surgeons: Messrs. W. Smith, G. Southam, F. A. Heath, E. Lund, and Geo. Bowring. Assistant-Surgeons: Mr. S. M. Bradley and Mr. Walter Whitehead. Obstetric Physician: John Thorburn, M.D. Ophthalmic Surgeon: Mr. Thos. Windsor. Visiting Apothecaries: Messrs. T. Standring and J. P. Bateman. Resident Medical Officer: G. Reed, M.D. Senior House-Surgeon: T. Jones, M.B. Junior House-Surgeon: R. W. Lyell, M.D. Physicians' Assistants: Messrs. Richard Hughes, S. H. Owen, M.D., and Mr. B. Addy. Secretary: Mr. B. Brown.

NEWCASTLE-UPON-TYNE INFIRMARY.

This Infirmary contains 230 beds. Medical and Surgical clinical lectures are delivered, and clinical instruction is given in the wards. There are special wards for the treatment of children, ophthalmic and syphilitic diseases. Physicians: Dr. Charlton, Dr. Embleton, and Dr. Phillipson. Surgeons: Dr. Heath, Mr. Russell, Dr. Arnison, and Dr. Armstrong. Assistant-Surgeons: Mr. A. Bell, Dr. Hume, Mr. J. Hawthorn, and Mr. C. S. Jeaffreson. Senior House-Surgeon: Dr. Page. Junior House-Surgeon: Mr. G. Rowell. Fees for hospital practice and clinical lectures: twelve months, seven guineas; six months, five guineas; three months, four guineas. Perpetual fee, seventeen guineas; or, if paid by instalments, first year seven guineas; second year, six guineas; third year, five guineas. Four resident clinical clerks and four non-resident dressers are nominated by the Medical Board half-yearly.

SHEFFIELD SCHOOL OF MEDICINE.

The winter session will commence on October 1. Anatomy, Descriptive and Surgical, Mr. Skinner and (vacant). Demonstrations of Anatomy, Messrs. Clarke, Skinner, and T. H. Morton. Physiology, Mr. Thos. Leeds and Mr. S. Morton. Principles and Practice of Medicine, Dr. Frank-Smith. Principles and Practice of Surgery, Mr. W. F. Favell, Mr. Parker, and Mr. A. Jackson. Chemistry, Mr. Allen. Dental Mechanics, Mr. G. Mosely. Clinical Medicine, Dr. De Bartolomé, Dr. Law, and Dr. Frank-Smith. Clinical Surgery, Mr. Barber, Mr. W. F. Favell, and Mr. Parker.

Summer session, commencing May 1, 1873.—Midwifery and Diseases of Women, Dr. Hime. Materia Medica and Therapeutics, Dr. Young. Medical Jurisprudence and Toxicology, Mr. Baker and Mr. Harrison. Botany, Mr. Birks. Practical Chemistry, Mr. Allen. Dental Surgery, Dr. Merryweather. Demonstrations of Pathology and Microscopy, Mr. Hallam (at the Infirmary). Demonstrations of Operative Surgery, Mr. Favell and Mr. Parker, F.R.C.S. Demonstrations of Practical Histology and Physiology, Dr. Thomas. Practical Surgery, Mr. Hallam.

Medical and Surgical Practice.—Sheffield General Infirmary.—Physicians, Dr. De Bartolomé, Dr. Law, Dr. Frank-Smith. Surgeons, Mr. Barber, Mr. Favell, Mr. Parker. House-Surgeon, Mr. Hallam.

The Infirmary contains 200 beds for in-patients.

The fees for perpetual attendance at the Infirmary are £15 15s. for Medical, £21 for Surgical, practice. For twelve months' practice: Medical, £10 10s.; Surgical, £6 6s. Six months': Medical, £6 6s.; Surgical, £4 4s.

Public Hospital and Dispensary.—100 beds. Physicians, Dr. J. Hall, Dr. Law, and Dr. H. J. Brandon. Surgeons, Mr. Chesman, Mr. A. Jackson, and Dr. Keeling.

Sheffield Hospital for Diseases of Women.—Medical Officers: Dr. Jackson, Dr. Keeling, Dr. Hime, and Mr. Woolhouse.

Table of Fees, including Demonstrations.—Anatomy and Physiology, first course, £6 6s., second course, £4 4s.; Practice of Medicine, first course, £4 4s., second course, £2 2s.; Practice of Surgery, first course, £4 4s., second course, £2 2s.; Chemistry, first course, £4 4s.; Midwifery and Diseases of Women, first course, £3 3s.; Materia Medica, first course, £3 3s.; Medical Jurisprudence, first course, £3 3s.; Botany, first course, £3 3s.; Practical Chemistry, first course, £3 3s.; Practical Physiology, £3 3s.; Practical Surgery, £3 3s.

For further information apply to the staff of the institution.

Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42.

All further information may be obtained on application to the Hon. Secretary, Dr. A. Jackson, St. James's-row, Sheffield.

MEDICAL SCHOOLS AND HOSPITALS IN SCOTLAND.

UNIVERSITY OF EDINBURGH.—1873-74.

Principal—Sir Alex. Grant, Bart., LL.D.

The session will be publicly opened with an introductory address by the Principal, on Monday, November 3, 1873. The classes for the different branches of study will be opened as follows, and will meet daily (Saturdays excepted) unless otherwise stated:

Faculty of Medicine.—Materia Medica, Professor Sir Robert Christison, Bart, M.D.; Chemistry, Professor Crum-Brown, M.D., D.Sc.; Surgery, Professor Spence; Institutes of Medicine or Physiology, Professor Bennett, M.D.; Midwifery and Diseases of Women and Children, Professor Simpson, M.D.; Clinical Surgery, Professor Lister; Clinical Medicine, Professors Bennett, Laycock, Maclagan, and Sanders; Anatomy, Professor Turner, M.B.; Natural History, Professor Wyville Thomson; Practice of Physic, Professor Laycock, M.D.; General Pathology, Professor Sanders, M.D.; Anatomical Demonstrations, Professor Turner; Botany, Professor Balfour, M.D.; Medical Jurisprudence, Professor Maclagan, M.D. The lectures on Botany, Natural History, and Medical Jurisprudence are given in the summer session.

Royal Infirmary, at noon, daily. Practical Anatomy, Wednesday, October 1, under the superintendence of Professor Turner. Practical Chemistry, under the superintendence of Professor Crum-Brown. Practical Physiology, under the superintendence of Professor Bennett.

During the summer session, lectures will be given on the following subjects:—Botany, Professor Balfour; Practical Physiology, including Histology, Professor Bennett; Medical Jurisprudence, Professor Maclagan; Clinical Medicine, Professors Bennett, Laycock, Maclagan, and Sanders; Clinical Surgery, Professor Lister; Anatomical Demonstrations, Professor Turner; Practical Chemistry, under the direction of Professor Crum-Brown; Practical Anatomy, under the superintendence of Professor Turner; Natural History, Dr. Carus for Professor Wyville Thomson; Medical Psychology and Mental Diseases, with practical instruction at an asylum, Professor Laycock; Operative Surgery, Professor Spence; Practical Pathology and Morbid Anatomy, Professor Sanders; Clinical Gynæcology, Professor Simpson.

A table of fees may be seen in the Matriculation Office and in the Reading-room of the Library.

SCHOOL OF MEDICINE, EDINBURGH.

The practical anatomy rooms and chemical laboratories open on October 1. The introductory address will be delivered by Dr. George W. Balfour, on Monday, November 3, at eleven o'clock. Lectures commence on Tuesday, November 4.

Winter Session, 1873-74.—Surgery, Dr. P. H. Watson, Dr. Joseph Bell, Dr. Chiene, and Dr. John Duncan; Chemistry (lectures, Practical Chemistry and Analytical Chemistry), Dr. Stevenson Macadam; Midwifery and Diseases of Women and Children, Dr. Matthews Duncan; Physiology, Dr. Bell

Pettigrew and Dr. McKendrick (Royal Infirmary); Clinical Medicine (Royal Infirmary), Drs. Rntherford Haldane, George W. Balfonr, and Grainger Stewart, and Dr. Matthews Duncan (for Diseases of Women); Clinical Surgery (Royal Infirmary), Dr. P. H. Watson and Mr. Annandale; Anatomy (lectnres, Anatomical Demonstrations and Practical Anatomy), Dr. P. D. Handyside; Medical Jurisprudence, Dr. Littlejohn; Practice of Physic, Dr. Rntherford Haldane, Dr. Cland Muirhead, and Dr. Grainger Stewart; General Pathology, Dr. John Wyllie; Vaccination, Dr. Husband.

Summer Session, 1874.—Classes open on Thursday, May 4.—Materia Medica and Therapeutics, Dr. Thomas R. Fraser; Midwifery and Diseases of Women and Children, Dr. Keiller and Dr. Angus Macdonald; Medical Jurisprudence, Dr. Littlejohn; Anatomy (Practical Anatomy, Surgical Anatomy—demonstrations and examinations), Dr. P. D. Handyside; Chemistry (Practical Chemistry, Analytical Chemistry), Dr. Stevenson Macadam (Royal Infirmary); Clinical Medicine (Royal Infirmary), Drs. Rntherford Haldane, G. W. Balfour, and Grainger Stewart, and Dr. Matthews Duncan (for Diseases of Women); Clinical Surgery (Royal Infirmary), Dr. P. H. Watson, Mr. Annandale; Vaccination, Dr. Husband; Diseases of the Eye (with practical instrnction in the nse of the ophthalmoscope), Dr. Argyll Robertson; Diseases of Children, Dr. Stephenson; Insanity, Dr. J. Batty Tnke; Surgical Appliances and Operative Surgery, Dr. Joseph Bell; Operative Snrgery and Surgical Anatomy, Dr. Chiene; Practical Surgery, Dr. Duncan.

Fees.—For a first course of lectnres, £3 5s.; for a second, £2 4s.; perpetual, £5 5s. To thiose who have already attended a first conrse in Edinburgh the perpetual fee is £2 4s. Second course of Midwifery, £1 3s. Practical Anatomy (six months' course), £3 3s. Anatomical Demonstrations, £2 2s.; with Practical Anatomy, £1 1s.; perpetual, £4 4s. Practical Chemistry, £3 3s.; Analytical Chemistry, £2 a month, £5 for three months, or £10 for the session of six months. Vaccination, £1 1s. For snmmer courses of Clinical Snrgery and Clinical Medicine, each £2 4s.; Practical Anatomy (inclnding Anatomical Demonstrations, Operative Surgery, Diseases of the Eye) and Insanity, each £2 2s.

The minimum cost of the education in this School of Medicine for the donble qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, inclnding the fees for the joint examination, is £90 4s., which is payable by yearly instalments during the period of study; whilst the minimum cost for the single qnalification of either Physician or Surgeon, including the fee for examination, is £80.

ROYAL INFIRMARY, EDINBURGH.

In this Hospital a portion of the beds is set apart for Clinical Instruction by the Professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the Ordinary Physicians and Surgeons. Special instruction is given on Diseases of Women, Physical Diagnosis, etc., and on Diseases of the Eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye; also to cases of incidental delirium or insanity. Professors of Clinical Medicine, Dr. Bennett, Dr. Laycock, Dr. Maclagan, Dr. Sanders. Extra Physicians and Lecturers on Diseases Peculiar to Women, Dr. J. Matthews Duncan, Dr. Alex. R. Simpson. Ordinary Physicians and Lectnrers on Clinical Medicine, Dr. Rntherford Haldane, Dr. Geo. W. Balfonr, Dr. T. Grainger Stewart. Assistant-Physicians, Dr. Clande Mnirhead, Dr. Thos. R. Fraser. Consulting Surgeons, Dr. Dunsmure, Dr. J. D. Gillespie. Professor of Snrgery, Mr. Spence. Ordinary Acting Snrgeons, Dr. P. H. Watson, Mr. Thos. Annandale (Lecturers on Clinical Surgery), Dr. Joseph Bell. Professor of Clinical Surgery, Mr. Lister. Ophthalmic Surgeons, Mr. Walker, Dr. D. A. Robertson. Extra Surgeon for treatment of Ovarian Diseases, Dr. Thomas Keith. Assistant-Surgeons, Dr. John Duncan, Dr. John Chiene. Dental Surgeon, Dr. John Smith. Pathologist, Dr. James B. Pettigrew. UNIVERSITY OF ABERDEEN—FACULTY OF MEDICINE.

Winter Session, commencing on Wednesday, October 29.—Anatomy, Professor Struthers, M.D., £3 3s. Practical Anatomy and Demonstrations, Professor Struthers and the Demonstrator, £2 2s. Chemistry, Professor Brazier, £3 3s. Institutes of Medicine, Professor Ogilvie, £3 3s. Surgery, Professor Pirrie, £3 3s. Practice of Medicine, Professor Macrobin, M.D., £3 3s. Midwifery and Diseases of Women and Children, Professor Inglis, £3 3s. Zoology, with Comparative Anatomy, Professor Nicol, £3 3s. Medical Jurisprudence, Professor Ogston, £3 3s.

Summer Session, commencing on the first Monday in May.—Botany, Professor Dickie, £3 3s. Materia Medica (100 lectnres), Professor Harvey, £3 3s. Practical Anatomy and Histology, Professor Strnthers and the Demonstrator, £2 2s. Practical Chemistry, Professor Brazier, £3 3s. Zoology, with Comparative Anatomy, Professor Nicol, £3 3s.

Matricnlation fee for the winter and summer sessions, £1. For the summer session alone, 10s.

Royal Infirmary: Perpetual fee to hospital practice, £6; or first year, £3 10s., second year, £3. Clinical Medicine, Drs. Smith Beveridge and A. Frazer, £3 3s. Clinical Surgery, Drs. Pirrie, Kerr, and Fiddes, £3 3s. Pathological Anatomy, Dr. Rodger, £2 2s. Practical Ophthalmology, Dr. A. D. Davidson. Dental Surgery, Mr. Williamson.

For further information, apply to Dr. Macrobin, Dean of the Faculty of Medicine.

ABERDEEN ROYAL INFIRMARY.

The Infirmary contains about 300 beds. Consulting Physician: Dr. A. Harvey. Physicians: J. W. F. Smith, R. Beveridge, Angus Fraser. Surgeons: Messrs. W. Pirrie, D. Kerr, D. Fiddes, and A. Ogston. Ophthalmic Surgeon: Dr. Alex. D. Davidson. Pathologist: Dr. James Rodger. Dental Surgeon: Mr. Williamson. Resident Superintendent and Apothecary: Dr. R. Rattray. Resident Assistant-Physician: Mr. A. Craigmyle. Resident Assistant-Surgeon: Mr. J. P. Lumsden. Pathologist and Curator of Museum: Dr. J. Rodger. Treasurer and Secretary: Mr. W. Carnie.

UNIVERSITY OF GLASGOW.—FACULTY OF MEDICINE.

The classes open for the winter session on Monday, October 27, 1873, when an introductory lecture will be given by Professor Macleod, M.D.

Chemistry, Practical Chemistry, and Chemical Laboratory, Dr. Anderson, £3 3s. Practice of Physic, Dr. Gairdner, £3 3s. Anatomy, Anatomical Demonstrations, and Practical Anatomy, Dr. Allen Thomson and Demonstrator, £6 6s. Materia Medica, Dr. Cowan, £3 3s. Forensic Medicine, Dr. P. A. Simpson, £3 3s. Surgery, Dr. Macleod, £3 3s. Midwifery, Dr. Leishman, £3 3s. Institutes of Medicine, Dr. A. Buchanan, £3 3s. Pathology, Dr. J. Coats, £3 3s. Clinical Medicine and Clinical Surgery, Physicians and Surgeons of Royal Infirmary.

Further information may be obtained from the Registrar of the University.

ANDERSON'S UNIVERSITY, GLASGOW.

Anatomy, Professor George Buchanan, M.D.; Demonstrator, Mr. H. E. Clark. Chemistry, Professor Thorpe, Ph.D. Institutes of Medicine (Physiology), Professor E. Watson, M.D. Surgery, Professor Dunlop, M.D. Materia Medica, Professor Morton, M.D. Practice of Medicine, Professor McCall Anderson, M.D. Midwifery (in summer), Professor J. G. Wilson, M.D. Medical Jurisprndence (in summer), Professor A. Lindsay, M.D. Ophthalmic Medicine and Surgery, Dr. Wolfe.

Class Fees.—For each of the above conrses of lectures, first session, £2 2s.; second session, £1 1s.; afterwards free. Anatomy Class Fees: For both courses (lectures and demonstrations on Practical Anatomy), first session, £4 4s.; second, session, £4 4s.

Fees for clinical lectures, on Medicine, £3 3s., on Surgery, £3 3s.

Medical Superintendent, Dr. M. Thomas. Secretary, Mr. H. Lamond, 64, West Regent-street.

SCHOOLS AND HOSPITALS IN IRELAND.

SCHOOL OF PHYSIC, UNIVERSITY OF DUBLIN.

The School is under the joint government of the Board of Trinity College and the King and Queen's College of Physicians.

Institutes of Medicine, Professor Law. Materia Medica and Pharmacy, Professor A. Smith. Surgery, Professor R. Smith. Anatomy and Surgery, Professor M'Dowel. Practical Anatomy, Dr. Bennett. Chemistry, Professor Apjohn. Practice of Medicine, Professor Moore. Midwifery, Professor Sinclair. Botany, Dr. E. Perceval Wright. Medical Jurisprudence, Professor Travers. Comparative Anatomy and Zoology, Professor Alexander Macalister, M.D. Physics, Professor John Leslie, M.A. Hospital practice and clinical lectures at Sir Patrick Dun's Hospital.

SIR PATRICK DUN'S HOSPITAL.

Consulting Physician, William Stokes, M.D., Regius Professor of Physic. Consulting Surgeon, Robert Adams, M.Ch., Regius Professor of Surgery. The clinical lectures in Medicine and Surgery are delivered by—Physicians: Robert Law, M.D., King's Professor of the Institutes of Medicine; William Moore, M.D., King's Professor of the Practice of Medicine; Aquilla Smith, M.D., King's Professor of Materia Medica and Pharmacy; Edward B. Sinclair, M.D., King's Professor of Midwifery. Surgeons: Robert W. Smith, M.Ch., Trinity College, Professor of Surgery; Benjamin G. M'Dowel, Professor of Anatomy; Edward H. Bennett, M.Ch., University Anatomist; Richard G. Butcher, M.D., University Lecturer in Practical Surgery. The Physicians and Surgeons attend for clinical instruction on alternate days.

Hospital fee for twelve months, including nine months' clinical lectures, nine guineas. Attendance on this Hospital is recognised by all licensing bodies.

ST. VINCENT'S HOSPITAL, DUBLIN.

The winter session will commence on Wednesday, October 1, 1873. Physicians: Dr. Francis J. B. Quinlan and Dr. Robert Cryan. Surgeons: Dr. Edward D. Mapother and Mr. William H. O'Leary. Surgeon-Dentist: Mr. William J. Doherty. Apothecary: Mr. Boland.

Further particulars may be learned on application to the Secretary, or at the Hospital during the hours of attendance.

THE QUEEN'S UNIVERSITY IN IRELAND.—QUEEN'S COLLEGE, BELFAST, FACULTY OF MEDICINE.

The lectures will commence on Tuesday, November 4. Anatomy and Physiology, Dr. P. Redfern. Chemistry, Dr. Thomas Andrews. Practice of Medicine, Dr. James Cuming. Practice of Surgery, Dr. A. Gordon. Materia Medica, Dr. J. S. Reid. Midwifery, Dr. R. F. Dill. Medical Jurisprudence, Dr. J. F. Hodges. Natural Philosophy, Dr. Everett. Zoology and Botany, Dr. R. O. Cunningham. The demonstrations in Anatomy are delivered by Dr. Charles. The courses of Botany and Practical Chemistry, and a second course of Experimental Physics, will commence in May. The lectures in Midwifery and in Medical Jurisprudence are also summer courses.

Fees.—Anatomy and Physiology—First course, £3; each subsequent course, £2. Anatomical Demonstrations and Practical Anatomy—each course, £3. Practical Chemistry, £3. Other medical lectures—first course, £2; each subsequent course, £1.

Two medical scholarships are awarded to the students of each year of the medical course. The examinations commence on October 20.

Belfast General Hospital.—Clinical Instruction—Perpetual Fee, payable in one sum of £10 10s., or in two instalments of £5 5s. each on entering for the first and second years. Hospital fee, 10s. 6d. each session. Four resident pupils are appointed each session.

Belfast Lying-in Hospital.—Fee for the session, £3 3s.

QUEEN'S COLLEGE, CORK, FACULTY OF MEDICINE.—Session 1873-74.

Anatomy, Physiology, and Practical Anatomy, Dr. J. H. Corbett. Practice of Medicine, Dr. D. C. O'Connor. Practice of Surgery, Dr. W. Tanner. Materia Medica, Dr. P. O'Leary. Midwifery, Dr. J. R. Harvey. Natural Philosophy, Mr. John England. Chemistry and Practical Chemistry, Dr. M. Simpson. Zoology and Botany, Dr. J. R. Greene. Clinical Medicine and Clinical Surgery, at the North and South Infirmaries, by the Physicians and Surgeons of these institutions. Clinical Midwifery, at the Lying-in Hospital. The medical session will be opened on Monday, November 3, 1873, and the lectures will commence on the same day.

Eight scholarships, value £25 each, are awarded to students of Medicine.

For further information apply to Mr. Robert John Kenny, Registrar.

QUEEN'S COLLEGE, GALWAY, FACULTY OF MEDICINE.—Session 1873-74.

Anatomy and Physiology, and Practical Anatomy, Dr. Cleland. Practice of Medicine, Dr. N. Colahan. Practice of Surgery, Dr. J. V. Brown. Materia Medica, S. M'Coy, Esq., F.R.C.S.I. Medical Jurisprudence, Dr. J. P. Pye. Midwifery and Diseases of Women and Children, Dr. R. Doherty. Chemistry, Dr. T. H. Rowney. Natural Philosophy, Dr. A. H. Curtis. Botany and Zoology, Dr. A. G. Melville. Logic and Mental Philosophy, Dr. T. W. Moffett. The County Galway Infirmary, Town, and Fever Hospitals are in the immediate vicinity of the Queen's College.

Eight scholarships of the value of £25 each, and exhibitions varying in value from £12 to £16, are appropriated to students pursuing the course for the degree of M.D.

Fees.—Anatomy and Physiology, £3, first session; afterwards, £2. Practical Anatomy, £3; Practical Chemistry, £3; Operative Surgery, £3; other classes, £1 for each course extending over one term only—£2 for each course extending over more than one term—and £1 for each re-attendance on the same. The College session is divided into three terms. The first term commences on October 21, 1873, and ends on December 23, 1873.

For further information, application may be made to Professor Moffett, Registrar.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—SCHOOL OF SURGERY.—Session 1873-74.

The public lectures and the usual winter course will commence on October 30. Anatomy and Physiology, Dr. Mapother. Descriptive Anatomy, Dr. Bevan and Mr. Morgan. Surgery, Dr. Stokes and Dr. J. S. Hughes. Practice of Medicine, Dr. Little. Chemistry, Dr. Barker. Materia Medica, Dr. Macnamara. Midwifery, Dr. Sawyer. Medical

Jurisprudence, Dr. Davy. Practical Chemistry, Dr. Barker. Botany, Dr. Minchin. Hygiene, Dr. Cameron. Dissections, under the direction of the Professors of Anatomy and the Demonstrators, Drs. Croly, Stoney, Stoker, Ormsby, Kilgarriff, and Wheeler, commence on October 1.

The summer session commences in April and terminates in July, including Materia Medica, Medical Jurisprudence, Botany, Practical Chemistry, Midwifery, Ophthalmic and Aural Surgery, and Hygiene.

The fee for each of the above courses is £3 3s., except Comparative Anatomy and Hygiene, which are free.

For further information, application to be made to the Registrar, John Brennen, Esq., at the College.

One year's attendance recognised by Examining Boards.—Fees: For the Physicians' practice, £10 10s.; for the Surgeons' practice—one year, £20; two years, £30; perpetual, £40. Pupils resident and non-resident. Physicians—Dr. Copeman, Dr. Eade, Dr. Bateman. Honorary Consulting Surgeon—Mr. Nichols. Surgeons—Mr. Firth, Mr. Cadge, Mr. Crosse. Resident Medical Officer—Mr. J. R. Bammgartner. Assistant-Surgeons—Mr. Williams, Dr. Beverley.

New Town Dispensary, 17, Tristle-street, Edinburgh.—Hour of visit, 2 to 3 daily. Medical Officers—Drs. Dyce, Cunynghame, Brakenridge, Affleck, Cadell, Dunsmure, Wyllie, Underhill, and Cumming. Vaccination on Tuesdays and Fridays, at twelve. Midwifery cases attended at their own homes by the pupils under the superintendence of Dr. Angus Macdonald. Practical Pharmacy at two and at seven. Fee for six months, £3 3s.; three months, £2 2s. Secretary to Medical Officers—Dr. R. J. Blair Cunynghame.

Glasgow Royal Asylum for Lunatics.—The Asylum contains nearly 600 patients, including all classes and rates. A limited number of pupils are permitted to witness the practice. Clinical instruction is given. Fee, £2 2s.

Royal Dispensary, Edinburgh.—Consulting Physician—Professor Sanders. Consulting Surgeon—Professor Spence. Consulting Physicians-Accoucheur—Dr. Keiller and Dr. J. Matthews Duncan. Medical Officers—Dr. William Stephenson, F.R.C.S.; Dr. Cairns, F.R.C.S.; Dr. Linton, F.R.C.P.; Professor Spence, F.R.C.S.; Dr. George W. Balfour, F.R.C.P.; Professor Sanders, F.R.C.P.; Dr. W. Husband, F.R.C.S.; Dr. James Andrew, F.R.C.P.; Dr. D. Wilson, F.R.C.S.; Dr. R. P. Ritchie, F.R.C.P.; Dr. F. W. Moinet, F.R.C.P. Midwifery Department—Dr. Wilson, Dr. Andrew, Dr. Cairns, and Dr. Stephenson. Vaccination—Dr. Husband. Apothecary—Mr. R. Urquhart. Secretary to Medical Officers—Dr. Andrew.

Edinburgh Eye Infirmary, 6, Cambridge-street, Lothian-road.—Number of beds, 6. Surgeons—Mr. B. Bell and Dr. Joseph Bell. Three months' attendance fee, £1 1s. Instruction in the use of the Ophthalmoscope is given. Hour of visit, one to two daily. Average number of out-patients, 900 to 1000.

Glasgow Eye Infirmary.—Physician—Dr. Harry Rainy. Consulting Surgeon—Dr. George Buchanan. Surgeons—Drs. William Brown and Thomas Reid. Assistant-Surgeons—Drs. M. Charteris, Robert Watson, Thomas Spence Meighan, and Hector C. Cameron. Secretary—George Black, 88, West Regent-street. Hour of visit, 1 p.m. Students' fee for six months' attendance, £2 2s.; or for one year's attendance, £3 3s. To those attending, or who have attended, the lectures on the Eye in Glasgow University, £1 1s. for six months, or £1 11s. 6d. for twelve months.

Royal Hospital for Sick Children, Meadowside House, Edinburgh.—Consulting-Physicians: Professor Sir Robert Christison, Bart., Drs. Charles Wilson, Graham Weir, and Matthews Duncan. Consulting-Surgeon: Professor Spence. Pathologist: Professor Sanders. Ordinary Physicians: Drs. Stephenson, Ritchie, Linton, and Brakenridge. Extra Physicians: Drs. James Dunsmure, jun., and James Andrew. Assistant-Physician: Dr. James Crawford Renton. Surgeon-Dentist: Dr. Smith. Ophthalmic Surgeon: Dr. Argyll Robertson. Resident Physician: Dr. P. Macpherson Grant. Honorary Secretary: Mr. John Henry, 10, St. Andrew-square. Fees: To hospital, three months, £1 1s.; to dispensary department, three months, £1 1s.

Dispensary for Skin Diseases, 63, John-street, Glasgow.—Physician—Dr. McCall Anderson. House-Physician—Dr. Provan. Number of new cases annually about 1400. Practical courses on Diseases of the Skin are held during the summer session. Fee for the course £1 1s. James Grahame, Hon. Secretary. This Dispensary is in connexion with the cutaneous wards in the University Hospital, which is at present in course of erection.

Glasgow Dispensary for Diseases of the Ear, 241, Buchanan-street.—A course of lectures and clinical instruction is given to the students attending the Dispensary during the months of May, June, and July. Average number of cases treated, 800 annually. Surgeon and Lecturer, James Patterson Cassells, M.D., M.R.C.S. Lond., F.F.P.S. Glasg.

The Aberdeen Royal Lunatic Asylum.—Contains about 450 beds. Physician and Clinical Teacher—Dr. Jamieson.

PRIVATE TEACHERS.

Mr. J. Erle Benham, 20, Deverenx-court, Temple, E.C. (formerly of King's College, London), has commenced to take his classes, and to give private instruction for the various Preliminary Examinations in Arts of the College of Surgeons.

Mr. E. Bellamy, F.R.C.S., 59, Margaret-street, Cavendish-square, W., reads privately with gentlemen preparing for the Fellowship and Membership Examinations of the Royal College of Surgeons.

Dr. Coales, LL.D., M.A., prepares candates in class or by private lessons for the following examinations:—London University: Preliminary, Scientific, and Matriculatiou. College of Surgeons: Preliminary, Fellowship, and Membership. Apothecaries' Hall: Preliminary Membership. Resident pupils received. 119, Gower-street, W.C.

Captain Demangel, B.ès.Sc., B.A. Lond., 5, Colville-road, Notting-hill, W., receives four resident and a few non-resident pupils. Preparation for Matriculation at the London University, and Preliminary Examination at Royal College of Surgeons and Apothecaries' Hall.

Mr. Hanbury, M.A., 24, Old-square, Lincoln's-inn, W.C., reads with his class for the Preliminary Examination in Arts, College of Surgeons, and for the Matriculation Examination of London University. Mr. Hanbury is assisted by efficient lecturers in French and Chemistry. Resident pupils are received in house at Clapham.

Mr. H. M. Hewitt, B.A. Camb. and Lond., double First-classman in Honours, 82, Gower-street, W.C., prepares for the London University examination, First and Second B.A., College of Surgeons, etc.

Mr. Thomas Lyle (of the University of London), Forest House, 89, Forest-road, Dalston, N.E., prepares gentlemen for the Examination in Arts at the Apothecaries' Hall and the College of Surgeons; also for matriculation at the London University. Resident pupils received.

Mr. Moxon (of the Dublin University), 31, Courtney-road, Highbury-hill-park, has vacancies for candidates for the Royal College of Surgeons Preliminary Examination, etc.

Mr. Murray, B.A., Arkteon House, Wray-crescent, Tollington-park, N., prepares for the Preliminary Examinations at Royal College of Surgeons and Apothecaries' Hall, and the Matriculation at University of London.

Mr. J. Pincott, F.R.G.S., Tellham House School, Brixton-hill, S.W., prepares for the Preliminary Medical and Law Examinations, and for the Matriculation Examination of the London University.

Rev. F. Pearce Pocock, M.A. Cantab., A.K.C., 26, Hillmarton-road, Camden-road, London, N., and 61, High-street, Hastings, prepares candidates for the Arts Examinations of the London University, College of Surgeons, and Apothecaries' Hall.

The Drs. Power continue daily their classes preparatory for the various competitive and pass examinations, at the Lecture-rooms, 8, Red Lion-square, Holborn, W.C.

Mr. F. A. White, B.A. (Classical and Mathematical Honours, Cambridge,), 52, Kensington-gardens-square, W., prepares for the Matriculation (London), College of Surgeons, etc.

[For fees, etc., see Advertisements.]

SUPPLEMENT TO THE STUDENTS' NUMBER

OF THE

MEDICAL TIMES AND GAZETTE.

Containing Advertisements of London and Provincial Hospitals and Medical Schools.

LONDON, SATURDAY, SEPTEMBER 13, 1873.

MIDDLESEX HOSPITAL.

The WINTER SESSION 1873-74 will open on WEDNESDAY, OCTOBER 1st, with an INTRODUCTORY ADDRESS, at 3 o'clock, by Mr. HENRY MORRIS, M.A. Lond., F.R.C.S.

LECTURES FOR WINTER SESSION.

Medicine: Dr. Greenhow, F.R.S. Surgery: Mr. De Morgan, F.R.S. Practical Surgery: Mr. Hulke, F.R.S., Mr. Lawson, Mr. Henry Morris, M.A. Lond. Diseases of the Eye: Mr. Hulke. Descriptive and Surgical Anatomy: Mr. H. Morris. Physiology: Mr. Lowne, F.L.S. Chemistry: Mr. Heisch. Pathological Anatomy: Dr. Cayley, Dr. John Murray. Practical Anatomy: Dr. R. Liveing and Mr. Hensman. Parasitic Diseases: Dr. Cobbold, F.R.S. College Tutor: Dr. R. Liveing. Clinical Lectures on Medicine and Surgery: The Physicians and Surgeons. Ditto on Diseases of Women and Children: Dr. J. Hall Davis. Ditto on Diseases of the Eye: Mr. Hulke, F.R.S.

LECTURES FOR SUMMER SESSION, COMMENCING MAY 1ST, 1874.

Midwifery and Diseases of Women and Children: Dr. J. Hall Davis. Materia Medica and Therapeutics: Dr. Thorowgood. Medical Jurisprudence: Dr. R. King, B.A. Cantab. Botany: Mr. Hensman. Practical Chemistry: Mr. Heisch. Practical Physiology and Histology: Mr. Lowne, F.L.S. Comparative Anatomy and Zoology: Mr. Hensman. Psychological Medicine: Dr. Henry Rayner. Clinical Lectures on Medicine and Surgery: The Physicians and Surgeons. Ditto on Diseases of the Eye: Mr. Hulke, F.R.S. Practical Demonstrations on Diseases of the Skin: Dr. R. Liveing. Ditto on Diseases of the Throat: Dr. John Murray.

HOSPITAL STAFF.

Consulting Physicians—Dr. F. Hawkins, Dr. A. P. Stewart, Dr. Goodfellow. Physicians—Dr. H. Thompson, Dr. Greenhow, F.R.S., Dr. R. Liveing. Obstetric Physician—Dr. J. Hall Davis. Assistant-Physicians—Dr. Cayley, Dr. John Murray, Dr. R. King. Consulting Surgeon—Mr. Shaw. Surgeons—Mr. De Morgan, F.R.S., Mr. Nunn, Mr. Hulke, F.R.S., Mr. Lawson. Assistant-Surgeons—Mr. Henry Morris, Mr. Andrew Clark. Dental Surgeon—Mr. Tomes, F.R.S. Assistant Dental Surgeon—Mr. Turner.

The Hospital contains 305 beds. There are special departments for Cancer (36 beds), for Diseases of the Eye, Diseases of Women and Children, and Syphilis. Demonstrations are given in the Out-patient Department on Diseases of the Skin, of the Throat, of the Ear, and of the Eye.

SIX RESIDENT CLINICAL APPOINTMENTS are open to the Students of the Hospital annually.

TWO ENTRANCE SCHOLARSHIPS, of the annual value of £25 and £20 respectively, each tenable for two years, are awarded at the commencement of the Winter Session.

TWO BRODERIP SCHOLARSHIPS, of the annual value of £30 and £20 respectively, each tenable for two years, are also awarded every year for proficiency in Clinical Knowledge.

The GOVERNORS' PRIZE of TWENTY GUINEAS is given annually to the Student who shall most have distinguished himself during his three years' curriculum.

TWO CLINICAL PRIZES, of the value of SIX and FOUR GUINEAS respectively, are awarded to the candidates who stand third and fourth in the competition for the Broderip Scholarships.

NUMEROUS VALUABLE CLASS PRIZES are also given.

ALL CLERKSHIPS and DRESSERSHIPS are awarded without fee.

The Clinical Clerk and Dresser of the Physician and Surgeon of the week dine at the Board Room Table, to have the opportunity of seeing accidents and other fresh cases admitted during the evening. A limited number of General Students are also allowed, under certain regulations, to dine at the Board Room Table.

The COLLEGE TUTOR *superintends and assists the Students, especially those who are preparing for examinations, without extra fee, and thus the necessity of obtaining private instruction is obviated.*

MEDICAL REGISTRAR, SURGICAL REGISTRAR, RESIDENT MEDICAL OFFICER, DEMONSTRATOR of ANATOMY.—These valuable appointments are open to qualified men as they become vacant.

GENERAL FEE for the curriculum required by the Royal College of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

Fee for DENTAL STUDENTS, Forty Guineas, which may be paid by instalments.

Some Members of the Staff receive Students as boarders.

For further information apply to the Dean or the Resident Medical Officer, at the Hospital.

MIDDLESEX HOSPITAL ENTRANCE SCHOLARSHIPS.—Two Scholarships of the annual value of £25 and £20 respectively will be offered for competition at the commencement of the Winter Session, 1873-74. Each Scholarship is tenable for two years, provided the Scholar conducts himself satisfactorily. These Scholarships are open to all gentlemen who commence their Medical Studies in October, 1873. Successful Candidates will be required to become general Students of the College. The Examination will take place on September 27th and following days, and the result will be declared on October 4th. For full particulars as to subjects of Examination, &c., apply to the Dean.

MIDDLESEX HOSPITAL COLLEGE DINNER.—The Annual Dinner of the Past and Present Students of the Hospital and their Friends will take place at ST. JAMES'S HALL on OCTOBER 1st, at 6.30 p.m., Dr. GREENHOW, F.R.S., in the Chair. The cost of the Dinner will be 7s. 6d., exclusive of Wine. Gentlemen intending to be present are requested to communicate with the Dean on or before September 30th.

JOHN MURRAY, M.D., Dean.

St. Bartholomew's Hospital and COLLEGE.

—The WINTER SESSION will begin on WEDNESDAY, OCTOBER 1st.

The Clinical Practice of the Hospital comprises a service of 710 beds, inclusive of 34 beds for convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College Regulations.

For all particulars concerning either the Hospital or College application may be made, personally or by letter, to the Resident Warden of the College. A handbook will be forwarded on application.

St. Bartholomew's Hospital and COLLEGE.

SCHOLARSHIPS IN SCIENCE.

Two Scholarships in Science have been founded at St. Bartholomew's Hospital:—

1. An Open Scholarship of the value of £100, tenable for one year, to be competed for in September. The subjects of examination are Physics, Chemistry, Botany, and Zoology. The successful candidate will be required to enter at St. Bartholomew's Hospital in October next.

2. Preliminary Scientific Scholarship of the value of £50, tenable for one year, to be competed for in October next by Students of the Hospital of less than six months' standing. The subjects of examination are identical with those of the Open Scholarship.

For further particulars and syllabus of subjects, application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital.

University of London.

MATRICULATION AND PRELIMINARY SCIENTIFIC EXAMINATIONS.

Two Classes are held at St. Bartholomew's Hospital in each year for the Matriculation Examination at the University of London—from OCTOBER to JANUARY, and from MARCH to JUNE.

(1) Classics, French, English, Modern Geography, & English History.	Malcolm Laing, M.A. Trin. Coll., Cambridge.
(2) Mathematics and Natural Philosophy	The Rev. E. S. Carlos, B.A. Trin. Coll., Cambridge.
(3) Chemistry	T. Eltoft, F.C.S.

Fee for the Course of Three Months ... Ten guineas.
Fee for (1) or (2) ... ... Five guineas.
Fee for (3) ... ... Two guineas.
The Class is not confined to Students of the Hospital.

Mr. Laing is prepared to hold a Class also for the Preliminary Examinations in Arts at the Royal College of Surgeons and Apothecaries' Hall.

PRELIMINARY SCIENTIFIC EXAMINATION.

A Class in the subjects required for the Preliminary Scientific Examination is held from January to July, and includes all the subjects required, as follows:—

Chemistry	H. E. Armstrong, Ph.D.
Botany	The Rev. G. Henslow, M.A. Cantab., Lecturer on Botany to the Hospital.
Zoology and Comparative Anatomy	W. S. Church, M.D. Oxon., Lecturer on Comparative Anatomy to the Hospital; late Lee's Reader in Anatomy at Christ Church, Oxford.
Mechanical and Natural Philosophy	P. J. Hensley, M.D. Cantab., Fellow of Christ's College, Cambridge, Tutor to the Hospital.

Fee to Students of the Hospital ... Six guineas.
To others ... ... Ten guineas.
Fee for any single subject ... ... Three guineas.

For further information application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital.

Royal School of Mines.—Department of SCIENCE and ART.

—During the Twenty-third Session, 1873-74, which will commence on the 1st of OCTOBER, the following COURSES of LECTURES and PRACTICAL DEMONSTRATIONS will be given:—

1. Chemistry, by E. Frankland, Ph.D., F.R.S.
2. Metallurgy, by John Percy, M.D., F.R.S.
3. Natural History, by T. H. Huxley, LL.D., F.R.S.
4. Mineralogy, } by Warington W. Smyth, M.A., F.R.S., Chairman.
5. Mining, }
6. Geology, by A. C. Ramsay, LL.D., F.R.S.
7. Applied Mechanics, by T. M. Goodeve, M.A.
8. Physics, by Frederick Guthrie, Ph.D., F.R.S.
9. Mechanical Drawing, by Rev. J. H. Edgar, M.A.

The Fee for Students desirous of becoming Associates is £30 in one sum, on entrance, or two annual payments of £20, exclusive of the Laboratories.

Pupils are received in the Chemical Laboratory, under the direction of Dr. Frankland, and in the Metallurgical Laboratory, under the direction of Dr. Percy. These Laboratories will be reopened on October 1st.

Tickets to separate Courses of Lectures are issued at £3 and £4 each.

Officers in the Queen's Service, Her Majesty's Consuls, Acting Mining Agents and Managers may obtain Tickets at reduced prices.

Science Teachers are also admitted to the Lectures at reduced fees.

His Royal Highness the Prince of Wales grants Two Scholarships, and several others have also been established by Government.

For a Prospectus and information apply to the Registrar, Royal School of Mines, Jermyn-street, London, S.W.

TRENHAM REEKS, Registrar.

NOTE.—By order of the Lords of the Committee of Council on Education, the instruction in Chemistry, Physics, Applied Mechanics, and Natural History will be given in the New Buildings, in the Exhibition-road, South Kensington.

St. George's Hospital Medical School.

—The WINTER SESSION will commence on WEDNESDAY, 1st OCTOBER, with an Introductory Address by Mr. Brudenell Carter, at 2 p.m., in the Hospital.

Consulting-Physicians—Dr. Wilson, Dr. Pitman.
Physicians—Dr. Fuller, Dr. Barclay, Dr. Ogle, Dr. Wadham.
Assistant-Physicians—Dr. Dickinson, Dr. Whipham.
Physician-Accoucheur—Dr. John Clarke.
Consulting-Surgeons—Mr. Cæsar Hawkins, Mr. Cutler, Mr. Tatum.
Surgeons—Mr. Hewett, Mr. Pollock, Mr. Henry Lee, Mr. Holmes.
Assistant-Surgeons—Mr. Rouse, Mr. Pick.
Ophthalmic Surgeon—Mr. Brudenell Carter.
Orthopædic Surgeon—Mr. Brodhurst.
Aural Surgeon—Mr. Dalby.
Dentist—Mr. Vasey.

A Maternity Department and Departments for Ophthalmic, Dental, and Aural Surgery are arranged in connexion with the Hospital School.

LECTURERS.

Descriptive and Surgical Anatomy—Mr. Rouse.
Physiology and General Anatomy—Dr. Cavafy.
Physiological Histology—Mr. Herbert Watney.
Chemistry—Dr. Noad, F.R.S.
Physiological Chemistry—Mr. Moore.
Medicine—Dr. Barclay.
Psychological Medicine—Dr. Blandford.
Surgery—Mr. Holmes.
Ophthalmic Surgery—Mr. Brudenell Carter.
Orthopædic Surgery—Mr. Brodhurst.
Operative Surgery—Mr. Pick.
Pathology—Dr. Dickinson.
Midwifery—Dr. John Clarke.
Materia Medica—Dr. Dickinson.
Forensic Medicine—Dr. Wadham.
Aural Surgery—Mr. Dalby.
Dental Surgery - Mr. Vasey.
Botany—Dr. Whipham.
Comparative Anatomy—Dr. Cavafy.
Morbid Anatomy—Mr. Haward.

Clinical Lectures by the Physicians and Surgeons every week.

On payment of one hundred guineas at entrance, a Pupil becomes perpetual to the Hospital Practice and all the Lectures.

Compounders pay forty guineas on admission, forty guineas for the second year, and ten guineas for each subsequent year, until their payments shall have reached one hundred and ten guineas, when they become Perpetual Pupils.

Gentlemen may enter separately to Medical or Surgical Practice, or to any single course of Lectures.

Dental Pupils are admitted on payment of £45.

Special Courses of Physiological Chemistry and Microscopical Anatomy are now added to the Lectures on Physiology.

Demonstrations of Skin Diseases and Lectures on Public Health will form part of the course of Lectures on the Practice of Medicine; and Students will be required also to attend the separate course of Lectures on Pathology.

In connexion with the Lectures on Surgery, a course of Practical Surgery will be given, including the use of the Laryngoscope. A separate course of Lectures on Diseases of the Eye, with Demonstrations of the use of the Ophthalmoscope, will be given, as well as Demonstrations on Operations in Surgery. Attendance on each of these courses will be required of Surgical Pupils.

In the Maternity Department, special Clinical Instruction will be given on Diseases peculiar to Women, and Practical Instruction in Vaccination to those who require certificates of proficiency.

Courses of Lectures on Psychology and Comparative Anatomy are given during the Summer Session.

The appointments of House-Physician and House-Surgeon, which are held for twelve months, are filled up half-yearly from among the Senior Students, according to merit. These Officers now receive their board and lodging free, and no payment is made for the Appointment.

Clinical Clerks and Dressers are also appointed without payment, and provision is made that each Student should have the opportunity of holding these offices during his attendance.

The offices of Obstetric Assistant, Curator of the Museum, Medical and Surgical Registrars, and Demonstrator of Anatomy, with salaries of from £50 to £100 attached to each, are held out for competition annually. The William Brown Exhibitions of £100 per annum, tenable for two years, and of £40 per annum, tenable for three years, are bestowed after a competitive examination. The Brackenbury Prizes in Medicine and in Surgery, of £40 each, are awarded annually. Clinical Prizes are offered by Sir Benjamin Brodie, Dr. Acland, and by the Treasurer of the Hospital. Sir Charles Clarke's "Good Conduct" Prize, the Thompson Medal, and the H. C. Johnson Memorial Prize are also to be competed for each year. A general examination of all the Students is held at the end of the Summer Session, and Prizes and Certificates of General Proficiency are given to the most deserving.

Further information may be obtained from Dr. Barclay, the Treasurer, or Dr. Wadham, the Dean of the Medical School, and from any of the Lecturers and Medical Officers of the Hospital.

St. George's Hospital School Dinner.

—The ANNUAL DINNER of the ST. GEORGE'S HOSPITAL MEDICAL SCHOOL will take place at WILLIS'S ROOMS, King-street, St. James's, on WEDNESDAY, OCTOBER 1st, 1873.

Dr. ACLAND, Regius Professor of Medicine, Oxford, has kindly consented to preside.

Gentlemen desirous of being present are requested to send their names to J. WHIPHAM, M.B., Hon. Sec., St. George's Hospital.

Guy's Hospital.—The Medical Session

commences in October. The Introductory Address will be given by James Hinton, Esq., on WEDNESDAY, the 1st of OCTOBER, at 2 o'clock.

MEDICAL OFFICERS.

Consulting Physicians—Sir W. Gull, Bart., M.D., D.C.L., F.R.S.; G. Owen Rees, M.D., F.R.S.
Physicians—S. O. Habershon, M.D.; S. Wilks, M.D., F.R.S.; F. W. Pavy, M.D., F.R.S.; W. Moxon, M.D.
Assistant-Physicians—C. Hilton Fagge, M.D.; P. H. Pye-Smith, M.D.; Frederick Taylor, M.D.
Consulting Surgeons—J. Hilton, Esq., F.R.S.; E. Cock, Esq.
Surgeons—J. Birkett, Esq.; J. Cooper Forster, Esq.; Thomas Bryant, Esq.; Arthur E. Durham, Esq.
Assistant-Surgeons—H. G. Howse, M.S.; N. Davies-Colley, M.C.
Consulting Obstetric Physician—Henry Oldham, M.D.
Obstetric Physician—J. Braxton Hicks, M.D., F.R.S.
Assistant Obstetric Physician—J. J. Phillips, M.D.
Ophthalmic Surgeon—C. Bader, Esq.
Assistant Ophthalmic Surgeon—C. Higgens, Esq.
Surgeon-Dentist—J. S. A. Salter, M.B., F.R.S.
Assistant-Surgeon-Dentist—H. Moon, Esq.
Anral Surgeon—James Hinton, Esq.
Medical Registrar—Frederick Taylor, M.D.
Surgical Registrar—J. F. Goodhart, M.D.
Apothecary—James Stocker, Esq.

The Hospital now contains 715 beds. Of these, 221 are for Medical cases, 250 for Surgical, 26 for Gynæcological, 48 for Syphilitic, and 50 for Ophthalmic cases. There are also 30 children's cots and 84 reserve beds, with 8 in private rooms.

In connexion with the Lying-in Charity, about 2000 cases are annually attended by the Students.

Number of patients relieved during the year, about 81,000.

WINTER SESSION LECTURES.

Medicine—Dr. Wilks and Dr. Habershon.
Clinical Medicine—Dr. Habershon, Dr. Wilks, Dr. Pavy, and Dr. Moxon.
Surgery (including Demonstrations in Practical Surgery)—Mr. Birkett and Mr. Cooper Forster, assisted by Mr. Rendle.
Clinical Surgery—Mr. Birkett, Mr. Forster, Mr. Bryant, and Mr. Durham.
Anatomy (Descriptive and Surgical)—Mr. Durham and Mr. Howse.
Physiology and General Anatomy—Dr. Pavy and Dr. Pye-Smith.
Clinical Lectures on Midwifery and Diseases of Women—Dr. Braxton Hicks.
Chemistry—Dr. Debus and Dr. Stevenson.
Experimental Philosophy—

DEMONSTRATIONS.

Anatomy—Mr. Davies-Colley, Mr. Rendle, and Mr. Clement Lucas, Demonstrators.
Practical Physiology—Dr. P. H. Pye-Smith.
Morbid Anatomy—Dr. C. Hilton Fagge.
Cutaneous Diseases—Dr. C. Hilton Fagge.

Clinical Lectures in Medicine, Surgery, and Midwifery weekly.

Special Classes are held in the Hospital for Students preparing for the Examinations of the University of London and of the College of Surgeons.

The Museum of Anatomy, Pathology, and Comparative Anatomy (Curator, Dr. Fagge) contains 10,000 specimens, 4000 drawings and diagrams, an unique collection of Anatomical Models, and a series of 400 Models of Skin Diseases.

Gentlemen desirous of becoming Students must give satisfactory testimony as to their education and conduct. Fees:—£40 for the first year; £40 for the second; £20 for the third; and £10 for succeeding years of attendance. 100 Guineas in one payment entitles the Student to a perpetual ticket.

The House-Surgeons and House-Physicians, the Obstetric Residents, the Clinical Assistants, Dressers, Dressers in the Eye Wards, and Clinical Clerks are selected from the Students, according to merit.

Six Scholarships, varying in value from £25 to £40 each, are awarded at the close of each Summer Session for general proficiency.

Two Gold Medals are given by the Treasurer—one in Clinical Medicine, and one in Clinical Surgery.

A Voluntary Examination takes place at entrance, in Elementary Classics and Mathematics. The first three candidates receive respectively Prizes of £25, £20, and £15.

Several of the Lecturers have vacancies for Resident Private Pupils.

For further information apply to Mr. Stocker.

Guy's Hospital, July, 1873.

The London School of Dental Surgery

and DENTAL HOSPITAL of LONDON, 32, SOHO-SQUARE.—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1.

LECTURES.

Mechanical Dentistry—Mr. J. S. Turner, M.R.C.S., L.D.S., on Wednesday, at 7 p.m.
Metallurgy in its Application to Dental Purposes—Mr. G. H. Makins, M.R.C.S., F.C.S., on Friday, at 6.30 p.m.

The SUMMER SESSION will commence in MAY, 1874.

Dental Surgery and Pathology—Mr. Samuel Hamilton Cartwright, M.R.C.S., L.D.S., at 8 a.m.
Dental Anatomy and Physiology (Human and Comparative)—Mr. C. S. Tomes, B.A. Oxon., M.R.C.S., L.D.S., at 8 a.m.

General Fee for Special Lectures required by the Curriculum, £15 15s.

DENTAL HOSPITAL OF LONDON.

		Dental Surgeons.	*Assist.-Dental Surgeons.*
Monday,	9 a.m.	Mr. Fox...	Mr. Moon.
Tuesday,	,,	Mr. Underwood	Mr. Medwin.
Wednesday,	,,	Mr. Gregson	Mr. C. S. Tomes.
Thursday,	,,	Mr. Coleman	Mr. Lane.
Friday,	,,	Mr. H. Harding	Mr. Bartlett.
Saturday,	,,	Mr. A. Hill	Mr. Samuel Hamilton Cartwright.

Dental House-Surgeon, Mr. Claude Rogers, who attends daily from 9 a.m. to 2 p.m.

Fee for Two Years' Hospital Practice required by the Curriculum, £15 15s. Further particulars may be obtained on application to the Dental Officer of the day, or the Treasurer, Mr. S. Cartwright.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION will be opened on WEDNESDAY, OCTOBER 1st, with an Introductory Address, at 4 p.m., by Professor Edgar Sheppard, M.D.

LECTURERS.

Anatomy, Descriptive and Surgical—Prof. John Curnow, M.D.
Physiology— } Prof. W. Rutherford, M.D.
Practical Physiology— } Demonstrator: Urban Pritchard, M.D.
Chemistry— } Prof. C. L. Bloxam, F.C.S.
Practical Chemistry— } Demonstrator: W. N. Hartley, F.C.S.
Medicine, Principles and Practice of—Prof. George Johnson, M.D.
Surgery, Principles and Practice of—Prof. John Wood, F.R.S.
Clinical Surgery—Prof. Sir William Fergusson, Bart., F.R.S.
Hygiene—Prof. W. A. Guy, M.B., F.R.S.
Botany—Prof. Robert Bentley, F.L.S.
Materia Medica and Therapeutics—Prof. A. B. Garrod, M.D., F.R.S.
Obstetric Medicine and the Diseases of Women and Children—Prof. W. Playfair, M.D.
Forensic Medicine—Prof. D. Ferrier, M.A., M.D.
Comparative Anatomy—Prof. T. Rymer Jones, F.R.S.
Pathological Anatomy—Prof. L. S. Beale, M.B., F.R.S.
Dental Surgery—Prof. Samuel Cartwright, F.R.C.S.
Ophthalmology—Prof. J. Soelberg Wells, M.D., F.R.C.S.
Practical Surgery—Prof. John Wood, F.R.S.
Psychological Medicine—Prof. Edgar Sheppard, M.D.
Dean of the Faculty—Prof. Bentley, F.L.S.
Medical Tutor—Evan B. Baxter, M.D.

KING'S COLLEGE HOSPITAL.

CLINICAL LECTURES are given five times a week by the Physicians and Surgeons. Clinical Instruction is also given in Diseases of the Throat and in Skin Diseases.

Physicians—Dr. G. Johnson, Dr. L. S. Beale, Dr. A. B. Garrod, Dr. Duffin.
Assistant-Physicians—Dr. Yeo, Dr. Kelly.
Physician for Diseases of Women and Children—Dr. W. Playfair.
Assistant Obstetric Physician—Dr. T. C. Hayes.
Surgeons—Sir W. Fergusson, Bart.; John Wood, F.R.C.S.; H. Smith, F.R.C.S.
Surgeon-Dentist—S. Cartwright, F.R.C.S.
Ophthalmic Surgeon—J. Soelberg Wells, M.D., F.R.C.S.
Assistant-Surgeon—H. Royes Bell, F.R.C.S.
Pathological Registrar—C. Kelly, M.D.
Sambrooke Registrars—R. Birch, M.R.C.S.; W. Rose, M.R.C.S.
Administrator of Chloroform—Charles Moss, M.R.C.S.
Vaccinator—W. Dunn, Esq.

An Ophthalmic Department and a Ward for Children are attached to the Hospital.

The Physician's Assistant, Physician-Accoucheur's Assistant, and House-Surgeon, as also their assistants, clinical clerks, and dressers, are selected by examination from among the Students, without extra fees.

SCHOLARSHIPS, REGISTRARSHIPS, AND PRIZES.

WARNEFORD SCHOLARSHIPS.—Students enter ng the Medical Department of this College in October, 1873, will have the exclusive privilege of contending for two Scholarships of £25 each for three years. These Scholarships are given for proficiency in Divinity, Classics, Mathematics, History, and English. The subjects may be ascertained by applying to the Secretary.

Five Medical Scholarships are awarded at the close of each Winter Session for proficiency in professional subjects—viz., one of £40 for two years, one of £30 for one year, and three of £20 for one year.

A Warneford Scholarship of £25 for two years is also annually awarded for proficiency in Divinity and Hospital Practice.

SAMBROOKE REGISTRARSHIPS.—Two of £50, tenable for two years, are annually awarded to matriculated Students of this department.

DANIELL SCHOLARSHIP.—One of £20, for two years, given for proficiency in Chemistry, is open to Students of the Medical Department.

Endowed Prizes, of the value of £25, £15, £10, and £4 4s. each, and College Prizes of the value of £60 are annually awarded.

For further information apply personally, or by letter marked outside "Prospectus," to J. W. Cunningham, Esq., Secretary.

Westminster Hospital Medical School.

—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st, when an Introductory Address will be delivered by Mr. Cowell. After the Address the Prizes will be distributed, and a Conversazione will be held in the Board-room.

There are numerous Prizes and Scholarships, and all the Resident Appointments, Registrarships, &c., are open to the students without additional fee.

HOSPITAL STAFF.

Physicians—Dr. Basham, Dr. Fincham, Dr. Anstie.
Assistant-Physicians—Dr. Gibb, Dr. Sturges, Dr. Allchin.
Surgeons—Mr. Holthouse, Mr. Pearse, Mr. Cowell.
Assistant-Surgeons—Mr. Davy, Mr. Cooke, Mr. Bond.
Obstetric Physician—Dr. Frederic Bird.
Assistant Obstetric Physician—Dr. Potter.
Surgeon in charge of the Eye Department—Mr. Cowell.
Surgeon in charge of the Skin Department—Mr. Bond.
Dental Surgeon—Mr. Walker.

LECTURERS.

Clinical Medicine and Surgery—Dr. Basham, Mr. Holthouse. Medicine—Dr. Anstie. Surgery and Practical Surgery—Mr. Pearse, Mr. Cowell. Anatomy—Mr. Davy. Dissections—Mr. Cooke, Mr. Ramsay. Physiology—Dr. Maclure. Practical Physiology—Dr. Allchin. Chemistry and Practical Chemistry—Dr. Dupré. Dental Surgery—Mr. Walker. Materia Medica—Dr. Sturges. Botany—Mr. E. M. Holmes. Midwifery—Dr. Bird. Pathology—Dr. Allchin. Forensic Medicine and Hygiene—Dr. Potter, Dr. Dupré. Psychological Medicine—Dr. Sutherland. Ophthalmic Surgery—Mr. Cowell. Skin Diseases—Mr. Bond. Comparative Anatomy—Mr. Carter Blake. Natural Philosophy—Mr. Brooke, F.R.S.

Numerous changes have been made so as to afford increased facilities for clinical and scientific study. Full particulars may be obtained from the published Prospectus, which will be forwarded on application.

The Examination for the Entrance Scholarships will be held on the 25th and 26th of September.

GEORGE COWELL, Dean of the School.

Westminster Hospital, Aug., 1873.

The London Hospital and Medical COLLEGE.

The next WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st, 1873, when the Introductory Lecture will be given, at 3 p.m., by M. Prosser James, M.D., Lecturer on Materia Medica at the College.

General Fee to Lectures and Hospital Practice, £90, payable in two instalments of £45 each. Library Fee, £1 1s. Special entries can be made to Lectures or Practice.

The Hospital contains 600 beds. There are Medical and Surgical Wards for Children, Wards for Syphilis, Special Departments for Diseases of Women, Diseases of the Eye, Diseases of the Ear, Diseases of the Skin, and special arrangements for Diseases of the Throat. A Maternity Department exists for the delivery of lying-in women at their own homes. 775 cases were attended last year by the Students of the Hospital.

For instruction in Mental Diseases, Students can attend, without further fee, the practice of Dr. John Millar, Medical Superintendent of Bethnal House Asylum, a few minutes' walk from the Hospital.

Clinical Lectures, both Medical and Surgical, will be given every week, and practical instruction imparted in all the Departments.

The In-patients during 1872 were 5392, and the Out-patients 64,275—total, 69,667.

At the Medical College, which has been enlarged, Lectures will be given on all the subjects required by the Examining Boards.

Members of the Staff and Lecturers at the College:—

Mr. J. Luke, F.R.S.	Dr. Fenwick.	Mr. Reeves.
Mr. John Adams.	Dr. Woodman.	Dr. Head.
Mr. Curling, F.R.S.	Mr. Jonathan Hutchinson.	Dr. Palfrey.
Dr. Herbert Davies.	Mr. Maunder.	Mr. Barrett.
Dr. Andrew Clark.	Mr. Couper.	Dr. Letheby.
Dr. Ramskill.	Mr. Walter Rivington.	Dr. Meymott Tidy.
Dr. Langdon Down.	Mr. Jas. Adams.	Dr. Prosser James.
Dr. Hughlings-Jackson.	Mr. Waren Tay.	Mr. J. E. D. Rodgers.
Dr. Morell-Mackenzie.	Mr. McCarthy.	Mr. Gilbert Baker.
Dr. Sutton.		Mr. A. Sanders.

The following Prizes and Appointments are offered, without any further payment, to Students paying the general fee of £90:—

Seven Scholarships to be offered for competition in the Winter Session:

1. A Scholarship of £30 to the Student of less than three months' standing who passes in October the best examination in the subjects required at the Preliminary Examinations.
2. A Scholarship of £20 to the Student of less than three months' standing placed second in the above examinations.
3. A Scholarship of £20 in Human Anatomy for first-year Students; to be awarded in April, 1874.
4. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first-year and second-year Students; to be awarded in April, 1874.
5. A Hospital Scholarship, value £20, for Clinical Medicine; to be awarded in April, 1874.
6. A Hospital Scholarship, value £20, for Clinical Surgery; to be awarded in April, 1874.
7. A Hospital Scholarship, value £20, for Clinical Obstetrics; to be awarded in April, 1874.

The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial), 1874.

Money Prizes to the value of £60 given annually by the House Committee for zeal in Dressing Out-patients and knowledge of Minor Surgery.

Certificates of Honour in all the Classes according to the results of the General Examinations at the end of the Session, and Special Certificates to those who have fulfilled with credit the duties of the Hospital Appointments.

Four House-Surgeoncies, tenable for three or six months, and Dresserships to In-patients, open to all.

Dresserships to Out-patients, with the privilege of competing for the Prizes above mentioned.

The office of the Resident Medical Officer, tenable for two years, with a salary of £75 the first year, and £100 the second year.

The office of Junior Resident Medical Officer, tenable for six months.

Four Medical Assistantships, held for three months, with residence and board in the Hospital for three weeks.

The office of Resident Accoucheur, tenable for six months.

N.B.—The holders of all the resident offices are provided with rooms and board free of expense.

Four offices of Clinical Assistants in the Out-patients' Department, each at a salary of £40.

The office of Medical Registrar, salary 25 guineas.

The office of Surgical Registrar, salary 35 guineas.

Prosectors of Anatomy, Ward Clerks, and Post-mortem Clerks.

A prospectus, giving details, will be forwarded on application to the Bedell of the London Hospital Medical College, Turner-street, E.

Further information may also be obtained from Mr. James E. Adams, Treasurer, 10, Finsbury-circus, E.C., or Mr. Waren Tay, Vice-Dean, at the Medical College.

University College, London.—The

SESSION of the FACULTY of MEDICINE will commence on WEDNESDAY, OCTOBER 1st, 1873. Introductory Lecture at 3 p.m., by Dr. F. T. Roberts, B.Sc.

LECTURES IN WINTER SESSION.

Medicine—Professor J. Russell Reynolds, M.D., F.R.S.
Practical Physiology and Histology—Professor Burdon-Sanderson, M.D., F.R.S.
Anatomy and Physiology—Professor Sharpey, M.D., F.R.S.
Chemistry—Professor Williamson, F.R.S.
Anatomy—Professor G. V. Ellis.
Comparative Anatomy—Professor Grant, M.D., F.R.S.
Surgery—Professor Marshall, F.R.S.
Practical Surgery—Mr. Berkeley Hill, M.B., F.R.C.S.; Mr. Christopher Heath, F.R.C.S.; Mr. Marcus Beck, M.S., M.B., F.R.C.S.
Dental Surgery—Mr. Ibbetson, F.R.C.S.

LECTURES IN SUMMER SESSION.

Botany—Professor Oliver, F.R.S., F.L.S.
Midwifery—Professor Graily Hewitt, M.D.
Medical Jurisprudence—Professor Maudsley, M.D.
Practical Chemistry—Professor Williamson, F.R.S.
Mental Diseases—Lecturer, W. H. O. Sankey, M.D.
Hygiene and Public Health—Professor Corfield, M.A., M.D.
Materia Medica and Therapeutics—Professor Ringer, M.D.
Palæozoology—Professor Grant, M.D., F.R.S.
Operative Surgery—Mr. Christopher Heath, F.R.C.S.
Pathological Anatomy—Professor H. Charlton Bastian, M.D., F.R.S.
Ophthalmic Medicine and Surgery—Professor T. W. Jones, F.R.S.
Analytical Chemistry—Professor Williamson, throughout the Session.

UNIVERSITY COLLEGE HOSPITAL.

Physicians—Sir W. Jenner, Bart., K.C.B., M.D., F.R.S.; Dr. Reynolds, F.R.S.; Dr. Wilson Fox, F.R.S.; Dr. Ringer; Dr. H. Charlton Bastian, F.R.S.
Obstetric Physician—Dr. Graily Hewitt.
Physician to the Skin Infirmary—Dr. Tilbury Fox.
Assistant-Physicians—Dr. F. T. Roberts, B.Sc., Dr. W. R. Gowers.
Assistant Obstetric Physician—Dr. John Williams.
Surgeons—Mr. Erichsen, Mr. Marshall, F.R.S., Sir Henry Thompson, Mr. Berkeley Hill, Mr. Christopher Heath.
Assistant-Surgeon—Mr. Marcus Beck, M.S., M.B.
Ophthalmic Surgeons—Mr. Wharton Jones, F.R.S., Mr. J. F. Streatfeild.
Dental Surgeon—Mr. Ibbetson, F.R.C.S.
Surgical Registrar—Mr. R. J. Godlee, M.B., B.S.
Assistant Medical Officer in the Skin Department—Mr. J. Tweedy, M.R.C.S.
Resident Medical Officer—Mr. Walter Rigden, M.R.C.S.

CLINICAL INSTRUCTION.

Medical Clinical Lectures by Prof. Sir Wm. Jenner, Prof. Reynolds, and Prof. Graily Hewitt; also by Dr. Wilson Fox, Holme Professor of Clinical Medicine, whose special duty it is to train the pupils in the practical study of disease. Dr. Roberts, the Assistant Teacher of Clinical Medicine, also gives special instruction in the methods of physical diagnosis and of clinical observation.

Surgical Clinical Lectures by Mr. Erichsen, Holme Professor of Clinical Surgery, Professor Marshall, and Sir Henry Thompson.

During the Summer Session Mr. Hill and Mr. Heath will instruct the first year's students twice a week in the observation and examination of patients.

Lectures on Ophthalmic Cases by Mr. Wharton Jones and Mr. Streatfeild.

Clinical Lectures on Diseases of the Skin by Dr. Tilbury Fox.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Three Entrance Exhibitions, of the respective values of £30, £20, and £10 per annum, tenable for two years.

An Atkinson Morley Scholarship for the promotion of the study of Surgery, £45 a year, tenable for three years.

Sharpey Physiological Scholarship, about £95 a year, tenable for three years.

Filliter Exhibition for proficiency in Pathological Anatomy, £30.

Liston Gold Medal for Clinical Surgery.

Dr. Fellowes's Medals for Clinical Medicine, two Gold and two Silver.

Alexander Bruce Gold Medal for Pathology and Surgery.

Cluff Memorial Prize, awarded every other year for proficiency in Anatomy, Physiology, and Chemistry.

The next Examination for the Entrance Exhibitions will be held on the 25th and 26th of September.

Prospectuses and the regulations concerning the Exhibitions and Scholarships may be obtained on application, either personally or by letter, at the Office of the College.

JOHN MARSHALL, F.R.S., Dean of the Faculty.
JOHN ROBSON, B.A., Secretary to the Council.

City of London Hospital for Diseases OF THE CHEST, VICTORIA-PARK.

CONSULTING PHYSICIANS.

Thomas B. Peacock, Esq., M.D. | J. Risdon Bennett, Esq., M.D.
Edmund Lloyd Birkett, Esq., M.D.

CONSULTING SURGEON.

John Hilton, Esq., F.R.S., Surgeon-Extraordinary to Her Majesty the Queen.

PHYSICIANS.

Stephen H. Ward, Esq., M.D. | John C. Thorowgood, Esq., M.D.
James Andrew, Esq., M.D. | Henry G. Sutton, Esq., M.B.

ASSISTANT-PHYSICIANS.

Augustus B. Shepherd, Esq., M.B. | W. H. Corfield, Esq., M.B.
Eustace Smith, Esq., M.D. | J. B. Berkart, Esq., M.D.

RESIDENT MEDICAL OFFICER.

George C. Franklin, Esq.

The Hospital affords accommodation for 164 In-patients. During the last year 763 cases were under treatment in the wards, and 13,535 were relieved as Out-patients.

In-patients admitted since the wards were opened in 1855, 9230; Out-patients admitted since the establishment of the Institution in 1848, 220,300.

Information respecting medical instruction at the Hospital may be obtained on application to the Physicians.

Offices, 24, Finsbury-circus, E.C.

Charing-cross Hospital Medical School.

—The WINTER SESSION will commence on WEDNESDAY, the 1st of OCTOBER, when the Introductory Address will be delivered by Edward Bellamy, F.R.C.S., at eight o'clock in the evening.

Two Entrance Scholarships of £30 and £20 respectively, the Llewellyn Scholarship of £25, the Golding Scholarship of £15, the Governor's Clinical Gold Medal, besides the usual Class Medals, are open to competition among the Students.

Three Resident Officers are selected from among the Students every six months.

MEDICAL OFFICERS.

Consulting-Surgeon—Henry Hancock, F.R.C.S.
Physicians—F. W. Headland, M.D., A. Julius Pollock, M.D., Alexander Silver, M.D.
Assistant-Physicians—T. Henry Green, M.D., R. Douglas Powell, M.D., G. V. Poore, M.D., J. Mitchell Bruce, M.D.
Surgeons—Edwin Canton, F.R.C.S., F. Hird, F.R.C.S., Richard Barwell, F.R.C.S.
Assistant-Surgeons—E. Bellamy, F.R.C.S., W. Fairlie Clarke, F.R.C.S., J. Astley Bloxam, F.R.C.S.
Physician-Accoucheur—J. Watt Black, M.D.
Physician for Diseases of the Skin—E. Sparks, M.B.
Dentist—John Fairbank, M.R.C.S.
Registrars—J. Mitchell Bruce, M.D., M. McHardy, M.R.C.S.
Chloroformist—Archer Farr, L.R.C.P. Edin., L.S.A.

LECTURERS.—WINTER SESSION.

Anatomy and Physiology—Alexander Silver, M.A., M.D.
Practical Histology—J. Mitchell Bruce, M.D.
Anatomy, Descriptive and Surgical—Richard Barwell, F.R.C.S.
Anatomical Demonstrations—J. Cantlie, M.A.
Chemistry—C. W. Heaton, F.C.S.
Medicine—F. W. Headland, B.A., M.D.
Surgery—Edwin Canton, F.R.C.S.
Clinical Medicine—A. Julius Pollock, M.D.
Clinical Surgery—Henry Hancock, F.R.C.S.

SUMMER SESSION.

Materia Medica—R. Douglas Powell, M.D.
Midwifery—J. Watt Black, M.A., M.D.
Botany—Edward Dowson, M.D.
Forensic Medicine—G. Vivian Poore, M.D.
Practical Chemistry—C. W. Heaton, F.C.S.
Pathology—T. Henry Green, M.D.
Psychological Medicine—W. J. Hunt, M.D.
Skin Diseases—E. Sparks, M.A., M.B.
Comparative Anatomy—A. H. Garrod, B.A.
Operative Surgery—E. Bellamy, F.R.C.S.
Bandaging, &c.—W. Fairlie Clarke, M.A., F.R.C.S.
Surgical Pathology—J. Astley Bloxam, F.R.C.S.

Fees for the full course of Lectures required by the University of London, the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries, £76 5s. (including the Matriculation Fee of £2 2s., involving no examination), which may be paid in five instalments. Composition fee for Dental Surgery, £42 2s.

Further information may be obtained by application to the Dean, at the Hospital.

A. J. POLLOCK, M.D., Dean.

Hospital for Consumption and Diseases

of the CHEST.—PUPILS are admitted to the practice of the Wards, and the Out-patient Department of the Hospital, on payment of a Fee of Three Guineas for three months, or Five Guineas for six months. Certificates of attendance on the Medical Practice of the Hospital are recognised by the University of London, the Apothecaries' Society, and by the Army, Navy, and Indian Board.

PHILIP ROSE, Hon. Sec.
Brompton, September 8, 1873. HENRY DOBBIN, Sec.

Royal Veterinary College, Great

COLLEGE-STREET, CAMDEN TOWN, LONDON.—OPENING of the WINTER SESSION.—The LECTURES will be commenced on WEDNESDAY, OCTOBER 1. The Introductory Address will be delivered by Professor Cobbold, M.D., at 1 p.m. The Educational Staff consists of—

Professor J. B. Simonds, Principal of the College and Lecturer on Pathology.
Professor W. Pritchard, Lecturer on Anatomy, General and Comparative, of Domesticated Animals.
Professor R. V. Tuson, F.C.S., Lecturer on Chemistry, Materia Medica, and Toxicology.
Professor G. T. Brown, Lecturer on Physiology, Therapeutics, and Pharmacy.
Professor T. S. Cobbold, M.D., F.R.S., Lecturer on Botany, Parasites, and Parasitic Diseases.
Assistant-Professor J. W. Axe, Demonstrator of Anatomy.

The Hospital Practice is conducted by Professors Simonds and Pritchard.

In addition to the Hospital Practice the Students have the daily advantage of attending the Examination of Horses for Soundness.

Hospital Surgeons are appointed annually to act under the Professors.

Monitors, Clinical Clerks, Dressers, and Prosectors are periodically selected from the Class.

Gentlemen intending to commence their studies this session will be required to present themselves for Matriculation on Thursday, the 25th of September.

The Matriculation Examination is conducted by the College of Preceptors. Fee 1 Guinea. College Entrance Fee 25 Guineas, the payment of which confers the right of attendance on all the Lectures and Collegiate Instructions, with the exception of Practical Chemistry.

Students are required to attend one Summer and two Winter Sessions at least before being eligible for Examination for the Diploma of the Royal College of Veterinary Surgeons.

A Life Subscriber of 20 Guineas, or one of 2 Guineas annually, to the Institution, is entitled to have admitted into the Infirmary, for medical and surgical treatment, an unlimited number of horses or other animals, his own property, at a charge only for their keep. Also to have the opinion of the Professors as to the treatment of any animal he may desire to retain in his own possession, without the payment of fees.

August 16th, 1873. JAS. B. SIMONDS, Principal.

St. Thomas's Hospital,

ALBERT-EMBANKMENT, WESTMINSTER-BRIDGE, S.E.—The MEDICAL SESSION for 1873 and 1874 will commence on WEDNESDAY, the 1st OCTOBER, 1873, on which occasion an Inaugural Address will be delivered by Dr. J. Harley, at Two o'clock.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

PRIZES AND APPOINTMENTS FOR THE SESSION.

The Wm. Tite Scholarship, founded by the late Sir Wm. Tite, C.B., M.P., F.R.S., the proceeds of £1000 Consols, tenable for three years, was awarded last Session.

First Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, and £5.

Second Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, £5; the Dresserships and the Clinical and Obstetric Clerkships.

Third Year's Students—Winter Prizes, £20, £15, and £10; Mr. George Vaughan's Cheselden Medal; the Treasurer's Gold Medal; the Grainger Testimonial Prize; the two House-Physicianships; the two House-Surgeoncies; the Resident Accoucheurships. Two Medical Registrarships, at a salary of £40 each, are awarded to third and fourth years' Students, according to merit.

The Solly Medal, with a Prize of 10 Guineas, will be awarded at the end of the Session to a Student of the third, fourth, fifth, or sixth years, for the best Report of Surgical Cases.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.
Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.
Physicians—Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison.
Obstetric Physician—Dr. Barnes.
Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.
Ophthalmic Surgeon—Mr. Liebreich.
Assistant-Physicians—Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne.
Assistant Obstetric Physician—Dr. Gervis.
Assistant-Surgeons—Mr. F. Mason, Mr. Hy. Arnott, Mr. W. W. Wagstaffe.
Dental Surgeon—Mr. J. W. Elliott.
Resident Assistant-Physician—Dr. Evans.
Resident Assistant-Surgeon—Mr.
Apothecary—Mr. R. W. Jones.

Medicine—Dr. Peacock and Dr. Murchison. Surgery—Mr. Sydney Jones and Mr. MacCormac. General Pathology—Dr. Bristowe. Physiology and Practical Physiology—Dr. Ord and Dr. John Harley. Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe. Anatomy in the Dissecting-room—Anatomical Lecturers, Mr. Rainey and Dr. R. W. Reid. Practical and Manipulative Surgery—Mr. Croft. Chemistry and Practical Chemistry—Dr. A. J. Bernays. Midwifery—Dr. Barnes. Physics and Natural Philosophy—Dr. Stone. Materia Medica—Dr. Clapton. Forensic Medicine and Hygiene—Dr. Stone and Dr. Gervis. Comparative Anatomy—Mr. C. Stewart. Ophthalmic Surgery—Mr. Liebreich. Botany—Mr. A. W. Bennett. Dental Surgery—Mr. J. W. Elliott. Demonstrations Morbid Anatomy—Dr. Payne. Mental Diseases—Dr. Wm. Rhys Williams.

T. B. PEACOCK, M.D., Dean.
R. G. WHITFIELD, Medical Secretary.

For entrance or prospectuses, and for information relating to Prizes and all other matters, apply to Mr. Whitfield, Medical Secretary, St. Thomas's Hospital, S.E.

The Hospital for Sick Children,

49, Great Ormond-street, Queen-square, Bloomsbury.

The Practice of this Hospital, in both In- and Out-patient Departments, is open to Practitioners of Medicine and Students daily, on presenting their cards. Clinical Instruction in the Diseases of Children is constantly given by the Physicians and Surgeon.

Dr. West attends on Tuesday and Friday at 9 o'clock.
Dr. Dickinson attends on Monday and Thursday at 10 o'clock.
Mr. Thomas Smith attends on Wednesday and Saturday at 9 o'clock.

In the Out-patient Department, the Assistant-Physicians and Surgeon attend as follows:—

Dr. Gee—Tuesday and Friday at 9 o'clock.
Dr. Cheadle—Monday and Thursday at 9 o'clock.
Dr. Phillips—Tuesday and Friday at 9 o'clock.
Dr. Lee—Monday and Thursday at 9 o'clock.
Mr. Howard Marsh—Wednesday at 9 o'clock.

September, 1873. SAMUEL WHITFORD, Secretary.

Royal London Ophthalmic Hospital,

MOORFIELDS.

LECTURES DURING THE WINTER SESSION, 1873-74.

Mr. CRITCHETT will deliver a Course of Eight Lectures on "OPERATIONS on the EYE," to commence on Tuesday, October 21, at 12.30 p.m., and to be continued weekly at the same hour for two months.

Mr. SOELBERG WELLS will deliver a Course of Twenty CLINICAL LECTURES and OPHTHALMOSCOPIC DEMONSTRATIONS, to commence on Thursday, October 30th, at 4 p.m., and to be continued weekly at the same hour for five months.

Certificates will be given.

Both Courses will be open to Pupils of the Hospital. Terms for Pupils—Six months, three guineas; Perpetual, five guineas. Attendance every morning at 9 a.m. Operations daily at 11 a.m.

St. Peter's Hospital for Stone in the

BLADDER and DISEASES of the GENITO-URINARY ORGANS.

Surgeons—W. J. Coulson, Esq., F.R.C.S.; W. F. Teevan, Esq., B.A., F.R.C.S.

Patients are seen daily at 2 p.m., except Saturday, and on the evenings of Wednesday and Saturday at 6 p.m. Operations on Monday at 3 p.m. Lithotomy and Lithotrity on September 15.

Clinical Demonstrations and Practical Instruction will be given every week. The Practice of the Hospital is open free to all Students and Members of the Profession.

HOSPITAL FOR DISEASES OF THE THROAT,
GOLDEN-SQUARE, W.

HONORARY MEDICAL STAFF.

Consulting Physicians—Archibald Billing, M.D., F.R.S.; Sir William Jenner, Bart., M.D., F.R.S.
Consulting Surgeon—Sir William Fergusson, Bart., F.R.S.
Physicians—Morell-Mackenzie, M.D.; Hunter Semple, M.D.; M. Prosser James, M.D.
Surgeon—George Evans, Esq.
Assistant-Surgeon—Pugin Thornton, Esq.
Dentist—Oakley Coles, Esq.

The Medical Officers give daily Laryngoscopic Demonstrations on the cases under treatment.

The Hospital is open to occasional Professional visitors; but those who wish to acquire practice in the use of the laryngoscope by constant attendance are required to enter as Students.

Fee for Three Months' Instruction	£3 3 0
Perpetual Fee	5 5 0

Out-patients attend daily, at 2·30 p.m., and the Wards are visited when the out-patients have been seen.

Between 3000 and 4000 out-patients, and from 150 to 200 in-patients, are treated annually.

H. K. EVANS, Secretary.

St. Mary's Hospital Medical School.—

The INTRODUCTORY LECTURE by Dr. Shepherd, WEDNESDAY, OCTOBER 1st, 1873, at 8 p.m. To be followed by a *Conversazione* in the Board-room of the Hospital.

MEDICAL OFFICERS AND LECTURERS.

Consulting Officers—Dr. Chambers, Sir James Alderson, M.D., F.R.S., Dr. Sibson, F.R.S., Mr. Conlson, Mr. Lane, Mr White Cooper.
Physicians—Dr. H. Jones, F.R.S., Dr. Sieveking, Dr. Broadbent.
Assistant-Physicians—Dr. Cheadle, Dr. Lawson, Dr. Shepherd.
Surgeons—Mr. Spencer Smith, Mr. Haynes Walton, Mr. J. R. Lane.
Assistant-Surgeons—Mr. Gascoyen, Mr. Norton, Mr. Edmund Owen.
Physician-Accoucheur—Dr. Alfred Meadows.
Assistant Physician-Accoucheur—Dr. Wiltshire.
Surgeon in Charge of the Ophthalmic Department—Mr. Haynes Walton.
Aural Surgeon—Mr. Allen.
Surgeon-Dentist—Mr. Howard Hayward.
Medical Tutor—Dr. J. Reginald Stocker.
Other Lecturers—Dr. Wright, Dr. Randall, Mr. Mivart, F.R.S., Dr. Trimen.

The course of teaching at this School insures careful and complete preparation for all the Examining Boards, the Public Services, and the higher University Examinations. Special instruction is given to Students preparing for the Examinations of the University of London.

The Medical Tutor daily assists the Students in their clinical work and in preparing for the final Examinations, so that the training of every individual Student is supervised. Ophthalmic, Aural, and Dental Surgery, Comparative Anatomy, Histology, and Pathology are carefully and systematically taught both by Lectures and Practical Demonstrations. There are also departments for the Diseases of Women and Children, of the Eye and Ear, of the Skin and of the Throat.

SCHOLARSHIPS.

Three Scholarships of £40 for Three Years.
An Exhibition of £20 for One Year.

One of the Scholarships and the Exhibition awarded every year by open competition in Natural Science previous to entrance at the School.

A Scholarship of £20 in Anatomy, carrying with it the appointment of Assistant-Demonstrator.

A Scholarship of £20 in Pathology, carrying with it the appointment of Assistant-Curator.

These are awarded annually.

PRIZES.

Prizes are given in each class at the close of every session.

APPOINTMENTS.

Three House-Surgeoncies, each tenable for one year.
A Resident Obstetric Assistantship, tenable for six months.

These Resident Medical Appointments are open to the Pupils without expense of any kind, and are equivalent to four Scholarships of the annual value of £50.

In addition to the preceding, there are the following paid appointments, the holders of which are eligible for re-election.

The Resident Registrarship, of the value of £100 a year, with board and lodging.

The Demonstratorship of Anatomy, of the value of £50 a year.

The Medical Tutorship, of the annual value of £100.

For the Prospectus and Address to the Students by Sir Dominic Corrigan, Bart., M.D., M.P., apply to Mr. Knott, the Registrar, at the Hospital, or to

W. B. CHEADLE, M.D., Dean of the School.

West London Hospital,
HAMMERSMITH-ROAD, W.

Number of beds, 68. In-patients, 407; out-patients, 20,240.

Consulting Physician—Dr. Henry Maudsley.
Consulting Physician-Accoucheur—Dr. W. O. Priestly.
Consulting Surgeons—Samuel Armstrong Lane, Esq.; William Bird, Esq.
Physicians—Dr. Goddard Rogers; Dr. Thorowgood.
Physician for Diseases of Women—Dr. Wiltshire.
Surgeons—William F. Teevan, Esq.; Alfred Cooper, Esq.
Surgeon for Diseases of the Eye—B. J. Vernon, Esq.
Junior Physicians—Dr. Fish; Dr. Ferrier.
Junior Surgeons—J. A. Bloxam, Esq.; H. T. Butlin, Esq.
Surgeon-Dentist—H. E. Sewill, Esq.
Analytical Chemist—William Crookes, Esq., F.R.S.
Resident Medical Officers—Two House-Surgeons and an Apothecary.

The Practice of this Hospital is open to all Students and Members of the Medical Profession. Gentlemen desirous of acting as Clinical Clerks or Dressers can obtain any information on application to the Secretary, Mr. T. Alexander, at the Hospital.

Bethlem Hospital.—With a view of

extending the experience requisite for the efficient Medical Treatment and Management of the Insane, this Hospital is open for the admission of Two RESIDENT MEDICAL STUDENTS, who have recently obtained their diplomas to practise Medicine and Surgery.

They will be permitted to reside in the Hospital for a term generally not exceeding Six Months, and will be provided with such apartments, rations, and attendance as the Committee shall consider reasonable.

They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory.

Applications for the Appointments, with testimonials, to be forwarded to Bridewell Hospital, Blackfriars, E.C., addressed to A. M. Jeaffreson, Esq., on or before Saturday, October 11th, 1873.

The Election will take place on the 13th of October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

Candidates must attend at Bridewell Hospital on Monday, October 13th, at 12 o'clock.

September 13th, 1873. A. M. JEAFFRESON, Clerk, &c.

Royal Free Hospital,
GRAY'S-INN-ROAD.

Physicians—Dr. O'Connor, Dr. Cockle, Dr. Rickards.
Surgeons—Mr. De Méric, Mr. Gant, Mr. Hill.

There being a wide field for Medical and Surgical Practice at this Hospital, Students have excellent opportunities for gaining a bedside knowledge of Medicine and Surgery, and for the study of Pathology and Morbid Anatomy, and can prepare for examinations by attending a course of three or six months' Clinical Instruction. Vacancies for Clinical Clerks.

For particulars apply to any member of the Medical Staff, at the Hospital, daily at 2 p.m.

The Birmingham Clinical Board.—
THE GENERAL and QUEEN'S HOSPITALS, BIRMINGHAM.

THE GENERAL HOSPITAL.

Consulting Physician—George Fabian Evans, M.D.
Consulting Surgeon—D. W. Crompton, F.R.C.S.
Physicians—Dr. Fletcher, Dr. Russell, Dr. Wade, Dr. Foster.
Surgeons—Mr. Baker, Mr. Pemberton, Mr. Bartleet, Mr. Goodall, Mr. Jolly.

THE QUEEN'S HOSPITAL.

Consulting Surgeon—William Sands Cox, F.R.S.
Consulting Surgeon-Accoucheur—Samuel Berry, F.R.C.S.
Physicians—Dr. Fleming, Dr. Johnston, Dr. Heslop, Dr. Sawyer.
Surgeons—Mr. West, Mr. Gamgee, Mr. Furneaux Jordan, Mr. Wilders.
Obstetric Surgeon—Mr. John Clay.
Dental Surgeon—Mr. Charles Sims.

The Practices of these Hospitals are amalgamated for the purpose of Clinical Instruction, under the direction of the Birmingham Clinical Board, by whose order all Schedules will be signed and all examinations conducted.

The Hospitals have a total of upwards of 400 beds.

4500 in-patients and 45,000 out-patients are treated annually.

APPOINTMENTS.

At the General Hospital	Resident Medical Assistant Resident Surgical Assistant Two Resident Dressers.	Tenable for six months.
At the Queen's Hospital	Resident Medical Assistant Resident Surgical Assistant Resident Obstetric Assistant	Tenable for six months.

Clinical Prizes to the value of £40 will be given annually.

SCALE OF FEES.

Fees for attendance for Four Years	£31 10 0
One Year's attendance	15 15 0
Six Months' ditto	10 10 0
Special Department for Midwifery and Diseases of Women (optional)	2 2 0
Dental Fee (optional)	1 1 0

The fees are to be paid to Dr. Foster, 16, Temple-row, or Mr. John St. S. Wilders, Temple House, Islington-row, from whom any further information may be obtained.

The Owens College, Manchester.—

The SESSION 1873-74 will be opened in the New Buildings in Oxford-road.

PRINCIPAL—J. G. GREENWOOD, B.A.

PROFESSORS and LECTURERS.

Greek	Professor J. G. Greenwood, B.A., Fellow of Univ. Coll., Lond.
Latin	Professor A. S. Wilkins, M.A., Fellow of Univ. Coll., Lond.
Comparative Philology	
	Assistant Lecturer in Greek and Latin, Mr. Edwin B. England, M.A.
English Language and Literature	Professor A. W. Ward, M.A., Fellow of St. Peter's Coll., Camb.
Ancient and Modern History	Assistant Lecturer, Mr. T. N. Toller, M.A., Fell. of Christ's Coll., Camb.
Mathematics	Professor Thomas Barker, M.A., late Fellow of Trin. Coll., Camb.
	Assist. Lecturer, Mr. A. T. Bentley, M.A.
Natural Philosophy	Professor Balfour Stewart, M.A., LL.D., F.R.S.
Physical Laboratory	Professor Thomas H. Core, M.A.
	Demonstrators: Mr. F. Kingdon. Mr. A. Schuster, Ph.D.
Civil and Mechanical Engineering	Professor Osborne Reynolds, M.A., Fellow of Queens' Coll., Camb.
Geometrical and Mechanical Drawing	Assistant, Mr. John B. Millar, B.E.
Logic, and Mental and Moral Philosophy	Professor W. Stanley Jevons, M.A., F.R.S., Fellow of Univ. Coll., Lond.
Political Economy	
Jurisprudence and Law	Professor James Bryce, D.C.L., Fellow of Oriel Coll., Oxford.
	Assist. Lecturer, Mr. T. E. Holland, M.A., B.C.L., late Fell. of Exeter Coll., Oxford.
	Ditto, Mr. J. B. Gunning Moore, M.A.
	Ditto, Mr. Wm. R. Kennedy, M.A., Fell. of Pembroke Coll., Camb.
Chemistry	Professor H. E. Roscoe, B.A., Ph.D., F.R.S.
	Senior Demonstrator, Mr. C. Schorlemmer, F.R.S.
Chemical Laboratory	Junior Demonstrator and Assistant Lecturer, Mr. W. Dittmar, F.R.S.E.
	Assistant Demonstrators: Mr. W. C. Williams. Mr. H. Grimshaw.
Organic Chemistry	Lecturer, Mr. C. Schorlemmer, F.R.S.
Animal Physiology and Zoology	Professor W. C. Williamson, F.R.S.
Vegetable Physiology and Botany	
Practical Physiology and Histology	Professor Arthur Gamgee, M.D., F.R.S.
Geology and Palæontology	Lecturer, Mr. W. Boyd Dawkins, M.A., F.R.S., F.G.S.
Mineralogy	Lecturer, Mr. Charles A. Burghardt, Ph.D.
Oriental Languages	Professor T. Theodores.
German and Italian	
French Language and Literature	Lecturer, Mr. Hermann Breymann, Ph.D.
Free Hand Drawing	Lecturer, Mr. William Walker.
Harmony and Musical Composition	Lecturer, Mr. Fred. Bridge, Mus.B.

The next SESSION commences on the 7th October.

Candidates for admission must not be under fourteen years of age, and those under sixteen will be required to pass a Preliminary Examination in English, Arithmetic, and the Elements of Latin.

Prospectuses of the several departments of the Day Classes, the Evening Classes, and the Medical School, and of the Scholarships and Entrance Exhibitions tenable at the College, will be sent on application.

J. HOLME NICHOLSON, Registrar.

Manchester Royal School of Medicine,

incorporated with THE OWENS COLLEGE.

Principal—J. G. Greenwood, B.A.

Director of Medical Studies—George Southam, F.R.C.S.

LECTURERS.

General Anatomy and Physiology—William Smith, F.R.C.S.
Practical Physiology and Histology—Arthur Gamgee, M.D., F.R.S.
Descriptive Anatomy—Samuel M. Bradley, F.R.C.S.
Practical Anatomy—T. Beswick Perrin, M.R.C.S., F.L.S.
Comparative Anatomy and Botany—W. C. Williamson, F.R.S.
Chemistry—Henry E. Roscoe, B.A., Ph.D., F.R.S.
Medicine—Wm. Roberts, M.D., B.A., F.R.C.P.; J. E. Morgan, M.D., M.A., F.R.C.P.
Surgery—George Southam, F.R.C.S.; Edward Lund, F.R.C.S.
Physiology and Pathology of the Eye—Richard T. Hunt, M.R.C.S.
General Pathology—Henry Simpson, M.D., M.R.C.S.
Midwifery—John Thorburn, M.D., L.R.C.S.
Materia Medica—Alex. Somers, M.R.C.S.
Forensic Medicine—G. Morley Harrison, M.R.C.S.
Hygiene and Public Health—Arthur Ransome, M.D., M.A., M.R.C.S.
Clinical Medicine—The Physicians to the Royal Infirmary.
Clinical Surgery—The Surgeons to the Royal Infirmary.
Medical Tutor—T. Beswick Perrin, M.R.C.S., F.L.S.

The WINTER SESSION will commence on the 1st OCTOBER, 1873. The Opening Address will be delivered by Professor Gamgee, M.D., F.R.S. Attendance will be given from 12 to 1, at the College, Oxford-street, up to the 14th October, for registration.

Three Scholarships, of the value respectively of £20, £15, and £10; the Platt Physiological Scholarship of £50, tenable for two years; and the Dumville Surgical Prize, value £20, are offered for competition. Prizes are also awarded at the end of the Session.

A Fee of 40 guineas admits to the whole of the Lectures for qualification (except Practical Physiology), and a further Fee of 40 guineas to the Hospital Practice of the Royal Infirmary.

Prospectuses may be obtained from the Registrar, at the College or at the School.

J. HOLME NICHOLSON, Registrar.

The Queen's College, Birmingham.

(Incorporated by Special Act of Parliament.)

1873-74.

VISITOR—The Right Rev. the LORD BISHOP of the DIOCESE.

PRESIDENT—The Right Hon. the EARL of LICHFIELD.

VICE-PRESIDENT—The Hon. and Rev. G. M. YORKE, M.A.

WARDEN—The Rev. HARMAN CHALONER OGLE, M.A., Fellow of Magdalen College, and late Tutor of Magdalen College and Magdalen Hall, Oxford.

FACULTY OF MEDICINE.

The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st. The Introductory Address will be delivered by Professor Clay, at 3 p.m.

PROFESSORS OF THE MEDICAL FACULTY.

WINTER COURSES.

Medicine—James Russell, M.D. Lond., F.R.C.P., Physician to the General Hospital; Balthazar Foster, M.D., F.R.C.P., Physician to the General Hospital, Consulting-Physician to the West Bromwich Hospital.
Surgery—Oliver Pemberton, F.R.C.S. Edin., Surgeon to the General Hospital; Furneaux Jordan, F.R.C.S., Surgeon to the Queen's Hospital, Consulting-Surgeon to the West Bromwich Hospital.
Anatomy—Charles J. Braccy, M.B. Lond., Surgeon to the Children's Hospital, Senior Surgeon to the Hospital for Women; W. Thomas, M.B. Lond., F.R.C.S.
Physiology—Richard Norris, M.D.; T. H. Bartleet, M.B. Lond., F.R.C.S., Surgeon to the General Hospital.
Chemistry—Alfred Hill, M.D., F.C.S., Medical Officer of Health and Analyst to the Borough of Birmingham, and Analyst to the County of Warwick.
Demonstrators of Anatomy—Robert Jolly, M.D., F.R.C.S. Edin., Surgeon to the General Hospital; H. Campbell Pope, M.R.C.S.

SUMMER COURSES.

Midwifery—John Clay, M.R.C.S., Fellow of the Obstetrical Society; John Bassett, M.D., Fellow of the Obstetrical Society.
Diseases of Women and Children—Samuel Berry, F.R.C.S., Consulting Surgeon to the Children's Hospital and to the Hospital for Women; R. C. R. Jordan, M.D. Lond., Physician to the Children's Hospital.
Forensic Medicine and Toxicology—Thomas Swain, M.R.C.S.; Alfred Hill, M.D., F.C.S.
Practical Chemistry—Alfred Anderson, F.C.S.
Botany—William Hinds, M.D.
Materia Medica and Therapeutics—J. St. S. Wilders, M.R.C.S., Surgeon to the Queen's Hospital, and to the Eye and Ear Hospital; Edward Mackey, M.B. Lond., Extra Acting Physician to the Children's Hospital.
Ophthalmic Surgery—J. Vose Solomon, F.R.C.S., Surgeon to the Eye Hospital.
Dental Surgery—Thomas Howkins, M.R.C.S., Surgeon-Dentist to the Children's Hospital.
Comparative Anatomy—Thomas Savage, M.D., F.R.C.S., Surgeon to the Hospital for Women.
Registrar—R. Jolly, M.D.
Medical Tutor—H. Campbell Pope, M.R.C.S.

DEPARTMENT OF ARTS.

Sub-Warden—The Rev. Thomas Bates, M.A. Oxon.
Classics—The Rev. T. Bates, M.A.; William Bates, B.A. Lond.
Mathematics—The Rev. H. Edwards, M.A. Cantab.
French—Monsieur Jean O'Flanagan.
German—Dr. Karl Dammann.
Drawing—Mr. C. Docker.

SCHOLARSHIPS AND PRIZES.—Two Warneford Scholarships, the Sands Cox Prize (£20), the Warden's Prize, and Class Prizes are awarded annually.

FEES.—The Composition Fee for all the Lectures required by the Examining Boards is Fifty Guineas, payable by two equal instalments.

Students may reside within the College, under the supervision of the Warden and Resident Tutors. Fee, including rooms and board, £50 per annum.

In the Arts Department Students are prepared for the Matriculation Examination of the London University, or any of the Preliminary Examinations.

HOSPITAL PRACTICE.—Arrangements have been made whereby all Students of the College will in future attend the Clinical Lectures and Practice at both the General and the Queen's Hospitals for a common fee, and under such regulations as may from time to time be made by the Birmingham Clinical Board. The Fees for Hospital Practice (£31 10s.) are to be paid to either Dr. Foster, 16, Temple-row, or Mr. J. St. S. Wilders, Bath-row, Birmingham, Joint-Secretaries to the Birmingham Clinical Board. For details see College Prospectus.

The prospectus of the Medical Department, and further particulars, may be obtained by application to the Rev. the Warden, at the College; to Professor Foster, M.D., 16, Temple-row, Birmingham, Physician to the General Hospital, and Professor Wilders, Temple House, Islington-row, Surgeon to the Queen's Hospital, Honorary Secretaries to the Birmingham Clinical Board; or to Professor Swain, 62, Newhall-street, Hon. Sec. to the Professors.

Bristol Medical School.—The Winter

SESSION will commence on WEDNESDAY, OCTOBER 1. The following Courses of Lectures will be delivered:—

Anatomy—Mr. Board and Mr. Dobson.
Physiology—Mr. Atchley and Dr. Spencer.
Chemistry—Mr. Coomber.
Medicine—Dr. Martyn and Dr. Fox.
Surgery—Mr. Coe and Mr. Tibbits.

Dissections are superintended by Messrs. Chute, Lawrence, and Elliott.

Competitive Examinations are held amongst Students of the first, second, and third years respectively, and Prizes of Money, Instruments, and Books are awarded annually.

The Certificates of this School are accepted by all the Examining Boards.

The General Perpetual Fee is fifty-five guineas.

Medical and Surgical Hospital Practice and Clinical Lectures are attended at the Royal Infirmary or at the General Hospital, at which Institutions additional Prizes and Scholarships are annually offered for competition amongst the Students.

GEORGE FORSTER BURDER, M.D., Hon. Sec.

Medical School, Old Park, Bristol, August, 1873.

University of Durham.—College of

MEDICINE, NEWCASTLE-UPON-TYNE.—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st, at 2 p.m., when the President, Edw. Charlton, M.D., D.C.L., will present the Medals and Certificates of Honour to the successful candidates.

The Annual Report of the Council will be read by the Registrar, Luke Armstrong, M.D.

The Inaugural Address will be delivered by Luke Armstrong, M.D.

WINTER SESSION, commencing OCTOBER 1st, 1873.

Physiology—G. H. Hume, M.D.
Anatomy—T. C. Nesham, M.D.; Luke Armstrong, M.D.; and J. Russell, M.R.C.S.
Dissections—James Reoch, M.A., M.B., M.C.
Medicine—E. Charlton, M.D., and G. H. Philipson, M.A., M.D.
Surgery—G. Y. Heath, M.D.
Principles of Chemistry—A. F. Marreco, M.A.
Mental Diseases—T. O. Wood, L.R.C.P. Ed.
Practical Pharmacy—Barnard S. Proctor.

SUMMER SESSION, commencing MAY 1st, 1874.

Midwifery—C. Gibson, M.D.
Botany—H. E. Armstrong, M.R.C.S.
Medical Jurisprudence—B. Bramwell, M.D.
Therapeutics—Thomas Humble, M.D.
Materia Medica—W. C. Arnison, M.D.
Practical Chemistry—A. F. Marreco, M.A.
Operative Surgery—G. Y. Heath, M.D.
Pathological Anatomy—C. J. Gibb, M.D.
Practical Physiology—James Reoch, M.A., M.B.
Medical Tutor and Demonstrator—James Reoch, M.A., M.B.

Hospital Practice at the Newcastle Infirmary, which contains 230 beds, and in which the required Clinical Lectures are delivered. Number of patients last year, 16,696.

Composition fee, 17 guineas.

Four Resident Dressers are chosen from the senior Students every six months. Fee, £10.

Physicians—Dr. Charlton, Dr. Embleton, Dr. Philipson.
Surgeons—Dr. Heath, Mr. Russell, Dr. Arnison, Dr. Armstroug.
Assistant-Surgeons—Mr. A. Bell, Dr. Hume, Mr. J. Hawthorn, Mr. C. S. Jeaffreson.

Midwifery, Diseases of the Eye, and Insanity can be specially studied.

Composition fee to all the Lectures, 50 guineas.

The Laboratories, Libraries, and Museums are open daily.

Medical Scholarships in the University:—Four Scholarships at £25 a year, each tenable for four years by Students residing at Durham or Newcastle, and not of sufficient standing to proceed to a Licence in Medicine. A Scholarship will be awarded in October next.

Dickinson Memorial Scholarship—viz., £15, for general proficiency.

At the end of each Session a Silver Medal and Certificates of Honour will be awarded, after examination, to the best Students in each class.

By a recent Act of Convocation, the terms necessary for Degrees in Medicine and Surgery may now be kept by residence either at Durham or Newcastle.

LUKE ARMSTRONG, M.D., Registrar.
W. CHR. ARNISON, M.D., Secretary.

Newcastle-upon-Tyne, August, 1873.

The Wolverhampton and South

STAFFORDSHIRE GENERAL HOSPITAL. (A Clinical and Training Institution for Gentlemen intended for the Medical Profession.)

Founded 1848.—Beds 210.

MEDICAL OFFICERS.

Dr. Millington. | Mr. Vincent Jackson.
Dr. Totherick. | Mr. J. O'B. Kough.
Mr. C. A. Newnham.
House-Surgeon—Mr. Ravenhill.
Physician's Assistant—Dr. Nankivell.

This Hospital contains large Male and Female Accident Wards, Wards for cases of Burn, General Medical and Surgical Wards, a Ward for Diseases peculiar to Women, a Children's Ward, and a detached Fever wing; also a commodious semi-detached Out-patient Department. To the General Wards a Clinical Room is attached, in which the analysis and microscopic inspection of the Urine is conducted, also Ophthalmoscopic and Laryngoscopic examinations.

This Hospital is an excellent Institution for preparing and training gentlemen intended for the Medical Profession, and it offers to them unsurpassed opportunities of acquiring a complete professional groundwork and an elementary knowledge of medical subjects previously to their entering at a Medical College.

Instruction is given in Chemistry, in Natural Philosophy, and in the Anatomy of the Dry Bones, Ligaments, and Viscera.

The course of Practical Surgery includes the use of Surgical Apparatus, the performance of Surgical Operations, and the demonstration of Morbid Surgical Anatomy.

In the Hospital the pupils are required to attend daily in the Casualty Room, in the Out-patient Department, and in the Wards, the instruction afforded being of the most practical nature—including Bandaging, the Application of Splints, Tooth-drawing, and every kind of elementary professional detail; likewise how to observe and examine patients.

The art of Dispensing, the Preparation of Drugs, and of Pharmaceutical Compounds, can also be learnt in the Hospital Dispensary and Laboratory.

Operations are performed every Thursday, at eleven o'clock, and Practitioners are welcomed. The practice of the Hospital is recognised by all the examining boards.

Fees for Hospital Practice—One year, ten guineas; Perpetual, twenty guineas.

Some Members of the Honorary Staff receive Resident Pupils.

For further particulars apply to Mr. Vincent Jackson, Honorary Secretary to the Medical Committee, 46, Darlington-street, Wolverhampton.

Leeds School of Medicine.—The

WINTER SESSION will commence on WEDNESDAY, 1st OCTOBER. The Introductory Address will be delivered by Thomas Scattergood, Esq., at four o'clock.

LECTURES AT THE SCHOOL.

Anatomy—Mr. James Seaton, F.R.C.S., Dr. R. T. Land, Mr. J. A. Nunneley.
Physiology (including the Practical Course)—Messrs. C. J. Wright and James Walker.
Medicine—Dr. Heaton and Dr. Allbutt.
Surgery (including the Practical Course)—Messrs. Claudius G. Wheelhouse, F.R.C.S., T. Pridgin Teale, F.R.C.S., and T. R. Jessop, F.R.C.S.
Chemistry—Mr. Thomas Fairley.
Materia Medica—Dr. John Edwin Eddison.
Midwifery—Mr. William Hall.
Forensic Medicine—Mr. Thomas Scattergood.
Botany—Mr. Edward Atkinson.
Pathology—Dr. Eddison.
Comparative Anatomy—Mr. C. G. Wheelhouse, F.R.C.S., and Dr. Allbutt.
Demonstrators of Anatomy—Messrs. R. P. Oglesby, E. Robinson, and A. F. McGill.

Clinical Lectures are given by the Physicians and Surgeons to the Infirmary.

Ophthalmoscopic Demonstrations are given by the Surgeons to the Eye and Ear Department.

Demonstrations in Operative Surgery are given by the Lecturers on Surgery.

Demonstrations of Skin Diseases are given in the Infirmary.

Instruction in Vaccination is given by Mr. Holmes, one of the Public Vaccinators.

Besides the Infirmary, there is a large Dispensary and a Fever Hospital, both of which are open to Students of the School.

Special Prizes of the value of £10 each are given in the classes of Clinical Medicine, Clinical Surgery, and Forensic Medicine.

Silver and Bronze Medals are given in the Class Examinations.

Composition Fee, entitling to attendance upon all the required courses of School Lectures, 44 guineas. The fees for attendance upon the Medical and Surgical Practice of the Hospital are 20 guineas each for three years, and proportionally less for single sessions.

All applications for Tickets should be made to the Treasurer, Dr. Heaton, Claremont, Leeds. The Prospectus, and any further information about the School, may be obtained from the Secretary, Dr. Eddison, 29, Park-square, Leeds.

Leeds School of Medicine.—The

ANNUAL DINNER will be held at the GREAT NORTHERN HOTEL, at half-past five o'clock, on WEDNESDAY, OCTOBER 1st. Former Students and others interested in the School are invited to attend.

Tickets (price 7s. 6d. each, not including wine) may be obtained from Mr. Mayer, at the Hotel. Gentlemen who expect to be present are particularly requested to send their names to the Secretary as early as possible.

Sheffield School of Medicine.—

SESSIONS of 1873-4.—The WINTER SESSION will commence on WEDNESDAY, OCTOBER 1st, when the Introductory Lecture will be delivered by Henry Jackson, Esq., Fellow and Assistant-Tutor, Trinity College, Cambridge, in the Anatomical Theatre at 4 p.m.

LIST OF LECTURES.

Anatomy, Descriptive and Surgical—Mr. W. Skinner, Mr. E. Skinner.
Demonstrations of Anatomy—Mr. Clark, Mr. T. H. Morton; Vacant.
Physiology—Mr. Thos. Leeds and Mr. S. Morton.
Principles and Practice of Medicine—Dr. Frank-Smith.
Principles and Practice of Surgery—Mr. W. F. Favell and Mr. Parker, F.R.C.S.; Mr. A. Jackson.
Chemistry—Mr. Allen.
Dental Mechanics—Mr. G. Mosely.
Cliuical Medicine—Dr. Bartolomé, Dr. Law, and Dr. Frank-Smith.
Clinical Surgery—Mr. Barber, Mr. W. F. Favell, and Mr. Parker, F.R.C.S.
Practical Surgery—The House-Surgeon, at the Infirmary.
Practical Physiology—Dr. Thomas.

SUMMER SESSION, commencing MAY 1st, 1874.

Midwifery and Diseases of Women—Dr. Hime.
Materia Medica and Therapeutics—Dr. Young.
Medical Jurisprudence and Toxicology—Mr. Baker and Mr. Harrison.
Botany—Mr. Birks.
Comparative Anatomy—Mr. W. Jackson.
Practical Chemistry—Mr. Allen.
Dental Surgery—Dr. Merryweather.
Demonstrations of Pathology and Microscopy—The House-Surgeon, at the Infirmary.
Demonstrations of Operative Surgery—Mr. Favell and Mr. Parker, F.R.C.S.
Diseases of the Eye—Mr. Clarke.

Perpetual fee for attendance on all the Lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42.

Prospectuses and all further information may be obtained upon application to the Hon. Secretary,

ARTHUR JACKSON, St. James's-row, Sheffield.

The Cavendish Medical and Surgical

HOME.—Trained and efficient RESIDENT NURSES are sent out from this Institution on the shortest notice. Patients can have the best accommodation, with every necessary for operations, &c. For particulars, &c., apply to the Directress, Mrs. Talbot, No. 13, New Cavendish-street, Portland-place, W., or to Mr. David Bain, Secretary. A separate establishment for ladies.

For continuation of Medical School and Hospital Advertisements, see second page after Literary Matter.

London: Printed by PARDON & SON, of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and Published by J. & A. CHURCHILL, at the Publishing Office, 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—September 13, 1873.

ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture VII.—Valvular Diseases.

(*Continued from page* 222.)

Diagnosis, Prognosis, and Treatment.

Diagnosis.

In my last lecture I gave you a brief description of the different forms of valvular disease. I now proceed to speak of the symptoms by which they are severally characterised, and the means by which they may be detected during life.

1. *Obstructive Disease of the Aortic Valves.*—The appearance of patients labouring under this form of valvular affection is, if the disease do not exist to a very marked degree, rather that of persons in vigorous health. They have a flushed face and full, bounding pulse, and are liable to throbbing and sense of fulness in the head, and to palpitation, especially on using active exertion or under any excitement, while stooping, or after taking food, and especially after taking stimulants. They are also liable to fits, active hæmorrhages, and inflammatory affections of different organs, but especially of the brain.

On examining the chest the area of dulness in the region of the heart will be found large, and the impulse of the organ powerful. On auscultation, a murmur will be heard with the systole of the heart at the base, or about the level of the third cartilage, and this murmur will be propagated in the course of the aorta, so as to be loudly audible in the interspaces between the third and second and the second and first cartilages on the right side of the sternum. It may also be heard in the arteries of the neck, and frequently to the left of the spine posteriorly, though decreasing in intensity as we recede from the point of origin.

2. *Incompetency of the Aortic Valves.*—It has already been explained that this condition may be either primary or may supervene on obstructive disease. Whichever be its mode of origin, a patient labouring under regurgitation from the aorta into the ventricle presents generally a very different appearance from one in whom there is simple obstruction. He has usually a careworn, anxious expression of countenance, and is generally pallid, and complains of shortness of breath and faintness on exertion, and suffers not unfrequently from a transient feeling of unconsciousness on any active exertion or excitement. The temporal arteries are often observed to be contorted and beat visibly, and the same condition will be detected in the radial and other superficial arteries. In cases of this kind, and especially when the incompetency supervenes on previous obstructive disease, the area of the heart's dulness will be found to be increased, and especially on the left side, so that the apex is felt to beat further to the left than natural, and there is a soft murmur heard with the diastole at the base of the heart, or about the level of the third left cartilage, and propagated in the course of the ventricle down the left side of the mid-sternum.

There is also in these cases a very peculiar pulse, to which the terms *splashing*, *jerking*, *water-hammer*, have been given, but which is, I think, best indicated by the first term. This pulse is at one moment large and full, but rapidly disappears under the finger, and its peculiarity is readily understood when the incompetency of the valves and the condition of the left ventricle are considered. You will recollect that I have said that in cases of incompetency of the aortic valves the left ventricle becomes large and powerful; it must, therefore, throw a large column of blood into the aorta with much power at each beat, and hence the largeness and fulness of the pulse; but as, in consequence of the incompetency of the aortic valves, the blood immediately begins to regurgitate into the ventricle, the pulse rapidly disappears. These conditions equally explain the contorted forms of the arteries and their visible beat. The so-called splashing or regurgitant pulse exists, however, much the most characteristically in cases of obstructive and regurgitant disease of the aortic valves, and especially when the latter supervenes upon the former, and more particularly in men who have been accustomed to follow laborious occupations. In women and children, in whom the secondary changes in the left ventricle less readily ensue, the pulse seldom acquires its most characteristic form, though it may be often readily recognised. This kind of pulse is also much influenced by the position of the patient; thus, it will be made still more rapidly to disappear by causing the patient to sit up in bed or to stand, or even by simply raising the arm—the force of gravity in emptying the artery being thus added to the tendency of the blood to regurgitate during the diastole of the heart. In the combination of obstructive with regurgitant disease, the physical signs will readily be understood to combine the characteristics of the two separate forms of affection. In these cases the area of dulness is often very greatly increased—not usually in the vertical direction, for the weight of the heart causes it to drag downwards, and the ascending portion of the aorta becomes elongated, and the organ occupies a very oblique position, so that the dulness usually extends further on the left side and below the proper level, the apex of the heart beating to the left of the line of the nipple, and perhaps an inch and a half below that body in the fifth or sixth interspace. The murmur which is heard is a double one, to which the term "see-saw" may well be given. The first or systolic portion of the murmur is most loudly heard and most prolonged in the course of the aorta, or at the upper part and right side of the sternum; the second or diastolic portion is, on the contrary, most distinct and prolonged in the direction of the left ventricle or to the left of the middle third of the sternum. The murmur may therefore be indicated in the former situation thus—see-saw; in the latter thus—see-saw.

3. *Obstructive Mitral Disease* is generally seen in its most marked forms in young persons. They are often very delicate-looking, having a pale face, though generally with a slight flush about the cheeks and somewhat purple lips, and often the face is somewhat tumid. The pulse is generally small, and often quicker than natural, and the patients are subject to shortness of breath, and are very susceptible to cold, under which they suffer from various forms of chest affection. The area of dulness on percussion in the region of the heart is not very much altered, though it is generally increased on the right side. There is often a purring tumour to be felt at the apex. The murmur, which indicates the existence of narrowing of the mitral orifice, produced by the flow of the blood from the auricle into the ventricle, is heard at the time of the contraction of the auricles or immediately before the commencement of the ventricular contraction, and has hence received the name of *pre*systolic. When it exists in a characteristic form it is heard most distinctly between the left nipple and the lower end of the sternum. It is also heard at the point of pulsation of the apex of the heart, but is not loudly conveyed towards the left axilla, and is not heard, or only very indistinctly, at the lower angle of the left scapula. It has a peculiarly loud rough sound, and terminates quite abruptly.

4. *Mitral Regurgitation* is sometimes a primary, sometimes a secondary affection. When there is simple regurgitation from dilatation of the orifice or giving way of the chordæ tendineæ, the valves themselves being unaffected, so as not to be sources of obstruction, the symptoms and signs of the disease exist in their most characteristic form. The patient has a very livid and puffy face, the lips are purple, and the extremities much congested, and the feebleness of the circulation is shown by the colour very slowly returning into the integuments when they are blanched by compression. The pulse, also, is very feeble and sometimes quick, and from the dilatation of the left ventricle and the thinning of the walls which rapidly occur in these cases, the action of the heart often becomes irregular both in force and frequency, though it is by no means necessarily so in all cases. For the same reason the congestion of the lungs, of the parenchymatous organs, and of the system generally is also extreme. Bronchitis, œdema of the lungs, and pulmonary apoplexy generally occur, and the patient has great dyspnœa, troublesome cough, copious spumous dark or bloody expectoration, jaundice or albuminous urine, and head symptoms, and dropsy of the serous cavities and cellular tissue rapidly ensue. In such cases, also, the dilatation of the right side of the heart often becomes extreme, and there is incompetency of the tricuspid valve, shown by the pulsation of the jugular veins. The area of dulness is greatly extended in the longitudinal direction, both on the right and left sides. The pulsation of the apex of the heart is widely diffused, and is often not to be distinctly felt; and a murmur accompanies the systole of the heart, which is most loudly heard at the apex, is propagated

towards the left axilla, and is distinctly audible in the left, and often in the right, dorsal region.

In their simple forms obstructive mitral disease and regurgitant mitral disease are generally very readily recognisable by the physical signs; but often the two are combined, and, indeed, very generally incompetency ensues upon obstruction, the valves, which, in the first place, give rise to constriction, becoming ultimately hard and unyielding, so as not to close during the systole of the heart, and so allowing of regurgitation. In cases in which the two conditions exist the diagnosis is often attended with great difficulty. The murmur caused by the constriction should immediately precede that which indicates the occurrence of regurgitation, and it is often very difficult correctly to observe and analyse the sounds. These difficulties especially exist in cases which are advanced, in which the action of the heart is very irregular, and the murmur very imperfectly audible or entirely absent. Indeed in many such cases it is impossible to effect a decided diagnosis, and the nature of the disease can only be conjectured from the general symptoms. Tricuspid obstruction is of such rare occurrence that it is hardly necessary to dwell upon the diagnosis; and regurgitation through the right auriculo-ventricular aperture, though it is of common occurrence, and may undoubtedly occasion a murmur, is generally readily to be recognised from the pulsation which is observed in the jugular veins.

In addition to the physical signs which have been mentioned, others are occasionally detected, which, if of less practical importance, are nevertheless of great interest. Such are the cases in which murmurs which are distinctly musical are heard. I have known such murmurs to be heard in cases in which there were long, loose vegetations projecting from the aortic valves; and in one case, in which there was mitral incompetency from dilatation of the orifice, the valves not being diseased, the murmur was quite musical. Still more curious are those cases in which murmurs are heard so loudly as to be distinctly recognisable by the ear placed near the chest without the intervention of the stethoscope; and in some cases murmurs are heard at a considerable distance—one or two feet—from the patient, and often are unpleasantly audible to the patient himself. Some years ago I had a case of this kind in the hospital. The murmur was distinctly heard without the stethoscope on standing near the patient, and with the stethoscope it could be heard in the smallest arteries—those of the hand, and the dorsal artery of the foot.

(*To be continued.*)

ORIGINAL COMMUNICATIONS.

CASE OF

STRICTURE TREATED BY MR. F. JORDAN'S METHOD PER RECTUM.

By L. STROMEYER LITTLE, F.R.C.S., etc.,
Late Surgeon to the London Hospital.

A Portuguese seaman, aged 23, was admitted into the Shanghai General Hospital, suffering from stricture of the urethra. He stated that for more than a year he had had difficulty in making water, and that for some months he had only been able to do so by drops. He had often had gonorrhœa. He was a healthy muscular man; when examined, a large instrument passed easily about two inches and a half down the urethra and then came to a dead stop. The same occurred with all the various kinds and sizes of elastic and metal bougies. He passed water at the rate of a drachm a minute. He was kept quiet for some days, and then small instruments were tried through a Stromeyer guide catheter, but without success. The urethra, from the point where the stricture commenced down to the bulb, was very hard, but not much enlarged externally. Endoscopic examination afforded only negative results. When the patient had been three weeks in the hospital without any prospect of cure without operation, I determined to open the urethra from the rectum on Mr. Furneaux Jordan's plan, and either pass a bougie forwards from the wound in the rectum, thereby dilating the stricture, or by causing all the urine to pass per rectum for a time, give the strictured urethra rest, and then attempt its dilatation. The patient, after having been made to retain his urine for eight hours, was placed in the lithotomy position under chloroform, and, with the left forefinger in the rectum for a guide, the urethra was opened in front of the prostate to the extent of half an inch at least. An elastic *bougie à boule* was now passed from the wound towards the meatus, and although its point could be felt in the urethra in front of the scrotum it could not be passed further. Other kinds and sizes of bougies were tried with a like result. A large elastic catheter was now passed into the bladder from the rectum, and tied *in situ*, and forty drops of laudanum were given by the mouth.

The patient removed the catheter during the following night, but it was easily replaced in the morning. He did not suffer in any way from the operation. The catheter was retained three days, and on the fourth day, as the patient complained of passing urine by the penis, an attempt was made to pass a bougie through the penis, but without success. Three days later, however, a No. ½ elastic bougie was passed through and left in the stricture. This, after eight hours, was replaced by a larger one. From this date, every morning and evening the bougie was changed for a larger one, until No. 12 was passed. Up to this time the urine flowed entirely per rectum. As the stricture was now sufficiently dilated, a No. 12 catheter was passed every eight hours into the bladder and all the urine drawn off, so as to discourage any escape by the rectum. This treatment was continued for five days, when, on the morning of the fifth, the patient being unwilling or unable to hold his water until the catheter was passed, voided it naturally.

Examination with the speculum showed that the wound in the rectum was healed. The patient was discharged from the wards, provided with a bougie to keep his stricture dilated. One month later he presented himself in all respects sound.

Cases of stricture are common among the sailors in this hospital, and are usually treated by gradual dilatation; but as this case presented difficulties which could not be overcome without operation, and as the operation selected is still a novel one, the case is recorded. The operation did not seem to me quite so easy as it is described, but it is, doubtless, a safe way of opening the urethra without a guide, and very much simpler and less severe than by the perineum. Mr. Jordan recommends operating through a speculum, but I had not sufficient confidence in being able—with the speculum—to keep the middle line. In this respect, therefore, I departed from Mr. Jordan's valuable proceeding, discarded the speculum, and trusted to the forefinger as a guide. The subject of this case being a young man, the sphincter ani was very tight, and closed firmly on the finger and knife, hindering their movements. It would do no harm to divide the sphincter muscle, and such a proceeding would certainly make the operation easier. The operation seems suitable to many strictures which are not impermeable, for when the urine has not to pass over the stricture, dilatation can proceed much more rapidly, with less pain, with less inflammation, and, consequently, with less constitutional disturbance.

Shanghai.

ON PROFESSOR ESMARCH'S MODE OF PERFORMING BLOODLESS OPERATIONS.

By WILLIAM MACCORMAC,
Surgeon to St. Thomas's Hospital.

The importance of the simple and efficient method briefly described by Professor Esmarch at the second Surgical Congress in Berlin, for preventing loss of blood during operations on the limbs, appears to me so great, that I take the earliest opportunity of communicating my experience on the subject, brief though it be.

A little girl, 5 years old, struck the left tibia, twelve months ago, against a stone; necrosis followed, and when admitted to Hospital a year afterwards a sequestrum could be felt in the tibia enclosed by a considerable thickness of new bone. Whilst the patient was being chloroformed, I applied, pretty tightly, an ordinary elastic bandage from the toes to the middle of the thigh. The bandage was two inches wide and five yards in length, and, thus applied, the bandage forced all, or nearly all, the blood from the limb into the body. When the patient was fully narcotised, I wound a half-inch indiarubber rope around the thigh immediately at the upper border of the bandage, and sufficiently tightly to obstruct all the afferent vessels. Hooks previously attached to the extremities of the rope furnished a ready means of fastening it, as well as of removing it at plea-

sure. The bandage first applied was now unrolled, when the limb presented a blanched appearance. The operation was then commenced; some new bone removed, so as to get at and take away a considerable-sized sequestrum. During the entire time not a single drop of blood appeared in the wound; a sponge was not once required, and the facility with which the operation was conducted and finished requires to be seen to be realised. The tissues were divided, so far as bleeding was concerned, just as they might have been on the dead body. This operation was performed in St. Thomas's Hospital on August 16 in the present year, Esmarch's method for producing local anæmia being then practised, I believe, for the first time in Britain. Since the operation the little patient has progressed very favourably, and, although carefully watched, no peculiarity which might be attributed to the use of the apparatus has been observed either in the wound or in the limb.

Since then other operations for necrosis have been performed, and an excision of the knee lasting thirty-five minutes, also an amputation of the thigh, and in no instance has one single drop of blood been lost. The advantages of such a plan are so palpable as not to need much insisting upon. The generality of hospital patients can ill spare a serious loss of blood, and such a loss often proves inevitable during operations for extensive necrosis of bone. In amputations the greater part of the blood of the lost extremity is preserved, to the advantage of the patient. The duration of operations will be much shortened, as there is neither blood nor the constant dabbing of sponges into the wound to remove it, to interfere with the surgeon's sight. No accident or ill consequence at all appears to follow the use of the apparatus. In cases where amputations require to be performed for gangrene, or where there is a deposit of septic material in the limb about to be operated upon, there might be a risk of the elastic bandage forcing some portion of the septic material into the circulation. In the further use of the apparatus this possibility must be kept in view. Anyone will be surprised, in trying it upon his own arm, to find what a small amount of pressure of the india-rubber rope will stop the pulsation of the radial artery, and the femoral can also be stopped with no great exercise of force. Doubtless the history of surgery abounds with many attempts to empty limbs of blood previous to amputation, and to arrest hæmorrhage during their performance. Stromeyer, in 1853, as he relates in his "Maxims," adopted a plan precisely similar in principle, in an operation on a brachial aneurism. He bandaged the limb to a point just above the aneurism, and then applied a tourniquet. The loss of blood was very small during the operation. Billroth mentions that when he was assistant to Von Langenbeck in 1853 and 1854 a somewhat similar plan was tried in the clinique in Berlin. Vanzetti, of Padua, relates in the *Italian Medical Gazette* that Dr. Silvestri, in Vicenza, has employed bandaging and the indiarubber rope compression above it in amputations; but, this notwithstanding, to Professor Esmarch must be attributed the credit of devising and making known a most simple, practicable, and efficient plan for wholly preventing loss of blood during operations, of whatever kind, when performed upon the extremities of the body.

TREATMENT OF DELIRIUM TREMENS AND ALLIED DISEASES BY LARGE DOSES OF DIGITALIS.

By FREDERICK IRVING DE LISLE, L.R.C.P.,
Medical Officer of the St. Peter Port Hospital, Guernsey.

As the attention of the profession has been directed to this subject by the inquest alluded to in your article headed "The Relations between Prescribers and Dispensers," the reports of the following cases in which digitalis has been administered with the best results, when opium and morphia in large doses, so greatly relied upon and advocated by some members of the profession, have failed, may prove interesting, more especially as it appears, from the communications forwarded to the *Kent Coast Times*, that some practitioners are either ignorant of its beneficial effects in this disease, or that large doses are well tolerated in delirium tremens, and that it is both justifiable and incumbent on the practitioner prescribing digitalis to do so boldly—giving doses, in fact, that, if experience had not proved otherwise, would be excessive.

I had not intended to publish these cases, as I fancied that the subject was almost threadbare: many contributions on the subject having appeared in the various medical journals since the time when that illustrious practitioner who once graced our sister isle—Mr. Jones, of Jersey—first wrote on the subject, and Drs. Garrod, Ringer, and others having alluded to it in their works on therapeutics.

I have selected these two cases out of my notes of several, as the presence of cardiac affections might have deterred many, as I was deterred at first, from administering this drug. It may not be out of place to add that, owing to the cheapness of spirits, delirium tremens is of deplorably frequent occurrence amongst the poorer classes here.

Case 1.—*Lumbago accompanied and followed by Delirium Tremens.*

Timothy T., aged 30, a coachman. Patient has lived and drunk hard; has been exposed to wet and vicissitudes of weather. Has been troubled with cough, unaccompanied by expectoration, for the last two or three years. Is unmarried, and has suffered from every form of disease incidental to youthful indiscretion. Never had rheumatic fever, but has suffered from chronic rheumatic pains for some years, always increased by exposure to wet and cold. For the last year he has noticed that he has become very short of breath, "quite broken-winded," and has been attacked with palpitation of the heart when walking fast up hills, when running, and doing any hard manual labour. Family history good. Patient is tall and slightly built, but well knit.

July 27.—Patient lies straight in bed, and moves with great difficulty owing to pain in the back. Pain is increased by pressure. Most tender part is at third lumbar vertebra. Is covered with clammy perspiration, acid in reaction. Urine acid, and deposits red sand on cooling. Pulse 80, soft and compressible; temperature normal; pupils dilated; respiratory sounds healthy. Heart: There is a regurgitant mitral bruit, an exocardial creaking, and a slight roughness with the systolo at the base, heard along the course of the aorta. Tongue bright red and abnormally clean, not tremulous. Ordered ℞. Pot. iodidi ʒ j., pot. bicarb. ʒ ij., tinct. guaiaci, mucilaginis gum acaciæ āā ℥ss., aq. camph. ad ʒvj.—one tablespoonful to be taken every four hours. ℞. Liq. morph. acet. (P.B.) ʒ j., aq. ad ʒij.—half at 10 p.m., and to be repeated an hour after if necessary.

28th.—Pain is greatly alleviated. The draught produced some slight heaviness, and patient dozed for about half an hour, but did not sleep. Pulse 86. To repeat the draught ordered yesterday. 10 p.m.: I was summoned in great haste, as he was raving and perfectly intractable. Patient was quiet on my arrival, but complained of excruciating pain in the lumbar region; said that since six o'clock it had been so intense as to madden him and prevent his lying in bed, and, although still great, was to some extent alleviated. He had taken the whole of the draught without any effect. A grain of morphia was injected subcutaneously in three times, after which the patient appeared to be dozing off. I then left.

29th.—Did not sleep, although he was relieved from the pain. The pain has returned this morning. Pulse 78, soft and compressible; skin clammy. Ordered emp. lyttæ 14×6, to be applied across the loins. ℞. Liq. morph. acet. ʒ iij., aq. camph. ad ʒij.—half at bedtime, and the remainder an hour after if necessary. Repeat the mixture.

30th.—The blister has risen well and the pain is relieved, but patient was unable to sleep last night. Tongue clean; pulse 80, soft and compressible. Repeat the draught.

31st.—Pain gone, but still no sleep. Urine scanty and high-coloured. Bowels confined. Skin moist and clammy. Appetite very small; patient manages to take a little milk and beef-tea, about half a pint of each, during the day. Tongue clean, not tremulous. Pulse 80. Ordered ℞. Tinct. hyoscyami ʒ ij., aq. camph. ad ʒiij.—half at bedtime, and to be repeated in an hour if necessary. Sulphur as a laxative.

August 1.—No appetite; pupils dilated; tongue clean, not tremulous; no sleep. Am informed that when I am away patient whistles and sings, and often tries to get out of bed, and at night is delirious and sometimes violent. Bowels confined. Ordered ℞. Tinct. opii ʒ vj., aq. camph. ad ʒvj., a sixth part to be taken every hour until sleep is produced. ℞. Pulv. jalapæ co. ʒ ss. to be taken the first thing to-morrow morning. Not to have a light in his bedroom. To be allowed an ounce and a half of whisky during the day.

2nd.—No sleep. Bowels freely opened by powder, which was given last night by mistake. Patient howled, screamed, and sang. At about five this morning he became so violent

that the attendants were frightened and left him, locking the doors to prevent his egress. He nevertheless escaped by the window and went to the stables. He returned quietly to bed on being ordered to do so by his master. Complains that he sees imps and monkeys looking in at the window, and grinning at him. Pulse 82; skin clammy; tongue clean, not tremulous. Ordered ℞. Inf. digitalis ℥viij., one ounce to be taken every two hours while the restlessness continues. If the patient becomes quiet the dose to be reduced to half an ounce, and the interval to be four hours between the doses.

3rd.—After taking the first dose of the medicine patient became calm, and almost immediately after the second dose—10.30 p.m.—he dropped off into a sound sleep, from which he did not awake until eleven o'clock the following morning. Pulse 76, full and strong; skin moist and warm; tongue clean, but rather red. Patient is perfectly rational and calm. Ordered to take half-ounce doses of the infusion of digitalis every four hours.

After this the patient had no return of his delirium, but remained under my care for rheumatism until August 7, when he was sufficiently recovered for me to take my leave, although he was still weak. Notwithstanding the success attending the treatment of this case, it had a melancholy ending. On August 8 after doing his morning work in the stable, the patient's master, who had treated him with the greatest kindness and consideration during his illness, and had even sat up one night with him, told him that he might remain quiet for the rest of the day, but ordered him not to leave the premises. This order he disobeyed, and made calls at several public houses, and about eight that evening found himself at the Cobo Hotel, separated from the beach by the road. He remained drinking in the bar, and left the house about nine o'clock. The next morning he was found on the beach, in front of the hotel, about six feet below high water-mark, quite dead, lying on his face with his arm under his forehead. There was a bruise under the left eye, and blood had issued from the left nostril, staining his neckerchief, shirt, and the stones on which his face rested. His clothes were wet, and death was caused by drowning. The way in which he came by his death in my opinion was this. After leaving the inn, he went down on the beach, and when walking along he tripped and fell forward, receiving the blow before alluded to, by striking against a stone that was sticking up, and against which the left side of his face was found resting. The stunning effects of the blow, coupled with the stupefying effects of the spirits he had drunk, sent him into a deep sleep, and the tide, which was flowing, rose over him and drowned him.

Case 2.—Rheumatic Cerebritis.

Mrs. S., aged 40, sent for me on September 10, 1872. Found her in bed in a very excited state; said that she had been unable to sleep for three nights, and attributed the sleeplessness to pains in her limbs; said that she had been wet through about a week previously, and had suffered ever since—the pains had been more intense during the last three days. Pulse 90, small and compressible; tongue furred and very slightly tremulous. Heart was not examined, as there was too much noise going on to allow of its being done satisfactorily. The woman was the wife of a sergeant now pensioned off, and had drunk hard and lived badly in every way for many years. Had never had rheumatic fever, but had suffered from pains in the limbs, which she attributed to rheumatism, after every exposure to wet and cold. Ordered a pill containing one grain of opium and one grain of extract of henbane every two hours; beef-tea and milk *ad libitum*, and no alcoholic stimulant. I may here state that this woman was in about the worst kind of room that can be conceived for treating a case of delirium. Adjoining the premises were some steam flour and saw mills that were constantly at work, and the rattle of which was plainly heard in the room; below there was a carpenter's shop, with several men at work, and the noise of sawing, hammering, and other things incidental to their work was most distracting to my patient; and lastly, the neighbourhood swarmed with children, who played in the courtyard just under her windows.

September 11.—Has had no sleep. Has fancied that devils and other abominations were running about her room all night. Pulse 96, small and compressible; tongue furred, and not tremulous; skin moist and clammy. Has taken about a pint of beef-tea and about a quart of milk. She is very thirsty, and drinks large quantities of cold water, and is very abusive to the attendants because they will not give her any gin. The amount of opium in each pill to be increased to two grains, and to be taken every hour.

12th.—Has had no sleep, but has shrieked, screamed, and sworn all night long, and disturbed the neighbours. Has taken her pills regularly; has taken fifty-four grains of solid opium in thirty-six hours, without any sedative effect being produced. Tongue furred; bowels continue open; pulse 88, small and compressible; skin clammy. Ordered inf. digitalis ℥j. every second hour. Evening: Has remained quiet ever since about half an hour after taking the first dose of the mixture, but has been kept awake by the noise. Everything has been quiet now for the last hour; is inclined to doze. Pulse 70, fuller and stronger than I have yet felt it. Heart slightly dilated; a loud bruit is heard with the systole at the base of the heart. Skin warm and moist. To take the medicine every four hours instead of every two hours; but if the patient sleeps she is not to be awakened on any account.

13th.—Pulse 70, full and strong. Patient slept uninterruptedly and quietly for twelve hours last night; is perfectly calm and rational. Skin warm and moist; perspiration acid, and has a strong typical smell; joints painful and tender, but not swollen; heart's dulness less circumscribed than last night. Patient feels inclined to eat; allowed to have a chop with her dinner, and eggs and bread-and-butter for breakfast, with tea or coffee. Ordered inf. digitalis ℥ss. every four hours. Evening: Has been quiet all day. Joints of left wrist, knee, and ankle are inflamed and intensely painful. Temperature 102°. Perspiration profuse, acid in smell and reaction. Ordered ℞. Pot. bicarb. ℥ij., pot. nit. ʒij., tinct. hyoscyami ℥iv., aq. camphorem ad ℥vj.—℥ss. every second hour.

14th.—Pains in the joints less, and swelling somewhat gone down. Patient slept well at intervals, but was several times awoke by the pain caused by turning in bed. Temperature 100°. Tongue furred, not tremulous. Continue the mixture.

15th.—Joints still a little tender, but swelling has gone down. Temperature 99°; pulse 86, full, but compressible. Skin warm and moist.

16th.—Patient is incoherent in her speech, does not know anyone, and is universally abusive; she lies in bed muttering to herself, with her eyes semi-closed; does not attempt to get out of bed. Pulse 106, thin and small; skin clammy. On inquiry, I find that a friend called upon her yesterday, bringing with her three bottles of gin, which these two worthies finished between them, my patient taking by far the larger share. She refuses food, and swears coarsely at all who speak to her. Ordered ℞. Infus. digitalis ℥j. every hour. Noon: Patient remains in the same state, and has not slept. Pulse 100, fuller and stronger; skin moist and cold. Will not protrude her tongue, each request to do so bringing down a volley of the coarsest and filthiest abuse upon me. She has taken beef-tea frequently, and her medicine regularly. To continue the digitalis. 4 p.m.: Has not slept, and continues in a state of low muttering delirium. Pulse 100, more wiry and jumping; skin clammy. Will not protrude the tongue. To discontinue the digitalis and take ℞. Tinct. opii ℥j. every hour. 9 p.m.: Low muttering delirium; skin clammy; pulse 140, so small that it can scarcely be counted. Patient gradually sank, and died at about ten o'clock the following morning.

My experience is, that so far from being a depressant, digitalis is, as one authority states—Dr. Ringer, I think—a "heart-tonic." Under its influence the number of pulse-beats are lessened, and the force of the heart's contractions are increased. In cases of dilated heart, and when that organ is doing its work inefficiently and irregularly, digitalis may be administered with the best results, and I feel satisfied that more harm is done by withholding the drug than by its exhibition.

A tremulous tongue, although a frequent symptom in delirium tremens, is by no means constant, for I have often seen cases in which the disease was well marked, and the tongue not at all tremulous. It may be a fortuitous circumstance, but all these cases were allied with rheumatism.

I am not disposed to regard primary attacks of delirium tremens anxiously; they usually, in my experience, get well, and that quickly, under the exhibition of digitalis and generous diet; but a relapse is almost absolutely fatal. There digitalis is of no benefit, and I fear that the same may be said of almost every drug in the Pharmacopœia. The delirium in these relapses is of a very asthenic type; the patient remains quietly in bed, mutters and talks to himself, but rarely if ever raises his voice, screams, or attempts to leave his bed.

Relapses appear more frequent in women than in men, and always follow some alcoholic excess. I have been in the habit lately of treating these relapses with a combination of tartar emetic and opium, but, except in the first case in which I administered it, I regret to say the results are not encouraging.

Patients after recovering from delirium tremens are frequently morose and melancholy, and sometimes have suicidal tendencies. I always, therefore, direct that the patient should be carefully and efficiently watched for some time after recovery appears complete.

I first used the infusion of digitalis, instead of the tincture, to test the truth or fallacy of the assertion, that the only benefit obtained from the use of this drug was due to the spirit contained in the tincture. I continue to use the infusion, as I find that I have better results from its exhibition. I usually give a fluid ounce of the freshly-made infusion every two hours, and as the patient becomes quieter I allow four hours to elapse between each dose, and afterwards lessen the dose to half a fluid ounce.

Although Trousseau has asserted that chronic rheumatism will not affect the heart, I have met with many cases of cardiac disease, and have seen fibrinous deposits about the valves of the heart after death, where the patients have never suffered from rheumatic fever, but rheumatic pains of a chronic form, extending over a period of many years, has been complained of.

SNAKE-POISONING AND ITS TREATMENT.

By GEORGE B. HALFORD, M.D.,
Professor of Anatomy, Physiology, and Pathology in the University of Melbourne, &c., &c.

(*Continued from page* 226.)

Those who have read or thought much of the recovery from poisons are aware that in many instances, if the circulation and respiration can be maintained sufficiently long, the patient will recover; and it seems that snake-poisoning is no exception to this rule. I have before said that those cases of snake-poisoning which to observers are the most fearful—viz., those attended with profound coma—are probably not the most dangerous, for they have yielded readily to the action of ammonia, and very probably in the manner here indicated: that is to say, by restoring the circulation and respiration so effectually that the patient's powers were sufficient to surmount (to speak in conformity with our real ignorance) the effects of the poison. I have also referred to the different effects produced by the poison on dogs and men, and referred them in former papers to the relative difference in their cerebral and spinal ganglia. I have for this reason urged upon the medical men of India to try injecting ammonia into the veins of men, even if they have failed of success with dogs. This leads me to say that snake-poison in its effects resembles in part both the anæsthetics and strychnine, and also those poisons which have, according to Broadbent, "the most diverse action on different classes of animals, being such as affect the cerebral ganglia, the functions and endowments of which vary so greatly in the animal series." Hence, as I have before said, all relative experiments should be made with animals of the same species.

In order to see with my own eyes the effect upon the heart's action of the injection of ammonia into the circulation, I with the assistance of Drs. Neild and Wooldridge made the following experiments:—

Experiment 1.—A large young dog was got under the influence of chloroform; the front of the chest was removed, and artificial respiration maintained, chloroform being occasionally dropped into the bellows. 11.27 a.m.: Half a drachm of liq. ammoniæ (B.P.), sp. gr. 0·959, was injected into the left external jugular vein. The heart's action was at once accelerated, but soon settled down to steady pulsations. 11.35 a.m.: Half a drachm more was injected into the right ventricle. Immediate increase of the heart's action ensued; consciousness returning, as evidenced by the reflex movements of the eyelids and by a withdrawing of the leg on pricking the foot. Pulsation powerful and steady. 11.45 a.m.: Completely conscious; struggling to get up. More chloroform was poured into the bellows. Soon became insensible again. 11.50 a.m.: Half a drachm was injected into the left ventricle. This was almost immediately followed by a contraction of all the muscles of the body, which soon subsided. Heart's pulsation very vigorous. 11.53 a.m.: Dog returning to consciousness; more chloroform poured into the bellows; soon again insensible. 12 noon: Half a drachm more was injected into the left ventricle. The same increased pulsation, followed by a slight universal spasm, as before. 12.2 p.m.: Dog quite conscious and struggling: more chloroform poured into the bellows. 12.11 p.m.: Dog again conscious and struggling; more chloroform poured into the bellows. 12.13 p.m.: Again quite insensible, pupils dilated, etc. 12.17 p.m.: Half a drachm more ammonia was injected into the right ventricle. Heart pulsated forcibly, the same general spasm following. 12.22 p.m.: Dog again conscious; more chloroform by the bellows. 12.26 p.m.: The dog being again quite insensible, I injected half a drachm more into the right jugular vein. In ten seconds the heart's action was increased, the same general muscular spasm following. Sensibility returning, as shown by the reflex action of the eyelids, etc. 12.33 p.m.: Quite conscious and struggling to get up; more chloroform in the bellows; soon again insensible. 12.36 p.m.: Half a drachm more injected into the left ventricle. Pulsations immediately increased, followed by the same general spasm, but in a milder degree. 12.40 p.m.: Heart's action powerful and steady; pulsations good all over the body. 12.43 p.m.: Dog again quite conscious; more chloroform given; soon insensible. 12.48 p.m.: One whole drachm was injected into the left ventricle. Heart's action immediately quickened, followed by the general spasm. Reflex action of eyelids returning. 12.57 p.m.: Dog quite conscious, and struggling hard to get up. He seemed to have as much vitality as ever; and a sufficient trial having been made, the heart was cut out and an end put to the experiment. On examining the cavities of the heart, there was not the least trace of irritation or inflammation, and the punctures through the muscular substance were scarcely visible. The vigour and persistence of the heart's contractions after removal from the body were greater than I had ever before witnessed.

Experiment 2.—Another large dog was chloroformed, the front of the chest removed, and artificial respiration maintained for one hour and twenty minutes, during which time the heart's movements were carefully observed. As in the former case, the injection of the ammonia had the effect of continually rousing the dog from the full influence of the chloroform, necessitating always a further supply of the anæsthetic before another quantity of ammonia was used. In this dog both jugular veins once, the right ventricle once, and the left ventricle three times, were injected with half-drachm doses of liq. ammoniæ (B.P.), sp. gr. 0·959. The results were precisely similar to those noticed in the other dog—viz., immediate increase of the heart's pulsation, settling down into steady beats; the same muscular spasms, followed by returning consciousness; and lastly, the same absence of any visible injury to the heart's cavities or walls.

In removing the front walls of the chest the intercostal vessels are necessarily cut, but they usually cease to bleed after a little exposure. It was so in the case of the two dogs the subjects of these two experiments. But immediately after the injection of ammonia the plugged extremities of the arteries burst open, and I was literally played upon by the little streams of blood converging towards me. It was easy to notice, likewise, the general effect of the ammonia circulating everywhere, the increased redness of the muscles, together with their firmer tone, and presently the general awakening of the dog from the stupor into which he had been thrown. What could be more favourable to recovery from snake-poisoning or any other deadly depressant? I concluded these experiments, in which I had been readily and ably assisted by my friends Drs. Neild and Wooldridge, with the utmost satisfaction, as they enabled me to see the heart's behaviour upon injecting the veins, and greatly explained the astonishing results which had been obtained by me and others in the colony when treating snake-bite upon this plan. Here is another example of the effects of ammonia upon the heart's action:—

A young man, after weeks of terrible dissipation and drinking, swallowed an ounce of chloroform. Some time after Mr. Gilbee was sent for; he found the man, as he believed then and since, dying. On the suggestion of Dr. Neild, they tried the injection of ammonia, using altogether two drachms of liq. ammon. fortior (B.P.). "After the first injection the pulse, which was previously almost imperceptible, got full and strong, and there was a general improvement; and at the second injection warmth was communicated to the extremities, which had previously been quite cold." In an hour or so the man could sit up and talk. He died, however, thirty-two hours after having been resuscitated. Of his death Dr. Neild

thus wrote in the Melbourne *Argus*—"I am desirous of establishing the fact that recovery, as the effect of the ammonia, was absolute and complete, as the man walked about the house and yard during the Thursday after, and I am sure that if he had been organically healthy he would have recovered completely; but the thorough saturation of the system with alcohol, added to an advanced stage of visceral disease, produced a degree of exhaustion under which he could hardly fail to sink."

Whilst I was just arranging my thoughts, even yesterday, as I write to-day, Dr. Farrage, of Melbourne, drove out to me, and gave me the following narrative. He had, he said, been called out two nights back to see a lady who had some hours before swallowed one ounce of Collis Browne's chlorodyne. She was totally insensible, pupils contracted, limbs relaxed, surface of the body cold, pulse nearly imperceptible, jaws closed, breathing irregular, with scarcely a sign of life about her. She was too far gone to use the stomach pump. He expected, and so told her husband, that every moment would be the last. It suddenly occurred to him to try the injection of ammonia. He went to a chemist close by, and obtained half a drachm of liq. amm. fort. (B.P.), mixed this with one drachm and a half of water, and injected the whole within one minute into the median cephalic vein. In a few minutes the pulse became perceptible, and by twenty minutes a complete reaction was established, strong steady pulse, good breathing, and general warmth returned to the whole body. The insensibility, however, did not pass away for some time after. The patient made a good recovery. Dr. Farrage states that he had never in his whole experience seen anything so remarkable, satisfactory, and decided as the results of this treatment.

It is clearly seen, then, that the injection of ammonia into the veins, or even into the heart itself, is followed by steady and powerful ventricular contraction and free circulation throughout the body. The freer circulation through the lungs must be beneficial whenever there are volatile poisons, as chloroform, in the blood, as these readily escape with the expired air. The increased warmth is evidence of general oxidation throughout the system.

I have found that the stupor induced in dogs by chloral hydrate is immediately removed by the same treatment. It is interesting to notice that when ℈ij. or ʒj. dissolved in warm water is injected into the peritoneal cavity, it takes exactly three minutes for symptoms of intoxication, staggering, etc., to show themselves. In several dogs thus experimented upon the symptoms commenced in all three minutes after injecting.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

OPERATIONS BY MR. SYDNEY JONES.

Amongst other operations performed at St. Thomas's Hospital on Wednesday, September 3, were two in which somewhat novel (so far as English practice is concerned) expedients were had recourse to.

A boy with very extensive ulceration about the knee involving nearly the whole circumference of the limb, was subjected to amputation of the thigh by Mr. Sydney Jones. The plan advocated by Esmarch for prevention of hæmorrhage during operations was adopted. Details of this mode of proceeding have been given (by Mr. MacCormac) in a late number of the *Medical Record*. An elastic bandage was first firmly rolled on the limb from below, upwards, so as to force out the blood; a tubular indiarubber cord was then securely fixed around the limb immediately below Poupart's ligament. The bandage was then removed. Mr. Sydney Jones in his remarks before operating stated that he had already tried, and satisfactorily, this mode, having in a private case amputated the leg without loss of any blood.

In the amputation under present remark there was no bleeding at all during the operation. The principal vessels were twisted before loosening the tubular constricting cord; and after its removal two or three smaller vessels were secured, also by torsion.

In another case, in which there was enormous distension of the bladder, the aspirator was used by Mr. Sydney Jones. The distension reached considerably above the umbilicus. Curiously enough the man suffered no discomfort—he had had traumatic stricture for over fifteen years. Urine was dribbling *guttatim* from the penis. A very small catheter had been introduced on two previous occasions, but recent attempts to pass an instrument had not been successful.

To relieve the distension the aspirator was used, the puncture being made in the median line about one inch above the pubes. A large basonful of urine was drawn off by this mode. As the distension, more or less, had probably existed for some considerable time, it was not thought advisable to empty the bladder completely at once.

CHARING-CROSS HOSPITAL.

CASE OF CHRONIC VOMITING—DILATATION OF THE STOMACH.

(Under the care of Dr. POLLOCK.)

A. K., male, aged 65, a tailor by trade, was admitted into Charing-cross Hospital on July 22, complaining of frequent attacks of profuse vomiting. He gives the following account of himself:—

He had scarlatina when thirteen years of age; no other serious illness. He has long been dyspeptic, and especially troubled with wind. Two years ago the present symptoms began—namely, pain in the belly and vomiting. He was at first ill with uncontrollable vomiting and abdominal pain for about two weeks; from these he recovered, to have a second similar attack some short time after. The second attack was a more protracted one. Ever since, he has had the same symptoms occasionally, recurring about twice a week, often more frequently. The sickness has prevented any food being kept on the stomach at the time, and the vomit has consisted first of food and then of bile. The pain was chiefly above the navel; it preceded the sickness and led on to the vomiting, which apparently relieved it; there seems to have been much feeling of tension along with it. There was never diarrhœa, but on the contrary constipation for days, and never jaundice. The last attack of this kind was a few days before admission. On the evening of the 19th he was sick, and brought up a large quantity of vomit. After filling the pot with this, he ejected, towards midnight, a much darker material than he ever had before; of his own accord the patient says this was "like coffee." He did not faint. He had been ill some twenty-four hours in this attack before the "coffee stuff" was ejected, and he had some twelve hours previously vomited a little blood for the first time. His wife saw the blood; the patient himself can give but little account of it. Twenty years ago the patient had "dry pox" with a suppurating bubo. About ten years ago, he had some growth on the penis, and he has frequently had a crop of spots on the brow, but never elsewhere. His children have never suffered from syphilitic symptoms.

A sallow, pale man, without much aspect of illness. He can sit up, and has no vomiting or pain at present. There is little or anything peculiar about the belly physically. It is not enlarged, is quite symmetrical, and is generally resonant, except over the liver. The lower hepatic border may be seen, felt, and percussed out in nearly the usual situation. There is no tenderness. The flanks are resonant over the region between the umbilicus and liver, and around the former there is a very distinct fluctuation and succussion sound, evidently gastric. No tumour is to be felt in any situation. Constipation for the last four days. Tongue somewhat furred. He has beef-tea only.

July 23.—Last night and on the previous night the patient wakened about three o'clock, and felt heartburn, and "as if he would be sick"; the feeling was "as far up" as the middle of the sternum. This sensation passed off in a few minutes. No vomiting since admission. His bowels are now freely moved by castor oil.

28th.—The patient began to vomit on the 26th, at 7.30 p.m., and ceased vomiting at 6.45 this morning. During this time he has brought up no less than 150 ounces.

On the 27th the sickness occurred at three different times—in the morning, at 8 p.m., and at 10.30 p.m. Last night

the patient was twice sick. The vomit is more greenish in character this morning than yesterday. The patient did not seem particularly prostrate after the great vomiting. His bowels were not opened since the 26th. He has had an enema, and passed a fair stool. The tongue is slightly foul. At present (1 p.m.) there is no gastric tenderness. There is but little tympanites, and the liver is seen moving in the usual position. There is general tympanitic percussion sound when the belly has been handled for a few minutes; the transverse region of the abdomen, corresponding to a band round the umbilicus of (say) three or four inches width, begins to present movements in a semicircular fashion—from left to right only. The swelling is first caught sight of close under the umbilicus, and in a few seconds has rolled itself out of sight in the right hypochondrium. This movement is unattended with pain, and is repeated at intervals of about a second, as long as watched. On deep palpation in the spot where the movement ceases to be seen there is felt a very doubtful firmness obliquely between the umbilicus and the right inferior rib-border. There is exceedingly distinct succussion sound and fluctuation over most of the abdominal surface. Urine alkaline, with a copious grey deposit; dull on heating, cleared by a drop of acid.

29th.—As well as could be wished. No pain or sickness. The tongue is clean and moist. He eats fish.

August 2.—Continues well.

4th.—The patient has vomited again. On the afternoon of the 2nd he felt rather full after having his milk (*i.e.*, "tea"), but not pained; he went to sleep, and about 10 p.m. wakened with a mouthful of vomit. No vomiting during the night. Next morning he had some castor oil for constipation. At 3 p.m., at 5 p.m., and at 8 p.m. the vomiting returned, but has not appeared since. About half as much fluid was rejected as on the last occasion, and the character seems to be just as before. This morning he is sitting up as if nothing had happened: he has no appetite. There has been but little pain beyond a windy feeling during this attack.

5th.—Since the last note the patient has continued well. He left the Hospital to-day.

The treatment consisted of bismuth followed by quinine, with a blister to the epigastrium.

CASE OF HYSTERIA IN THE MALE.

(Under the care of Dr. HEADLAND.)

W. M., a currier, aged 21, was admitted into Charing-cross Hospital on June 2, 1873. On reaching the ward, which he did with evident difficulty, the patient seated himself immediately and gasped for breath. His look was anxious, and he jerked his chest and belly upwards and downwards in a distressed manner. He complains of shortness of breath, or rather difficulty of breathing, of pain when he swallows, and of a sensation of lumps in the throat; withal he speaks loudly, clearly and without the slightest dyspnœa objectively. The pulse is quiet. He states that he has had sore throat for three weeks, and that he had a similar attack some months ago. He has been otherwise healthy. When put to bed the patient lies perfectly quiet until he is approached, when the gasping and forced respiratory jerking recommence. There is slight redness of the fauces; neither to the eye nor to the finger introduced into the pharynx is there any perceptible swelling; but there is great difficulty in making this examination—the patient curls up his tongue, shuts his mouth, pulls away one's hand, and cries that he is choking. There is no sub-maxillary swelling, no distortion or pain about the larynx; neither is there abnormal pulsation in the neck or chest, nor thrill, and the sternum and the top of the chest are resonant on percussion. There is no palpitation; the heart is of normal size and quiet; the pupils are equal. Pulse at the wrists 84, regular; equal on the two sides. The tongue is coated; the temperature is normal. He was ordered to take a compound asafœtida pill twice a day and quinine mixture.

June 3.—The patient's condition remains much the same. Similar gasping movements when he is approached.

4th.—The patient has a cold shower-bath daily, with threatened repetition after each fit of choking. When eating his dinner he gulps down the morsels in a distressed-like manner, nodding his head, and making exaggerated movements of swallowing.

10th.—The patient is very much better; there is very little globus. The baths have been stopped. He leaves the Hospital to-day.

BRISTOL GENERAL HOSPITAL.

DELIRIUM TREMENS: A VIOLENT ATTACK RAPIDLY SUBDUED BY CHLORAL, AIDED BY CHLOROFORM.

(Under the care of Dr. MARTYN.)

[Reported by Mr. J. H. THOMAS.]

J. A., AGED 30, admitted August 14 into the Bristol General Hospital under the care of Dr. Martyn.

Patient is a seaman. He is a tall, powerful-looking man. During the last fortnight he has got drunk every day. Last night his friends said he became very strange in his manner, and talked great nonsense.

On admission (10 a.m.) he was in a state of tremor. Skin hot and perspiring; tongue tremulous; eyes bright; anxious expression of face. Incessantly talking; said he "saw a snake coming to eat him up." Injection morphiæ hyd. gr. $\frac{1}{3}$ was administered; and milk and beef-tea ordered. For the next two hours he was quiet, and slept; but then woke up, would get out of bed, and become so violent that a strait-waistcoat was put on. 1.30 p.m.: Injection of morphia repeated, but with no effect. 4 p.m.: Chloral hyd. gr. xxv. 6 p.m.: Injection of morphiæ hyd., gr. ss. 7 p.m.: As neither morphia or chloral had any effect on him, and it required three or four people to keep him in bed, chloroform was given to anæsthesia, and its effect kept up by repeated inhalations until 9 p.m. He continued quiet for another half-hour. 10 p.m.: Chloral hyd. (gr. xl.) was given, and chloroform again administered. Slept well for four or five hours.

August 15.—10.30 a.m.—Very restless for the last two or three hours. Chloral hyd. gr. xxx. and tinct. opii. ℥xx. were given, and chloroform administered to send him off. 1.30 p.m.: Slept until now, when he awoke and became restless. Chloral hyd. ʒj. was given. 9.30 p.m.: Drank his milk and beef-tea to-day, but took nothing yesterday. Has been very restless for the last few hours; will not take his draught. Chloroform was therefore given to anæsthesia, and the draught (chloral hyd. ʒj.) was poured by way of the nose into his stomach. Has not once been sick after the chloroform.

16th.—Three one-drachm doses of chloral hydrate were given during the day. Patient slept well.

17th.—Patient had the same amount of chloral as yesterday. Slept well.

18th.—Patient had one drachm of chloral to-day in one dose, and half a drachm at night.

19th.—Had a restless night, but no more chloral was given, as he has now entirely recovered his senses.

22nd.—Discharged. He was weak, but not to any marked extent. Walked out of the Hospital all right, with the exception of a little stagger.

THE INDEX EXPURGATORIUS IN RUSSIA.—We are informed that the publications of Dr. Stanski on the "Spontaneity of Matter" have been prohibited in the Russian Empire. —*Gazette Médical*, September 6.

A CURER OF BLINDNESS OF BODY AND SOUL.—The *Vraie France*, a Lille journal, contains the following article:—"M. le Dr. Bribosia, the eminent oculist, has been appointed a director of the Ophthalmological Institute recently established at Tournay. A chevalier of the Order of Leopold, and member of the Belgian Academy of Medicine, M. Bribosia had the direction of the Ophthalmic Hospital at Namur for several years. As sincere a Christian as he is a skilful practitioner, he has, we are informed, restored sight to numbers of the blind, and cured by his counsels many souls of a far more dangerous and incurable blindness."—*Presse Belge*, Sept. 7.

A VERY severe and unusual accident was brought to hospital from the Kiangnen Arsenal. A youth, aged 20, had the whole of his scalp torn off, by his tail becoming entangled in machinery while in motion. On admission, he was deluged in blood and pulseless. Dr. Sibbald succeeded in replacing the torn scalp, but unfortunately a large portion of it sloughed afterwards, and left an exfoliation of part of the frontal bone. The patient has now been in hospital six months, and there is still a very large granulating surface, which is slowly contracting, and although the patient is very anæmic there is some hope of his ultimate recovery. Skin-grafting was tried in the case, but failed.—*Report of the Chinese Hospital at Shanghai, by Dr. James Johnson.*

SATURDAY, SEPTEMBER 20, 1873.

A WORD TO TEACHERS.

Last week we devoted much space and not a little care to provide for the wants of the Student: this week we would wish to do something more for him by offering a few suggestions to those who are his Teachers. This is the more necessary, since from our London system it follows that the great part of the work of teaching is entrusted to the hands of the younger men, many of whom have to commence the arduous duties of a teacher of medicine without anything like an adequate training beforehand. Indeed, this want of training in our teachers is a serious evil: men have to train themselves as they strive to teach, and meanwhile the student suffers. Many a man has found out to his cost that it is not given to every man to be a teacher; but he has found it out too late, and something like shame and disappointment have followed the discovery. When hospital and school appointments went more exclusively hand in hand than they now do, it came to each man's turn to take up a certain subject; if he did not, he was in a measure passed over: the consequence was, the insertion of innumerable square sticks in round holes, and *vice versâ*, and for this the student paid the penalty; and—in part, at least—on this account arose the outcry against lectures (it should have been against lecturers), which has hardly now subsided. Nevertheless, we are bound to confess that for the teacher himself, if earnest in the pursuit of his calling, the plan was not without its advantages, for by the time he came to be a teacher of the highest and most important branches—clinical medicine or surgery—he could not fail to be a well-informed man, of a wide acquaintance with the literature of subjects which otherwise would, in all probability, have been closed to him. But it is the Student we should consider; and assuredly this system is not the best for him. It is the day-dream of some men that they will one day see one or two great schools started in London for the education of the student in theoretical knowledge, leaving to the hospitals the more practical work in medical education. This we fear we shall not see, though there can be no doubt that such a system would be advantageous to the student; but mutual jealousies are not likely to allow such a scheme to be consummated, and meanwhile we must do the best we can with the materials and means at our disposal.

The basis of the present system of medical teaching consists of lectures, so many of which, as a rule, the student has to attend before he can be what is called "signed up." Now here in the teacher's hands is a powerful instrument, if he cares to use it. He is always sure of an audience, and an audience worth studying. Few can be so critical as medical students; none make better listeners if they have anything worth listening to. The first point, we take it, in the making of a successful teacher is to be able to carry his audience with him—if possible, not to leave a single laggard behind. Now, if a man's attention is fixed on a piece of paper or a book, he cannot see whether he is doing so or not; therefore we counsel all young teachers to acquire, at whatever expense of time and trouble, the faculty of extempore address. The time and trouble so spent are but capital placed out at interest, which later time will amply repay. This, too, we may say for the encouragement of young lecturers: that if they consider those who are now the lights of the profession, whose even-flowing discourse is listened to with greedy ears and envious hearts, they have only attained to their present pre-eminence by the assiduous cultivation of their talents in a like manner. We could mention the names of many high in our ranks who even now never make an appearance in public without a careful rehearsal of what they have got to say, and to this secret do they owe their success as public speakers. Let, therefore, all young teachers begin in the same fashion. Let them never attempt a lecture without careful preparation—even, if necessary, commit it to memory; and the habit so begun will speedily fructify, and bear good fruit. Unfortunately, it is too true that some men will never make very successful teachers; their material may be quite as good as another's, but faults in manner and style of delivery—still more, a want of sympathy with their audience, always promptly responded to—incapacitates them for the work of teaching. Nevertheless, much may, by persistent effort, be done with even the most unpromising materials; and the story of Demosthenes must be encouraging to even the most backward.

Next, as regards the lecture itself. Too often it is looked upon both by teacher and student as a disagreeable thing, to be got over as speedily as possible. The driest of material is dished up in the most unpalatable possible manner, with the most chilling effect upon the student; nevertheless, it is a fact that students can be got to listen eagerly to the driest material if the teacher only throws a little life into it. Again, too frequently the student listens to exactly the same material served up very likely in a worse style than he reads it at home in his text-book; under such circumstances it is hardly in human nature to listen with patience to a lecture which is practically a waste of time. For the lecture should ever contain something not to be found in the text-book, if it be only comment and explanation of it. In point of fact, in many subjects it is not a bad plan to select a book, to tell the student "Here is a volume which contains the essentials of my subject: make this your text-book, and I shall take it for granted in my lectures that you have done so, for they will consist mainly of explanation, comment, and development of what is therein contained." But lectures can always be made a better means of teaching than text-books, if the teacher will only try to make them so. First, there is the living speaking to the living—the powerful influence of the *vivâ vox*, which allows of amplification, illustration, and reiteration until a subject is thoroughly mastered. This cannot be done in a book without making it horribly tedious, and so the only resource the student has is to read and re-read till he has or has not mastered any given passage. It is for this reason that a lecture which

seems so eloquent when addressed to the ears, is so bald and disjointed when addressed to the eye in print. Lectures, as we have said, are the basis of our present system, be it good or bad; by all means, therefore, let us make the best of lecturing. Much has been said in favour of the tutorial system as compared with that of lectures; but in truth there is no antagonism—the two can readily be combined, and always are so by a skilled teacher. An hour is too long to devote to lecturing alone, and the attention of the student flags before it is over. This is not an invariable rule, but is so in most instances; an exceedingly good plan, therefore, is to devote a certain portion of the hour to an examination, either as to what has just been said, or what was said a day or so before. This admits of explanations being given, the necessity for which might never have been thought of save for the examination testing the students' ideas of what has been said; for what a man means to say, and the effect of what he does convey to another, are two very different things. There can be no doubt of the efficacy of this plan in teaching.

But when all is said and done, we must come to what is at once the basis and the crown of English teaching—that is, ward work. It is generally admitted that our clinical teaching here in London is not what it ought to be; and the reason is probably this,—that a successful clinical teacher is generally also a successful practitioner, and so has his attention abstracted from his hospital duties somewhat too freely. Again, men only come into the possession of wards and clinical beds when they are somewhat advanced in life, when they have less time and inclination for such work than they would have as younger men. It is highly desirable that the younger men should have a chance of doing something in this way as early as possible, and therefore the plan of giving up a certain number of beds to the junior officers for the purpose of teaching and study, as is done in some hospitals, is very highly to be commended.

Nevertheless, it has seemed to us in our experience of hospital teaching, especially of clinical medicine in London, that there is too much show and too little substance in it. Too frequently the process of education consists veritably in what used to be called "Walking the hospitals." The physician or surgeon goes round with a troop of students at his heels, hears the report of his house-physician or house-surgeon, asks how the patient's bowels are, how he slept last night, and how he eats his food; looks at his tongue, feels his pulse, and, if he be of a scientific turn, inquires what his temperature was last night and this morning; perhaps says a word to the students—tells them it is a case of dropsy or an interesting specimen of paralysis,—and goes on. But this is not teaching, and the student can hardly be blamed if, with such a system, he does not learn. Too often, again, we have observed, when there is something more earnest in the way of teaching, that the teacher thinks more of himself than he does of his pupils—he has little crotchets to air, little points of controversy to settle in his own favour, but he does not strive earnestly to master the case before him, and to convey that masterful knowledge to his pupils. The true teacher is altogether forgetful of self, and strives only to improve his pupils' knowledge.

Among the successful leading clinical teachers in London two different plans are pursued. One man goes round his wards dealing with case after case, questioning his pupils, and testing in every way the accuracy of their knowledge; another, instead of dealing with half a dozen cases, sticks to one only, and goes into that thoroughly—sometimes only taking up one particular feature in a case, for even the mechanism of diagnosis has to be taught and learned. No doubt this is drudgery, but it is very essential; and whilst leaving to the great masters and teachers of our art and science the higher flights of eloquence, and a display of acumen which requires a grasp only to be acquired by years of experience, any man can begin with the other, and so endeavour gradually to attain to the knowledge and power which will justify him in endeavouring to imitate the great exemplars of our profession.

But we have a much more serious word to say to our young teachers before we close. Too often we find that when the diagnosis is made and written down, the process of educating the student stops till perhaps the diagnosis comes to be verified post-mortem. This should not be. We are not paid to study disease, but to try to cure it; and though an accurate diagnosis is very important, it does not greatly help the patient. We should teach the student how to treat disease, as well as how to recognise it. Now, the student's knowledge of therapeutics is generally very unsatisfactory, and his knowledge of materia medica even more so. Nowadays, when there is no apprenticeship to teach men to handle and recognise drugs, it is even more incumbent on hospital teachers to attend to prescribing than it used to be. They should teach not only what drug is best in such-and-such a case, but also what is the best form in which to administer it. True, this requires an accurate knowledge both of materia medica and pharmacy—departments of knowledge it is too much the fashion to decry, but which are very necessary, if we are to become expert prescribers, skilled in the art of treating diseases, and still more so if we are to teach the same art. In this respect, however much we may have improved in others, we are not in advance of our forefathers as far as regards the rules for prescribing. We have seen nothing in recent days which at all comes near those laid down more than a century ago by Gaubius.

THE MEDICAL USES OF ELECTRICITY.—No. III.

Therapeutical Use of Electricity.

Having treated of the value of electricity in diagnosis, we now proceed to speak of its value and use in the treatment of disease. That, when opportunely and rightly employed, it is a means of great power and real value in the treatment of a considerable range of disease, is now fully and clearly proved. But as we have already observed, but few comparatively of our brethren are well informed as to its ascertained remedial properties or as to the limits within which (so far as we at present know) it may be usefully or safely employed. Many undervalue its therapeutical power, while granting that it does possess some; others doubt whether it has any; and others disbelieve in it altogether. And, again, some as greatly overestimate it, expect far too much from it, and credit it with the power of effecting absolute impossibilities. But though electricity cannot renew nervous tissue, and therefore cannot cure a paralysis caused by destructive cerebral or spinal lesion; and though it cannot restore muscular power where a muscle has been entirely cut off from the influence of the brain or the spinal cord, or when the muscular fibres are wholly degenerated or atrophied; yet when the right kind of electricity is employed, and rightly applied, we can by its help cure, relieve, or arrest disease. We can soothe or stimulate diseased or disordered muscle and nerve; we can cure or relieve over-action (spasm) and pain (neuralgia); cure some forms of aphonia, and of peripheral paralysis; renew the nutrition of muscles wasting from disease; restore the circulation and raise the temperature of a paralysed limb; and recall or lower sensation. And, though it is not any part of our intention to enter into the field of surgery, it is also known that the surgeon has successfully employed electricity to coagulate the blood, to disperse tumours, and for other purposes. It will be well, also, to state here that while it is our intention to confine our observations to the therapeutical uses of electricity in medicine as distinguished from surgery, we shall not attempt to describe fully or in much detail the medical uses even of this agent: any such attempt would demand far more space than can be given to these papers. Our purpose,

let it be remembered, is only to point out the affections in which the power of electricity to cure or to relieve disease has been most clearly and indisputably proved.

First we will treat of its use in relieving or curing pain.

Its therapeutic value in this respect is invaluable, and has been established beyond the possibility of dispute or doubt. In all the true neuralgiæ, and especially perhaps in the very worst of them—the most terrible and savagely intense of all painful affections,—electricity rightly chosen and applied displays often a remedial power not only unsurpassed, but unrivalled by any other known means. But this use of it is not so generally known or understood even yet (among us, at least) as is its employment in the different forms of paralysis. And the reason of this is perhaps not far to seek. Duchenne was the apostle of faradisation, Remak of the constant current; and the teaching of Duchenne has always been more accessible to, and better known by, the mass of the profession than has been the teaching of the German school. Moreover, Faraday was the discoverer of the induced electric current, and that fact has also not a little helped to make faradisation more popular and better known with us than the constant current; consequently it came about that for a long time it was generally believed in this country that the rotatory electro-magnetic, or magneto-electric machines, were sufficient for all electro-therapeutic purposes; and, indeed, very many of our brethren still suppose that this is the case, and when they have obtained one of these machines believe that they are fully equipped for the remedial employment of "electricity." But it is absolutely certain that in the treatment of painful affections the constant current has a far wider usefulness and a far higher value than faradisation has; and we suspect that even the strongest believers in faradisation will allow, with Dr. Beard, of New York, that in the treatment of true neuralgia "the galvanic (*i.e.*, the voltaic or constant) current will oftentimes succeed where the best faradic fails, and even in those cases where faradisation relieves, and promises to cure, galvanism may do the work in a much shorter time."

In some painful affections, and some that are often improperly called neuralgiæ, faradisation is undoubtedly of great use; but in the neuralgiæ proper the constant voltaic current is almost always the form of electricity which ought to be employed, both the electrodes being firmly pressed upon the skin and held there, neither of them being moved about: that is, the current must be the voltaic, and must be *constant*, not interrupted; and the electrodes must be applied so as to include in the circuit the affected nerve. As to the number of the cells employed, this must be regulated by the sensations of the patient, and according to the region affected; they should be as many as can be borne without pain or serious discomfort; and in the face five cells will be fully enough to begin with. In this part fifteen or twenty cells will most likely be the highest power that can be borne or safely employed, the application being discontinued for a while and the number of cells reduced whenever any giddiness occurs. Elsewhere a higher power may be used. Whether the doctrine that in true neuralgia the posterior root of the nerve is the seat of disease be accepted or not, it is, we suppose, generally held that it is best to place one of the electrodes as nearly as may be over the point of origin of the affected nerves, and the other over the painful spot; or, should there be more than one painful spot, then over the several spots in succession. The direction of the current has by some been considered of importance, and directions have been given to apply always the positive electrode to the seat of disease; but the necessity for this is not clear; and some experts are convinced that the direction of the current—whether it should be ascending or descending—is not therapeutically a matter of any importance whatever. The electrodes should be furnished with well-wetted sponges of large size, and the application be made for short periods—about five minutes,—and repeated oftener than once a day if necessary.

Cases of neuralgia of the most intense character have been not only rapidly relieved, but permanently cured by this means. Niemeyer's two cases are perhaps the most striking. Dr. Anstie, in quoting them, observes—"The patients were respectively aged 64 and 74, and the duration of the neuralgia had been respectively five and twenty-nine years; in both the pain was of the most severe type, and in both the success was most striking. In one, every possible variety of medication and several distinct surgical operations for excision of portions of the affected nerves had been quite vainly tried." Such brilliant success as this is not always to be expected; but many very striking cases besides have been recorded. Dr. Russell Reynolds has mentioned the case of a lady who for twenty years had suffered from very severe neuralgia of the ophthalmic branch of the fifth nerve, recurring every day, and greatly injuring her general health, and which was not merely relieved, but removed, by a single application of the constant current. Dr. Althaus, also, has published the case of a lady who for twenty-five years had suffered from most violent neuralgia on the left side of the face. Three applications of the constant current from four cells of Bunsen's battery were, he says, "sufficient to cure her of a disease which for twenty-five years had embittered her life."

While all the best authorities on the use of the constant current agree in estimating very highly its remedial power in neuralgic affections, they vary in their experience of its value in the different forms of this disease. Thus, Eulenberg, whose experience has been very large, thinks very highly of it as a palliative in trigeminal neuralgia, but rather doubtfully as a curative; while Dr. Anstie credits it with more of a curative power. And while Eulenberg has found sciatica the most curable of the neuralgiæ by this means, Dr. Beard has had least success as to *cure* in this form of neuralgia, though he has generally obtained *relief*. His experience leads him to consider gastralgia as more amenable to the constant current than the other remedies.

In migraine, or true sick headache, the constant current has been found very beneficial, the electrodes being applied to each temple or to the mastoid processes. A very low power must be used, two or three cells. The application must not be for longer than about sixty seconds, and it must be discontinued on the occurrence of any giddiness, or if the patient exhibits any symptom of uneasiness in the head or the epigastrium. In all the true neuralgiæ, then, the diagnosis having once been clearly made, the constant current is the form of electricity to use; and used rightly, so as to act gently and steadily, without exciting pain or other nervous disturbance, it may be employed fearlessly and with immense advantage.

This kind of electricity has also been successfully employed in toothache. M. Bouchaud states (*vide Bulletin Général de Thérapeutique*, July 15)—"If in odontalgia we employ a continuous or constant current, derived from a mean of ten elements, applying the positive pole to the cheek on a level with the painful tooth, and the negative pole to the anterior lateral region of the neck, we are enabled almost always in the course of a few minutes to procure nearly absolute relief, which in the majority of cases persists indefinitely." M. Bouchaud's paper on the subject is well illustrated by cases; and he has found the constant current useful even when the teeth were carious and the gums inflamed and swollen.

If for any reason it is determined to apply the faradic current in neuralgia—and sometimes it is beneficial—the rough coarse current supplied by a rotatory magneto-electric machine should not be ventured on, but the most gentle and steady current of this kind derivable from a volta-faradic apparatus. In some painful affections, however, faradisation may be

employed, not only usefully, but with much greater advantage than the constant current. Such are the pseudo-neuralgiæ called "hysterical," and the hysterical hyperæsthesiæ. In these affections it is desirable or necessary to excite pain, and the ordinary rotatory machines will serve for the purpose. The current must be used to affect the skin only, not to penetrate deeper; the skin must therefore be carefully *dried*, and dry metal electrodes used—one being placed on an "indifferent spot," and the other moved about over the affected part; or, the patient holding one of the brass handles of the machine, a coarse wire brush may be applied over the affected region.

THE ASHANTEE WAR.

Bravery and a somewhat foolish contempt for the enemy have brought about the serious *contretemps* the particulars of which have just reached us from the West Coast of Africa. Commodore Commerell and his boats' crews have been entrapped in an artfully-planned ambuscade, and appear to have been shot down by a perfect broadside of slugs at a distance of something like fifteen yards. The great wonder is that, considering the unprepared and defenceless state of the little expedition up the river Prah, the boats ever got back with anybody alive on board to tell the tale.

Unfortunately, it is not only the long list of killed and wounded which we have to deplore in this disaster; the savage mind on the Coast will immediately consider the Ashantees invincible, and those allies who are expected to swell our ranks will be considerably diminished in numbers by this occurrence. We suppose, however, that those persons who have all along considered that there existed no necessity for punishing the invasion of our territory, will now admit that there is but one course to pursue, and that is to read all the various tribes along the Coast a lesson so severe that peace shall remain unbroken for years to come.

Sir Garnet Wolseley, with a brilliant staff, has already sailed for the seat of operations, and it would appear, from recent announcements, that it has been decided to despatch two regiments from this country to act against the Ashantees, which will be embarked from Ireland about the beginning of December. The corps selected are said to be the 2nd battalion of the 23rd Regiment and the 2nd battalion of the Rifle Brigade: these will form the nucleus of a force, to be supplemented with native troops, and it is sincerely to be hoped that too much dependence will not be placed upon our coloured allies, since it must not be forgotten that at heart they are infected with a standing dread of the powerful and bloodthirsty king against whom they will be called upon to act.

We presume that the authorities have duly weighed the exigencies of the forthcoming expedition, and are prepared with some plan of action founded upon ample and superior knowledge of the locality to be traversed; otherwise the contradictory and dolorous letters which have been daily published in the columns of the leading journal would prognosticate nothing but disaster for our arms. It must not be forgotten, however, that similar gloomy forebodings were rife before the commencement of the Abyssinian campaign, with how much reason the complete and satisfactory results therein obtained fully demonstrated.

We should certainly have thought, looking at this subject from the principal point in which we regard it—the sanitary—that it would have been better if the Government, instead of sending men from this country, had diverted two of those regiments from India whose term of service there had expired, and who about the month of December would be coming home in the India troopships. The men of these corps would be to some extent acclimatised by long residence in a hot climate; the vessel transporting them could have been ordered to proceed round the Cape of Good Hope, and, if the hostilities are to be of such short duration, could have waited and brought them on to England after the work had been achieved. As it is, every precaution will be taken before despatching the two regiments from here. No man will be allowed to embark unless in the most satisfactory state of health; and the whole of them should be revaccinated. Another man-of-war will be sent out to act as a hospital-ship off Cape Coast Castle, in addition to the *Simoom*, already on the spot. A large medical staff will be provided for the treatment of the sick, and full supplies of all medicines and medical comforts necessary. Nor is all this forethought and preparation unnecessary, for it would appear that the present rainy season has been peculiarly pestilent and terribly fatal to Europeans; but, with a perfect knowledge of the deadly climate in which the operations must be carried out, nothing which could prevent or alleviate sickness will be omitted; and—given the necessity—surely England should be better prepared in the present day than in former times to assert her prestige upon any portion of her vast dominions.

An opinion appears to be generally disseminated that the present trouble might have been averted if the grant of a seaport had been made to the Ashantee king; but whatever concessions may eventually be made in this matter, it should be borne in mind that treaties, to be of lasting use, can only be entered into *after* we have read the enemy a lesson which he is not likely soon to forget. Anyone who has had dealings with savage tribes will admit that to hold our hands now would be construed by the Ashantees as an admission of our weakness, and very few years would elapse before the feud, thus patched up, would burst forth again. In fact, this last attack upon our arms in the river Prah removes all possibility of negotiating, and until Sir Garnet Wolseley has fully carried out the duties entrusted to him, we must make up our minds that many lives and some treasure will have to be expended; and if, as is apparent, little honour is likely to accrue from the most successful achievements, we must remember that, so long as we profess to extend our protection to the settlements which we have founded and fostered on the West Coast of Africa, so long must we be content to expend both blood and money to secure safety for our settlers and respect for our name when the disagreeable but enforced necessity arises.

THE WEEK.

TOPICS OF THE DAY.

On the 8th inst. Professor Hughes Bennett, of Edinburgh, was elected Corresponding Member of the National Academy of Medicine of France. He received twenty-eight votes, and Professor Van Benedin eight.

We regret to observe that Dr. Charles F. K. Murray, Surgeon to the *Rattlesnake*, is amongst the wounded in the disaster on the river Prah. Dr. Murray's injury is reported as "contusion of the left forearm from gunshot; slightly." In reference to Dr. Charles Murray's services in the unlucky action, Commodore Commerell, in his despatch, writes—"Surgeon Charles F. K. Murray had paid the greatest attention to them (the wounded) while in the river, besides returning the fire of the enemy from the boat (the whaler, manned and armed, which had been placed under Dr. Murray's command) he was steering."

The annual meeting of the Pharmaceutical Society has been held at Bradford this week. The President is a Mr. H. B. Brady, of Newcastle. In his address he made some remarks upon the endeavours made by the Home and Foreign Governments to produce the cinchona alkaloids. He said—

"Few subjects had been so frequently before pharmaceutical readers during the past ten or fifteen years as the efforts of

the Governments of Holland and Great Britain to introduce the various species of cinchona into their respective colonies. It would be hardly possible to overrate the importance of the enterprise, and it was one which interested alike the pharmaceutist, the botanist, and the votary of economic science. The latest official return placed the number of trees in cultivation in the island of Java at two millions. Plantations in Ceylon and Jamaica were reported to be prospering. The pet idea of the Indian Government, to manufacture on the spot a preparation supposed to consist of the crude mixed cinchona alkaloids, to sell at a very low price, was one which could not be regarded with much favour. Any such product, however carefully made, must be of very uncertain composition, and, as is well known, samples which have reached this country have even contained poisonous metallic impurities. If cheap alkaloids are required, red bark will yield cinchonidine, the value of which as an antiperiodic is now well ascertained, and many species give cinchonin cheaply enough. But surely it were better that Government should confine its attention to providing the material, and leave it to those who have larger technical knowledge and practical experience to supply the low-priced alkaloids they desire."

He also expressed himself as dissatisfied with the standard of the Pharmaceutical Society's examinations, and said that the possession of its certificate was not a sufficient guarantee of the possessor's fitness to perform such scientific duties as those devolving on public analysts. We quite agree with him in the latter conclusion, but we cannot recognise in this a reason for increasing the stringency of the examinations of the Pharmaceutical Society. These tests are already quite sufficient to insure the fitness to dispense medical prescriptions and sell drugs of those who are subjected to them. Any higher scientific aim seems to us beyond the scope of the purpose for which the Society was instituted.

A Mr. R. Hampson read a paper, in which he recommended that medical men prescribing unusually large doses of medicine should specially append their initials to the dose. The paper seems to have been written in consequence of the recent inquest at Ramsgate, in which a druggist did not dispense the prescription for large doses of digitalis ordered by a duly qualified medical man, and the patient died of delirium tremens. There could be no objection to such a rule if it were made universal; but, usually speaking, the signature at the end of the prescription must be held a sufficient guarantee for its contents, and in case of doubt arising we think the dispenser is bound to place himself in communication with the prescriber.

A woman named Amelia Hopkinson has died at Hanwell, after being removed there from St. Pancras Workhouse, contrary to the order of Dr. Hill, the resident medical officer. It appears that the woman was also seen by a Mr. Bastable, an independent medical practitioner, who gave the order for her removal. We agree with the coroner's jury who investigated the case, that it is to be regretted "that Dr. Bastable did not more fully acquaint himself with the state of the said Amelia Hopkinson by consulting with Dr. Hill; and they are of opinion that in future the certificate of fitness for removal would be more appropriately taken from the surgeon in daily attendance than from the surgeon who had only seen the patient to certify as to her state of mind." When two medical practitioners are in attendance on a case of insanity, the order for removal to an asylum should not be made without the consent of both. In case of difference of opinion a third should be consulted.

We understand that as many as sixty applications from this country for medical appointments in the Atchinese expedition have been received by the Dutch Government; but, so far as we know, at present the services of only two Englishmen have been accepted. These are Dr. Charles Mayo, Fellow of New College, Oxford, formerly Director of the Alice Hospital, Darmstadt; and Mr. J. C. Galton, M.A., M.R.C.S., formerly staff-surgeon in the same Hospital. These gentlemen leave England on Saturday next, the 27th instant, at the latest.

ILLNESS OF MEDICAL PRACTITIONERS.

It is with deep regret we announce the serious illness of two distinguished *confrères* of the Irish School of Medicine. Professor Robert W. Smith, of the University of Dublin, and Dr. Robert Law are both stricken down by disease—in each case of a very serious character indeed. To the last-named gentleman's illness we have already had occasion to refer. He was slowly rallying from an attack of cerebral hæmorrhage, when, on Saturday night, the 6th inst., a second attack occurred.

OLD FRIENDS WITH NEW FACES.

Our forefathers were wont to burn tar and naphtha, and make great fires of wood and coal, and burn sulphur, as a means of disinfecting and purifying the air in times of great plague and sickness; and our foremothers (if we may use such a term without disrespect) set great store by lavender and rose-leaves and rosemary and divers aromatic herbs, chiefly of the labiate order, which they kept in their rooms, their linen-presses, wardrobes, cupboards, drawers, and boxes. We younger folks have, perhaps, too quickly condemned these practices as foolish and unmeaning. Chemists have long taught us to recognise sulphurous acid, produced whenever sulphur is burnt, as a powerful disinfectant. Carbolic acid, found in tar and produced by the combustion of wood and coal, is also one of our most popular antiseptics. But there seems little doubt that we may carry our vindication of our ancestors and ancestresses a little farther, and claim for their sweet herbs and fragrant things a higher use than the doubtful one of ministering to the pleasure of the olfactory nerves. Dr. Day, of Geelong, has shown that many substances of the hydrocarbon group, ether, kerosene, naphtha, turpentine, and many tinctures slowly develope peroxide of hydrogen by exposure to light and air. Now, all the labiate family, and nearly all the odorous substances the men and women of old times were partial to—the ingredients of their pots-pourris and scent-vases—contain hydrocarbons which acquire this very property of absorbing oxygen and developing peroxide of hydrogen which Dr. Day thinks to be identical with the antozone of Schönbein. In his first communication to the *Lancet* (in 1864 and 1865), Dr. Day imagined that ozone was thus generated, but further experiments, and particularly the reaction with guaiacum resin, have convinced him that these hydrocarbons generate or acquire antozone, or, in other words, the peroxide of hydrogen. In a paper read before the Medical Society of Victoria on June 4 last, and published in the *Australian Medical Journal* for June, 1873, Dr. Day carries his investigations a step further, and recommends strongly the use of papers, muslins, and other textile fabrics soaked in kerosene, gasoline, benzine, and paraffin, etc., which have been thus exposed to the air. But the most interesting part of this communication is first the indirect evidence of the remarkable immunity from disease enjoyed by workers in petroleum, furnished by Dr. Berry White, Assistant-Surgeon in charge of troops, and Civil Surgeon, Dibrooghur, in reference to Makoom, in Upper Assam, where there are petroleum works, for the details of which we must refer to our Australian contemporary; and secondly, the fact referred to by Dr. Day, of the remarkable permanency of the hydroxyl or peroxide of hydrogen formed in this spontaneous way—some of the sheets of paper having been prepared seven or eight months before, and still giving the reactions of this substance. Dr. Day gives the preference to gasoline, which is almost identical with benzine. He also uses ozonic ether (such as Robbins, of Oxford-street, prepares, which is really a solution of peroxide of hydrogen) in the proportion of one part to eight of lard, in cases of scarlatina, as a means of preventing the spread of that disease. The use of lard or sweet-oil for that purpose has long been popular in England, in measles as well as scarlatina; but if it can be shown that the ozonic ether

and lard can be kept combined sufficiently long, we think Dr. Day's ingenious plan a decided improvement. Dr. Day informs us, by letter, that fresh animal fats, lard, and suet, often contain in their natural state peroxide of hydrogen, loosely combined, which can be demonstrated by manipulation and appropriate tests. One of the Victoria speakers, Dr. Jonasson, thought there might be danger in the use of petroleum papers, on account of their giving off inflammable vapours, but even supposing this to be so, the risk seems to us to be very easily guarded against.

CHOLERA ABROAD.

By the courtesy of the Medical Department of the Local Government Board, we are enabled to publish the following official information respecting the progress of cholera abroad up to September 6:—

		Cases.	Deaths.
Prussia—			
Königsberg (government)	June 22 to Aug. 9	892	352
„ (town) ..	Aug. 14 „ Aug. 20	303	120
„ „	Aug. 21 „ Aug. 27	345	150
Gumbinnen (government)	July 2 „ July 31	13	10
Danzig „	June 2 „ Aug. 8	573	323
Marienwerder „	May 22 „ Aug. 8	1540	854
Brandenburg—			
Berlin (town)	July 21 „ Aug.		
Potsdam (government) ..	July 16 „ Aug. 1	55	41
Frankfort „	July 9 „ Aug. 3	41	24
Pommerania—			
Stettin (government) ..	Aug. 3 „ Aug. 8	41	24
„ (town, police dist.)	Aug. 4 „ Aug. 19	31	23
Posen—			
Posen (government) ..	July 27 „ Aug. 9	100	51
Bromberg „ ..	May 26 „ July 31	559	351
Saxony—			
Magdeburg (town) ..	July 18 „ Aug. 7	214	91
„ (rest of government)	July 18 „ Aug. 7	21	9
Schlesien—			
Breslau (government) ..	June 28 „ Aug. 12	147	78
Oppeln „ ..	June 11 „ July 20	182	103
Hanover—			
Landderstein Luneburg .	Aug. (?) „ Aug. (?)	85	57
Munich—			
Aug. 30.—Cases average from 45 to 50 daily.			
Vienna—	Aug. 22, 23	83	52
	Aug. 23, 24	184	81
Warsaw—	May 18 to Aug. 17	1553	556
	Aug. 1 „ Aug. 15	1111	410
Disease general throughout the kingdom; particularly prevalent in the valley of the Vistula.			
Pesth—			
Buda-Pesth	Aug. 13 to Aug. 19	477	215
„	Aug. 20 „ Aug. 26	367	189
Disease very severe over almost the whole extent of Hungary.			
Cronstadt—			
Aug. 26.—1 death (a British sailor) in port.			
Riga—			
Aug. 25.—Several cases among shipping.			
Memel—			
Aug. 19.—4 cases reported.			
Hamburg—	Week ending July 26	26	19
	„ Aug. 2	104	49
	„ Aug. 9	206	113
	„ Aug. 16	213	155
	„ Aug. 23	175	
Antwerp—			
Aug. 7.—Isolated cases.			
Havre—			
Sept. 2.—Cholera first reported as probably present here on August 19; now stated to be undoubtedly present in the port, at Rouen, and at intermediate points between that town and Havre.			
Italy—		Cases.	Deaths.
Genoa, Aug. 19.—Cholera in very mild form in city.			
Venice—City	July 8 to Aug. 18	641	356
Province	Aug. 18	26	20
Trieste—	July 25 „ Aug. 13	63	19
Brescia—Province	Aug. 17 „ Aug. 23	20	12
Parma— „	Aug. 17 „ Aug. 23	38	28
Reggio d'Emilia—Province.	A few cases.		
The Danube—			
Ibraila	Aug. 4 to Aug. 19	162	101
Galatz	Aug. 8 „ Aug. 22	101	70
Ismail	Aug. 6 „ Aug. 16	6	6
Reni	Aug. 5 „ Aug. 16	12	7
The Principalities—			
Bucharest, Aug. 22 ..	July 7 „ Aug. 20	5079	1720
Bulgaria—			
Rustchuk, July 30.—Scattered.			

ASSOCIATION OF FACTORY MEDICAL OFFICERS.

An advertisement which appeared in this journal on the 6th instant was addressed to those members of the profession holding appointments as factory certifying surgeons throughout the United Kingdom, calling them together to a meeting at Leeds, to be held on the 19th of the present month. This body of medical men now numbers nearly or quite a thousand; and although they do not come prominently before the public in their official capacity, they yet exercise most important sanitary duties wherever manufacture is carried on. In several articles published in this journal a few months since we drew attention to the purpose of the factory laws, and to their administration; consequently we have no present intention to repeat the information conveyed in those papers, but only desire to incite all factory medical officers to associate themselves together for the protection, not only of their own interests, but also of those of the working-classes, who would suffer by any diminution or withdrawal of the medical organisation provided by the Factory Acts. If official wishes could be realised the medical duties required would be dispensed with, and those now called upon to perform them would find themselves speedily disestablished and disendowed. Witness the latest utterances from the Factory Office, of which the following has no uncertain sound:—"I am bold to say that the provisions of the Factory Acts can be carried out unaided by medical men." This is no novel declaration, as reference to reports of former years will make clear, and it therefore might seem unnecessary to call upon those concerned in the matter to be up and doing in order to contradict this bold assertion, and to make good their position and usefulness in the eyes of the public, were we not cognisant of much inertness among many, accompanied by something akin to timidity towards those in "brief authority."

ZYMOTIC DISEASES IN MELBOURNE.

The correspondent of the *Times*, writing from Melbourne under date of July 17, states, "An outbreak of puerperal fever, the first of its kind, carried off five patients from the lying-in hospital in as many days; about twenty deaths soon followed from the severe epidemic in other localities, and there was a wide-spread feeling of alarm, which has now ceased with its cause. There has been a coincident prevalence of diphtheria, scarlatina, and hooping-cough."

TYPHOID FEVER IN THE NORTH.

Typhoid fever is very prevalent in the district of the Rhymney Valley. There have been many cases at Tirphil, New Tredegar, Cwmsyfioch, and the Darran, and several have proved fatal. Two medical gentlemen are prostrated with the fever, having caught the disease in the discharge of their duties.

FEVER AT BRENTFORD.

This comparatively insignificant town has been recently brought into considerable notoriety by the accounts published in the daily papers of the prevalence of scarlet fever in the town. The brewery situated on the banks of the river, about the centre of the town, is that which has hitherto made this town what it is. We have instituted an inquiry into the sanitary condition of the town, which will, we think, reveal a state of incompetence on the part of the local authorities which is lamentable in the extreme, and should, for their own sakes, be made as public as possible. It is the more incumbent upon the authorities to make a searching inquiry into the condition of this town for the double reason of its suburban situation, and of its connexion with the proposed main drainage scheme. Application has been made by Mr. Montgomery, one of the local magnates, to the Local Government Board, for a special inquiry to be made by one of their inspectors. This request has, we understand, been granted, and will be published shortly. In the meanwhile we have sent down our Special Commissioner, and he reports as follows:—"It is not surprising that such towns as Richmond and Brentford should have delayed so long in effecting the much-needed reform for the disposal of their town sewage. Provided with a natural outlet for their excrementitious products so simple and so comparatively safe to themselves (because so much less influenced by the tidal back-flow than towns nearer the metropolis), it is of little importance to them how they pollute the river for their neighbours lower down, so long as they are saved the necessary outlay for the construction of a more complete system of drainage. The delay of the Thames Conservators and of the Metropolitan Board of Works to compel the towns situated on the Thames to remedy this grievance is most culpable, for to it may probably be traced the cause of the present epidemic. While they are discussing plans for the construction of weirs, with the idea of promoting a more rapid and efficient scour of the bed of the river, fever nests are cropping up in every direction from the very rapid increase in the population of towns where drainage is a very secondary consideration." Our Commissioner called upon Dr. Davies, one of the leading practitioners of the town, who informed him that, while no doubt the town was in a very backward state with regard to efficient measures of sanitary reform, they were for that reason the less able to combat with an extraneous source of pollution derived from the contamination of a small stream flowing in an open ditch through the centre of the town. Our Commissioner made inquiries at all the houses situated on the banks of the stream above mentioned, from General Scott's works at Ealing down to the river Thames, as also in some of the most densely populated parts of the town, and the conclusion he arrived at was as follows:—In one house only out of about fifty visited on the banks of this small stream had scarlet fever prevailed, and in this case other sources of contamination were probably present. The house in question, though situated close to the stream, was the last of a row of about twelve cottages, all of which drained past this house into the stream; but the floods which have prevailed of late served one important purpose, for this common drain burst open, and it was then found that the outlet into the stream was blocked up; so that, although too late to remedy the evil (three of the occupants' children being ill with the fever), a very fruitful source of malaria was now revealed. The town itself, with a population of over 10,000, is in a most unsatisfactory state. It is situated on a narrow strip of land, between the river on the south and the railway on the north side. From the main street, which passes through the town, several small courts and alleys lead up to densely packed hovels, in many of which typhoid, scarlet fever, and intermittent fever abound. The stream above mentioned conducts the Ealing sewage (after precipitation according to the lime process of General Scott) under one of the most densely populated parts, and empties itself into the Thames. The epidemic of scarlet fever, although probably aggravated by this foul open drain, does not appear to have been directly caused by it. It seems, however, clearly wrong on the part of the Ealing authorities that they should attempt to justify their own source of pollution by diverting attention to other sources of contamination. On the other hand, it would be difficult to find a town in a more disreputable state than this, both as regards water-supply and drainage. The Grand Junction Waterworks are close at hand, and yet the water supplied to the town is in many cases most objectionable. Many of the inhabitants, rather than drink that which is supplied to them, purchase water brought in carts from a neighbouring spring. Notwithstanding the natural outlet provided for the discharge of excrementitious matter, cesspools are to be found in all the older parts of the town. According to the latest information, it appears that Mr. Montgomery, one of the local magnates, who instituted the inquiry in the first instance, admits that the sanitary state of the town is most defective; and he is probably right in considering that the present epidemic has been aggravated by the effluent water contaminated with the Ealing sewage passing through the centre of the town.

TYPHOID FEVER IN WOLVERHAMPTON.

We regret very much to find that the epidemic of fever in this town has proved fatal in about six of the cases attacked, and that the Rev. George Everard has lost three children from this cause. The origin of the disease has been clearly traced to milk contamination. No new cases of typhoid have occurred during the past few days. The local authorities are carefully carrying out a system of sewer disinfection, and they expect by this means to check the progress of the epidemic. Probably as soon as the dairyman's pump is sealed up the epidemic will cease altogether.

CHANGES IN THE ARMY MEDICAL DEPARTMENT.

We stated last week (says the *United Service Gazette* of the 13th inst.) that some reduction in the *personnel* of the Army Medical Department was under consideration. "We were not then in a position to communicate the intention of Mr. Cardwell, but we learn now that about thirty-five places in the surgeons' list are to be abolished. This will be only the commencement, however, for the scheme is to extend the plan which obtains now in outlying places in the colonies, of employing surgeons in private practice when economy shows that such would be more advantageous to the public purse than stationing an army surgeon at the place where there are but few troops. The chaplains' department is formed and worked on this principle, we think, and that it is which Mr. Cardwell and his advisers are thinking of following with the Army Medical Department." We can only say that up to the present we have received no intimation of the changes announced by our contemporary, but we will endeavour to ascertain the correctness of the intelligence for the benefit of our numerous readers whom it may concern.

ARMY MEDICAL OFFICERS FOR THE GOLD COAST.

Surgeon-Major Jackson (of the 100th Regiment) and Surgeon Atkins have volunteered for service on the Gold Coast, and have already sailed with Sir Garnet Wolseley; and Surgeons Saudford Moore, M.B., and J. H. Moore have also volunteered for the same service, and embark this week for Cape Coast Castle.

A FLOATING EPIDEMIC-HOSPITAL FOR DUBLIN.

At last a decided step in the right direction has been taken by the sanitary authorities—the Board of Guardians of the South Dublin Union, to whom the Local Government Board for Ireland recently entrusted the preservation of the port and city of Dublin from a cholera visitation. At a meeting of the Guardians held on Thursday, September 4, Mr. Byrne (a member of the Board) said that he had been in communication with a well-known Dublin shipbuilding firm—that of Messrs. Bewley, Webb, and Co., of the North Wall—as to the feasibility of constructing, at a small cost, a suitable floating flat-bottomed structure; and he held in his hand their specification to erect such a floating hospital, able to accommodate sixteen patients, and giving a space of 40 ft. by 20 ft. and 10 ft. high, at a cost of £975. This would be very cheap, and would, he trusted, be found adequate to any emergency likely to arise. He therefore proposed the adoption of Messrs. Bewley's estimate. The washing, etc., in connexion with this form of the proposed hospital would, he might mention, be performed on deck, and be thus more conducive to sanitary results. The proposal was agreed to—the contract to be completed on or before November 6 next. Although any danger of a cholera invasion will, we trust, have passed away before the day named in the contract, we may congratulate the Dublin citizens on having carried their point as to the advisability of constructing an epidemic-hospital for their port, to which cases of cholera or other infectious diseases may be removed from vessels arriving in the bay.

THE ARMY MEDICAL WARRANT IN INDIA.

By the last mail which reached us from India we have news that a memorial of grievances entailed on medical officers of the army by the recent Royal Warrant was about to be presented to Lord Napier. We are glad to find that an agitation against what is unfair and impolitic in the new Warrant is being carried on in India, as tending to show how widespread and general is the dissatisfaction aroused by the obnoxious clauses. Doubtless the memorialists will receive the stereotyped reply that "the matter shall be taken into consideration." Nevertheless, these respectful protests from all quarters may have the effect of urging on the authorities to reconsider the unpopular portions of their Warrant, and to perform a necessary act of justice in a graceful manner.

RESULTS OF BURNS BY PETROLEUM.

The general phenomena observed by Dr. Chairon, and which he has communicated to the French Academy of Medicine, on the cases of some persons he attended who were injured by the late explosion of petroleum at Rueel, near Paris, were as follows:—The pain, which was at the first very moderate, increased to a terrible intensity after a few hours had elapsed. Nearly all had a violent shivering of more or less duration (which was at times spasmodic), an insatiable thirst, constant and exhaustive vomiting, and an almost continuous delirium. The burns were attended by enormous swellings and tumefaction. A strange fact was that all the sufferers believed that everything they ate or drank tasted and smelt of petroleum.

TESTIMONIAL TO A PHYSICIAN.

Last week there was a right pleasant gathering at the Mechanics' Hall, at Nottingham, partly for the distribution of prizes of successful candidates who had been examined in various subjects, and partly for the presentation of a testimonial to Dr. Elder. It appears this gentleman during last winter had gratuitously given some important lectures on "Health" at the institution. These were numerously attended, and excited considerable interest. In a remarkably happy speech the chairman, Mr. Richard Enfield, concluded his remarks in the following words:—

"When he uncovered what was before him, he thought that those who saw the present would say it had been selected with admirable taste. The timepiece constituted a beautiful memorial of the past winter's work, and in giving it to Dr. Elder, on behalf of the meeting, they would all join with him, he thought, in hoping it might long be an ornament of a happy home, and that it would number many pleasant, useful hours of Dr. Elder's future life, often reminding him of those who assembled round him last winter for instruction, as well as of the present gathering, at which it was awarded as a testimonial of their sincere regard and appreciation. He had much pleasure in presenting Dr. Elder, on their behalf, with the timepiece and with a purse of gold."

Dr. Elder having responded in a suitable speech, was loudly cheered. The meeting was one of a very gratifying character, and equally honourable to the donors and the receiver.

PROSECUTION UNDER THE MEDICAL ACT.

Mr. H. Ker, of 110, Copenhagen-street, Caledonian-road, was last week fined in the mitigated penalty of £5 for having unlawfully, wilfully, and falsely pretended to be a doctor. The proceedings were instituted by Dr. John Thomas Slater, of 1, Thornhill-crescent, Caledonian-road. It appeared that when visiting his patients, Dr. Slater had a bill placed in his hand relating to Caledonian-road Provident Dispensary, 110, Copenhagen-street, from which it appeared that Mr. Harding, of Guilford-street, Russell-square, was the surgeon, and the resident medical officer "Dr. H. Ker, late of the Clerkenwell Provident Dispensary, King's-cross-road." The name of Dr. H. Ker not being found in the "Medical Directory," Mr. Sutherin, a surgeon's assistant, went to the dispensary and saw the defendant, and asked him to prescribe for him for sore throat. Having prescribed for him and entered his name in a book, he paid him 1s. For the defence, it was not denied that the defendant was not registered, but it was stated he had served his full time, and was qualified to act as a surgeon. He had served under several well-known members of the profession, and had first-class certificates as to his ability and competency. In addition to that, he held a certificate from the Philadelphia College, United States, stating that he had passed the examination at that College, and was entitled to practise in medicine and surgery. Mr. T. M. Harding, of Guilford-street, Russell-square, said that he had been in practice as a surgeon for the last twenty years. The defendant acted as his assistant at the premises in Copenhagen-street. It was not an uncommon thing in the profession to have branch practices. He attended at the infirmary every day, and it was his wish to see every patient. He did not authorise the defendant to prefix the title of "Dr." to his name on the bills. He wished the defendant to call himself "resident officer." He had not entered into any deed of partnership with the defendant. There was some talk about taking the premises jointly with the defendant for the purposes of the dispensary, but there had not been time to carry the arrangements into effect. This case shows that, properly acted upon, the Medical Act is sufficiently stringent to meet most cases of the assumption of titles by unqualified practitioners. The question at issue was in a nutshell. Mr. Ker was neither registered nor possessed any qualification which entitled him to be registered.

ADULTERATED MILK.

The Wandsworth police magistrate inflicted, on Saturday, a fine of £10 and costs, or two months' imprisonment, on Philip Meredith, a dairyman, of Old Town, Clapham, for selling milk mixed with water. The defence was that pure milk was sold at 5d. per quart, and those who paid 4d. knew that the milk was adulterated with water. The magistrate said that "recent events had shown how important it was

not to let milk vendors have any option in the matter of mixing water with milk, so as to prevent them from using contaminated water, and to protect the public from typhoid."

DEFECTS IN THE SANITARY ACT.

As new causes for sanitary inquiry present themselves, so are new defects discovered in the Public Health Act. In reply to an inquiry on the subject, Mr. Oakeshott, Medical Officer of Health, Hornsey, stated at the last meeting of the Local Board that he could not find he had power to visit the dairies in the district, Hornsey being out of the metropolitan area. If sanitary improvements are to attain anything like a national practical result, fuller powers must be given to our medical officers of health. The gravity of the defects of the present Act demand the early attention of the Legislature in the next session for their rectification. It is a subject upon which the public mind is aroused. The dangers of delay or of piecemeal legislation in respect to it are now fully seen and understood.

INDIAN CENSUS AND STATISTICS.

During the first two months of 1872 a census of the whole Indian Empire was taken, except in a few provinces in which the people had been carefully numbered a few years before. The eight provinces under British rule contain 939,922 square miles, and 184,166,134 people. If we add the remaining districts under native rulers, or held temporarily by the English, the sum totals amount to more than a million and a half of square miles, and nearly 240 millions of inhabitants. China contains about 1,300,000 square miles, and although inferior by about one-fifth in area, contains 300 millions of people, or 60 millions more than the whole of India. The Russian Empire, nearly four times the size, has only 95 millions of people. British India is as large as all Europe except Russia, but this contains only 190 millions of people. The United States are nearly as large as India, but as yet have only about 32 millions of people. Apart from the learned or root languages—Sanskrit, Pali, and Arabic—there are about thirty dialects, Aryan, Mongolian, and aboriginal, in which schools are taught and endeavours are made to create a pure literature. (The total number of languages is nearly 200.) In the Bengal provinces the zeal and labour displayed in enumerating the 67 millions of human beings scattered over 250,000 square miles were immense. At least 60,000 boats in the great rivers, containing a floating population of 300,000 souls, were boarded and counted. Passengers were reckoned on arriving at the railway terminus. In jungly places, where wild beasts were feared, the enumeration was effected during the day; otherwise the bulk of the work was done on the night of January 25. Census forms, in seven or more languages, to the number of 6½ millions, were printed by the convicts of Alipore gaol. The total cost of this gigantic operation was only £21,600. "Under careful supervision," says *The Annals of Indian Administration*, in the year 1871-72 "the people numbered themselves. The happy idea was hit on of issuing honorary letters of appointment to the most intelligent and respectable inhabitants, after they had satisfied the authorities of their ability for the task. So coveted was the honorary office of enumerator, that many who were rejected as unfit or passed over as not required, petitioned Government to remove the insult." In Hooghly the work was most laborious, and one enumerator died from tramping about in the mud and exposure to the sun. In hilly districts each chief took the census of his own clan or dependents: "In Southalistan, the village headmen knotted strings of four colours,—black for male adults, red for female adults, white for boys, and yellow for girls. In some villages, three people were told off to keep the reckoning, which was done by so many seeds or small pieces of gravel, one person keeping count of the men, another of the women, and the third of the children. Here it was pleasing to see the pride of the simple village elders in their work." Out of the 67 millions in the province of Bengal, there are under 23,000 "Europeans, Americans, and other non-Asiatics," more than 30 millions of Hindoos, about 14 millions of aborigines undergoing conversion into Hindoos (just as a Welsh or Irish family becomes English), 20 millions of Mahommedans, and about 50,000 native Christians. The aborigines—the original people, whom the Hindoos conquered and enslaved, and drove to the hills—are fast being transformed into new castes of so-called "Hindoos." Population is very dense in fertile and richly cultivated districts, amounting to 691 to the square mile in Tirhoot.

VENTILATION OF HOSPITALS.

A recent number of *Hygiene*, an American publication devoted to sanitary science, contains a report of a paper read before the Public Health Association of New York, on "Architectural Hygiene," by Mr. Carl Pfeiffer, the Secretary of the American Institute of Architects. In the first annual report of the Roosevelt Hospital, recently erected in New York from his designs, the managers acknowledge that the unusual proportion of favourable results experienced since the opening of the Hospital is due in a very great measure to the successful ventilation of the building. "For this they are indebted to the skill of the architect, and he has the satisfaction of knowing that his efforts have been crowned with signal success in the most difficult part of hospital construction."

CHOLERA AND SMALL-POX IN INDIA.

We learn from India that cholera is prevalent along the Ganges in the North-West Provinces, and the disease has broken out with extraordinary violence in Roy, Bareilly. Small-pox of a bad type is prevalent in Binapore, Bengal. Twenty-seven deaths in Madras from the same disease occurred between August 1 and 12. Our correspondent at Madras writes:—

"The cholera has been raging fearfully in the city of Bangkok, in Siam. It is said that 600 persons died on the 30th June, and that 1864 bodies were burned in the last week of that month. It is supposed that 10,000 out of 300,000 inhabitants have perished. The temples are said to be full of dead bodies. Cholera is also said to have appeared at Singapore."

NEW SANITARY TRAP.

Now that typhoid fever and other maladies of a kindred type are so generally prevalent, it may not be out of place to direct our readers' notice to a newly invented sanitary and ventilating trap, which has been brought under the favourable notice of the Royal Society of British Architects and the Royal Institute of British Architects, from the members of both which bodies it has called forth the highest commendation. It is called "The Radcliffe Sanitary and Ventilating Trap," is easy of application to existing systems, and of moderate price. The noxious vapours and gases which now so commonly enter our houses from imperfect and defective traps are a well-known fruitful source of illness and disease.

DEATH OF PROFESSOR CZERMAK.

We regret to hear that Professor Czermak, the eminent physiologist, died at Leipzic on Tuesday, the 16th inst. We hope to give in an ensuing number a sketch of his career.

FROM ABROAD.—BUDGET OF THE ASSISTANCE PUBLIQUE FOR 1874—DISEASES OF CHILDREN IN MASSACHUSETTS—THE CHOLERA IN THE FRENCH ACADEMY OF MEDICINE.

The "Assistance Publique" of Paris has just presented to the Préfet de la Seine its Budget for 1874. This, which in 1873

amounted to 26,962,000 fr., has been raised to 28,150,000 fr. (£1,126,000), the increase of 1,188,000 fr. being caused by the great rise in prices and wages. The number of beds proposed to be maintained is the same as in 1873—viz., 20,161, of which number 9311 are devoted to the aged and infirm, 8277 to the sick, and 2081 to the insane. Those who are expected to come under the care of the administration are estimated on the same scale as in 1873—viz., 303,099,—and are divided into two categories. The first of these consists of 111,099 individuals "treated" in the hospital or hospices, and the second of 192,000 individuals "succoured" under the following circumstances: Indigent persons registered at the Bureaux de Bienfaisance, 102,000; sick persons treated at home, 43,000; women delivered at their own houses, 10,000; necessitous persons temporarily assisted, 30,000; and infants placed out by the nursing department. But the Assistance Publique also extends its guardianship over 8601 insane persons placed out in asylums either in the department or the provinces, and 26,000 *enfants assistés* placed in the country. Towards meeting the wants of these 377,000 individuals, the Assistance has at its disposal an ordinary revenue calculated for 1874 at 9,044,000 fr., being an increase on that of 1873 of 113,800 fr., due to an augmentation of the value of its property, and the products of its gardens, dairies, etc., as also of the tax levied for the poor on the theatres. As already said, the budget is fixed for 1874 at 28,150,000 fr., of which sum 11,520,000 fr. will be derived from a municipal subvention. Numerous new works and improvements are projected at several of the hospitals, and 1,000,000 frs. is to be devoted towards the construction of the new hospital at Menilmontant, in the crowded 20th Arrondissement, and which it is expected will be completed in 1876. No new vote has been taken for the new Hôtel-Dieu, upon which so much money has been thrown away, as the sums voted in former years and carried forward will suffice to carry on the works for another year after these have been resumed.

From an interesting paper on "Children's Diseases in Massachusetts," read by Dr. J. O. Webster before the Massachusetts Medical Society (and reported in the *Boston Journal*, August 14 and 21), we take the following facts:—

Dr. Webster's observations are founded on the returns of infantile mortality for the years 1865-70 inclusive; and from these he finds that the mortality of children under 5 years of age in the entire State for those six years was about 6·50 per 1000 of population—the highest mortality being 7·25 in 1865, when dysentery and diphtheria were prevailing, and the lowest 6·21 in 1866. For eleven of the cities of the State, having a population of over 20,000 each, the rate rose to 8·75, while for the remainder of the State it stood only at 5·20. The percentage of deaths (during the first five years of life) to births was—for

	First year.	Second year.	Third year.	Fourth year.	Fifth year.
Massachusetts . .	14·9	5·3	2·5	1·6	1·1
Eleven cities . .	18·7	6·8	2·9	1·9	1·3
Rest of the State . .	12·3	4·3	2·2	1·4	1·0
English life-table . .	14·6	5·2	2·7	1·8	1·3

It is found that of the children born alive in Massachusetts about 15 per cent. die in the first year, 5 in the second, $2\frac{1}{2}$ in the third, $1\frac{1}{2}$ in the fourth, and 1 in the fifth—results almost identical with those of the English life-table. Moreover, in the eleven cities referred to, $18\frac{1}{2}$ per cent. die in the first year, $6\frac{1}{4}$ in the second, $2\frac{3}{4}$ in the third, while in the fourth and fifth years the mortality is only slightly in excess of that for the State at large.

Referring to the various causes of the great mortality in childhood, Dr. Webster observes that while *residence in the large towns* has been shown to be more fatal (three to two), this only applies to certain portions of these; for an analysis of the mortality of Boston for 1870 shows that in the best districts of that city infantile mortality is very low. In fact, "residence in a city, and other things being equal, is as healthy for children as in the country." The *seasons*, as with ourselves, exercise great influence, about 20 per cent. of infantile mortality occurring in the first two quarters of the year, 37 in the third, and 23 in the fourth. The high percentage of the summer months is due to the prevalence of intestinal disease, 84 per cent. of the deaths occurring in that quarter being due to cholera infantum, 57 to diarrhœa, and 76 to dysentery. In the cold months, from December to April, about 60 per cent. die from pneumonia, and as many from croup from November to March. Diphtheria carried off about 40 per cent. from October to January; but consumption destroys about an equal number of lives every month. Seasons, too, influence the mortality of eruptive fevers; for 70 per cent. of the deaths from measles occur between March and August, and 65 per cent. of those from scarlatina between December and May. The *neglect of sanitary laws* is exemplified by the greater mortality among the foreign children. Thus, during 1867-70, of all dying under five years, 41·5 per cent. were of American and 58·5 of foreign parentage, although of the total mortality 55 per cent. were of American and only 45 per cent. of foreign parentage. Eighteen per cent. of the mortality is attributed to the use of *improper food*, maternal suckling being rare in America. *Insufficient clothing* is a frequent source of fatal disease among children, and is sadly contrasted with that of adults, who are so much better able to bear a low temperature. "One simple direction will suffice: Always dress a child more warmly than is required by an adult for the same temperature." Although the "hardening process" has somewhat gone out of fashion, the idea still remains that it is proper to take children out every day, and that they may be allowed to sleep in cold rooms. The winters are far too cold in New England to allow of the former practice being followed with impunity, and air at a temperature of 50° Fahr. is probably the lowest that an infant should be allowed to breathe when its vital powers are reduced during sleep. More than 20 per cent. of the infantile mortality is caused by *epidemic* and *infectious* diseases, which are largely preventable.

In specifying the diseases which have proved most fatal in children, Dr. Webster states that those of the digestive organs occasion nearly a fourth (23 per cent.) of the deaths, those of the respiratory organs about one-fifth, developmental diseases (including atrophy and debility) one-sixth, and typhoid and eruptive fevers, tubercular disease, and affections of the nervous system, each one-tenth. "Although our infantile mortality is no greater than that of other countries, it is differently distributed among the diseases, bowel affections being much more common here than abroad, and nervous diseases holding there a much more important place than here. Pulmonary diseases also cause over double the infant mortality in England that they do in Massachusetts."

Whether genuine cholera has actually invaded France, as stoutly maintained by some, and as stoutly denied by others, it will certainly give rise to one of those tremendously wearisome debates in the Academy of Medicine which are among the things that foreigners can only wonder at, without possessing either the desire or ability to imitate. A cholera-debate, indeed, has been smouldering at the Academy for years past, but has been put off from time to time on various pretexts, but really because even the most seasoned members seem to have dreaded entering upon it. Two famous reports on cholera have never yet been discussed—viz., that presented by M. Briquet, in 1865, relating to the epidemic of 1849; and that of M. Barth, in 1869, relating to the epidemics of 1854 and 1865. These, to all appearance, would still have reposed for an indefinite period had not a communication on the present

alleged epidemic aroused into activity that most energetic of debaters and most inexhaustible of talkers, M. Jules Guérin. He only takes up one point for discussion—the question of *diarrhœa in relation to cholera*,—but with this he intends to deal exhaustively, considering it as it precedes or accompanies epidemics of cholera, and as it precedes or accompanies particular cases of the disease. At present he has not got further than the history of premonitory diarrhœa, for which he has had a whole *séance* to himself, the report of his address occupying more than twenty closely printed pages in the *Bulletin;* and the probability is that he will require two or three more *séances* before he has had his say out,—for it seems to be a rule at the Academy to always begin a subject again *de novo*, and never to assume anything as proved, however often it may have been told or demonstrated; and accordingly the orator felt himself justified in going through the entire history of premonitory diarrhœa, from his discovery of it in 1832 to the present time, reproducing facts, figures, and narrations which have been repeatedly published in this country and in France, and with which all interested in the subjects are well acquainted.

The immediate cause of this debate was a letter addressed to the Academy by M. Lecadre, Médecin des Epidémies at Havre, giving an account of the recent outbreak of cholera in that city. While admitting the occurrence of numerous deaths, he denies that the cases have exhibited the symptoms of Asiatic cholera, and regards them as examples of cholera *nostras* of a severe type. In this opinion he was joined by some members of the Academy; but M. Guérin insisted that the disease was really cholera in its premonitory stage, and then proceeded to deliver his elaborate essay on diarrhœa in relation to cholera. Two hospital physicians of Havre also, writing to the Academy, state that M. Lecadre, Médecin des Epidémics though he be, must have entirely neglected observing the cases both in their private and hospital practice, or he would have at once declared them to be genuine specimens of Asiatic cholera. Thus here, as always with respect to early cases of this disease, observers—apparently quite competent—are at issue with respect to its identification. These Havre cases are also assisting, in conjunction with preparations against the ingress of the disease made in other maritime districts, to render quarantine regulations ridiculous. While vessels—especially those coming from "abominable" Germany—are harassed by every possible regulation and impediment, thousands of foreigners are arriving from all parts of Europe by rail, untrammelled and unfeared.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Forty-third Meeting.

(*From our Special Correspondent.*)

The British Association has changed its quarters from Brighton, where the meeting was held last year, to a very different locality, situated in the very heart of the manufacturing districts of Yorkshire. The town of Bradford, which is now the temporary home of the Association, is distinguished for the rapidity with which it has developed itself from comparative obscurity to magnificence and importance, until it has attained almost the dimensions of a capital. The town itself forms one of a cluster of townships, the others being Bowling, Horton, and Manningham, together constituting the borough of Bradford; and the enormous and rapid strides it has made may be estimated from the fact that whereas the population of the borough in 1801 was only 13,264, it is now (1873) estimated at 156,609. The parish of Bradford, which includes the outlying population as well as the townships, is returned by the Bradford Superintendent Registrar as comprising 257,713 persons. As is well known, Bradford was originally the centre of the worsted trade, but at present a number of other materials, as cotton, silk, alpaca, mohair, etc., enter into the composition of the goods made in the Bradford district.

The town lies in the hollow of a basin, surrounded by an amphitheatre of hills, and it was formerly an unsightly aggregation of narrow and ill-built streets spreading along the hillsides, and the drainage and other sanitary arrangements were, and indeed still are, defective, and the water-supply was insufficient. The quantity of this fluid furnished by nature is most copious, as may be supposed from the geographical conditions of the locality, encircled as it is by a belt of hills, all furnishing their quota from the clouds; but the arrangements for rendering it available for the wants of the population were for a long time clumsy and defective. The energy of the inhabitants, however, headed by the Corporation, has done very much to improve the sanitary state of the borough, the old waterworks having been bought up, a new scheme of water-supply been inaugurated, the cattle fairs formerly held in the public streets having been removed, and many other improvements of a similar nature having been effected. Among the most important of these have been the formation of a wholesale meat market and abattoir, the establishment of baths and wash-houses, the abolition of intra-mural interments and the substitution of two extensive cemeteries in the suburbs, and the opening of two large parks for the recreation of the people. In reference to this last provision, which especially affects the mass of the population, it is in contemplation to appropriate three more portions of land for this object, so that eventually Bradford will possess five recreation-grounds in different quarters of the borough, all within easy reach of the homes of the residents.

The drainage, however, is necessarily defective, for the town lies in the heart of Yorkshire, almost equidistant from the sea to the east and to the west, the distance being about fifty miles in either direction. The great rivers—the Humber to the east, and the Mersey and the Ribble to the west—which drain the counties of Yorkshire and Lancashire are at a great distance from Bradford, which communicates with the Humber only through the medium of a very small river—the Aire—which is wholly insufficient to receive, still less to purify, the sewage of so dense a population. Nor is even this small river situated near enough to Bradford to carry off the sewage; for the Aire is connected with the town by a still smaller tributary stream called the Bradford Beck. Hence the problem of disposing of the sewage has here always been, and still remains, a very difficult one—on which, however, the proceedings and the discussions now instituted at the British Association may perhaps throw some important light, and offer some useful suggestions. We find from a report of Mr. Netten Radcliffe, dated July 17, 1872, that enteric fever is endemic at Bradford; and the same authority attributes the fact to the defective manner in which the excrementitious matter of the population is disposed of, the common privy system being the prevailing mode adopted for the purpose. It was stated in evidence before the Rivers Pollution Commission in 1866 that there were from 12,000 to 14,000 privies in the borough; upwards of 6000 *middensteads*, as they are called, or receptacles into which the contents of the privies are periodically emptied; and not more than 1500 water-closets. The middensteads are emptied when they are full, but not on any systematic plan, and the ordure is carried away at the expense of the corporation through the agency of contractors, and is sold to the neighbouring farmers, or when not immediately purchased it is carted to and deposited in any old quarries or other hollows which can be made available for the purpose. Besides the prevalence of enteric fever, a great amount of mortality prevails at Bradford among children, which is accounted for partly by the circumstances just mentioned; but it is also due in a great measure to the negligent or erroneous manner in which the infant population are nourished by the mothers.

The proceedings of the present meeting of the British Association commenced on Wednesday evening at St. George's Hall, when Dr. Carpenter formally resigned the Presidency, and Professor A. A. Williamson assumed the office and delivered the inaugural address.

Although the new Town Hall, a very magnificent and imposing structure, was opened last week, and now forms one of the most striking features of the town, it is inapplicable to the purposes of the meeting, in consequence of the comparatively

limited accommodation of the rooms in presence of the large number of members and associates who are assembled on the present occasion. Different edifices have therefore been selected as being more suitable, the Exchange having been given up for the time as a reception-room, St. George's Hall for the addresses and for one of the *soirées*, the Mechanics' Institute for another *soirée* and for some of the meetings, while the sections are accommodated at other buildings in various parts of the town. The Biological Section, which comprises the three departments of Natural History, Anatomy and Physiology, and Anthropology, are lodged at the Church Institute, and the Chemical Science Section at the schoolroom of the Unitarian Chapel.

The President of the Biological Section is Dr. Allman, who is also President of the Department of Zoology and Botany, while Professor Rutherford, M.D., presides over the Department of Anatomy and Physiology, and Dr. Beddoe over that of Anthropology. Dr. W. J. Russell is the President of the Chemical Section.

The meeting promises to be a great success. More than 1100 members and associates had inscribed their names before the commencement of the proceedings, and probably the number will amount to upwards of 2000 before they are terminated. As usual, there is a considerable proportion of ladies among the number. Among the most important subjects to be discussed, that of "fuel" will no doubt be generally interesting; while in reference to sanitary matters, there will be an inspection of the Bradford Sewage Defæcating Works as a part of the programme. The medical profession of Bradford are taking an active part in promoting the objects of the meeting, and among the evidences of good feeling existing towards their brethren, we may mention that they have invited their *confrères* coming from a distance to an entertainment at the Victoria Hotel this evening (Saturday).

SNAKES.

(*From our Correspondent.*)

In Madras in 1870-71 the number of human lives said to have been destroyed by beasts of prey and poisonous snakes was 2225, and the number of cattle 5314. The rewards paid for killing tigers, etc., amounted to £2511. Only £2 14s. was spent in rewarding the destruction of snakes. But an official return for the year from April 1, 1872, to March 31, 1873, shows a very different state of things. In March, 1872, seventy-four snakes were destroyed in the whole Presidency, and the reward of 2 annas, or 3d., for each poisonous snake amounted to 18s. 6d. But month by month the serpenticidal zeal of the population was more and more aroused, till in March, 1873, the number of snakes destroyed was 425,057, and the rewards not less than £5313 4s. 1½d. Taking the year as a whole, the number of snakes destroyed in the Presidency was more than one million and a quarter, and the money paid in rewards was £15,728 16s. 9d., which numbers would have been trebled had every part of the Presidency been equally zealous. The Madras Government seems to have repented of its liberality, and to have thought that even snake-killing might be too dear; therefore, by an order dated May 28, 1873, they have restricted the reward to cobras only, and have fixed it at one anna, or three-halfpence, per cobra. It was alleged that some of the natives used to breed cobras on purpose to get the rewards; but considering the immense quantity of land which seems not to be cultivable profitably for human food, and which is covered with prickly pear and other wild plants, there really seems to be no limit to the number of snakes which might be captured.

Very few cases of snake-bite in India are seen by European or medical authorities. The poison is too rapid. We get an incidental glimpse occasionally from indirect sources of the details. For instance, in the "Report of the Society for the Propagation of the Gospel" a poor Christian thus describes the death of his daughter:—"Three months after her marriage in a field in the wilderness a snake bit her. Her husband dragged her towards home as far as he could. Her legs were cut by the stones and bleeding. When he could carry her no longer he laid her near a thicket, and ran for help, but *the ants had begun to eat her face* before he could return."

It must in candour be said that some authorities consider the accounts of the numbers of men and animals destroyed by snakes very much exaggerated, and affirm that many women and others who are murdered are said to have died from snake-bite. On this point we can offer no opinion. Certain it is that nothing is more rare than to hear of Europeans bitten. The cases known can be reckoned on the fingers, and amongst them are two of eminent military men in the Madras Presidency, one bitten by a cobra in the hand, one over the os sacrum (by a small snake which had concealed itself in the *chaise-percée*), and both these gentlemen recovered. A Brahmin friend tells me that he was bitten on the head by a cobra in the middle of the night, when a child of ten years old, in bed. He speedily became insensible, and so continued for some hours. He was taken at once to a holy *guru* (a poison doctor), who knows *muntrums* or sacred spells of force almost to draw the moon from its orbit. This sacred person was candid enough to say that his muntrums were of less efficacy against the cobra than against other snakes. However, he did his best, and my friend recovered with nothing worse than an abscess. On the other hand, a little boy was brought in a drowsy state to the Triplicane Hospital last week who had got a bite in his hand when thrusting it into a hole in a garden wall to search for a bird's nest. He died in an hour and a half after he was bitten, spite of the administration of brandy and potass by month and enema.

There is an "Elementary Treatise on Ophiology," (a) with a descriptive catalogue of the snakes found in India and the adjoining countries, by Edward Nicholson, Assistant-Surgeon Royal Artillery, and now employed as scientific chemist and naturalist by the Government. This is a short, precise, and careful description of the structure and classification of *all* the snakes, venomous and others; and the author, like other enthusiastic naturalists, loves his pets, makes slight of the harm they do, and writes "in hope of dispelling the lamentable prejudices entertained in India against some of the most beautiful and harmless of God's creatures." Hence he minimises their alleged ill effects, and ascribes a good deal that is said to exaggeration and sensationalism. Such snakes as are truly oviparous generally deposit their eggs in a mass of decaying vegetation for the sake of warmth and moisture, and are believed to watch them, but not to incubate in the same way as most birds. Dr. Nicholson has in vain endeavoured to hatch snake eggs in captivity. The thin outer shell dries and becomes shrivelled. With reference to the notion that young snakes when in danger can seek refuge by crawling into their mother's throat he has no experience of his own, but conceives it to be quite possible, "for young snakes could certainly do without air for half an hour, and a snake's stomach is sufficiently capacious to allow a frog to croak *de profundis* when he evidently occupies a position two feet from the daylight."

Snakes feed on any small animals, eggs, fish, and above all on frogs. They may feed on each other. "I have seen," says Dr. Nicholson, "two snakes who had caught the same frog between them manœuvre very cleverly, when their noses met: the one who got his head within the other's jaw would certainly have gone down along with the frog if he had not freed himself from the frog and snake too by a sudden effort." Snakes drink water freely, but Dr. Nicholson has never succeeded in getting them to drink milk, and disbelieves the stories of their robbing dairies and sucking cows. He also greatly discounts the stories of pythons swallowing large animals, and says that "the pressure which the largest snake can exercise is very mild indeed," just enough to keep their prey from escaping. "Neither do snakes lick their crushed prey ('slaver it over' is the term used in story and simile) before swallowing it. If the prey is active, after catching it with their teeth they throw a few folds round it simply to prevent it from struggling, and then bolt it as they would a frog." Dr. Nicholson gives a very interesting chapter on *The Serpentarium*, showing where to look for snakes of different kinds; how to catch them and carry them home; how to feed them and facilitate the casting of the skin, and to tame and train them; how to kill them humanely and preserve them for the museum; how to distinguish the various species; and how to treat snake-bite, in which his remedies are very modest. But he believes that only the cobra and the daboia, or chain viper, amongst Indian snakes, are fatal to man. I must add a little gossip, if I may, some day, on the religious or superstitious and phallic history of snakes. R. D.

A HEART WITH FIVE CAVITIES.

On Tuesday evening, Mr. Langham held an inquest at the St. Margaret's Board-room, York-street, Westminster, on the body of Maria Smith, aged 30, who died under the following peculiar circumstances:—It appeared from the evidence that deceased, whose real name was Phillips, resided at 12, Union-court, Westminster. On Friday last, deceased, who had long complained of her heart, called a neighbour to her room, who, seeing deceased was evidently in a dying state, called for further assistance, and sent for a medical man, but before his arrival she exclaimed, "I am dying!" and fell on to her right side, dead. Mr. George Fenton, 28, Great Smith-street, Westminster, remarked to the coroner that this was a case of peculiar interest, as there was only one other similar case recorded in medical annals known to him. On Friday he was called to see deceased, whom he had known by sight for about twelve months, and found her lying on the bed, warm but dead. He had since made a post-mortem. On examining the thorax he found the lungs slightly congested, and on separating the heart from the lungs he found the pericardium adherent over the whole surface. In carefully dissecting it off he found a most extraordinary formation—viz., five cavities. The extra cavity was anterior to the left ventricle, and communicating with it by two small holes. One was just below the semilunar valves, and was tendinous all round, and smooth and shining; the other was more at the apex of the ventricle, rather larger than the superior one, and was covered with a valve somewhat similar to the other valves of the heart. The heart was in a most abnormal condition, being almost three times the ordinary size, weighing twenty-three ounces. There was a small fibrinous clot in the extra cavity, and the valves on the right side were inflamed and thickened. The liver was soft, and weighed one pound heavier than it ought to have done. The kidneys were small and much congested, and the capsule was very loose. No doubt the condition of the heart had caused death. The jury, after a few remarks, returned a verdict of death from natural causes. In a note received from Mr. Fenton, he adds—"I have no doubt at some time or other it was a true aneurism of the heart, but the woman having had acute inflammation of both pericardium and endocardium, and the former being adherent at the time the walls of the ventricle were ruptured saved the life of the woman. I may further state that the size of the cavity was somewhat larger than the ventricle, and the anterior wall was wholly tendinous and smooth. Of course its inner wall would be the muscular wall of the left ventricle, and not so smooth, with the two holes communicating, the upper one being about the size of a quill, round, tendinous, and smooth; the lower one somewhat larger, and covered by the columnæ carneæ of the ventricle on one side, and the valve spoken of on the other. The capsules of both kidneys were non-adherent, and stood in the same relation to the kidneys as the pericardium does to the heart in a healthy state."

The Cholera in Paris—Health of M. Nélaton.

The cholera has caused a certain panic here, and although the mortality has not been so great as might have been expected, the disease was assuming rather alarming proportions, having visited nearly every arrondissement in the town. The quarters most tried have been Belleville and la Roquette, two of the most populous districts of Paris, and where the inhabitants are not remarkable for cleanliness and sobriety. The disease, however, is on the decline, as is shown by the mortuary return issued from the office of the Prefect of Police, there having been only six deaths in all on Saturday, the 13th inst., and five on Sunday, from cholera.

I am glad to be able to inform you that M. Nélaton is much better, and I have learned from Dr. Moutard-Martin, his friend and medical attendant, that the illustrious patient has been able to take a little food, and even to move out of his bed.

Adulteration of Butter.

A case has just been terminated here which shows how much has yet to be done before tests so indubitable can be discovered as to secure unanimity among highly skilled witnesses concerning the adulteration of some of our commonest articles of daily food. Nine or ten months ago the Chief Inspector of Nuisances purchased from a firm of extensive butter merchants a sample of butter at 7d. per lb., and submitted it to Dr. Campbell Brown, the borough analyst, for examination. On that gentleman's certificate a summons was taken out against the vendors for selling adulterated butter. The summons was resisted, a denial of the alleged adulteration offered, and scientific evidence in favour of the purity of the butter adduced. In view of the direct conflict of scientific evidence before him, the stipendiary magistrate resolved to call in the aid of a third expert, whose opinion should be decisive. One eminent chemist after another was asked to undertake the examination, but declined, till at length the duty was accepted by Professor Anderson, of the University of Glasgow, and his report contains so much that is interesting, with not a little that is curious, that I do not scruple to copy it at length. It is as follows:—

"I have carefully examined and analysed the sample of butter for the purpose of ascertaining whether it is adulterated, and find it to contain—

Fatty matter	84·77
Curd	1·12
Salt	5·65
Water	8·46
	100·00

"As far as the results of chemical analysis are concerned, this sample of butter presents no special peculiarities. The salt is present in almost exactly the proportion in which it is said to be used in the best dairies—viz., one ounce to the pound of butter; the water is not excessive, and the curd only a very little above the proportion usually found in good butter. It is obvious, therefore, that neither salt nor water—the two substances most generally employed as adulterants—has been used in this case, and if any foreign substance be present, it must be some inferior variety of fat.

"I have therefore directed my attention most particularly to this point; and on examining the different processes described in books for detecting foreign fats in butter, I am bound to say that I have found the whole subject in an exceedingly unsatisfactory state. Microscopic examination is the process on which the greatest reliance was placed. Ordinary butter under the microscope is seen to consist entirely of exceedingly minute granules, in which no trace of crystalline structure can be detected; while all ordinary fats—such as tallow, lard, etc.—are completely crystalline, and consist of small radiated groups of needle-shaped crystals. The appearance of these crystals does not afford any means of determining the nature of the fat in which they are formed; for the constituents of all fats are so similar in external characters that they cannot be identified, except in those cases in which they contain some peculiar substances. Thus, tallow and cocoanut oil may be distinguished in a rough manner by their peculiar smells, which are really due to the presence of a small quantity of certain odorous fats, and of other odorous principles the nature of which is still very imperfectly understood.

"If the mere presence of a crystalline fat is to be taken as conclusive evidence of adulteration, then this sample of butter must undoubtedly be considered as adulterated. But it appears to me that there are other matters to be taken into consideration which must materially modify this opinion, and of these the proportion which these crystals bear to the whole mass of butter is a matter of primary importance.

"It is here necessary for me to point out a very important difference between a chemical analysis and a microscopic examination. In the former the different constituents are actually separated, and their relative proportions determined by weight. In the latter the separation and weighing of the different substances are impracticable, and any estimate of the relative proportions of the different constituents is a matter of

judgment and opinion, the value of which is mainly dependent on the experience of the individual, and is at best no more than an approximation. After careful and repeated examination I am of opinion that the crystals contained in this sample of butter certainly do not exceed 5 per cent. of its whole weight, and are probably considerably less than that quantity.

"Now, it appears to me that the facts just stated are entirely opposed to the view that these crystals are the result of deliberate adulteration. The person who has made up his mind to adulterate is not likely to be satisfied with the additional profit which would be obtained by the addition of 5 per cent. of the cheapest fat that could be purchased; and it is scarcely necessary to say that the number of fats that could be profitably used to adulterate butter which, I understand, is sold at 7d. per lb., is necessarily extremely restricted.

"A number of experiments which I have made, chiefly in connexion with this case, further lead me to doubt how far the presence of crystals in butter can be considered as an indisputable proof of adulteration. I find that nothing is easier than to make pure butter assume a completely crystalline appearance under the microscope, so that the eye cannot distinguish it under the microscope from tallow. On the other hand, tallow can be converted into a state in which, under the microscope, it might possibly pass for genuine butter. It further appears to me by no means certain that genuine butter, when kept for a long time, may not, to a certain extent, acquire a crystalline character. I have been unable to find any facts bearing on this opinion in books, and, of course, have not had time and opportunity for making experiments on the matter. But it is well known that a similar change takes place in other substances, and there are various circumstances which make me think it not impossible that it may occur in butter.

"As the result of the whole examination, I am forced to come to the conclusion that there is no evidence to show that this sample of butter is adulterated. It is undoubtedly of most inferior quality, and I am not surprised that suspicion has arisen as to its genuineness; but I am not prepared to describe it as adulterated, and, in fact, believe that much of its present peculiarities is due to the length of time it has been kept.

"Thomas Anderson.

"University of Glasgow, September 6, 1873."

On this report the summons was dismissed. Professor Anderson does not seem to have done anything towards rendering the whole subject of the detection of inferior fats in butter less unsatisfactory than he confesses to have found it. The matter is not so hopelessly obscure, however, as his report implies. Dr. Brown himself has done what Professor Anderson admits that *he* has not—viz., kept butter (*i.e.*, pure butter) for many months, and found that there were no more crystals in it at the end than at the beginning of that time; yet on the assumed possibility of such crystals in some way or other making their appearance in genuine butter as the result of keeping it the verdict hung. True it is, as Dr. Anderson remarks, that it is easy to make pure butter assume a completely crystalline appearance under the microscope—very much easier, indeed, than to make it appear to have only a small percentage of crystals; but it is nowhere assumed—indeed, elsewhere it is expressly denied—that the conditions for producing any such change could have been present in the butter that was the subject of this examination. It seems almost a pity that Dr. Anderson, finding the subject so obscure, and not having any time to throw any original light on it, did not follow the example of the other eminent men to whom application was made, and decline to interfere. As for Dr. Brown, few men have higher qualifications for the prosecution of this kind of work; and the laborious and conscientious way in which he has for a long time pursued it, and the new light that he has been thus enabled to throw on some methods of detecting adulterations, are manifested by his able and eminently practical articles communicated to the *Chemical News*, "Manchester and Liverpool Medical Reports," etc.

BIRMINGHAM.

September 12.

Instructions of Medical Officer of Health—The Gaol Appointment—Resignation of Dr. Fleming—Death of Dr. Evans—Musical Festival.

Diarrhœa having become somewhat prevalent here, our energetic Medical Officer of Health has issued, for the information of the public, an excellent code of instructions for its amelioration and prevention. They are as follow:—1. Observe temperance in eating and drinking. 2. Avoid improper and unwholesome food, such as tainted meat or fish, or unsound and unripe fruit. As the majority of deaths occur in infants, the greatest care should be taken in feeding them. Young infants should be suckled or fed with sweetened milk, either with or without the addition of water. 3. Drink no water which is muddy, or offensive, or under suspicion of contamination by surface impurities. Where there is no choice, a suspected water should be boiled and allowed to cool before being used as a drink; water so prepared should not be used for a longer time than one day. 5. Allow no accumulation of decaying or refuse matter in the neighbourhood of dwellings. Much that is thrown out of houses might be advantageously disposed of by being thrown behind the fire. 6. Report foul ash-pits or privies, untrapped drains, and other sources of nuisance to the medical officer of health or inspector of nuisances. 7. Practise personal and domestic cleanliness and free ventilation of houses by opening windows and doors during certain parts of the day. 8. Disinfect immediately all discharges from patients.

The Gaol is still without a permanent Surgeon. In our last communication we stated that there were four candidates for the office, but not one of them was selected by the magistrates, who have again urged the Town Council to raise the rate of income to the original sum of £200 a year, as they are of opinion it is the only way to obtain the services of a really good and competent officer.

We regret to state that Dr. Fleming, through ill health, has resigned the office of Physician to the Queen's Hospital, with which he has been connected for fifteen years, and on which he has shed great lustre by his rare talents as a physician and clinical teacher. In the latter capacity one of his former pupils, Dr. Sawyer, speaks of him in the following true and eulogistic terms:—"As a clinical teacher, for closeness of observation, clearness of reasoning, and conciseness of teaching, he had never been surpassed." The governors of the Hospital have only honoured themselves by proposing that Dr. Fleming be made Consulting Physician to the Hospital as a reward for his past valuable services.

Sad to record the melancholy fact, one of our most distinguished physicians has been taken from us. Dr. Evans died a short time since in the plenitude of renown as a doctor of the highest order. He had been leading physician here for many years, and until latterly senior Physician to the General Hospital. Dr. Evans was better known by his prodigious practical knowledge and experience in his profession, and by his diagnostic skill in the detection of diseases of the chest by the stethoscope. The *tactus eruditus* he possessed to perfection. In these acquirements he stood unrivalled in the provinces. To the school of Laennec he was, we are informed, indebted for the possession of the grand and important truths as revealed by the stethoscope, the enunciation of which has rendered the name of Laennec illustrious in the annals of medicine. Dr. Evans was not only an eminent physician, but he was a gentleman in the full significance of the term. Studying the feelings of the general and younger practitioner, he made himself deservedly popular and beloved, and his memory will ever be held in kind and grateful remembrance.

Our triennial musical festival is just over. The pecuniary results have been most gratifying. The noble sum of about £13,000 has been thus raised for the benefit of the General Hospital, whose sphere of usefulness will be thus considerably enlarged by this bountiful and needful addition to its funds. Truly,

"Music hath charms."

Increase in Consumption of Horseflesh in Paris.—During the first six months of 1867 there were consumed 893 horses, asses, and mules, furnishing 166,030 kilogrammes of meat. For the first six months of 1870—*i.e.*, prior to the war—the animals were 1992 in number, giving 366,440 kilogrammes. For the corresponding period in 1873, 5186 animals have been butchered, furnishing 883,840 kilogrammes, without counting the heart, liver, brain, tongue, etc., which are consumed like those of oxen. The same progress has been made in the consumption in the provinces. The horses are bought for this purpose at from 120 fr. to 150 fr. each, this new industry having increased the value of horses that are worn out, but not diseased, by more than 100 fr.—*Union Méd.*, August 26.

GENERAL CORRESPONDENCE.

THE DAIRY REFORM COMPANY.

Letter from Mr. D. Maconochie.

[To the Editor of the Medical Times and Gazette.]

Sir,—We venture to ask your permission to lay before your readers our view of the deplorable disaster which has happened to us, in the belief that both you and your readers will then take a very different view of the case.

Of course, looking back upon what has happened, it is easy to criticise, and we see now that the prudent course for us, whilst totally disbelieving what we regarded as an erroneous theory based upon a misapprehension, would have been immediately to have asked that the matter should be investigated by the Local Government Board. Had we done so on the receipt of Dr. Whitmore's first letter, no one could have blamed; us but then, after all, it is not every day that honest dealers are accused of poisoning their customers, and they cannot be expected always to know what would be the prudent thing to do, and all we could do was to judge of the facts laid before us. Now, we confidently assert that the facts laid before us by Dr. Whitmore on August 5 did not point to the milk at all. Had the statement been that there appeared to be an *increase* of typhoid in Marylebone, and that some of the cases appeared to have a curious connexion with our milk, we should have been much more alarmed; but the statement made to us was that there was a fresh "outbreak" of typhoid in Marylebone, the whole of which was attributable to our milk, and the more we investigated it the more did we find that this statement was not the fact—that there was no fresh "outbreak," because there had been no cessation of typhoid in Marylebone. And similarly we found, as, indeed, Dr. Whitmore did not seek to deny, that there were other cases which could not be attributed to the milk. No doubt the word "outbreak" is used by medical men, and also by veterinary surgeons, to signify the occurrence of any fresh case or cases arising from a new source of infection, even although occurring in presence of other cases from older and previously known sources of infection. I trust that so illogical a use of the word will be discontinued in consequence of the sad teaching of the Marylebone so-called outbreak, for it was unquestionably the use of this word more than any other circumstance that made us regard the evidence as not merely insufficient, but as altogether irrelevant,—as having nothing in all the wide world to do with milk. But, misleading as was this statament, we were still more thrown off our guard and led to reject the evidence as absolutely worthless on account of the belief—indeed, conviction—which Dr. Whitmore laboured under, that the whole affair was easily accounted for by the supposed fact of the whole or a greater part of our milk coming from a sewage farm.

Now, Sir, the directors appeal to you and your readers to say whether it is reasonable to blame any educated persons for rejecting and scouting the evidence put before them under such circumstances. They were told—first, that there was an outbreak, when they found that there had been no cessation of the fever; and they were then told that it was milk which had produced this non-existing outbreak, and no wonder! because it came from a sewage farm,—when none of it came from any farm within scores of miles of any example of sewage irrigation. It is evidently wholly irrelevant that we should be told now that Dr. Whitmore only laboured under the erroneous conviction as to a sewage farm for half an hour. He did not tell us so then, and how could we suppose that such was the case? We did not go by imaginations; we went by hard facts, and we unhesitatingly say that the facts were all in our favour on August 5. Moreover, Dr. Whitmore's first letter was more than hesitating. But we are now blamed because, instead of simply refusing to close our premises in reply to the second letter, we offered to do so if he would compensate us. We thought that we were making a great concession in favour of what we supposed was his crotchet by making that offer, for the facts against the milk, so far as we knew them, were still the same on the 8th as on the 5th. By that time we had what appeared to be—and what I say medical men, when they are able to reason calmly on the matter, will agree with us in saying was—complete evidence in favour of the milk. Unfortunately, that evidence turns out not to be true in two particulars; but we did not know this, and we were not to blame for it. It was again medical men, and not we ourselves, who were to blame, if anyone was to blame; but surely we have not lived beyond the age in which accidents occur with no one being to blame. We have not sought to blame either Dr. Whitmore for telling us that all our *employés* were free from typhoid, nor have we blamed the medical attendant of our one *employé* who was ill, and who at a later period declared his illness to be typhoid, nor have we blamed the medical attendant of the farmer who died for concealing from his family the fact that he was suffering from typhoid; but we say if blame is to be fixed anywhere it is to be fixed upon those gentlemen, and not upon ourselves, and we refuse to bear it.

The correspondence with Dr. Murchison has lately been of so painful a nature that we would rather not refer to it at all. But it perhaps is sufficient to say that—

1. When he wrote to us the matter was in the hands of the Government;
2. His letter contained a different version of facts from those officially given to us by Dr. Whitmore;
3. It contained statements that, on the face of them, could not be exact; and
4. The postscript contradicted the letter.

Perhaps the prudent course—had we been the cold-blooded, unfeeling, physiological experimentalists which we have been accused of being—would have been to have acknowledged the receipt of his letter, and stated that we had forwarded a copy to the Local Government Board. Being, however, sincerely desirous of getting at the truth, we immediately answered his letter frankly and fully, and we only wish that he had been as frank as we were, and had not left us in ignorance of the facts in his possession, although, as it happened, the particular supply of milk which had done the mischief was cut off within thirty-six hours of the receipt of his letter; and, probably, after the letters and telegrams which we had sent down to the country during those thirty-six hours, no poisonous matter ound its way into the milk. But if any blame is to be thrown upon anyone as to the "Murchison incident"—as the French would call it—we again distinctly refuse to bear it, and we say it is he himself who is to blame; and we beg your readers to note seriously what we say, and not to jump at the conclusion that we are ignorant, cold-blooded, mercenary, or possessed of any of the other unamiable qualities which have been attributed to us, because, surely, out of this disaster we should all try to learn something. We have learnt our lesson by taking precautions—not to prevent milk becoming contaminated with infection in case an infectious disorder breaks out on a farm, for that we firmly believe to be next to impossible; but the lesson that we have learnt from this disorder has been to take precautions immediately to cut off the supply of milk from any farm on which infection occurs, for we are firmly persuaded that it is the only way in which purity can be attained. And we now beg our friends of the medical profession to learn a lesson—that honest men of business will always act under any such circumstances, should they ever occur again, as we acted, if asked to close their business, not merely on suspicion, but on apparently unfounded suspicion. If medical men wish to persuade practical men of business to close business premises on account of some infectious disorder believed to be spread by that business, they must take great pains in submitting the evidence, whatever it may be, to those men of business. They must not, as Dr. Murchison did, communicate it through third persons, or withhold it as he also did; but they must either pronounce a confident and, so to say, oracular opinion that the illness is produced in some way by the business, without any qualifying expression; or they must carefully explain the nature and bearing of the whole of the evidence, and above all they must keep nothing back, and they must not treat honest men of business as wilful poisoners having antagonistic interests to the medical profession. If evidence is carelessly prepared, and hastily written letters are sent, with inconclusive, contradictory evidence and hasty opinions, precisely similar disasters will be repeated to the end of time. We speak thus plainly because we know what we say to be true, and although we cannot complain of the tone of the criticisms in your paper, we have been held up to public odium in some of your medical contemporaries, and we are determined that the truth shall be known, and whatever blame may attach to anyone, shall not at all events be attached to us.—I am, &c., D. Maconochie, Secretary and Manager.

*** From a sense of fairness we publish the above letter, although we do not wish it to be supposed that we in any

degree consider that it meets the points urged in our leading article of the 6th inst., neither can we allow that any blame can be thrown upon the medical men who warned the directors of the Dairy Reform Company—least of all upon Dr. Murchison. The *tu quoque* argument is the last resource of a beaten disputant. We allow that it is easy to be wise after the event, and in so far as Mr. Maconochie admits that the Dairy Reform Company ought to have applied to the Local Government Board immediately on the receipt of Dr. Whitmore's first letter, he allows that the course which the Company did pursue was neither the best nor the wisest. No one can for a moment suppose that a board of directors, presided over by Mr. Hope, would have allowed for any consideration poisonous milk to be circulated amongst their customers had they believed it to be poisonous. And the fact that they did not believe it to be poisonous is the only excuse that can be offered for their requirement of pecuniary indemnity before they stopped its circulation. But human belief is too often under the influence of interest. The warning letters of Dr. Whitmore acquired their force from the gravity of the issue. It was the grave interests at stake which, in our opinion, should have aroused the Company to immediate action—either to stopping the supply or at least to making a full scientific investigation as to the possibility of contamination at the sources whence their milk was procured. This was not done; and whilst we acquit the Dairy Reform Company of wilfully and knowingly imperilling the lives of the public, we think that their course of action was sadly deficient in caution, and was characterised by a most unfortunate disregard of the warnings of duly constituted medical authority.

THE EXAMINATIONS AT THE IRISH ROYAL COLLEGE OF SURGEONS.

LETTER FROM MR. A. H. JACOB.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have reason to believe that the Registrar of the Royal College of Surgeons in Ireland has forwarded to you, for publication in your Students' Number, educational regulations of the College similar to those which have been published last and previous years. In order that the publication of details which are calculated to mislead the student may be avoided, I think it right to inform you that the regulations to which I refer are applicable only to a few fourth-year students, and that all future examinations for students who commenced their studies after October, 1870, will be held on an entirely different system, and in other subjects than those set forth in the old regulations.

On July 29 last the Council of the College—on my motion—adopted a resolution that the new system of examination, "subject to such alterations in its terms as may meanwhile be made, be brought into effect at the next and future sessional examination of the College, and that the October examination be deferred until the date in December fixed by that scheme." Not having immediate access to official copies of this scheme, I beg to send herewith a pamphlet which contains a verbatim copy of it, and would venture to suggest that, if the old regulations be published, it would be proper to append the foregoing statement of the expressed determination of the Council with regard to the examination of students now pursuing their studies. I am, &c.,

A. H. JACOB, F.R.C.S.I.,
A Member of the Council.

79, Harcourt-street, Dublin, September 10.

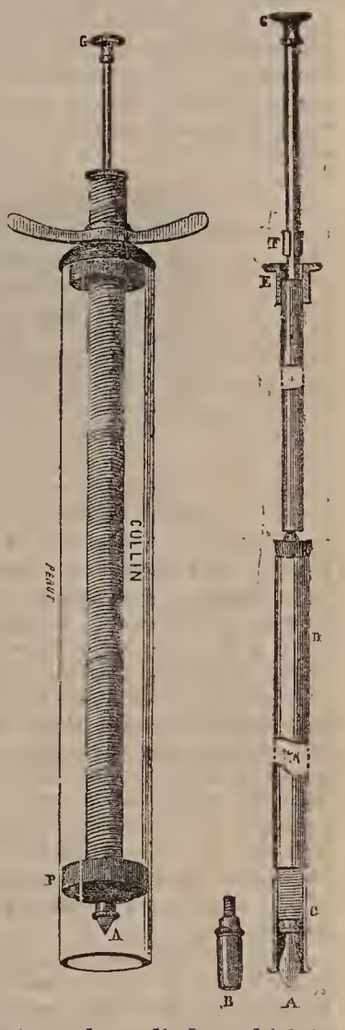
*** The new regulations provide that the sessional examinations essential for the granting of the letters testimonial be three in number, instead of two as at present, and must be passed by the candidate within the following periods:—(*a.*) The primary examination, after the termination of the second summer session. (*b.*) The secondary, after the third summer session. (*c.*) The pass or practical examination, after the fourth summer session. Each examination will occupy two days, of which the first is to be devoted, in the primary and secondary examinations, to the writing of answers to printed questions; and in the pass examination, to clinical examination and operative surgery; and on the second day, in all cases, to *vivâ voce*.

A NEW UTERINE SCARIFICATOR.

LETTER FROM DR. A. BOGGS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I do not generally approve of bleeding in uterine disease, but there are cases in which local depletion is useful. This is effected by leeching or by scarification either of the uterus itself or of its neighbourhood. The former situation is preferable, as relief or cure is more rapidly obtained, and with considerably less loss of blood. Leeching has its inconveniences, not only from the time it takes up, but many ladies object to the application of those loathsome animals, whether externally or internally, and I have known some to fall into fits at the mere sight of them. Scarifying or puncturing the uterine neck has been resorted to as a substitute for leeching, and this is done with a lancet or bistoury fastened on to a stem or with an instrument made for the purpose.



Many instruments have been devised for puncturing the uterine tissue, but I have found none so well suited for the purpose as that just invented by M. Collin, successor to Charrière, the well-known instrument-maker in Paris. The "nouveau scarificateur uterin" is a very ingenious instrument, and is a combination of a scarificator and an aspirator, or rather Pravaz's hypodermic syringe without the perforated needle. It is, in fact, the artificial leech on a large scale, and is composed of a glass cylinder, which is adapted to the uterine neck with or without the aid of a speculum. The air is thus exhausted by a few turns of the piston, which is a screw, and which runs through the cylinder. This has the effect of producing a certain degree of tumefaction in the part which is included in the extremity of the cylinder, and which is then punctured by a sharp-pointed stem (A), which passes through the piston. This is then withdrawn (the cylinder remaining *in situ*), and fixed after the puncture is made, the depth of which is regulated by a check or "curseur" (G). This done, the blood rushes into the cylinder, which it fills in a few minutes.

Finding the instrument so convenient for the purpose for which it is intended, I obtained the permission of M. Collin to give an account of it through your journal for the benefit of my British *confrères*, and in order that they may form an idea of its mechanism I must refer them to the accompanying engraving, the block of which M. Collin has kindly left at my disposal. I am, &c., ALEX. BOGGS, M.D.
(late of H.M.'s Indian Army).

13, Boulevard de Courcelles, Paris, Sept. 12.

THE UNIVERSITY SCIENCE COMMISSION.

[To the Editor of the Medical Times and Gazette.]

SIR,—In speaking of the proposals of the last new University Commission this week, you forbear to compare them with those put forward by yourself in January and February last. Allow me to say that I very much prefer your scheme. The notion of the Commissioners seems to be "More professors"; why, very few of those already in office can get a class to lecture to! The notion of the monopolists in possession is "More highly paid college tutors"; this is intelligible enough. I would respectfully suggest that the notion "More students"

might be tried with advantage as a leading principle. And I am firmly convinced that Oxford will never be changed from a place of gentlemanly lounging into a national centre of knowledge accessible to all unless the corrupt monopoly of the colleges be first swept away. This being done, the colleges can be made of the greatest use, each being constituted the permanent head-quarters of some one or more branches of knowledge. Let those interested in the progress of medicine see to it, or medicine will be again left out in the cold.

September 1. I am, &c., OXONIENSIS.

NEW INVENTIONS.

IMPROVED WATERPROOF PADDING FOR SPLINTS.

WE have received from Messrs. Arnold and Sons, of West Smithfield, a specimen of indiarubber padding for splints, which we think will prove worthy the attention of surgeons. The padding is in sheets, consisting of parallel lines of tubing arranged at a distance of three-eighths of an inch apart; the intermediate flutings are perforated by punched apertures equidistant five-eighths of an inch from each other, so that equable pressure can be maintained on the splint without

interfering with natural discharges. These sheets may be cut to any required size, and are always clean and ready for use. Solidity can readily be given to the pad by inserting in the parallel tubes soft metal wires or common canes, and then a glue or starch bandage superimposed; such a form of mechanism is admirably fitted for treating simple fractures of the lower extremities in children. The diagram represents the sheet laid flat, and the lower line shows well a section of the parallel tubes of a splint. The padding has been manufactured at the suggestion of Mr. Richard Davy.

OBITUARY.

WILLIAM BARKER, M.D., F.K.Q.C.P.I.

WITH deep regret we announce the death of this esteemed member of the profession, at the age of 63 years. The sad event occurred at his residence, Hatch-street, Dublin, on September 11. For some months back Dr. Barker's health had been gradually failing, until at last decided symptoms of hepatic disease showed themselves, and increasing, finally determined the fatal result. Dr. Barker was Professor of Chemistry in the school of the Royal College of Surgeons in Ireland, and Professor of Natural Philosophy in the Royal College of Science, Dublin. He had held the degree of Doctor of Medicine of the University of Dublin since 1742, and had been a Fellow of the King and Queen's College of Physicians since 1845. In private life Dr. Barker was universally beloved for his many engaging qualities of disposition, and among those who followed his remains to the tomb were many who felt that they had lost a friend indeed. Besides being almost passionately fond of music, he was himself a skilled musician, and was wont from time to time to beguile the evening hours after a hard day's work in either listening to or taking part in a performance of classical music. In his capacity as Professor of Chemistry, first at the Royal Dublin Society, and subsequently at the College of Surgeons, he had won a well-earned reputation as an erudite chemist and a painstaking and successful teacher.

JAMES CRUIKSHANKS, L.F.P.S. GLASG.

THIS gentleman died on the 9th instant. He had been in practice for nine years at Ayton, Berwickshire, and was much respected.

MEDICAL NEWS.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Sept. 4:

Johnstone, Charles Richard, Haxley, Yorkshire.
Vincent, Henry Bird, East Dereham, Norfolk.
Waylen, George Swithin Adee, Devizes.

The following gentlemen also on the same day passed their primary professional examination:—

Brummitt, Robert, Guy's Hospital.
Owen, Gwatkin, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ADDY, B., M.R.C.S., L.S.A.—In-door Physician's Assistant to the Manchester Royal Infirmary, *vice* R. Hughes.

BERRY, WILLIAM, M.R.C.S. Eng., L.R.C.P. and L.R.C.S. Edin.—Junior Assistant Medical Officer, Workhouse Hospital, Manchester.

HUNT, W. J., M.D. St. And., F.R.C.P. Edin., L.R.C.P. Lond.—Assistant-Physician to the Metropolitan Free Hospital.

WALKER, JOHN HARRISON, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A.—Medical Officer of Health for the Township of Pickering, Yorkshire.

NAVAL APPOINTMENTS.

ADMIRALTY.—John Elliott, Staff-Surgeon additional to the *Duncan*; Thomas L. Bickford, and George Gibson, Surgeons to the *Charybdis*, to be commissioned on September 24; George H. Madeley, Surgeon to the *Pembroke* for temporary services; Dr. James A. Allen, Surgeon to the *Crocodile*.

BIRTHS.

BATCHELOR.—On September 11, at Stratford St. Mary, Suffolk, the wife of Ferdinand C. Batchelor, L.R.C.P., M.R.C.S., of a son.

BIGLAND.—On September 4, at Chichester Lodge, 65, Warwick-gardens, Kensington, W., the wife of T. B. Bigland, M.R.C.S. Eng., L.S.A., of a daughter.

BLOXAM.—On September 4, at 21, Mount-street, Grosvenor-square, the wife of William Bloxam, M.D., of a daughter.

GORDON.—On September 2, at Woolwich, the wife of Dr. H. G. Gordon, Deputy Surgeon-General, of a daughter.

GRABHAM.—On September 4, at the Pico do Infante, Madeira, the wife of Michael Grabham, M.D., M.R.C.P., of a daughter.

GRANT.—On August 18, the wife of J. A. S. Grant, M.A., M.D., C.M., Egyptian Medical Service, Cairo, of twins (son and daughter).

GRANT.—On September 7, at Westerton, Huntly, N.B., the wife of R. A. P. Grant, M.R.C.S. Eng., Army Medical Department (late 43rd Light Infantry) of a daughter.

HENDERSON.—On July 1, at Darjeeling, in the Sikkim Himalayas, the wife of Dr. George Henderson, Officiating Superintendent Royal Botanic Gardens, Calcutta, of a son.

HOPKINS.—On September 7, at 180, Shoreditch, the wife of Alfred Boyd Hopkins, M.R.C.S., of a son.

JEFFERY.—On September 10, at Carter's-corner House, near Hailsham, Sussex, the wife of G. A. Jeffery, M.D., of Trinity House, Eastbourne, of a daughter.

KING.—On September 14, at Camberwell, the wife of Thomas W. King, M.D., of a daughter.

LINDSAY.—On September 2, at Mickleover, Derby, the wife of J. Murray Lindsay, M.D., prematurely of a son.

LONG.—On September 15, at 93, Richmond-road, Dalston, the wife of Mark Long, M.D., of a son.

LYNCH.—On September 12, at 41, Chepstow-villas, W., the wife of J. Roche Lynch, L.R.C.P. Lond., of a daughter.

MASON.—On September 7, at Tywardreath, Cornwall, the wife of S. Mason, L.F.P.S. Glasgow, M.R.C.S. Eng., L.S.A., of a daughter, stillborn.

SMITH.—On September 2, at Rochester, Kent, the wife of Robert Smith, F.R.C.S., L.F.P.S., Assistant Colonial Surgeon, Freetown, Sierra Leone, West Africa, of a daughter.

WINKFIELD.—On September 7, the wife of W. B. Winkfield, L.R.C.P., M.R.C.S. Eng., L.S.A., of a son.

MARRIAGES.

BARKER—BATH.—On September 10, at Glastonbury, Eustace V. P. Barker, youngest son of the late William D Barker, M.D., to Frances Elizabeth, only daughter of Richard Bath, Esq.

BLAND—TEALE.—On September 11, at Hoddesdon Church, William Charles, eldest son of the late John Bland, M.R.C.S. Eng., of Durham, to Ellen Marion (Nellie), youngest daughter of W. H. Teale, Esq., The Rye, Hoddesdon, Herts.

CAMERON—MACLEAN.—On September 10, at the parish church, Kew, Lieutenant-General Sir Duncan Alexander Cameron, G.C.B., to Flora, fourth daughter of Andrew Maclean, M.D., Deputy Inspector-General, Royal Military College, Sandhurst.

CROWTHERS—WARD.—On September 3, at Elm, Cambridgeshire, Wallace George, only son of Robert Crowthers, M.D., of St. Leonard's-on-Sea, and county Tyrone, Ireland, to Fanny Robinson, second daughter of Augustus Henry Ward, Esq., of Oldfield House, Elm, Wisbeach, Cambridgeshire.

DEEPING—WARWICK.—On September 11, at the parish church, Southend, George Davison Deeping, Esq., to Marianne, second daughter of W. R. Warwick, M.D., M.R.C.S. Eng., L.S.A.

DOUGLAS—SHAW.—On September 4, at the parish church, Whitby, W. T. P. Douglas, B.A., M.B. Cantab., of Newbury, Berks, to Agnes Maria, daughter of the late John Shaw, Esq., of Attercliffe, Yorkshire.

GILMAN—OXLEY.—On September 4, at St. Jude's Church, Southsea, Francis Gilman, of Shanghai, fourth son of Ellis James Gilman, Esq., of The Boltons, S.W., to Gertrude Lina, third surviving daughter of T. Oxley, Esq., H.M. Bengal Medical Service (Retired List).

GRAIN—COPLANN.—On September 13, at the parish church of St. Leonard's-on-Sea, John Henry Grain, Esq., of Lewisham-hill, Kent, to Martha Janet Sved, younger daughter of the late James Copland, M.D., F.R.S., of Old Burlington-street, London.

LARKIN—WOON.—On September 17, at St. Saviour's, Southwark, Frederick George Larkin, M.R.C.S. Eng., of 44, Trinity-square, and Union-street, S.E., to Jane Maria (Jennie), second daughter of the late William Wood, M.R.C.S. Eng., L.S.A., of 28, Trinity-square, and Union-street, S.E.

LYONS—ELWELL.—On September 4, at the parish church of Wednesbury, Alfred De Courcy Lyons, M.R.C.S., son of the Vicar of Wednesbury, to Carew, youngest daughter of the late Edward Elwell, Esq., of Wood-green, Wednesbury.

MAXWELL—ASHBY.—On September 9, at the parish church, Hove, Brighton, Thomas Maxwell, M.B., of King's College, Cambridge, to Elizabeth Eyre, second daughter of the late John Eyre Ashby, LL.D., of Enfield, Middlesex.

NORRIS—BROWN.—On September 9, at the parish church of St. Wolfran, Grantham, Lewin C. C. R. Norris, M.A., of Utterby, Lincolnshire, eldest son of the late Major Charles Norris, to Josephine, second daughter of Joseph J. Brown, M.D., of Grantham House.

PEARSE—MORRISON.—On September 10, at St. Peter's Church, Belsize-park, Reginald J. Pearse, Esq., of Genoa, to Mary Maud, youngest daughter of the late Wm. Morrison, F.R.C.S.

PARKER—DAMES.—On September 3, at Trinity Church, Clapham-common, Walter Augustus Parker, L.R.C.P., M.R.C.S., of Winchester, second son of the late Captain-Commandant Charles Parker, of the Hyderabad Contingent, to Caroline Charlotte, second daughter of the late Captain George Longworth Dames, of H.M.'s 66th Regiment.

RAY—HARRISON.—On September 4, at St. John's, Brixton, Herbert F. H. Ray, Esq., of Eastdowne, Anerley-park, Norwood, third son of the late Edward Ray, M.D., F.R.C.S. Eng., of Dulwich, to Elizabeth S. (Bessie), youngest daughter of the late Thomas R. Harrison, Esq., of 53, Russell-square, London.

THWAITES—GROVE.—On September 3, at the parish church, Hampton, Christopher Thwaites, City Engineer, Norwich, son of the late Sir John Thwaites, Chairman of the Metropolitan Board of Works, to Emma, second daughter of John Grove, M.D., Spring-grove, Hampton, Middlesex.

WILLOUGHBY-OSBORNE — WILLIAMSON.— On August 27, at St. Paul's Episcopal Church, Edinburgh, Eric James Michael Willoughby-Osborne, Esq., youngest son of Major-General Willoughby-Osborne, of Hawford, to Jane Napier, third daughter of Thomas Williamson, M.D., F.R.C.S.E., Leith.

WILY—EVANS.—On September 12, at St. Mary's, West Brompton, Richard F. Wily, Paymaster R.N., to Mabel Marian Gwendolen, only daughter of W. J. Evans, M.D., of Finborough-road.

WINKFIELD—WILSON.—On August 28, at Windsor, Alfred Winkfield, F.R.C.S., of Oxford, to Rosalie Anna, third daughter of the late Henry Wilson, Esq., of Crofton Hall, Yorkshire, formerly Captain in H.M.'s King's Dragoon Guards.

WIRGMAN—WILLIAMS.—On September 9, at Hemingford Abbots, Hunts, Thomas Ernest, second son of the late Ferdinand Charles Wirgman, Esq., of Timberham Lodge, Reigate, to Mary, second daughter of the late Owen W. Williams, M.D., of Hemingford Abbots, Hunts.

WORNINGHAM—GREEN.—On September 4, at St. Giles's, Camberwell, John Douglas Pennington, eldest son of the late John Wordingham, M.D., of Kensington, to Fanny, only daughter of the late William Henry Green, Esq., and only granddaughter of the late Thomas Green, Esq., of Westerham, Kent.

DEATHS.

COBB, REGINALD, son of Frederic Cobb, M.D., of Frensham, Surrey, at Christchurch, Canterbury, New Zealand, on September 3, aged 35.

DICK, LAURENCINE JOSEPHE, wife of William Dick, M.D., Inspector-General of Army Hospitals, and daughter of the late Charles Malo, Marquis de Rune, of Warsy, Picardy, at Marine-parade, Brighton, on September 6.

GIDLEY, MARY ANNE, wife of Gustavus Gidley, M.D., J.P., at 19, Durham-terrace, Westbourne-park, on September 13, aged 58.

LYFORD, HENRY GILES, M.D., F.R.C.S., late of Winchester, at his residence, Round-hill-crescent, Brighton, on September 10.

PAYNE, CHARLES HENRY, M.D., M.R.C.S., L.S.A., late of Wimbledon-hill, at Maida-vale, on September 16.

PENNELL, RICHARD LEWIN, M.D., at Cheriton Bishop, Devon, on September 12, aged 80.

SLACK, HENRY KELSALL, eldest son of Robert Slack, M.D., of Brandon-parade, Leamington.

YARROW, GEORGE ALEXANDER, infant son of G. E. Yarrow, M.D., at 87, Old-street, E.C., on September 4, aged 8 months.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

CHELTENHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to E. T. Brydges, Clerk to the Urban Sanitary Authority, Public Offices, Cheltenham, on or before October 11.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to John Binks, Esq., Honorary Secretary, Wakefield.

EASTERN DISPENSARY, BATH.—Resident Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Francis Savage, Esq., Hon. Secretary, 10, Beaufort-buildings East, Bath, on or before September 24.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Registrar. Particulars may be obtained from the Hospital.

MANCHESTER ROYAL INFIRMARY.—Pathological Registrar. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Weekly Board, on or before September 20.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Medical Officers Candidates must be duly qualified. Applications, with testimonials, to P. Goldschmidt, Esq., Chairman of the Board, 100, Albert-square, Manchester, on or before October 15.

QUEEN'S HOSPITAL, BIRMINGHAM.—Fourth Physician. Candidates must be duly qualified. Applications, with testimonials, to the Committee, on or before October 3.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Candidates must be duly qualified. Applications, with testimonials, to the Treasurer, Robert Tweedy, Esq., Truro, on or before October 8.

ST. THOMAS'S HOSPITAL.—Resident Assistant-Surgeon. Candidates must be F.R.C.S. Eng. Applications, with testimonials, to the Treasurer.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bideford Union.—Mr. Edgar Cox has resigned the Bideford District; area 3196; population 5742; salary £45 per annum.

Bridgnorth Union.—Mr. Robt. Stuart has resigned the Fourth District; area 10,192; population 4550; salary £40 per annum.

Conway Union.—Mr. W. M. Williams has resigned the Creuddyn District; area 17,235; population 7899; salary £50 per annum.

Narberth Union.—Mr. Maurice G. Evans has resigned the Third District; population 4470; salary £35 per annum.

Newmarket Union.—Mr. Robt. Fyson has resigned the First District; area 570; population 3261; remuneration per case.

Abingdon Union.—Mr. John S. Barrett has resigned the Third District; area, 13,796; population, 3064; salary, £110 per annum.

Brentford Union.—Mr. J. C. T. Nicoll has resigned the Seventh District; area, 4526: population, 3292; salary, £40 per annum.

Stoke-upon-Trent Parish.—Mr. Haslam Davis has resigned the Bucknall and Bagnall District.

Ulverstone Union.—Mr. John Morison has resigned the Broughton West District; area, 28,956; population, 3169; salary, £42 per annum.

APPOINTMENTS.

Belper Union.—George Harvey, L.R.C.S. Ire., L.R.C.P. Edin., L.A.H. Dub., to the Wirksworth District.

Buckingham County.—James A. Wanklyn, M.R.C.S. Eng., as Analyst.

Hollingbourn Union.—David G. Browne, M.D. & C.M. Q. Univ. Ire. to the Headcorn District.

Stafford County.—Wentworth L. Scott, as Analyst for the Northern Division; and Edward W. T. Jones, F.C.S., as Analyst for the Southern Division.

Alresford Union.—Charles E. Covey, M.R.C.S. Eng., L.S.A., to the Second District.

Barnstaple Union.—James W. Cooke, M.R.C.S. Eng., L.S.A., to the Fourth District.

Blandford Union.—Hauteville H. J. Sterling, M.R.C.S. Eng., L.S.A., to the Holworth District.

Tenterden Union.—Richard Minors, M.R.C.S. Eng., L.S.A., to the Rolvenden District.

Wandsworth and Clapham Union.—Edward C. Haden, M.R.C.S. Eng., L.S.A., to the Workhouse and the Infirmary.

SUPERANNUATION ALLOWANCE.

Sudbury Union.—Mr. George King has been granted a retiring allowance of £30 after having served as Medical Officer for the First District since the formation of the Union in 1835.

THE library of the Royal Medical and Chirurgical Society was reopened on Thursday, the 11th inst.

DR. H. SANDFORD, of Brixton, has been appointed Medical Officer of Health for the combined districts of Bromyard, Hereford, Ledbury, Leominster, and Weobly, at a salary of £500 per annum.

IT is stated that an application to the Court of Queen's Bench has been made by a parishioner for a mandamus to compel the vestry of St. George's, Hanover-square, to remedy the defective drainage of Park-lane, the Vestry having refused an application made to them on the subject.

THE Belper Board of Guardians have rejected the application of Dr. Cantrell for a superannuation allowance after thirty-five years' service as Medical Officer for the Wirksworth District.

THE *Homeward Mail* states that no less than 14,529 persons lost their lives by snake-bites in 1869, and in 1871 there were 18,078 deaths reported as caused by dangerous animals of all classes; but Dr. Fayrer is of opinion that systematic returns would show that there are more than 20,000 deaths annually from snake-bites.

ACADÉMIE DE MÉDECINE.—At the meeting on the 9th instant, Professor Hughes Bennett was elected Foreign Corresponding Member in the Section for Anatomy and Pathology.

The Finance Committee of the Aberdeen Parochial Board recently recommended that the salaries of the Medical Officers should be increased from £40 to £47 per annum; but the Board negatived the recommendation by a majority of one, it being argued during the discussion that Poor-law medical appointments were not so much for money as to give a start to young doctors!

Mr. Thomas P. Edwards has been presented with an illuminated address and a purse containing eighty sovereigns by the inhabitants of Ballyboggan, as a mark of esteem on his resigning as Medical Officer of the Dispensary District from ill-health, after a service of nearly a quarter of a century; and the Board of Guardians of the Edenderry Union have granted him a pension equal to two-thirds of his salary.

Royal College of Surgeons.—From the annual report of the receipts and expenditure at this institution which has just been published it appears that the former amounted to £13,311 16s. 5d., and the latter to £12,276 6s. 2d., showing a gratifying balance of £1035 10s. The largest amount of the income was derived from fees paid by candidates for the diplomas of Fellowship, Membership, Midwifery, and Dental Surgery, which produced £10,713 7s.; rent of chambers adjoining the College, £991 1s. 6d.; fees paid on election into the Council, Court of Examiners, and Fellowship amounted to £231; the receipts on account of the various trust funds were £290 16s. 2d.; dividends on stock (£36,000) produced £1062. The largest item in the expenditure was in fees paid to members of the Council, Courts, and Boards of Examiners—viz., £4761 9s. 3d.; for salaries and wages to officers and servants in the three departments of College, Museum, and Library, £3314 16s. 9d. was paid; a slight reduction in amount of pensions has taken place, which now stands at £353 12s.; Government and parochial taxes and stamps (exclusive of postage) absorb the large amount of £1034 1s.; expenses incidental to examinations, as patients, subjects, bandaging, refreshments, etc., £168 11s. 1d.; lectures and oration, £265 11s.; for alterations, repairs, and painting, £580 11s. 2d. was expended. The following is a summary of receipts:—College income, £13,021 0s. 3d.; trust funds, £290 16s. 2d.; total, £13,311 16s. 5d. The summary of disbursements for College purposes is £12,092 16s. 1d.; trust funds, £183 10s. 1d.; or a total of £12,276 6s. 2d. Will the authorities of the College be able to exhibit such a fair account and balance when it only draws a share of examination fees under the Conjoint Scheme?

Glasgow Medico-Chirurgical Society.—The first meeting of this Society for this session was held in the Faculty Hall on the 5th inst. The following are the office-bearers for session 1873-74:—*President:* Dr. Robert Scott Orr. *Vice-Presidents:* Dr. Andrew Fergus and Mr. John Reid. *Council:* Mr. J. Pollock, Mearns; Dr. R. Renfrew; Dr. George Miller; Dr. T. D. Buchanan; Dr. R. Stewart, Coatburg; Dr. James Scanlan; Dr. Alexander Patterson; Dr. James Dunlop. *Secretaries:* Dr. Robert Perry and Dr. Joseph Coats. *Treasurer:* Dr. H. R. Howatt.

Suicide in the United States.—The statistics of 1870 show an increasing tendency to suicide throughout the country. The percentage was 3·06 per 100,000. In 1860 it was 3·02, and in 1850 2·01. Now, it occurs to us that a comparison of these ratios with the percentages of suicides occurring in our life-companies, would go a good way towards settling the bearings of the suicide clause. If the proportion of suicides bears no heavier on the insured than on the country at large, it is pretty strong argument in favour of those who hold that no man in his right mind would destroy his life for the sake of the insurance. But if, as we are inclined to suspect, cases of self-murder are excessive among this class, the companies ought, in the interests of society as well as their own, to take away all mercenary motives to the crime. As usual, the male sex greatly predominates—more than three-fourths being men. Suicide is rare among women who have reached maturity, the majority of the cases being confined to the romantic period of girlhood. Men, on the contrary, resort to it in numbers increasing with age. Ten suicides occur among the whites to one among the blacks; the cheerful, contented disposition of the latter shows where lies the exciting cause of suicide. It is the product, not of mental rust, but of wear and tear. The rate is higher in the bustling communities of the North than in the more quiet South. But the German and French minds, of all others, appear to be particularly prone to suicide. These nationalities stand nearly as three to one as compared with the Irish, and four to one compared with the native American. The depressing effect of leaving home and country is exhibited in the heavy ratio among all classes of our foreign population. —*New York Medical Record* (*from Insurance Monitor*).

Opium land pays a price in Malwa unknown in any other part of India. Meadow land about a market town in England is scarcely more remunerative to landlords than thousands of square miles blooming with the poppy are to the chiefs of Malwa.

Indian Mortality.—During the first week of August the deaths in Madras were 266, being seven above the average of the corresponding week for fourteen years. There was no death from cholera, the mean of fourteen years being forty-three. The deaths from diarrhœa and dysentery were forty—the precise average. Fevers destroyed thirty-six, which number is five below the average. Of the deaths there were of Europeans, 3; East Indians, 2; Mahommedans, 29; and Hindoos, 232. During last May, over the whole Presidency of Madras (population 31,312,150) there were seventeen deaths from cholera and 4416 from small-pox.

Composition and Quality of the Metropolitan Waters in August, 1873.—The following are the returns (by Dr. Letheby) of the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	—	—	—	—	—	—
West Middlesex	17·33	0·010	0·125	0·001	13·6	3·0
Southwark & Vauxhall	18·00	0·043	0·036	0·001	13·8	3·3
Chelsea	18·81	0·083	0·120	0·001	14·8	3·3
Lambeth	17·77	0·059	0·110	0·002	13·8	3·3
Other Companies.						
Kent	27·43	0·005	0·248	0·000	20·8	5·8
New River	17·63	0·026	0·098	0·000	14·0	2·6
East London	17·05	0·026	0·125	0·000	13·6	3·3

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was slightly turbid—namely, in those of the Lambeth, and the Southwark and Vauxhall Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 126,144,369 gallons; and the number of houses supplied was 504,579. This is at the rate of 37·6 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 24·9 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

The returns of the Grand Junction Company have not been received.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

A Member.—The library and museum of the College of Surgeons will be re-opened on Wednesday, October 1.

A Student of St. Thomas's.—The examinations will take place about the middle of November at the College of Surgeons.

Mr. R. F. Snape.—The person is an unqualified practitioner. His name does not appear in the Register of the General Medical Council nor in the "Medical Directory."

Nicholas F.—Apply to the Secretary of the Apothecaries' Hall.

A Reader.—A recent number of the *Journal of Anatomy and Physiology* contains an exposition of Mr. Garrod's views.

Gwent.—The seventeenth annual congress of the Social Science Association will be held at Norwich on October 1 and successive days.

Jabez.—At the late competitive examination there were fifteen candidates for the Medical Service of the British Army, and fourteen for that of the Indian Army.

D. M. B.—The Vestry of St. Pancras have passed a resolution condemning the proposed additional outlay of £12,500 to adapt the Cleveland-street Workhouse as a hospital for sick paupers.

J. M.—Apply at once to Apothecaries' Hall; you may be in time for the preliminary examination, which is recognised by the College of Surgeons, and, passing this, could commence your professional studies in October. The registration will take place during the first fortnight in that month.

Clifton.—The London Hospital, Whitechapel-road, was instituted in November, 1740.

Professor Tyndall on Education.—Professor Tyndall's sentiments on education in general are interesting, and his account of his own education is a valuable piece of autobiography:—

"Two rival methods (he says) now solicit attention. . . These are the classical and the scientific method. I wish they were not rivals; it is only bigotry and shortsightedness which make them so, for assuredly it is possible to give both of them fair play. . . The proper study of a language is an intellectual discipline of the highest kind. If I except discussions on the comparative merits of Popery and Protestantism, English grammar was the most important discipline of my boyhood. . . Knowing the value of English so well, I should be the last to deny or even to doubt the high discipline involved in the proper study of Latin and Greek. That study, however, has other merits. . . It is organised and systematised by long-continued use. It is an instrument wielded by some of the best intellects of the country in the education of youth, and it can point to results in the achievements of our foremost men. What, then, has science to offer which is in the least degree likely to compete with such a system? I cannot do better than by recurring to the grand old story from which I have already quoted. Speaking of the world and all that therein is, of the sky and stars around it, the ancient writer says:—'And God saw all that he had made, and behold it was very good.' It is the body of things thus described which science offers to the study of man."—*Address to Students in "Fragments of Science"* (London, 1871).

The late Mr. Paliologus.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In a late number of your paper I see noticed the death of Mr. Paliologus, Surgeon in the Army. The name is a remarkable one, and it seems as though it must be identical with *Palæologus*, the name of the last emperors of the Eastern empire. Constantine Palæologus, the last emperor, fell by the hand of the Turks at the capture of Constantinople in 1452. Members of the ex-imperial family escaped to Italy, and from Thomas, brother of Constantine, was descended Theodore Palæologus, who came from Pesaro, in Italy, to Clifton, near Landulph, in Cornwall, where notices of his death in 1636 are to be found to this day in the parish register, and on a monumental brass in the church. It is believed by Sir B. Burke (from whose work on the vicissitudes of noble families I gather this information) that this branch of the family became extinct with the death of Theodore's grandson in 1678, and that no male representative exists. Had there been one found, he would have been raised to the throne of Greece in 1831. But of what stock was the Paliologus whose death you chronicle?

I am, &c., X. B.

P.S.—From the same work of Sir B. Burke I extract a notice of the late Archibald Stewart, also a Surgeon in the Indian Service:—"Here," says Burke, "his health failed, and he returned to his native town, Queensferry, where he established himself as a surgeon, and for many years gained a hard livelihood as a country practitioner, riding over the broadlands which had owned his ancestors as lords, and gathering a few shillings per visit from the vassals of his fathers. He died about the year 1830, leaving an unmarried sister, the last of his ancient and noble race." Amongst his ancestors were the most royal and princely families in Scotland, and he was "The Stewart"—the heir male of the great house of the Lord High Stewards of Scotland, co-heir of the ancient Lords of Lorne and Princes of the Isles, as well as of the kings of Scotland.

Tilley.—A medical congress is to be held at Vienna before the close of the Universal Exhibition, to exchange opinions as to the merits of the surgical instruments and appliances exhibited, and on other subjects.

C. T. T.—Dr. Littlejohn, Medical Officer of Health, Edinburgh, gave evidence before the Rivers Pollution Commissioners. The evidence has been lately printed.

Cid.—The records of the Register Office of Births, Marriages, and Deaths in England began in 1837.

Mack.—The Examiner of Medical Inventions at the Patent Office at Washington is debarred from female assistance, and is compelled to keep a male clerk; but medical inventions are the only exception; the other examiners have now a lady clerk, who takes charge of the official correspondence, etc.

Sheffield General Infirmary.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I have the honour to forward you the following report, for publication, of a case attending the accident room of this Infirmary.

I am, &c., Fred. W. Jordan, Asst. House-Surgeon.

H. A., aged 15, received a blow from a boy's fist over the left eye, in the situation of the superciliary ridges. There was no pain and no swelling. Next morning, when he was blowing his nose rather forcibly, the left upper eyelid suddenly became very much distended. The tumefaction gradually lessened, but did not entirely disappear. The next day but one after the accident the patient was again blowing his nose rather hard, when the swelling returned, but not to such an extent as before. On examination it was found quite soft and compressible, crepitation being felt, slightly reddened and painless. In five days from that of the accident the swelling had lessened considerably in size, and it could not then be made to increase on the patient blowing his nose. I presume that here there was fracture of the superficial plate of the frontal bone into the frontal sinuses, and that the act of blowing the nose forced air through the fracture, and so set up emphysema of the eyelid. By the sixth day the aperture had closed, and so the escape of air became impossible.

B. N. P.—1. No. 2. The Treasury was authorised by an Act passed in the last session to advance to the Public Works Loan Commissioners £3,000,000, to make loans to sanitary authorities under the Public Health Act and the boards under the Education Act. The repayments may be spread over fifty years at an interest of 3½ per cent.

A Correspondent at Mount Barker, Adelaide, writes:—"Of our gold fields in the 'Northern Territory' many reefs are turning out very productive, but many will be failures. I may mention, if you are asked the question, that there are far too many young medical men coming out to these colonies. Numbers will be and are at present disappointed."

Unpaid Sanitary Services.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The election of the Medical Officer of Health for East Sussex is now taking place, and some of the candidates for the appointment have paid me the compliment of sending me their "testimonials," concerning the issuing of which by men of mature years I have my own opinion; but they are issued, and from one of them I extract the following: "Should he be elected, I shall be most willing to co-operate with him," and the same thing is mentioned in others. I do not agree with those gentlemen; their intention is wrong. Unpaid co-operation—and that I take it is what is meant—is an injustice to the whole body of Poor-law medical officers that individuals have no right to inflict. The poor-law medical officer in a rural, if not in an urban district, is the only man in the district who knows all the bye-places, and backs and fronts of houses, and often their insides as well as their outsides. It is to him that the medical officer of health must look for co-operation; he is part of the sanitary machinery; and why should that portion of the machinery work without grease? This is what the gentlemen referred to, in giving testimonials to their friends, pledge themselves to do. I trust they will reconsider and abandon their intention, and that the Poor-law medical officers throughout the country will combine with the hope and intention of obtaining remuneration for services that must be had. You, the editors of other medical periodicals, and the Poor-law Medical Officers' Association, will I feel sure give us all the assistance in your power; and if we are but true to ourselves and properly represent our case to our respective boards of guardians, our claims are so clear that they must be admitted.

I am, &c., Wm. Elliott Porter,
Medical Officer, Third District, Cuckfield Union.

Lindfield, Sussex, September 17.

N. I. S.—There were last year 25,705 coroners' inquests held in England and Wales, and in the year before 25,898.

An Irishman.—The Lord Lieutenant, in his reply to the governors of the Dublin Lunatic Asylum, has declined to grant an inquiry into the alleged partiality of Dr. Nugent in conducting the inquiry into the death of the patient Deanford. With regard to the charges and insinuations against Dr. Nugent, that his report was not a fair one, his Excellency found, from Dr. Nugent's explanations and also from the reports in the newspapers sent him, that his report was a perfectly unbiased one, and therefore his excellency could not permit the investigation to be held into Dr. Nugent's conduct.

Margate.—Great dissatisfaction prevails in Margate in consequence of the admirable Sea Infirmary in that town not having participated in the London Hospital Sunday Fund. In answer to the objection that it is a provincial hospital, its friends contend that the chief benefits it confers are upon the sick inhabitants of the metropolis. No one can doubt the immense importance of the hospital to the welfare of a vast number of the sick children of London, and we think it has established its claim to participate in the funds raised in London by a Hospital Sunday collection.

Metaphysics.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I was struck with the clever and Platonic soliloquy suggested in the *Medical Times and Gazette* of the 6th inst., in the lines headed "Metaphysics." I could not help carrying the sentimental mood a little more onward, which I am sure the author could do much better.

My double self a mystic union gives,
Each one is conscious that the other lives;
Yet still more mystic, and as surely true—
Revealed by Holy Writ to me and you,—
This double self from union must break,
And each a diverse course and object take:
That which is made from earth returns to earth,
And that to God who gives the heavenly birth.

I am, &c., One of your Readers.

Medicus.—Harvey made his experiments in 1616 and 1618. It is commonly said that he first promulgated his opinions in 1619, but the manuscript of his lecture which he delivered before the College of Physicians, and which is preserved in the British Museum, refers them to April, 1616.

A Union Medical Officer.—There is great diversity of opinion in the profession on preserved Australian meat. The consumption has increased in England. The importation, which in 1866 was only £300, amounted last year to £890,000, but large quantities were transhipped for the use of emigrants and others. Its introduction into the dietary of some public institutions has succeeded, in others it has failed. But a considerable improvement must be effected in the system of preserving it before the profession will generally, we think, recommend its use, especially where it is to take the place of home-produced meat.

The Climate of Colorado.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The territory of Colorado is becoming every year better known in Eastern America as the great American sanitarium. Every summer large numbers of invalids come from the East to spend weeks or months in these mountains, returning, according to universal testimony, in most cases greatly benefited. But Colorado is not yet properly appreciated, as it will surely be, as a winter residence for the invalid.

The climate of Colorado is highly praised at large for its healthiness. Here in the foot-hills of the Rocky Mountains we have the best of it, there being drawbacks to places on the prairie, such as Denver and Greeley, which we in the hills escape.

The Seasons.—Spring is the least pleasant time here, as throughout the United States: the winds are high, the changes of temperature sudden and extreme. But these changes do not produce bad effects in the human constitution, as they would in England. The summer is delightful, the air

balmy and delicious, the heat very seldom, if ever, oppressive. Sunstroke is, I understand, unknown in this region. The early summer is the wettest time of the year, yet so dry that irrigation is necessary for the crops, the rainfall being rarely sufficient for them. The autumn is the pleasantest part of the year: only poetry could adequately describe it. The winter is also generally very pleasant. Our first snowfall this season was on October 28. We have had several since, lasting each about twelve hours or less. After every one the clouds cleared away immediately, and the sun shone clear as at midsummer. In the middle of the present month (November) we had a spell of extreme cold at night—my thermometer standing on three days at 8 a.m. at 3°, 5°, 8° below zero Fahr. This must seem terrible to an Englishman, but it is not really so. The nights are indeed cold, but the days usually delicious. The air now, as all the year round, sweet and mild, clear, pure, very bracing, but not irritating. The sky is even in winter of such a deep and lovely blue as the finest day of an English summer cannot show. As night gathers in the blue changes to violet equally intense. And night by night the evening star, hanging like a great lamp over our south-western hill, twinkles like a fixed star.

Such is the climate throughout this foot-hill region—generally clear, bright days, with clear, cold nights, now and then interrupted by storms of snow or wind. Snow does not lie long. The cattle find their own food. I lately sent five calves away to a valley four miles off; they will have to shift for themselves there throughout the winter. The grass, self-cured upon the stalk, is abundant enough to feed them. Last winter, one of unexampled severity, while the snow lay on the prairie outside the hills for thirteen weeks together, and numbers of cattle froze and starved, here it never lay for more than thirteen days at a time. Warm airs blow among these valleys and rapidly dry up the snow. Hence last winter, while the loss of life among cattle was very great outside, here in the hills the stock did well and kept fat. While the thermometer reached 27° below zero at Collins, four miles outside, here at the same time it stood at 5°. In the summer we have equally the advantage as regards the extremes of heat.

The most noticeable points for the invalid coming here are—the great elevation, and the dryness of the air. My aneroid barometer usually indicates about twenty-three inches, rising to nearly twenty-four (rarely quite so high), showing an elevation above the sea-level of five to six thousand feet. The atmospheric dryness is very great. Timber never seems to season enough. Wheels of waggons made for the market of this territory are, I am told, boiled in oil, and even then shrink in their tires. We do not find this dryness at all unpleasant. My house stands in a beautiful valley, the most striking features of which are magnificent steep cliffs of red sandstone to the east, and on the north-west the very beautiful canon or gorge out of which flows our river—a clear mountain stream. The banks, covered with great masses of wild grape-vines, require very strong adjectives to express their loveliness.

As to the curative effects of the climate, testimony is unanimous and unimpeachable that it is very highly efficacious in cases of even considerably advanced consumption, not to speak of other complaints.

The classes of patients to whom temporary residence here offers special advantages are—*a*. The consumptive. *b*. Cases of asthma, chronic bronchial and throat affections. *c*. The debilitated; the numerous class of patients who need general bracing of the constitution, such as youths who, from over-study or any other cause, are below the normal standard of health and vigour for their years; men who have broken down from over-work in business; persons who have inherited a feeble constitution and cannot pursue their calling in life to advantage.

We are close to scenery of the grandest character. Colorado is commonly spoken of as the Switzerland of America. People who have travelled here and in Switzerland report that our scenery is equal to that of the Alps; some (but they are Americans) say it is finer. We are some forty miles from Long's Peak—about 15,000 feet above the sea-level. Our river starts from one of its glaciers. Our home scenery is, as I have already said, very beautiful, and the contrast of the mountain range with the great prairie is sublime. The artist and photographer can find here a new and magnificent field of work. The invalid can take just as much or as little exercise as his powers allow without fatigue, and yet always be amid fine scenery. And I can think of nothing more invigorating to mind and body than riding over the great prairie in front of the snowy range. The artist, naturalist, and sportsman can find here full occupation. The flora and fauna are very various and interesting. To be shot are—elk, deer, antelopes, bears, wolves, and other vermin; eagles, hawks, grouse, wing and water fowl in great variety, humming-birds, etc. Our river abounds with fine trout. The geology of this region has never, I believe, been adequately investigated.

Thus, then, an intelligent person need be at no loss for occupation. The pursuit of art, natural history, or sport might well, I think, compensate for the main drawback of this place—the limited amount of refined society. I must not fail to add that farming, stock-raising, and dairy work may be learned at home or in the immediate neighbourhood; mining (gold or silver) at some distance. And the student of the high science of man may observe a rapidly growing civilisation under new and interesting conditions.

Another point deserves attention. A young man is sent from home for his health to some spot, for instance, on the Mediterranean. He has nothing particular to do, has ample means, and is presented with every form of enervating pleasure. The relaxing climate disinclines to exertion, incites to pleasure amid a society where a laxer moral code prevails than in England. Hence, no doubt, many an invalid misses his recovery, or, if he attains it, is disqualified for the active business of life when he returns home. Here are no opportunities for dissipation, while all the surroundings invite to a manly, active life.

Many a person might be attracted by this account, but discouraged by the distance from home. This distance need be no real obstacle. No journey of equal length round about Europe could be made with so little discomfort. The traveller crosses the sea in one of the finest steamships in the world. From New York he has at command Pullmann's "Palace Cars" (which are said to have no match in Europe) as far as Cheyenne, on the Union Pacific Railroad—that great line which joins New York to San Francisco. From Cheyenne another train goes, in two hours and a half, to Greeley, an interesting colony, whence a drive of thirty-two miles brings the traveller to this house.

The best time of the year for the invalid to come out would be the spring, as soon as the sea can be crossed with comfort. I brought my family out in the very early spring. We had a bad sea voyage, but though one of my children was under six months old we reached Longmont all well, having met with nothing we could really call a hardship.

Everyone interested in our present subject should read what Sir C. Dilke says in his "Greater Britain" of Colorado and its climate.

I am, &c.,
F. B. Hutchinson.

Finbagh, Namaqua, Lorimer County, Colorado, U.S.

A Doctor's Log.—No. III.

An awning on deck; the shipping of native stokers more resembling wild beasts than human beings, especially when caged in sheep pens; the metamorphosis of artillery officers into pastry-cooks in white clothes; the appearance of straw hats, helmets,—all significant symptoms. Passing from the Gulf of Suez to the Red sea, notice languidly the supposed track of the Israelities, the peaks of Sinai and Horeb, fleecy, fluffy, purple-looking mountains of sand; read that the Arabian gulf, altogether about 1400 miles long, 130 wide, is notorious for sand-banks, dangerous shoals, coral reefs, and terrible heat; observe the sunset orange, shading off into every colour of the spectrum; and, in common with other passengers, complain of lassitude, nausea, sledge-hammer headache, disturbed dreams, incessant thirst, also loathing for food, a hatred to neighbours, a wish to be alone, away, back in England,—bother the rupees. There are fourteen men in hospital, nothing serious about, fourteen attending; also about six women and children in hospital, about sixteen or twenty attending at the utmost. Now twenty days out from Portsmouth: one labour; also one child lost, aged eight weeks, dry nursed, and alluded to previously. Bronchitis and diarrhœa still trouble some, especially where the mothers are wanting in tact, experience, or obedience. For instance, this very morning, prowling about the deck, several young infants at the breast, teething, had their bare heads exposed to the sun, the purple face, the stupor, the tinged veins indicative of threatening cerebral mischief. Yet every woman has been presented with printed instructions what to eat, drink, and avoid, and how to manage the children. Considering the number on board, everything in the way of food and management thoughtfully arranged. None of the bother of depending on medicine-chests, there being a neat dispensary inhabited by a qualified compounder, a "Jack-in-the-box," ready at any moment. Still the children require constant supervision, and the cases do not answer the helm as on shore. Two infants—one weaned, the other nursing—each suffering from dry, husky, croupy cough, high pulse, restless nights, fits of violent passion, dirty tongue, disordered secretions; the general symptoms nothing, but the dry hoarse cough so horrible to hear in croup, laryngismus stridulus, laryngitis, diphtheria, and thrush. The tonsils are inflamed and swollen and covered with white patches, and occasionally the spasms resemble those of hooping-cough. In addition to general principles, attention to alimentary canal, warm bath, sinapisms to throat, chest, and back; chlorate of potash, carbonate of ammonia and calumba, expectorants, milk, wine, beef-tea, and the swabbing out the throat with strong solution of borax tried to-day. The younger infant has the better chance; the mother put into good order and taking quinine. The other child, refusing milk, subsists on lime-juice and beef-tea. Two children at Suez distinctly whooped; since arrival in Red Sea much better. For spasmodic affections, notably hooping-cough, Dr. Doyle, R.N. (the assistant-surgeon on board), speaks highly of tincture of cantharides, but beyond change of air I have no faith in any particular remedy. The Egyptian stokers have assumed their summer clothing, consisting of a rag around the loins, somewhat startling the ladies. Supposing the "Doctor's Log" written for general readers, how easy it would be to sketch a few characters on board,—to describe the old soldier; the splendid wife, with clean, healthy children, always neatly dressed, ever active; she has heaps of baggage, a splendid canteen, knows all the rules, regulations, dodges, the good seat at dinner, the waiters' names, how to get plenty of ice and comforts innumerable for her sick husband. You may be sure she could give an excellent dinner in the desert, where a Jew or even a Scotchman would starve. In return for an infallible prescription (compound colocynth, ipecac., podophyllin)—I hope to learn a trick or two about children. On the other hand, the lovely, elegant young girl—fragile, delicate, helpless, very pleasant to meet, clever at accomplishments—too often resembles "Dora" (and you remember what a miserable *ménage*, what a comfortless home David Copperfield had!) Amongst the males there are all ages, from the young subaltern going abroad full of adventure—tiger-shooting and pig-sticking—up to the colonels, anxious to shake the pagoda-tree before it withers. Some have married early—"We can get on in India, don't you know; my wife is mad to go." Some are gladly returning to a country congenial as to climate and associations; others merely obediently go at the call of duty; whilst a few bear the stamp of debt or failure, or, having played their cards badly, philosophically hope for a turn of luck. In addition to a deputy-inspector, a surgeon-major, six assistant-surgeons, all going to different places, we have a naval surgeon and assistant on board—a regular gang of doctors, all very harmonious—no squabbling about "ethics," or stealing each other's patients—"unprofessional conduct"—or struggling for hospital appointments. We have substantial pet grievances, and having seen neither *Medical Times* nor *Lancet* since leaving England, the grievances come in handy for discussion, and our thoughts are our own.

One evening, after an admirable theatrical performance of the *Area Belle*,—the part of Tosser the Grenadier, partial to cooks and cold mutton, well sustained by Dr. Greig, R.A.; the farce of *Little Toddlekin* also capitally acted, the part of the invalid who comes to London to consult the faculty in Savile-row assumed by Lieutenant Armitage—the subject of fire at sea somewhat occupied attention. When the fire-bell is rung every port is to be closed—the troops keeping perfect silence will fall into detailed places—the women remain in quarters—the sick in hospital, under charge of medical officers, prepared for removal. In short, each man at his post will endeavour to prevent panic and confusion, especially amongst ladies and their children, who, under charge of the quarter-master, remain in the saloon. The number and position of pumps, directions regarding prisoners, lunatics, books, valuables, and the disposal and duties of officers and men, the sentries over the spirit-room, and the isolation of gunpowder, are carefully laid down and rehearsed, everything depending on discipline. The narrative of the *Birkenhead* we are never tired of reading. How well the troops were controlled: standing shoulder to shoulder, rigid as on parade, they gave one British cheer whilst sinking in the doomed vessel beneath the waves. Medical men, of all others, should be prepared to be useful in peril at sea.

APPOINTMENTS FOR THE WEEK.

September 20. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

22. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

23. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

24. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

25. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

26. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Dr. Horatio Wood's Method of Mounting Fresh-water Algæ.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 6.

BIRTHS.

Births of Boys, 1131; Girls, 1117; Total, 2248.
Average of 10 corresponding years 1863-72, 1950·1.

DEATHS.

	Males.	Females.	Total.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·63 in. The lowest was 29·43 in. on Tuesday evening, and the highest 29·77 in. on Friday evening.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

St. Bartholomew's Hospital and

COLLEGE.—The WINTER SESSION will begin on WEDNESDAY, OCTOBER 1st.

The Clinical Practice of the Hospital comprises a service of 710 beds, inclusive of 34 beds for convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College Regulations.

For all particulars concerning either the Hospital or College, application may be made, personally or by letter, to the Resident Warden of the College. A handbook will be forwarded on application.

St. Bartholomew's Hospital and

COLLEGE.

SCHOLARSHIPS IN SCIENCE.

Two Scholarships in Science have been founded at St. Bartholomew's Hospital:—

1. An Open Scholarship of the value of £100, tenable for one year, to be competed for in September. The subjects of examination are Physics, Chemistry, Botany, and Zoology. The successful candidate will be required to enter at St. Bartholomew's Hospital in October next.

2. Preliminary Scientific Scholarship of the value of £50, tenable for one year, to be competed for in October next by Students of the Hospital of less than six months' standing. The subjects of examination are identical with those of the Open Scholarship.

For further particulars and syllabus of subjects, application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital.

University of London.

MATRICULATION AND PRELIMINARY SCIENTIFIC EXAMINATIONS.

SPECIAL CLASSES for these Examinations are held at St. Bartholomew's Hospital. The Classes are not confined to Students of the Hospital.

A Class for the Matriculation Examination is held twice in each year, from October to January, and from March to June.

A Class for the Preliminary Scientific Examination is held from January to July.

For particulars, application may be made personally, or by letter, to the Warden of the College, St. Bartholomew's Hospital.

St. Thomas's Hospital,

ALBERT-EMBANKMENT, WESTMINSTER-BRIDGE, S.E.—The MEDICAL SESSION for 1873 and 1874 will commence on WEDNESDAY, the 1st OCTOBER, 1873, on which occasion an Inaugural Address will be delivered by Dr. J. Harley, at Two o'clock.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

PRIZES AND APPOINTMENTS FOR THE SESSION.

The Wm. Tite Scholarship, founded by the late Sir Wm. Tite, C.B., M.P., F.R.S., the proceeds of £1000 Consols, tenable for three years, was awarded last Session.

First Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, and £5.

Second Year's Students—Winter Prizes, £20, £15, and £10; Summer Prizes, £15, £10, £5; the Dresserships and the Clinical and Obstetric Clerkships.

Third Year's Students—Winter Prizes, £20, £15, and £10; Mr. George Vaughan's Cheselden Medal; the Treasurer's Gold Medal; the Grainger Testimonial Prize; the two House-Physicianships; the two House-Surgeoncies; the Resident Accoucheurships. Two Medical Registrarships, at a salary of £40 each, are awarded to third and fourth years' Students, according to merit.

The Solly Medal, with a Prize of 10 Guineas, will be awarded at the end of the Session to a Student of the third, fourth, fifth, or sixth years, for the best Report of Surgical Cases.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.
Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.
Physicians—Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison.
Obstetric Physician—Dr. Barnes.
Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.
Ophthalmic Surgeon Mr. Liebreich.
Assistant-Physicians—Dr. Stone, Dr. Ord, Dr. John Harley, Dr. Payne.
Assistant Obstetric Physician—Dr. Gervis.
Assistant-Surgeons—Mr. F. Mason, Mr. Hy. Arnott, Mr. W. W. Wagstaffe.
Dental Surgeon—Mr. J. W. Elliott.
Resident Assistant-Physician—Dr. Evans.
Resident Assistant-Surgeon—Mr.
Apothecary—Mr. R. W. Jones.

Medicine—Dr. Peacock and Dr. Murchison. Surgery—Mr. Sydney Jones and Mr. MacCormac. General Pathology—Dr. Bristowe. Physiology and Practical Physiology—Dr. Ord and Dr. John Harley. Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe. Anatomy in the Dissecting-room—Anatomical Lecturers, Mr. Rainey and Dr. R. W. Reid. Practical and Manipulative Surgery—Mr. Croft. Chemistry and Practical Chemistry—Dr. A. J. Bernays. Midwifery—Dr. Barnes. Physics and Natural Philosophy—Dr. Stone. Materia Medica—Dr. Clapton. Forensic Medicine and Hygiene—Dr. Stone and Dr. Gervis. Comparative Anatomy—Mr C. Stewart. Ophthalmic Surgery—Mr. Liebreich. Botany—Mr. A. W. Bennett. Dental Surgery—Mr. J. W. Elliott. Demonstrations Morbid Anatomy—Dr. Payne. Mental Diseases—Dr. Wm. Rhys Williams.

T. B. PEACOCK, M.D., Dean.
R. G. WHITFIELD, Medical Secretary.

For entrance or prospectuses, and for information relating to Prizes and all other matters, apply to Mr. Whitfield, Medical Secretary, St. Thomas's Hospital, S.E.

The London Hospital and Medical

COLLEGE.—The next WINTER SESSION will commence on WEDNESDAY, OCTOBER 1, 1873, when the Introductory Lecture will be given at 3 p.m. by M. Prosser James, M.D., Lecturer on Materia Medica at the College.

General fee to Lectures and Hospital Practice, £90, payable in two instalments of £45 each. Library fee, £1 1s. Special entries can be made to Lectures or Practice.

The Hospital contains 600 beds.

The In-patients during 1872 were 5392, and the Out-patients 64,275—total 69,667.

The following Prizes and Appointments are offered, without any further payment, to Students paying the general fee of £90:—

Seven Scholarships to be offered for competition in the Winter Session:

1. A Scholarship of £30 to the Student of less than three months' standing who passes in October the best examination in the subjects required at the Preliminary Examinations.
2. A Scholarship of £20 to the Student of less than three months' standing placed second in the above examinations.
3. A Scholarship of £20 in Human Anatomy for first-year Students; to be awarded in April, 1874.
4. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first-year and second-year Students; to be awarded in April, 1874.
5. A Hospital Scholarship, value £20, for Clinical Medicine; to be awarded in April, 1874.
6. A Hospital Scholarship, value £20, for Clinical Surgery; to be awarded in April, 1874.
7. A Hospital Scholarship, value £20, for Clinical Obstetrics; to be awarded in April, 1874.

The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial), 1874.

Money Prizes to the value of £60 given annually by the House Committee for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to appointments, &c., see the prospectus, which will be forwarded on application to the Bedell of the London Hospital Medical College, Turner-street, E.

Further information may also be obtained from Mr. James E. Adams, Treasurer, 10, Finsbury-circus, E.C.; or Mr. Waren Tay, Vice-Dean, at the Medical College.

Charing-cross Hospital Medical School.

—The WINTER SESSION will commence on WEDNESDAY, the 1st of OCTOBER, when the Introductory Address will be delivered by Edward Bellamy, F.R.C.S., at eight o'clock in the evening.

Two Entrance Scholarships of £30 and £20 respectively, the Llewellyn Scholarship of £25, the Golding Scholarship of £15, the Governor's Clinical Gold Medal, besides the usual Class Medals, are open to competition among the Students.

Three Resident Officers are selected from among the Students every six months.

MEDICAL OFFICERS.

Consulting-Surgeon—Henry Hancock, F.R.C.S.
Physicians—F. W. Headland, M.D., A. Julius Pollock, M.D., Alexander Silver, M.D.
Assistant-Physicians—T. Henry Green, M.D., R. Douglas Powell, M.D., G. V. Poore, M.D., J. Mitchell Bruce, M.D.
Surgeons—Edwin Canton, F.R.C.S., F. Hird, F.R.C.S., Richard Barwell, F.R.C.S.
Assistant-Surgeons—E. Bellamy, F.R.C.S., W. Fairlie Clarke, F.R.C.S., J. Astley Bloxam, F.R.C.S.
Physician-Accoucheur—J. Watt Black, M.D.
Physician for Diseases of the Skin—E. Sparks, M.B.
Dentist—John Fairbank, M.R.C.S.
Registrars—J. Mitchell Bruce, M.D., M. McHardy, M.R.C.S.
Chloroformist—Archer Farr, L.R.C.P. Edin., L.S.A.

LECTURERS.—WINTER SESSION.

Anatomy and Physiology—Alexander Silver, M.A., M.D.
Practical Histology—J. Mitchell Bruce, M.D.
Anatomy, Descriptive and Surgical—Richard Barwell, F.R.C.S.
Anatomical Demonstrations—J. Cantlie, M.A.
Chemistry—C. W. Heaton, F.C.S.
Medicine—F. W. Headland, B.A., M.D.
Surgery—Edwin Canton, F.R.C.S.
Clinical Medicine—A. Julius Pollock, M.D.
Clinical Surgery—Henry Hancock, F.R.C.S.

SUMMER SESSION.

Materia Medica—R. Douglas Powell, M.D.
Midwifery—J. Watt Black, M.A., M.D.
Botany—Edward Dowson, M.D.
Forensic Medicine—G. Vivian Poore, M.D.
Practical Chemistry—C. W. Heaton, F.C.S.
Pathology—T. Henry Green, M.D.
Psychological Medicine—W. J. Hunt, M.D.
Skin Diseases—E. Sparks, M.A., M.B.
Comparative Anatomy—A. H. Garrod, B.A.
Operative Surgery—E. Bellamy, F.R.C.S.
Bandaging, &c.—W. Fairlie Clarke, M.A., F.R.C.S.
Surgical Pathology—J. Astley Bloxam, F.R.C.S.

Fees for the full course of Lectures required by the University of London, the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries, £76 5s. (including the Matriculation Fee of £2 2s., involving no examination), which may be paid in five instalments. Composition fee for Dental Surgery, £42 2s.

Further information may be obtained by application to the Dean, at the Hospital. A. J. POLLOCK, M.D., Dean.

Hereford Proprietary School and

TECHNICAL COLLEGE supplies a sound Modern and Classical Education, supplemented, in the case of pupils intended for the Medical Profession, by regular Courses of Chemistry, Botany, and Materia Medica, for Forty-five Guineas per annum. The Michaelmas Term begins on Wednesday, September 17th. Address, the Rev. J. J. LOMAX, B.A., T.C.D., Principal. References to Medical Men.

ORIGINAL LECTURES.

LECTURES ON DISEASES OF THE HEART.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,
Senior Physician to St. Thomas's Hospital.

Lecture VII.—Valvular Diseases.

Diagnosis, Prognosis, and Treatment.

(*Continued from page* 320.)

Prognosis.

In order fully to understand the relative degrees of danger which attend different forms of valvular disease, and to estimate the probability of life being prolonged or rapidly terminated, it is necessary to point out the different modes in which death may occur, and the sources of danger to be apprehended. These may be classed under the following heads:—1. Failure of muscular power in the heart from gradually advancing disease, from atrophy and disorganisation of the muscular structure, or from impairment of the general strength. In this way the cavities anterior to the seat of obstruction become dilated, and their walls thinner and looser in their texture, or undergo interstitial changes, such as fatty degeneration. They are thus no longer capable of contracting with sufficient power to propel the blood through the smaller vessels and capillaries, and there is liability to sudden cessation of action and to death by syncope. 2. Congestion of the organs anterior to the seat of obstruction. This condition is a necessary result of the former, if of sufficiently long duration. The effects may be shown in the heart and pericardium, in the lungs, the liver, the kidneys, the brain, and in the system at large, causing effusion in the pericardium or pleural cavities, œdema of the lungs, bronchitis, pulmonary apoplexy and hæmoptysis, various morbid changes in the liver, kidneys, and brain, and general dropsy; the pulmonary, hepatic, renal, and dropsical symptoms being the most common. 3. Thrombosis of the cavities adjacent to the seat of obstruction or in more distant vessels, or embolism from the separation of the clots so formed or of inflammatory exudations, and their conveyance in the course of the circulation into some of the smaller vessels, especially those of the brain, giving rise to obstruction in the vessels of the extremities or to softening of the brain, and to apoplectic extravasation and paralysis.

These sources of danger are respectively more prone to arise in some forms of valvular disease than in others, though they may occur in any case and be variously combined, or present themselves in succession at different times in the same case.

Obstructive disease of the aortic valves may long continue without seriously impairing the general health of the patient; but it predisposes to the occurrence of various serious complications, more especially to active inflammatory and hæmorrhagic affections, particularly of the brain. Ultimately, with the failure of the muscular power of the heart, evidences arise of obstructed circulation and of congestion of the parenchymatous viscera, and there may be general dropsy; or the constricted orifice may be further obstructed by inflammatory exudations or clots, and the secondary effects of their displacement may ensue.

Incompetency of the aortic valves, whether a primary or secondary condition, is a much more serious defect than obstruction, for the circulation is with difficulty maintained when a large portion of the blood propelled into the aorta at each beat of the heart immediately regurgitates into the ventricle. The power of the left ventricle is also exhausted by the almost constant distension to which the cavity is subjected, the ventricle therefore rapidly becomes dilated, and sudden death is especially apt to ensue from failure of contractile power and syncope. In consequence, however, of the strength of the left ventricle, and especially when the organ is much hypertrophied, as in the cases in which incompetency supervenes on previous obstruction, the alterations in the right side of the heart do not quickly occur, the lungs and parenchymatous organs remain for a considerable time free from serious disease, and general dropsy does not readily ensue. In regurgitant disease of the aortic valves life is seldom much prolonged; a large portion of the cases prove fatal within a few months or a year or two, though in exceptional cases the patients do sometimes live for several years. The orifice may, however, apparently contract, and lessen the degree of incompetency, and so life may be prolonged. The duration of life is, however, always uncertain, and sudden death is apt to ensue in cases not otherwise very threatening. Thrombosis and embolism also may occur, and produce various complications which may immediately endanger life.

Obstructive disease of the mitral valve may be compatible with the prolongation of life for a considerable time, though probably scarcely so long as in the corresponding disease of the aortic valves. It, however, produces permanent congestion of the parts anterior to the constriction, and thus the left auricle becomes dilated, the lungs are liable to various congestive and inflammatory affections, the right side of the heart is hypertrophied and dilated, and the parenchymatous organs are congested, and ultimately dropsical affections ensue, though generally only after the state of obstruction is combined with incompetency, or after the occurrence of some other serious complication, as of the lungs or kidneys. There is also danger in these cases of thrombosis of the affected orifice and embolism of distant vessels, with their effects.

Regurgitant disease of the mitral orifice produces all the effects of mitral impediment in their most aggravated forms; the left ventricle rapidly dilates, and the action of the heart may quickly become irregular both in force and frequency. The lungs are intensely congested, and œdema, apoplectic extravasations and hæmoptysis, and broncho-pneumonia are very generally occasioned. The liver and kidneys also become congested and diseased, and dropsical symptoms ensue, and if they be not relieved the patient dies in no long time, rather from the secondary affections of other organs than from the direct effect of the disease of the heart itself. There is no doubt, however, that in many cases of this kind the symptoms are relieved, and the patient recovers from the attack and regains his previous condition, and may enjoy a fair state of health for some years, though always liable to recurrence of the same severe symptoms from very slight causes. The condition, therefore, is less serious than regurgitant disease of the aortic valves, though much more dangerous than either of the forms of obstructive disease.

The danger connected with these several forms of disease I place, therefore, in the following order, beginning with those which are most serious:—

Aortic regurgitant disease.
Mitral regurgitant disease.
Mitral obstructive disease.
Aortic obstructive disease.

It has, however, previously been stated that two or more sets of valves may be coincidently affected, and it has been shown that combined disease of the aortic and mitral valves is by no means of uncommon occurrence. It is evident that such combination must constitute a very serious form of disease, as the various sources of danger incidental to each particular form are in such cases very greatly aggravated.

In estimating the probable result in any given case of valvular affection, other circumstances besides the special form of disease must also be taken into consideration. Such are—

1. The cause of the disease, its duration, and the rapidity with which the symptoms have advanced, as indicating its probable nature and its active or passive character.

2. The degree of impediment to the circulation which it occasions, and the power of the heart to overcome the obstruction, as indicated by the force and regularity of its beat and the relation of its impulse to the pulse at the wrist, and by the amount of congestion in the lungs and other organs.

3. The presence or absence of serious complications—as of the lungs, liver, brain, kidneys, etc.,—the existence of dropsical symptoms, of a gouty or rheumatic diathesis, and of an anæmic or purpurous condition of the blood.

4. The circumstances in which the individual is placed, as affording the means of obtaining rest of body and mind and protection against atmospheric changes, together with the proper regulation of diet and facilities for medical treatment. The sex, age, occupation, residence, and previous habits of the patient may all, also, affect the prognosis.

In reference to the means of ascertaining the degree of impediment to the circulation, it must be understood that the intensity and character of the murmur attendant on valvular disease afford but little information. For the production of a murmur two elements are necessary: there must be a source of obstruction to the circulation, and the blood must be propelled with power through such constriction. A loud murmur may be produced by a very slight amount of obstruction, and a very

great degree of obstruction may be attended by little or no murmur. The former must be supposed to be the explanation of those cases in which murmurs are heard for many years, though perhaps during this time the patient has remained entirely or nearly free from symptoms of cardiac disease. Of the latter we have frequent examples in hospital practice. A patient is admitted with bronchitis and a very embarrassed circulation, the action of the heart and the pulse being very irregular both in force and frequency, and the different viscera and the system generally congested, with usually more or less dropsy. On listening over the heart, however, no murmur may be heard. After a time, when, under the influence of rest, a genial temperature, and suitable treatment, the bronchitic symptoms have subsided and the action of the heart has become stronger and more regular, a mitral regurgitant murmur is detected, and increases in intensity with the improvement in the condition of the patient and in the power of the heart, till, at the time of discharge, when the patient considers himself perhaps well, there is a loud murmur heard over a large portion of the front of the chest. So, also, it often happens that in cases of advanced mitral regurgitant disease the action of the heart is extremely irregular, there being two or three very imperfect contractions followed by one of greater power; and while with the former no murmur will be heard, there will be a short whiff with the more powerful beat.

In cases of chronic valvular disease which have for some time been almost entirely latent, more active symptoms are often excited by cold, giving rise to bronchitis, and so to great aggravation of the congestion in all parts of the system, and to various secondary affections of the viscera. Often, also, from the same cause, the kidneys become congested and dropsical symptoms suddenly set in.

In cases in which there is a combination of renal and cardiac symptoms, it becomes an important question, in estimating the probable result, to know which of these affections has been the primary one. If the renal disease have been the first, the cardiac affection must almost necessarily advance; if, on the contrary, the cardiac were the primary defect, the renal symptoms may be only due to congestion of the kidneys, and the general condition may admit of very great alleviation, and the patient may recover the state of comparative health which preceded his attack. In deciding this point, the state of the urine will afford great assistance. In cases of simple renal congestion, though the quantity of urine passed may be small, the specific gravity does not generally fall below the healthy standard; whereas in those cases in which the renal disease is primary, the specific gravity of the urine is usually low whatever be the quantity of water passed.

As regards the importance to be attached to the dropsical symptoms in cases of valvular disease, there is some difficulty in making a general statement. The occurrence of a certain amount of puffing of the face and swelling of the lower extremities, if the heart be not very seriously embarrassed and the viscera not much involved, and especially if the kidneys be free from disease, is often readily recovered from; but the occurrence of considerable anasarca, of effusion into the tissue of the lungs and pleural cavities and into the pericardium and peritoneum, with marked congestion of the viscera, must always be regarded as involving immediate danger, and affording but little prospect of material relief.

In men valvular affections most commonly originate either in active inflammation or in over-strain of the valves from violent and long-continued muscular exertion, and they generally follow an active and rapid course, and the heart readily becomes hypertrophied. In females, on the other hand, though rheumatic affections are also a common cause of disease, a considerable proportion of cases originate in emotional causes. In them, also, the disease most commonly assumes a passive form, and the cavities of the heart have a tendency to dilatation, and the muscular walls to become atrophied and undergo interstitial changes.

In early life valvular affections are almost always either congenital or occur in connexion with rheumatism. In middle age they originate frequently both in inflammation and in injury or gradual yielding during muscular efforts, and at both periods they are apt to assume an active form and to progress rapidly; while in advanced life they are generally the result of fatty or atheromatous disease of the valves and muscular structure, or occur in combination with renal disease or with a gouty state of system. In advanced age, in addition to the valvular mischief, the cavities are generally dilated, and the heart affection is often passive in its character, and sometimes, indeed, entirely latent.

The residence of the patient, especially if that be in a hot climate and malarious district; his occupation as exposing him to the weather and to alterations of temperature and so rendering him liable to rheumatic or other inflammatory affections, or requiring the exertion of great physical force, or causing prolonged and severe mental labour; and his habits, if at all intemperate,—are all influential on the progress of valvular disease.

Treatment.

The time at our disposal precludes the possibility of my entering fully into the treatment of cases of valvular disease, and will only allow me to give a brief summary of the principles which should guide us in our efforts to afford relief to the various different forms.

1. In aortic obstructive disease we must endeavour to regulate the action of the heart, which in the earlier stages may be excessive, and in the latter may, on the contrary, be unequal to overcome the obstruction.

2. In aortic regurgitant disease the power of the heart is always defective, and our efforts must be used to enable it to maintain the circulation and to avoid the tendency to exhaustion and to death by syncope.

3. In mitral obstructive disease the danger is also partly from failure of muscular power and partly from congestion of the parts anterior to the seat of constriction.

4. In mitral regurgitant disease there is great impediment to the onward flow of the circulation, but the especial sources of danger lie in the engorgement of the lungs and parenchymatous viscera, and we must endeavour to invigorate the action of the heart and remove the visceral congestion.

In all the forms of disease the means employed to accomplish these indications must be partly hygienic and partly medicinal. The patient must be directed to avoid active exercise, and especially anything of the nature of athletic sports; his mind must also be occupied, but severe mental labour must be avoided. He must live on nutritious but unstimulating and easily digestible food, and must either avoid stimulating beverages altogether or take them only in a dilute form and in very limited quantity—claret, sherry, or brandy being preferred to port or malt liquors.

In the first and third forms of disease, in addition to the hygienic means, the digestive organs should be regulated by mild alteratives and bitter tonics: blue pill or grey powder with rhubarb may be taken as required, with alkalies and bitter infusions—colombo or gentian; and when the power fails and the patient is anæmic, iron, more particularly in the form of the citrate, phosphate, or carbonate, may be given. Hydrocyanic acid is also often very useful in quieting the action of the heart and relieving dyspeptic symptoms in cases of this kind.

In the second form of disease, while similar regulations, both dietetic, regimenal, and medicinal, should be enforced, the power of the heart must be upheld to guard against the special danger of syncope. Food must be taken small in quantity and at frequent intervals, and stimulants must be given, those before referred to being selected. The special remedies also for this condition are tonics—more particularly iron—given in combination with quinine, etc.

In the fourth form, and especially when there is marked congestion of the lungs or other viscera and dropsical symptoms, we must endeavour to promote elimination, more particularly by the bowels and kidneys, while upholding the muscular power of the heart. Mild alteratives and aperients—mercurials, rhubarb, the alkalies,—and diuretics—the acetate or nitrate of potash, nitric ether, etc.—may be given, and must be combined with or followed by the employment of iron and other tonics, the perchloride of iron being in these cases preferred.

In carrying out these several indications the greatest care will be needed not unduly to depress the power of the patient. There are, indeed, few classes of cases the treatment of which so severely taxes the powers of the physician.

It is well known that digitalis exerts special action on the heart, lessening the frequency of its pulsations and proportionately increasing their power, and it has been supposed to be particularly efficacious in the treatment of cardiac affections, especially those in which the action of the heart and the pulse are weak and irregular. I cannot, however, but think that its use has been too generally and too indiscriminately had recourse to. For a time it unquestionably does produce the

effects mentioned, but if long continued, even in small doses, it exerts a very depressing influence, and I have repeatedly seen cases in which it has very greatly aggravated the symptoms. Indeed, I believe it to be much more useful as a diuretic than for its special action on the heart. It is probably the most efficient diuretic which we possess, and is especially useful and valuable in cases of dropsy, and particularly when dropsy occurs in cases of mitral regurgitation, while it is injurious in cases in which the power of the heart is deficient, as in cases of incompetency of the aortic valves. In all cases in which it is employed, and especially if its use be long continued, even in small doses, it requires the greatest care. In some cases where there is very great congestion of the lungs and right side of the heart, as in mitral regurgitation, it has been proposed to have recourse to small general bleedings to relieve the overloaded venous system. I have known a small bleeding, combined with the exhibition of stimulus, to be the means of rallying, when in most extreme danger, a patient labouring under asthenic bronchitis, and it is obvious that the treatment is equally applicable to cases of heart disease.

Generally speaking, the causes which in chronic cases of valvular disease entail the greatest suffering on the patient, and tend most to aggravate his malady and accelerate the fatal event, are increased pulmonary congestion or renal complication resulting from cold, or disorder of the digestive organs originating in various ways, or excitement of mind and over-exertion of body; and special care should be exercised to protect him against these influences. In many cases, if the patient be placed in favourable circumstances, life may be prolonged and a large amount of health and vigour be enjoyed for many years. As, however, he is little likely to submit to the requisite restraints, unless made aware of their imperative necessity, it is right that he should so far be informed of his state as to make him see the importance of the regimen advised; but it would be alike wanting, both in consideration for his feelings and in sound professional policy, abruptly to tell him that he was labouring under serious cardiac disease.

ORIGINAL COMMUNICATIONS.

NOTE ON

AMPUTATION THROUGH THE KNEE-JOINT.

By C. F. MAUNDER,
Surgeon to the London Hospital.

The opportunity of performing amputation through a healthy knee-joint occasionally presents itself, and many surgeons avail themselves of it. From observation of such a case recently under care, the question of removing the patella or not has forced itself upon me. My own experience does not enable me to answer the question, being too limited, and the evidence for and against, numerically considered, being evenly balanced. On the one hand, a case progresses favourably to recovery; on the other hand, acute synovitis results: and this is the point to which I wish to draw attention now. On visiting the above case some few days subsequent to operation, the stump to the unpractised eye looked very well—indeed, too well. It was nicely rounded, the natural depression above the patella being lost. This even surface aroused suspicion, the more especially when it was stated that the patient had that day lost appetite, had vomited, and had a high temperature. The synovial prolongation above the patella was doubtless distended with inflammatory effusion, which could not escape. A free incision was made in the mesian line above the patella, and a quantity of offensive semi-purulent fluid escaped. The bad symptoms quickly subsided. In the course of a few more days pus had gravitated upwards along the outer side of the limb, and a "drainage"-tube was introduced. The detention of secretion above the patella after section of the synovial sac below is explained by the probability that fluid must accumulate both above and below this bone in order to lift it from the groove in which it lies in the femur, but under the altered circumstances it acts as a plug. Fluid readily escapes below through the wound. Against the possible uninterrupted favourable progress after this method of operation when the patella is left, we must put the complication alluded to, and certainly it gave rise to much pain, slight septicæmia, and retarded recovery. On the other hand, cutting away the patella adds something to the severity of the operation; and, other things being equal, the knife should be employed as sparingly as possible. To perform this operation satisfactorily, great attention to details is requisite.(a) At present I incline to removal of the patella.

SUBCUTANEOUS URETHROTOMY

FOR TWO STRICTURES OF THE URETHRA WHICH HAD PREVIOUSLY BEEN TWICE OPERATED ON BY THE SO-CALLED METHOD OF IMMEDIATE DILATATION—GOOD RESULT.

By W. F. TEEVAN, B.A., F.R.C.S.,
Surgeon to the West London Hospital; Surgeon to St. Peter's Hospital; and late Lecturer on Anatomy at the Westminster Hospital.

The operation of subcutaneous urethrotomy is little known or practised in this country, but it is the one which strongly recommends itself to us for adoption whenever an operation may be required. It may be safely said that if a stricture be large enough to admit of the introduction of a dilator or urethrotome, you can cure the complaint by gradual dilatation without the slightest risk to the patient's life. There are, however, a few cases where, although the stricture may be dilated to the fullest extent, it yet so rapidly contracts again that an operation is indicated; and there are also instances of hard, horny strictures complicated with abscesses and fistulæ where an operation is called for, as much for the purpose of giving a free vent to suppurating tissues as for the enlargement of the canal to its natural calibre. In the first case subcutaneous urethrotomy is indicated, but in the latter instances external urethrotomy. The subcutaneous division of strictures, introduced into practice by Dr. Henry Dick, is the only operation which holds out any prospect of a real cure for stricture, as it is the only method that is in unison with the teachings of surgical pathology and experience; it possesses all the advantages of external urethrotomy or perineal section without the disadvantages of an external wound, and it is superior to internal urethrotomy because it always insures a complete division of the strictured parts, which that operation does not.

J. N., a strong, healthy sailor, aged 52, came to St. Peter's Hospital as an out-patient on June 1, 1872. He stated that he had suffered from strictures for upwards of twenty years, and that eight years ago he had been operated on at a hospital in London, where his stricture were forcibly split and an instrument regularly passed for some time afterwards. The complaint, however, returned as bad as ever, and one year and a half ago he visited the hospital where he had previously been, and submitted to a repetition of the former operation, a catheter being regularly introduced for some weeks afterwards. In the meantime the patient had learnt to pass the instrument himself, and used it twice every week till he was forced to desist through the occurrence of some heavy weather at sea. After an interval of ten days he again tried to pass the catheter, but failed, as the strictures had in the meantime contracted. When the patient came under my care I could only pass a No. 3 bougie, and that with considerable difficulty. Examination showed that there were two strictures encircling the urethra like iron rings. The distal stricture was half an inch broad and four inches from the orifice; whilst the other one was a quarter of an inch broad and two inches and three-quarters down the urethra. By the end of the month the urethra had been enlarged by gradual dilatation to No. 9; but when the patient came to the hospital, ten days later, the strictures were found to have again contracted, and would only admit No. 4. He was then admitted into the hospital, and a No. 4 elastic catheter was passed into the bladder and left there for an hour, when it was replaced by a larger instrument. By continuing this method of treatment for six hours the patient's urethra was dilated to a No. 8, when the patient could no longer persevere, on account of the increasing pain. Next day the strictures were again found to have contracted, so that only a small instrument could be introduced. It was now clear that an operation was called for, and accordingly on July 26, in the presence of Dr. Henry Dick, Dr. Green, and Dr. Magrath, I passed a fine straight staff through

(a) *See* "Operative Surgery," second edition, p. 228. By C. F. Maunder.

the strictures, and completely divided both of them, subcutaneously, with a small tenotome, which I introduced beneath the skin by making a small puncture. The contracted tissues were so dense and hard that their division was attended with a creaking noise plainly audible to those present. A very large catheter was then introduced into the bladder and left there for half an hour. Blood oozed away from the urethra for ten minutes after the operation, but none escaped through the valvular puncture made by the tenotome. The patient's urine was drawn off the same evening and three times the next day. On the third day the use of the catheter was relegated to the patient, who passed it once a day till he left the hospital, on July 31—five days after the operation—not having had a single bad symptom nor having been confined to bed. The patient came to the Hospital on September 2 to report himself before sailing. He was then passing No. 14 elastic catheter with ease twice a week, and was in all respects quite well. The ends of the divided strictures could be plainly felt beneath the skin united by bands of supple and non-indurated tissue.

The strictures were in the first instance the result of a long-continued gleet, and the splitting (lacerating) operations to which this man had been subjected had only given temporary and delusive relief, for each operation had been followed by a more speedy return of the complaint. One point of great interest was that the patient had had his strictures treated thirty years ago on board the *Dreadnought* by the system of gradual dilatation. It would thus appear that the results of that treatment were more abiding than those produced by immediate dilatation, which was in reality complete rupture or laceration. The strictures became converted into traumatic ones by the surgical lacerations to which this patient had been subjected; for such strictures as his, uncomplicated as they were with abscesses or fistulæ, were rarely seen unless produced by accidental or surgical injury. No two operations were so dissimilar in character as forcible dilatation and subcutaneous urethrotomy, for the former was an exhibition of blind force, whilst the latter was a demonstration of applied skill.

10, Portman-square.

CASES OF

POISONING BY LEAD IN DRINKING-WATER.

By J. W. VON TUNZELMANN, M.D. Lond.

Sir,—Having recently attended some serious cases of lead poisoning in private houses of the best sort in this neighbourhood, which I found, after considerable anxiety, to be owing to the drinking-water (derived from a well in each of the cases) having become contaminated with lead to a dangerous extent, I take the liberty of sending them to you for publication, as they may serve as a hint to others who may be required to attend similar cases in this neighbourhood, or in other places where, the geological nature of the district being similar, the same deleterious action may be going on, resulting in the poisoning of the drinking-water from its solvent action on the leaden pipe by which it is drawn from the well.

I am, &c., J. W. von Tunzelmann, M.D. Lond.

10, St. George's-road, Wimbledon, September 18.

Case 1.—I was requested, on June 11 this year, to see the cook in one of the best houses in the outskirts of Wimbledon, and found that she had vomited everything that she had taken (according to report) for about three weeks. She vomited also a green bilious-looking watery fluid frequently, but mostly at night. There was a yellowish tint of the skin of the face, and the conjunctivæ were decidedly yellow. There was also constipation, but there was no pain either in the right hypochondrium or at the epigastrium. The region of the liver was not tender to pressure or even strong percussion, and the region of hepatic dulness was not increased. The urine high-coloured, but not saffron-coloured. The case seemed a puzzling one. I was told that she had had a similar attack four years previously, which was then attributed to the smell of fresh paint in the house. In a few days the vomiting was considerably relieved, and she was able to retain some cold beef-tea, but only in very small quantities at a time. This went on till July 14, when she was so much better—the bowels also acting regularly—that I expected soon to leave her quite well, and found her still progressing on the 21st. But on the 23rd the vomiting returned, and on the following day she was worse than ever. The weather meanwhile had set in very hot, and I could only attribute this relapse to that; but still there was no pain in the region of the liver or at the epigastrium, and none in the abdomen except, when she retched much, in its lower part, evidently of a myalgic nature, from fatigue of the abdominal muscles. The vomiting continued for some days, and she became so weak that I was obliged to give her champagne, which she relished greatly, taking about half a bottle a day without vomiting it. This she continued about a week, and then began to take beef-tea in small quantities; and subsequently, the weather becoming cooler, she improved rapidly, and up till August 6 there had been no vomiting. On the 9th also she was still free from it, but complained of a loss of power in her hands, so that she could scarcely do anything with them. All this time the patient had not been confined to bed, though obliged to lie on the bed the greater part of the day on account of excessive debility. As this form of paralytic weakness of the arms is a well-known effect of lead among painters, and as this illness had been very anomalous throughout, I examined her gums and found the "blue line" most distinct along the alveolar border of the lower jaw. I therefore took home some of the drinking-water furnished by a well in the house, and, testing it with a solution of sulphuretted hydrogen, found that the water became of a distinctly brownish tint, showing the presence of lead. I also took a specimen to Dr. Frankland, of the Royal College of Chemistry, who tested it, and stated in his report to me about it that it contained "so much lead as to render it quite unfit for domestic use"; but he also told me that he had never had to analyse well water for lead before.

The house is a semi-detached one, and there is a common well midway in front of the two houses, from which a leaden pipe leads to the kitchens, a distance of about twelve yards on each side.

Case 2.—In the adjoining house the housekeeper had in the winter (in February) anasarca of both legs, which continued for about three months. There was no albumen in the urine. The anasarca was relieved by treatment, and she continued free from it from the end of May till the beginning of July, when it returned, and was again relieved in about a fortnight; this also, I have no doubt, was caused by the lead. She used to complain frequently of excessive nausea. She has not the "blue line" on the alveolar border of the inferior maxilla, but she has a leaden hue of skin, and the buccal mucous membrane also has a leaden hue.

August 18.—I was sent for to-day in great haste to this patient because she was suddenly seized with a loss of power in her hands while occupied with household duties (she awoke last night with a numb feeling in them which frightened her). The mistress feared a paralytic stroke, but I was able to relieve the mind of the lady by telling her that the state of the servant was owing to the lead with which her system had become saturated, and that I did not expect it would get worse now, as the water from the pump had not been used for four days.

19th.—Better, but complains of a numbness in her legs as well as in her arms.

After this she quickly improved, and now (September 18) only complains of neuralgia in her legs.

In the adjoining house (No. 1), where I had the case of "lead jaundice," I have been since told that a young gentleman, a relative of the family, was seriously ill last summer with what was described as "most severe colic, almost amounting to inflammation of the bowels"—evidently lead colic, though not recognised as such by the medical man in attendance on him (from London).

The lady told me that at Christmas, having for some time had great difficulty in getting the pump to act, they had it examined, and found that the pipe (a leaden one) was completely "corroded away" in some places. It was replaced by a new leaden one. The owner of the houses is now going to have the leaden pipes removed, and replaced by patent pipes of lead lined with tin, on the recommendation of an architect of eminence.

Case 3.—I have at present also under my care a young lady who has had diplopia to a most alarming extent for about three months, owing apparently to a sluggish action of the muscular apparatus of the eye (it is very apparent in the movements of the iris), which at first puzzled me completely, the health otherwise being perfectly good. I now find that this case also is owing to the water of the well being strongly impregnated with lead. She suffers from excessive languor. The house is about half a mile from the other two, but on the same

hill, and no doubt the water is of the same quality. When the symptom first showed itself, after having existed for about three weeks, she was sent to Hastings for a while (about three weeks), and improved while there. When she returned home the improvement ceased to progress. She then went away again (to Chislehurst) for three weeks, and improved so much as to be able to drive a pony phaeton, which she could not do even while at Hastings, on account of the double vision. After being away for three weeks she returned, and again the improvement ceased to progress. She is now going to the Lakes for six weeks, which will, I have no doubt, remove the remaining trouble, while the well will be made fit for use by having the leaden pipe, by which the water is drawn from it, replaced by a pipe of galvanised iron.

Case 4.—The mother of this young lady consulted me on August 15 for pain in the back (lumbar region), with very abundant pale urine. I had not then tested the water of this well, but suspected it to contain lead. After I had tested it and found the lead, I told her of the other cases which I was attending, and she then informed me that she had for some time had an unpleasant numb feeling in her hands and arms, evidently the commencing lead palsy.

These cases remind one strongly of the celebrated Claremont poisoning cases which happened in the same county, being almost within sight of this place.

August 30.—Dr. Frankland has determined the quantity of lead contained in the water of the well which supplied the semi-detached houses in which Cases 1 and 2 occurred. He finds it is 1·547 grain per imperial gallon—*i.e.*, 55 per cent. more than the water which caused the alarming symptoms among the late ex-royal family of France at Claremont about twenty-five years ago.

The general quality of the water is shown by an analysis, with which I have been favoured, of the water of the well of a house situated about ninety yards from the house in which Cases 3 and 4 occurred, made by Dr. Medlock at the end of last year. Two specimens were examined; one was dipped directly out of the well, the other drawn through the pump, but the water had been allowed to lie all through the night in the pipes before it was drawn off. "The specimen taken direct from the well contains about twenty-five grains of mineral ingredient per gallon, consisting of chloride of sodium and sulphate of lime; there are only traces of carbonates; there are present traces of ammonia, nitrous and nitric acids, which cause it to act very strongly on lead. *Per se* the water is in every respect fit for domestic use, but the sample which had been left in the leaden pipe all night contains a dangerous quantity of lead, and ought not to be used either for drinking or cooking."

Dr. Medlock advised the substitution of block tin pipes for lead. The owner of this house was led to suspect the presence of lead in the water of his well by perceiving an unpleasant effect in his throat after drinking the water, together with having heard that in a house close by the leaden pipe of the well had become corroded. This is the fourth well to my knowledge, in a small area, where the same deleterious influence has been at work. The houses in which my cases occurred have been built about fifteen years. The soil of the hill on which they stand is a light gravel of considerable depth resting on clay (the "London clay" of geologists); it contains, no doubt, lime in very small quantity only.

The importance of these cases consists in the fact that the character of the water of surface-wells is now known to depend entirely on the nature of the soil through which the rainfall percolates; and as there are other districts, especially in the neighbourhood of London (all the different commons and heaths for instance), where the geological formation is essentially the same, the same deleterious influence may be at work in houses supplied by wells in them, though in many cases no doubt unperceived, on account of the quantity of lead held in solution by the water not being so great as in these cases, and consequently not having produced such grave disturbance of the health in any of their inmates.

I should recommend that wherever obscure cases of gastric disturbance or of paralytic or dropsical symptoms occur, the drinking-water should forthwith be tested for the presence of lead.

The Board of Health at Gibraltar has decided that all vessels from Marseilles, Toulouse, Cette, and other southern ports of France shall be subjected to five days' quarantine.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

FRACTURE OF SKULL—SUPERFICIAL LACERATIONS OF CONVOLUTIONS OF BOTH CEREBRAL HEMISPHERES — REMARKABLE GYRATORY MOVEMENTS OF LEFT ARM—HIGH TEMPERATURE.

(Under the care of Mr. HULKE.)

Injuries to the head affecting the brain are at all times interesting, and not less so to the physiologist than to the surgeon. The following case offers two features worthy of notice—a singular gyratory movement of the upper limb of the opposite side to that where the cerebral convolutions were more deeply and widely torn; and a remarkable rise of temperature, which was attributed to cerebral inflammation, of which, however, after death, no indications were found. The greater damage to the brain on the side opposite to the fracture and scalp wound is also worthy of notice.

A strong, very muscular labourer, aged 30, was found insensible in a doorway at 11.45 p.m. on February 1, 1873, and shortly afterwards brought to the Hospital. He was completely insensible; blood trickled from the left ear; and slightly behind, and to the left of the vertex, was a scalp wound about one inch long. It was dressed antiseptically, and a bag of ice was placed on the head.

February 2.—A restless night; unconscious. Temperature and pulse have risen. ℞. Calomel gr. iij., haust. sennæ co. ℥j.; six leeches behind left ear.

3rd.—1 p.m.: Right upper limb straight, rigid, lying parallel to trunk; its thumb flexed on palm, and fingers also bent. Left upper limb: Fingers flexed, and thumb bent into palm; forearm slightly flexed on arm; rigid. When touched, as when pulse is felt, a rapid and repeated circular movement of limb obliquely across the trunk (somewhat as in turning a wheel) occurs. This movement is repeated about twenty times, the excursions becoming less rapid and less forcibly made towards the close, when the arm remains still and rigid until again touched. At about the tenth act there is also marked opisthotonos. Pulse 144; quite insensible; occasionally moans; purge has not acted; temperature rising. Twelve leeches behind the ears. 9.45 p.m.: Breathing laboured; slightly stertorous. Bled from arm to ten ounces, after which respiration became easier. ℞. Ol. tiglii ♏ij. 11 p.m.: Temperature, 103·9; breathing quieter.

4th.—9 a.m.: Pulse 180, temperature 103·5°, respiration 62. 3.30 p.m.: Temperature 104·4°. 5.30 p.m.: Temperature 104·2°. 7.30 p.m.: Temperature 105·1°. 9.30 p.m.: Temperature 105·7°. 11 p.m.: Died. The croton oil had not produced any stool. Ice had been continuously applied, except for a short interval, during which the pulse was very weak.

At the examination of the corpse next day an extensive starred fracture of the skull was found beneath the external wound. It radiated through the squamous and petrous portions of the temporal bone, crossing the tympanum, and ending in or very near the foramen lac. med. basis cranii. The dura mater was not torn; a large blood-clot, apparently proceeding from some branch of the middle meningeal artery, separated it from the inner surface of the cranium. Beneath this the convolutions at the outer and upper surface of the middle lobe of the left cerebral hemisphere were superficially but extensively lacerated, and the surface of the brain was flattened by the pressure of the clot outside the dura mater, and also by hæmorrhage in the pia mater. The outer surface of the right middle cerebral lobe was rather more extensively lacerated than on the left side, and the rents were also deeper. The meshes of the pia mater and the sulci were here also distended with blood-clot. The base of the brain and also the corpora striata bore no trace of injury, and around the lacerations there were not any appearances indicative of inflammation.

COMPOUND FRACTURE OF SKULL WITH PROTRUSION OF BRAIN SUBSTANCE—SIMPLE FRACTURE OF LEFT THIGH AND LEFT FOREARM—SEPARATION OF LOWER EPIPHYSIS OF RIGHT RADIUS, RESEMBLING A COLLES FRACTURE—DEATH.

(Under the care of Mr. MORRIS.)

[For notes we are indebted to Mr. Lewis, Senior House-Surgeon.]

The following case is of interest as showing the muscles which were concerned in preventing the reduction of a fracture exactly resembling a Colles fracture. It is not often that an opportunity occurs for examining the cause of the deformity of this kind of fracture:—

T. S., aged 5, was admitted on August 13, about 12 midday, moribund, having a few minutes previously fallen out of a third-floor window. On admission the patient was profoundly collapsed. Breathing stertorous. Both eyeballs fixed, the right being turned inwards. Pupils contracted almost to a pin's head, and did not respond to light. On examination the roof of the left orbit was found to be quite detached, and the frontal bone of the same side comminuted. Over left parietal bone was a contused lacerated wound about one inch and a half long, running transversely and leading down to a fracture, and through which brain substance and blood oozed. There was bleeding from left nostril and ear. No suffusion of conjunctiva, but much ecchymosis of both eyelids, including the skin over frontal bone. Besides the above injuries, there was a simple transverse fracture of left thigh, an impacted right Colles, and a simple fracture of both bones of left forearm. Death took place within an hour after admission into the Hospital.

The post-mortem examination was made by Mr. Smith twenty-two hours after death. Considerable effusion beneath pericranium and on surface of brain. Several other fractures were seen involving the great wing of sphenoid, ethmoid, and occipital and temporal bones. Extensive laceration of convolutions of brain of left side. On dissecting down upon the fracture, there was found to be nearly complete separation of epiphysis of lower end of radius, the periosteum upon the extensor surface of bone being unruptured. The displacement exactly resembled that of a Colles. The extensor ossis metacarpi and primi internodii tendons, the radial extensors, and supinator longus, were all tense; the last and first were divided without result. Some amount of reduction followed the division of radial extensors, but *complete reduction* was not effected *until the tendon of flexor carpi radialis was divided.*

CASES UNDER THE CARE OF MR. HULKE.

Case 1.—*Laceration of Forearm, with Compound Fracture of Ulna, caused by the Bite of a Bear.*

Lacerated wounds inflicted by the larger carnivores are not often seen in this country. They do not present any peculiar features, but exhibit the common characteristics of torn wounds—relatively slight bleeding and much sloughing, the latter being caused by the tearing through of immense numbers of capillary bloodvessels when the soft tissues are stretched beyond the limits of their elasticity.

An Irishman, aged 65, visiting the Zoological-gardens, thinking, as he afterwards said, that bears were harmless, and not savage as lions and tigers, stepped inside the railing, and, putting his hand between the bars of the cage, courteously offered a brown bear a biscuit, and proceeded to pat him. Bruin, not accustomed to such familiarity, perhaps also preferring a mixed diet to one exclusively vegetable, seized his forearm with his mouth, and with his forefeet hugged him, and tried to pull him into the den. With some difficulty the Irishman was rescued from his painful embraces and brought to the Middlesex Hospital. The skin, with the fascia and cutaneous venous net, was torn off the flexor muscles from the middle of the forearm nearly to the wrist, from which it was hanging as a ragged flap. The muscles also were very much torn, and the long, thin tendon of the palmaris longus was severed. At the outer side of the forearm, just beyond this great laceration, were two punctured wounds, and below it were two other punctured gashes near the wrist—one over the ulna, which at this spot was broken. At and above the elbow from the shoulder downwards were several long grazes, evidently made by the beast's claws. The ulna artery was felt pulsating, but no beat could be detected in the radial at the wrist and amongst the lacerated parts; what appeared to be this artery completely severed was discernible. He said that he had lost an immense quantity of blood, but there was no evidence of this, his clothes and the dressings which had been temporarily applied not being much wetted. The slight shook seemed mainly due to fright, and it soon passed off after taking a little brandy and an opiate. The shreds of torn tissue were trimmed with scissors, the flap laid down again on the forearm, after it and the wounds had been thoroughly washed with a solution of carbolic acid, and an antiseptic dressing was applied. Most of the flap sloughed, and the grazes at the inner side of the elbow festered, but at the end of a month cicatrisation was well advanced, and the wound had become so small that he was made an out-patient. The broken ulna had united.

Case 2.—*Acute Glossitis—Leeching—Recovery.*

Acute glossitis is a rare affection, and its causes are not usually very apparent. In the following case no mercury or any other of the substances commonly assumed capable of producing it had been taken, but the patient had been out of health for three weeks before its accession. She was unable to state certainly whether the lymphadenitis, which complicated the case, preceded the onset of the glossitis or the reverse. Assuming the former to have happened—and her account rather favoured this view,—possibly stasis in those glossal lymphatic vessels which were in communication with the inflamed glands, and a retrograde infection of these vessels from the glands, inducing angioleucitis, followed by extension of the inflammatory process to the other tissues of the tongue, is the true explanation of the case. The preponderance of the swelling on the left side of the tongue favours this view. The benefit from leeching was decided.

A stout blonde, aged 36, was admitted into Regent ward on June 12, with an acute swelling of the tongue, which had begun five days previously. The tongue was hard, purple, and so swollen that it distended the mouth and projected beyond the teeth, preventing the jaws being closed. The teeth were encrusted with tartar, and the gums were red and slightly swollen. Under the left angle of the lower jaw was a tender, painful, lobulated swelling, like a cluster of lymphatic glands. The soft parts beneath the chin were swollen, hard, and tender. She said that she had had the glandular swelling from childhood, adding that in early life two pieces of it had been cut out. After being out of sorts for three weeks—pains in head, neck, and shoulders—her tongue rapidly swelled, so that very soon she could hardly swallow even fluids and scarcely speak. With an effort she got down haust. sennæ co. ℥j. Four leeches were put on her tongue; they drew well, and their bites bled very freely. The purge produced three stools.

13th.—Tongue much less swollen—it has receded inside the teeth; glandular swelling more tender. Four leeches to be put on it.

14th.—Glandular swelling smaller; great pain in the tongue in the night; the tongue is not so fixed. Three more leeches to be put on it.

16th.—Tongue paler and much smaller. The finger can now be passed into the mouth, and the swelling and hardness are found chiefly to affect the left side of the tongue. Swallowing is less difficult, and speech is not so indistinct. She has little pain—this is in the neck, below the chin.

17th.—Tongue rather more swollen than yesterday; pain under chin is greater; constipated. Haust. sennæ co. ℥j.; three leeches.

After this the tongue quickly diminished, and it soon became naturally soft and mobile, with corresponding improvement of speech and swallowing; but a tender, brawny hardness spread from the chin downwards to the sternum, and from the left across to the right side of the neck. This subsided more slowly, without suppurating, under leeches and hot poultices. She went home convalescent on July 19.

Case 3.—*Inflammation of the Sacro-Iliac Joint.*

Inflammation of this joint is of unfrequent occurrence. It may be mistaken for sciatica and for coxitis, but a careful examination will usually suffice to prevent such errors of diagnosis.

A *petite* brunette, aged 37, was admitted into Regent ward, October 7, 1871. Over her right sacro-iliac joint was a tender, oblong, fluctuating swelling, deeply seated, and not movable upon the bones beneath, whilst the superficial tissues were freely movable upon it. Pressure on the trochanter major or on the crest of the ilium in a direction perpendicular to the spinal column caused sharp pain in the swelling: but when

the haunch-bone was firmly fixed the thigh could be freely moved without pain. Careful and repeated measurements showed that the limb was not shortened.

The patient stated that one year previously, in the place of the present swelling she began to feel an aching pain, which she attributed to rheumatism. A medical man thought it sciatica, and treated her for this.

The swelling was painted with iodine, and the ilium with the sacrum were fixed with a stout, closely fitting belt, and pot. iod. gr. iij. were given her three times a day.

With occasional remissions the pain decreased, the swelling perceptibly lessened, and she became able to bear without discomfort firm pressure on the ilium, and even rather rough handling. She went home at Christmas with injunctions to rest several weeks longer. This order was very imperfectly obeyed, and a slight relapse occurred, the pain returning and the swelling becoming larger, but they soon again yielded to complete rest.

SATURDAY, SEPTEMBER 27, 1873.

THE EXCLUSION OF CHOLERA.

Public attention was called to a fatal case of cholera, which was said to have been imported from Havre into Southampton, by a letter which appeared in the *Times* of September 17. Further information as to the case is given in a letter from the Deputy Chairman of the Sanitary Committee of the Southampton Corporation, which appeared in the same paper on Friday last week. It seems that the vessel in which the patient arrived was visited by Dr. Wiblin, the medical officer of the port, on Sunday, the 7th inst., who was assured by the captain that he had no case of sickness of any kind on board. The captain attached his signature to this statement. The history of the case is suggestive. It is well known that there is cholera at Havre. On September 6 the vessel in question—the steamship *Allianee*—was lying in Havre dock when the man fell overboard. His head is said to have stuck in the mud, and after his rescue an emetic was given, and he is reported to have vomited a quantity of black muddy water that he had swallowed. For a day or two he showed no particular symptoms of any ill effect; but by Wednesday, the 10th instant, when the ship had arrived at Southampton, he had become very ill. He was put on shore, and left in a cab for his own lodgings. Thence he was taken to the infirmary, where he died, and his death was certified as from "cholera." The cab, bedding, etc., have since been disinfected, and the town continues healthy. The fact of the man having swallowed a quantity of the filthy water of the Havre harbour, and dying within a week afterwards of cholera, is at least a curious coincidence. The writer of this article recollects a similar case, which occurred during the prevalence of cholera at the East-end of London in the last epidemic. A man who had been previously quite well fell into a creek of the river in the neighbourhood of the docks. On being rescued he said he had swallowed a quantity of the dirty water. Vomiting and purging soon after supervened, and he was brought to the Great Northern Hospital with all the symptoms of Asiatic cholera, rice-water dejections and vomiting, cramps, and blue surface. He survived to the stage of secondary fever, when he died with arrested renal secretion.

As we have said, such cases at least suggest that the choleraic poison may have been swallowed in the dirty water of the harbour, which received the impurities of the infected neighbourhood. It is at least certain that symptoms resembling Asiatic cholera do not ordinarily result from an accidental ducking. That drinking-water is one ordinary channel by which choleraic poison is distributed we hold to be proved as certainly as any fact in the whole range of etiology, and therefore it must be considered at least as most probable that in such cases as those we have related the poison was thus introduced into the system. These cases, moreover, suggest a caution to the inhabitants of seaport and riverside towns during the prevalence of cholera. Men and boys should not bathe in sewage-polluted streams and harbours during the continuance of an epidemic.

The other lesson which the Southampton case affords is one of vigilance to the medical officers of ports. It appears that in this case the captain on Sunday, the 7th, was justified to a certain extent in returning his ship's crew to Dr. Wiblin as healthy, for the unfortunate man who on the previous day had fallen into the Havre water was not then complaining, nor was he much unwell until the Monday, when the ship sailed for Cherbourg. On Wednesday he was again at Southampton, and was put on shore with the symptoms of cholera. The case affords evidence of the extreme difficulty of maintaining safety by any means short of imposing quarantine on all vessels arriving from infected ports. Had Dr. Wiblin seen each of the ship's crew on Sunday, the 7th, it is not improbable that the man in question would have presented no symptoms that would have aroused his suspicion, and yet it can scarcely be doubted that he at that time was in the incubative stage of the disease. Of course quarantine would be felt as a most irksome and severe penalty were it imposed upon the Channel steamers. The voyages occupy only ten or twelve hours, and a quarantine of less than five or six days would be comparatively valueless. The deputy chairman of the Southampton Committee observes in his letter that if it were considered advisable to impose it, the local sanitary authority has not the power. We have no doubt that Dr. Wiblin at Southampton, and other medical officers at ports, will do all that experience can suggest or vigilance accomplish, but, with cholera in nearly every seaport town from the Baltic to Havre, their watchfulness will be severely tried. In consequence of the case at Southampton, we learn from the letter already referred to that Dr. Wiblin now inspects every ship arriving at Southampton from whatever port before any of the crew and passengers are permitted to disembark, and Dr. Tarrell, quarantine medical officer at Havre, inspects all emigrants before embarking by steamers for Southampton. But still, with the disease so close to our shores, and the daily traffic that unites us with the Continent, we cannot but think that our chief hope of safety is in the

advanced period of the year and the generally improved sanitary state of our large towns.

THE MEDICAL USES OF ELECTRICITY.—No. IV.

Therapeutical Use of Electricity.

Electricity has been successfully employed in the treatment of some painful affections besides those mentioned in our last article, as in the pains excited in strained, lacerated, or over-fatigued muscles, and the suffering of chronic fibrous rheumatism. But the use of this agent in these affections is not yet clearly defined, and we shall therefore not treat of it here.

The widest field for the application of electricity, and especially for the "localised employment" of it, is no doubt in the treatment of paralytic conditions; and we will now treat of its application in these various affections.

In paralysis from cerebral disease, great care must be taken not to employ it too soon. If the paralysis has come on suddenly, or if, though it has come on gradually, there is giddiness or pain in the head, or any sensation of weight or fulness of the head, too much caution cannot be used—some fresh mischief may occur under such circumstances, and its occurrence will be attributed to the electrical treatment, though it may be merely and entirely a coincidence. It is far better, in such cases, to wait for a time—for four or more months—before resorting to the employment of electricity, as it is advisable to wait before using any other kind of treatment that would disturb or excite a patient. If none of these head symptoms are present, and the disease has only gradually come on, no such degree of caution is necessary, though then also care should be taken, as we have before said, not to alarm or agitate a patient by a parade of the electrical apparatus or by the mode of using it.

When it is decided to employ electricity, the first step to be taken is to test the excitability of the muscles by the faradic and interrupted-voltaic currents; and the mode in which this is to be done we have already described. The manner in which the muscles respond to the test—that is, the amount of contractility they show—will tell what good may be looked for from the employment of electricity. If the contractility is normal, though voluntary power is abolished, electricity will do nothing towards restoring the power of the will over them; if the contractility is somewhat, but only slightly, diminished, the condition of the muscles may be improved; and when the contractility is found to be markedly reduced, but not abolished, great good may be achieved—the contractility may be gradually brought back till it equals that of the healthy muscles, and then it may be that the paralysis will be found to have been lessened, and now and then even cured. And in all cases this good at least will most likely have been obtained: the nutrition of the muscles will have improved, and colour and warmth have been restored to the skin. This is by itself a gain of great importance, for the muscles and the neighbouring tissues are thus kept in a proper state of fitness and readiness in case the disorder of the brain or of nerve-power that caused the paralysis be restored, and the influence of the will over the muscular part of the locomotive apparatus be regained. And further, it appears to be certain that electrical action on the muscles, peripheral electrical excitement, as it may do harm to, so also may aid the recovery of, the nerve-centres. That it does act on them is shown by the fact that peripheral galvanisation of the limbs is often observed to excite a peculiar sensation of taste.

Having tested the excitability of the muscles, it will be best, as perhaps the most useful general rule, to treat them by means of the current to which they most readily answer; or to employ the interrupted voltaic current where the excitability is normal, and the faradic where it is diminished.

If voltaism is employed it must be by the interrupted, not the continuous current. Large-sized sponges should be used, well wetted with salt and water, and one (the upper one of the two—that is, the nearest to the central organs of the nervous system) being kept steadily on one spot, the other should be moved slowly down along the course of the muscles; so that every part of each of them is successively brought into the circuit of the current, and by the movement of the lower sponge the current is *interrupted*. And here we may again remark that, therapeutically, it does not matter whether the current is direct or inverse; only it must be remembered that the direct current acts more strongly on the muscles than does the inverse, and that the current must not be so strong as to excite pain: it must be just strong enough to cause contraction of the muscles not strong enough to hurt.

This rule applies also to the employment of faradisation. The patient is not to be hurt or wearied; and whenever, during the use of any form of electricity, the patient feels faint, or giddy, or sick, or has pain in the head or a sensation of sinking or uneasiness in the epigastric region, the application must be stopped for a while.

If the faradic current is the form of electricity selected, sponges or metallic buttons covered with chamois leather are to be used; and they must be *well* wetted, or the current may only irritate the skin, instead of penetrating to the muscles. Moreover, the rheophores should never be widely separated; it is important to localise the action of the current as strictly as possible; and, with this view, it is best to use poles of such shape and size that both can be easily held in one hand. Then the muscles are to be faradised *seriatim*, each being picked out, and, according to its size, the current being passed through the whole at once, or through different parts successively, so that no portion of it shall escape being electrised. Particular points will be found in the arm and leg (and in other parts, as in the face), at which, on application of the current, the effect on the muscles will be stronger than when it is applied elsewhere. These, called by Duchenne "points of election," are the places at which the motor nerves entering the muscles lie most superficially.

Electrisation may be successfully employed to relieve, or even cure, the "late rigidity" of hemiplegia. In an early stage of it the tendency to cramp may be removed, and the rigidity cured; and even in old and severe cases, when the nails have dug into the palm of the hand, considerable alleviation and benefit may be obtained. Either the faradic or the interrupted voltaic current, applied to the antagonising muscles, will do good, but the greatest benefit will be gained by applying faradisation to the antagonistic muscles, and aiding it by sending a continuous voltaic current down the rigid muscles; voltaise the flexor muscles, and faradise the extensors.

In *paraplegia*, from myelitis, meningitis, or hæmorrhage into the cord, electrisation must not, of course, be used while any active mischief exists; and there will be often much difficulty in determining when it may be safely employed. But the affected muscles may be now and then tested by the interrupted voltaic and the faradic currents, and when it appears that the time has arrived when electrisation may be used, one of the forms, or perhaps both, may be applied in the manner already described. In some of these cases, the only good that can be gained is an improvement in the power of the sphincter of the bladder and rectum: if their power for retention has been lost, electricity will sometimes restore it. To act on the sphincter of the rectum, one sponge-pole, well wetted, of the faradic current, is to be placed on the sacrum, and the other applied to the anus; if the vesical sphincter is to be treated, apply one sponge to the perineum just behind the scrotum, and the other above the symphisis pubis. This will in some cases, to some extent at least, prevent involuntary evacuations, and thus give considerable relief. Or the paralysis may be incomplete, and then larger benefit may be obtained. The

good to be looked for may be measured by the state of electro-excitability of the muscles; if entirely abolished, no good can be done, and none if it be normal; but where it is diminished more or less, the nutritive condition at least of the muscles may be improved.

In the "essential paralysis" of infancy and childhood electrisation may be of considerable use if employed before the muscular tissue is too much degenerated. In this form of infantile paralysis the affection comes on suddenly, the faradocontractility of the muscles is more or less diminished, they waste, and their tissue undergoes the fatty degeneration; and they are affected by secondary contractions. Not rarely it will be found that when the affected muscles answer but little, or not at all, to the faradic current, they will respond to a slowly interrupted voltaic current, and are even more than normally sensitive to it. The good that electrisation can do here is to improve and to preserve the nutrition of the muscles, and so prevent wasting, degeneration, and contraction; and in some cases even more than this may be done, for if the affection of the cord can be cured, the peripheral electrical treatment may forward the cure. Where there is still response to faradism this form of electricity is the best to use, care being of course taken not to frighten or pain the child. Where the irritability to the interrupted voltaic current is *increased*, it will be best to treat the case at first with this current. In a little time it will be found that the reaction to the faradic current is restored, and that the excitability to the interrupted voltaic current lessens; then faradisation only may be employed. The disease is almost invariably a tedious one, and the treatment must be continued for a very long time—for months, or years even. But so long as there is any response to electrisation there is a hope of benefit. Dr. Radcliffe says that "if the paralysed muscles retain their electro-contractility and sensibility, and so show that they have not passed into that state of fatty degeneration into which they always tend to pass eventually, there appears to be scarcely any limit to the time in which improvement, and even complete recovery, is possible."

CHANGES IN THE ARMY MEDICAL DEPARTMENT.

We last week published a statement which had appeared in a contemporary on the subject of a contemplated reduction in the *personnel* of the Army Medical Department. We took occasion at the same time to remark that no intimation of the projected alteration had reached us. Further inquiry has tended to confirm the opinion we formed on reading the paragraph alluded to—namely, that the intentions of Mr. Cardwell had been, to say the least, anticipated by the journal in question.

We have every reason to believe that the Medical Department itself has not even been consulted in the matter; and although the random legislation of the present day does not certainly appear to aim at producing popular reforms in the various departments of the army, we can scarcely conceive it probable that the authorities would go out of their way to render the medical service of the army more uninviting than it is at the present moment.

The agitation on the subject of the unpopular changes which have been brought about in the service by the promulgation of the last Medical Warrant has not yet subsided, and may only be said to slumber until such time as Parliament reassembles, when, unless Mr. Cardwell previously decides to modify the obnoxious portions, the whole matter will again be brought forward in the House of Commons. The projected scheme for extending the plan of employing private practitioners to take charge of troops at outlying stations is in itself open to many objections. It has for many years been the custom to obtain the services of resident medical men where detachments have consisted of insignificant numbers, and in these cases, as the demands to be met have been comparatively few, the service has in no way suffered; but at larger and more important depôts it is not so clear that the troops would command that constant and undivided attention which the peculiar exigencies of the Service require. There are numerous details to be carried out by medical officers in charge over and above the mere hospital attendance. One rule of the Service, for instance, stringently enforced, provides that a medical officer shall invariably be present during ball practice. It will thus be seen that a resident practitioner would have but little time left to him for private practice, and one set of patients—either the military or his own—must suffer. Again, barracks are not unfrequently situated at some distance from the different towns to which they are attached, and in these cases much delay would ensue in summoning the surgeon should his services be necessary at inconvenient times. Even granting that the chaplain's department of the army is worked on this system, we scarcely think that the two cases admit of comparison, the cure of bodies requiring, as a rule, a prompter attention than the cure of souls.

We have merely thrown out these few hints as showing, in our opinion, some of the objections which we imagine to exist against the plan spoken of by our contemporary; but we presume that the authorities themselves, more especially the heads of the Medical Department, are sufficiently alive to the best method of providing medical attendance for our soldiers; and we must again express our conviction that the changes which have been announced are, at all events for the present, merely speculative.

THE WEEK.

TOPICS OF THE DAY.

The meeting of the British Association—of which we give elsewhere an extended report—has been signalised this year by the contribution of several very remarkable papers in biology. The inaugural address of Professor Allman, the President of the Biological Section, was, we think, especially valuable, inasmuch as it indicated with great fairness the present value and position of the evolution theory in biological science. Dr. Allman is an advocate for the admission of the theory as a practically useful one to the scientific biologist, and as a theory capable of leading on to splendid generalisations. But amongst its difficulties the greatest seemed to him "the unbroken continuity of inherited life, which it necessarily required through a period of time whose vastness was such that the mind of man was utterly incapable of comprehending it"—a period of time so immeasurable that from the chalk formations to the present era was merely like a swing of the pendulum in comparison with it. Was the faculty of reproduction so lasting as this? His comparison of the evolution hypothesis to an algebraic fiction, which, although not really true in itself, might prove of great value as a working hypothesis, was an especially happy one.

Of Professor Ferrier's experiments on brain function we have already expressed our high opinion; they are certainly amongst the most remarkable physiological researches of modern times. The objections to them are, however, numerous: in the first place, they seem not to be confirmed by pathological facts observed in the human subject; in the second place, the brain is in an unnatural condition, the calvarium being partially removed and the brain in contact with atmospheric air; thirdly, the circulation through the organ must be affected by the operation and the resulting conditions; fourthly, the stimulus applied is electricity, which is not the same as nerve-force; fifthly, the animal is placed under the influence of chloroform, the sensory functions are abolished, and the blood is temporarily poisoned. All these

circumstances must be taken into consideration before the value of the results can be justly estimated.

The experiment as to female doctors in the Bristol Children's Hospital has come to an abrupt termination by the resignation of Dr. Eliza Walker, the cause of the heartburning. In the daily papers is published a correspondence, including apologies to Dr. Ward Bush, interference with whose functions was the prime cause of offence. This correspondence ends with a letter from Dr. Eliza Walker, from which we make the following characteristically feminine extract :—

"They (the members of the staff) must have known how important it was to the cause I represent that the experiment of my appointment should prove successful. It behoved them, as gentlemen, to be lenient to a fault which few men have not at one time or another been guilty of, in consideration that in compelling my resignation they would injure not so much an individual as a just cause which has as yet too few supporters. Moreover, although an outbreak of anger placed me at the mercy of Dr. Bush—of this as a natural consequence of my weakness I do not complain—it did not place me in the same relation to the rest of the staff. I am of the same profession as themselves ; common courtesy, common fairness, commanded that I should be heard in my defence. The worst criminal is not judged unheard, and I think I could have shown that all the provocation was not on my side. I decline altogether to submit to their code of honour ; their position I unhesitatingly challenge. Much as I may be to blame, I cannot charge myself with injustice, unfairness, or neglect of duty. To me they have been unjust, unfair; and, as to neglect of duty, you know that without any notice they left the entire medical charge of the hospital and dispensary to chance and me."

We learn from Vienna that up to September 19 there had been 2755 cases of cholera in the city, of which 1111, or two-fifths, have proved fatal. On the above date forty-one fresh cases were announced, indicating an abatement of the malady.

Our Madras correspondent writes, under date August 27 :— "Latest advices represent cholera decreasing in Siam, but raging at Singapore; quiet in India. Small-pox is still wandering from place to place where it can find new victims."

Mr. Erichsen will deliver the Introductory Lecture at University College on October 1, in place of Dr. Roberts, who, we regret to say, has been prevented by indisposition.

THE CASE OF ALLEGED CONSPIRACY.

The case of William and Mary Tuckfield, which has been before the magistrate of the Westminster Police-court on several occasions, came on again for hearing on Wednesday last. It will be remembered that the above defendants, together with Dr. Edgcombe and Mr. Webb, a solicitor, were charged with conspiring together to defraud the Metropolitan Railway Company of £2000, as damages for injuries stated to have been received by Tuckfield on the Company's line. We cannot do better than reproduce the following report of the last examination from the *Times* newspaper :—

"The cross-examination of Dr. March (the medical man who had attended the case throughout, Dr. Edgcombe having been called in as consultant), resumed after a lapse of three weeks, showed that Dr. Cooper, one of the doctors employed by the Company, on May 3, 1872, had endorsed the view of the matter taken by the witness. Dr. Kellett had also approved the treatment prescribed, and it was considered beneficial. The cupping over the spine seemed to do Tuckfield good, and witness's assistant had, like, Dr. Edgcombe, believed in the case as genuine. Mr. Webb had also always been led to believe the case was genuine, and, in fact, the injuries seemed likely to have been caused by a railway accident. The witness hesitated when the question was put to him whether he believed Tuckfield had been in the accident or not, but at length he gave an opinion in favour of the defendant. After this evidence, Mr. Montagu Williams said he had heard the evidence that day, and, looking to all the circumstances of the case, he felt it his duty to say that he could not carry on the case of conspiracy any further ; he would therefore withdraw from the prosecution. Mr. Lewis said Dr. Edgcombe and Mr. Webb had courted a full investigation. Dr. Edgcombe had been in the profession forty-five years, and in 1828 was surgical prizeman at Guy's Hospital. Mr. Woolrych said he perfectly agreed with the remarks of Mr. Lewis, and from the first he had had some doubts upon the matter. After what they had heard that day he was bound to acquit the gentlemen charged of all complicity in anything like a conspiracy or fraud with the Tuckfields ; the medical gentlemen employed by the Company were proved to have agreed that the symptoms and injuries were those of a railway accident, and the Company had offered to compensate the defendant Tuckfield. Mr. Williams said the charge of perjury against the Tuckfields would still stand, and, as he was not prepared with the country evidence that day, he should ask for a remand. Tuckfield was sent to the House of Detention, and his wife liberated on bail."

We heartily congratulate Dr. Edgcombe on his entire and honourable acquittal. We have received several communications respecting some severe and, as has now been proved, unjust comments made upon him while the subject was still *sub judice*. We agree with our correspondents that such remarks were not only premature but unjust. It is a wholesome axiom of English law that every man should be considered innocent until he has been found guilty.

MEDICAL PREPARATIONS FOR THE GOLD COAST.

Further supplies of medicines and instruments are being got ready for despatch, at an early date, to Cape Coast Castle. The medicines are ordered to be put up in small quantities for the use of detachments, and also to render them as portable as possible. It is of course probable that in a march upon Coomassie the only means of transit would be the shoulders of the natives, or at best the China barrows, as they are called, which are being got ready at the Royal Arsenal, Woolwich ; in either case the more reasonable the size and weight of the packages to be carried, the less risk they will run of actual loss or damage. Another of her Majesty's ships, the *Victor Emmanuel*, is being fitted as a hospital ship to be stationed off Cape Coast Castle, and she will leave this country for her destination with every modern appliance for the care and comfort of the sick and wounded which can be devised. The latest reports from the Coast are much more satisfactory as regards the amount of sickness prevailing ; the most unhealthy season may now be said to be over for some time ; and it should be borne in mind that the exceptional amount of sickness amongst the first detachment of the Royal Marines sent out was entirely due to the fact of their arriving on the Coast just at the commencement of the rains, and must not be taken as a criterion of what we are to anticipate when the regiments about to be sent out are landed. The 86th Regiment at the Cape of Good Hope is announced as likely to be added to the force to be despatched. The men of all three regiments are to be furnished with clothing adapted for operations in a tropical climate; and we may venture to hope that if Sir Garnet Wolseley can organise a scheme for prompt and rapid action, if the troops can be brought off the Coast at the identical moment they are required, without any long and tedious waiting, the dreary anticipations of enormous sickness and mortality may not be verified. The cunning of the savages will of course be exercised in delaying our operations as much as possible, so that the next unhealthy season may find us on the Coast with the work still undone ; but this must be avoided at all hazards. The capture of Coomassie will have the same effect in Africa that the taking of Magdala produced in Abyssinia : our prestige has only to be decisively established to bring all the various tribes into subjection. And when we have once more restored peace, it would be well if the governing powers were to turn their attention to the sanitary improvement of the stations on the West African Coast. The climate is certainly about the worst to which Europeans can be exposed, but that is scarcely a

reason why no steps should be taken to stop all sorts of customs and abuses which at the present moment tend to swell the death-roll of the settlements.

DEATH OF M. NÉLATON.

The great French surgeon, whose painful illness has excited in the professional and public mind an interest raising it to the rank of a national event, has at length, after several times being on the verge of death, expired. We shall furnish our readers with a memoir of his career at a future period, and in the meantime transcribe the following notice from the *Union Médicale*:—

"On Sunday, September 21, at nine o'clock in the morning, a great medical intellect passed away. After several months of a lingering and painful illness, M. Nélaton has succumbed to an organic affection of the heart. The considerable place which he occupied in contemporary surgery will make him the object of a detailed appreciation; and at present we can only render our homage to the character and the qualities of heart of the *confrère*, the friend, and the private individual. There can be but one voice raised in praise of the benevolence, the simplicity, and the modesty of this eminent man, who, having attained the highest honours, took as much pains to dissimulate his elevation as others would have to make a vain display of it. M. Nélaton was good and charitable. Never did any misfortune knock in vain at his door, and often he went in search of it; and we ourselves have many times had the honour of being the vehicle of his good confraternal works, when these had to be undertaken simply and discreetly.

"Member of the Institute and of the Academy of Medicine, M. Nélaton also belonged to almost all the learned societies in the world. He descended voluntarily from his chair of Clinical Surgery as soon as he found his sight failing him, and no longer belonged to the Faculty which his teaching had rendered so illustrious other than as Honorary Professor. Raised by the Emperor to the dignity of Senator, he lost this at the September Revolution. He was Grand Officer of the Legion of Honour—a distinction which has been accorded to none others of the medical profession than himself, M. Rayer, M. Ricord, and M. Lévy. There is no example of any practitioner having enjoyed the public confidence to the extent of M. Nélaton. Neither Boyer, Marjolin, Dupuytren, Roux, Velpeau, nor Jobert ever approached the vogue of M. Nélaton. M. Ricord alone has nearly reached the same level."

BONES FROM DISSECTING-ROOMS.

An extraordinary quantity of human bones has been found in the excavation for the foundation, upon which workmen have been for some time engaged, of the new wing of the London Hospital, the site of which will be the old Medical College. A shed which stands in a corner adjoining the works is filled to the roof with these bones. Besides these, no less than fifty-two coffins, filled with bones, have been removed to Ilford for reinterment. It is calculated that what remains will fill thirty more coffins. The contents of each coffin weigh two hundredweights, making in all about eight tons of bones. Taking the average weight of a human skeleton to be fourteen pounds, it is found that this shed contains all that now remains of no less than 1280 human beings. They are in an excellent state of preservation, though they have evidently been beneath the ground for a great number of years. It may be mentioned that at the time the great Windmill-street School of Anatomy ceased to exist an immense quantity of bones was found in deep, dry wells, the accumulation from the dissecting-room of probably half a century.

MANUAL OF FAMILY MEDICINE FOR INDIA.

The prize offered by the Government of India in Resolution No. 431-40, dated October 31, 1871, for the compilation of the best Manual of Family Medicine for India, has been awarded to Surgeon-Major W. J. Moore, of the Rajpootana Political Agency.

CONVICTIONS UNDER THE ADULTERATION ACT.

During the past week the magistrates at the various metropolitan police-courts have inflicted heavy fines on milkmen who have added water in quantities more or less to their milk. There is no evidence that any other kind of adulteration had been practised. The fines varied from £20 to £1 and costs. One of the magistrates stated "that if the milk had been adulterated with anything injurious to health he should have fined the defendants in the full penalty of £50." It would be difficult to determine what *could* be more "injurious" than the addition of bad water.

LODGING-HOUSES AND DISEASE IN BLOOMSBURY.

Dr. Ross, the Medical Officer of Health, thus describes the common lodging-houses of Bloomsbury:—

"Tramps, wife deserters, beggars, pickpockets, and woman of bad repute occupy the common lodging-houses in this quarter—the southern portion of St. Giles's. There are more than 2000 of these persons, the large majority of whom are single, or at least live as celibates. They are nevertheless prolific. A considerable amount of sickness and mortality in St. Giles's, and a large proportion of the cost for supporting its pauperism, are caused by the occupants of these houses. It would be a mercy to the labouring poor to scatter these people from their haunts. Only a limited number of houses harbouring them should be allowed in each district. By massing these outcasts together as they are in St. Giles's, they are effectually cut off from all humanising influences, and their moral corruption only becomes more aggravated."

PRESCRIBERS AND DISPENSERS.

A committee which had been appointed by the Pharmaceutical Society to make a suggestion as to the best way in which practitioners should indicate that any large dose they order is done so intentionally, have suggested that the initials of the prescriber should be placed against the ingredient. It has been resolved that this suggestion should be communicated to the heads of the various medical societies throughout the country. This is a very good precaution, and one which, we hope, will be generally carried out. It will prevent such unseemly contests as that which lately took place at Ramsgate.

THE ST. LUKE MEDICAL ASSOCIATION.

The sermon in connexion with the anniversary meeting of the religious society for students and practitioners bearing the name of "St. Luke the Physician," will be preached by the Rev. Dr. Irons, rector of St. Mary Woolnoth, Lombard-street, at St. Thomas's Church, Regent-street, on the evening of Monday, October 20. The general meeting will be held in the adjacent school-rooms immediately after the service. Professor Bentley, of King's College, London, will preside.

DECLINE OF TYPHUS FEVER IN LIVERPOOL.

Dr. Trench, the Medical Officer of Health, reported to the Liverpool Health Committee last week that there had been no death from typhus in Liverpool—an exemption which had not been reported since 1848.

SNAKE-POISON.

The *Times of India* says the Snake-poison Commission has sent to Australia for a quantity of Australian snakes in order to give Mr. Halford's remedy a fair trial.

FROM ABROAD.—PROFESSOR PETTENKÖFER ON OZONE—ABUSE OF MEDICAL CHARITIES IN THE UNITED STATES—DALTONISM IN RAILWAY EMPLOYÉS.

Professor Max von Pettenköfer (Berlin *Klin. Woch.*, No. 34), writing on the subject of "Ozone and Cholera," observes that it is to be expected that during the new outbreak

of the disease the often-repeated question will be asked again, Whether there is any connexion between the localities of the epidemic and the amount of ozone contained in the air?—a position that has been both denied and maintained. In fact, the inquirer is not yet in possession of the means of proof, as the methods hitherto employed only show the amount of ozone approximatively—they are rather ozonoscopes than ozonometers. A principal defect consists in the fact that in the usual method by exposing ozone papers no account is taken of the quantity of air which in a given time comes in contact with them. Believing that to this circumstance—the too small ventilation—the absence of ozone reaction in closed dwelling-places is due, Professor von Pettenköfer induced Dr. Wolfhügel to examine the amount of air that is needed in the open air to obtain the ozonic reaction on the iodised paper as compared with that required within buildings. One thousand litres of air in the open constantly induced obvious reaction, while the air of the different rooms of the Munich Physiological Institute—even those of them that were quite uninhabited and spacious—did not induce the slightest reaction, even when from 10,000 to 12,000 litres were brought in contact with the paper. This is the more remarkable, as it is well known that the air of rooms, even when the windows and doors are closed, constantly undergoes change, if in only a slight degree. As we, therefore, live in our dwellings for the most part without ozone in the air, the smaller or greater quantity in the open air cannot exert any great direct influence on our well-being. It is not, however, asserted that the amount of ozone in the free atmosphere may not play an important part in the economy of nature; but we are in want of some method for indicating with exactitude the variations in this amount.

The subject of the "Abuse of Medical Charities" excites a good deal of attention on the other side of the Atlantic, as well as among ourselves, and an editorial article in the number of the *Medical Record* for September 1 contains some observations that have, to some extent, their application to ourselves. After adverting to the mean advantage often taken of the liberality of the profession, the writer adverts to the important point of the encouragement held out to these abuses by the profession itself:—

"To blame the profession for much of this state of things appears at first rather startling, but we believe that the charge can be fairly substantiated. . . . . It has often occurred to us that there is altogether too much said by ourselves about the charity of our profession; that if the public are not aware that we profess and exercise this virtue, it has certainly been no fault of ours. The public hear so much of our charity that they are beginning to think they are conferring a favour upon us by giving us an opportunity to exercise our propensity in that respect. We not only tell them of our Samaritan virtues, but are too much inclined to force their exercise upon the people. This disposition is seen in the struggle for hospital and dispensary appointments. If a new dispensary is founded or a new hospital projected, the most strenuous efforts are made to secure a place on the medical staff, and the trustees are at once impressed with the belief that of all the services that can be rendered to the institution, the purely professional ones are the cheapest. The public are not backward in having the same idea. No sooner are these institutions opened, than every facility is offered to the public to avail themselves of the privileges; and, if all other means fail to make a show of patronage, regular advertisements are issued for patients. These institutions must make a show of the number of patients treated, else there will be no reasonable excuse for their establishment, and no encouragement to the benefactors. It is easily seen that this very system encourages an abuse of charity which the medical profession directly abet by the very eagerness with which they serve these so-called charities.

"Many medical men go still further, and, we are sorry to say it, under cover of charity, found institutions for the cure of a specialty, and advertise for patients. We have known of more than one institution of this sort where, patients were actually coaxed to come, that the number of applicants might prove it to be prosperous, and offer an excuse for seeking an appropriation from the legislature. In view of this state of things, is it right to assume that none but the pure charity-patient was treated?—is it fair to presume that even ordinary measures were taken to guard against fraud on the part of the applicants?"

The injustice and injury committed by many of these institutions upon young rival and struggling practitioners are forcibly dwelt upon. All these abuses we are familiar enough with here, but there is one which the writer adverts to that has not yet become developed amongst us. It is the practice with the American hospitals to receive other patients besides the pauper class on payment of a stipend for board; and, in some of the poorer institutions, any patients who are willing to defray these charges are admitted whatever their means may be, "no further questions being asked."

"There are cases in which the attempts to cheat the profession of legitimate fees are too open to admit of question; and yet the practice is tolerated in all our large institutions, the authorities of which appear by this open defiance of ordinary justice to own the medical staff body and soul, by compelling them, on pain of jeopardising their positions, to attend these patients the same as if they were deserving paupers. Now, we claim that there is in this way of doing things a little too much of institution, and too little of doctor. But can we expect anything more of managers who are made to believe that medical men are so eager to give their services to these charities, that they will resort to all sorts of intrigues for influence to obtain positions, and all sorts of subterfuges to retain them afterwards? The supply of medical men is so much greater than the demand, that directors and managers can afford to be independent. Such is the only explanation of the paradox that the most useful men to the institution are the ones who have the least to say in its general management, and are servants to all. Some of the hospitals, not satisfied with meeting their expenses in this way, have dared to go further in their unfair dealings towards the medical staff: not only have they received patients well able to pay medical fees, but they have made an extra item in the patients' bills for medical services, which services, as an institution, they received gratis! As an offset to such a practice, it is a rule that no physician or surgeon shall use his position in the hospital for the sake of making money. Under the circumstances just mentioned, we fail to see where the justice of this arrangement is. The doctor is not a hireling of the house, but in the relation to it of a benefactor; and if any attempt be made to remunerate for medical services pure and simple, to whom do they belong? If the doctor dare not expect such rewards, what interpretation can we give to the right of the hospital to demand them?

"In view of a state of affairs like the above, it is in vain to look for much help from hospital authorities towards correcting abuses of medical charity; all we can do in a professional way lies in ourselves. We cannot cure the evils, but we can do a great deal towards preventing them. It may not be possible to overturn the present hospital management, but there is much to be done to make the managers feel the worth, influence, and power of the medical staff; and, by the right sort of action, desirable reforms can be instituted. In dispensaries, physicians are in a more independent relation to the authorities, and can exercise an almost absolute right to refuse aid to the undeserving. Much more is this the case in our college clinics. We are by no means jealous of the amount of real charity done to the poor of New York, but we do not care to have it overdone. When the profession can claim to treat gratuitously 300,000 paupers annually in New York City, not counting those in hospital, and it knows at the same time that not one out of every ten of the young medical men in that city can barely earn a living, we think that it is about time to look into the matter, to consider whether the occasion is not opportune for proving the force of the proverb—'Charity begins at home.'"

In the Medical Section of the French Association for the Advancement of Science, M. Favre read a very interesting memoir (since published in full in the *Lyon Méd.*, September 14), on "Daltonism in relation to the Working of Railways." From his statistical account the affection would seem to be of

considerable frequency, although no accidents are recorded as having arisen from its presence. He gives the particulars of several cases both of congenital and of traumatic Daltonism, and arrives at the following conclusions :—1. Candidates for employment on railways should be carefully examined with regard to their power of perceiving colours. 2. Those who cannot distinguish red with ease should be rejected. 3. Those (who are more numerous) who mistake other colours than red may be admitted, but their infirmity should be carefully noted in order that they may be made the subjects of ulterior examination. 4. Agents or *employés* who receive bruises or wounds of the eyelids, eyes, or head, or have suffered from cerebral concussion, should be examined as regards colours, both at the commencement and the termination of their interrupted service. 5. After any serious disease, before the *employé* is allowed to resume his service, an examination as to colours is absolutely necessary. 6. Those who are suspected of addiction to drinking, or who make an excessive use of tobacco, should have the condition of their vision frequently examined. 7. A periodical examination of colours should be instituted, especially for those charged with special and laborious tasks.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Forty-third Meeting.

(*From our Special Correspondent.*)

The departments of the Association devoted especially to the exposition of anatomical, physiological, and sanitary science have excited a very great, and indeed unexpected, amount of attention. The second Sub-section of Biology—namely, that of Anatomy and Physiology—has attracted a great number of visitors, and, uninviting as discussions on the theory of spontaneous development, or on the functions of the brain, or similar topics may appear to the general public, these subjects seemed to possess some especial charm for the members and associates, who crowded the rooms where they were introduced. Professor Ferrier's address on the Localisation of Functions in the Brain, indeed, appeared to be pre-eminently attractive, for not only was the hall in which it was delivered filled to excess by an audience, fully one half of which consisted of the fair sex, but the assembled multitude listened with the utmost patience and apparent interest to anatomical details with which many a tyro in the medical schools would have found it difficult to grapple. It is only justice to Dr. Ferrier to state that his address was able in the extreme, and that, although he spoke without the aid of any notes, his exposition was as luminous as if he had written out all the details beforehand.

Dr. Allman's Inaugural Address on Biology.

The business of the Section on Biology was opened by an inaugural address by Professor Allman, M.D., which was characterised by extensive learning and no less an impressive eloquence. In reference to the hypothesis of evolution, he spoke with the enthusiasm of a lover of nature and with the caution of a philosopher, and, while admitting the splendid generalisations to which the subject might lead, he yet regarded the deduction of the necessary conclusions as beset with difficulties. One of the chief of these, he said, in the way of the doctrine of evolution, when carried to the extreme length for which some of its advocates contended, was the unbroken continuity of inherited life, which it necessarily required through a period of time whose vastness was such that the mind of man was utterly incapable of comprehending it. They had no reason to suppose that the representative faculty in organised beings was endowed with unlimited power of extension, and yet, to go no further back than the Silurian period, the hypothesis required that in the same period the ancestors of the present living forms must have existed, and that their life had continued by inheritance through all the ramifications of a single genealogical tree down to our own time. Was the faculty of reproduction so wonderfully tenacious as all this? Had the strongest which had survived in the struggle for existence necessarily handed down to the strongest which should follow them the power of continuing as a perpetual heirloom the life which they had themselves inherited? or had there been many total extinctions and many renewals of life? or finally, was the doctrine of evolution only a working hypothesis, which, like certain algebraic fictions, might yet be of inestimable value as an instrument of research, furnishing the biologist with a key to the order and hidden forces of the world of life. What Liebig, and Newton, and Hamilton had been to the physicist, was it not that which Darwin had been to the biologist? But even accepting as a great truth the doctrine of evolution, they must not attribute to it more than it could justly claim. No valid evidence had yet been adduced to lead to the belief that inorganic matter had become transformed into living otherwise than through the agency of a pre-existing organism, and there remained a residual phenomenon still entirely unaccounted for. No physical hypothesis founded on any indispensable fact had yet explained the origin of the primordial protoplasm, and, above all, its marvellous properties, which rendered evolution possible. Natural selection, the struggle for existence, the survival of the fittest, would explain much, but not all. The properties with which the primordial protoplasm was endowed, its heredity and its adaptability for these properties, were their cause and not their effect. For the cause of this cause they had sought in vain among the physical forces surrounding them, until they were at last compelled to rest upon an independent volition, a far-seeing, intelligent design. Science might yet discover among the laws of physics the cause it looked for. It might be that light, heat, electricity, magnetism, when manifesting themselves through the organisable protoplasm, became converted into the phenomena of life, and that the poet had unconsciously enunciated a great scientific truth when he spoke of

> "Gay lizards glittering on the walls
> Of ruined shrines, busy and bright,
> As though they were alive with light."

Dr. Rutherford's Address on Anatomy and Physiology.

Dr. Rutherford's address to the Sub-section on Anatomy and Physiology comprised a general sketch of the present condition of those sciences, showing how closely they were connected with one another, but urging that, owing to the great development of physiology, they required to be taught by separate professors. Physiology, indeed, unlike anatomy, which was a science of demonstration only, rested upon a tripod consisting of anatomy, physics, and chemistry; and the most minute anatomy, the most recondite physics, and the most complex chemistry must all be taken into account in the study of the physiology of living beings. He strongly insisted upon the necessity of establishing practical schools of physiology throughout the country, and pointed to the efforts already made in the London medical schools, in Edinburgh, Cambridge, Manchester, and elsewhere in this direction. He thought that the endowment of a dozen such laboratories would immensely aid in the development of physiological research amongst us. We might, he said, anticipate great benefit to the community not only from an advance of physiology, but from a diffusion of a knowledge of its leading facts amongst the people. This is now being carried out in our schools on a scale which is annually increasing. Thanks to the efforts of Huxley, the principles of physiology were now presented in a singularly palatable form to the minds of the young. The instruction communicated does not consist of technical terms and numbers, but in the elucidation of the principal events which happen within our bodies, together with an explanation of the treatment which they must receive in order to be maintained in health. Considering how much may be accomplished by these bodies of ours if they be properly attended to and rightly used, it seems to be a most desirable thing that the possessor of the body should know something about it, not only because such knowledge affords him much material for suggestive thought—not only because it is excellent mental training to endeavour to understand the why and the wherefore of the bodily actions, but also because he may greatly profit from a knowledge of the conditions of health. He concluded by remarking that thorough adoption of hygienic measures—in other words, of measures which are necessary to preserve individuals in the highest state of health—cannot be hoped for until a knowledge of fundamental physiological principles finds its way into every family. This country has taken the lead in the attempt to diffuse a

sound knowledge of physiological facts and principles among the people, and we may fairly anticipate that this will contribute not a little to enable her to maintain her high rank amongst nations; for every step which is calculated to improve the physiological state of the individual must inevitably contribute to make the nation successful in the general struggle for existence.

Professor Ferrier on the Localisation of Functions in the Brain.

As we have before remarked, Professor Ferrier's communication excited very great interest. It was probably expected that his researches, and the conclusions to which they have led, would lend some countenance to the system of phrenology, but such is very far from being the case. It is not too much to say, however, that the facts disclosed by Dr. Ferrier are of the highest importance to physiological science, and if they shall be confirmed by subsequent observers, or extended by future experiments of his own, they will throw almost an entirely new light upon the connexion of the different parts of the brain with the actions, the sensations, and the instincts of living beings. The great interest and importance of this communication are our apology for introducing Dr. Ferrier's views at some length, the more especially because, as his experiments were very numerous, they require individual explanations to render their meaning intelligible.

All are agreed, he said, that it is with the brain we feel, and think, and will; but whether there are certain parts of the brain devoted to particular manifestations is a subject on which we have only imperfect speculations or data too insufficient for the formation of a scientific opinion. The general view is that the brain as a whole subserves mental operations, and that there are no parts specially devoted to any particular functions. This has been recently expressed by so high an authority as Professor Séquard. The idea rests chiefly on the numerous facts of disease with which we are acquainted. There are cases where extensive tracts of brain are destroyed by disease, or removed after a fracture, apparently with no result as regards the mind of the individual. Along with these facts we have others which are very curious, and which hardly seem to agree with this doctrine. One of these is that when a certain part of the brain is diseased, in aphasia, the individual is unable to express himself in words. Other curious phenomena have been well described by Dr. Hughlings-Jackson—viz., that certain tumours or pathological lesions in particular parts of the brain give rise, by the irritation which they keep up, to epileptiform convulsions of the whole of one side, or of the arm or leg or the muscles of the face; and from studying the way in which these convulsions show themselves he was able to localise very accurately the seat of the lesion. The great difficulty in the study of the function of the brain has been in the want of a proper method. When we study the function of a nerve, we make our experiments in two ways. In the first place, we irritate the nerve by scratching or by electricity, or by chemical action, and observe the effect; and in the second place, we cut the nerve, and observe what is lost. In regard to the brain and nervous system, the method has been almost entirely, until recently, the method of section. It has been stated by physiologists that it is impossible to excite the brain into action by any stimulus that may be applied to it, even that of an electric current; they have, therefore, adopted the method of destroying parts of the brain. This method is liable to many fallacies. The brain is such a complex organ that to destroy one part is necessarily to destroy many other parts, and the phenomena are so complex that one cannot attribute their loss to the failure only of the parts which the physiologists have attempted to destroy. About three years ago, two German physiologists, Fritsch and Hitze, by passing galvanic currents through parts of the brains of dogs, obtained various movements of the limbs, such as adduction, flexion, and extension. They thus discovered an important method of research, but they did not pursue their experiments to the extent that they might have done, and perhaps did not exactly appreciate the significance of the facts at which they had arrived.

I was led (said Dr. Ferrier) to the experiments which I shall have to explain by the effects of epilepsy and of chorea, which have been supposed to depend upon irritation of parts of the brain. I endeavoured to imitate the effects of disease on the lower animals, and determined to adopt the plan of stimulating the parts of the brain by electricity after the manner described by Fritsch and Hitze. I have operated (he said) on nearly a hundred animals of all classes—fish, frogs, fowls, pigeons, rats, guineapigs, rabbits, cats, dogs, jackals, and monkeys. The plan was to remove the skull, and keep the animal in a state of comparative insensibility by chloroform. So little was the operation felt that I have known a monkey, with one side of the skull removed, awake out of the state induced by the chloroform, and proceed to catch flies or eat bread and butter. When the animal was exhausted I sometimes gave it a little refreshment, which it took in the midst of the experiments. Referring next to his experiments on cats, Professor Ferrier stated that on applying the electrode to a portion of the superior external convolution the animal lifted its shoulder and paw (on the opposite side to that stimulated) as if about to walk forward; stimulating other parts of the same convolution, it brought the paw suddenly back, or put out its foot as if to grasp something, or brought forward its hind leg as if about to walk, or held back its head as if astonished, or turned it on one side as if looking at something, according to the particular part stimulated. The actions produced by stimulating the various parts of the middle external convolution were a drawing up of the side of the face, a backward movement of the whiskers, a turning of the head, and a contraction of the pupil respectively. A similar treatment of the lower external convolution produced certain movements of the angles of the mouth; the animal opened the mouth widely, moved its tongue, and uttered loud cries, or mewed in a lively way, sometimes starting up and lashing its tail as if in a furious rage. The stimulation of one part of this convolution caused the animal to screw up its nostrils on the same side; and, curiously enough, it was that part which gave off a nerve to the nostril of the same side. He then explained in like manner the results produced by the stimulation of corresponding or homologous parts of the rat, the rabbit, and the monkey. Acting upon the anterior part of the ascending frontal convolution, the monkey was made to put forward its hand as if about to grasp. Stimulation of other portions acted upon the biceps, or upon the zygomatic muscles. The part that appeared to be connected with the opening of the mouth and the movement of the tongue was homologous to the part affected in man in cases of aphasia. Stimulation of the middle part of the temporo-sphenoidal convolution produced no results; but the lower part of the temporo-sphenoidal, when acted upon, caused the monkey to shut its nostrils. No result was obtained in connexion with the occipital lobes. These experiments, he said, had an important bearing upon the diagnosis of certain kinds of cerebral disease, and the exact localisation of the parts affected. He was able to produce epileptic convulsions in the animals experimented upon, as well as phenomena resembling those of chorea. The experiments were also important anatomically, as indicating points of great significance in reference to the homology of the brain in lower animals and in man, and they likewise served to explain some curious forms of expression common to man and the lower animals. The common tendency, when any strong exertion is made with the right hand, to retract the angle of the mouth and open the mouth on the same side, had been stated by Oken, in his "Natur-Geschichte," to be due to the homology between the upper limbs and the upper jaw; the true explanation being that the movements of the fist and of the mouth are in such close relation to each other that when one is made to act powerfully the impression diffuses itself to the other parts of the brain, so that the two act together. The experiments had also a psychological significance. There was reason to believe that when the different parts of the brain were stimulated, ideas were excited in the animals experimented upon, but it was difficult to say what the ideas were. There was, no doubt, a close relation between certain muscular movements and certain ideas which would prove capable of explanation. This was supported by the phenomena of epileptic insanity. The most important guide on the psychological aspect of the question was the disease known as aphasia. The part of the brain which was the seat of the memory of words was that which governed the movements of the mouth and the tongue. In aphasia the disease was generally on the left side of the brain, in the posterior part of the inferior frontal convolution, and it was generally associated with paralysis of the right hand; and the reason might be supposed to be that the part of the brain affected was nearly related to the part governing the movements of the right hand. It was essential to remember that the movements of the mouth were governed bilaterally from each hemisphere. The brain was symmetrical, and he held it to be a mistake to suppose that the faculty of speech

was localised on the left side of the brain. The reason why an individual lost his speech when the left side of the brain was diseased was simply this:—Most persons were right-handed, and therefore left-brained, the left side of the brain governing the right side of the body. Men naturally seized a thing with the right hand, and they naturally therefore used rather the left side of the brain than the right, and when there was disease there the individual felt like one who had suddenly lost the use of his right arm. After describing some further experiments on pigeons, Professor Ferrier alluded to the results of stimulating the different ganglia. Stimulation of the corpora striata caused the limbs to be flexed; of the optic thalami produced no result; of the corpora quadrigemina produced, when the anterior tubercles were acted upon, an intense dilatation of the pupil, and a tendency to draw back the head and extend the limbs as in opisthotonus; while the stimulation of the posterior tubercles led to the production of all kinds of noises. By stimulating the cerebellum various movements of the eyeballs were produced.

Dr. George Harley alluded to the effect of mental emotion on the bodily functions, and the possibility of producing disease by simply acting upon the nervous system. Referring to phrenology, he said it was one thing to localise function in the interior of the brain, and quite another to specify functions by manipulating the external cranium; and he quoted a saying of Flourens with reference to phrenology—"Les hommes qui la pratiquent sont des charlatans, et les hommes qui la croient sont des imbéciles."

Dr. Carpenter congratulated Professor Ferrier on the success of his experiments, and congratulated science on the possession of such an able exponent. He remarked that the great work of the brain is done in the cortical substance, and in Dr. Ferrier's experiments the first effect of the stimulus is upon that particular substance, producing an intensification of the circulation through it: being in that respect different from the ordinary stimulation of a nerve which acts upon the fibrous substance of the medullary matter of the brain. His explanation of Dr. Ferrier's experiments was that a kind of ideational state was produced, of which the instrument is a certain portion of the cortical substance—that state acting not directly upon muscular movements, but upon the automatic apparatus, telling it to perform certain actions. He had long since expressed his disbelief in phrenology, which maintained that the animal functions were placed at the back of the head, and the intellectual at the front. Dr. Ferrier's experiments tended to show that the real seat of the intellectual functions was in the posterior part of the brain.

Dr. Brunton alluded to the faculty of will and of self-restraint as distinguishing man from the lower animals, and said that this faculty was probably situated in the anterior part of the brain. It was noticeable that criminals, who were deficient in that faculty, possessed only a small portion of brain in front of the head. Speaking of the importance of a bleod supply to the brain, he mentioned that he had on one occasion found himself unable to write and compose in consequence of a state of exhaustion, and on laying his head on the table, instead of sitting upright, the better supply of blood thus obtained enabled him to pursue his task. The dyspepsia common among literary men he attributed to the want of an adequate supply of blood to the digestive organs, in consequence of too much going to the brain for its intellectual work.

Professor Burdon-Sanderson said that the stimulation in Dr. Ferrier's experiments was, contrary to Dr. Carpenter's supposition, exactly like the ordinary excitation of a nerve, and the effect was produced in an extremely short space of time.

Dr. Crichton Browne thought that the labours of Gall and Spurzheim ought not to be overlooked in a discussion on the localisation of functions of the brain—a principle which they distinctly enunciated. It was a curious fact that Dr. Ferrier located the memory of words in the very part indicated by the phrenologists as the organ of language. He had witnessed the experiments of Dr. Ferrier, and was astounded at the marvellous manner in which the response was given (as predicted) to the stimulus applied.

A paper was read by Sir Duncan Gibb

On the Vocal Organs in Living Centenarians.

The subject, he said, was one of interest, for it was determined during life, and presented some new facts, necessitating a modification of the views generally entertained regarding such old people. He had visited and examined nine living and undoubted centenarians in various parts of the kingdom, and he gave their names, residences, dates of examination, and authentic records of their birth, two being males and seven females. The thyroid cartilage, felt in the neck, was more prominent in the males, but in all it was freely movable, and possessed a resiliency and softness that showed that the changes of old age as usually seen were absent; and this was so with the other cartilages and the rings of the windpipe. With a little reflecting mirror the interior of the vocal organs was found to be in a condition more approaching that of the young than the old, with free motion and activity of the vocal cords, the colour of which showed an absence of what are known as senile changes. The voice therefore was good, clear, soft, and melodious in all, but rather loud in two cases. The chest capacity was fairly good in all, and the breathing unimpeded, for not only was the epiglottis vertical, but the cartilages of the ribs were not ossified. The movements of the chest therefore corresponded to persons of the age of twenty-five or thirty. Every organ in the body being healthy, and the special senses for the most part perfect, the conclusions were arrived at that there was a complete absence of those changes which are usually seen in most persons of seventy or eighty, such as calcification of the vocal cartilages and the bloodvessels and ossification of the costal cartilages. It is the fact of the absence of such changes that permits the attainment of the great age of ninety-five or a hundred years; and therefore the views heretofore held regarding old age must be modified, at any rate so far as centenarians are concerned.

Dr. J. Milner Fothergill read a paper on

The Heart and Brain.

He said that while the brain had always been regarded as the organ representing intelligence, the heart had been held to be the centre of emotions, and especially such as were associated with endurance. Talent was a cerebral endowment, but courage was a cardiac quality. Fixity of purpose and energy depended largely upon a firm and well-acting heart. There were numerous nerve-branches connecting the nervous system with the heart and furnishing it with motive power. Through the sympathetic nerves the heart was connected with the emotions, and when the nerve-force was discharged freely the heart's action was in unison with it, and the contractions were powerful. In addition to this there was the vagus nerve, which controlled, regulated, or inhibited the heart's action. When the roots of this nerve were flooded with blood, the heart's action was held back or inhibited and its contractions controlled. This was often instanced when a person rose from a recumbent attitude to an upright posture, and the opposite was the case when resuming again the recumbent posture. By the beautiful backward and forward play of the inhibitory fibres of the vagus the brain was secured against any failure of blood supply, as also it was guarded from an overflow, which would threaten its integrity. In disease, however, this balance was disturbed, and when this was the case failure of the brain was the consequence. Several instances of this had been furnished by medical experience, such as inability in some persons to study unless in certain positions, attacks of loss of consciousness, extraordinary delusions, etc. The author then touched upon the several causes, both natural and artificial, of insanity, and the mental peculiarities of patients suffering under heart disease, and instanced the case of Charles V., when he abdicated in the great hall of Brussels, as a case where disease, not being brain disease, had an effect over the mind. Sustained action in the brain was only to be secured by a full and efficient blood supply, as was instanced in the case of sleep, where the blood supply of the brain had to be largely cut down in order to admit of sleep or cerebral inactivity, or in the temporary brain failure which occurred when the blood-stream was cut off by the garotter. However powerful a brain might be, it always depended for its powers on the arterial current supplied to it by the circulatory centre. Intelligence halted when the brain was crippled by an insufficient blood-stream. It might be therefore concluded that the waves of nerve-force, which resolved themselves into either psychical resolution or sustained muscular effort, were dependent in their turn upon a well-maintained succession of blood-waves, supplied by a firm and vigorous heart.

Dr. Burdon-Sanderson on the Electric Phenomena which accompany the Contraction of the Leaf of Venus's Fly-trap (Dionæa Muscipula).

Professor Sanderson showed that certain electrical phenomena which accompany the contraction of muscle and the activity

of nerves in animals, also occur in those parts of plants which exhibit similar functions, and stated that Mr. Darwin had made observations (not yet published), which coincided with the views held by Mr. Bennett, that the leaves of Dionæa possessed the power of digesting, just as the stomach digests food. Although it was much easier to experiment upon plants than animals, from the fact that the former could be kept longer alive, it was strange that, although the subject of electrical currents in animals had been thoroughly investigated, the question of such currents in plants had been overlooked.

Professor Williamson regarded the paper read by Professor Sanderson as one of those little straws which showed how the wind was likely to blow for many a year to come. Taken in connexion with the paper read yesterday by Professor Ferrier, he could see that it would be the opening up of a new era in animal and vegetable physiology. These two channels of inquiry were likely to lead to as important results as the spectroscope in other parts of science. Nothing had been so much neglected in England as vegetable physiology.

Professor Rutherford said he was specially interested in the subject of the origin of electrical currents in living tissues. Professor Hermann, of Zürich, who had confined his attention to muscle and nerve, contended that electricity was not generated in the living tissue, but was only produced when the tissue was injured in some way. He was glad that the experiments made by Professor Sanderson would tend to put an end to this idea, inasmuch as he had found that electricity was generated without any injury being inflicted to the tissue at all.

Microzymes as Partial Bionta.

A paper on this subject was read by Dr. John Ross. Microzyme is a general term employed by Béchamp to designate those lowest organisms which are found in putrefactive fluids, and are now known to be present in all infective fluids. Microzymes are minute, more or less spheroidal specks of protoplasm, not more than the 1-20,000th of an inch in diameter. The object of the paper is to show that although the microzymes of putrefaction and those of infective fluids are morphologically of the same order, yet physiologically they are of different orders. Hæckel uses the same term (*βιων*) to designate a physiological individual, and he divides bionta into three orders—1. The actual bion, which represents the highest developed form of the individuals of the species; 2. The potential bion, which includes all the forms of the individual till the highest developed form is attained; and 3. The partial bion, which represents a portion detached from a higher organism, that has the capacity of maintaining an independent existence for some time, but is not able to develope into an actual bion. The microzymes of putrefactive fluids are either actual or potential bionta, but there is good evidence to prove that those of infective fluids are merely partial bionta. When vaccine lymph and hay infusion a few days old are examined, the living particles found in each are very different. The former do not elongate into the staff-shaped bodies called bacteria; their motions are semi-rotatory instead of oscillatory, and they form clusters very similar to those which blood corpuscles form. Pus-corpuscles are said to be from the 1-2500th to the 1-3000th of an inch diameter, but in reality pus contains living units of all sizes, from the 1-2500th of an inch down to the minutest speck of protoplasm. If those units which vary from the 1-15,000th to the 1-20,000th of an inch are to be regarded as corpuscles, those which pass the limit of 1-20,000th of an inch must be of the same essential nature, even if we call them particles. Again, pus-corpuscles may be seen to cast off buds from the surface, and some of these are not more than the 1-20,000th of an inch, and are morphologically indistinguishable from vaccine particles. These buds are undoubtedly partial bionta, and this renders it probable that the others are of a similar nature. After death from some diseases the fluids of the body contain numerous microzymes, and are highly infectious; in a few days the microzymes multiply in myriads, but the fluids soon lose all infective power. This shows that the physiological relations of the first set of microzymes are very different from those of the second. The first set are more allied in their action to pus, tubercle, and cancer; while the second have no powers but those possessed by the microzymes of ordinary putrefactive fluids. Several experiments upon frogs show the close relationship which exists between infective microzymes and white blood and pus-corpuscles, all of which tend to prove that these microzymes are merely partial bionta.

Remarks on Professor Huizinga's Experiments on Spontaneous Generation.

Under this title, Dr. Sanderson communicated some new experiments relating to the debated question of spontaneous generation. In the well-known work of Professor Charlton Bastian on the "Origin of Life," the author recorded an experiment which had attracted much attention from physiologists. This experiment consisted in charging a flask having a capillary orifice with an infusion of turnip, to which cheese had been added in very small quantities, and then boiling the flask and closing it hermetically after ten minutes' ebullition. Dr. Bastian found that although the liquid contained in the flasks so prepared had been subjected to the temperature of 212° Fahr., bacteria were always produced. The result had been confirmed by Dr. Sanderson himself, and more recently in another form by a Dutch observer, Professor Huizinga, of Gröningen. But Dr. Sanderson, in a communication made to *Nature* in June last, showed that if, by performing the ebullition under increased pressure, the temperature was correspondingly increased, the result was different. The experiment, in short, failed, the liquid remaining free from living forms, although it was placed under all the conditions which were favourable to their development. Recently, Dr. Sanderson had subjected Dr. Huizinga's experiment to similar repetition. Huizinga used, not turnip, but an artificial mixture of very complicated composition, contrived for the purpose of obviating some of the objections which had been made to Dr. Bastian's employment of turnip infusion with cheese. On subjecting flasks charged with this liquid to the ebullition under pressure, he found that here, as before, the liquid remained barren. Dr. Sanderson further stated that in order to show that the fluid treated in the way described was still capable of supporting living forms when they were introduced into it, he added to some of such liquid a drop of distilled water, and in twenty-four hours bacteria were developed in large quantities. In conclusion, he stated that he did not hold that spontaneous generation was impossible—he did not regard the heterogenists as scientific heretics, but he was not aware that up to the present moment there was any proof that they were right.

As both the above papers involved the question of spontaneous generation, the discussion on both was taken together.

Mr. Ray Lankester, speaking of Professor Sanderson's paper, said that he himself had tried the same experiments, and in every case where ebullition was resorted to no bacteria were produced. When proper precautions were taken to boil for a sufficient length of time, life was never developed. Referring to Dr. Ross's remarks, he said the word "microzyme" was applied rather vaguely to things which were physically different from bacteria. Microzymes were particles which were found in disease and septic matter; while bacteria were a crop of minute plants which made their first appearance as minute spherical particles which might easily be mistaken for bacteria. The proposition, therefore, about microzymes appearing in putrefying infusions related not to bacteria, but to particles in the bodies of the animals diseased.

The President, Dr. Rutherford, referring to Dr. Sanderson's experiments, said there remained one important question, as to whether the heat had been so great that the organic matter had been altered in such a way that it could no longer produce spontaneous forms. The main point, as Dr. Sanderson had informed them, was that he found that although the fluid, after ebullition, produced no living forms, it was capable of supporting them after they were introduced, just as they could be supported in a glass of distilled water. He thought, however, that more facts on this subject should be obtained before a decided opinion could be pronounced on either side.

Professor Sanderson, in reference to the important question suggested by Professor Rutherford, said that experiments were made in June last with Dr. Bastian's liquid and the turnip-cheese liquid. In each case, after the liquid had been kept for a certain time, and it had been ascertained that no change had taken place, the flask was opened and a small drop of distilled water was put into it. The liquid at once became turbid, and bacteria were produced, showing that the liquid still retained its capability of maintaining bacterial life. Referring to Dr. Ross's paper, Professor Sanderson said that lately it had been found that in a great many diseases bacteria existed in diseased products, but the question still remained whether these were specific bacteria or not—whether they were morbid poison or accidental products. With reference to the question of vaccine, he had always had considerable doubt. There was no difficulty in seeing the organic forms which

existed in vaccine fluid. Dr. Ross had given a correct description of them; but he (Professor Sanderson) could never come to the conclusion whether these round particles were characteristic of vaccine or not, as they were to be found in other products of the organism which did not possess definitely a morbid character. Dr. Obermeyer, who unfortunately died of cholera in the course of investigations he was making on the subject, had discovered a characteristic form of bacteria in relapsing fever. He found that these bodies existed and appeared to have definite forms; and the accuracy of his description had since been confirmed by high medical authorities. There were various other diseases in which such forms were found, and they were also discovered in cattle disease. In this disease, which was a most fatal one, it had been found that bacteria were present in the blood in great numbers. It had also lately been proved, by the most careful investigations, that bacteria also existed in the blood of certain perfectly healthy individuals. He thought the words bacteria and microzymes were very confusing to those unacquainted with the subject. Another fact in relation to bacteria was that they did not develope into any other forms. The most careful observation showed that they did not go beyond the form which they first assumed, which would in some measure negative the view advanced by Dr. Ross.

The Purification and Utilisation of Sewage.

This very important question was introduced and discussed in the Chemical Section on Monday. As we mentioned last week, the town of Bradford is placed, by its geographical conditions, in a very difficult position in relation to its drainage and sewage, and plans which are adopted successfully elsewhere are inapplicable to this large manufacturing centre situated in the heart of England, at a considerable distance from the sea on either side, and unconnected with any great river except through the medium of one or two insignificant streams. If the enormous mass of excreta from the crowded population of Bradford, together with the drainage from the extensive manufactories, were allowed to pass into the small river Aire, they would poison its waters, and be especially obnoxious to the neighbouring town of Leeds, through which the Aire flows in its passage towards the Humber. Again, any attempt to utilise the sewage in the most productive manner—namely, by spreading it over the land, and thus fertilising the soil—would be unsuccessful, on the ground of the enormous expense which such a scheme would involve, considering the dense population of the area from which the sewage is derived. Hence a number of expedients of various kinds are and must be adopted, with greater or less success, to effect the double object of draining the town and at the same time preserving the health of the inhabitants; and it cannot be said, notwithstanding the zeal of the Corporation and the ingenuity of its engineers, that either of these objects has hitherto been successfully accomplished. At present it is found that, comparing the small tributary stream, the Bradford Beck (which runs into the Aire), with the outflow of the sewage itself, the former is the more unwholesome stream of the two, and consequently it is out of the question to overload the natural current with the artificial drain. The sewage therefore is purified, as far as possible, by artificial means, and by the application of mechanical works and chemical agencies, which to a great extent deodorise and purify the enormous mass of waste material continually flowing from the town and the suburbs. The whole question is too extensive to enable us here to consider it in all its bearings, and we can only direct attention to some parts of the report on the general subject of the purification and utilisation of sewage which was presented to the British Association, especially selecting those portions which bear upon the sanitary condition of the population. With this view we present the following substance of an abstract, presented by Dr. Corfield, of all the reports presented by the Committee of the Association on the Treatment and Utilisation of Sewage. The final opinions of the Committee were in substance as follows:—

I. All conservancy plans, including midden, heap, and cesspool systems, dry ash, and dry earth closets, pail closets, etc., are quite incompetent as solutions of the general question of the removal of the refuse matters of a population; they only deal with a small part of the liquid manure; towns which resort to one of them require to be sewered, and the sewage requires to be purified. The manure produced is in all cases (except in that of simple pails or tubs, where no extraneous materials are added) poor, and will only bear the cost of carriage to a short distance, taking into consideration the cost of collection, that produced by the dry earth system being, even after the earth has been used three times over, merely a good garden mould. Moreover, these plans all violate one of the most important of sanitary laws, which is that all refuse matters which are liable to become injurious to health should be removed instantly, and then be dealt with afterwards. With all these plans it is an obvious advantage on the score of economy to keep the refuse about the premises as long as possible, and the use of deodorants of various sorts, or even of disinfectants, proves that this is the case, and that these systems all depend upon a fallacious principle. They should therefore be discouraged as much as possible, and only resorted to as temporary expedients, or with small populations, in very exceptional instances.

II. The water-carriage system, on the other hand, is based upon a sound principle—that of removing all the refuse matters at once and in the cheapest possible manner by gravitation,—and ought to be resorted to in all but the most exceptional cases. The opinion of the Committee that all sewers should be made of impervious materials, and that separate drains to dry the subsoil should be constructed where necessary, has already been most emphatically expressed. The freest possible ventilation of sewers, house drains, and soil pipes, in order to prevent accumulations of foul air, is also essential. With regard to the utilisation of sewage, the Committee has come to the conclusion that the precipitation processes that it has examined are all incompetent, and necessarily so, to effect more than a separation of a small part of the valuable ingredients of sewage, and that only a partial purification is effected by them. Some of them may, however, be useful as methods of effecting a more rapid and complete separation of the sewage sludge.

The upward filtration process only effects a clarification of the sewage, and is therefore no solution of the question.

By properly conducted sewage irrigation a solution is afforded to the question of sewage utilisation. It has already been stated that a precipitation process, or some clarifying process, may be found useful. In all instances it is essential that the land should be well underdrained, and that the sewage should all pass through the soil and not merely over it; otherwise, as has been shown, it will only occasionally be satisfactorily purified. The catch-water, or, as the Committee has termed it, the "supersaturation" principle, is not defensible either on agricultural, chemical, or sanitary principles; an irrigation farm should therefore carry out intermittent downward filtration on a large scale, so that the sewage may be always thoroughly purified, while at the same time the maximum of utilisation is obtained.

It is certain that all kinds of crops may be grown with sewage, so that the farmer can grow such as he can best sell. Nevertheless, the staple crops must be cattle food, with occasional crops of corn; and it is also certain from the analysis of the soil that it has become very much richer, and that the manurial constituents of the sewage accumulate in it. Cattle should be fed on the farm, which leads to a vast increase in the production of meat and milk—the great desiderata of the population producing the sewage. Thus the system of farming must be specialised and capital concentrated, the absence of which conditions has proved a great barrier to the satisfactory practical solution of the sewage question.

In reference to the influence of sewage farms upon the public health, the following important information is given:—The Committee has not been able to trace any ill effects to the health of the persons living around sewage farms, even when badly conducted; nor is there any proof whatever that vegetables grown thereon are in any way inferior to those grown with other manure. On the contrary, there is plenty of evidence that such vegetables are perfectly suited for the food of man and beast, and that the milk given by cows fed on sewaged grass is perfectly wholesome. Thus Mr. Dyke, Medical Officer of Health for Merthyr Tydfil, states that since the abundant supply of milk from the cows fed on irrigated grass the children's mortality has decreased from 48, 50, and 52 per cent. of the total deaths to only 39 per cent., and that so far from diarrhœa having been made more prevalent by the used of sewaged cabbages, "last year the Registrar-General called attention to the fact that diarrhœa was less prevalent in Merthyr than in any place in England and Wales." And he expressed his belief in "the perfect salubrity of the vegetable food so grown."

With regard to the assumption which has been made that

entozoic disease would be propagated by irrigation, all the evidence that the country has been able to collect, and more especially the positive facts obtained by experiments, are against such an idea; and the Committee is of opinion that such disease will certainly not be more readily propagated by sewage irrigation than by the use of human refuse as manure in any other way, and probably less if the precaution be taken of not allowing the animals to graze, but always having the grass cut and carried to them.

The reading of this report was followed by an able paper by Mr. McGowen, the Town Clerk of Bradford, showing that the local conditions prevented that town from following out the suggestions and recommendations of the Committee, but that all the steps had been taken which were hitherto practicable to render the excreta innocuous. Whether eventually some plan may not be devised for rendering the valuable materials derived from the populous town of Bradford available for the improvement of the land of the adjacent parts of Yorkshire, is a subject well deserving of the most careful consideration. It was urged by many of the speakers that it is very easy for theorists at a distance to devise plans and to enact laws for the disposal of excrementitious matter, but it is practically very difficult to determine what is best to be done in each special locality with its peculiar geographical features, its meteorological conditions, the habits and pursuits of its population, and other considerations.

The President and members of the Bradford Medico-Chirurgical Society on Saturday evening entertained at dinner, at the Victoria Hotel, a number of members of the British Association belonging to the medical profession, and at the present time visiting the town of Bradford. There were present Dr. W. B. Carpenter, the retiring President of the Association; Professors Allman, Balfour, Rutherford, Struthers, and Binz; Sir Duncan Gibb; Drs. Beddoe, Fothergill, Harley, Semple, Leet, R.E.; and of non-medical visitors there were Dr. A. W. Williamson (the President of the Association), the Right Rev. Bishop Ryan, Rev. Dr. Campbell, etc. Dr. J. H. Bell, the President of the Society, occupied the chair, and John Foster, Esq., F.R.C.S., occupied the vice-chair. After dinner the usual loyal toasts were proposed, followed by "The British Association," responded to by Drs. Williamson and Carpenter; "The Bradford Medico-Chirurgical Society," proposed by Dr. Carpenter, and responded to by Dr. Goyder; "The Universities and Colleges, British and Foreign," proposed by the Rev. A. G. Russell, M.D., and responded to by Professor Balfour (Edinburgh), Dr. Lauder Brunton (London), and Professor Binz (Bonn); and "The Guests," proposed by Dr. Brown, and responded to by Drs. Allman and Crichton Browne (of Wakefield). A very agreeable evening was spent by the party, and much satisfaction was expressed at the hospitality displayed by the Society and the rest of the local medical profession to their brethren.

The Bradford Medico-Chirurgical Society is established for the purpose of advancing the progress of medical science in the district, and this object is carried out by meetings and discussions held at stated intervals. It is also a medico-ethical society, and offences against professional morals are punished by exclusion (after due investigation) of the delinquents. The Society holds an anniversary festival, and the opportunity of the meeting of the British Association was seized for the double purpose of keeping the annual dinner and inviting as guests the members of the profession coming from a distance.

Tactus Eruditus. — At the last meeting of the Académie des Sciences, Professor Bouillaud made a verbal communication on the pulse in its normal condition. He stated that it is possible to distinguish four in place of two periods in the normal pulse—*i.e.*, a first pulsation separated by a period of rest from a second pulsation much more feeble than the first, and itself followed by a period of rest. The observation must be made upon a person with a slow pulse of not more than 40, in order to become convinced of the reality of this statement. M. Bouley observed that while his colleague was making his statement he had tried in vain to recognise this double pulsation on himself. M. Bouillaud replied that he could well believe this, for during thirty years he had never suspected the existence of this double pulsation, which can only be easily perceived in persons with slow pulse.—*L'Institut*, September 17.

GERMAN ASSOCIATION FOR THE ADVANCEMENT OF NATURAL SCIENCE AND MEDICINE.

(*From our Special Correspondent.*)

The forty-sixth annual meeting, which is held this year at Wiesbaden, commenced on Thursday, September 18. The German Association, which was instituted as far back as 1821, closely resembles the British Association in many respects; but there is this difference between the two societies specially important to our profession, that in Germany pure medicine in its various departments is fully represented at the meetings, no fewer than ten out of the twenty sections being strictly professional, and four more very intimately connected with medicine. Thus the German Association corresponds after a fashion both with the British Association and the British Medical Association. It differs, however, from the latter in several important respects. Members require no recommendation for election beyond their being authors in science or medicine, and in the same way anyone who is engaged in these pursuits may attend as an associate by paying the small fee of 12s. The Association possesses no collection of any kind, and no property. In a word, the primary aim of the German Association is to enable the scientific and medical men of the country to become personally acquainted with each other. The business is deputed annually to a president or commissioner elect and a secretary, who belong to the town in which the meeting is to be held, the place of meeting changing from year to year. The German Association is a very flourishing one, and this year at Wiesbaden the Congress is the largest that has ever met, the number of visitors reaching 1201. Its chief end, as expressed above, is steadily kept in view, and the members and associates spend their annual week together as much for the sake of social enjoyment as for the exchange of scientific opinion. It is said that the character of the Congress has already changed considerably since the fusion of German interests. Before 1870 there was more excitement in the meetings and round the dinner and supper tables over the subject of an united Fatherland than there can possibly be now with their most sanguine hopes fulfilled.

As we have said, this year's Congress is the largest that has ever met, and the reasons for this are not far to seek nor difficult to find. Wiesbaden is one of the very foremost of German watering-places, and this probably not only from the value of its warm springs and baths, but from the mildness of its climate and the wonderful beauty of its situation. It lies on the three or four low hills, and in the intervening hollows, at the foot of the famous Taunus mountains, which shelter it from the north, and but a few miles from the Rhine, which flows across its southern landscape. The town itself is handsome, interesting, and clean, and the newer streets are amongst the finest to be seen in Germany. The best part of the Rhine scenery is within an hour's journey of Wiesbaden, and about the same distance in the opposite direction lies Frankfort-on-the-Maine, one of the richest and most fashionable of Continental towns. Wiesbaden is accordingly full of life and gaiety. The once famous gaming-tables no longer keep the sensitive away, for they were closed on the last day of 1872—much to the benefit of the town, into which ever since that date there has been an influx of men of wealth and years who come when the poet promises them—"Verjüngt der sieche Greis." The cost of living at Wiesbaden is of course high, but on the present occasion this has not been allowed to stand in the way of a successful meeting of the Association. In fact, it has been all in the other direction, the administration having secured rooms in the hotels and lodging-houses at fixed prices, and some of these so moderate that they amount to almost nothing, the rooms being given gratis. Further, in case the reputed poverty of so many of the scientific men of Germany should still prevent them from making a long and somewhat expensive journey by rail to the western borders of the country, arrangements were made with many of the railways for a reduction of fares—some as much as one-half. The success of the Congress is further insured by the choice of September as the month of meeting, the weather in Germany being then perhaps the finest of the whole year. On the present occasion it is most pleasant and enjoyable: the days are bright but cool,

and the evenings so mild that the promenade concerts in the open air do not end till nearly ten o'clock.

With the wonderful combination of attractions before them—of scenery, fashionable living, recreation of every kind, and, to commence the day, a few hours of professional intercourse sufficient to create an appetite for relaxation—the German *savants* and physicians have naturally crowded to Wiesbaden. The President of the meeting is the well-known Fresenius, director of the chemical laboratory and professor in the agricultural institute in the town. He has already been so long famous in his own as well as in other countries that, as he said himself in his introductory address, he has held the presidency before, more than twenty years ago. Dr. L. Haas is associated with Fresenius in the presidency, and Dr. Arnold Pagenstecher and Dr. Haas, jun., are the general secretaries of the meeting. The universities and hospitals of Germany are well represented at the Conference. Among the most distinguished visitors are the following:—Professors Virchow, Langenbeck, Frerichs, and Westphal, from Berlin; Bartels and Kupfer from Kiel; Eberth from Zürich, Rindfleisch from Bonn, Gerlach and Ziemssen from Erlangen, Falck and H. Schmidt from Marburg, Meynert and Beigel from Vienna, Arnold and Simon from Heidelberg, His from Leipzig, Kollmann from Munich, Jürgensen from Tübingen, etc. Those who are familiar with German work and literature will miss several names from the preceding list. The winter session in the universities begins next month, and many of the professors are spending September at home, availing themselves of the quiet vacation to do private work. Austria sends but a very few of her many famous men to the Conference. But there are other and more sad reasons for the absence of other familiar names. Within a short time Germany has lost more than one of the most distinguished and promising members of our profession. Professor Czermak, well known, especially in connexion with laryngoscopy, is just dead. Obermeier, of Berlin, who was so rapidly making his reputation as a pathologist, as the profession well knows, fell a victim, only a few weeks ago, to his scientific zeal. Those who were best acquainted with Obermeier, and the facts of his fatal attack of cholera, are not surprised at the result, for it is not only certain that he kept specimens of choleraic discharges and organs in his room, but it can scarcely be doubted that he had injected blood from a cholera patient under his own skin. In the section of pathological anatomy, the name of Professor Cohnheim is wanting. We regret to say that Cohnheim has been unable to work for the last eight months from an affection of the larynx, which it is now feared may be of a more serious character than was at first suspected. The Congress is, however, mainly constituted, to all appearance, by the general medical profession of the land; and but for the unmistakable German features and the foreign tongue, one might almost fancy, in a sectional meeting, that one had slipped back into the second week of August in London. It is very different in the general meetings, and in the intervals of work, when the numerous representation of the fair sex reminds one rather of the British Association.

The programme of the meeting is briefly as follows:—The Congress lasts a week—from September 17 to September 24; three general meetings are held—the first on the first day, the second on the fifth day, and the last on the seventh; three forenoons are occupied with the meetings of sections for reading and discussing papers, the exhibition of patients and apparatus, etc.; Sunday is reserved for excursions to interesting places in the neighbourhood; and, finally, every afternoon and evening there is some special entertainment in the shape of a dinner, concert, ball, opera, or otherwise. A journal, published every morning, contains the programme of the day, a list of the subjects in the various sections, a list of the associates who have arrived at Wiesbaden, and a short account of the proceedings of the previous days. The general meetings at Wiesbaden are held in the large hall of the Kurhaus, one of the finest of its kind in the world; and at them the formal business of the Association is transacted, as well as the special addresses delivered. The sections meet in four different buildings in the immediate vicinity of each other, and the business here is conducted in a fashion very similar to that adopted at the British meetings. There is free discussion and provision for frequent reply. The amount of real work, however, got through in a forenoon is by no means great. The president of the several sections is changed from day to day; two secretaries in each section superintend the business part of the proceedings, and take brief notes of the discussions. The Germans are famed for their early habits, and here they fully sustain their character in this respect—at eight in the morning several of the sections begin their work, and one at least even half an hour earlier; by half-past twelve all is over; at one everybody is at dinner; and, after an afternoon and evening's relaxation and amusements, by ten o'clock, or shortly after, everyone is in bed.

(To be continued.)

ON HYSTERICAL ANOREXIA.(a)

By Dr. LASÉGUE,
Professor of Clinical Medicine in the Faculty of Medicine of Paris; Physician to La Pitié Hospital.

(Continued from page 266.)

The anorexia gradually becomes the sole object of preoccupation and conversation. The patient thus gets surrounded by a kind of atmosphere, from which there is no escape during the entire day. Friends join counsels with relatives, each contributing to the common stock, according to the nature of his disposition or the degree of his affection. Now, there is another most positive law that hysteria is subject to the influence of the surrounding medium, and that the disease becomes developed and condensed so much the more as the circle within which revolve the ideas and sentiments of the patient becomes more narrowed. The fault does not altogether lie in a pathological vitiation of disposition. Under the influence of sensations, which in more than one particular resemble the impressions of hypochondriacs and the delirious ideas of the insane, the hysterical constantly find themselves unable to resist this domination by a voluntary effort. At the most, distraction of attention enables them to forget at intervals, and these are the sole respites they obtain. The more their attention is intensified, the more does their idea of *malaise* become developed, and at the end of a variable time of this mischievous concentration the patient enters upon a new phase, and, systematising after the manner of certain of the insane, she no longer troubles herself in search of arguments. The responses become still more uniform than the questions.

Tired of supplications, if the endeavour be made to insist, the attempt will be still more fruitless than those which preceded it. In fact, what is to be said? The patient, when told that she cannot live upon an amount of food that would not support a young infant, replies that it furnishes sufficient nourishment for her, adding that she is neither changed nor thinner, and has never refused encountering any task or labour. She knows better than anyone what she requires, and, moreover, it would be impossible for her to tolerate a more abundant alimentation. When told that this inanition will at last induce disease of the stomach, she says that she never was better, and suffers in nowise, her state of good health contradicting all these fears. And, in fact, the pains attendant on the early stages have diminished or disappeared or only return at long intervals—an amelioration attributed by her to the regimen she has pursued. The fasting, indeed, is not absolute, and in nowise resembles the refusal of food in melancholia. The anorexia has not increased, and especially it has not become transformed into the analogous disgust for food felt by some phthisical and many cancerous patients. The patient willingly joins her family at meals, on the condition that she is allowed to take only what she wishes.

What dominates in the mental condition of the hysterical patient is, above all, the state of quietude—I might almost say a condition of contentment truly pathological. Not only does she not sigh for recovery, but she is not ill-pleased with her condition, notwithstanding all the unpleasantness it is attended with. In comparing this satisfied assurance to the obstinacy of the insane, I do not think I am going too far. Compare this with all the other forms of anorexia, and observe how different they are. At the very height of his repugnance, the subject of cancer hopes for and solicits some aliment which may excite his appetite, and is ready for all kinds of trials, although incapable of triumphing over his disgust. The dyspeptic, without organic lesion, exhausts his ingenuity in varying his regimen, and complains with all the bitterness habitual to those who suffer from affections of the stomach. Here we have nothing like this, but, on the contrary, an inexhaustible optimism, against which supplications and menaces are alike of no avail: "I do not suffer, and must then be well," is the

(a) *Archives Générales de Médecine*, April, 1873.

monotonous formula which has replaced the preceding, "I cannot eat because I suffer." So often have I heard this phrase repeated by patients, that now it has come to represent for me a symptom—almost a sign.

If I attach to this mental condition an importance that perhaps will appear exaggerated, it is that in fact the whole disease is summed up in this intellectual perversion. Suppress this, and you have an ordinary affection which at last yields to the classic procedures of treatment. Carry it to its extreme—and you will never go too far—and then you have a dyspepsia bearing no resemblance to others, which pursues a foreknown course, and which will not be relieved by habitual means. Moreover, I do not believe that gastric hysteria is any exceptional occurrence, for in other hysterical localisations we meet with at least an equal indifference, however inconvenient and painful their manifestations may be. The subject of hysterical convulsive cough does not demand relief from a spasm which is so irritating, and sometimes so ridiculous. She joins in the chorus of those who are pitying her; but when active treatment is in question, she is more indifferent than zealous in the matter. It is the same with paraplegic patients condemned to absolute repose, and who are willing to live in this way, without ever insisting that their attendants, exhausted in useless attempts, should have recourse to heroic measures.

[Professor Laségue, after adducing some interesting examples of other hysterical localisations, for which we have not space, continues thus]—

In the end the tolerance of the economy, marvellous as this is, becomes exhausted, and the disease enters upon its third stage. Menstruation, which up to then had been insufficient and irregular, now ceases, and thirst supervenes. An examination shows retraction of the abdomen, which has not been observed before, and palpation indicates a progressive diminution of its elasticity, an habitual symptom in prolonged inanition. The epigastric region has become tender to pressure, although the patient complains of no spontaneous pains. An obstinate constipation no longer yields to purgatives. The skin is dry, rugous, and without suppleness. The pulse is frequent. Emaciation makes rapid progress, and with it the general debility increases. Exercise becomes laborious, the patient remaining willingly lying down; and when she rises she suffers from vertigo, a tendency to sickness, or even attacks of syncope. The countenance is pale, without the lips being colourless. An anæmic cardio-vascular souffle is almost constant, and which, often existing in advance of the affection, rarely fails to appear at its late period. This sketch is far from representing exactly the individual diversities that are observed. Sometimes it is the emaciation, sometimes the debility, sometimes the anæmia, with its accompanying local or general accidents, that is most prominent; while exceptionally nervous spasmodic disturbances, neuralgias, etc., arise, the active symptoms seeming to become effaced in proportion as the strength of vital resistance is diminished.

The appearance of these signs, the import of which can escape no one, redoubles anxieties, and the relatives and friends begin to regard the case as desperate. It must not cause surprise to find me thus always placing in parallel the morbid condition of the hysterical subject and the preoccupations of those who surround her. These two circumstances are intimately connected, and we should acquire an erroneous idea of the disease by confining ourselves to an examination of the patient. Whenever a moral element intervenes in a disease, as here it does without any doubt, the moral medium amidst which the patient lives exercises an influence which it would be equally regrettable to overlook or misunderstand. True and sincere affliction has succeeded to remonstrances. By the force of sentiments as much as by the necessities caused by new sufferings, the hysterical subject has been constituted really a sick person, no longer taking part in the free movements of common life. It seems to me that this unconscious change in the respective positions of the patient and her friends plays here a considerable part. The young girl begins to be anxious from the sad appearance of those who surround her, and for the first time her self-satisfied indifference receives a shock. The moment has now arrived when the physician, if he has been careful in managing the case with a prevision of the future, resumes his authority. Treatment is no longer submitted to with a mere passive condescendance, but is sought for with an eagerness that the patient still tries to conceal. The struggle thus established between the past and the present is a curious one to observe, and easy of proof providing that the investigation is in nowise allowed to be suspected.

Two courses are now open to the patient. She either is so yielding as to become obedient without restriction, which is rare; or she submits with a semi-docility, with the evident hope that she will avert the peril without renouncing her ideas and perhaps the interest that her malady has inspired. This second tendency, which is by far the more common, vastly complicates the situation. It is no easy thing to re-establish the regular function of a stomach which has so long been condemned to repose. We meet with alternatives of success and failure, and frequently only obtain a very insufficient result. I know patients who ten years after the origin of the affection have not yet recovered the aptitude of eating like other people. Their health is not deeply affected, but their amendment is very far from representing a cure.

Sometimes some unexpected event comes to break through the course of the disease—a marriage, grief, or some great moral perturbation. At others it is some physical occurrence, as a pregnancy or a febrile affection; but there are cases which resist both classes of these modifying agents. As a general rule we must look forward to a change for the better only taking place slowly—by successive starts; and we should be on our guard against affirming beforehand the amount of amelioration with which we must rest content.

Well founded as anxiety in these cases may be, I have never yet seen an anorexia terminate directly in death; but, in spite of this experimental assurance, I have passed through repeated perplexities. It is probable that the pathological sensation—the primary cause of the inanition—disappears by the fact of the increasing cachexia. It is not only of fever that we may say that it resolves spasmodic action, for the same property appertains to a great number of other morbid conditions. Delivered of her sub-delirious pre-occupation, the hysterical patient passes into the condition of other dyspeptic patients, and only presents the same difficulties in her cure that we are accustomed to meet with. Hysteria, whatever extreme violence it may attain, is not itself mortal, but it may become the occasional or indirect cause of fatal diseases; and first among these is pulmonary tubercle. The hysterical anorexia itself is always cured more or less completely at the end of years, passing through the period of decrease with an appetite that is limited or exclusive, and occasionally fantastical. I attended with Trousseau a young woman who, having been thoroughly hysterical from the time of puberty, became, without appreciable cause, the subject of an invincible anorexia. She had reached such a state of emaciation and debility that she could no longer leave her bed. Her food consisted exclusively of some cups of tea with milk. Obstinate constipation had led to serous diarrhœa, with pseudo-membranous exudations. Nevertheless she became pregnant, and under the influence of that condition she set her wits to work to find out some article of food agreeable to her stomach. During six months she lived only on *café au lait*, into which she cut slices of pickled cucumbers, only adding very gradually some feculents to this singular diet. At the present time she is in a most satisfactory state of health, although always remaining excessively lean. Generally the appetite limits itself to aliments less singularly chosen, and then a free career is given to the fancy. I remember a patient 26 years of age, who, living in a distant province, neither would nor could eat anything but a biscuit made by a particular Paris baker. Many confine themselves to a particular kind of vegetable, refusing both meat and bread; while others will only take viands, the taste of which is disguised by spices. Although these capricious restrictions are a favourable sign, the patients continue to submit themselves without any desire to the diet they have chosen for want of a better. The anorexia persists indefinitely for long after they have returned to the ordinary regimen. I have never known the disease relapse, and, once established, the relative or complete cure is maintained. At the period when the hysterical affection had yielded, or had assumed other forms, I have endeavoured to obtain from the patients some more precise information concerning the sensations they had experienced, and which had induced them to avoid food. None of them have been able to furnish me with anything more exact than what I have reported. The typical formula employed during the course of the disease was reproduced—"I could not; it was too strong for me, and, moreover, I was very well."

The cases which have served me as a basis for this memoir are eight in number, all women, the youngest being 18, and the eldest 32. Hysteria manifested its presence in all by various symptoms, and in one only there had not been paroxysms.

She was chloro-anæmic, and her mother had suffered from two attacks of hysterical hemiplegia. It was easy enough to assign the date of the commencement of the affection, but the anorexia was lost while passing through such insensible shades that the precise period of its termination could not be fixed. Speaking as nearly to the truth as possible, we may say that the affection, comprising the various phases that have been indicated, has never persisted for a less time than from eighteen months to two years.

Although these cases are few in number, they so much resemble each other that the latter ones found me in no indecision in regard either to diagnosis or prognosis, and, in fact, all passed on according to rule. In describing this variety, I proposed to myself, as I said at the commencement, to detach a species or a fragment, but especially to signalise the considerable part that is played in certain forms of hysteria by the mental disposition of the patient, and to point out yet once more the intimate relation that attaches hysteria to hypochondriasis.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

Cholera in Paris—Guérin on its Origin and Propagation—Relations of Summer Diarrhœa to Cholera—Treatment of Cholera—Diagnosis of Cerebral Mischief—Value of Results of Treatment as Diagnostics—Death of Professors Coste and Nélaton.

Paris, September 22.

The Parisians are greatly terror-stricken by the presence of cholera in their capital, and I have heard some well-meaning people here remark that the hand of Providence is evidently turned against the French, as no sooner had the Prussians evacuated the territory than they have been replaced by an enemy more insidious and much more certainly deadly. The cholera has invaded the capital, and its course has been traced to Havre and Hamburg, whence it was imported by a family who lately arrived from the latter place. Whether the importation took place exclusively by this family is rather hypothetical, but what is more certain is that the disease was imported from Hamburg by a vessel from that port which put in at Havre, and that soon after its arrival there the cholera broke out and has been reigning at Havre since July 19. Following the course of the Seine, it broke out at Rouen on August 5, and reached Paris about September 5, between which date and the 8th inst. there had been about sixty fatal cases reported in the hospitals and town. This naturally excited alarm, and, as is usually the case on such occasions among our Gallic friends, there was more talk than work, and, instead of taking measures to prevent the spread of the disease, they were trying to find out where it came from. The Academy of Medicine and other medical bodies have taken up the subject; and M. Jules Guérin, who is known as a caviller, but at the same time is a great *savant* and one of the most practical men of the profession, has opened a discussion at the Academy as to the origin of cholera, which he believes to be engendered spontaneously or locally (*sur place*), and that importation of the germ is not the only means of the propagation of the disease. "This last doctrine," he says, "was an unfortunate one, and was founded on a very restricted system of pathology and sterile therapeutics, which had the effect of overthrowing national interests, and induces governments to prescribe prophylactic measures scarcely worthy of the middle ages." M. Guérin's theory of the spontaneous or local origin of cholera would appear to be supported by the occurrence of isolated cases in persons who had no communication whatever, directly or indirectly, with the family supposed to have imported the disease into Paris. For instance, M. Raynaud, Physician to the Lariboisière Hospital, has brought to the notice of the Société Médicale des Hôpitaux that three persons occupying the same house were brought to the hospital affected with cholera, and that five patients who were in the same ward suffering from other diseases were also affected with the malady; but unfortunately the report does not state whether the five patients were seized before or after the admission of the other three. Dr. De Ranse, one of the editors of the *Gazette Médicale*, also brings to notice the fact of three patients in the Hôpital St. Louis having died from cholera on September 6, and that three or four others in the same hospital were undergoing treatment for the disease. These patients, Dr. De Ranse adds, had been admitted into the hospital long before the outbreak of cholera in Paris, and none of them had gone out after its appearance. These cases, Dr. de Ranse thinks, could not have been affected by importation; but unfortunately for the thesis of these learned physicians, they seem to have lost sight of the date of the arrival of cholera from Hamburg, where it was raging, which arrival, according to the official report, took place on August 27, and consequently ten days before its outbreak in Paris. The inference therefore is that the disease was imported by this family, and that the hospital patients above noticed were victims of this importation; but how it got to them is another question, which I must confess I am not prepared to answer. M. Guérin also believes the disease to be contagious, and very properly insists upon the isolation of cholera patients as one of the first and most important prophylactic measures that should be taken on an outbreak to prevent the spread of the disease. M. Guérin likewise treated of summer diarrhœa in its relations with cholera; and, so far as I can make out, he believes that diarrhœa not only constitutes one of the symptoms of cholera, but that an epidemic of the former might lapse into an epidemic of the latter—in other words, that summer diarrhœa, if treated in time, is more readily curable, but, if neglected, might, with the concordance of certain conditions of the "medical constitution," engender the choleraic poison. This is certainly far-fetched, and I do not believe he will have many followers either in or out of the Academy. In fact, M. Fauvel, whose works on cholera are well known, intends taking up the cudgels, and is to respond to-morrow to M. Guérin's arguments. The discussion will, I am sure, be most interesting, but whether the speakers will throw much further light on the subject remains to be seen—though I question it greatly, as I often think we know as much as we ever shall know about the nature of this dire affection; for since its first appearance, more than half a century ago, our knowledge has not much increased as to its real pathology, much less as to its therapeutics. M. Guérin divided his discourse as follows:—(1) Diarrhœa which precedes an invasion of an epidemic of cholera; (2) that which accompanies the epidemic; (3) the diarrhœa which precedes each particular case of cholera—into which latter he more fully entered.

This, I must confess, is to me not very intelligible, unless M. Guérin means to show that simple diarrhœa and cholera are one and the same disease. The worthy doctor forgets, however, that diarrhœa is a symptom of many affections, and that cholera is a disease *per se*—a morbid entity,—and that diarrhœa is one of its most constant and earliest symptoms.

As for treatment, there seems as much confusion about this as about the etiology or the pathology of the disease. Every variety and form of treatment is adopted in the hospitals here, such as emetics, purgatives, opiates, astringents, stimulants—in the form of tea and rum *ad libitum*, a most nauseous mixture at any time, but more particularly so in the time of cholera. It is, however, being used as a sort of universal remedy by the French for the disease, though I have heard many people say that the very idea of the mixture excites nausea and vomiting. Isolation of cholera patients to my mind constitutes one of the most essential of the prophylactic measures that should be taken to prevent the spread of the disease, but whether it is considered such by the French physicians or not I cannot say; one thing, however, is certain—that in an epidemic of cholera, as in an epidemic of small-pox or any other contagious disease, persons so affected are placed in the ordinary wards among the other patients, and it is only when the disease has spread somewhat and taken a firm hold in the place that they think of separating the patients. The hospital cases referred to in the first part of my letter are examples of this culpable negligence. There are others of which I am personally cognisant, but these facts are so well known that I need not trouble your readers with them.

But if French physicians in general are wanting in therapeutics, their powers of diagnosis are something wonderful, and much to be admired. I have just witnessed an example of this in a case under the care of Dr. Ball, who, by the way, is an Englishman, but was brought up in the French school. A woman, aged about 40, was suffering from facial hemiplegia of the left side, accompanied by amaurosis of the right eye. The patient was subject to epileptic fits, and the paralytic symptoms which first affected the left side were becoming

manifest on the right side of the face, when the patient was carried off by cholera, which she caught in the ward. In the lifetime of the patient Dr. Ball had diagnosed a tumour at the base of the brain over the petrous portion of the right temporal bone, and compressing the nerves that pass over and through it. The death of the patient offered an opportunity for verifying the diagnosis. But this was not the only point of interest in the case, for during the life of the patient it was not sufficient to diagnose a tumour in the brain, but what the nature of that tumour was, and in an able lecture by Dr. Ball on the subject he referred to the almost insurmountable difficulties that beset the question. One of the means employed for arriving at anything like a correct diagnosis consists in the use of certain therapeutic agents. For instance, where syphilis is suspected, as it was in the case under notice, notwithstanding the protestations of the patient to the contrary, the usual anti-syphilitic treatment should be adopted. Dr. Ball accordingly prescribed Gibert's syrup, composed of mercury and iodide of potassium, which was followed by marked and rapid improvement in the state of the patient. But what added to the difficulty of the diagnosis was, the patient had no marks of syphilis on her body, and even at the autopsy Dr. Ball felt some hesitation in pronouncing the tumour to be of syphilitic origin, so much did it resemble in size and consistence a glioma; but a small spot of disease on the internal surface of one of the parietal bones removed all doubt in the matter.

This reminds me of a case I witnessed some years ago at the Hôpital des Cliniques, in which M. Nélaton, experiencing some difficulty as to the etiology of a tumour of the breast in a married woman aged about thirty-eight, administered the iodide of potassium internally, applying mercurial ointment externally, and cured the patient. At the Hôpital Lariboisière, a man, aged thirty-seven, was lately admitted in M. Tillaux's ward with a suspicious-looking ulcer on the dorsum of the tongue, near its left border. M. Tillaux questioned the man, and thoroughly examined him, but could find no trace of syphilis, particularly as the man most strenuously persisted in denying that he had been exposed to contagion. Notwithstanding this, M. Tillaux pronounced the ulcer to be a chancre, as it bore all the characteristics of that lesion, and the result of the anti-syphilitic treatment to which the patient was subjected confirmed but too strongly M. Tillaux's diagnosis.

The medical profession and science in general have sustained a great loss by the death of Dr. Coste, the eminent physiologist of the College of France, which has just taken place from an obstruction of the bowels. He was born in 1807, and from a very early age took to the study of embryogeny; he was a great piscicultor, and the inventor and propagator of ostreiculture in France. In 1834 the Academy of Sciences awarded him a gold medal for his researches on the generation of mammifers and the formation of embryos; and to enable him to develope his ideas on these subjects, he was attached to the Museum of Natural History at the Jardin des Plantes, where the young *savant* so distinguished himself that a special chair was created for him at the College of France. In 1851 he was elected Member of the Academy of Sciences in the room of M. de Blainville, shortly after which he was made Chevalier of the Legion of Honour. M. Coste, having noticed the great loss of aquatic embryos that took place in the rivers of France, devoted himself to the study of the art of multiplying fish by means of artificial fecundation. In consequence of the favourable reports that he had made on his new experiments, a model piscine was founded at Huningue, in the Upper Rhine. This establishment furnished in two years nearly 600,000 salmon and trout, with which the river was peopled. In 1855 M. Coste was charged with the peopling the artificial lake and river in the Bois de Boulogne with fish, and in 1862 he was appointed Inspector-General of River and Coast Fisheries. He published a very important work on practical instructions in pisciculture, which has already passed through two editions, and constitutes the principal guide on the subject; and on the eve of his death he had just brought to a termination his work, intended to serve as a basis for regulating the sardine fishery on the coast of France.

Science and medicine, but principally that branch of the latter termed surgery, will have to deplore another great loss in the death of Dr. Nélaton, which, though long expected, took place somewhat suddenly at his residence at Paris, at 9.30 a.m. yesterday. August Nélaton, born in 1807, was certainly one of the most eminent surgeons of the age. He took his degree of Doctor of Medicine and Surgery in 1836, and attained the highest scientific and professional status that a man could aspire to. In 1856 M. Nélaton was elected member of the Academy of Medicine in the section of Pathological Surgery, and at his death was Grand Officer of the Legion of Honour and Honorary Professor at the Faculty of Medicine of Paris. Although from his numerous occupations and an immense *clientèle* M. Nélaton could not devote much time to writing, yet the science and art of surgery had benefited greatly by his rare contributions. But if he had no other title to eminence, his success in the extraction of the bullet from Garibaldi's foot would immortalise his name. M. Nélaton leaves a widow, two daughters, and a son to bemoan their loss; the latter, a lad about twenty-one, is a medical student, and promises to walk in the enlightened path of his father.

The mortuary returns for the week ending September 19 shows a mortality of 125 from cholera in town and hospitals, whereas in the week preceding the number was 150. The sanitary condition of Paris is in other respects excellent.

September 24.

In my obituary notice of M. Nélaton I omitted to mention, among his titles, that he was made Member of the Institute in the room of the late Jobert de Lamballe; and in 1868 he was raised to the dignity of Senator—a distinction hitherto accorded to only a few of the medical profession. He was also member of several learned societies throughout the world. His funeral took place yesterday, the service having been performed in the little church in the Rue de Chaillot, near the Champs Elysées. The church was so full that many of those who attended were obliged to wait outside to follow the procession to the cemetery. Notwithstanding the absence from Paris of many of the friends and admirers of the deceased, there were several notabilities in and out of the profession to be seen at the funeral, among whom may be mentioned General de Ladmirault, the Military Governor of Paris; General Vinoy, the Grand Chancellor of the Legion of Honour; Admiral Jurien de la Gravière; M. Léon Renault, the Prefect of Police; Doctors Ricord (who seemed very much affected), Demarquay, Baron Larrey, Conneau, Campbell, and many others of less note, among whom were also to be noticed several of the clients of all classes of the deceased. The procession started from the church about two in the afternoon, the pall being borne by Drs. Bouillaud, Bouchardat, Depaul, and Béclard. The son and brother of the deceased were the chief mourners. Both the Academies of Medicine and of Sciences, as well as the School of Medicine, were represented by deputations in their official costumes, and the deceased having been Grand Officer of the Legion of Honour, the due military honours were paid to his rank. All along from the church to the cemetery the streets were lined with people to witness the procession, and on its arrival at the Père la Chaise, the coffin, after a short service, was laid in a family vault. The funeral was much simpler than it otherwise would have been, not only from his social position, but from the high offices he held under Government. In accordance with the wishes of the deceased, no funeral oration was pronounced.

OBITUARY.

DONALD DALRYMPLE, M.D. and M.P.,

Died suddenly at Southampton on Friday week, aged 59 years. The deceased was born at Norwich in 1814, in which town he afterwards practised. He became a Member of the College of Physicians, London, in 1859, but retired from the profession in 1862. He was a magistrate and Deputy Lieutenant of Norfolk and Chairman of the Governors of the King Edward Schools at Norwich. The deceased gentleman represented Bath in the House of Commons, but had announced his intention not to seek re-election for that city. It is understood the deceased never quite recovered from the effects of his too hurried visit to the United States in the winter of 1871 and 1872; the fatigues he then underwent told, it is said, to some extent on his constitution. Dr. Dalrymple was a member of a family which shed lustre upon our art. His father was a great surgeon, and his brother John one of the ablest and most philosophical ophthalmic surgeons of the day. Dr. D. Dalrymple is not associated with any works on professional subjects. He will be remembered chiefly for a Bill which he introduced into Parliament on more than one occasion for the treatment of habitual drunkards. In this he was actuated by the most philanthropic motives. We have frequently, in the pages of this journal, expressed our opinion on the character and merits of this Bill—which, if

in some respects Utopian and impracticable, might, we think, form the foundation of a useful and practicable measure. The remains of Dr. Dalrymple were removed from Southampton to Norwich for interment.

ALEXANDER WORTMANN, L.R.C.P.L.,

A MEDICAL practitioner at Gibraltar, has, owing to a matrimonial disappointment, committed suicide. He sat down in a chair, placed the muzzle of his gun in his mouth, and pulled the trigger by means of a piece of string which he had previously attached to it, and his head was shattered to pieces.

MEDICAL NEWS.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BROWN, GEORGE, L.S.A.—Demonstrator of Anatomy to the Westminster Hospital Medical School, *vice* Mr. Ramsay, resigned.

LEVINGE, E. G., A.B., M.B. Univ. Dub., L.R.C.S.I.—Assistant Medical Officer to the Borough Lunatic Asylum, Newcastle-on-Tyne.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—Robert Nelson, Surgeon to the *Serapis*.

WAR OFFICE.—MEDICAL DEPARTMENT.—Surgeon Edward M'Carthy, M.D., retires upon temporary half-pay; Surgeon Robert Edward Bredon, M.D., resigns his commissiou.

BIRTHS.

FEGAN.—On September 22, at 1, Charlton-park-terrace, Charlton, S.E., the wife of Richard Fegan, M.D., L.R.C.P., of a daughter.

HAYES.—On September 17, at 5, Villa-road, Brixton, the wife of Surgeon-Major W. H. Hayes, Bengal Medical Service, of a daughter.

MIDDLETON.—On September 14, at Dublin, the wife of Surgeon J. Middleton, M.D., Army Medical Department, of a daughter.

ROWLANDS.—On September 6, at 4, Spilman-street, Carmarthen, the wife of James D. Rowlands, M.R.C.S. Eng., L.S.A., of a daughter.

SPENDER.—On September 14, at Bath, the wife of John Keut Spender, M.D., of twins—a son and daughter.

MARRIAGES.

BEALES—COBB.—On September 11, at St. Peter's Church, Congleton, Robert Beales, M.D., J.P., to Sarah Georgiana, elder daughter of the late John Cobb, Esq.

HEATH—MAYNARD.—On September 18, at the Catholic and Apostolic Church, Bridgnorth, Christopher Heath, F.R.C.S. Eng., of 9, Cavendish-place, Cavendish-square, W., to Gabrielle Nora, third daughter of the late Captain Maynard, R.N., of The Croft, Bridgnorth.

HOPE—MARTIN.—On September 17, at Dowlais, Glamorganshire, John Hope, M.R.C.S., Elden-square, Newcastle, eldest son of Thomas Murray Hope, Esq., Westoe, South Shields, to Jessie Anne, only daughter of George Martin, Esq., Dowlais.

McMULLEN—PRINCE.—On September 17, at the Abuey Congregational Church, Stoke Newington, William McMullen, L.K.Q.C.P., L.R.C.P.I., Brixton, to Charlotte Maria (Lottie), eldest daughter of W. Prince, Esq., of Stoke Newington and Kingsland-gate.

RIDLEY—HALL.—On September 10, at the parish church, Hempnall, Norfolk, James Ridley, M.D., son of George Ridley, Esq., J.P., of Tullamore, King's Co., to Emily Elizabeth Sarah, daughter of the Rev. George Hall, vicar of Hempnall.

WITHERS—WHITEHOUSE.—On September 18, at Christchurch, West Bromwich, Richard Walter Owen Withers, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., of Shrewsbury, to Martha, third daughter of the late Joseph Whitehouse, Esq., of Handsworth.

DEATHS.

COOKE, JOHN CHARLES, M.R.C.S.E., L.S.A. Lond., late of Newent, Gloucestershire, at the residence of his son, Montague House, Hastings, on September 19, aged 66.

CRUICKSHANKS, JAMES, L.F.P.S. Glasg., at his residence, Ayton, Berwickshire, on September 9, aged 43.

DALRYMPLE, DONALD, M.R.C.P., F.R.C.S., M.P. for Bath, on September 19, after a few hours' illness, aged 59.

DYMOCK, ARCHIBALD, M.D., M.R.C.P. Lond., J.P., eighth son of the late William Dymock, W.S., of Edinburgh, at Louth, Lincolnshire, on September 17.

FENTON, EMILY, wife of C. D. Fenton, M.D., at Doncaster, on September 17, aged 57.

GIDLEY, GUSTAVUS, M.R.C.P., J.P. for the county of Kent, at 19, Durham-terrace, Westbourne-park, on September 22, nine days after the death of his wife, aged 64.

WILLIAMS, W. R., M.R.C.S. Eng., L.S.A., at 41, Finchley-road, South Hampstead, on September 21.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

CHELTENHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to E. T. Brydges, Clerk to the Urban Sanitary Authority, Public Offices, Cheltenham, on or before October 11.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimouials, to John Binks, Esq., Honorary Secretary, Wakefield.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Medical Officers Candidates must be duly qualified. Applications, with testimonials, to P. Goldschmidt, Esq., Chairman of the Board, 100, Albert-square, Manchester, on or before October 15.

QUEEN'S HOSPITAL, BIRMINGHAM.—Fourth Physician. Candidates must be duly qualified. Applications, with testimonials, to the Committee, on or before October 3.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Candidates must be duly qualified. Applications, with testimouials, to the Treasurer, Robert Tweedy, Esq., Truro, on or before October 8.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

West Ward Union.—Mr. Thos. J. E. Brown has resigned the Morland District; area 22,170; population 2575; salary £25 per annum.

APPOINTMENTS.

Carnarvon Union.—John Jones, M.R.C.S. Eng., L.S.A., to the Llanrug District.

Romney Marsh Union.—Richd. R. Daglish, M.R.C.S. Eng., L.S.A., to the Brookland District.

THE next session of the Bavarian Diet has been postponed on account of the prevalence of cholera.

IN Wolverhampton the typhoid epidemic is proving rather serious. In all twelve deaths have been reported. In two fatal instances the residence shows no defect, but the families in which these occurred received milk from a dairyman whose milk is suspected to be polluted.

WE are glad to see that the announcement of the death of the third child of the Rev. George Everard at Wolverhampton from typhoid fever is contradicted.

THE Portumna Board of Guardians have increased the salary of the Medical Officer of the Portumna Dispensary District from £100 to £120 per annum, and a proposition to increase the salaries of the other medical officers is to be considered at the next meeting.

TEN PERSONS were on Thursday week fined 20s. and costs by the Marylebone magistrates for refusing to have their children vaccinated. The Paddington Board of Guardians prosecuted.

AN outlay of £10,000 is to be made in improvements, hygienic and otherwise, in the North Surrey District Schools at Anerley. We hope these improvements will have the effect of greatly diminishing ophthalmia, which has so long been prevalent among the children at these schools.

THE Portuguese Government having declared the port of Hull infected with cholera, the Medical Officer of Health, Mr. Fearne Holden, has published a certificate that the port is entirely free from cholera.

AT an inquest held by Dr. Lankester on Saturday last, at Hampstead, on the body of a boy who was found drowned in the Vale of Health Pond, Hampstead Heath, the jury returned a verdict of death from accidental drowning, and, at the suggestion of the Coroner, added a rider to their verdict calling the attention of the Metropolitan Board of Works to the dangerous condition of the Vale of Health Pond, and strongly recommending to the Board the propriety of converting the ponds on Hampstead Heath into public bathing-places for comfortable and healthful bathing. The Coroner pointed out that the question was a metropolitan one.

DEATH OF PROFESSOR COSTE.—Science has sustained a terrible loss in the person of M. Coste, who has just died in his sixty-fifth year, in consequence, it is said, of intestinal strangulation. His magnificent works on embryogeny procured for him the creation of a special chair in the Collége de France. Born near Montpellier, M. Coste commenced studying medicine under Delpèch, but, becoming absorbed by his favourite embryological studies, he never took his doctor's degree. These studies, among other fertile results, led to his interesting researches on pisciculture which have of late years so familiarised his name with the public, and promise to open new and important sources of alimentation.

WHAT NEXT?—A committee of homœopathic physicians in Prussia, speaking for their branch, have addressed a formal petition to Prince Bismarck, requesting that professional chairs for homœopathy may be added to the universities.

and that medical inspectors may be appointed to insure proper supervision of the homœopathic practice.

ST. THOMAS'S HOSPITAL.—At a meeting of the Grand Committee on Tuesday, the 23rd instant (Sir Francis Hicks in the chair), Mr. Alexander Oberlin McKellar, F.R.C.S., of the Royal Free Hospital, was elected Resident Assistant-Surgeon in the vacancy occasioned by the promotion of Mr. Wagstaffe as Assistant-Surgeon. Dr. McKellar, who has seen considerable practice already, served also throughout the Franco-German war. The Committee of Management of this Hospital may be congratulated on the admirable selection of its medical and surgical staff. The inaugural address will be delivered on the 1st proximo by Dr. Harley.

DR. ALEX. S. MERRICK, the Assistant Medical Officer of the Cork District Lunatic Asylum, having been appointed Resident Medical Superintendent of the Donegal Lunatic Asylum, Letterkenny, the Governors of the former, at their last meeting, upon the motion of Sir Thomas Tobin, passed the following resolution:—"The well-deserved promotion of Dr. A. S. Merrick to the position of Resident Medical Superintendent of the Letterkenny District Lunatic Asylum necessarily deprives this institution of his valuable services: we, the Governors, feel we cannot allow his departure from us without recording the high sense of respect we entertain towards him, the confidence placed in him, and the great satisfaction we always experienced at the manner he discharged his very responsible duties during the period (nearly three years) he was connected with this institution. Many of us have had constant opportunities of observing the attention and regularity he invariably evinced in the working of this large Asylum—the largest (except Richmond) in this country,—more particularly since the decease of the late resident superintendent, Dr. Power, when the entire responsibility of the efficient management of the Asylum devolved on him. His uniform care and kindness to the unfortunate patients entrusted to his charge have invariably met with the cordial approbation of the Board of Governors. The promotion of Dr. A. S. Merrick from this Asylum we hail with feelings of pride and pleasure at the well-merited recognition of his services by his Excellency the Lord Lieutenant. At the same time we regret losing so valuable, so painstaking, and so efficient an officer, and we feel confident that he carries with him to his new sphere of duty the good opinion and best wishes of this Board for his future advancement and welfare in life."

EPIDEMIC OF ACUTE GOÎTRE.—An epidemic of goître, or thyroiditis, has prevailed for the last three months at St. Etienne, and the War Office has sent special inspectors to investigate the causes, which at present are quite obscure. The disease obstinately resists the iodine treatment, any amendment being followed by speedy relapse. At first the epidemic only affected the men of the 75th Regiment of the Line, but it has since extended to those of the 96th, as well as to the cavalry—the entire garrison, indeed, being menaced by it. In the neighbourhood of the barracks the civil population remains entirely free from the disease, not a single case among them having been met with.—*Gazette Méd.*, September 20.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Aqua.—The hospital for the non-alcoholic treatment of disease, in Gower-street, will be opened next month. Sir Walter Trevelyan is president.

An Army Surgeon.—The total area of British India is officially stated at 950,919 square miles.

Guest.—Received with thanks.

Titus.—The total cost of inquests in England and Wales, including salaries and expenses, last year was £78,534 18s. 7d., being an average of £3 1s. 1d. on each inquest; in the previous year it was £80,446 10s. 9d., or £3 2s. 1d. in each.

Dr. S., Guy's.—Mr. Bransby Cooper died suddenly at the Athenæum Club on August 18, 1853. The report of the post-mortem examination of his body will be found in the *Medical Times and Gazette*, vol. xxviii., p. 248.

H. M., Norwich.—The late Mr. Donald Dalrymple, M.P. for Bath, was admitted a Member of the Royal College of Surgeons on August 19, 1836, and a Fellow on June 1, 1854. With another member of the House of Commons, Dr. Brady, he attended the memorable meeting convened in reference to the Medical Acts Amendment Bill; and always took a great interest in the affairs of the College, and was present and spoke at the last festival of the Fellows at the Albion Tavern. A bust of his lamented brother adorns the Hall of the College of Surgeons.

The Carl Kidnappers.—The leading article in the *Times* on the infamous conduct of Dr. Murray and his associates, two of whom were sentenced to fifteen years' penal servitude, will surely induce the University of which he is graduate to remove him from its roll.

A Fellow.—There will be one absolute vacancy in the Council of the College of Surgeons next July, caused by the resignation of the last life member,—viz., Mr. J. F. South, who was elected so long ago as 1841.

D. Sussex, Kensington, inquires what progress has been made with regard to the "John Hunter Memorial Window" for Kensington parish church, to which he subscribed some time since. Messrs. Frank Buckland or J. J. Merriman, the honorary secretaries, are the gentlemen to whom he should apply.

Examination.—Excited Student: Did I pass my examination, Doctor? Doctor (with proud scorn): No, Sir. [Off dances student radiant with smiles.] Doctor: You misunderstand me; you failed, sir! Incorrigible Student: Ah! but I won a bet, you see. [Doctor staggers.]

Frank C. G.—The lines,

"I am an Englishman, and naked I stand here,
Musing in my mind what raiment I shall wear,"

are to be found in a work by Andrew Borde, a physician and miscellaneous author of eccentric character in the sixteenth century, entitled "A Right Pleasant and Merry History of the Mylace of Abingdon," etc.

A DOCTOR'S LOG.—No. IV.

(*Continued from page* 346.)

One hot, stifling morning in the Red Sea, when the glare of the sun, the feeling of being smeared with hot treacle, the sickening smell of sheep and garlick, were peculiarly oppressive, Mr. Hewlett, the chief engineer, kindly allowed me to visit the engine-room, stoke-hole, and the screw-alley, the latter (unless memory fails) 125 feet long. One officer, Mr. Kubbs, kindly answered medical questions, and in addition showed his registers, likewise explained all arrangements down below. The temperature of the engine-room was 100° Fahr., that of the stoke-hole 98°, and the sea water 76°; these numbers occasionally rising to 120°, 118°, and 84° respectively. There were forty-two European stokers in addition to thirty-six natives, the duties of the latter mainly consisting in filling the trucks with coals, each truck on a tramway overhead leading to the furnaces. Apparently the Europeans have to stand the most heat, and do so remarkably well, if temperate, careful as to flannel and the avoidance of chills. My informant, a water-drinker, had been four years in present ship without a finger-ache, enjoying life, sleeping well, not particularly thirsty, although constantly exposed to heat—a married man, his wife and children healthy. The only illness at all common amongst stokers appeared to be rheumatism; but as to skin diseases, ophthalmia, hepatitis, dysentery, apoplexy, or epilepsy, nothing could be ascertained beyond the fact that most of the present stokers had been three years employed, and beyond burns, scalds, and injuries, seldom complaining. It stands to reason, after prolonged absence on shore in England, the heat at first causes loss of weight and dyspepsia, conditions soon ameliorating. Incidentally, from other sources, it was very pleasant to hear that many of the sailors were water-drinkers, some married with comfortable homes, and not a few with money in the savings bank.

Whilst on the subject of temperature, as a matter of comfort, cleanliness, and convenience, white clothes on shore of course should be worn, but on board ship, with a limited kit, difficulties about washing, white jackets and trousers soiled only too rapidly; blue serge far more serviceable, the same going up country. The heat, say to-day, February 8, in latitude 17·31° N., longitude 40·23° E., is only 92° Fahr. in the sun, about 80° in the shade, about 83° in the cabins under the saloon on the starboard side; and before the hint is forgotten, in going out always try to get on the port side—the reverse coming home. The sirocco warm damp wind makes everyone feel wretched, in a bath of perspiration, greasy, and dirty. At night some officers sleep on deck, others out in passages under the poop, the ladies and remainder in their cabins. The ventilation (facilitated by steam) in some cabins and portions of the ship excellent, especially where there are ports in the centre; where light and air are limited rather trying—tossing, turning, steaming, or else feeling like a hot cinder, sleep for hours either vanished or obtained by fits and starts, the breathing becomes oppressed, a sensation as if suffering from pneumonia, the lungs will not expand, the heart's action laboured, the pulse slow and feeble; and as the long hours of the night drag on, the condition somewhat improves only when the gong sounds for breakfast. Many people would disbelieve all this, fortunate in their ignorance. Mr. Hewlett, who states that stokers are good for eighteen years' work in all climates, informs me that for years 140° of Fahr. have not troubled him—a perfect salamander! Writing without the advantage of book reference, it is impossible to compare the health of the soldiers with sailors, nor is the comparison fair, the latter commencing as children; and many a puny lad by good living, sea air, and healthy occupation has shaken off the infantile taint of scrofula, phthisis, debility, and what not when transformed into the jolly Jack Tar, who, in addition to partiality for rum, tobacco, hornpipes, and the succour of lovely woman in distress, is a first-rate man at his own business, obedient, respectful, brave, and contented, as remarked before.

Some people, too, have an idea that naval medical officers sometimes oscillate between brandy-and-soda and the microscope, unaware that from time immemorial naval surgeons have been the pioneers of medical science as well as distinguished naturalists and observers in far distant unexplored quarters of the globe; for the army doctor also has leisure and opportunity of seeing strange things and curious countries, but being on shore hunting, shooting, fishing, a thousand things divert his attention compared to his professional brother cooped up in a ship. In the way of sanitation but little to say, excepting that the men, pumped on with the hose every morning, appear on parade, their short sleeves rolled up, chest exposed, legs bare for medical inspection daily. The women and children are looked at, their quarters visited and meals attended; the ship authorities are very keen to detect and prevent any nuisances; the troop hammocks and blankets are brought up every morning (except Thursdays, reserved for women and children), and hung over the ship side-rails to be aired.

Whilst at dinner the alarm "A man overboard!" given; instantaneously a trigger pulled, lowers a life-buoy with a blazing port-fire attached indicating position at night; with almost equal rapidity, two boats quietly pull off, the engine stops, the huge vessel swings round. The lad, who fell about

thirty-five feet into the warm salt waves, swam to the buoy, which resembling a floating basket with bars underneath to keep off sharks, contains, in a locker, liquid suction food sufficient for twenty-four hours' sustenance. In 1870, out of a force of 46,710 sailors and marines, 478 were lost in the *Captain*, 41 in the *Slaney*, 28 fell overboard, 4 capsized, 2 washed overboard, 4 found drowned, 1 fell from a pier, another from a buoy, and 5 otherwise drowned.

The last evening in the Red Sea very oppressive. The wind rising, the ports unavoidably closed, whilst, to crown misery, a full-flavoured ayah sleeps close to the cabin door, vitiating the atmosphere; still further we think of the Black Hole at Calcutta, and of Messrs. Shadrach, Mesech, and Abednego. On deck the damp, moist, salt, sandy wind induces abdominal cramp and rheumatic pains (but Paradiso compared to down below, generally termed Pandemonium), whilst, the extraordinary indescribable splendour of the moon shedding a brilliant flood of quicksilver effulgence over the endless expanse of water—sleep vanished.

February 10: Pass between the mainland and a miserable island called Perim, containing a lighthouse, and a fort garrisoned by two companies of native infantry. Aden, a volcanic cinder with but one tree and no water is bad enough, but a gay and festive place compared to Perim. The Straits of Babelmandeb lead us into the Indian Ocean, with 1719 more weary miles to Bombay, and about 1000 miles up country after. Bring not the bagpipes to people in trouble. In spite of endless resources, time drags most wearily—ages apparently have elapsed since leaving England; besides, it makes all the difference which way the horses' heads are turned, some already wondering will they lose their health or their lives in Hindostan, or return to the old country to find themselves forgotten. We intend to be at Bombay in eight days *D.V. and weather permitting*, and as the Scotchman said, to reach final destination about a week after *anyhow*.

(*To be continued.*)

COMMUNICATIONS have been received from—

Dr. Von Tunzelmann; Dr. Ward Cousins; Dr. Hogg; Dr. Bathurst Woodman; Mr. Chatto; Dr. Semple; Mr. Lockhart; The Secretary of University College; Mr. R. Kershaw; Mr. Erichsen; Dr. Henry MacCormac; Mr. E. V. Levinge; Mr. J. Coone; Dr. Phillips; The Spleen; Mr. A. F. Barker; Mr. Walter W. Reeves; Mr. T. M. Stone; Dr. E. Symes Thompson; Mr. N. Alcock; Dr. Fayrer; Dr. Bruce; Mr. George Brown; The Principal of King's College; Mr. Matthew B. Sutton.

BOOKS RECEIVED—

Fawcett and Bazley's Speeches on the Factory Acts Amendment Bill—Smee's Letters on Milk, Typhoid Fever, and Sewage—English Matrons and their Profession, by L. F. M.—Wilson's Lectures on Dermatology, 1871-73—Fry's Royal Guide to the London Charities—Report of the Training Hospital, Tottenham—Wilson's Anatomist's Vade Mecum, ninth edition, edited by Buchanan—Nicholson's Outlines of Natural History—Flint's Principles and Practice of Medicine, fourth edition—Toulon: Its Advantages as a Winter Residence, by an English Resident.

PERIODICALS AND NEWSPAPERS RECEIVED—

Gazette Médicale—London Medical Record—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—Birmingham Morning News—Gazette Hebdomadaire—Pharmaceutical Journal—L'Union Médicale—Tribune Médicale—Gazette des Hôpitaux—Le Mouvement Médical—Le Progrès Medical—La Fraucc Médicale—The Grant College Students' Journal—Journal of the Scottish Meteorological Society, July.

APPOINTMENTS FOR THE WEEK.

September 27. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

29. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

30. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

October 1. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

Royal Microscopical Society, 8 p.m. Mr. F. Kitton, "A Description of some New Diatomaceæ." Dr. Maddox, "On an Organism found in Fresh Pond-Water."

2. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

3. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 20.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·61 in. The lowest was 29·08 in. on Monday at noon, and the highest 29·99 in. on Friday at noon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

THE

TENDENCIES OF MODERN SURGERY:

BEING THE INTRODUCTORY ADDRESS DELIVERED AT UNIVERSITY COLLEGE, OCTOBER 1, 1873.

By PROFESSOR ERICHSEN.

GENTLEMEN,—In no department of science has the intellectual activity of the present age wrought a greater change in a comparatively short space of time than in that of medicine.

In a period that is within the ready memory of many, which to me seems but as yesterday, though it is separated from us by a span of years equal to the lifetime of the generation, the changes that have taken place in medicine in almost all that concerns its pathology, and in much that relates to its practice, have been so continuously great, and their progress at times so rapid—indeed, so sudden and so unexpected—as almost to amount to a revolution.

For truly it has been by no slow and progressive movement, but by sudden leaps and great bounds, that medicine has been carried forward in its onward march since that time when the microscope first became an instrument of daily necessity in the elucidation of its pathology, and anæsthetics of hourly employment in its practice.

The study of the causes that have influenced in so signal and undoubtedly in so favourable a manner the onward progress of the science and art of medicine is full of interest—not as a subject of barren antiquarian research, but as one having an important and vital bearing on the future of our profession. And it is as interesting as it is useful to point out the circumstances that appear to have more directly and immediately led to the great changes that we see around us—to endeavour to gain from them an insight into the direction towards which modern medicine is tending, and to trace out those lines of thought and of action that may most profitably be followed in the immediate future with the best prospect of yielding the speediest and the richest harvest of practical results. But to do this with the whole of the great subject of medicine would not only occupy more time than I have at my disposal, but would lead me into paths with which I am but imperfectly acquainted; and I will therefore restrict myself to the consideration of these questions as they affect that department of medicine in the study and practice of which my life has been spent, and in the teaching of which I have been engaged in this College and in that Hospital for nearly a quarter of a century.

There are essentially and distinctly two great schools of surgery in this country—the *practical* and the *scientific*. But although I may broadly divide modern surgery into these two schools, I do not for one moment wish it to be supposed that I consider them as being absolutely separated by a hard and fast line. What I mean is, that there is a tendency in the mind of every surgeon to gravitate more or less distinctly in one direction or another towards the practice of the art or the study of the science of surgery.

We will examine briefly the more distinctive characteristics of each of these schools, trace their more recent advances, and endeavour to penetrate into their immediate future.

And first let us take the practical school. Rendered resplendent as it has been by the names of the Heys and of the Clines, of the Coopers and Aston Key, of Liston, Crampton, and Syme, it is that which is and ever has been the most popular in this country, for it is most in accordance with the practical genius of the British people, with their inborn and instinctive aptitude for mechanical pursuits and manipulative action, as it is also certainly that which is most in unison with the primary objects of a practical calling such as that of the surgeon.

In tracing the progress of surgery as a practical art, and determining the causes that have led to the great development of its mechanical and manipulative departments, I must carry you back with me for a short period in its history, and ask you to devote a few minutes to the contemplation of what operative surgery was but one generation back, how it has since progressed, and then to consider not only the main causes that have led to that progress towards perfection, but to direct our attention to the course which it is at present tending to take.

One generation back—say thirty-five years ago—the anatomical school of surgery had reached its acmé of development. Popular prejudice had been arrayed against the study of anatomy, but it had been prosecuted with zeal by a chosen few. Those practical anatomists necessarily became the operating surgeons of the day. By them surgical anatomy was assiduously studied, and those operations which had for the basis of their successful performance a thorough knowledge of the relations and structure of different parts of the human frame, such as the ligature of the larger arteries, the operation for strangulated hernia, and that of lithotomy, were often and doubtless skilfully practised. If we add to these the frequent performance of amputations, rendered necessary by the very imperfect knowledge that surgeons then possessed of the pathology of diseases of the joints and bones, the removal of some tumours, chiefly of the breast, and the performance of a few of the many minor operations which have now so greatly multiplied in frequency, we shall have a *résumé* of all that took place and that might be witnessed in the operating theatre of those days.

If one of those great men whose names we justly venerate as those of the giants of a past generation of surgeons; if the Clines or the Coopers—aye, even the Listons and the Aston Keys—were to revisit, not "the pale glimpses of the moon," but the scene of their former triumphs, and were to appear again in that bright light of professional observation and in the broad glare of that not altogether unfriendly criticism that is shed on the central figure in the operating theatre of one of our metropolitan hospitals, he would find that in many cases he would have to learn his work afresh, and that he would be more fitted to take his seat on the benches amongst the pupils than his stand in the area amongst the teachers of his art. But not only would this be the case during the operations themselves—it would be equally so when he witnessed the treatment of the wound: the arteries closed by torsion, acupressure, or carbolised catgut for ligatures, metallic wire for sutures, antiseptic muslin, guards and protectors for dressings, and skin-grafting for the promotion of cicatrisation.

By some of the distinguished surgeons of the period of which I am speaking, operations were doubtless admirably and skilfully performed; but it is equally certain that by a large proportion of surgeons they were done timidly, slowly, often in a slovenly manner, without definite or precise rule.

In fact, thirty-five years ago surgery had fallen in its manipulative art into a sluggish and almost stagnant state. In the two greatest operations in surgery—those for stone and for aneurism—there had been no advance in one since Cheselden, nearly a century before, had so successfully operated; or in the other since John Hunter, more than half a century previously, had linked his name inseparably with the operation for aneurism.

But this stagnation could not long endure, and the breath that gave new life to surgery, and that infused fresh vigour into its art, came from the north.

Whilst surgery slumbered in the south, it had for some years been endowed with an extreme degree of activity in the north, and it was rapidly becoming revolutionised and perfected in its art by the skill, the energy, and the teaching of a band of distinguished men—nearly cotemporaneous—who gave lustre to the great school of surgery which at that time flourished in the northern metropolis. To Lizars and to Liston, to Syme, and to the youngest, but not the least brilliant, of that bright constellation of northern stars, to William Fergusson, British surgery is undoubtedly indebted for much that is its peculiar glory and chief characteristic in its operative department; and it was at this period and from that school that modern British surgery drew its deepest inspiration, and received its first great and decided impulse in all that relates to its art and manipulative department. The great characteristics of this school of surgery were boldness in the conception, and rapidity, precision, and simplicity in the performance of operations. By the boldness of their conceptions, these surgeons were led to contemplate and successfully to execute operations that had never or but rarely been attempted in this country.

The rapidity with which these operations were conducted, was, in those pre-anæsthetic days, as much valued by the patient as it was admired by the surgical spectator.

But the great merit of this school, and that quality which has exercised the most marked and enduring influence on operative surgery in this country, was the introduction of the most perfect simplicity, combined with the most accurate precision in the method of operating. These surgeons used few and uncomplicated instruments, and they taught that the knife might be wielded in surgery in a practised hand with the same skill and the same certainty that the master of a craft exercises in the handling of any instrument that is employed in his calling.

In all these respects, Robert Liston, the then foremost member of that band of distinguished surgeons, was excelled by none. His influence was soon felt after his arrival in London, and his example is often unconsciously imitated in many an operating theatre at the present day. I would willingly, if time permitted me, pay a tribute of respect to his transcendent surgical genius, to which full justice has never yet been rendered. Cut off in the fulness of his matured experience and of his professional activity by a death as sudden as it was premature, Liston died too early for the full accomplishment of his fame, but not too soon for the fruition of his example.

Cotemporaneous almost with Liston's death, though preceding it by a few months, occurred that other great event which more than any other has tended to raise modern surgery in its manipulative department to the highest point of excellence. For the introduction of anæsthesia not only enabled the surgeon to practise many operations which the fortitude of a patient would hardly have enabled him to endure, but it tended to popularise operative surgery in the profession, and by inducing many men to become operating surgeons who would otherwise have shrunk from the daily infliction of suffering as a necessary part of their calling, it greatly extended the habit and the practice of operating, and made that the business of the many which had previously been the attribute of the few.

During the ten years which immediately preceded the introduction of anæsthesia, surgery partook of that great advance which characterised all the natural and physical sciences. In those days of mechanics' institutes and of societies for the promotion and diffusion of useful knowledge, surgery did not lag behind in the race, and the zeal with which surgery had been studied led to the establishment of various distinct departments within the precincts of the art itself, in each of which the treatment of numerous surgical affections by operative means was diligently and extensively carried out. That operation which had been devised by the genius and perfected by the skill of Stromeyer, became the foundation on which the great department of orthopædic surgery was reared. Ophthalmic surgery became an art in itself, rather than a branch of general surgery. Plastic surgery and the surgery of diseases peculiar to women had each their own special adepts, and conservative surgery had its limits widely extended. At this time, also, many operations that had previously fallen into disuse were revived, were frequently practised, and took an established place in surgery. Lithotrity came to be practised in the hospitals, and was slowly substituted there for lithotomy. That great triumph of the surgeon's art, ovariotomy, was frequently practised and greatly improved; and various other operations received a new and vigorous impulse. The whole of the art of surgery in its manipulative department was carried by the combined efforts of a number of active and zealous practitioners to a point of perfection far beyond any that it had heretofore attained, and very far in advance of what it had occupied but a very few years previously.

The gain resulting from this advance in our art can never be lost, and has been permanently secured to surgery and to mankind. There is no retrogression in surgery. Every conquest that has been made has been permanently secured. The march has ever been onward, and year after year some new position has been occupied—often, it is true, after a hot contest of opinion. But once gained it has never been lost, and thus our standpoint has ever been pushed further in advance. For skill in art is a tradition which is hereditarily transmitted, if not by the individual, yet by the profession to which he belongs, from which he has acquired and to which he transmits it.

What our predecessors have done we well know and can readily accomplish. In what we can do our successors will not fail.

That there must be a final limit to development in this department of our art there can be no doubt. The art of surgery, like all other manipulative, plastic, or imitative arts, can only be carried to a certain point of excellence. An art may be modified,—it may be varied,—but it cannot be perfected beyond certain definite limits. And so it must be with surgery. There cannot always be fresh fields for conquest by the knife. There must be portions of the human frame that will ever remain sacred from its intrusion—at least, in the surgeon's hand.

That we have nearly, if not quite, reached these final limits there can be little question. When we reflect that every large artery up to the aorta itself has been ligatured—that each of the six large articulations and many of the bones have been resected—that the amputation of each limb up to the shoulder- and hip-joints is a matter of ordinary surgical occurrence—that large tumours having the most intricate anatomical connexions have been removed from every surgical region in the body, from the base of the brain to the lowest organ in the pelvic cavity—when we reflect, I say, on triumphs of the surgeon's art that are expressed by operations such as these, we can scarcely believe that much remains for the daring of the boldest to devise, or the skill of the most dexterous to accomplish, in the extension of that art in the direction of the operative department of our profession, and that he must in future be content to repeat, though possibly in a modified and improved manner, those operations that have been inaugurated by the genius and perfected by the skill of his predecessors.

It is true there are yet regions that have rarely been successfully invaded by the scalpel, though they have been contemplated as possible seats of future surgical operations. But it has yet to be determined whether the extirpation of the kidney and of the spleen is more than a bold experiment on the power of endurance of the human frame; whether it is a surgical triumph or an operative audacity.

I believe, then, that we have at length reached something like finality in the mere manipulative art of surgery; though I hesitate much to use that word "finality," for I know well how apt a man is to suppose that art to the prosecution of which he has devoted his life to have attained its final limit of perfectness. Yet, looking at the question as dispassionately as I possibly can, I cannot but come to the conclusion that we can scarcely hope to pass far beyond the line at which we have arrived in the direction of extreme precision and almost absolute certainty in the mechanical performance of the operations of surgery, and that in this direction the progress of modern surgery is nearly barred. At the same time we may reasonably expect that the methods of practising operations may from time to time be materially modified and improved by the skill of individual operators, by the ingenuity of surgical mechanicians, or possibly by the introduction of new agents, such as electricity, as aids to our art.

But if operative surgery has attained its most brilliant results;—if the knife has been carried triumphantly, and with the most successful issues, into almost every part of the human frame; if the surgeons of this generation have gone far beyond their predecessors in boldness of conception as they have excelled them in precision and certainty of execution, so that we may look upon modern surgery as having attained in its operative department as high a degree of perfection as the most consummate anatomical knowledge and the extreme development of manual skill can carry it,—yet there is another direction that practical surgery has taken which is apparently so opposed to that which I have just been describing, that it is not easy at first to understand how it could have progressed simultaneously and cotemporaneously in both lines.

For strange and, at first sight, paradoxical as it may appear, whilst surgery was making rapid strides in its purely operative department, there has been *pari passu* a corresponding tendency to limit the number and to lessen the severity of those very operations, and to substitute for the knife manipulations of a gentler character, by which the same effects were sought to be effected. For it has now come to be considered as a truism that mere mechanical dexterity does not constitute true surgical skill, and that the perfection of surgery consists in producing the desired result by the smallest expenditure of force. Expenditure of force by the surgeon entails a corresponding exhaustion of power on the part of the patient. This signifies loss of vitality, and consequent diminution of reparative action.

I might adduce numberless illustrations of this marked tendency in modern surgery to lay aside the knife and to substitute for it other and milder methods of treatment. We see this every day in the minor departments of surgery—in the treatment of carbuncle, for instance, without indelibly marking

the patient with the sign of the cross; in the frequent successful application of electricity and elastic tension in the treatment of deformities as substitutes for indiscriminate tenotomy; in the substitution of escharotics for the knife and the gouge in the treatment of chronic caries of bones; in the whole of the so-called "conservative surgery," which seeks the preservation of the limb by the sacrifice of the diseased part only, just as by a ruder surgery the preservation of the body was sought to be effected by the amputation of the partially spoiled limb.

But the two most conspicuous illustrations that I can give of this remarkable tendency in modern surgery to lay aside the knife wherever and whenever possible, and to obtain the greatest possible result at the least expenditure of force, is in the treatment of those two diseases—aneurism and stone—which, more than any others, have occupied the thoughts and absorbed the attention of the most distinguished members of our profession.

There is no episode in surgery more interesting in itself or more closely illustrative of the truth of the proposition that I now advance, and more typical of the direction taken by modern surgery, than the history of the progressive changes that have of late years taken place in the treatment of aneurism. The surgeon has discarded the knife for the compressor; that instrument for the simple pressure of the finger or flexion of the limb; and, finally, it has been shown that the slower consolidation of decolorised fibrine is not necessary, but that the rapid deposition of dark clot is amply sufficient for the cure of the disease in its worst forms.

In looking to the future, so far as the treatment of aneurism is concerned, I cannot but think that there is yet an agent destined to play a great part; and that electro-puncture, or the process by electrolysis, deserves the fullest attention on the part of the practical surgeon. The experiments and researches of Dr. John Duncan and of Cineselli establish the undoubted fact that in electricity we possess an active agent for the cure of aneurism, which may succeed in many cases beyond the reach of knife, compressor, or finger; and that may in others be advantageously used in conjunction with these means.

Another conspicuous illustration of the tendency in modern operative surgery to substitute milder for the more heroic methods of treatment is in the general adoption of lithotrity in all practicable cases instead of lithotomy. But even in this direction the tendency is to still further attempt at reducing the frequency of the necessity for operating in cases of stone by endeavouring to prevent the formation of calculi, or, if once formed, to aid in their solution. For, as Simpson truly says, "Surely the time is not far distant when a higher chemistry will thus enable us to remove some calculi without the horrid necessity of the knife or lithotrite."

Thus, then, it would appear as if the practical school of surgery had nearly reached its final limit of development so far as the mere manual mechanism of the art is concerned, and that, after having attained to something like finality in this direction, the stream of surgical thought is turning aside into a new channel, the direction of which will tend to limit the unvarying use of the knife, to render its employment more restricted and exceptional, and to substitute for it other means for the accomplishment of those ends that formerly could only be attained through its instrumentality.

But if modern operative surgery has attained to so high a pitch of perfection in all that relates to boldness of conception and to precision of execution, so that we can scarcely hope to see any further progress in these directions; and, indeed, if the most advanced modern surgery is seeking to lay aside the scalpel and the bistoury for milder methods of treatment—if, in fact, the practical school of surgery has, so far as our present means and our present knowledge are concerned, reached, or nearly so, its final development, the case is widely different with the other great school of surgery—the *scientific*.

For here, truly, so far from having approached the final limits of our subject, we are but as yet halting on the threshold. And whether we regard the science of surgery in its relations to the essential nature, the character, and the pathology of surgical diseases and injuries, or whether we consider it in reference to all those circumstances which, independently of the mechanical skill of the operator, influence for good or for ill the results of his procedures, we have a field before us as vast as it has hitherto been little cultivated.

We have seen how the practical school of surgery has been developed of late years, and to what a point of perfection it has attained; now let us briefly examine the position and the immediate future of the scientific school.

The *Hunterian* or *scientific* school of surgery, though less numerously represented than the practical, has been illustrated since the days of its great founder—John Hunter—by names that are amongst the most brilliant in the annals of British surgery. The Bells and Abernethy, Travers and Brodie, exercised by their writings and their teachings a most potent influence on the surgical mind of this country, and laid the foundation of the British school of scientific surgery; and it is around this nucleus of surgical pathology that scientific surgery has gradually developed. But still this school could scarcely be considered as existing in a concrete and definite form until "surgical pathology" was consolidated into a system in those admirable lectures delivered nearly a quarter of a century ago at the Royal College of Surgeons by Sir James Paget, and which have never been surpassed for depth of philosophic research and comprehensiveness of scientific thought.

Since that period surgical pathology has been regarded as a distinct department of medical science, and has advanced with a rapidity that has fully kept pace with pathological science in its more medical aspect. And if I do not dwell upon these advances in a more special manner, it is because their consideration would lead me too far afield into the general domain of pathology, and too widely apart from that of surgery properly speaking.

It is easy to speak of, but indeed it is not easy to say in what the "science of surgery" actually consists. We are, I think, too apt to speak of it as a distinct and separate branch of the natural sciences; to regard it as existing in a defined and concrete shape, like the science of astronomy or of chemistry; as being something more definite than what in reality it is—merely a branch of general, biological, and pathological science—that portion of it which is specially connected with the *rationale* of surgical processes and operations. In many cases it consists, perhaps, rather in the application of knowledge, derived from the cultivation of other and collateral departments of science, to purely surgical ends.

We see this conspicuously illustrated in some of the more recent advances of surgical science and in its application to practice.

It is by this application that the science of surgery has made such great progress of late years, and it is in this direction that we may probably look for its most brilliant achievements in the future. Every department of physical and natural science may thus be, and has been, laid under contribution by the scientific surgeon to aid in the development of his own branch of knowledge.

Thus, by calling in the aid of physical science, we find that electricity is beginning to play a part destined, doubtless, before long to be a great and most important one in the diagnosis and treatment of various surgical ailments. The use of electricity in the diagnosis of the true nature and special cause of various kinds of deformity of the limbs and their treatment, by Duchesne, is one of the happiest applications of physical science to a surgical end. The application of the same agent to the cure of aneurism and nævus by electrolysis of the contained blood, or to the ablation of vascular parts without risk of hæmorrhage, by that instrument as beautiful as it is ingenious—the galvanic écraseur—are all instances of this application of a physical science to a purely surgical end.

It might be supposed that ordinary descriptive anatomy (if I can venture to dignify it as a science) had been so minutely studied that there were few, if any, applications of that science to surgery that had escaped practitioners of our art. But where can we find a more happy example of the application of an apparently dry and uninteresting anatomical fact to scientific surgery than in the study of the anatomy of the ilio-femoral ligament by Bigelow, and the complete revolution that this study has effected in our knowledge of the mechanism of the dislocations of the hip-joint and in their methods of reduction. A somewhat analogous application of a seemingly barren anatomical fact in surgery is to be found in Amussat's great operation of colotomy being dependent on the anatomical relations of so obscure a structure as the mesocolon in the left lumbar region.

Perhaps ophthalmology supplies the most copious and the most precise illustration of the combined application of physical and exact science to the elucidation of surgical phenomena. Donders truly says that "in the doctrine of the anomalies of refraction and accommodation the connexion between science and practice is more closely drawn together

than in any other part of medicine." At this point, in fact, and at this only, does surgery become an exact science. But here it is as exact as any other department of optics, and not only are its precepts based on exact rules, but its diagnosis and treatment are founded on laws that are as accurately determined as they are fixed and unvarying.

The application of the results of the more advanced doctrines of natural science have equally tended to the realisation of some of the most important achievements of which modern surgical science can boast.

Without entering into a discussion of the vexed question of generation—for whether that may be spontaneous or must be by germs I leave to the philosophers to decide,—I may say that the idea of one of the greatest triumphs of modern surgical science was furnished to Lister by the study of the doctrines of Pasteur on the production of diseases in some of the lower tribes of animals by the development of organisms, which in their turn when deposited on congenial media were capable of producing changes of a fermentative and disorganising character; and we owe the method of treating wounds known as the "antiseptic treatment" to the direct and happy application of these doctrines to the practice of surgery.

There is probably, however, no collateral branch of knowledge that has a closer and more direct bearing upon the advance of surgical science than has *hygiene;* and if I do not greatly err, it is in this direction and in its application that we ought to look for some of the greatest improvements in modern scientific surgery. Hygiene has a double relation to surgery: it may be considered—(1) in its application to the prevention of diseases and deformities that render surgical interference necessary; and (2) in its influence on the results of such interference or operations.

The influence of hygienic measures in the prevention of purely surgical diseases is well illustrated by the possibility of preventing the formation of certain forms of calculus, by the adoption of measures calculated to modify or to arrest those impairments of assimilation of which the ultimate formation of stone in the urinary organs is the last link in a lengthened chain of morbid actions.

That hygienic measures properly applied may even be influential in the prevention of congenital deformities and defects, there is every reason to hope. Take that most distressing congenital deformity, a cleft palate: what is apparently more hopeless so far as preventive hygiene is concerned? But yet, if we learn the lesson taught by the Rev. Dr. Haughton from some of the lower animals, we may possibly by its application to the human female prevent the occurrence of that most distressing defect, and possibly other similar ones, as spina bifida, in her offspring. For this curious fact had been noted, that the lion cubs born in zoological gardens were uniformly affected with cleft palate. This was attributed to the nature of the food given, the lioness being fed with masses of meat attached to large and strong bones, which the animal was unable to crunch and devour. It was thus deprived of its due supply of phosphates. These were afforded to the lioness in the Dublin Gardens by giving her rabbits and other small animals, the bones of which she could readily devour. The result has been that a litter of cubs has been born without the usual deformity, and with normally developed palates.

But it is by its influence on the results of operations rather than to their prevention that the application of hygiene to surgical science has been, and will be, attended by the most important consequences.

It is the study of those circumstances which, independently of the mere manipulative skill of the operator, influence the results of his operations, and often counterbalance all the good that the most advanced art, wielded by the most consummate skill, can effect.

And here I do not speak of the mere local results; so far as they are concerned, there is but little to be desired. The results of most plastic, conservative, and ophthalmic operations are as satisfactory as the most sanguine could hope for or the most critical expect. So also with respect to that multitude of minor operations that are practised for the relief of various distressing maladies, and which are followed by the happiest consequences. But when we come to consider the issues of those greater and graver operations by which the life of a patient is directly imperilled, we are constrained to admit that success in results has lagged far behind and borne no relation to perfection in the execution of the operation, and that in this respect the highly polished art of modern surgery far outshines its science. But success in the results is, after all, the thing to aim at, and no amount of manual dexterity can compensate for its want. Dexterity is only one element of success, and however important it is to be dexterous operators, it is better still to be successful ones.

We have, as has already been seen, carried the art of surgery to the highest degree of perfection of which, as an art, it is susceptible. But although we have undoubtedly immensely improved on the rapidity, the precision, and the simplicity of our operations, we are constrained to admit that we have not succeeded in rendering them proportionately less fatal. And here the surgeon has a wide field open before him in the future; and I can fairly say that there is no direction in which it can be cultivated that promises a more fruitful harvest than in endeavouring to make the success of the result balance the skill in the performance of an operation.

For it is useless—worse than useless, it would be criminal—to deny or to ignore the fact that the mortality resulting from or consequent upon the greater operations has not only not diminished of late years, but has, there is reason to believe, in some cases actually increased. The present death-rate after lithotomy—even when making allowance for the application of lithotrity to the more favourable cases—is quite as great as it was in the days of Cheselden or of the great Norwich surgeons. Herniotomy is at least as fatal as it was in the hands of Hey and of Cooper; and the result of the ligature of the larger arteries has actually in some cases—as in that of the common iliac—become more unfavourable of late years.

Whatever explanation we give of it, the fact remains certain, that the present rate of mortality after amputations of all limbs in the largest metropolitan hospitals of Great Britain is at least one in three; in those of Paris (Malgaigne and Trélat) nearly one in two; in Germany as nearly as possible the same—*i.e.*, nearly one in two. In military practice the recent experiences deduced from the results of operations on the wounded in the great wars of modern times is equally unfavourable. But to these I shall not do more than allude, as the disturbing and destructive influences at work during the progress of active war are so peculiar and so great that they remove these cases into a category of their own, entirely apart from amputations in civil practice.

But this fact is certain, and it is as melancholy as it is true and incontestable, that, taking the average mortality after amputations of all four limbs in the largest hospitals, in the hands of men of the most consummate skill in the great centres of civilisation, we come to this result, that the mortality calculated on large numbers varies from 35 to 50 per cent., but is steady and unvarying between these figures. This is a result that is but little creditable to surgery; and in some amputations, as of the thigh and at the hip-joint for injury, the mortality rises to the frightful and astounding height of from 60 to 90 per cent. In fact, so constantly do these numbers come out in hospital and army returns, that surgeons have almost come to regard them as representing the necessary or (so to speak) the normal rate of mortality after amputations.

But is this really so? Must hospital surgeons ever remain content in losing from one-third to one-half of *all* their amputation cases, and nine-tenths of some? Is this frightful death-rate the necessary result of the operation, and thus beyond the control of our science and the skill with which the art is exercised; or is it dependent on causes that are preventable, and which may be counteracted or removed? Surely here is ample scope for science to aid the operations of our art, and to supplement it where it ceases to be any longer efficient.

That this may be done Simpson has abundantly proved. Without going into details, which would here be alike unnecessary and tedious, it may be stated broadly that having collected a large and nearly equal mass of statistical returns of consecutive operations performed in large and in small hospitals, in country, mining, and private practice, he found that of 2089 cases of amputations in large hospitals in this country, 855, or 1 in 2·4, had died; whilst of 2098 in country and private practice the deaths were only 226, or at the rate of 1 in 9·2.

It is quite possible that Simpson's figures may not be absolutely but only approximately correct, and that certain sources of fallacy have introduced themselves into his tables. But making all reasonable allowance for every possible source of error, the difference is so great between the operation of amputation in and out of hospital that the material result cannot be affected—viz., that a mortality of 1 in 2·4, or in other words of more than 40 per cent., is not a necessary

result of amputations; that it is greatly the result of the circumstances in which the patient is placed after the operation; and that it may be materially reduced, according to Simpson, by nearly three-fourths, so as to amount to less than 12 per cent., by an alteration of these circumstances; and that the mortality so dependent on circumstances which admit of alteration, of modification, and probably of rectification, is certainly equal to that which exceeds 1 in 9, or 12 per cent.

But when we come to analyse these results more closely, some startling facts are elicited. Thus, amputation through the forearm cannot surgically be considered a very serious operation. It is not likely to prove fatal by any conditions dependent on or inherent in it—as, for instance, by shock or hæmorrhage,—but can only become fatal by the intrusion of other and adventitious circumstances dependent on causes existing outside the operation itself. Well, what is the result? That of 377 cases occurring in private and country practice only 2 died, whilst of 244 in hospitals no less than 40 died, being 1 in 188 against 1 in 6.

Surely here is a condition of things most unsatisfactory in itself, and not very creditable to modern surgery, and one in which we may hope that the further cultivation of the science may do much to aid the progress of the art of surgery.

But it would be an error to suppose that it is only in amputations that hospitalism exercises its injurious influences and leads to such disastrous results. It is doubtless more or less so with all operations by which extensive wounds are inflicted, and in none more so than in that which we may consider with justice and with pride as one of the greatest glories of the modern school of British surgery—I mean ovariotomy.

Nothing is more interesting and instructive than the early history of ovariotomy. It owes its origin and its establishment in practice entirely to the success that attended its performance in the hands of country and private practitioners. Almost all, if not all, the early successful cases were done on private, and not on hospital patients. It was tried in the London hospitals, but so great was the mortality following the operation when performed in hospitals, that there was the greatest danger of its falling entirely into disrepute and neglect. The operation was denounced as unjustifiable, and the operators were stigmatised in opprobrious terms by two of the most eminent, and ranked amongst the boldest, of the operating surgeons of that day—Lawrence and Liston. It has never taken its place as an operation practicable like others in large metropolitan hospitals. It has been proved by a sad and disastrous experience that if ovariotomy be practised in a large hospital, and if the patient be placed in a general ward—or even if she be secluded in a private one, but if she is exposed to hospital influences,—her chance of recovery is rendered so small that no prudent surgeon will now undertake the operation in such circumstances. For the mortality after ovariotomy in hospitals amounts to 76 per cent., whilst in private practice Spencer Wells at most has lost only 24 per cent., or less than one-third of the hospital rate of mortality. And this amount of loss is, with increasing aptitude and experience, actually still on the decline; and Keith, of Edinburgh, has achieved the marvellously successful return of 27 deaths in 144 cases, or about 18 per cent.

That which holds good with amputations and ovariotomy must surely be equally applicable to other great operations, and would doubtless be found to be so if their comparative statistics were worked out; and if the rate of mortality after amputations is nearly four times, and that after ovariotomy more than three times, as great in large general hospitals as it is in small institutions and in private practice, a more or less correspondingly high rate of mortality may be supposed to attach itself to other of the great operations by which life is directly imperilled.

Here, then, is a vast and most fertile field to which you who are commencing your studies may direct your attention with the greatest advantage, and which you who after this session will go forth into the world to practise, may cultivate with a double advantage to humanity and to yourselves.

In conclusion, then, gentlemen, although I believe that we have nearly reached to something like final perfection in the mere art of manipulative surgery, let me beg of you to do your best to acquire dexterity and precision in its operations, and not to undervalue their importance. These qualities are easily attainable in early professional life; they can never be acquired later. It is the simple physical education of the eye and the hand that is required: like all physical exercises, it is of ready attainment in youth.

But let me urge upon you most earnestly not to neglect the study of those sciences which I have shown you sublie even so practical a subject as surgery, and which are probably even of greater importance in their connexion with other departments of the profession. But unless you intend to become philosophers, do not study those sciences: interesting and, indeed, captivating as most of them are, for their own sakes, use them only so far as they are subservient to the great object of the studies of at least ninety-nine out of every hundred of you,—that of preparing you to become practitioners. And bear this in mind, that the foremost men in our profession have ever been, and still are, those who are the greatest practitioners of its art, and that there is no calling more interesting in its practice, and more independent and useful in its exercise, than that of medicine in its largest and highest sense.

ABSTRACTS OF

THE INTRODUCTORY ADDRESSES DELIVERED AT THE OPENING OF THE MEDICAL SCHOOLS.

GUY'S HOSPITAL.

Referring to the resignation of his post by Dr. Owen Rees, Mr. Hinton remarked that among the names of which Guy's Hospital was proud there was none which could be looked back upon with a deeper satisfaction, or which by universal consent was more closely identified with all that was most profound and helpful in the application of chemistry to pathology and practice.

The lecturer then proceeded to dwell on the connexion between medicine and other sciences and branches of life, illustrating the connexion there was with those sciences even which were apparently the most remote. The mind and its workings were also a most important field of study for the physician, for he must be able to separate what is mental and what bodily in the ailments which come before him. In this way man is approached under a new aspect. In science, in art, in social order, and in moral life man lives on from age to age. Society is an organism. If the structure of the lower creatures claimed our study, and we felt that we could not expect to understand aright the human frame unless knowing also these less perfect forms, how can we withhold our study from that grander life arising thus before our eyes, and to the progress of which we and our efforts are tributary powers. Moreover, could one molecule of our frame and its diseases be known if the life were ignored which it served or marred? How, then, could these atom-minds and bodies of our fellows be known save by knowledge of the life they helped to constitute? Thus it is that inevitably the student of life has for his study the whole realm of nature. "The tales of our ancestors tell us of a cup offered to Thor to drink: it seemed but a fair goblet—a few gallons, enough perchance to drown a man—such as he had often quaffed, and he took it laughingly; but for all his drinking the cup became no emptier,—it was the sea he drank. And to you also gentlemen is offered a cup—a fair sized cup, just the knowledge of the human frame; a fair goblet for a thirsty soul. But drain it, drink your fill, exhaust your power,—you will find it as full as ever. It is the ocean you are drinking."

They would feel a pleasure, almost as of a victory gained, when conducted through researches by which the hard-drawn line between the organic and inorganic effaced itself before their eyes, and laws of physics illumined the recesses of life. This process, he thought for his part, would go on indefinitely, until all that seemed distinctive of life had been included under physical laws. But not, therefore, would life be resolved into physics; rather, physics would be revealed as life. Having disproved the fiction of a vital force endowed with powers other than those of universal force, a triumph worth achieving would have been obtained over ignorance and false impressions. It would have been demonstrated that there is no dead world. A distinction drawn through partial seeing had been the cause of the deception. Of this there are other instances.

The unity of motion in every place is clear to us; but to the

Greeks, looking at motion as presented by the sense, it seemed diverse. The motions in the heavens, never ceasing, were "incorruptible"; the terrestrial ones, always ceasing, "corruptible." But we know that all motion is unceasing; and as all motion is incorruptible, so all nature is living. The reason it has not been so apprehended is, that in the organic world we are presented with wholes; in the inorganic with but fragments. Wherever the relations of force are seen in a complete form we tend to recognise life. Perhaps the organic world might be truthfully regarded as an organ put forth by nature, having as its office the storing up of force and its liberation for ulterior ends.

This storing up of force and its liberation is of constant occurrence throughout all nature, but when met with in the organic world it is called nutrition and function. Nor is this relation of force peculiar to the physical,—it runs through the intellectual and moral life. As such a view would add to the interest of their work, the lecturer said that he would try to present them with an outline, though necessarily a very brief one. If in studying any subject a false assumption be started with, there is only one way in which it can be corrected. The false assumption must be traced out in its consequences until through the weight of their unreasonableness they have to be let go, and a different thought accepted. The *reductio ad absurdum* of Euclid is an instance. An effort, a strain is put on the mind, and as it ceases the premiss is corrected. Force is stored up, and as it is set free a function comes which is the change in the fundamental thought. The discovery of the unity of force, the last great generalisation of science, came about in this way. The senses present to us a great many apparently different forces, and the results of examining nature on this assumption were traced out. The mind was surrounded with fictitious entities, imponderable fluids, and so on, without end. What a weight of supposition to bear! But it fell at last, and the strain and tension of the mind found relief in the thought of a simple constancy of action appearing under various forms. The identity of the raising of a weight with the nutrition of a muscle is recognised, and the fall with its contraction; but is there not an equally obvious parallel in the living process of the mind? The toilsome raising of the weight of false hypotheses, and its sudden downfall, effecting how plain a function.

The lecturer then quoted a passage from Shelley, showing that he had felt this relation in the mental life. Thus it is that knowledge comes by crises—sudden changes in thought gradually prepared for. In the moral life the same laws prevail. What was more striking in history than the false laws with which man had bound himself? As ignorance imposes falsity upon the thought, and makes even the powers of truth work error, so by a parallel necessity does lack of true goodness in the soul compel man to lay upon himself false laws, and make the very powers of good work an intenser evil. Nor arbitrarily is this done, nor wastefully, but through the same beneficence of life that rules in body and in mind to work the same end—by the toil of the nutrition to bring the gladness of the fruition. False laws, that make a tension in the life and set the soul at variance with itself, as they fall bring into the heart of man a true and better goodness, and even the darkness of superstition is preparation for the light.

Thus it was suggested that the studies of the physician placed him in a position which gave him a special advantage for every other study. "Like an heir just come of age, the physician of the present day is distracted with the wealth of his inheritance. It is for you to enter on its full and unembarrassed use. To the whole world of nature and of man the human body is the key, unlocking all its treasures. The physician stands at the centre, and sees all roads diverge, all roads clear and straight to him, because he holds in his hand a map of every land. His eye is fixed on the pattern to which all things conform. Into the very substance of his thought have grown, by long and loving search, the laws which speed the progress of the human soul, and breathe into the dust of earth the breath of life."

"Nor is this advantage one of theory alone, but eminently one of practice. The study of life must afford the best suggestions and the surest tests to every branch of human activity." This was illustrated in respect to society by one of the failures of medicine in the past—the excess to which bloodletting had been carried. The reason of the error was to be found in the apparent success which attended it. It was because that treatment did quiet the pulse, relieve pain, ease the breathing, cool the skin, remove the patient from a condition of intense distress and obvious danger to one of manifest relief, that men unsurpassed in intelligence and zeal for good persevered so long in methods which thwarted their own aim.

"But there is another living frame on which men also aspire to act the physician's part, the frame of the social organism; and is it not obvious how much our errors may teach men here? How strongly they tend to succumb to the very illusions which deluded us, and take no account of the living frame—victims like us of their own success; intent on meeting every evil by some direct force, as if this great life which man's heart and soul work out for themselves were a mere dead, mechanic thing. They do but follow in our steps, falling under the same temptation; but therefore should ours be the eyes to see for them." Finally, it was pointed out in how close a relation the physician stood to the moral life of man. As called upon to deal with his bodily necessities, he is the very revealer of the highest truths. "Of old there stood before a Man, on the one hand a law, enforced by the reputed wisdom and godliness of His age; this law on the one hand forbidding Him, and on the other a poor lame man's sorrow. The Man before whom the two claims came—God's, as all men said, and His fellows'—chose which He would heed;—and He gave us a new law. He cured the body; and mankind, never ungrateful, never unknowing of their friends, have called Him the Physician of the Soul. The needs of man interpret the laws of God.

"Thus, in the limitless extension of the knowledge which our art demands, we may see a proud meaning, a proud prophecy. In stretching out its hands on every side it does but establish channels through which into every department of life, even those which seem the most remote, it shall diffuse a vivifying and creative power."

The lecturer then concluded, after observing that the opening up of wider prospects after any advance should be no cause of discouragement. That harvest was no less rich which seemed to be absorbed in a larger seed-time.

KING'S COLLEGE.

The Introductory Lecture was delivered by Dr. Edgar Sheppard, who began by welcoming the students to a College which had furnished many of the metropolitan schools of medicine with able teachers, and would, he doubted not, continue the same career of usefulness and distinction. He should assume that though the motives were very varied which influenced men in the selection of a life calling, they had chosen the profession of which he was a member because they believed it to be a high and noble one, worthy of their ambition and their aims. There was a reason why he should not follow the common and legitimate course of giving a sketch of the allied sciences as bearing upon medicine, inasmuch as this had so recently been done within those walls by distinguished brain-workers, two of whom were members of their professional staff, at the most remarkable gathering of physicians and surgeons which had ever taken place in Europe. He would urge upon them the necessity of carefully studying those addresses, from which they would learn, among other things, that the investigations which were incessantly being carried on as to the causal phenomena of disease were leading to the conclusion that many existing maladies would, ere long, have neither a local habitation or a name. Meanwhile he would speak to them in a somewhat loose and desultory manner of what he should venture to term the "socio-political aspect of the profession." They must remember, after all, that it was in the drawing-room and the bedroom that they would learn the wear and tear of the thing—when brought into contact with my lord's prejudices and my lady's narrow and conventional thinkings. They must not only study medicine, but society—its varied character and phases. They must learn to adapt themselves in the largest sense to those with whom their avocation would bring them in contact. Many men failed in their profession—to wit, Dr. Lydgate in "Middlemarch"—because they could not temper their book-learning with a little worldly wisdom and a slight concession to conventional forms and prejudices. This was truly an age for making concessions, and a playful and polished way of making them would often effect a triumph over weaker brethren, and subvert a veritable stumbling-block in the way of progress which rigid philosophy would find it hard to displace. He could not help saying, in the presence of their respected Principal, that a large measure of the success that attended the career of a great and good bishop recently lost to the church of which Dr. Barry was a dignitary

and they were lay members, arose from this faculty of adaptiveness, manifested in a form of unusual grace and attraction.

Having further illustrated this subject, the lecturer proceeded to say that there was a certain critical attitude assumed by the lay element towards the three learned professions, at which they had no right to complain, for it exercised a wholesome corrective influence in scaring the empirical and pretentious. At the same time, he could not conceal from himself and them that in other ways it acted prejudicially and with results unfavourable to the progress of science. It was a mistake to make any profession common and unclean by spattering outsiders with a superficial knowledge of it. But this was done too frequently. Had not an ex-Lord Chancellor written a book by which one might learn to dispense with law altogether? And were not blank forms in the shop windows inviting them to make their wills and provide for those who were to come after them, before they had time and opportunity to provide even for themselves? Books about "Domestic Medicine," "Advice to Mothers," and such like, might be pregnant with kindly wisdom, but they did not bring forth fruit worthy of cultivation, or such as they would like to see growing upon their ideal tree of knowledge. It was this sort of thing, he feared, which had led to a recent experience which had no parallel in history, and had forced into opposition the liberal and time-honoured university of a northern capital. Heretofore it had been thought right to eliminate, during the educational processes to which all of us were subjected, everything that savoured of the masculine and ungentle from the sex to which they had not the privilege to belong, and everything that was effeminate from the sex to which had been given the lordly pre-eminence. But matters were undergoing a change. By fingers more delicate than theirs and his were now handled the test-tube and the scalpel. They who once thought it their highest privilege to "mind the house and bear children," had given themselves up to "quantitative analysis," and "minute cellular anatomy." The teachings of Fresenius and Virchow were superseding the injunctions of St. Peter and St. Paul. He trusted he should not be thought illiberal, for he had no desire to check the legitimate ambition of woman. It was only its unnatural development that he sought to stifle, and so in that College he protested against—

> "Prudes for proctors, dowagers for deans,
> And sweet girl-graduates in their golden hair."

Having alluded to the importance of contemplating women in a different aspect—as we used to know her, and should like to know her again,—and of insuring her good opinion, since so much of the success of the medical man depended upon it, the lecturer spoke of the modern doctrine of evolution, which places beyond a doubt the fact that "our mental and bodily structure is the direct outcome of that of preceding generations; and that we, the existing generation, are like the living fringe of the coral reef, resting on an extinct basis afforded by our forefathers, and shall in our own turn form a basis for our descendants." This is as much a socio-political as a physiological question, and therefore he put it before them. It had immense practical issues, and therefore merited from them the most careful study and consideration. "The morality of clean blood" (as Professor Tyndall expressed it) could not possibly be overlooked without involving the most serious consequences. They must not allow their feelings to get the better of their physiological instincts, but set the example to all about them by healthy alliances for social enjoyment and perpetuation of their kind. They would not wonder at his thus speaking to them if they had ever been in a position to see as much evil fruit from evil sowing as he had. The responsibility of those who knowingly, and in the face of well-established laws, transmitted to posterity the recognised abnormalities which constituted disease, was absolutely enormous.

From this and analogous points of view it was clear that the chief object of their profession in these days was rather to prevent than to cure disease. And, indeed, the maladies which scourged the race are more preventable, while it is not equally certain that they are more curable. But, says the practical man, who is hungry, and under the ignoble necessity of labouring for the meat which perisheth, What profiteth my study and my acquisition of therapeutic lore if there is left to me no field for its exercise? Moreover, is it not more clear that remedial agents (so-called) are less resorted to than formerly, and that our ablest physicians doubt the efficacy of drugs on which they once complacently relied? In fact, it was as common as it was wise to give our patients frequent doses of disguised nothing. Nevertheless, the young and hungry Æsculapius might console himself with the fact that never was the profession doing so much; never did it stand so high; never were its members so highly cultivated and so united; never did they reap such a pecuniary harvest as at the present moment. They would not forget the testimony which had recently been borne to them by the First Minister of the Crown in the hall of Lincoln's-inn. Nor was it far to seek for a reason why the profession was so growing in public estimation. The standard of education had been gradually and persistently raised, and the "healing on its wings" promised and proclaimed by their science was now of the largest and most comprehensive type. The lecturer then alluded to the aid which they derived in their warfare with disease and death from "the trained and gentle Nightingales of the sick-room." He spoke of ventilation, warmth, and rest as being more effective weapons than (with few specific exceptions) could be drawn from the huge armoury of the Pharmacopœia. And yet, as there was a fashion in everything, there was a fashion even in the exhibition of drugs. Supposed therapeutics, once lapped up so freely, were now scarcely ever administered. The explanation of this might be—and frequently, though not always, was—found in an enlarged knowledge, not only of the remedial agents themselves, but of the minute anatomy and physiological action of the structures upon which they were invited and supposed to exercise an influence. For instance, everyone knew the extent to which opium was formerly used in the treatment of delirium tremens and insanity. His special experience in these diseases enabled him to say that the value of this narcotic had been completely dwarfed by the giant hydrate of chloral. It was only fair to state, however, that the latter remedy was frequently resorted to very unnecessarily: that ladies kept it in their medicine chests, and that coroners had been under the painful necessity of sitting upon it. In fact, chloral is as much a pharmaceutical fashion as is golden hair-dye a pseudo-æsthetical in the geographical district known to us as Belgravia. Nor was this fashion confined to drugs; it extended to systems. He remembered the time when

> "——Each doctor took such pains
> To draw the blood from almost bloodless veins"

that pallor met one in nearly every adult face, the only exception being in the cheeks of my lady dowagers (as Thackeray expresses it), who, like the sun, are wont to grow redder towards their setting. But a different order of things succeeded. A great physician, whose name and memory would ever be revered in that College, stopcocked the life-blood of the whole nation. Dr. Todd threw down the lancet and took up alcohol. He taught that our duty was to *renew* life, and not to weaken it. The alcoholic beverages were taken up warmly in more senses than one by both the sexes in every ailment, and bloodletting became unknown save as a historic fact. One extreme, as so commonly happens, was succeeded by another. We had now sobered into the healthy mean, which admits that cases occasionally occur in which life is saved by the lancet, while alcoholic stimulants are at times essential to the preservation of life. He would further illustrate this system of passing from one extreme to another by a reference to the specialty to which he had allied himself. Formerly, as they well knew, the insane were subjected to almost unlimited restraint and seclusion, and their treatment was characterised by great harshness and brutality. The non-restraint practice then came to the fore, and has pushed to an extent which involved the not unfrequent occurrence of serious homicidal and suicidal casualties, which might otherwise have been prevented. All of large experience in this matter now admitted that occasional restraint by fastening the hands to the body was not only justifiable in exceptional cases, but imperiously demanded for the safety of the patient himself. And it was equally beyond a doubt that seclusion was as necessary for an excited brain as the withdrawal of light from an inflamed eye. Dr. Sheppard then urged the students to embrace all the advantages offered to them by King's College, and promised them, on behalf of the professional staff, all the assistance which they were capable of affording. Their work should be steady, and free from those spasmodic impulses which were not healthy in men, though said to be characteristic and unavoidable in the sex endowed with periodicity of function. Travel did so much in the way of improving men—so much that could not be described, but was always appreciated—that he would strongly recommend

it to them at the close of their collegiate career, and before they buckled on the professional harness. Then they would be furnished with ampler materials for thought, "be prepared to form riper judgments, and to adjust themselves to action with greater wisdom."

This, then, having been accomplished (the lecturer concluded), the real work begins—the practical application of all that you have taken so many years to acquire. But the wise, the earnest, the intelligent will not cease to acquire, and will ever consider themselves to be in a state of pupilage. In a busy and active professional life, they will day by day garner fresh treasure into their storehouse. "The more knowledge we get," said a Bishop Jackson of an earlier time, "the greater capacity we leave unsatisfied." There is one matter which, in the last place, I submit to you; for though to me it has always been specially noticeable, I am not aware that I have ever heard it alluded to or illustrated. It is this: the difficulties of a start in the medical profession are greater than in that of law or divinity, and this by reason of its complex and inexact nature as also by the issues which it involves. "It seems to me," says a quaint Dutch writer, "that the first fire of an Æsculapius must be of a deadly nature, when his later and calmer zeal may still prove so dangerous." "Aye, there's the rub,"—that first fire. A young lawyer may make his first will without much anxiety or doubt; a young clergyman preaches his first sermon, and though of course he may be very nervous, he can't do much harm, and he may do some good. At all events he will excite sympathy. He did his best; he meant well, and such like. But there will be no sympathy for you if you poke out a man's eye even after the most approved fashion and with the very best intentions.

Even the best educated and most skilful of young practitioners must feel the tremendous responsibility of (say) his first case of typhoid fever in an influential household; or (say) his first case of strangulated hernia at the hospital to which, after much rivalry and contention, he has first been elected; or (say) his first unnatural presentation in midwifery, among the croaking gossips who swarm round their sisters in the agonies of abnormal parturition. There is always someone to think and say you have done wrong in a fatal case, and even those who think you have done right may be reluctant to say so; and more than this, our doubts and difficulties extend in some measure over our whole subsequent career. There are few men—I doubt if there can be any men—of large judgment and experience to whom the occasion must not arise for self-scrutiny and examination, as to whether their conduct of such and such a case has been all that it ought to have been. Life is so mysterious a thing, and its attendant circumstances and surroundings are so varied, that even when we are acting on the most approved scientific principles (known to be so mutable) we may well doubt whether we are as successful as we ought to be in the art of prolonging it.

"I think there are only two things," said Coleridge, "which can justify a surgeon in performing the Cæsarean operation—first, that he should possess infallible knowledge of his art; and secondly, that he should be infallibly certain that he himself is infallible." What wisdom in the satire! Which of us is infallible? Which of us ever will be? No one, as I take it, until shall have come to him that "inevitable" which it is our daily mission to postpone. No one until he shall have "gotten the key of all mysteries which never is let down into the world, and begun the real life which errs and stumbles never more."

ST. THOMAS'S HOSPITAL.

The Introductory Lecture was delivered by Dr. John Harley on October 1. After a few introductory observations on the choice of a profession, the lecturer made the following remarks on the medical life:—"The medical man, however humble his associations may be, is constantly reminded that he is doing useful work. His aim is health, the first and best of human possessions. He is the minister of health, and varied are the emotions that attend his ministration. To-day, his heart is cast down by some new scene of unexpected sickness and sorrow; to-morrow, he is cheered by amendment, and, as the dark cloud gradually shows her silver lining, his feelings warm with satisfaction and joy that he has had some share—it may small, it may be large—in bringing about a happy issue. It is easy to mistake the road that leads to happiness; but nature is true to herself, and we shall not fail to know when we are on the right track. The whisperings of the heart are heard above the acclamations of the crowd, and to the sober-minded and humane to alleviate pain and disease by anxious thought and patient care is a pleasure purer, deeper, and more lasting than any that can spring from what are commonly esteemed more exalted sources. This, then, I take it, is the inspiration that leads you to medicine, and contents us all to labour on, regardless of the wealth and honours we see falling upon members of other professions. Men who follow the learned professions should ever be ready to prefer the dignity of their calling to the allurements of wealth. It is an honour to our profession that this principle is universally recognised and adopted. Entrance to the medical profession at once relieves you of the temptations and chagrins which attend the pursuit of wealth. Titles, too, ill become the man whose deep knowledge of life teaches him to set no high estimate on artificial distinctions. An order of merit to distinguish its possessor from the less industrious and less skilled of his *confrères* is a different thing. Such an order, though so tardily bestowed, would be a graceful compliment to a profession which has long served the State for a remuneration altogether inadequate to the charges imposed upon it; a profession which, at risks as great as those to which the soldier is exposed on the field of battle, is laboriously and successfully engaged in freeing suffering humanity from the bonds of disease; a profession whose members, in occupying the foremost place in the pursuit of science, have done more for the progress and enlightenment of the world than those of any other. As faithful followers of Medicine, then, we set aside wealth, public honours, and ease, and adopt a useful, unobtrusive, and honourable calling, which will amply satisfy our expectations, and in the end bring unalloyed satisfaction. If we have health, our honest exertions will bring us a sufficiency of this world's goods. If to health we should add length of days, we may be sure of a competency and an honoured old age. The daily work of the profession is full of interest, and, to a thoughtful and observant mind, it will furnish every kind of intellectual exercise and enjoyment. Man, in all his phases, variations, humours, and derangements, is the object of our study, and to know him we lay under tribute every phenomenon of nature and ransack every casket where life is stored."

In reference to his curriculum, the lecturer took occasion to observe that the students' present course of study was more adapted to the wants of those who intended to practise as consulting physicians and surgeons than to the requirements of the general practitioner. In order to give the latter a more practical education, he proposed the adoption of a modified apprenticeship and the addition of a home-patient department to our hospitals. "By the former of these arrangements, the medical disciple would be articled to a medical man for a term of three years, during which, or before commencing his studies at a medical school, he would be required to pass two preliminary examinations,—the one in arts, at the end of the first year of his articles; the other in chemistry, botany, and materia medica, at the end of the third year; when, having eliminated these subjects from his curriculum, he would devote himself exclusively to the study of anatomy, physiology, medicine, surgery, and midwifery, at the medical school, during another period of three years. By the second arrangement, that portion of the city within a given radius of the hospital would be divided into districts, and each placed in charge of a member of the medical staff appointed for the purpose. Patients too ill to attend the hospital, and precluded, either by the nature of their illness or by various contingencies, from admission into its wards, would be visited at their homes by students, during the sixth and last year of their study, under the directions of the proper officers. By these arrangements a more perfect education of the student would be effected, while the adoption of the second would confer a great boon on a number of poor sufferers, and make the administration of our hospitals more complete."

In reference to lectures—which constitute so important a part of the medical curriculum—Dr. Harley remarked, "Both your studies and examinations are becoming every year more practical, and we may look forward to the not very distant time when the lecturer shall have become the more useful demonstrator, and the student shall be referred to his handbook for theoretical views and systematic arrangements, the motto of both being—'*Facta præstantiora verbis.*'

"The student is provided with admirable text-books on every subject of his study; and as they are usually the well-digested compilations of the lecturer himself, his lectures are at best but a repetition of the printed pages which he puts into

the hands of his pupils. Oratory, no doubt, produces a more powerful effect than the most vigorous writing; but Eloquence herself is tongue-tied when dry bones and a tanglement of nerves, bloodvessels, and muscles are the only theme. Something may be said in favour of lectures on medicine, because fever, ague, and madness cannot be isolated like a cancerous tumour or a broken bone, and put before the student; but chemical experiment and botanical facts are so completely within the reach of individual observation that lectures on these subjects might be made entirely subsidiary to demonstration. Lectures on physiology, too, may be reduced to narrow limits now we have our course of practical study. And here I must ask you to look not to the laboratory only for practical physiology, but to the wards and prescribing-rooms also. There you will find hosts of wonderful experiments done by Nature herself, demonstrating truths which can never be determined by artificial mutilations. And do not forget that the practical physiology I speak of, and the experimental physiology which appears to be so attractive just now, are very different things—for the one is natural and the other artificial. Be careful, too, that you do not neglect the education of your tactile sense by the use of instruments which, though pretty and good in theory, are inconvenient and bad in practice."

Turning to the means of preventing and curing disease, the lecturer observed—"We can speak of great triumphs. Slow as we have been to learn that it is not good to keep our filth about us, and sip it in the dog-days, we can now point to plague, cholera, enteric fever, ague—the loathsome brood of a filthy soil—and say, The march of these is within our control. But even here there is much to learn. In dealing with the question of infection you have need to be most wary, or else your perception will be dimmed by dogmas worthy of the darkest days of ignorance, and your observation misled by the hasty and insufficient conclusions of the day. The prevention of disease is an exciting topic for a humane and virtuous mind. The transmission of disease is no less interesting. It is a question of immense importance whether disease, arising from a single source, can be propagated indefinitely in successive generations of otherwise healthy individuals. It will doubtless be found that as there is in animals and plants a constant tendency to throw off superadded qualities, so a given disease will wear itself out and disappear in the course of a few generations, provided the victim heirs strive to attain a healthy standard and avoid similar contamination. Nature is careful of her progeny, and, granting her pure associations, she will, I believe, prove this by ridding her children in the course of three or four generations of the monstrous parasites that disfigure and debase them.

"To recognise the successive progeny of disease to the fourth generation, and refer them to their originals, will be noble work for some of you. What if cruel cancer should be found a distant remove of syphilis? One form of this disease is, we are almost sure, an exuberant variety of the primary disease. Should we not lop off the primary disease from outraged society, and prevent the anguish and destruction of an innocent posterity? Verily I believe if Medicine could work out her beneficent will, she would lead us a great way along the road to Paradise.

"In our present state of knowledge we know not how much disease would remain, if the preventable ones were actually prevented, and their effects allowed to die out by healthy associations. But we do know that, apart from the self-polluting influence of man and animals, a condition of perfect health—*i.e.*, a perfectly balanced and constantly uniform state of the body—can never exist so long as the external conditions upon which life is dependent continue in a perpetual state of variation. The body must share these mutations, and the balance is disturbed as often as it does so. Health fluctuates accordingly; the transition periods from change to change being coincident with periods of incipient but scarcely perceptible morbid action. Those are healthiest who can most readily adapt themselves to these changes; and if the more weakly could always use vigilance and the care that prudence dictates, many of the diseases over which we have no other control would be prevented. But there is a limit to human foresight and self-denial, and so, in spite of all our prophylactics, we shall never want an enemy to cope with.

> "'Rough winds do shake the darling buds of May,
> And summer's lease hath all too short a date;
> Sometimes too hot the eye of heaven shines,
> And often is his gold complexion dimmed;
> And every fair from fair something declines,
> By chance on nature's changing course untrimmed.'"

Referring to therapeutics, the lecturer spoke of the difficulty which attended the study of the action of medicines—a difficulty which often led inconsiderate men either to ignore the value of drugs altogether, or to adopt some one remedy, and ride it rough-shod over every disease. While deprecating in strong terms the abuse of alcohol and narcotics, he observed in reference to chloral hydrate—"The theory of its action is so simple that it was intelligible to all, and in a very brief space of time the drug was known in almost every family invaded by disease. Medical men prescribed it freely and indiscriminately, and in some cases continuously. Patients thus accustomed to the use of the remedy supplied themselves and even their friends with it. When they would be oblivious, they took chloral hydrate, and sometimes passed from oblivion into death. Medicine is thus made to reverse her intent. Laxness in prescribing narcotics and continuing them, often for slight ailments, until the too-willing patient is wrecked in mind and body, is a terrible indiscretion. At this moment there are hundreds of patients looking for the arrival of their medical attendants to inject another grain or two of morphia beneath the skin. Only four hours ago they had a similar dose, and four hours hence they will have another. They declare they cannot endure a rheumatic neuralgia or obscure hysterical pain, and they implore you to give them frequent and increasing doses of morphia, each of which carries them still further from real help, and eventually adds to their misery and degradation. Beware of this abuse of opium, or you will bitterly repent the recklessness which first led you into it, or the want of courage which prevented you from withholding it before it was too late to do so. The hypodermic syringe is a powerful and most valuable weapon, but those who use it should possess more wisdom than knowledge."

Alluding to the mode of study, Dr. Harley said: "There are two acquirements which are not thought of as necessary to a medical man, but which are of the utmost use to him. They are—sketching, and shorthand writing. From the first to the last day of your professional career, labour as hard as you will, you will find yourself a laggard on the heels of time. As a reporter attendant on nature, you want the means of instantaneously photographing and recording your cases. He who can delineate nature with a few touches of the pencil, and describe her moods by intelligible signs, will want only one more faculty in order to know her, and that faculty is observation. Learn to apprehend facts, simple facts, and fix them in your mind. Life, disease, death, are the facts you have to deal with, and these are not simple like those which engage the attention of the astronomer or the chemist, but complex. Each of these phenomena is a mosaic of facts, so perfectly fitted as to show no lines on the surface, and scarce a clue beneath. Your first object must be to discover and isolate these facts in your observation of the broken vessels which come before you,—to identify their connexion, trace their relations, and ultimately to do your tiny share in putting the wonderful puzzle together that makes 'this soft, sensible motion.' This is, indeed, the laborious work of ages. Do not be discouraged that the labour seems so little fruitful. Each one of us can do no more, perhaps, than recognise and isolate one bare, unconnected fact; but, like the fragment that is turned out of the dust-heap which marks the site of the ruined and forgotten city, your fact will—some time in the distant future—be recognised as the link wanted to complete a discovery which may result in untold benefits to the human race. 'Benefits to the human race.' Never forget that this is the object of all your study now,—of all the efforts of your maturer understanding and skill hereafter. Faithfully pursue that divine object, and thus shall you be daily 'laying up for yourselves treasures in heaven, where neither moth nor rust doth corrupt, and where thieves do not break through and steal.'"

WESTMINSTER HOSPITAL.

The Introductory Address was delivered by Mr. George Cowell, Surgeon to the Hospital and the Dean of the Medical School. He said: "It is related of Mr. Abernethy that, on entering the theatre of St. Bartholomew's Hospital on the occasion of delivering the introductory lecture, he cast his eyes over the crowded benches, and said, 'God help you, gentlemen! What is to become of you all?' In the present day we do not suffer from the same plethora of candidates aspiring to enter the medical profession. I do not know that it is especially a

matter for congratulation, but it is a fact that whilst the population has increased with marvellous rapidity, and whilst the number of medical schools has nearly doubled, the numbers of the profession have not increased in the same proportion, and are little more than they were in the days of Abernethy. We have, at all events, no cause for anxiety on behalf of all those who enter now as to the prospect of their finding sufficient scope for the exercise of their profession." After giving reasons for maintaining the old custom of the annual delivery of introductory lectures, a short sketch of the history of the Hospital and school was given, and mention made of the celebrated physicians and surgeons who have served the Hospital during the 159 years of its existence. Westminster is interesting as having been the first hospital established by the voluntary contributions of the public. The changes made in the school, and particularly in new arrangements with regard to clinical lectures and clinical teaching, were next alluded to. On the subject of preliminary examinations, the lecturer said: "There can be no doubt of the wisdom of requiring a sound preliminary education before entering upon medical study. It was not without astonishment that he heard the ex-President of the College of Surgeons of England enunciate, in the last Hunterian Oration, a contrary opinion. The reason Mr. Hancock gave was, that the establishment of the preliminary examination had abolished the old-fashioned apothecary, who, with his shop and unambitious tastes, was *par excellence* the poor man's doctor. If preliminary examination achieve nothing more than the severance of the remaining links which seem to unite a noble profession with a retail vending of drugs —a bond which has done much to depreciate in the eyes of an often unthinking and unreasoning public the dignity which appertains to our calling—we shall have reason to be satisfied. But its object is much greater than this. The study of classics and mathematics trains the mind—the reasoning powers. Just as we develope the body by the proper exercise of its various muscles, so must the mind be developed by early training its reasoning powers. No one would dream of teaching a man the art of fencing until he had been put through a course of gymnastics to develope to some extent a precision and ease and rapidity of movement; and can it be wise to put a man to study a profession which requires more than any other the facile use of the reasoning faculty without first training those faculties by the gymnastics of preliminary education?" The possession of a well-trained mind was shown to be every year more imperative, so rapidly were the subjects of medical science growing and multiplying. Perseverance was the best cure for every neglect in this early training; and John Hunter was quoted as an example.

The objects of a medical school were then discussed, and the student warned against grinders and abbreviated text-books. Work got up in that way would not be remembered six months. Each man must get up his work for himself, and if it is to be of any use to him he must digest it and assimilate it for himself. After showing the student the best way of doing this, and referring to the necessity of the student making the dissecting-room his special field of study, and avoiding the wards as much as possible during his first year, the lecturer criticised the present regulations of the examining bodies as not consistent with the wise division of the examination into a primary and a practical examination. Men who came up for three years only of study at the Hospital and College were obliged to attend hospital practice, when they ought to be engaged in the study of anatomy, physiology, and chemistry—subjects quite sufficient to require their whole time and energies. The reason so many men failed to pass the primary examination was that the counter-attraction of the wards tempted men to neglect their proper work. The rapid progress of physiology and pathology was then contrasted with the slow advance of the knowledge of therapeutics. The study of the latter was rendered obscure and difficult by the habitual use and efficacy of moral treatment, and the presence in the human body of a power—call it a tendency to health or what they will—which, without treatment, or in spite of it, will gradually, so long as no organic disease exists, lead to a re-establishment of healthy function. The story of Sir Samuel Garth, Physician to George I., was quoted. Coming one night to the Kit Cat Club, he declared he must soon be gone, as he had many patients to attend, but some good wine being brought, he forgot them. Sir Richard Steele, who was of the party, reminded him of the visits he had to pay, when Garth pulled out his list of fifteen, and said: "It's no great matter whether I see them to-night or not, for nine of them have such bad constitutions that all the physicians in the world can't save them, and the other six have such good constitutions that all the physicians in the world can't kill them."

The value and necessity for the study of physiology was enlarged upon, and the nature of the reasoning upon which such sciences were built up was contrasted with the mode of reasoning in an exact science, such as mathematics, the difference explaining why it was possible to calculate the magnitude and course of an unseen planet, when it was so difficult to discover the use of a spleen or a supra-renal capsule. The supposition that science and religion were opposed to each other was then combated, and it was shown that although some apparent antagonism from time to time arose even between one branch of science and another, it rarely happened that such antagonism could not soon be proved to have no reality. The facts of theology had been revealed to us, but their full meaning we did not yet grasp any more than we did those of the sciences referred to. There was a unity of purpose and identity of design throughout the whole, to which the idea of antagonism or contradiction was repugnant. It had been remarked the other day at Bradford that it was just as absurd now to judge religion by the facts of science as it was in the days of Galileo to judge science after a religious test; but it seemed to him that in the long run the harmony of the two was so complete that he did not fear to submit either to the scrutiny of the other. What he feared was lest we mistake the speculations of scientific men, the theories of those who have allowed their imagination to carry their thoughts far beyond the conclusions that their facts will warrant, into the unseen world of fancy. These, he said, must not be mistaken for true science, for a calm and careful consideration would ever convince us that just as the concurrence of the various conditions necessary to the most ordinary phenomenon inclosed the most irresistible proofs from natural evidence of unity of design, and consequently of the unity of the Creator, so true was it that conclusions which were contrary to, and at variance with, revealed truth were visionary and worthless. In conclusion, the highest attributes of the profession were insisted upon, and it was shown that if medical men could not look forward to high honours and rewards, still in no profession could they look back upon a long life of usefulness with greater pleasure or with a more perfect consciousness of having aided their fellow-men. "And may each of us, gentlemen, when we come to the last years of life, look back with pleasure on the good work we have been permitted to perform, and may we then, as now, say with Wordsworth—

"'O! that our lives, which flee so fast,
In purity were such
That not an image of the past
Should fear that pencil's touch!
Retirement then might bravely look
Upon a soothing scene;
Age steal to his allotted nook,
Contented and serene:
With heart as calm as lakes that sleep,
In frosty moonlight glistening,
Or mountain rivers, when they creep
Along a channel smooth and deep
To their own far-off murmurs listening.'"

*** Several of the Introductory Addresses unavoidably stand over till next week.

THE Kent Water Company have now provided a constant supply of water to such parts of St. Mary, Rotherhithe, St. Paul and St. Nicholas, Deptford, as are bounded on the north and east by the river Thames, on the east by the Surrey Dock and Canal, and on the south by Evelyn-street and Princes-street, Deptford.

PARISIAN HEALTH STATISTICS. — According to the *Bulletin de Statistique Municipale* of November, 1872, just issued, and which still bears the name of M. Calmon, then Préfet of the Seine, the highest ratio of mortality—viz., 27 per 10,000—occurred in the fourteenth arrondissement (Observatory); the lowest—10 per 10,000—was observed in the ninth (Chaussée d'Antin). The diseases that proved most fatal were consumption 590, apoplexy 207, bronchitis 195, pneumonia 180, inflammation of the bowels 129. Regarding infants, the highest mortality during the first year of life occurred at the age of two months—viz., 49. Between the ages of one and two years the deaths were 93; of two and three, the same.

SATURDAY, OCTOBER 4, 1873.

THE INTRODUCTORIES.

Again the time has come for opening our columns to reports of the "Introductory" Lectures delivered at the reopening of the several medical schools; and, as is our wont, we again devote a little space to comment on the lectures. Again, also, we venture to express our regret that at one of the oldest, largest, and most famous of medical schools the "introductory lecture" is conspicuous by its absence. Why this is we know not. We cannot believe that in these days, and at such a well-managed and efficiently-officered school, there is any dread that the audience would offend by a noisy and indiscreet overflow of youthful spirits; nor do we suppose that the authorities think that an annual "hospital school dinner," presided over by one of the senior and most distinguished members of the medical, or surgical, or teaching staff can fully, as well as pleasantly, replace the "Introductory," given, as a rule, by the youngest and least-tried member. The lecture is meant, and ought to be, something more and better than an opportunity for a pleasant *réunion* of the old and the young *alumni* of the school. It may, at any rate, be well used to give new students some warning as to the difficulties and temptations that lie before them, some hints as to how best overcome or avoid them, and some gracious words of welcome and encouragement. It is not difficult, however, to conceive that men lately appointed on the staff may not unwillingly acquiesce in a change which relieves them of a difficult and onerous, though honourable, task. It is by no means an easy thing to give a really good introductory lecture —introductory not to any one course of lectures, but to medical school life; and though it gives a man an opportunity of showing something of his cast of mind, and of giving some insight into his intellectual powers and acquirements, and some reason for the faith in him that led to his appointment, yet it may well be that he would rather avoid a *rôle* in which it is much more easy to obtain a mere *succès d'estime* than a real and genuine success.

Dr. Roberts had been appointed to give the Introductory Lecture at University College, but unhappily was disabled by indisposition, and his place was supplied by Professor Erichsen, who delivered the excellent address which we have the pleasure of presenting *in extenso* to our readers. From the character of it, we may venture, without being thought too curious, to suppose that the learned Professor made use for the purpose of some of the reflections and arguments that had occurred to him when musing on the Address in Surgery, which he, in his turn, had been prevented by illness from giving at the late meeting of the British Medical Association. He took for his theme the "Tendencies of Modern Surgery," and dwelt on the great advances made during the last few years "in the department of medicine," which he has himself studied, practised, and taught. Speaking first of the progress of surgery as a practical art, he remarked that "thirty-five years ago surgery had fallen in its manipulative art into a sluggish and almost stagnant state. In the two greatest operations in surgery—those for stone and for aneurism—there had been no advance in one since Cheselden, nearly a century before, had so successfully operated; or in the other since John Hunter, more than half a century previously, had linked his name inseparably with the operation for aneurism."

But this state did not long last. "Whilst surgery slumbered in the south, it had for some years been endowed with an extreme degree of activity in the north," and from the great school in the northern metropolis "modern British surgery drew its deepest inspiration, and received its first great and decided impulse in all that relates to its art and manipulative department"—an impulse that, aided by the discovery of anæsthesia, and through the combined efforts of many active and zealous practitioners, has carried practical surgery "to a point of perfection far beyond any that it had heretofore attained, and very far in advance of what it had occupied but a very few years previously." The Professor thinks, indeed, "that we have at length reached something like finality in the mere manipulative art of surgery," and that "we can scarcely hope to pass far beyond the line at which we have arrived in the direction of extreme precision and almost absolute certainty in the mechanical performance of the operations of surgery, and that in this direction the progress of modern surgery is nearly barred"; but, at the same time, he points out that "the stream of surgical thought is turning aside into a new channel, the direction of which will tend to limit the unvarying use of the knife, to render its employment more restricted and exceptional, and to substitute for it other means for the accomplishment of those ends that formerly could only be attained through its instrumentality"; and in this direction we may hope for new triumphs and continued progress.

The Professor then turned to the *scientific* school of surgery, and here, he observes, "we are but as yet halting on the threshold. And whether we regard the science of surgery in its relations to the essential nature, the character, and the pathology of surgical diseases and injuries, or whether we consider it in reference to all those circumstances which, independently of the mechanical skill of the operator, influence for good or for ill the results of his procedures, we have a field before us as vast as it has hitherto been little cultivated." And he shows how "every department of physical and natural science may be, and has been, laid under contribution by the scientific surgeon to aid in the development of his own branch of knowledge," and points out to the students that it is "by this application that the science of surgery has made such great progress of late years, and it is in this direction that we may probably look for its most brilliant achievements in the future." In this direction especially he appealed to them to work, while by no means neglecting the acquirement of dexterity and precision in operative surgery, assuring them that "here is a vast and most fertile field, to which you who are commencing your studies may direct your attention with the

greatest advantage, and which you who after this session will go forth into the world to practise, may cultivate with a double advantage to humanity and yourselves." We have but sketched out the backbone of Professor Erichsen's admirable address. Our readers will go to the address itself to learn how fully he developed his arguments, and how happily he illustrated them.

At Guy's Hospital, Mr. Hinton, after referring in graceful and well-merited terms of praise to Dr. Owen Rees and his connexion with the Hospital, went on to treat of the connexion between medicine and the other sciences and branches of life, showing that it exists even with sciences apparently most remote from it. The physician must study also the mind and its workings, in order that he may be capable of separating what is mental in disease from what is bodily; and, indeed, the student of life must extend his studies throughout the whole realm of nature. Those who know Mr. Hinton's published works will expect him to speak of the "researches by which the hard-drawn line between the organic and inorganic effaced itself before their eyes, and laws of physics illumined the recesses of life. This process, he thought for his part, would go on indefinitely, until all that seemed distinctive of life had been included under physical laws. But not, therefore, would life be resolved into physics; rather, physics would be revealed as life. Having disproved the fiction of a vital force endowed with powers other than those of universal force, a triumph worth achieving would have been obtained over ignorance and false impressions. It would have been demonstrated that there is no dead world." He observed that the "storing up of force and its liberation is of constant occurrence throughout all nature, but when met with in the organic world it is called nutrition and function. Nor is this relation of force peculiar to the physical—it runs through the intellectual and moral life." And his lecture was an ingenious and philosophical setting forth of this view. His exposition of his theory could not fail to interest his auditors, although it is difficult to suppose that it equally succeeded in convincing them.

At King's College, Dr. Edgar Sheppard delivered a discourse of a very different, and certainly not less practically useful, style. Recommending to his hearers a careful study of the addresses which had been so lately delivered within the walls of the College, at the meetings of the British Medical Association, he took for the subject of his own lecture what he termed "the socio-political aspect of the profession," and enforced on the students the necessity of studying "not only medicine, but society—its varied character and phases. They must learn to adapt themselves in the largest sense to those with whom their avocation would bring them in contact." "This is truly an age," he remarked, "for making concessions, and a playful and polished way of making them will often effect a triumph over weaker brethren, and subvert a veritable stumbling-block in the way of progress which rigid philosophy would find it hard to displace." And he happily illustrated this teaching by a reference to "the faculty of adaptiveness, manifested in a form of unusual grace and attractiveness," of the late Bishop of Winchester. He gave useful warning against attempts to make "any profession common and unclean by spattering outsiders with a superficial knowledge of it," and in that view questioned the real usefulness of books on "domestic medicine" and the like subjects. He even ventured, with playful audacity, to attack the medical-woman movement, remarking that "they who once thought it their highest privilege to mind the house and bear children" had given themselves up to "quantitative analysis" and "minute cellular anatomy." The teachings of Fresenius and Virchow were superseding the injunctions of St. Peter and St. Paul. We fear that if Dr. Sheppard should meet Miss Jex-Blake and any of her gentle medical sisterhood, they would do their best to give him a *mauvais quart d'heure*. He next spoke of the "modern doctrine of evolution," and of the importance of what Professor Tyndall has termed "the morality of clean blood," and of the triumphs achieved and to be achieved by medical science in the prevention of disease. He discoursed on the high value of ventilation, warmth, and rest in the treatment of disease; of fashions in the exhibition of drugs and in systems of treatment; of the necessity of steady work, "free from those spasmodic impulses which are not healthy in man, though said to be characteristic and unavoidable in the sex endowed with periodicity of function"; and of the advisability and improving power of travel at the close of the collegiate career. His lecture, though far more entertaining and readable than a vast deal of what is called "light literature," is also full of useful warnings and practical wisdom.

At St. Thomas's Hospital, the Introductory Lecture was delivered by Dr. John Harley, who drew a high-toned picture of medical life, that would, we suspect, hardly be fully accepted by all his hearers. All would, no doubt, agree—in theory, at least—with the statement that, "to the sober-minded and humane, to alleviate pain and disease by anxious thought and patient care is a pleasure purer, deeper, and more lasting than any that can spring from what are commonly esteemed more exalted sources"; but we doubt whether all would be with the lecturer when he added—"This, then, I take it, is the inspiration that leads you to medicine, and contents us all to labour on, regardless of the wealth and honours we see falling on the members of other professions"; or would quite appreciate his assertion that "entrance to the medical profession at once relieves you of the temptations and chagrins which attend the pursuit of wealth." But all would fully agree with him that "men who follow the learned professions should ever be ready to prefer the dignity of their calling to the allurements of wealth," and allow that our profession does fully recognise and adopt this principle. In speaking of the present curriculum of study, Dr. Harley observed—and, we think, rightly—that it is more adapted to the wants of consulting physicians and surgeons than to the requirements of the general practitioner; and he would amend it, in the interests of the latter, by "the adoption of a modified apprenticeship, and the addition of a home-patient department to our hospitals"; and certainly his proposed arrangements for these additions would, if they could be effectively carried out, greatly improve the practical education of the student. On the prevention of disease the lecturer grew enthusiastic and eloquent. "Verily I believe," he says, "if Medicine could work out her beneficent will, she would lead a great way along the road to Paradise. In our present state of knowledge we know not how much disease would remain if the preventable ones were actually prevented and their effects allowed to die out by healthy associations." We fear that, though sanitary science is beginning to be acknowledged and encouraged, it will be a long time yet before man is forbidden to transmit and propagate disease and tendencies to disease. When speaking of therapeutics and the difficulties attending the study of the action of medicines, Dr. Harley took the opportunity to speak strongly against the excessive use of chloral hydrate and the hypodermic injection of morphia. He asserts that both are frightfully abused, and with reference to the latter he remarks—"The hypodermic syringe is a powerful and most valuable weapon, but those who use it should possess more wisdom than knowledge." Finally, the lecturer made some remarks on the mode of study, and strongly recommended the student to cultivate those two (certainly most desirable) acquirements—sketching and shorthand writing.

Mr. George Cowell, in his lecture at the Westminster Hospital, defended the wisdom of requiring a sound preliminary education before entering on medical study, and pointed out its great value in training the reasoning powers, and that as the subjects of medical science are rapidly growing and

multiplying, the possession of a well-trained mind becomes more and more imperative. He warned the students against abbreviated text-books and crammers, telling each one that he must get up his work for himself, and must digest and assimilate it for himself. He gave the students advice on the best way of working, and found fault with the examining bodies for requiring men to attend hospital practice "when they ought to be engaged in the study of anatomy, physiology, and chemistry"; and at the close of his lecture he combated the idea that there is any real antagonism between science and religion. His lecture is altogether a good specimen of an older style of the "Introductory" than is generally given now.

We shall continue our notice of the "Introductories" next week. They are all deserving of commendation; some are especially admirable; but all that we have at present seen are earnest and useful enough to be quoted in favour of a continuance of the custom of giving "Introductory Lectures."

THE ASHANTEE WAR.

By the last advices received from the West Coast of Africa there appears to be little change in the situation at the seat of war. The rainy season had not quite terminated, but the excessive sickness which had previously prevailed was still decreasing. Cape Coast Castle and the environs are reported to be very unhealthy, but this is scarcely to be wondered at when the enormous increase to its population is taken into consideration. The natives under our protection, who were driven from their homes by the hostile invasion, have camped and quartered themselves in every available spot without the slightest regard to sanitary considerations, and as many of them were suffering from small-pox when they arrived, the sickness of the station during the past few months must of necessity be looked upon as abnormal.

The medical staff on the spot appear to have borne up exceedingly well under the execution of their arduous duties. The principal medical officer, Dr. Home, was at Cape Coast Castle, and Surgeon-Major Mosse at Elmina. Surgeon-Major Rowe, who has been suffering from a slight attack of fever, was also doing duty at Cape Coast Castle, the remainder of the medical staff being attached to the different stations and redoubts, with the exception of Surgeon Wright, who had been invalided to Madeira suffering from dysentery.

Sir Garnet Wolseley will no doubt realise the important fact that, whatever operations are undertaken, the force to be employed must have done its work and left the Coast again by the month of March next. This fact the authorities at home will do well to bear in mind, so that all demands may be promptly and energetically met. There is, we firmly believe, no reason why an expeditionary force arriving at the seat of operations at the exact moment required, and provided with everything needful in the shape of medical stores, both prophylactic and remedial, should suffer exceptionally in a march towards the interior. The drinking-water must of course be carefully watched, tea or coffee being made, if possible, the principal beverage of the troops; but this point is one which is sure to be attended to by Sir Garnet Wolseley, as the Red River Expedition under his command abundantly proves.

The screw-liner *Victor Emmanuel* is receiving all her fittings at Portsmouth to convert her into a hospital-ship, and she is expected to leave this country in about six weeks' time. Much discussion has arisen as to the best spot for establishing a sanatorium, and several places on the West African Coast have been indicated, but we are decidedly of opinion that the sick or wounded should be promptly conveyed to this country. For this purpose some fast and comfortable vessels might be detailed, such as the *Himalaya*; the invalids would thus be removed altogether from the influence of a dangerous climate, and would have much greater chances of recovery. This system, if we mistake not, was carried out during the Crimean War. Certain vessels were there employed in carrying the sick and wounded from Balaklava to the hospitals at Scutari.

It is rumoured that the 1st West India Regiment, at present stationed at Jamaica, is to be despatched to Cape Coast Castle, but whether as an addition to the corps already mentioned as about to take part in the expedition, or to replace one of them, has not transpired.

Many arrangements are left, and will have to be left, in abeyance until a report has been received by the War Office from Sir Garnet Wolseley. When that officer has, from personal inspection and inquiry, decided upon a plan of operations, much which is now only a matter of conjecture will be definitely decided upon, and upon his report all final arrangements will have to be based.

THE WEEK.

TOPICS OF THE DAY.

The letter of our Liverpool correspondent recounts another importation of cholera from Havre. Two vessels—the *Rosaire* and *Hortense Dusantoy*—have arrived at Liverpool from that port. In the former there have been three deaths, but fortunately the existence of the disease was known to the authorities before there had been much communication with the shore. The case of importation by the other vessel, the *Hortense Dusantoy*, is somewhat similar to that by the steamship *Allianee*, which we noticed last week. The *Hortense Dusantoy* came into port on Thursday, the 25th, and it was not until Saturday that one of her crew applied for admission at the Southern Hospital. He was found to be suffering from cholera, and was taken to the Toxteth-park Workhouse Hospital, where he died the following evening. The case affords another example of the impossibility of excluding any disease which has a period of incubation without the establishment of quarantine.

Cholera seems to be dying out in Italy. On September 29 no case had occurred for some days in Venice; and a telegram from Rome of the same date reports the disease decreasing everywhere except at Naples.

In Lord Houghton's opening address at the meeting of the Social Science Congress, which begun at Norwich on Wednesday, his remarks on the condition of sanitary legislation had rather a desponding tone. He said—

"No practical progress, I fear, has been made in the vexed question of sanitary reform. Day after day it comes before us illustrated with fresh disaster and moral difficulty. The conflict of powers can only be averted by some absolute authority, and even when that authority is established it too often refuses to move. There could be no better evidence of the exigencies and embarrassments of the present state of things than the story of the Bill which Mr. Powell and Sir Charles Adderley introduced during the late session. It was evidently supported by the Government; but the new arrangement, which prevents any fresh matter from being brought on after half-past twelve having delayed the second reading, when it had passed the next stage the session was too far advanced for any further procedure. The loss of this measure is much to be regretted. It would, among other useful enactments, have given to rural sanitary authorities the power of making by-laws and of compulsory purchase, which are now only possessed by the urban authorities, and would have enabled the Local Government Board, by order, to supersede the sanitary authority in cases of non-performance or neglect. It will, perhaps, be found necessary in future legislation on this pressing subject to give to a much smaller proportion of the inhabitants than is now required the means of setting the Local Government Board in motion, and owners must have more power to act independently of their tenants."

It is proposed to fit the China barrows for the Gold Coast with water-tanks and charcoal filters, so that the troops should have

a good supply of filtered water for cooking and drinking purposes. The men are also to be supplied with pocket charcoal filters similar to those which were used in the Abyssinian expedition.

In Dr. Whitmore's report on the late outbreak of typhoid fever in Marylebone and the adjoining parishes, presented last week to the Marylebone Vestry, the number of families who suffered is stated to have been ninety, and the number of persons attacked 320. The percentage of deaths had not been arrived at, on account of the removal of some of the patients, but about twenty fatal cases were known, of which only five or six terminated in Marylebone. One died in France, one in Wales, and others in different parts of the country. The precautions he had adopted to check the spread of the fever, which had incontestably originated in milk supply, were the continuous flushing and disinfection of the sewers with sulphate of iron and carbolic acid, the watering of the streets with a weak solution of carbolic acid, and the sprinkling of all gullies and air-shafts with carbolic powder, packets of which were also distributed amongst the poorer classes. Posters and handbills with sanitary directions were also distributed. We are glad that the number of cases falls short by 180 of the number which had been announced, and that, considering the nature of the disease, the mortality has been so remarkably small. In the epidemic of typhoid at Wolverhampton, supposed also to be due to contaminated milk, fourteen persons have died. We notice that, in consequence of the fines recently inflicted on dairymen for selling adulterated milk, the metropolitan milk vendors are proposing to raise the price of milk from fourpence to fivepence a quart. This will be a serious change for large classes of the poor, and as we believe it to be entirely unnecessary, we hope the public will not meekly submit to it.

MEDICAL MEN AND THEIR PRESCRIPTIONS.

One day last week a medical practitioner appeared before Mr. Woolryeh, at the Hammersmith Police-court, to prefer a complaint against a chemist who, in compounding a prescription entrusted to him to make up, had substituted an ingredient which was deleterious to the patient for one which had been prescribed by the applicant. The magistrate appeared to be of opinion that, as a chemist was not an apothecary, the case would not come within the meaning of Act 55, George III. The applicant further explained that the most important item of the prescription had been tampered with, and stated that he believed it to be a common practice with chemists to substitute articles on their own responsibility for those of an expensive character, which they might not happen to have in stock. Mr. Woolryeh said the matter was one of great importance, and should be looked into, but he was afraid that unless the patient died through the alteration which, without authority, had been made in the prescription, there were no means of punishing the offender. The applicant expressed his thanks to the magistrate for the attention with which his complaint had been listened to, but observed that whilst the law remained in its present defective condition the public were daily in danger of being killed through the physician's prescription being thus unwarrantably tampered with. There can be no doubt that the practices thus brought to light are of great importance to the sick generally; but we cannot imagine that the better class of chemists would follow such an unjustifiable course. Every prescription ought to be compounded with the most scrupulous accuracy down to the minutest details, and it should be borne in mind that the slightest deviation from the written instructions which it contains may have the effect of nullifying the entire care and attention with which the medical man has been studying his patient's case. If, as the present case shows, such flagrant breaches of confidence are really perpetrated, we can only counsel both physicians and patients to be certain of the character of those firms to whom they entrust the making up of their medicines.

INQUESTS IN ST. PANCRAS WORKHOUSE.

The increased number of inquests which have been held during the past two years in the St. Pancras Workhouse was a subject of some discussion at the last meeting of the Board. The result was, that a resolution was carried that Dr. Hill be requested to provide the Board with a list of the names of all persons who had died in the workhouse during the past two years on whom inquests had been held, and also the ages of the said persons, together with the verdicts of the juries. The discussion began with the Rev. W. R. Arrowsmith, who said it was high time the guardians took some steps to prevent so many inquests being held on persons dying in the workhouse. During the last year no less than sixty inquests had been held at the request of Dr. Hill. Some of them were, no doubt, absolutely necessary, but he believed the majority were not. It was only right that the Board should have a list of all the cases laid before them, and he would at the proper time move that it be transmitted to the Local Government Board. Mr. Salter said that in four cases referred to the verdict of the jury showed that Dr. Hill was justified in asking that inquests might be held. It was different in Dr. Ellis's time, as frequently the verdict returned then was—"Death from natural causes." He quite agreed that the return asked for should be granted. Under the circumstances, we do not see how the guardians can be blamed for moving for the return in question. It is necessary, however, that great care should be exercised in arriving at the conclusion that any inquest was unnecessary. The fact of the jury having returned a verdict of "Death from natural causes" would not necessarily show that the inquest had not been properly held. We shall look with some interest for the result of the inquiry.

MEDICINE IN INDIA.

To Sir William Grey, the late Governor of Bengal, as a correspondent of the *Pall-mall Gazette* states, is due the honour of initiating a scheme for driving European medicine into use amongst the people. He found himself face to face with great epidemics, which in the most populous and the richest districts of Bengal decimated the adult population, and left whole villages untilled. He accordingly devised a system of "training up a body of local practitioners able to apply simple remedies to ordinary diseases, such as cholera, small-pox, and epidemic fevers." Vernacular medical classes were opened, and the past three years have proved them to be a success. In the Medical College of Calcutta alone there are now 1400 students, and their numbers increase by twenty-five every year. Of these, 500 receive a high education through the medium of the English language, and from highly paid European professors. Nearly 800 obtain a shorter and less complete medical education in the Bengali language, at the hands of carefully selected native teachers. About 130 pupils, mostly men from Northern India, receive the same education in the Hindustani tongue. The success of the Calcutta Medical College has led to a demand for vernacular medical schools at other places throughout Bengal, and the insatiable Sir George Campbell comes to the front with a scheme for spreading such institutions throughout the country. He finds that Bengal with its 66¾ millions of people requires 34,000 medical practitioners, with an annual supply of 900 men yearly, to keep up the profession at this standard. Of course there is the invariable money difficulty. Sir George deplores that he has hitherto spent only £115,000 per annum on medical tuition, and winds up with the characteristic declaration that wherever the money is to come from, "the arrangements proposed

must be made." The italics are his own. But the naturalisation of English medical science means a revolution in the domestic habits and superstitious propitiatory rites of the people which would have taken away the breath of an Indian Governor in the days of John Company.

DR. TIDY ON THE ADULTERATION ACT.

DR. TIDY, Medical Officer of Health and Analyst for the Parish of Islington, in his report to the Vestry "protests against irregularities in the working of the Adulteration Act, which in some places unfortunately seem to be the rule. To purchase articles irregularly, to find them adulterated, and then to tell the tradesman (which the Act does not sanction) rather than to summon him, is merely playing with an important Act of Parliament; it is treating it as a creature of circumstances to be toyed with after one's own liking, and it can only end in bringing disgrace on chemical analysis and on the law which employs science for its help to punish the guilty and let go the innocent. To prevent the Act being a means of persecuting the dealer and of interfering with just trading on the one hand, or allowing our certificates to be the means of trade advertisements on the other, should be a matter of constant concern; while at the same time we should allow no false feeling to prevent our putting a stop to what has been too long an enormous source of addition to the money-bags of the fraudulent dealer, and so necessarily a cheat on the poor and a curse to us all."

IMPROPER ADMISSION OF FEVER PATIENTS INTO WORKHOUSES.

THE Visiting Committee of the Islington Board of Guardians very properly complained, at the last meeting of the Board, of the laxity of a system by which persons suffering from a contagious complaint were sent into the workhouse, which numbered nearly 700 inmates. It appeared that four cases of typhoid fever were admitted into the workhouse without a medical order. As soon as the medical officer saw the patients he ordered them to be at once isolated. The Committee expressed satisfaction with the prompt action of the medical officer, and the Board resolved that the matter should be investigated, with the view of preventing the recurrence of a proceeding so dangerous to the health of the inmates.

BABY-FARMING.

THE Metropolitan Board of Works have recently had their attention drawn to the fact that the provisions of the Infants' Life Protection Act have been much neglected. The present organisation for carrying out the provisions of the Act appears to be very defective. We hope, as the subject has been referred for consideration to the Works Committee, that some efficient means may be adopted by which the Act will no longer be almost a dead-letter. Several instances have lately shown how little has been done towards organising the active system of supervision which was intended by the Act. It seems that baby-farmers have recently established themselves beyond the boundary of the Metropolitan Board.

A FEVER-STRICKEN CITY.

SHREVEPORT (says the *Times* Philadelphia correspondent), the principal town of Northern Louisiana, located on the Red River, near the Great Raft, is suffering from a severe visitation of yellow fever. It has about 4600 inhabitants, half whites and half negroes, and has heretofore been a very thriving business-place. Now, however, through the dread an epidemic always inspires, the communication by rail has been stopped, and a fall in the river has almost cut off water communication. The fever is very malignant, causing an average of twenty deaths daily, and aid has been asked from New Orleans, St. Louis, and other cities, where the call is meeting with a liberal response.

MIDDLESEX HOSPITAL.

THE annual dinner of the Middlesex Hospital passed off well. Dr. Greenhow, F.R.S., occupied the chair, and there were present about eighty, including past and present students, members of the staff, etc. Major Walters and Major Maclean responded for the Army, Navy, and Reserve Forces; Mr. De Morgan, who was received with enthusiasm, for the Medical College; Mr. Rix and Mr. Arthur Tomes for the Past and Present Students. The Middlesex Hospital Minstrels, including Mr. Critchett, Mr. Hailstone, Mr. Adams, Dr. Semple, Mr. Gillespie, and the Rev. Mr. Walshe, the Chaplain of the Hospital, afforded much pleasure by the really capital vocal and instrumental music they gave.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THE annual meeting of this Society was held on the evening of September 29, in the library of the Newcastle Infirmary; Dr. Philipson, President, occupied the chair. The following is a list of the officers appointed for the ensuing year:—*President:* Dr. Philipson. *Vice-Presidents:* Drs. Burnup, L. Armstrong, Peart, and Mr. Broadbent. *Honorary Secretary:* Mr. Henry E. Armstrong. *Committee:* Drs. Denham, Humble, Arnison, B. Bramwell, and Page; Messrs. C. Carr, Russell, Hawthorn, and Redmond.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT the last annual meeting of the Society the following officers were elected for the year ensuing:—*President:* Dr. Henry Letheby. *Vice-Presidents:* Drs. H. G. Sutton, W. Hardwicke, and S. Gibbon. *Treasurer:* John Liddle, Esq. *Secretaries:* Drs. J. Northcote Vinen and Thomas Stevenson. *Council:* Drs. J. Adams, F. T. Bond, W. H. Corfield, T. O. Dudfield, W. T. Iliff, Price Jones, D. O. Maxey, C. M. Tidy, J. W. Tripe, and W. T. G. Woodforde; C. F. J. Lord, Esq., and J. Oakeshott, Esq.

DEATH OF DR. THURNAM, F.R.C.P., F.S.A.

WE regret to observe the death of Dr. Thurnam, of Devizes, the well-known author on British Crania and on other subjects of archæological, physiological, and psychological character. We hope to give our readers a notice of Dr. Thurnam's life and career in an early number.

FROM ABROAD.—THE PRÉFET DU RHÔNE AND THE ASSOCIATION FRANÇAISE—TREATMENT OF AMPUTATION-WOUNDS—EXCISIONS AFTER GUNSHOT INJURY.

M. ALGAVE, the editor of the *Révue Scientifique*, in his able report of the proceedings of the French Association for the Advancement of Science, recently held at Lyons, gives a curious account of the high-handed proceedings of M. Ducros, the Préfet du Rhône, whose name has so often been before the public of late. It seems that the Préfet was by no means favourable to the meeting of the Congress at Lyons at all, and used his best endeavours to prevent it, being under some kind of persuasion that it must have more or less of tendencies of a socialist description. One point was clear enough—it had been cordially invited to Lyons by M. Barodet, then Mayor of Lyons, and the Municipal Council, who had voted 20,000 fr. for its reception. This *fait accompli*, and the positive injunctions of the Government, compelled the Préfet to withdraw his opposition. However, he determined to keep the reception in his own hands, and simply ignored the Municipal Council, preventing their having anything to do with those who had supposed themselves to be their guests. His mode of manipulating the 20,000 fr. voted by the Council was what would be called in this country "cool," and rather in contrast with the liberality of our own chief magistrates. Issuing cards in his own name and that of his wife the

Countess for a grand dinner, he invited a selected number of the Association to meet his other guests, not including of course the Municipal Council who had provided the funds. With the rest of the money an evening reception was given; but this was so managed as to give just umbrage to the Association. No mention was made of them in the programme, the Préfet informing them a few hours before that they might all come in undress on showing their cards of membership. They were, in fact, treated just as ordinary travelling strangers are when passing through a town where a prefectorial *fête* is given. The consequence was that very few of the members attended, the *salons* being crowded by functionaries and inhabitants of Lyons, many of whom cared little about science, and who certainly were not aware that the first *fête* given by their Préfet was paid for out of money voted to do honour to its votaries.

It seems, however, that the Préfet was so well content with the way in which matters had gone off that he volunteered an address himself, and appeared unexpectedly for that purpose, resplendent with stars and orders, during one of the final business meetings. The address was an unintelligible muddle, in which the first chapter of Genesis and the Greek Argonauts figured in inharmonious proximity.

In the surgical section of the Congress, Professor Azam, of Bordeaux, read a paper on what seems to be an inexhaustible subject, the "Treatment of Amputation-Wounds." His plan consists in obtaining immediate union of the muscles and skin, while the deeper-seated parts are allowed to discharge by means of a drainage-tube, which is left in usually until the twelfth or fifteenth day. The results are, he says, very satisfactory, union being generally accomplished by the twelfth or sixteenth day, and in other cases by the twentieth or twenty-fifth day. M. Verneuil observed that this question is little more advanced than it was at the end of the sixteenth century —free exposure of the wound, its immediate union, and mixed methods like this of M. Azam's succeeding each other. This plan must be compared with others which consider that the danger proceeds more from the medium in which the patient is placed than from the wound, and of which Lister's and the occlusion and wadding dressings are examples. M. Azam's plan may suit well enough in the country or in small hospitals, but in Paris or Lyons, where the hospitals are certified cemeteries (*nécropoles assermentées*), all attempts at immediate union when they do not succeed are horribly dangerous; and when the accidents do ensue it is too late to recede. The chance of a more rapid cure cannot be pitted against the patient's safety. The extreme complication and tediousness of Lister's mode of dressing leads M. Verneuil to prefer in insalubrious localities the wadding dressing, with which he has reason to be more and more satisfied. M. Focher, surgeon to one of the smaller Lyons hospitals, has found this obtaining partial union of great service, employing, however, in place of a drain a tent, which in three days secures an open channel for the deep-seated pus, and may then be removed. M. Courty, of Montpellier, also approves of the practice of endeavouring to unite three-fourths or four-fifths of the wound, and endeavours to leave an issue for the pus at the most dependent angle of the wound, by bringing all the threads of the ligatures there. Lister's plan demands too much time and minute attention, and the occlusion dressing cannot always be safely employed. M. Ollier, of Lyons, explained a modification that he had made in his procedure. Of all means of treating wounds in a hospital medium, he observed the oil-bath is the only one absolutely certain, this being replaced at the end of twelve or fifteen days by simple dressing. The employment of this method was, however, attended with so much difficulty that it had to be abandoned, and for it was substituted the wadding dressing rendered immovable by silicate of potash. The latest improvement in this consists in bringing the edges together, applying a layer of phenicated wadding, and keeping the limb on a splint, a drain being also placed in the depth of the wound. This is all continued for forty-eight hours, during which period the chief danger from secondary hæmorrhage and septic accidents is present. At the end of this time the occlusion by wadding dressing is secured, this being also rendered immovable by means of silicate of potash. During two years and a half M. Ollier has not met with a case of pyæmia.

During the session of the Congress the members of the section inspected the Hôtel-Dieu of Lyons, and unanimously pronounced it to be totally unfitted for its purposes, and fraught with every evil that can characterise hospital construction. Its wards are too large, its ventilation is impracticable, and all the patients have to be supplied with close-stools. Moreover, intended alterations were pronounced to be mere illusions, and it was declared that no efforts could render passable as a hospital what was a sufficiently imposing-looking edifice that should at once be converted to some other use. A similar investigation of the Charité Hospital was followed by an equally unfavourable opinion—at all events, as regards its lying-in wards. It is sincerely to be hoped that this verdict, pronounced by such unimpeachable authority, will have its weight with the municipality.

At the second Congress of German Surgeons a discussion took place on a paper read by Professor von Langenbeck, on "The Results of Excisions performed during War." He observed that the unfavourable results of the excisions performed during the Schleswig-Holstein war as reported by Hannover, as well as the later observations collected by Kraatz, bearing on the ultimate utility of limbs so treated, had led most observers to prefer amputation. Langenbeck is, however, able to make a more favourable report, derived from his own military experience. He had met with several cases of excision of the shoulder and other joints in which very useful limbs resulted. Even the unsuccessful cases were not always to be attributed to the operation itself, but to the difficulty of applying appropriate apparatus in war time, or even to the interest which the patient had in maintaining his limb in such a condition that it would gain him a pension. Professor Busch, of Bonn, observed that civil practice had already taught us the difference there is in excisions performed in chronic disease or on account of injuries. While in the first case a stiff joint is formed, in which we can only obtain mobility with much trouble, when extensive injury has been present it is as difficult to procure a firm and useable joint. All kinds of means may have to be resorted to during perhaps a twelvemonth before a loose joint is converted into a serviceable one. In the late war he found some of his patients upon whom he had performed excision in a miserable condition, which he attributed much to their frequent removals and their falling into the hands of successive surgeons. Professor Esmarch believed that political antipathy had a great deal to do with the statements of Professor Hannover, of Copenhagen. During and after the first Schleswig-Holstein war he had had many opportunities of becoming acquainted with the views of the Danish surgeons on this subject, and always carried away the conviction that they were determined to oppose the operation of excision. After the war, also, they attacked it on every opportunity. The same prejudice plainly prevailed also during the war of 1864. As in the first war, the Danish surgeons did nothing to restore the utility to the limbs which had undergone excision in the German lazaretths. Dr. Danzel could quite confirm Esmarch's statements, having found this prejudice prevail even when complete movability had been established in a case of excision of the elbow. In general he is content with a stiff joint, for the limb is usually of more utility

than where this remains movable. Professor Langenbeck also suspects that the statements of Hannover are not free from prejudice. He referred to cases of Danes whom he had successfully treated, producing excellent and serviceable joints, both in the wars of 1848 and 1854, no mention of which is made in Hannover's statistics.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

No. XXX.

By J. F. CLARKE, M.R.C.S.

For nearly forty years on the Editorial Staff of the "Lancet."

THE LONDON UNIVERSITY.

(*Continued from page* 163.)

Quarrels of the Medical Staff — Rival Modes of Treating Erysipelas — Antagonistic Lecturers — The Office of House-Surgeon in the Hospitals of London obtainable only by Purchase — The System of "Concours" established at the North London Hospital — Stringency of the Test — Its Effects on the Students — Past and Present State of Medical Education — The Vast Improvements effected in late years.

As might have been expected, the quarrels which were carried on in the board-room of the Hospital were not confined to that arena; they were carried into the wards, and into the lecture-room. Remarks were occasionally made at the bedside which were intended to excite ridicule or contempt. The house-surgeon of one of the chiefs was scarcely on speaking terms with the house-surgeon of another. Indeed, I recollect that this antagonism was carried on to such an extent in one instance as to threaten personal violence. This condition of things was certainly favoured by at least one of the chiefs, and connived at if not encouraged by the other. In spite of all these disagreements, however, the medical officers as a body and individually were much respected and even beloved by the students in general. They, at all events, whatever bitterness their principals might feel, only regarded the quarrels with curiosity and amusement. Sometimes, indeed, these quarrels bordered on the ludicrous, if not on the truly comic. Thus, at a period when erysipelas was almost epidemic in the hospital, both amongst the medical and surgical patients, we had four practitioners of the highest eminence and skill treating the disease in four different and distinct ways! Elliotson was painting the patient with a strong solution of nitrate of silver; Thomson was smearing the surface over with mercurial ointment; Cooper, with his usual caution, modified the topical treatment by attempting to isolate the disease by drawing lines of lunar caustic near the margins of the eruption, to prevent it spreading beyond them; while Liston confined himself to the older mode of treating the disease locally by means of fomentations and the application of flour. But, notwithstanding his assumed contempt for medicine, he always administered powerful remedies internally. Belladonna at this time was much resorted to by the homœopathists, and this Liston employed, together with antimony, in what were regarded as "heroic" doses. Liston at this period was very frequently called into consultation with Dr. Quin, then the head of the "heresy," and was no doubt considerably influenced by the sagacity of that able and philosophical, but mistaken practitioner. It was curious to listen to the clinical lectures of the four principal medical officers of the Hospital, sometimes delivered the same week. Elliotson, always clear, decisive, and "rational," gave reasons for all he did, and justified his treatment with the nitrate of silver, and appealed to the results of that treatment. He would occasionally make a sly, good-humoured allusion to the "do-nothing" mode of treatment, but he was never coarse or ill-natured in his remarks on the practice of his colleagues. Thomson would drily, and with the most perfect coolness—as if, indeed, he and his colleagues had agreed to try a series of experiments on the treatment of the disease,—draw conclusions from all the cases, and would analyse, in his laboured manner, the results of the therapeutical agents employed. Cooper stuck mainly to his own cases, and if he did allude in any way to those of his colleagues, it was in a quaint, humorous style, without being offensive. He could, however, when he pleased, say very nasty things in a very quiet way. Liston's impetuous temperament urged him to say very uncivil and very bitter things. He ridiculed the idea of curing erysipelas by "turning a white man into a nigger," or by "drawing lines horizontally, perpendicularly, and slantingdicularly over a patient's body." His lectures, I believe, on certain occasions (and this was one of them) were carefully prepared. He was, moreover, assisted to some extent by one of the greatest masters of invective of the time. These lectures were usually well attended. What the effect of them was, so far as teaching the students, I leave others to judge; but the students certainly had the opportunity of witnessing and judging the results of very different modes of treatment. When the "North London" was established there was no hospital in London at which the office of dresser or house-surgeon could be obtained, even by the most meritorious student, except by a large payment of money. In some of these it was necessary to the candidate to have been an "apprentice" or pupil of one of the surgeons. For this apprenticeship very large sums of money were given—a thousand guineas being about the average payment. The effect of this was to "keep out in the cold" many of the best men in the institutions. To the medical staff of the North London Hospital medical students at that time were, and at the present time are, under a deep debt of gratitude for the course pursued in that institution. On its establishment it was determined that money and family influence should have no effect on the appointment of candidates to the posts of honour. The least favoured amongst them, *quoad* money and interest, stood the same chance of success as the most favoured in those particulars. None of the medical officers derived any emolument from the fees of students for attending the practice. These fees went directly to the support of the Hospital, without any drawback whatever. In order that the best men might be appointed to offices of honour and trust, the system of *concours* was established. Any student of the Hospital was entitled to enter into the contest, his only requirements being that he had attended a certain number of lectures at the College, and having for a certain time been an "entered" student of the Hospital. Under these circumstances it was all but impossible that an incompetent man could be elected. The ordeal he had to pass was most severe; not simply in the presence of a clique, but in the presence of his fellow-students, and of the students of all the hospitals in London. I recollect no instance in which the selection made met with the slightest disapproval on the part of anyone interested in the matter. The candidates were required to answer questions of a searching character, and to perform operations on the dead body before a public assembly. The *concours* days were of exceeding interest, as was evidenced by the crowded state of the theatre of the hospital which prevailed on those occasions. I recollect many of these "trials of strength" during the many years that I represented the *Lancet* in the Hospital. I regularly furnished reports of these proceedings to that journal, and it is not difficult to imagine the effect that they had on the other hospitals of the metropolis. At first the *concours* was attempted to be pooh-poohed, but this attempt was of short duration. The minds of the students of London were thoroughly impressed with the justice of the course pursued, and the "authorities" slowly and unwillingly were at length brought to the same conclusion. In order to show the thoroughly fair and practical ordeal to which the candidate for honours was subjected, I reproduce here one of the papers:—

"*Questions proposed for Answer in Writing.*—1. Describe the modes of taking blood from the arm and from the temple. What are the accidents which may occur during or after these operations? How would you remedy them? 2. What are the circumstances which would render necessary the operation of tracheotomy? Describe the operative procedure. 3. What circumstances distinguish a fracture of the neck of the thigh-bone from dislocation of the hip? 4. The anatomical relations of the common carotid artery. Describe the mode of applying a ligature to the artery, and the precautions to be taken during the operation.

"*Practical Examination in Public.*—Amputation of the great toe at the metatarso-phalangeal articulation; after-treatment. Amputation of thumb at metacarpo-phalangeal articulation. Describe the treatment for diffused aneurism of the arm. Describe the treatment of onychia (and definition). Apply a ligature to the brachial artery in the lower third of its course.

Apply a ligature to the femoral artery in the upper third of its course. Remove a foreign body from the meatus aud. extern. Apply the apparatus for fracture of the lower jaw."

Such were the examinations of the candidates for the house-surgeoncy of the North London Hospital, and no one will deny that they were stringent and practical. Looking at the fact that it is nearly forty years since the examination above referred to took place, I may fairly ask if there was any such searching examination at any of the colleges of surgeons in this kingdom? I believe not. Even now it may be questioned whether any collegiate test is much, if any, more likely to be effective than the old *concours* test of six-and-thirty years ago.

I have dwelt at some length on the establishment and career of the London University and the North London Hospital, as it represents a very important epoch in our profession, particularly as regards medical education and the future of the medical student. For though the "University" was not confined to medical teaching and included most of the other arts and sciences, its chief reputation rested on the medical department. The "University" was founded on the most liberal principles, and its council was composed of the ultra-liberal party. It may well be supposed that it met with the strenuous and determined opposition of those whose interest it was to "keep things as they were." Attacks upon it were made of the most unscrupulous character. It was attacked in Parliament, in the pulpit, and by the press. It was denounced as an "infidel" institution; was characterised as "that low place in Gower-street"; and one brilliant writer, in a paper which he edited at the time with much ability, called it "Stinkomalee."(a) But, thanks to the courage and ability of its medical staff, it flourished in spite of all opposition and ribald invective. For some years it had the largest class of any medical school in the metropolis. It has "turned out" some of the ablest, most accomplished, and most successful physicians and surgeons of the day. It is true that at the present time University College and Hospital have no just pretence to pre-eminence in any way. There is not a single school in London or the provinces that is not ably officered and conducted in such a manner as to make it a fitting place at which to obtain a first-rate and complete education. This has been the work of time; it has been slow, but it has been complete. There is now a generous and beneficial rivalry amongst the schools to be foremost in imparting sound and practical knowledge. But it is not an inopportune moment at the present, when the medical session has just commenced, to remind the students of the past. For many of the advantages they now possess, for many of the improvements in their education, and for the destruction of a gross monopoly of place by money and patronage, they are mainly indebted to the influence of "that *low* place in Gower-street," assisted by the unflinching and constant advocacy of a free and independent medical press. Every student at the present time may feel assured that, with proper diligence and conduct, he may, like the meanest soldier in the ranks of the Great Napoleon, "carry a marshal's *bâton* in his knapsack."

NÉLATON AS A CLINICAL PROFESSOR.

By Professor SAPPEY.

Quite in accordance with the simplicity which characterised his entire career, Nélaton forbade any addresses being delivered at his interment. Before this was known, however, the Faculty of Medicine, of which he was so distinguished an ornament, had deputed M. Sappey, Professor of Anatomy, one of the deceased's warmest friends, to prepare an address in their name. Although not delivered, Professor Sappey has since published this, and we reproduce those portions which relate to Nélaton as a clinical teacher:—

"What he was as Professor of Clinical Surgery a short parallel will exhibit. Nélaton was the pupil (the last remaining) of Dupuytren, and among all his titles none had more value in his eyes. From the day when he was first privileged to see and hear this celebrated man, to the moment when a slow agony confined him to his bed of suffering, the pupil continued to preserve for the master a deference only equalled by his lively admiration. Formed in this school, and endowed with the powerful faculties which had rendered him illustrious, he grew up as it were under the shadow of and in the worship of his master's memory. Thirty years later, the pupil had become the rival of the master. The surgeon of the Clinique had attained in Europe the high position which the surgeon of the Hôtel-Dieu formerly occupied. If the law which regulates our destinies could have permitted that they should then be brought into the presence of each other, the master would have felt proud of such a successor; and the pupil, still animated with the same feelings as when young, would have inclined with the same respect before him who he considered as the living personality of the genius of surgery.

"They resembled each other in the great qualities which constitute the man of superiority and the surgeon of eminence, but differed in all other aspects of their organisation. Both shone by that penetrating acumen which they displayed in the examination of patients, by the infinite art they possessed of grouping in the most natural succession all the observed phenomena, and by the lucidity with which they fixed upon the seat and nature of the disease. This determined, they showed the same skill in seizing the indications presented, and the same talent in fulfilling these. It was especially in difficult cases that it was a pleasure to see and hear them unfolding the picture of the disease. So far from dissembling the obscure points, they on, the contrary, brought them fully forward; and then, by the logical interpretation of the facts and their comparison with analogous facts derived from the annals of science or their own experience, and by a learned and luminous discussion of these, they gradually raised the veil under which the lesion to be combated with lay hidden, exhibiting it in most cases in all its completeness. He who has not seen our eminent colleague engaged in the struggle with one of these great surgical difficulties, and who has not been present at one of the lectures when he has diffused over the subject and among his auditory the bright clearness of his own mind, cannot have a just idea of the nature and elevation of his talent. To his operations he brought a firm and sure hand, calculating and foreseeing everything in advance, going straight to his object, and entirely absorbed in the interest of his patient. If one of those accidents which the most consummate knowledge does not always enable us to foresee presented itself, with admirable presence of mind he instantly modified his whole plan of the operation, and attained his end as certainly and as rapidly by this new procedure.

"As professors, both Dupuytren and Nélaton attained brilliant success. Both had their clinics crowded by pupils and foreign practitioners. On the part of these there was the same desire and eagerness to hear them both, and the same deference; and yet how different were these two masters! Dupuytren had a powerful constitution, fine stature, a proud physiognomy, and a severe expression. Grave, solemn, and imposing, he kept the crowd at a distance. When the time arrived for him to speak, his voice at the commencement seemed almost extinguished, becoming afterwards gradually raised until it filled the room. Now, animated by his clear, facile, abundant, and correct eloquence, he seized hold of the minds of his auditory, and held them suspended to his lips. Nélaton was simple and dignified, his attitude, language, and manners all expressing benevolence. The pupils surrounded and accosted him without fear. To any reflections or objections which were submitted to him he willingly replied, sometimes entering on discussions, and always in a tone of simplicity and marked courtesy. To be useful to his patients and to instruct his pupils—in a word, to fulfil the high mission that had been confided to him, and to fulfil it as well as possible—constituted his sole preoccupation. He had also the gift of lucidity, and the still rarer gift of captivating the attention of his auditors. But he attained this end less, perhaps, by brilliant forms of language than by the clinical developments into which he entered, and into which he knew how to infuse the most vivid interest.

"Dupuytren will remain the most accomplished type of the professor, and Nélaton the most perfect model of the clinician. Both the one and the other had the most exquisite appreciation of science, and yet both of them wrote very little. With them have disappeared in the tomb the accumulated treasures of their long experience. We may regret this immense loss, but we can only accuse the insufficiency of their strength. Constantly carried away in the whirlwind of a devouring life, they had neither the tranquillity nor the time necessary for prolonged labours. What they have not been able, however, to bequeath us in a durable form they have

(a) Theodore Hook.

transmitted by their voices to several generations of auditors. In their school have been formed pupils now spread over all parts of the globe; and their teaching has been a great centre of light for the propagation of sound doctrines in surgery, and a centre of diffusion for all that relates to the art of healing. If both the one and the other have well deserved at the hands of suffering humanity, so have both also well merited of science."

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Forty-third Meeting.

(*From our Special Correspondent.*)

The following abstracts of papers read at the British Association on subjects connected with Physiology and Medicine were unavoidably omitted last week from want of space:—

Dr. George Harley on the Mode of Formation of Renal Calculi.

Although this communication was of a strictly scientific character, it has at the same time an important practical bearing upon treatment. The following general laws were laid down by Dr. Harley as being applicable to all kinds of renal calculi:—1. In all cases of constitutional calculi the amount of solids excreted by the kidneys must be disproportionate to the amount of liquid. The liquid may be diminished, while the solids remain normal; or the solids may be in excess, while the quantity of liquid remains normal. 2. Calculi may occur at any period of life—from the cradle to the grave. 3. Constitutional calculi are frequently hereditary. 4. The deposition of a calculus in any part of the urinary system is always dependent on some special local cause. The cause may be trifling and temporary, but still it must exist. Once, however, the concretion has begun to form, the original exciting cause is soon lost sight of. 5. The vast majority of constitutional calculi, be their nature what it may—oxalate of lime, phosphate of lime, uric acid, xanthin, or cystin,—have their origin in the kidneys, and are transported elsewhere by the urine. 6. Renal calculi may be divided into two great classes—the organic and the inorganic. The substances composing the former are manufactured within the frame itself; the latter are the direct products of the food and the drinking-water. 7. The colour of a calculus does not necessarily depend on its nature, but on the amount of urohæmatin in the urine. Phosphatic and cystinic calculi form an exception to this rule, by refusing to combine with extraneous pigments. 8. There are three perfectly distinct modes in which crystalloid material is deposited in the formation of calculi. The first and rarest form of calculus is that which consists of a monster crystal, or an aggregation of monster crystals, which are only to be met with in the case of triple phosphates, oxalate of lime, and uric acid. The second is that in which a certain amount of colloid is united with the crystalloid material, one in which it may be said that small crystals separating from the super-saturated renal secretion become entangled in mucus, tube-casts, epithelium scales, or other colloid material, and by fresh aggregations around them gradually become closer and closer packed together until they assume the appearance and properties of a compact concretion. The last mode of formation is by the aggregation of molecular atoms, on the principle of molecular coalescence from the union of viscid or colloid material with earthy or organic crystalloid matter, in the manner of the formation of the dental tissues and shell structures described by Mr. George Rainey. To these three different modes of constitutional calculus formation the author gives the respective names of crystalline, crystallo-colloid, and molecular coalescence. In concluding, Dr. George Harley remarked that the calculi he had been describing must not be confounded with those which for the sake of distinction might be termed "accidentally acquired," such as vesical, which frequently have for their nucleus foreign substances, such as a pea, a barleycorn, a piece of bone, hair, wire, a fragment of sealing-wax, or a portion of catheter—the irritation of which excites the presence of tenacious mucus, blood, or even pus, with which the foreign body itself becomes coated, and in and around which crystalloid molecules and actual crystals are deposited and form the calculus. Finally, calculi are not always of uniform composition throughout; their composition varies at different times with the different states of health of the patient. The centre of the concretion may be composed of uric acid, then may come a layer of oxalate of lime, and over that another layer of uric acid or of phosphates; so that, in a section of a calculus, the clinical phases through which a patient has passed may be read as truthfully as the geologist can read the earth's history in the strata forming its crust.

The Action of Alcohol on Warm-Blooded Animals.

A paper on this subject was read by Dr. Binz, of Bonn, who related the details of a number of experiments performed by him, which went to show that one important effect of alcohol upon the human frame is to diminish the temperature to the extent of from three to five degrees Fahrenheit, this effect being produced by the action of the alcohol on the heart, causing more blood to circulate through the vessels of the skin, which are dilated, and thus a larger quantity of blood is cooled down. The alleged heat of the organism from alcohol, he said, does not exist. The subjective impression is, at least partially, the consequence of an irritation of the nerves of the stomach and of the enlargement of the vessels arising in the skin. When given in small quantities, the thermometer shows no extraordinary increase or decrease of the temperature of the blood; moderate doses, which need not lead to drunkenness, show a distinct decrease of about half an hour's duration or more; and strong inebriating quantities evince a still more decided lowering, lasting several hours. The decrease after moderate doses takes place most successfully in warm-blooded animals which have not for some time previously had alcohol administered. Dr. Binz injected under the skin of rabbits or dogs about a cubic centimeter of ichor, which in a short time produced death; but not so if, with the ichor, alcohol diluted with water was administered either by the stomach or the skin. In the latter case the animal was quite lively and took kindly to its food; so that alcohol need not, he contended, be a narcotic. His experiments, he said, showed a threefold action—the diminution of the heat of the body, reduction of the putrid processes, and raising of the action of the heart. Alcohol was more than a simple stimulant: it was a strong antipyretic and an equally powerful antiseptic. It was *à priori* to be expected that alcohol would not be without its influence on the metamorphosis of tissues. An agent that, consumed in large doses, clearly lowered the combustion, must also be supposed to decrease the urea and the carbonic acid; and this was in reality the case.

Report on the Heat of Arterialisation.

This was a communication by Professor Gamgee, the object of whose researches has been to ascertain whether, when venous blood comes in contact with oxygen gas, its temperature is perceptibly raised. The majority of experimenters who have investigated this question have arrived at the conclusion that if any heat is generated its amount is too slight to admit of detection. In a first series of researches, the results of which were read at the Edinburgh meeting of the Association, Mr. Gamgee had determined that when the blood of asphyxiated animals is shaken with oxygen its temperature is raised. In the experiments which formed the basis of the present report the ordinary venous blood was used. By means of a complicated apparatus furnished with a thermometer of extraordinary delicacy, Mr. Gamgee determined that, whenever venous blood is brought in contact with oxygen, its temperature is raised between three and four-hundredths of a degree centigrade.

(*To be continued.*)

New Disease.—Cattle Plague in a New Form.—The Brahmans of Terunakara have announced that a deity, in the shape of a granite ox of stupendous dimensions, and the pagoda of that place, has been attacked by a most painful boil. The sufferings of the deity demanded and received the utmost sympathy and liberal offerings from the faithful.

Carbolic Acid in Intermittent Fever.—Disagreement in opinion amongst medical men is of constant occurrence, but we have seldom met with a more positive contradiction as to the results of observation by competent persons than with respect to carbolic acid in ague. While MM. Déclat, Barrant, and others have reported that it is a means which never fails—succeeding in obstinate cases wherein quinine had been given in vain—Dr. Curschmann, of Berlin, reports (*Centralblatt*, September 6), as the result of numerous trials of large doses in well-diagnosed cases, that the acid is utterly worthless, succeeding in none of them; and he is lost in amazement as to how other observers have got their results.

GERMAN ASSOCIATION FOR THE ADVANCEMENT OF NATURAL SCIENCE AND MEDICINE.

(*Continued from page* 367.)

(*From our Special Correspondent.*)

THURSDAY, September 18, was chiefly occupied with the first general meeting and the first public dinner.

The proceedings of the first general meeting began with the speech of the President (Professor Fresenius), who opened the Conference with the following hearty welcome to the visitors:—

"The forty-fifth meeting of the German Association for the Advancement of Science and Medicine, at Leipzig, elected me the President of the present Congress, and in virtue of this my office I have the honour herewith to open the forty-sixth meeting. . . . .

"Gentlemen,—This is not the first time that I have had the honour of opening the meeting of the Association. One-and-twenty years ago—in the year 1852—on this very day, at this very hour, and in the same place, I greeted in the same capacity the twenty-first gathering. Those who were then young are now in the full vigour of manhood; those who were then at their best are now declining; and many who then strove with us and rejoiced with us are now resting from their labours. But the one-and-twenty years have not passed fruitless by. Established in fresh splendour, active, and onwards-striving, is seen the German land; afresh and in full earnest, in all the departments of life, has been sustained the fight, in which, better than in any other sign, is to be recognised the advance of man—the combat of truth with error: and mighty are the advances made in all the realms of science. Nor have the natural sciences and medicine been left behind. New methods of investigation have been discovered, hard problems solved, and we have set before us new and higher aims than before. And so the present offers us—truly a time of striving and advance—an opportunity of justifiable rejoicing, and in this spirit I offer you, in the name of the Commissioners, a hearty welcome. I bid you welcome on the beautiful Rhine, which, with better right than twenty years ago, we call the German Rhine. I bid you welcome in hospitable Wiesbaden, the blooming city, which since your last visit has more than doubled its population. May you be at home here amongst us, and may you enjoy our company. If this wish of your Commissioners is fulfilled, it is above all due to the friendly and powerful support which we enjoy on all hands—the gracious gift of his Majesty, our Emperor and King, the powerful co-operation of the royal authorities, the praiseworthy self-sacrifice and ready assistance of the magistrates, and the co-operation of the scientific and medical circles. Gentlemen, the purposes of our gathering may be variously comprehended, and have since Oken's time been variously comprehended. May this difference of opinion bring no discord into our rejoicings. As the sun scatters light and warmth, so may our meeting be allowed to enlighten and to vivify. The light of the beams of science will surely not be obscured by our hearts warming in the honest exchange of thankfulness for which the friendly festivities offer the best opportunity. Your Committee hope that they have been true to the words of Goethe—'Tages Arbeit, Abends Gäste'—as far as possible; at least, they endeavoured so to arrange the festivities that the time of work will not suffer thereby. Like every man, so every people has its peculiar fashion of living and working. The German nation like to think not only of the head but of the heart. This character is innate in us—we enjoy it,—and if we express it in our Conference we are not to be blamed. It is my fervent hope that in this, as in so many former meetings, we may furnish a proof that by it German science—so dear to us all—suffers neither want nor care."

A second welcome on the part of the Government was followed by the transaction of the formal business of the meeting. Professor Neubauer, of Wiesbaden, then proceeded to deliver a highly rhetorical and eulogistic address *in memoriam* of the great chemist whom Germany has lately lost—Baron Liebig,—and this was in its turn followed by an address by Professor Oscar Schmidt upon "The Application of the Theory of Evolution to Man."

The first day's proceedings were brought to a close with a public dinner in the hall of the Kurhaus.

The second and third days of the meeting were entirely devoted to sectional work. Among the most interesting papers read were the following:—In the Section of Anatomy and Physiology: "On the Influence of Flesh Diet upon the Formation and Excretion of Urea," by Professor Falck, of Marburg; "On the Effect of Water upon the Red Corpuscles of the Blood," by Professor Kollmann, of Munich; "On the Posterior Roots of the Spinal Cord," by Professor Gerlach, of Erlangen. In the Section of Pathological Anatomy: Dr. Hirschfeld, of Dresden, "Experimental Investigations on Typhoid Fever"; Professor Eberth, of Zürich, "On Fat Embolism"; and Professor Rindfleisch, "On Phthisis." In the Medical Section: Professor Jürgensen, of Tübingen, "On a Milder Form of Typhoid Fever"; Professor Mosler, of Greifswald, "On the Local Treatment of Caverns in the Lungs." In the same section Professor Ziemssen, of Tübingen, exhibited a boy suffering from congenital fissure of the sternum, and demonstrated the application of an apparatus for washing out the stomach; and Professor Waldenburg, of Berlin, demonstrated a portable pneumatic apparatus for treating cases of lung disease. In the Surgical Section the most interesting papers read included those of Professor Busch, of Bonn, "On Gunshot Wounds"; of Professor König, of Rostock, "On the Mechanism of the Hip-joint"; and of Professor Czerny, "On the Treatment of *Anus Præternaturalis*." In the Section of Surgery also a demonstration was given by Professor König of Esmarch's method of making the limbs bloodless previous to operation. In the Ophthalmological Section, among the papers read were those of Professor Schmidt, of Marburg, "On the Results of Dissections after Linear Extraction"; and of Dr. Samelsohn, of Cologne, "On the Treatment of Conjunctival Granulations by the Galvano-Caustic Method." In the Section of Gynæcology and Midwifery, Professor Spiegelberg, of Breslau, read a paper "On the Course of Delivery and its Management in Contracted Pelvis"; and Professor Dohrn, of Marburg, "Upon the Value of Premature Delivery in Contracted Pelvis." Professor Meynert, of Vienna, read a paper in the Psychology Section "On the Identical Regions in the Brain of Man and Apes." In the Section of Public Health, Professor Hirch, of Berlin, contributed "Notes on the Origin and Spread of Cholera"; Dr. Böhm, of Vienna, and Dr. Roth, of Dresden, discussed "The Relative Value of Large Hospitals and Barracks"; and H. Hoffmann, of Wiesbaden, read "Notes on the Examination of Eyes in the Schools of the Town."

On the evening of the 19th a grand concert was given to the visitors in the Kurhaus, and was attended by a very crowded audience; and on the following evening, a *Fest-Ball* was held in the same place.

The majority of the members and their lady friends joined the excursion to the Rheingau, on Sunday, the 21st, the principal places visited being Rüdesheim, Bingen, and St. Goar. The excursion was a complete success. Another smaller party visited the baths of Schwalbach on the same day.

At the second general meeting, on Monday, September 22, it was resolved to hold the next Congress at Breslau. At the same time Dr. Löwig, of that city, was elected President for the year, and Professor Spiegelberg Second Commissioner. When this business was concluded, Professor Virchow delivered an address "On the Natural Sciences: their Importance in the Moral Education of Mankind." Virchow spoke in his usual quiet and undemonstrative, but earnest and impressive style, and was listened to with marked attention for nearly two hours by a very crowded audience, who frequently manifested their approval by loud applause as some happy phrase or striking sentiment fell from the speaker. The address altogether was so remarkable and so full of what must interest every thoughtful man in England as well as in Germany that we will report it separately.

A second address was delivered after a short interval by Professor Sandberger, of Würzburg, upon the subject of the "Oberrheinthal in the Tertiary and Diluvial Periods." There were no sectional meetings on this day. In the evening there was a grand display of fireworks in front of the Kurhaus.

The forenoon of Tuesday, September 23, was occupied with the last of the regular meetings of sections. The chief interest was centred in the section of Pathological Anatomy, where it was understood that the discussion on phthisis and tubercle, opened by Professor Rindfleisch on Friday, would be continued by Virchow, Köster, Zenker, and other eminent authorities.

The audience were not disappointed, for they had the satisfaction of hearing the author of the cellular pathology discuss the vexed question of tubercle, scrofula, and phthisis, and make a lengthened statement of his views on the subject, which he has not published for several years. Rindfleisch—now so familiar to English readers through the medium of his "Manual of Pathological Histology"—briefly replied; and was followed in the discussion by Virchow again, Köster (of Giessen), Birch-Hirschfeld (of Dresden), Waldenburg (of Berlin), and Zenker (of Erlangen). The discussion was maintained throughout with every appearance of deep interest and earnestness on the part of the speakers, and occasionally with a considerable exhibition of excitement or even warmth. (A full report of this discussion will be given in the *Medical Times and Gazette.*) On the same day Dr. Ponfick (of Berlin) read a paper of great value "On the Anatomical Changes in Relapsing Fever."

Tuesday evening was evidently the last which a number of the visitors intended to spend at the meeting; and the *Festtrunk*, which began at half-past seven, proved to be the climax of the whole proceedings. This *Festtrunk* or drinking festival was held on the invitation and at the expense of the town of Wiesbaden, who crowned the hospitality with which they received and entertained their guests with a banquet in a style at once really splendid and thoroughly German. The wine, we need hardly say, was from the Rhine, and from the Rhine only; and so wonderful was its quality that the most accomplished *connoisseur* was loud in its praises, and vowed that he would never forget the 1868 Rauenthaler Pfaffenberg from the cellar of Manskopf-Sarasin in Frankfort-on-the-Maine. The supply of the wine was unlimited, and its effect was speedily manifest. The conversation became louder and more animated every moment; the *Anstossen* of the wine glasses ever merrier and more frequent. The well-known demonstrative affection of the Germans became increasingly conspicuous; and—forgive them, *Gott Bacchus!*—the flavour of the Rhenish nectar was soon lost in an universal cloud of tobacco smoke. Many a bond of eternal friendship taken in the old student days was now renewed, and many a fresh one formed; and this among men of every age—from the youthful practitioners and *Naturforscher* fresh from the late war, where they had laboured side by side, to the aged *Philosophen* and *Kliniker*, who may first have met at the foundation of the society more than fifty years ago. At short intervals a toast was given by some of the more eloquent of the company, who acquitted themselves as a rule in the most happy style, receiving due honour from the guests, who drank with equal heartiness and goodwill "Confusion to the Jesuits!" and "Long life to our cousins the monkeys!" Even more acceptable, if possible, to the company, and certainly more striking to a stranger, were the frequent songs—not from one voice, but from a thousand, accompanied by a military band. Each guest was presented with a song-book for the occasion, and the "Gaudeamus," the "Loreley," etc., were rendered in the very best student-fashion. But the crowning piece of all was that verse in the "Rheinweinlied" where the whole company, with a peculiarly mixed air of joviality and seriousness, rose to their feet as one man, and sang in the full strength of their enthusiasm—

"Am Rhein, am Rhein, da wachsen unsre Reben;
Gesegnet sei der Rhein!"

As we have said, the *Festtrunk* was truly the climax of the entire proceedings; and next day the majority of the visitors returned to their duties, refreshed in mind and revived in heart.

The third and last general meeting, which concluded this year's Congress, was held on Wednesday forenoon. The first address was delivered by Dr. Snell, on "The Scientific and Medical Standpoints in relation to Instruction in the Present Day;" the second by Dr. Radde, on "The Steppes of Russia;" and the last by Professor Meynert, of Vienna, on "The Mechanism of the Brain." The President then publicly thanked the members and associates in a few parting words; and Professor Virchow, in a short speech, proposed a vote of thanks to the President and Committee and to the town of Wiesbaden, which was carried with acclamation. Thus ended the forty-sixth meeting of the German Association for the Advancement of Science and Medicine.

The annual exhibition of instruments, books, etc., was of no great size, and insignificant when compared with that of the British Medical Association in August last. There was a good display of electrical apparatus by Hirschmann, of Berlin, and Fein, of Stuttgart; and of apparatus for transport, baths, etc., by Fischer and Co., of Berlin. Perhaps the best exhibition of all was the books, among which must be specially mentioned Pagenstecher's (of Wiesbaden) splendid atlas of the Pathological Anatomy of the Eye; two atlases of Medical Anatomy, by Luschka and Hoffmann respectively; and an atlas of the Syphilitic Diseases of the Skin and Mucous Membranes, by Kaposi, of Vienna. Dr. Stein, of Frankfort, exhibited some very wonderful photographs of scientific objects, the most remarkable of which were, perhaps, those of Dissections of the Abdomen in Pregnancy. There was also a very small display of new therapeutic agents.

REVIEWS.

Popular Lectures on Scientific Subjects. By H. Helmholtz, Professor of Physics in the University of Berlin. Translated by E. Atkinson, Ph.D., F.C.S., Professor of Experimental Science, Staff College. With an Introduction by Professor Tyndall. London: Longmans. Pp. 397.

Few books constitute more pleasing, none more instructive, reading than lectures to audiences of unskilled people by our masters in science, who have also the gift of language. Seldom have we read anything with more pleasure than some of Faraday's Christmas lectures to children, such as his "Lectures on a Candle," than which we know no better introduction to the study of chemistry. Such, too, is Giekie's "Story of a Boulder," Huxley's "Bit of Chalk," and some of Tyndall's discourses. But it is not given to everyone to have at once the gift of successfully following scientific pursuits and pleasantly expounding scientific truths; and we are only too glad to welcome these lectures by the foremost physicist in Germany—he especially who has been so successful in the study of those subjects which constitute the borderland between physiology and physics. The lectures are eight in number, and might be arranged in three categories. First come those intended to give to people whose training has not been in the way of physical science some notion of the scope and bearing of what the Germans call "*Naturwissenschaft*"—natural knowledge. These are—first, a discourse on the "Relation of Natural Science to General Science," delivered in the University of Heidelberg; an address "On the Aim and Progress of Physical Sciences," delivered at the opening of the annual meeting of naturalists and physicians, whose doings we are now recording—then coming together at Innsbrück, this year at Wiesbaden; and a lecture delivered before the German Society of Königsberg on Goethe's scientific researches. Helmholtz was one of the first to grasp in all its details the grand modern generalisation of the conservation of force, and to that a lecture which was delivered at Carlsruhe is specially devoted. Closely allied in many respects is the lecture "On the Interaction of Natural Forces," which was delivered at Königsberg. In a niche apart we must place the pleasant lecture "On Ice and Glaciers," which was delivered both at Frankfort-on-the-Maine and at Heidelberg. And lastly we have—perhaps the most valuable of all, as dealing with subjects Helmholtz has made peculiarly his own—two lectures—one "On the Physiological Causes of Harmony," the other "On the Recent Progress of the Theory of Vision"—lectures which we take leave to commend to all interested in physiological physics. It is these last which, as students of medical science, interest us most. The sensation of hearing, as we all know, depends on vibrations communicated to the auditory apparatus; but as constructed in man the apparatus is only capable of appreciating certain tones—viz., those contained within the area of from twenty vibrations a second to about 32,000 a second; more or fewer give rise to no appreciable sound. However produced, these vibrations are propagated in waves through the air. These waves are similar to those of water; in water waves any given particle of water or any splinter of wood moves upwards or downwards, but does not change its place horizontally. In air, however, the summit of a wave is, as it were, compressed, and so represented by a spot where there is increased density of the air. The wave is, as it were, flattened out, and hence the motion of a particle of air is rather to-and-fro than upwards or downwards. According to the length of a wave as measured from apex to apex—or, in the case of air, from one point of maximum density to another—is the pitch of the tone. Many shallow waves give a high pitch; few and mighty are those which produce deep tones; whilst the degree of density gives

loudness or intensity. But besides pitch and loudness tones have still another character, which is commonly called "quality" or "timbre," which seems to depend on the shape of the wave.

It is tolerably well known to all that if a note be struck or sounded before an open piano the string which corresponds to this note replies; and if more than one note be sounded, each string will, so to speak, pick out its own note and sound in unison with these. In this way such an instrument might be described as in a certain fashion resolving a confusion of sounds into their component notes. Our ear is in all probability an instrument of some such description. In the interior of the cochlea is, as all know, a kind of spiral partition, dividing it into the two scalæ. In one margin of this partition is a peculiar structure, known as the "organ of Corti," and which bears a striking resemblance to the keyboard of a piano, or rather organ. The conclusion is almost irresistible that each of these is intended to pick out its own peculiar note, and to respond to it, thus converting vibration into sensation. But the ear can do more. Each wave of sound may be made up of several smaller ones. Provided we have one wave of the same length as the definite form required, the hollows and crests may be filled up in any pattern, the whole producing a compound wave. This wave the ear can resolve into its component parts. If two tones be produced of exactly the same pitch, the ear does not so distinguish them—they either reinforce or destroy each other; but if the pitch is not exactly the same, the waves come upon the ear in different intervals, and so are split up, giving rise to a disagreeable sensation as they fall upon the ear, which is dissonance. This is greatest and most unpleasant when the two sounds are in pitch a semitone apart. With a whole tone it is less, and with a third it disappears, but not so perfectly as with a fifth, where the one tone makes two vibrations to the three of the other. To keep this or a smaller ratio, as 4 to 5 or 3 to 4, is the basis of harmony. Certain other considerations are, however, to be taken into account, but they are too recondite to be here dealt with. Let the reader refer to the original.

The lecture on the eye and vision is more extensive. It is divided into three parts—one considering the eye as an optical instrument, another the sensation of sight, and the third the perception of sight; that is to say, the sense of vision is dealt with from a physical, physiological, and psychological point of view. Here we cannot enter into a consideration of all the details of the function of vision, but the more important points are these:—What we call light is supposed to be due to the vibration of a hypothetical fluid universally present, which we term ether. These vibrations or waves travel excessively fast: some are high, some are low, but all travel at the same rate. All rays give rise to the sensation of heat, but some which give rise to heat do not, in the eye, produce the sensation of light; such waves are very long and high. Others again, which are very short, are characterised by powerful chemical properties, though hardly visible. Only the medium kind of rays produce the sensation of light. But even these differ among themselves—the longest visible rays are red; the shortest, violet; between we have all the colours of the rainbow. By a mixture of these, in certain definite proportions, we obtain white light.

But to convert these waves into sensations a peculiar organ is necessary. We shall not attempt to speak of the various structures in the eye necessary for accurate vision, but deal only with the sentient surface—the retina. The retina is essentially a nervous structure, and is, in fact, made up of ganglia such as are found in other parts of the nervous system; but we find the essential visual structure in the layer of what are called rods and cones, which in a certain way correspond to the pianoforte-looking keys in the organ of Corti. These rods and cones are all arranged perpendicularly to the surface, forming a regular mosaic, and each receives a slender nerve-filament. The impinging of the waves of ether on these gives rise to the sensation of light. But, as is well known, this is not the only stimulus to which these rods and cones, or rather the optic nerve, responds; a blow on the eye will give rise to the impression of a flash of light—here the nerve is excited by the sudden pressure, and the stimulus produces in the brain the usual effect of such stimulation, that is, the sensation we call light.

Space will not permit us to follow the philosopher further in his clear and interesting account of the physiology of vision. All of the lectures are exceedingly valuable and instructive, and we have only selected these as being more strictly medical than are some of the others. The fresh bloom is, perhaps, lost in their translation, for it is impossible to keep the freshness and *verve* of the original language in any translation; but they have all been rendered into good English, which is a great thing, and reflects credit on the translators. We heartily commend the work to such of our readers as may be fond of science in this guise.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

September 30.

REPORT OF MEDICAL OFFICER OF HEALTH—COMMENCEMENT OF CHOLERA.

An important report has just been presented to the Health Committee of the Liverpool Town Council by the Medical Officer of Health, Dr. Trench, concerning the action recommended to be taken by the Council as the port sanitary authority. At the present time vessels arriving in the port are inspected by the officers of Customs, and when any case of contagious disease exists notice has to be given to the mayor, in order that the infected person may by his authority be landed and removed to hospital, and the ship be disinfected. The arrangements under which this inspection is now carried out are so complete that Dr. Trench does not consider the appointment of any additional staff necessary at present. Should cholera break out, however, he advises that a staff should be extemporised for the daily visitation of the infected ships.

As to the establishment of a hospital-ship, he does not approve of this, because of the difficulty of communication between such an institution and the shore, and the consequent want of facilities for its management; but recommends the provision of a hospital for port sanitary purposes on the land bordering on a proposed quarantine area, and he recommends the Health Committee to put in force all the powers of compulsory purchase which they possess, in order to obtain as soon as possible a proper site for such hospital. He very properly represents the necessity for this as most urgent, considering the want of port hospital accommodation jeopardises the safety of the people. The hospital should be near where the ships are moored, be easily approachable by boats at all periods of the tide, and be so far removed from houses and public thoroughfares as to permit of complete isolation. He suggests that it should be a temporary construction of wood and iron, and that admission to its beds should be restricted to cases of cholera and choleraic diarrhœa, and that all other cases of infectious disease should be conveyed as at present to the workhouse hospital.

The report, of which the above is a short abstract, was written on August 26, and will be considered by the Health Committee at its meeting to-morrow (October 1). The consideration will not come too soon, for it is no longer a matter of question that fatal cases of cholera have been brought into the port.

These cases, four in number, were all imported from France, and their history, which is briefly as follows, seems to point to the necessity of much more stringent regulations than at present prevail bearing on the admission of possibly infected ships into dock:—One vessel, the *Rosaire*, on which there have been three deaths, put into Liverpool from Havre on her way to the West Coast of Africa on Sunday morning, and, having been boarded and examined by the Customs officers, was by three o'clock p.m. safely moored in the Georgia Dock. It then transpired that the captain was ill, and not long after this time two of the crew became ill also. No medical assistance was called until six the next morning, when Mr. Howard Pughe, F.R.C.S., was summoned to the ship. On Mr. Pughe's arrival the captain was not only dead but quite cold, and the two men, who had been subsequently seized, in a state of profound collapse, but without having suffered from diarrhœa. In a few hours these two men died, the one at 2 p.m. and the other at 8 p.m. yesterday—*i.e.*, the day on which they first became ill,—the disease having had a course of about eight hours in the first, and a little over twelve in the second case. There seemed to be a slight appearance of reaction after the first administration of remedies, but it quickly passed away. The three bodies were conveyed out to a distance and sunk in the sea last night, and the vessel then placed in strict quarantine, where she will be detained until the medical officer

of health is satisfied of her healthfulness. So far, then, as this ship is concerned, there has been no such communication with the town as would be likely to cause extension of the disease.

In the case of another ship the isolation of an infected sailor from it was almost as complete. This ship—the *Hortense Dusantoy*—came into port on Thursday last, the 25th inst., having called at Havre on her way hither. There seemed to be nothing in her condition to justify the Custom-house officers in putting her into quarantine and calling in the medical officer of health. On Saturday, however, one of her crew applied for admission to the Royal Southern Hospital, but, the case being judged suspicious, he was passed on immediately to the Toxteth-park Workhouse Hospital, where he died on the following evening. This man had severe choleraic discharges from the bowels, and was in a state of collapse when taken to the Royal Southern Hospital. Up to the present no further case has occurred; those which have occurred, however, are quite sufficient to prove that the time has come for the exercise of a stricter inspection than that carried out by the Customs officers.

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON.—The following is a list of the Candidates who have passed the recent First M.B. Honours Examination :—

Anatomy.

FIRST CLASS.

Pepper, Augustus Joseph, (Exhibition and Gold Medal), of University College.
White, Ernest William, (Gold Medal), of King's College.

SECOND CLASS.

Mercier, Charles Arthur, of London Hospital.

Physiology, Histology, and Comparative Anatomy.

FIRST CLASS.

Pepper, Augustus Joseph, (Gold Medal), of University College.

SECOND CLASS.

Jones, Arthur Henry, of Guy's Hospital.
White, Ernest William, of King's College.

Organic Chemistry, and Materia Medica and Pharmaceutical Chemistry.

FIRST CLASS.

Jones, Arthur Henry, (Exhibition and Gold Medal), of Guy's Hospital.
Pepper, Augustus Joseph, (Gold Medal), of University College.

SECOND CLASS.

Rogers, Thomas King, of University College.
Jones, Cyril Lloyd, White, Ernest William, } Equal. { of Guy's Hospital. of King's College.

The following is a list of the Candidates who passed the First B.A., First B.Sc., and Preliminary Scientific M.B. Honours Examinations :—

(FIRST B.A. AND FIRST B.Sc. CONJOINTLY.)

Mathematics and Mechanical Philosophy.

FIRST CLASS.

Hill, Micaiah J. M., First B.A., (Exhibition), of University College.

THIRD CLASS.

Edwards, Joseph, First B.A., Fawcett, William, First B.A., } Equal. { of Owens College. Private study.

(FIRST B.Sc. AND PRELIMINARY M.B. CONJOINTLY.)

Chemistry.

FIRST CLASS.

Thompson, Claude Metford, First B.Sc., (Exhibition), of University College.
Jones, John Viriamu, First B.Sc., of University College.
Christopher, George, First B.Sc., of University College.
Bedson, Peter Phillips, First B.Sc. and Prel. Sci., of Owens College.

SECOND CLASS.

Jones, David Rhys, Prel. Sci., of University College.
Hill, Samuel Alexander, First B.Sc. and Prel. Sci., of Royal School of Mines.
Davy, Henry, Prel. Sci., of Guy's Hospital.
Robson, Herbert, First B.Sc. and Prel. Sci., of University College.

THIRD CLASS.

Banks, William, Prel. Sci., Private Study.
Daniel, Alfred, Prel. Sci., Meek, John William, Prel. Sci., } Equal. { of University of Edinburgh. of Owens College.
Hopkinson, Charles, First B.Sc., Lodge, Oliver Joseph, First B.Sc. and Prel. Sci., Ryley, James, Prel. Sci., } Equal. { of Owens College. Private study. of University College.
Mears, William Pope, Prel. Sci., of London Hospital.
Harris, Thomas Frederick, First B.Sc., Private study.

Zoology.

FIRST CLASS.

Sheppard, Chas. Edward, Prel. Sci., (Exhibition), of St. Thomas's Hospital.
Daniel, Alfred, Prel. Sci., of University of Edinburgh.

SECOND CLASS.

Richmond, Charles Ernest, Prel. Sci., of Owens College.
Freund, Percy Herbert Edmund, Prel. Sci., of St. Thomas's Hospital.
Ray, Prasanna Kumar, First B.Sc. and Prel. Sci., of University College.

THIRD CLASS.

Stevenson, Leader Henry, Prel. Sci., of Guy's Hospital.
Nicholson, John Francis, Prel. Sci., of St. Thomas's Hospital.
Miller, Richard Shalders, Prel. Sci., of University College.

Experimental Physics.

FIRST CLASS.

Lodge, Oliver Joseph, First B.Sc. and Prel. Sci., Private study.

SECOND CLASS.

Sainsbury, Harrington, Prel. Sci., of University College.

THIRD CLASS.

Jones, David Rhys, Prel. Sci., of University College.
Jones, John Viriamu, First B.Sc., of University College.

Botany.

FIRST CLASS.

Banks, William, Prel. Sci., Cuming, Charles Henry, Prel. Sci., } Equal. { Private study. of University College.

SECOND CLASS.

Parker, William Rushton, First B.Sc. and Prel. Sci., of Caius College, Cambridge.
Jones, David Rhys, Prel. Sci., of University College.

THIRD CLASS.

Stevenson, Leader Henry, Prel. Sci., of Guy's Hospital.
Lloyd, David, Prel. Sci., Todd, John, Prel. Sci., } Equal. { of University College. of University College.
Barclay, Arthur, Prel. Sci., of University of Edinburgh.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Sept. 25 :

Churchward, Albert, South Penge-park, Anerley.
Rendall, John, 47, Trinity-street, Borough.

The following gentlemen also on the same day passed their primary professional examination :—

Golding, Reginald, St. Bartholomew's Hospital.
Hogg, Thomas B., Leeds School of Medicine.

At the Preliminary Examination in Arts held at the Hall on September 26 and 27,—108 candidates presented themselves ; of whom 32 were rejected, and the following 76 passed, and received Certificates of Proficiency in General Education—viz., in the first class, in order of merit :—

First : W. A. Sykes. Second : C. F. Campe, A. E. Cracknell, B. J. Guillemard, and R. E. Inman. Sixth : J. L. A. Hope, and W. Hugo, Eighth : W. J. Cant, D. Colquhoun, H. R. Dale, F. J. Driver, F. C. Gibbs E. P. Hayward, W. J. Milles, and B. Rigden.

In the second class in alphabetical order, viz. :—

R. W. Addems, A. Allen, N. Allsworth, W. W. Amsden, T. Baker, F. Bass, H. L. Bates, C. E. Beebe, A. S. Bradford, A. H. Bromilow, A. E. Clark, M. F. Cock, C. E. Cocksedge, C. Couzens, E. Cureton, L. W. Davies, W. C. Falls, W. Fowler, F. Frank, W. T. Freeman, E. Griffiths, J. L. Hall, J. T. Hay, W. B. Hodgson, H. Hopper, G. Hussey, N. Kingsford, H. J. G. L. Leith, H. J. Liebstein, M. E. Ling, A. P. Lungley, E. D. Maddick, C. Maunder, J. Montford, T. P. Morgan, H. B. Noble, G. E. Palmer, W. J. Parkinson, C. Plant, J. R. Purdue, F. F. L. Robertson, H. J. Scott, J. S. Scriven, F. J. Shaw, H. G. Statham, H. O. Stuart, E. Tatham, R. C. Thomas, T. F. Vaisey, C. J. Vlieland, E. C. Waller, M. Waite, A. S. R. Wainwright, E. C. Warren, T. F. Watts, J. M. Wheler, P. H. White, W. R. White, F. Wiles, H. Wilson, and A. L. Wing.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

PRESTON, WM., M.B. and C.M. Edin.—House-Surgeon to the Lancaster Infirmary and Dispensary, *vice* W. Berry, M.R.C.S. Eng., etc., resigned.

NAVAL APPOINTMENTS.

ADMIRALTY.—George B. Beale, and J. M. Hunter, Staff-Surgeons, second-class, to the *Fisguard ;* Mark A. Harte, Surgeon to the *Revenge ;* Alexander G. Bain, Surgeon to the *Northumberland*. Dr. Henry Fegan, Staff-Surgeon, 2nd class, to the *Active*. Dr. Samuel Campbell, Staff-Surgeon, 2nd class, to the *Devastation*.

BIRTHS.

ASHBURY.—On September 22, at Broxbourne, Herts, the wife of Charles John Ashbury, M.R.C.S. Eng., of a daughter.

BRADBURY.—On September 27, at Corpus-buildings, Cambridge, the wife of J. R. Bradbury, M.D., Linacre Lecturer of Physic, of a son.

FENN.—On September 23, at The Old Palace, Richmond, Surrey, the wife of Edward Liveing Fenn, M.D., of a son.

MARRIAGES.

BAUGHAM—DAVEY.—On September 24, at Frampton Cotterell, near Bristol, the Rev. T. A. Baugham, Prebendary of Lichfield Cathedral, to Frances Helena Mary, daughter of James George Davey, M.D., of Northwoods, Gloucestershire.

BUTLIN—BALDERSON.—On September 27, Henry Trentham Butlin, F.R.C.S., to Annie, eldest daughter of Henry Balderson, Esq., of Corner Hall, Hemel Hempstead, Herts.

COTTON—BIRNIE.—On September 23, at Kingston Church, Hants, John Cotton, M.D., Staff-Surgeon R.N. Hospital, Haslar, to Katherine Birnie, only daughter of the late James Birrell Birnie, Esq., and only surviving grandchild of the late Sir Richard Birnie, Kt.

DREW—MCINTYRE.—On September 23, at St. Stephen's Church, South Lambeth, William Thomas Drew, M.R.C.S. Eng., L.S.A., of Egham, to Mary, youngest daughter of the late Hugh McIntyre, Esq., of H.M. 3rd West India Regiment.

FENN—READ.—On September 30, at St. Peter's, Regent-square, W.C., George Keyworth Fenn, elder son of Thomas Fenn, Esq., of 14, Bedford-square, W.C., to Florence, youngest daughter of Reginald Read, F.R.C.P., L.S.A., of 1, Guilford-place, Russell-square.

GELL—DAVISON.—On September 26th, at the British Legation, Darmstadt, Thomas Silvester Gell, M.D., of St. John's Lodge, Kensal-green, W., to Jessie Elizabeth, only daughter of Frederick Davison, Esq., of 24, Fitzroy-square.

GRUNDAL—ROSENBLAD.—On September 24, at Trinity Church, Geneva, Adolf Grundal, M.D., of Stockholm, to Enriqueta Cumman, daughter of N. P. Rosenblad, Esq., of Buenos Ayres.

KOPPELOW—HALPIN.—On September 24, at the British Embassy, Berlin, Hermann von Koppelow, Lieut.-Col. 28th Regt. Rhenish Infantry, to Hetty, second surviving daughter of the late Charles Halpin, M.D., Cavan, Ireland.

LOWE—BARNSTON.—On September 30, at the parish church, Kidsgrove, Wm. Henry Lowe, M.D., to Emma, second surviving daughter of the late R. H. Barnston, Esq., of Crewe Hill, Farndon, Cheshire.

MACDONALD—JAMIESON.—On September 23, at Aberdeen, Donald MacDonald, M.D., Deputy Surgeon-General Bengal Army, to Isabella Jane, elder daughter of the late John Jamieson, Esq.

MURRELL—FENTIMAN.—On September 27, at the Church of St. Botolph Without, Aldgate, Herbert John Murrell, Esq., to Emily Alice, daughter of George Fentiman, M.D., Tower-hill, London.

OXLEY—GILMAN.—On September 23, at St. Peter's, Onslow-gardens, Captain Oxley, Madras Army, second son of Thomas Oxley, Esq., late Chief of the Medical Staff in the Eastern Settlements, to Mary Ann, third daughter of E. J. Gilman, Esq., of The Boltons, London.

SMITH—STANGER.—On September 25, at Hunstanton, John Elliott Johnson, fourth son of Joseph Smith, Esq., The Park, Nottingham, to Hannah Edith, younger daughter of the late William Stanger, M.D., Surveyor-General of Natal.

DEATHS.

BISHOP, JOHN, F.R.C.S., F.R.S., of 38, Bernard-street, Russell-square, at Strangeways, Marnhull, Dorset, recently, in his 76th year.

FRY, GEORGE, M.R.C.S., L.S.A., at High Beech, Loughton, Essex, on September 26, aged 53.

GOLDING, SARAH PELERIN, widow of Benjamin Golding, M.D., founder of Charing-cross Hospital, at her residence, 54, Cromwell-road, Kensington, on September 27, aged 74.

HODGES, the Rev. GEORGE BRUSHFIELD, eldest son of the late Edward Hodges, M.D., formerly of Bath and Kensington-park-road, at All Saints' Parsonage, East Clevedon, Somerset, on September 28, aged 32.

SKEY, ARTHUR, youngest son of the late Frederick Skey, C.B., F.R.C.S. Eng., F.R.S., on September 27, of typhus fever, aged 25.

THURNAM, JOHN, M.D., F.S.A., at the Wilts County Asylum, Devizes, very suddenly, on September 24, in the 63rd year of his age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BRIGHTON HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Applications, with testimonials, to the Secretary of the Medical Committee, at the Hospital, Dyke-road, Brighton.

CHELTENHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to E. T. Brydges, Clerk to the Urban Sanitary Authority, Public Offices, Cheltenham, on or before October 11.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—House-Surgeon. Candidates must be duly qualified and registered. Applications, with testimonials, to John Binks, Esq., Honorary Secretary, Wakefield.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Medical Officers, Candidates must be duly qualified. Applications, with testimonials, to P. Goldschmidt, Esq., Chairman of the Board, 100, Albert-square, Manchester, on or before October 15.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Candidates must be duly qualified. Applications, with testimonials, to the Treasurer, Robert Tweedy, Esq., Truro, on or before October 8.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Andover Union.—Mr. F. J. Hammond has resigned the Fifth District; area 15,043; population 2397; salary £65 per annum.

Peterborough Union.—Mr. J. B. Bodman has resigned the Castor District; area 7760; population 1470; remuneration 6s. per case.

APPOINTMENTS.

Barton-upon-Irwell Union.—Wm. M. Shearman, M.R.C.S. Eng., L.R.C.P. Edin., to the Swinton District.

Hemsworth Union.—Frederic T. Hindle, M.R.C.S. Eng., L.R.C.P. Lond., to the Fifth District.

Manchester Township.—Peter Tytler, B.M. and M.C. Univ. Aber., as Assistant Medical Officer at the Crumpsall Workhouse.

Rochdale Union.—Alexander Welsh, M.D. and M.C. Glasg., to the Whitworth District; Herod Turner, M.R.C.S. Eng., to the Spotland District and Workhouse.

Tendring Union.—Robt. C. Atthill, L.R.C.P. Edin., L.S.A., to the Seventh District.

WE are requested to announce that the ophthalmic operations at St. George's Hospital will for the future be performed on Fridays at 1.15, instead of on Wednesdays as formerly.

SMALL-POX is very prevalent in the neighbourhood of Market Lavington.

MORE than forty Port Sanitary Authorities have been constituted by the Local Government Board for English harbours.

IN November last, Mr. Hayward, the District Surveyor of the Parish of St. Giles, returned no less than 170 underground rooms as illegally occupied. At the present time there is not, reports Dr. Ross, the Medical Officer of Health, a single underground room illegally occupied in the district—the result of great efforts which have been made to prohibit the use as sleeping-rooms of all such places as have been occupied contrary to law.

THE Portumna Board of Guardians have increased the salary of Mr. James Pelly, Medical Officer for the Eyre-court Dispensary District, from £100 to £120 per annum, and that of Mr. William H. Blackton, Medical Officer for the Drummin Division of the Portumna and Drummin Dispensary District, from £33 6s. 8d. to £40 per annum.

Cholera in a severe form manifested itself on board the emigrant ship *Assyria*, which took from Calcutta to Madras, *en route* for Trinidad, 247 emigrant coolies or labourers. The ship, in proceeding to Madras, took on board a heavy cargo of *rice* (mark this!); the vessel was overloaded, the coolies crowded, diarrhœa broke out, and then cholera. The men were transferred to the *Pandora*, and sent up the coast to be put ashore in tents, and the *Assyria* ordered out to sea; but eight deaths had occurred already by August 31.

UNIVERSITY OF CAMBRIDGE.—Professor Humphry gives notice that the course of lectures on Practical Anatomy will commence on Wednesday, October 8, at 9 a.m., and be continued daily. The course of lectures on Anatomy and Physiology will commence on Thursday, October 23, at 1 p.m., and be continued on Tuesdays, Thursdays, and Saturdays. The dissecting-room will be open from October 1.

THE LATE DR. NÉLATON.—Amongst the distinguished men who attended to pay their last respects to this great and good member of our profession was the President of the Royal College of Surgeons, Mr. Thomas Blizard Curling, F.R.S.—a compliment to M. Nélaton's memory and to French surgery which was duly appreciated by our French friends, and no doubt will be warmly approved by Mr. Curling's colleagues at the College.

ROYAL COLLEGE OF SURGEONS.—The calendar of this institution has just been published, from which it appears that during the past collegiate year the Council or governing body of the College, which consists of twenty-four members, have held fourteen meetings, the fees paid to them amounting collectively to £231. The Court of Examiners, which consists of ten members elected by the Council exclusively from the Fellows of the College, held six meetings for the examinations for the fellowship, and fifty-two meetings for the primary and pass examinations for the membership. The fees paid for this heavy duty amounted to £3952 14s. 6d.—not by any means an exorbitant sum, especially to those having large practices, when the time necessarily occupied, often to a late hour in the evening, and during the most profitable time in the morning, is considered. The following statement of the number of candidates who presented themselves for the fellowship and membership respectively, with the results of the several examinations, will no doubt be read with some interest:—For the first-named distinction 90 candidates offered themselves at the primary examination; of this number 54 passed, and 36 were referred for six months. At the "pass" 33 were examined, of which number 19 passed and 14 were referred for one year. For the primary examination for the membership in anatomy and physiology, 702 candidates were examined; 503 were successful and 199 referred for three months. At the "pass" examination in surgical anatomy and the principles and practice of surgery and medicine there were 462 candidates; of this number 323 passed, 54 were approved in surgery but not admitted members until qualified in medicine, 60 were approved in surgery who afterwards qualified in medicine, and 85 were altogether rejected. The total number of diplomas granted amounted to 383. The Board of Examiners in Midwifery consists of four members; only two meetings were held to examine 18 candidates, half of whom passed, 6 were referred for three months, and 3 to a written examination. The fees paid to the Board are represented by the modest amount of £19 12s. The Board of Examiners in Dental Surgery consists of six members. During the year 16 candidates were examined, all of whom passed to the satisfaction of the Board, who appear to be better remunerated than the obstetric department, as for examining a less number of candidates they received more than double—viz., £42. The income of the College during the past year from all

sources amounted to £13,311 16s. 5d., and the expenditure to £12,276 6s. 2d. The analysis of the receipts and disbursements appeared in the *Medical Times and Gazette* recently.

MIDDLESEX HOSPITAL MEDICAL COLLEGE.—The prizes were distributed by Mr. Ross, Chairman of the Weekly Board. After the introductory address by Mr. Morris, Dr. Murray was able, as Dean, to present a most favourable account of the condition of the School. Scholarships and prizes, sessions 1872-73.—Broderip Scholarships, for the best examination at the bedside and in the post-mortem room: First, Mr. Samuel J. J. Kirby; second, Mr. Arthur Tomes; Governors' Prize, Mr. Arthur Tomes; Clinical Prizes, Mr. Henry Jackson and Mr. F. M. Williams (equal); Medicine, Mr. S. J. J. Kirby; Pathological Anatomy, Mr. Arthur Tomes; Anatomy, Mr. Alexander T. Scott; Surgery, Mr. E. F. Kissack; Practical Surgery, Mr. Arthur Tomes; Physiology, Mr. J. W. B. Mason; Chemistry, Mr. G. Sherman K. Bigg; Midwifery, Mr. J. W. B. Mason; Materia Medica, Mr. T. Cambridge; Practical Chemistry, Mr. W. Walker; Dissections, Mr. G. C. Karop; Medical Jurisprudence, Mr. J. W. B. Mason; Botany, Mr. A. Lucas; Practical Physiology, Mr. W. Walker; Psychological Medicine, Mr. Alexander T. Scott; Medical Society's Prizes, Mr. A. Tomes and Mr. S. J. J. Kirby. Entrance Scholarships, October, 1872: First, Mr. Reginald Paul; second, Mr. Walter Scott Thomson. Certificates of Honour: Mr. William E. Cree and Mr. William M. Beaumont in Clinical Knowledge; Mr. Arthur Tomes in Medicine; Mr. S. J. J. Kirby in Practical Surgery; Mr. David Hepburn in Anatomy, Physiology, and Surgery; Mr. George C. Karop in Anatomy and Physiology; Mr. J. W. B. Mason in Anatomy; Mr. Walter Scott Thomson in Chemistry; Mr. A. T. Scott in Forensic Medicine; Mr. E. Price in Materia Medica; Mr. T. Cambridge, Mr. G. Clements, and Mr. E. Price in Botany; Mr. Percy Cree in Practical Physiology; Mr. S. J. J. Kirby in Comparative Anatomy.

PEPPERMINT AND SEWAGE IRRIGATION.—M. Stanislas Martin, the well-known *pharmacien*, writing to the *Bull. de Thérapeutique*, September 15, draws attention to the great success which has attended the cultivation of this plant at Gennevilliers (see also *Medical Times and Gazette*, July 12, page 39), formerly an arid plain enclosed by one of the bends of the Seine, now a fertile garden. This has been brought about by sewage irrigation, in spite of enormous prejudices, which at one time were so great that land which now pays a heavy rental was obliged to be given gratis, in order to try the experiment. The success has been complete, as the vegetables grown attain an enormous size, and M. Martin submitted some of these to a comparative analysis. He found that the ashes of some of the plants which had undergone irrigation were richer in mineral principles than those cultivated by ordinary procedures. M. Chardin, a Paris perfumer, has utilised the sewage for the cultivation of labiated plants, and found the result so productive that he has had this year three hectares of land employed in the culture of peppermint. So vigorous was the growth, that he has had three crops in the year, and the essence produced by distillation is, he states, far superior in delicacy of aroma and taste to that imported from England, which is so renowned.

BEEF-TEA.—The Philadelphia Obstetrical Society recommend the following formula:—Mince with a sharp knife one pound of juicy lean beef, and put it with its juice into an *earthen* vessel containing a pint of tepid water, letting it stand for two hours. Strain through a clean cloth, squeezing well the meat and adding a little salt. Place the juice thus obtained over the fire, but remove it as soon as it has become browned. Never let it boil; otherwise most of the nutritious matter will be thrown down. Prepared in this way, the whole nourishment of the beef is retained in the tea, making a pleasant and palatable food. A little pepper or allspice may be added if preferred. The *Philadelphia Medical Times* (June 21) enters its protest against the statement that this or any other beef-tea "contains the whole nourishment of the beef." So prepared it can only contain such matters extracted from the meat as are soluble in water, the fibrin, muscular fibre, etc., being left behind, whilst kreatinin, carnin, and other products of destructive metamorphosis, with the inorganic salts, are dissolved. The only nutriment contained in this solution is albumen, and three drachms of this may be precipitated from a pint by nitric acid. "We do not mean to deny the value of beef-tea when properly used. We do mean to insist that as a food it is an extremely wasteful preparation, and that to tell the poor of a community that they are giving to their children all the nourishment of the beef in giving them beef-tea is to practise unwittingly a great fraud upon them. Moreover, we desire to call the attention of physicians to the fact that beef-tea contains so much potash that when given in large quantities it is a medicinal agent, and can only be intelligibly employed with a direct appreciation of this fact."

AN anonymous donor has placed a large sum in the hands of the Committee of the Birmingham and Midland Institute, for the foundation of a Lectureship on the Laws of Health, and also for a prize fund in connexion with the class. Dr. Corfield has been offered the post for this year, has accepted it, and will deliver an inaugural lecture in the Town Hall, Birmingham, on Thursday, October 9, at 8 p.m., on "Sanitary Progress." The course will begin on Tuesday, October 14, at 8 p.m., and be continued on succeeding Tuesdays until some time in April. It is intended more especially for the working classes, and both men and women will be admitted.—*Nature*.

QUICK WORK.—They have rather a rapid way of living and dying in Memphis. Dr. Miller relates a sprightly incident: At seven o'clock a man went to market, bought his breakfast, went home, cooked it, and was eating it when he was taken with cholera. He sent for Dr. Miller, who visited him at nine, prescribed, and told him that he would be back in an hour. At a quarter past ten he returned. The man was not only dead, but had been buried, and his room swept and garnished for another occupant.—*Boston Journal*, August 1.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN SEPTEMBER, 1873.—The following are the returns (by Dr. Letheby) of the Society of Medical Officers of Health:

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
Thames Water Companies.	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	—	—	—	—	—	—
West Middlesex	17·03	0·034	0·098	0·001	13·5	3·6
Southwark & Vauxhall	17·10	0·039	0·106	0·002	13·5	3·3
Chelsea	17·56	0·041	0·125	0·001	14·0	3·3
Lambeth	17·57	0·046	0·104	0·002	13·8	3·3
Other Companies.						
Kent	28·17	0·004	0·196	0·000	21·8	5·6
New River	17·17	0·023	0·110	0·000	13·6	3·0
East London	16·83	0·038	0·126	0·002	13·5	3·0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was very slightly turbid—namely, in those of the Southwark and Vauxhall, and the Lambeth Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 126,240,210 gallons; and the number of houses supplied was 504,905. This is at the rate of 37·7 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 24·9 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

The returns of the Grand Junction Company have not been received.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Chundar Coomar Dey, Calcutta.—Enclosure received.

Iota.—In our opinion, very objectionable.

Dr. Hartsen, Cannes.—We are glad to say, much improved.

A Provincial Student.—Registration is made at your school, and returns forwarded to London. Only metropolitan students have to attend at the College and Hall. It commenced on Wednesday last, 1st inst.

Beta.—The primary examination-papers, including those of the examination you passed, are published in the Calendar of the College of Surgeons, just out. You will find also those given at the pass examinations for the Fellowship and Membership.

Veritas.—The coroners' returns show that last year there were 1455 cases of suicide—1057 males and 398 females.

Vegetarian.—The average quantity of meat brought into London weekly from all sources, according to a recent report by the Superintendent of the Metropolitan Meat Market, was 2836 tons, of which 1335 tons were foreign and town-killed meat, and 1501 country.

Hure.—The report of the Sewage Committee of the British Association was in favour of irrigation, and against the theory that entozoic disease is propagated by the process.

A Subscriber.—Yes; we understand that the London members of the theatrical profession have subscribed upwards of £100 towards the proposed testimonial to Sir William Fergusson.

J. F. B.—Dr. J. Batty Tuke, Edinburgh, has been appointed by the patron, Dr. A. Morison, to the Morisonian Lectureship on Insanity in the Royal College of Physicians, Edinburgh.

Lyton.—A sanitary association for all Germany has been formed at Frankfort-on-the-Maine.

Fred S. A.—Coste, the celebrated naturalist, was almost sightless at the last, having destroyed his vision with the microscope. He was in his 66th year when he died.

Joseph P.—The late M. Nélaton's son is studying for the profession. He has passed his first examination in medicine. He is twenty-two years of age.

Nolens Volens.—Tom Hood's Ode to Dr. Hahnemann, the homœopathist—

"Doctor, forgive me if I dare prescribe
A rule for thee, thyself, and all thy tribe,
Inserting a few serious words by stealth.
Above all price of wealth,
The Body's Jewel—not for minds profane,
Or hands to tamper with in practice vain—
Like to a woman's virtue—is man's health,
A heavenly gift within a holy shrine!
To be approached and touched with serious fear
By hands made pure and hearts of faith severe,
Even as the priesthood of the *One* divine."

COMMUNICATIONS have been received from—Mr. J. Clay; Mr. A. Gamgee; Dr. Berry; Mr. E. O'Connell; Dr. John Harley; Mr. H. Jackson; Dr. Charlton; Mr. H. Lloyd; Dr. Tate; Mr. W. A. Goward; Dr. Alexander Harvey; Dr. Edgar Sheppard; Mr. E. Bellamy; Mr. Hinton; Mr. Scatterogood; Mr. Cowell; Dr. Chundar Coomar Bey; Dr. Latham; An April Fool; Mr. W. J. Marsh; Mr. J. Vincent; Dr. Hartsen; Dr. Caton; Dr. Letheby; Professor Humphry; Dr. Luke Armstrong; Mr. H. E. Armstrong; Mr. C. F. Maunder; Mr. J. Chatto; Dr. Bruce; Dr. Hans Lloyd; Dr. J. Laing; Mr. Thomas Scott.

BOOKS RECEIVED—Budfield's Report on the Health of St. Mary Abbotts, Kensington, for the year 1872—St. George's Hospital Reports, vol. vi.—Choléra, Préservation et Traitement par le Cuivre, par le Dr. V. Burg—Smith's Lectures on the Clinical Uses of Electricity—The Proper Treatment of Children, Medical or Medicinal: being the Annual Discourse before the Massachusetts Medical Society, June 4, 1873, by Dr. C. E. Buckingham.

PERIODICALS AND NEWSPAPERS RECEIVED—Lancet—British Medical Journal—Nature—Bell's Weekly Messenger—La France Médicale—Le Mouvement Médical—Gazette Médicale—Le Progrès Médical—La Tribune Médicale—Pharmaceutical Journal—Allgemeine Wiener Medicinische Zeitung—Le Bordeaux Médical—Gazette Hebdomadaire—Indian Medical Gazette—Science Gossip—Popular Science Review—Monthly Microscopical Journal—British and Foreign Medico-Chirurgical Review—The Obstetrical Journal of Great Britain and Ireland, No. 7, October—Public Health—Students' Journal and Hospital Gazette—Bulletin Général de Thérapeutique—Hampstead and Highgate Gazette—Medical Press and Circular—London Medical Record.

APPOINTMENTS FOR THE WEEK.

October 4. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

6. *Monday.*

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

7. *Tuesday.*

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

8. *Wednesday.*

Operations at University College, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

9. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

Hunterian Society (London Institution), 8 p.m. Dr. Sutton, "Cases of Typhoid Fever."

10. *Friday.*

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 27.

BIRTHS.

Births of Boys, 1137; Girls, 1097; Total, 2234.
Average of 10 corresponding years 1863-72, 2070·8.

DEATHS.

	Males.	Females.	Total.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	30·101 in.
Mean temperature	54·4°
Highest point of thermometer	72·5°
Lowest point of thermometer	38·2°
Mean dew-point temperature	47·1°
General direction of wind	Variable
Whole amount of rain in the week	0·00 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, September 27, 1873, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1873.*	Persons to an Acre. (1873.)	Births Registered during the week ending Sept. 27.	Deaths Registered during the week ending Sept. 27.	Temperature of Air (Fahr.) Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values.	Temp. of Air (Cent.) Weekly Mean of Mean Daily Values.	Rain Fall. In Inches.	In Centimetres.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·61 in. The highest was 30·36 in. on Monday morning, and the lowest 29·74 in. at the end of the week.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ABSTRACTS OF

THE INTRODUCTORY ADDRESSES DELIVERED AT THE OPENING OF THE MEDICAL SCHOOLS.

THE MIDDLESEX HOSPITAL.

The Introductory Address was delivered by Mr. Henry Morris, who, after a few words of welcome to the students, proceeded to describe the nature of the studies requisite for the profession of medicine.

"To be an accomplished workman at any craft requiring skill and intelligence you must know the nature both of the material you work upon and of the instruments with which you do the work. Now, the materials upon which as surgeons and physicians you will be engaged is no less than man himself—no less than the very crown of creation. Your subject matter is the same as that of the divine, the lawyer, and the politician; and though it is with different parts of that subject matter that each of these workers is primarily engaged, yet so connected are the tendencies and attributes of human nature that there is no distinct boundary for the one or for the other. The divine, however, is most concerned with man's moral nature and his relation to the Deity; the lawyer with man's acts and rights in his relation to his fellow-man; the politician with man's relations as a member of an independent community, and to the government which presides over that community; while the doctor has to do with man's body and mind in so far as they depart or are prone to depart from the condition known as health: with the relations of each of these to the other, and of the different parts of each to one another. All work separately, and sometimes ought to work conjointly, for man's good. There is, however, this difference between the divine and doctor on the one hand, and the lawyer and the politician on the other: with the two latter, the good of man collectively—that is, of the whole community of which he is a member—is the end to be secured, and the good of the individual is sought secondarily through the general good. The motto of these professions is or should be that of Bentham—viz., 'The greatest good of the greatest number': whereas with the former two the welfare of the individual is the first consideration; but as the safety and well-being of each individual is desired by them, so they too, but in a manner secondarily, work for the good of all.

"There is again a marked difference in the public recognition of the secondary duties of these two professions; for while those of the divine are, as they deserve to be, fully and appreciatively acknowledged—while the clergy have direct representation in the Upper House of the legislature, and numerous posts of honour and emolument for those entrusted with the State functions of their profession—the secondary, but still most important, duties of the doctor are for the most part either ignored by or unknown to our rulers, and the State functions of medicine get but trifling honour and scanty remuneration. This no doubt is partly accounted for by the fact that in ancient times exclusive attention was given to politics, morals, and law; and in more Christian times and countries to these subjects and to theology. The blind and inveterate prejudice of old, which considered the study of matter derogatory to man's dignity, and the superstition of religion, which till quite recently has been the irreconcilable foe to the investigation of nature, have no doubt delayed the recognition of the good to the community at large which medical men are able to effect. It required the Reformation to emancipate States and Corporations from the fetters of the Church, and it was only by the same great revulsion of all the elements of intellectual life that the rights of those sciences of observation and experiment upon which modern medicine is founded were established in the schools of philosophy. Nevertheless, you must know that it is both the individual and the social well-being of man that will be your care in life.

But what is man? I have already implied that he is a being composed of body, mind, and spirit. But what is his body? It is a vast and complicated assemblage of physical facts, and it has life; hence it involves a large number of chemical, mechanical, and vital processes. It has form intricate and varied in its details, and allied in its different parts to the forms of other beings; it is composed of structures, the functions of each of which are of importance in themselves and in their relations to the functions of other structures. For these reasons you must study chemistry and natural philosophy, human and comparative anatomy, botany, and physiology; and a knowledge of these subjects furnishes to the student of medicine that illumination which was needful to raise so complicated a science out of the abyss of blind empiricism. But these structures and functions and this form of man are liable to change, derangement, and decay; hence the necessity of a knowledge of morbid anatomy and pathology—subjects which in these latter days of medicine have made particular progress, and which, strange as at first sight it may appear, blend in a marvellous manner with the study of life and history. It was by the light of pathology that that eminent master of positivism, M. Littré, in some interesting essays on medical men and medical topics, attempted to show that the demonology and sorcery of the middle ages, and the table-turnings and spirit-rappings of our own day, are logically connected with certain states of mental disease. Next, what is man's mind? It is made up of sensations, emotions, will, and intellect. Through the sensations he is made aware of the states and conditions of his body, and its surroundings. By his emotions he experiences love, hate, fear, anger, and remorse, and when any of these are excessive or perverted, he becomes debased and lowered in his moral nature, or he ceases to be a responsible agent and to possess a sane mind in a sound body. Through his intellect, his will is appealed to, both by education and advice, to aid our efforts in the prevention and remedying of those pernicious changes to which the structures and functions of his body and the sensations and emotions of his mind are subject. Therefore you ought to become familiar with psychology, both normal and morbid, a science strictly and importantly connected with medicine, but one to which I venture to think sufficient attention is not given except by those who make mental diseases their special study. So much for the subject matter of your work. But besides the subject matter, it is requisite that you know well the means at your disposal for influencing and acting upon it. For this purpose you must study:—1st. Materia medica, which gives a descriptive account of drugs, and of their effects upon the human system. 2nd. The art of therapeutics, which instructs how to substitute physiological for pathological actions other than by the agency of drugs. 3rd. The various kinds of surgical instruments and appliances.

"Thus I have now enumerated the several subjects, a knowledge of which is necessary for the scientific and enlightened study of medicine, surgery, and midwifery, for the safe and intelligent practice of your profession. But there are two offshoots from this great tree of medicine to which your attention must be especially drawn. I just now said that the provinces of the lawyer, politician, and doctor are in places so closely connected that they sometimes quite encroach on one another. So true is this, that we have a branch of law medicine—viz., medical jurisprudence; and another of State medicine—viz., the science of public health. Both are of the highest importance. A knowledge of the former will but rarely be demanded of you; yet it is absolutely requisite, because the committal of any error therein will be very damaging to your reputation, both on account of the gravity and publicity of such a mistake. The latter—State medicine or public health—is one of the very corner-stones of the social safety of mankind. But, strange to say, it is far from taking that position which even any tyro in political science would give it if he were modelling out a perfect political society. When hundreds—nay, thousands—of our fellow-countrymen are annually destroyed by preventable diseases, no one can, I think, deny that the want of a properly adjusted system of sanitary medicine is one of the greatest imperfections of our political community. Preventive medicine we hear spoken of as one of the subjects of the day, and (with shame let it be admitted) so it is. Instead of working invisibly but efficiently, as an agency of prevention should work, we have lately seen it 'humbly petitioning' a Minister of State that it might be entrusted to competent authorities; and now we see it groaning under an Act of Parliament which has excited surprise, dissatisfaction, and indignation.

"For years the profession has been considering the question how to preserve health by preventing disease, and many of its leading members have devoted much time and labour to its solution. More than twenty years ago one of the consulting physicians of this Hospital (well known for his contributions

to our knowledge of specific fevers), on a similar occasion to this, completely refuted the reproach with which medical men are ignorantly taunted—viz., that they live by disease, and therefore naturally cannot be expected to bestir themselves in its prevention; as though medical men have ever refused to check the distribution of a justly suspected cause of epidemic poison until they were compensated for the pecuniary loss which would accrue to them! There are many highly informed men who possess both the knowledge and the will to bestir themselves (however suicidal their efforts to the selfish interests of their profession) to make our nation a more healthy and vigorous one than it is. But the truth is—and sooner or later it must be acted upon—that this knowledge is technical and minute, and cannot be suddenly implanted, at the instance of the Local Government Board, in the minds of men not specially trained for it. It is not to be wondered at that diseases which ought never to arise, or at least to spread, do nevertheless flourish amongst us while the present unsatisfactory system exists. We see at home the medical officers of district schools and the medical health officers subject to the opinions of lay inspectors who are unacquainted with the fundamental principles of sanitary science. We hear from abroad that in an African settlement, where the drainage and water-supply are recklessly neglected, and where small-pox and fever are rampant, not only is the sanitary inspector not a medical man, but the administrator is a military man, who first erected an arrangement for accumulating stinking refuse of all kinds under the nostrils of the residents, and then complains that he finds doctors the very bane of his existence, and that as long as he holds the reins he will have matters his own way!"

The kind of preliminary education best suited for those destined to recruit the ranks of medicine was next discussed. After stating that education meant much more than the study of books and the lessons of teachers, and quoting Locke to show that its purpose is as much to form the character as to train the intellectual faculties, the lecturer continued—

"It appears to me that we are living at a time when two opposite erroneous answers are given to this question. On the one hand there are those who, while they adhere to the old method of classical education, wish to superadd to it modern languages and nearly the whole range of natural sciences: after this manner has the matriculation of the University of London, in my opinion, erred. On the other hand, there are those who would give youths unchecked liberty of selection, and would not submit them to any kind of regulations, for fear of warping their genius or destroying their individuality and tendency to self-cultivation. . . . . But all candidates for a profession or for any calling which opens up social or intellectual distinction should be made to pass through a course of study, and a test which is general without being diffuse, and accurate without being special. . . . . To permit the unguided following of the mind would be to establish a system for the cultivation of specialities, and this would lead to the production of a large number of men of one book—'*cave ab homine unius libri.*' If the natural sciences are to constitute the leading feature of school education, they also will conduce to a very one-sided development of the mind. Moreover, considerable knowledge of natural sciences is quite compatible with a very insufficient standard of mental refinement and culture. The same, too, may be said, with even greater truth, of modern languages. On the other hand, it is universally admitted that a mixed classical and mathematical education is a humanising and refining one; that it occupies a most useful place in our national life, and that narrowness of mind and fanaticism are too often associated with the want of it. . . . . As a method of mental training the classics are considered by many authorities on education, such as Mr. Matthew Arnold, Mr. Goldwin Smith, and Mr. Mill, to have a greater power than any other; and certainly, so far as I am aware, no one has ever attempted to prove that in this respect any other system is superior to the classical. For these reasons, then, I feel sure it was a happy day for medicine when this kind of education was insisted on as the portal to the profession; and those in authority ought, I think, to look well about them before they talk of modifying or changing it." Having outlined the preparation requisite for the study of the profession, the method necessary for correctly following it was next considered.

"In the ancient schools of medicine there were, according to Celsus and Gregory, two distinct classes—the Dogmatici and the Empirici. The former did not reject the teachings of experience, but held that modes of treatment ought to be founded on some intelligent design; the latter professed to be guided by the experience of tried modes of treatment only, without any inquiry into the causes of disease, and without paying any attention to anatomy, physiology, or pathology, such as these subjects were at the time. The one school was therefore founded on an abuse of theory; the other on an exaggerated estimate of experience, too often only another name for chance. In the 'Novum Organon' we find the following aphorism upon the errors of these two schools:—'Qui tractaverunt scientias aut empirici aut dogmatici fuerunt; empirici, formicæ more, congerunt tantum et utuntur; rationales aranearum more, telas exse conficiunt: apis vero ratio medea est, quæ materiam ex floribus horti et agri elicit; sed tamen, eam propria falcutate vertit et digerit.'

"In this clever metaphor we have both a beacon as to what we must avoid and a guide as to what to follow. We must neither do as the ants, which only lay up and then use their store, nor as the spiders, which spin all out of themselves; but as the bee, which takes the middle course, and after gathering from abroad digests and arranges by its own faculty all that it has gathered. We must avoid the mistakes of the 'doctrinaires' and of the self-styled 'practical men.' We must avoid both false theory and blind empiricism. We must neither base our practice on *à priori* notions nor neglect to draw inferences from experience. We must purify our minds from all preconceived ideas and traditional prejudices, and then observe facts with acuteness and accuracy, and interpret them with wisdom. For this we must be both theoretical and practical.

"Theory, properly so called, is but a shorthand note to register a principle without which we could make but little progress. A theory—not a hypothesis or a guess,—when once framed, enables us to go on with our investigations without burthening our minds with the details of the particular instances whence it was drawn. . . . .

"Understand clearly, however, that yours is a practical, not a speculative science. Perhaps it is more correct to call it a scientific art. At any rate, medicine, like most of the sciences subsidiary to it, is a science of pure observation. It is a thinking exploration of man in health and in disease. It is a scientific study of facts through the faculty of observation. You must know how to observe that you may describe facts, and how to reason upon that you may explain and predict them. . . . . It is because of the constant demand upon the faculty of observation in medical men that each medical student ought to ask himself, 'How ought I to observe?' 'What are the methods of observing?'

"There are two kinds of observation at our service in the study of medicine—viz., the unassisted and the assisted. Unassisted observation is made by our senses without any arrangement for increasing their power. Assisted observation is that which is made by our natural senses aided by some artificial contrivance; such is observation with the microscope, the stethoscope, the laryngoscope, the ophthalmoscope, the sphygmograph, and the thermometer, and all the other various instruments with which the ingenuity of modern science has supplied us. But as with our modes of observing, so with the facts we have to observe: they may be of the simplest or most complicated character. Many are so obscure and so inaccessible that even with highly educated organs, and these, too, assisted by the most approved apparatus, we find it difficult—nay, but too often impossible—to introduce light and order into the chaos which defies it. And this difficulty is the greater because of the nature of the phenomena we are occupied with. This is such that we cannot employ a third method of observation much more precise and certain than the others I have mentioned: I mean observation under experiment. It is true that *disease* often makes up for this deficiency in our methods. Still, experimentation itself is for the most part quite unavailable in our investigation of cause and effect. Even if society and morality permitted the use of means by which we can artificially produce, or mingle, or modify phenomena, experimentation would have no significant place in medicine. So great is the solidarity (to use an expression introduced by M. Comte) in a human being, so difficult is it to study the various forces by which body and mind are influenced, that we cannot consider man's physiology apart from his mental and moral phenomena. We cannot study the normal, let alone the abnormal processes of digestion,

nutrition, or circulation, without reference to the moral and mental laws by which they are often influenced.

" ' All served, all serving, nothing stands alone :
The chain holds on, and where it ends—unknown.'

Nor can we separately examine the different organs composing man's body without destroying the very thing it is our aim to preserve—the perfection of the whole and of each part of that body ; because in

" ' Following life in creatures we dissect,
We lose it in the moment we detect.'

Now, the two methods of pure observation—the unassisted and the assisted—may be either unintentional or intentional, or, as, Herschel has described them, ' passive ' or ' active.' Unintentional or passive observation is of those phenomena which present themselves unsought to the observer. The only thing required for it is attention. The phenomena must be attended to, otherwise no impression of them will remain. Now, it is this faculty of attending to the facts and incidents which come before them without anticipation which has so much to do in making men good observers. Therefore, in the exercise of your calling—in fact, at all times and in all places—you should be on the alert to make little mental pictures and memoranda of all that occurs in the range of your senses. Newton, that leviathan in the exact sciences, has recorded his opinion that it was this habit of observation and attention which distinguished him from other men. It is this same habit which has characterised all men who have made themselves eminent in practical pursuits. It has existed as a natural gift in many eminent medical men. . . . . In active or intentional observation we do more than pay attention to accidental impressions : we observe in a definite matter with a definite purpose ; we select the phenomena to which we intend to attend, and we prepare ourselves for the process. We therefore exercise choice, intention, and attention. Observation when thus employed becomes investigation. This is the method of our deliberate examination of medical and surgical cases—of our researches in the dissecting-room and in the post-mortem theatre. It is too, of course, the nature of nearly all assisted observation ; for the mere fact that we are using means by which we increase the power of our senses implies the condition of choice, intention, and attention. Still, assisted observation may be unintentional as well as intentional ; and then the importance of attention again comes into special prominence. Thus, if we use the laryngoscope to remove a foreign body, we may at the same time accidentally observe an ulcer or a new growth ; or if we use the stethoscope to examine the lungs, we may unexpectedly hear the bruit of heart disease.

"In the exercise of intentional observation there are three dangers to avoid—first, the non-observation of things or parts of things we ought to observe, *i.e.*, their oversight ; secondly, the observation of things to the point, but in an imperfect manner ; and thirdly, the observation of things not to the point. . . . . All these errors you must try to avoid. The first you will escape by patience and sustained attention ; the second, by care and thoroughness ; and the third, by ascertaining what is and what is not relevant to the subject in hand, and directing your thoughts to what is important. But there is a fourth trap into which the ignorant and unwary are apt to fall—viz., the mistaking inference for observation. It is impossible to deny that in observing—and still more in description—inference is intimately blended with facts ; but for all that, when we make an assertion we ought to know how much of it is observation and how much inference from observation. . . . . This error depends upon the want of good mental development, so that the best way for us to avoid this fallacy is to bring to our profession minds as highly cultivated as possible. And here we have, I think, a strong argument in favour of early training, being, as I have advocated, accurate in mode rather than useful in purpose. Let us teach youths first how to know ; and knowledge itself will readily be gained by them afterwards. The conclusion, then, from these remarks is,—that to observe well we must educate thoroughly our organs of sense ; that as we have ears to hear, eyes to see, and hands to touch, we ought so to train and discipline them that they reach the highest possible degree of perfection. But we must not only see sights, hear sounds, and touch surfaces ; we must, in addition, perform all kinds of mental analyses and syntheses of the facts we observe, treating them as words and letters, resolving the former into their component letters, and building up the latter into words. To do all this requires great sagacity and sound judgment, and good powers of reasoning and paying attention."

The importance of holding hospital resident appointments was insisted on as the surest and best way of becoming practically acquainted with medical and surgical cases ; of gaining an insight into the discipline and management of a large medical institution ; and of giving the holder of these offices that most inestimable of all qualities for a doctor—self-reliance, based on conscious knowledge. For the guidance of those who would shortly leave the medical school and enter on the responsibilities of practice, the lecturer said,—" First, never forget to uphold the honour and dignity of your profession. You will not succeed in this by boasting and self-assertion ; but by an unobtrusive yet confirmed consciousness of the respect due from you and others to it, by shunning charlatanism and professional insincerity, and by not allowing self-interest to lead you as surgeons and physicians into representing a thing as plausible merely because it is popular. Know that you will owe much to your profession, and the best acknowledgment of your debt is to act honourably in and towards it. Bacon has said, ' I hold every man to be a debtor to his profession : from the which as men of course do seek to receive countenance and profit ; so ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto.' Secondly, endeavour in your professional capacity to raise the intellectual and sink the emotional side of your nature as much as possible. I do not mean, of course, by this that you are not to exercise sympathy and charity—which are two great weapons in the armoury of medicine. But these are not true emotions. Sympathy is the idea of pain in others, irrespective of pleasure or pain in ourselves, and it involves both the intellect and the will ; while real true charity is the intellectual recognition of the misery and want of others combined with the exercise of the will for their removal. But as the possessors of knowledge which is to be applied to the prevention and cure of disease, and the relief of pain, you have no right to listen to the dictates of selfish passions. Neither grief nor the fear of consequences, nor hatred, nor disgust, must thwart you in the execution of your mission. The darkness into which you have to cast the light, is human suffering ; the light is human skill. The solemn obligations of this possession must be your only guide. Thirdly, do not imagine that when your studies at a medical school have ceased you will cease to be students in your profession. Medicine is the last calling in which you can thus console yourselves. Science, like time, is always moving on ; and medical science must be no exception to the general progress. You must not therefore be satisfied to add to your experience in a matter-of-course sort of way as you live on and on. Years are not the measure of experience, and work will add much more to your stock of knowledge than time. Therefore work—not only to earn your living, but to keep yourselves abreast with what is going on in your profession. Work ! You will be happy, for, throughout life, work is happiness disguised ; and cessation from work is only pleasurable when it comes as rest and at intervals. But do not strive after the vain reputation of a ' busy man,' for that is but to tire yourselves and vex those about you. Neither be too ambitious in your work, for circumstances are not so arranged that all can snatch the laurels and the bays ; the majority have to be content with the elms and yews, and some even with the cypress. But be real and honest workers, and you will assuredly have your reward by proving yourselves benefactors in your generation. Nor must you allow your work either to harden your sensibilities or lead you into infidelity, as it is falsely stated by some to do. The true study of medicine ought to refine your feelings ; and, by showing you the limits of man's power over life and death, should increase your admiration and reverence of the Great First Cause. But do not confine your thoughts and occupations to your profession. The best and chiefest of your powers must, of course, be devoted to it. There is an old saying, ' Non multa sed multum,' and a modern one still better, that ' A man should know everything about something, and something of everything.' In either case your ' multum,' your ' something,' is medical science. But there is much in literature, in art, in other sciences besides your own, and in the recreation of society, that is worthy of your attention. In these are to be found the pleasures and embellishments of refined life ; and you will have more zeal and interest in your work if you indulge your leisure in some such tastes.

" But while employing your faculties in the acquisition of various kinds of knowledge, remember there ought to be something within you which can direct and purify this know-

ledge. It has been truly said that knowledge is but a mass of unprofitable materials until smoothed and squared and fitted to its place by wisdom. Therefore let us seek wisdom, that it may teach us, not to fashion our knowledge into an ornament, or a means to fortune only, but into a 'rich storehouse, for the glory of the Creator and the relief of man's estate.'"

CHARING-CROSS HOSPITAL.

Mr. Bellamy commenced his address by welcoming the students, remarking how that for those just entering upon the profession they were about to commence a most delightful period in their lives before the anxieties of practice had arrived, and that "they were then to be laying the foundation of that kind of training which was to fit them to enter the ranks of an army of men whose lives are to be devoted to the welfare of others rather than of themselves; and that they would find ample opportunities, during the time that they remained in the little world they had entered, to develope what must be regarded as a qualifying process, associated as they would be with different men, who have different tempers, habits, and manners, each of them a separate study—a study which should go on hand in hand with that most engrossing one, their profession, embodying the saying that the 'proper study of mankind is man,' and, as far as the medical man is concerned, of man in his normal and abnormal condition. No slight amount of what might be termed judicious steering would enable them to pass through this period scathless in self-respect and in reputation—to have on the one hand avoided contamination, and to have added, by their own examples, their quotum towards the moral tone of those with whom they had to do, and of the school they enter: endeavouring to act up to the characteristics of the young Englishman—manliness, high-mindedness, and a regard for the feelings of others."

Mr. Bellamy then proceeded to announce the additions to the hospital staff, of Dr. Bruce as Assistant-Physician, Dr. Sparks as Physician in charge of the Skin Department, and Mr. Astley Bloxam as Assistant-Surgeon, and remarked how Charing-cross Hospital might congratulate itself on its financial condition. "Scarcely a session passes," he said, "but we have to record some large addition to our buildings, and the consequent increase in our resources as a school; and the fact that we have pitched our tent on the 'finest site' in Europe should further stimulate all concerned with Charing-cross Hospital to make both it and its school worthy of this fortuitous circumstance."

He spoke of the movement known as Hospital Sunday, which would, he said, "no doubt, when in working order, be—and, indeed, has already been—a great boon to the unendowed hospitals, by a judicious allotment of funds. He did not of course allude to certain special hospitals, the support of which appeared to be rather an effort of misguided charity, and their maintenance a hindrance to the efficacy of the general hospitals, where the first men of our time, and the acknowledged leaders of British medicine and surgery, daily treat every form of disease which can present itself, without making any one form of malady unduly prominent." Mr. Bellamy called attention to the shameful abuse of hospital charity by those who were in receipt of incomes such as could enable them to pay for advice. He trusted that some effective measure might be taken to put a stop to the present state of matters, and stated that he had seen men whom he afterwards found out were in receipt of three or four guineas a week thus imposing upon the hospital charity. He then went on to speak of the school and of the new appointments made in it—Dr. Jas. Cantlie having been elected Demonstrator of Anatomy and one of the additional teachers of practical surgery, Mr. Clarke giving special instruction in surgical appliances, Mr. Bloxam in surgical pathology, and Mr. Bellamy in operative surgery on the dead body; whilst Mr. A. H. Garrod had been appointed to the chair of Comparative Anatomy. The lecturer then proceeded to speak of the great value of early education to medical students, and said that—"As it was impossible to overrate the advantages of a liberal education, so was it equally impossible to withhold a natural preference for such young men as had availed themselves of it. The general tone of the profession had been of late years vastly improved—not only on account of the exacting and searching nature of the professional examinations, but also on account of the generality of the preliminary test examinations." After entering fully into the subject of the *locus standi* of the educated medical man, he said that—"It was an unwelcome reflection (which might, however, enter one's mind) that the uneducated practitioner stood somewhat in the position of the ordinary artisan: called in when something wanted doing, and, when it was done, dismissed in much the same style. . . . . The subsequent development of the student's education depends partly on what he is taught, partly on how he is taught, and partly on how he learns." After discussing the manner by which these ends should be accomplished, he said that the man who passed through his student-life with the only end and aim in view of merely passing an examination, and there letting his learning or application cease, generally retained the kind of idea throughout his professional life, and was readily recognised as the hastily "run up" practitioner, who, besides being a useless was a very dangerous member of society. Mr. Bellamy then referred to the benefit that the annual publication of the successes or failures of candidates presenting themselves for examination at the College of Surgeons would have as a stimulus to fresh exertions on the part of both teachers and taught.

He next proceeded to review the several scientific subjects which would form their curriculum, and dwelt on those of anatomy and physiology at some length, alluding to the recent startling discoveries in the anatomy of the brain. The aim of all these scientific studies was as an introduction to the great subjects of pathology, medicine, and surgery, and he referred to the great difficulty there was of drawing any distinct line of demarcation between the latter. The surgeon, to practise sagaciously, must be thoroughly conversant with such technicalities as have been too frequently considered as the physician's province, whilst he has, in addition, a patient's well-being dependent upon his nerve and the steadiness of his fingers in directing the knife. The teaching of practical operative surgery has hitherto been much neglected in the student's course, and the necessity of his undergoing special training in the mechanical part of his profession, besides mere dissections, could not be too strongly insisted upon.

Mr. Bellamy then urged upon the students the necessity of hard work in the wards. As he had advised them in the scientific course almost to *live* in the dissecting-room, so, in their practical one, he counselled them almost to *live* in the wards and post-mortem theatre. Referring to the uselessness of "cram" in obtaining any insight into disease, he instanced a case he had been told of, of the difficulty experienced by a "show" prizeman in medicine in recognising a simple case of measles. He then went on to explain the several branches of the profession, such as surgeons, physicians, obstetricians, and general practitioners, which he termed "conventional," and observed that circumstances alone could direct them as to which branch of the healing art they should choose. Of the consultant, he said that "his position demanded the possession of a hospital appointment, and, having obtained it, that he must bide his time till he could get consultations. 'Biding time' implies a large outlay of what capital he possesses, real or ideal, for the sake of keeping up appearances, without any return for years; and 'obtaining consultations' depends either upon singular ability, connexions, or subtle tact in powers of ingratiation." He then spoke of how the lives of the generality of those he addressed would be spent—namely, as general practitioners,—and concluded by saying, "As such, you will be expected to have everything at your fingers' ends, and be up to every emergency; no difficult case should daunt you. Thoroughly provisioned for your campaign through life by early culture, good examples, a thorough appreciation of the attributes of gentlemen, and a sound practical and workmanlike knowledge of your profession, leaving no stone unturned lest there lie beneath it some latent energy which is being directed against your powers of observation and detection of disease, you will work your best and hardest to nerve yourselves for your future attempts to grapple with death and to delay his ultimate triumph. But do not, gentlemen, consider that professional accomplishments are to be 'the be-all and the end-all' of your attainments during these years of training. 'Make use and fair advantage of your days,' and let it be said of each of you what Valentine said of his friend Sir Proteus—

> "'His years but young, but his experience old;
> His head unmellowed, but his judgment ripe.
> . . . . He is complete in feature and in mind,
> With all good grace, to grace a gentleman.'"
>
> —*Two Gentlemen of Verona*, ii. 4.

LONDON HOSPITAL.

Dr. Prosser James, Lecturer on Materia Medica in the College, delivered the Introductory Lecture. He took as his subject the advances made in his own time in the medical sciences and the art of applying them, and drew most of his illustrations from those connected with the London Hospital. In the course of his lecture he said:—

"Great has been the progress made, and the London Hospital and its College has not been behind. Let me give you an illustration. Many of the most interesting problems relate to the form of various parts. We find certain parts fulfil certain functions. Why? Careless observers are often content to say no more. The man of true scientific mind desires to penetrate further; and this he may do either by reason or experiment. The true reasoner is the highest type of intellect. The experimenter, indeed, deserves our thanks for the facts he accumulates; but it is the reasoner who explains them. Harvey established his doctrine of the circulation of the blood by reason and experiment together; but many facts unknown to him have since been discovered, and they greatly enlarge our notion of the circulation. We may, indeed, describe the capillary or ultimate circulation as a modern discovery. The last contribution, however, to our knowledge of the circulation, to which I invite your attention, does not relate to this, but to the central organ—the heart. The openings through which the blood flows into, and out of, the cavities of the heart differ in size and shape. Why? The fact has been known from early times. The explanation might be supposed to accord with physical and mathematical laws. It was reserved for our senior physician, Dr. Herbert Davies, to prove that the several sizes and shapes are those best adapted to bring about the required result in the most perfect manner, and to furnish the formula for calculating one from the other, which may henceforth be termed Davies's law. And this law stops not within the domain of physiology, but gives us a further insight into pathology; for his explanation of the condition of the parts in health enables us to comprehend the effects of changes that are observed in disease.

"Physiology and pathology are so intimately connected that illustrations might well be classed under either. The next I take will serve as a stepping-stone to pathology: it relates to the nervous system, our knowledge of which has lately made immense progress, the London Hospital being again to the fore. Aphasia is a condition upon which much light has been shed, and the physiology and pathology of the nervous system have in my time been completely remodelled. More than one London Hospital man has worked at this subject, but no single individual has accomplished more than one of our present physicians, Dr. Hughlings-Jackson. It is indeed directly due to his clinical study of convulsions and other lesions that the greatest step has been taken towards the elucidation of the functions of the brain. He showed the way investigators should pursue. He predicted the discoveries that have just been announced as the result of the brilliant experiments carried out by Fritsch, Hitzig, and Ferrier, and which have completely realised his anticipations respecting the localisation of the functions of the brain. Regarding disease as an experiment made by nature, Dr. Jackson arrived at conclusions which Professor Ferrier's experiments have exactly confirmed, and which seem to show that the idea involved in what is called phrenology have after all a certain scientific basis. The geography of the brain is now being mapped out, and had Gall and Spurzheim pursued the method of Jackson and Ferrier, they might have been great discoverers instead of the constructors of an inadequate hypothesis.

"Speaking of the nervous system, it may be mentioned that diseases have lately been referred to it which used to be otherwise classed; for example, certain diseases of the skin. Rheumatism, also, has lately been referred to a sort of cerebro-spinal meningitis, but that great London Hospital veteran, Dr. Billing, long ago called it a neuritis.

"When I entered the London Hospital the microscope was by no means ignored, for Dr. Carpenter included microscopic demonstrations in his course of physiology; and assuredly with so eminent a microscopist as our professor it may be supposed that no school was in advance of this. But yet how great progress has since been made! To-day we can offer our students the most complete instruction in the use of the microscope; and the original work done in our laboratory is being applied to the elucidation of some of the most important medical problems.

"Looking back to the time of my entry into the profession, I recall one name that overshadowed the microscopic world. That name was Quekett; and even now, if anyone should ask what the Queketts (for there were two) did in histology, he would be likely to be answered in the one word—everything. From the Queketts a new era in microscopic work may be dated—and both of them were London Hospital men. Nor is our *Alma Mater* behindhand now; for one of the great questions of pathology at this time relates to recent investigations into the connexion of Bright's disease with certain definite changes in the vascular system. In explanation of the facts observed a theory has lately been proposed by one of our staff—Dr. H. G. Sutton—in conjunction with Sir William Gull. It is true that their theory has been warmly contested, and may be said to be still on its trial, but whether ultimately accepted or not, a mass of facts has been accumulated which must prove serviceable to other searchers after truth. In reference to this, I believe I am correct in stating that all the original work on which the hypothesis is based was performed within the walls of this College; and that nearly all the preparations were made in our laboratory. Thus we see that to this very day the London Hospital and its College maintains its reputation for microscopical research; and I take it that as London Hospital men you will feel an interest in one or two other landmarks of our progress in this department of pathology.

"Look at inflammation. This process, always an absorbing study, has been investigated with renewed vigour during the last twenty years—especially the last five or six. Virchow's cellular pathology seemed to reign supreme until lately, notwithstanding many indications of its inadequacy. It was not till 1867 that it was really deposed, chiefly through the attention bestowed on Cohnheim's researches. It is here curious to note that to Cohnheim is not due the credit of priority in the investigations and discoveries that have so largely displaced Virchow's theory, and brought us nearer to the pathology of an earlier time. For twenty-eight years before, nearly all the microscopic appearances of inflammation had been described by Dr. William Addison, whose views I perused when yet a student, and which had been accepted by Dr. Williams, whose 'Principles of Medicine' was one of my earliest text-books.

"The pathology of tubercle has been much studied with the microscope. Indeed, tubercle is of such absorbing interest to all physicians, that we naturally employ every means at our disposal to elucidate the problems gathered around it. The overwhelming influence of Laennec is still apparent, and when I began my career his theory was widely regarded as axiomatic, although Reinhardt had already published his investigations, and maintained that no such entity as tubercle existed. Opinion is now divided, and many seem to take a middle view, as if in one case tubercle could be regarded as a specific product, while in another it could be only a form resulting from the structure of the part where it is seen. Only a little while ago Villemin announced that he could produce tubercle in animals by inoculating them with the sputa of consumptives. Then many at once concluded that Laennec was right after all, and that Reinhardt must have been wrong. It was, however, very soon shown by English experimenters that rabbits, the animals employed by Villemin, were particularly liable to tubercle, and, moreover, that the inoculation of other material of a non-tubercular nature would give rise to tuberculosis. The first person to show this was Dr. Andrew Clark, a London Hospital physician, whose prior researches in phthisis had conferred upon him the highest distinction.

"I cannot leave this subject without making an announcement that I deem of the first importance. It is well enough known that consumption may be arrested, but it has hitherto been laid down that one form of it, laryngeal phthisis, is rapidly and necessarily fatal. Cases are, indeed, frequently spoken of as galloping consumption. Now, in such cases it has been my privilege to witness the arrest of the disease. In one instance the lungs as well as the larynx were affected, nevertheless the patient recovered and resumed employment as a public singer.

"We come now to the consideration of the practical aim of our art: and here I assert there are striking signs of progress. A few illustrations may be conveniently grouped around certain instruments that help us to detect or cure disease.

"Contrasting our present resources with those of our student days, nothing is more remarkable than the constant use to which

we now put the thermometer. When I entered this College the clinical value of the instrument was unknown, though it is true that important observations had been made with it. Now every physician carries one in his waistcoat pocket. Clinical thermometry is often said to have originated with Traube in 1851, for in that year he published his important observations, but it was some time before it began to influence practice. Twenty years before then, however,—namely, in the cholera epidemic at Newcastle-on-Tyne in 1831—a London Hospital physician, afterwards one of my teachers, Dr. Cobb, had employed the thermometer to measure the tendency to death, and he was assisted by Dr. Little and others. As, however, in so many other cases, all these observers had been anticipated. As early as 1754 Antonius de Haen had publicly taught in Vienna that the temperature of the body should be measured by a thermometer; and he showed not only that in fevers the heat was abnormally great when perceptible to the hand, but that even in the cold stage of intermittents, when the patient is shivering and his teeth chattering, the blood is already rising in temperature. When we remember how large a part increase of temperature plays in disease, how obvious it is to the physician, how constantly complained of by the patient, it is a matter of no small surprise that this heat should not have been measured at an earlier period; and this is the more remarkable when we consider how common it was to use the thermometer, an instrument which was itself invented by Sanctorius, a physician in the sixteenth century, for other purposes. It was an everyday remark that the hand could not be trusted to regulate the temperature of a bath, and yet physicians who knew this went through their lives trusting to their hands to distinguish the temperature of their patients' bodies, and never thought of applying a thermometer. And this, too, although from the earliest times increased temperature was recognised as the most important factor of fever. Galen defined fever as 'preternatural heat,' and Hippocrates had previously named it 'pyrexia.' Modern research is bringing us back to the conception of fever thus handed down from the Father of Medicine.

"Another new instrument for extending the range of vision is the laryngoscope. This instrument enables us to see distinctly the interior of the living larynx. It therefore brings the diseases of that organ within the range of vision. In diagnosis, it has changed conjecture into certainty. It is, moreover, available as a guide to treatment. By its aid we can watch the course of disease, we can apply local remedies, we can introduce various instruments into the larynx, and manipulate them when there.

When I left this Hospital the laryngoscope was unknown. Soon afterwards, as early as 1856, I related a case in which I detected and applied caustic to an ulcer by means of a laryngeal mirror and a reflector, thereby curing a patient who had been discharged as incurable from several hospitals. I was not then aware that the living larynx had been seen before; but since then it has been shown that others had anticipated me in seeing the organ, though no one had before then used a laryngoscope for the purpose of treating disease. Garcia, the great professor of singing, had previously used a mirror and reflected light to study the movements of the organ of voice, and in 1855 a description of what he saw appeared in the *Proceedings of the Royal Society*. Thus a scientific man preceded physicians, and pointed out to them a new means of diagnosis; for a late writer, Dr. Mandl, of Paris, tell us that Garcia urged him to apply his mirror to the investigation of disease. But even he was anticipated, for the late Dr. Babington had, in 1829, contrived a similar apparatus, which he called a glottiscope. This much, however, must be said, that he seems to have laid aside his instrument, while Garcia completed all he proposed, and was certainly the father of auto-laryngoscopy. His paper, buried in the *Royal Society's Proceedings*, became known to Türck, of Vienna, who tried to use the instrument on patients. He lent his mirror to Czermak, who greatly improved—we may say perfected—the apparatus, making it portable and convenient. From this time the progress of the art of laryngoscopy has been truly wonderful; and you know the zeal with which it has been pursued by another of my colleagues, Dr. Mackenzie. Nor is the use of the instrument confined to diseases of the larynx. It affords us information respecting general diseases, such as consumption, aneurism of the aorta, and other intra-thoracic tumours.

The lecturer then referred to the practical application of our knowledge in the treatment of disease, materia medica and therapeutics. Mention was made of electrolysis, the use of cool baths in pyrexia, and the introduction of new drugs, foremost of which was chloral hydrate.

The lecturer concluded with advice to students, and congratulations of their choice of a profession and of *Alma Mater*.

ST. GEORGE'S HOSPITAL.

The Address was delivered by Mr. Brudenell Carter, Ophthalmic Surgeon to the Hospital.

Mr. Carter commenced by saying that the utility of the introductory lectures had of late years been called in question, and by defending the ancient custom on several grounds. He then proceeded to discuss medical education in the sense of Paley's definition of education, as comprising every preparation made in our youth for the sequel of our lives. Among these preparations the storing up of knowledge occupies a high place; but the due and harmonious training of the faculties by which knowledge was to be applied was, he held, of even greater importance. His hearers would be called upon to attempt the solution of very difficult, because very complicated, problems; and it would avail them little to have filled their memories with learning, unless they had also cultivated the power of observing with accuracy, and the power of judging with discrimination. For the purposes of such cultivation they enjoyed many advantages over the students of preceding generations, especially the great advantage of being required to bring to their work minds exercised and strengthened by liberal education. They must not take it for granted, however, that this liberal education had done all for them, in the way even of preliminary training, that their minds required or could profit by; for much of the school teaching of the present day seemed to be guided by a belief that the introduction of compressed facts would mechanically expand the intellect; as if learning were a species of sponge-tent. He deplored the wide extent of knowledge now demanded from the young at various preliminary examinations, saying that it placed an obstacle, always formidable and often insurmountable, in the way of real education; and could only be attained by a sacrifice of thoroughness, and of some of the chief objects of teaching, in respect of everything that was said to be taught. These chief objects were to produce and cultivate a habit of careful attention to the meaning of words, and to accustom the mind to a high standard and to a certain kind of reasoning. Amid great laughter, he compared the show pupils of the period, who are able to write down marvellous answers to a multiplicity of questions, on a multiplicity of subjects, to the wooden cannon known among artillerymen as "quakers." These required for their production, in unlimited numbers, besides the blocks of wood, only a turning-lathe and a paint-brush, and they were placed, to deceive an enemy, in embrasures which would otherwise be vacant. There was, however, one grievous flaw in the analogy, for our English "competition wallahs," instead of being used to deceive an enemy, were used only to deceive ourselves. Unfortunately, our notions of education were still entirely empirical; and although physiologists were entering upon researches which promise to establish a science of mental culture, founded upon a study of the structure and functions of those portions of the nervous centres which are subservient to the acquirement and the application of knowledge, it would as yet be premature, even if it were possible, to speculate on the results to which these researches might lead. At present, in seeking the best attainable preliminary education for the profession of medicine, we could only use the common means ready to our hands, such as the dead and living languages—and of all languages the English language, in which our ideas are formed, and in which, chiefly, they have to be imparted—together with mathematics, physical science, and the indirect culture to be obtained from the topics of the day, from the personal tastes, and from the floating information of the social and domestic circles. With regard to all these, the results produced should be of a far higher kind than any superficial or fleeting proficiency in the studies or pursuits themselves. The aim should be to use these studies as agencies for the development of the qualities of mind which would be most useful to the medical student, and which would best qualify him to pursue his allotted path with diligence and with success. These were, first, the power of observation—the power of searching out and recognising facts, so as to obtain materials for the operations of the judgment; secondly, the faculty of imagination, by which to link together the known

with the unknown; thirdly, the power of maintaining a suspended judgment whenever certainty was unattainable; fourthly, the love of truth. Under each of these heads he discussed its special bearings, showing the uses of the several faculties, the means by which they might be cultivated, and the errors which might arise from their being absent or deficient. With regard to the love of truth, he warned his hearers that truthfulness was not something easy and natural, but that in fact, and in its widest sense, it was one of the last attainments of the disciplined and cultivated intellect. He said that children and the uneducated could no more adhere strictly to truth than ordinary persons could walk upon a tight-rope; and pointed out, even among the educated, the common preponderance of a desire to know what is said over a desire to know what is true. But nothing short of a desire to know what is true can furnish an adequate motive for the careful investigation of disease, or could overcome the temptation of floating easily along the current of the fashionable doctrine of the day. He then proceeded to consider the relation of the special departments of practice to the work of the hospital as a whole, telling his hearers that a man who practised any single branch of the profession, without a sound knowledge of the whole, was not a specialist, but a charlatan; and that, whatever might be their future aims, they would best qualify themselves for success by becoming general practitioners in the most comprehensive sense, and by leaving differentiation to be accomplished in the future. There was, however, one branch of special study that demanded their closest attention, and that was the study of the varieties of human temperament and character, so that they might learn to use the mind of each patient as an instrument for promoting the recovery of his body. The Apostle said of his own work, "Even as I please all men in all things, not seeking mine own profit, but the profit of many that they may be saved"; and medical men must be actuated by the same spirit if they would heal the infirmities of their brethren. In the conclusion of his oration the speaker dwelt in terms of pride upon the high character of the profession, and, calling to mind the words of Mr. Prescott Hewett on some former occasion —"It is not enough for a doctor to be honest; he must be chivalrous"—he urged the duty of the medical man to place the gifts with which God had endowed him at the service of suffering humanity. Estimated on a money basis, it was said the profession was "hardly worth following."

> "So think the vulgar. Life and Time
> Ring all their joys in one dull chime
> Of luxury and ease."

For his own part, he believed there was no enjoyment superior to the systematic and harmonious exercise of the faculties of the mind, no satisfaction greater than that afforded by the fulfilment of duty, and that no lives were happier than those of the great majority of the profession. If he were asked to define the sources of their happiness, he would call to his aid one of the greatest writers of fiction that ever lived, who owed much of his greatness to his profound and accurate knowledge of realities, and who, probably on that account, had rendered to doctors more justice than they had received from many of his weaker brethren. He meant Charles Dickens, who had placed his story of "Bleak House" in the mouth of a heroine who became a doctor's wife, and who thus concluded her narrative:—"We are not rich in the bank, but we have always prospered, and we have quite enough. I never walk out with my husband but I hear the people bless him. I never go into a house of any degree but I hear his praises or see them in grateful eyes. I never lie down at night but I know that in the course of that day he has alleviated pain and soothed some fellow-creature in the time of need. I know that from the beds of those who were past recovery thanks have often, often gone up in the last hour for his patient ministration. Is not this to be rich?" "In this quotation," he said, "we have a picture by a master hand, and I will only observe concerning it that it is given to each one of us, if we will, to realise the picture for ourselves. It would ill become me to mar its effectiveness by any further words of mine."

ST. MARY'S HOSPITAL.

Dr. Shepherd commenced his address by saying that the medical profession is one from which ease of body is most certainly absent; it demands continual personal discomfort. Even beyond the time when we may expect some fair return for our labour, it uses us as slaves. In spite of this we love it, and our love for it is our greatest boast. After some remarks on the success of St. Mary's students during the past year, he stated that his particular subject for discussion that evening would be the Relation of the Medical Man to Society. "Addison, in No. 21 of the *Spectator*, writing of the crowds who throng to the three professions of divinity, law, and medicine, interprets, I hope not quite fairly, a fact which he had noticed in his own time. He says—'If . . . . we look into the profession of physic, we shall find a most formidable body of men. The sight of them is enough to make a man serious, for we may lay it down as a maxim, that when a nation abounds in physicians, it grows thin of people.' I cannot think that this maxim as so laid down has much truth nowadays; whatever truth it has should become less with each succeeding year, as the real science of medicine makes more ground among ourselves, and through us bears more upon those whose advisers in all relating to their health we are. Still, we of a later age have no reason to plume ourselves; seeing that Galen reminds us that Homer himself speaks of the dignity of this profession—

> Ἰητρὸς γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄλλων,—

we are the rather bound to examine ourselves, that we may not fall far below this ideal character." After remarking that we have happily given up, long ago, the *rôle* of "Æsculapius of old, that counterfeit god," as Burton ("Anat. Melanch.") calls him, and that our curing depended upon our care, and the latter upon our knowledge of health and disease, he insisted that the type of our mind ought to react upon the mind of the people; our science ought to come home to the people. We are very much to blame if both in its physical and moral aspects the nation is not bettered by the existence in it of a well-educated body of medical men. And the worth and force of our teaching will depend on the degree in which we take to heart the importance of this our relation to the outside world. He showed what had been done by the professors of medicine for the prevention of diseases—especially epidemic ones—by teaching people to recognise and avoid the causes of them; and how in this way Science had grown out of, and conquered, an ignorant δεισιδαιμονια. He held that our lesson is to landlords and builders even more strongly than to those who were the immediate sufferers from cholera and fever; and to all, even those in other respects most highly educated, who live on in ignorance of, often in despite of, the conditions under which all life exists.

Another great lesson of which, if we but choose, we ought to be the best teachers, is that a mere belief in authority is not the best guide of human knowledge. Careful observation and patient experiment alone give us sure ground on which to tread, sure reasons on which to base a wider science. He quoted Hallam's statement that an undue respect for authority had interfered with the revival of medicine at the commencement of the sixteenth century. He sketched briefly the gradual growth of more certain knowledge, and urged that medical men, if they would be true teachers, must not be slaves to the Idols of the Den. He spoke of the almost necessary tendency of the present day to specialism, and of the necessity of a large general knowledge for the due and right understanding of any particular subject; and for this purpose he thought that if we read a little more and wrote a little less, our knowledge would be more thorough.

"And not only physically and intellectually, but morally also, are we teachers. For we have to be guardians of the public morality in cases where our own morality in dealing with our patients is concerned. Perfect honesty is our sole safeguard against quackery." The lecturer quoted from the *Spectator's* paper on "Quacks" (No. 572), in reference to that "branch of pretenders to this art (*i.e.*, of medicine), who, without either horse or pickle-herring, lie snug in a garret, and send down notice to the world of their extraordinary parts and abilities by printed bills and advertisements." He continued—"It is not only the herbalist and the bone-setter, but with shame be it said, it is nowadays the well-educated specialist who sings with quite as lusty a voice as they—

> "'See here, see here—a doctor rare,
> Who travels much at home:
> Come, take his pills—they cure all ills,
> Past, present, and to come.'

The College of Physicians has, in its wisdom, thought fit lately to warn its members of this evil; and I conceive that it is the bounden duty of us who are members of that College to bear the warning with us."

Two other duties which form part of the medical man's

relation to society—loyalty between members of the profession, and the necessity of providence for accident or disease—the lecturer approached with delicacy. In summing up these and other relations, he thought that the *Geist* of medicine is not, as Mephistopheles describes it, easy to scize upon; and that the highest duty of medical men is to be in more senses than Homer wrote it, "men worth many others."

Referring to the education of women for the medical profession, he urged that the experiment should be tried quietly, fairly, and completely. "That a woman can be a doctor, and follow her vocation not only according to her lights, but with success, has been proved by one who not long ago passed happily through 'the great pain and peril of childbirth.' Others there are more noisily striving for her position. To shut our eyes to the apparent usurpation of work and duties, and even bodily exercise, natural to the harder man, would seem to savour of a dangerous self-satisfaction. The question is a social one, and must be settled, as all social questions will settle themselves, by the result of experience and the public good."

With regard to the hypothesis of evolution, in which he expressed his firm belief, he was convinced that (the opposition to it based on scientific grounds being left out of the question) the aversion to it so common in a very large number of minds was caused by insufficient knowledge of the evidence, coupled with the horror—of which the Edinburgh Reviewer denies the existence—that nature is aggrandised at the expense of man. He combated the idea that the position of man was affected by modification of structure, or the supposed presence or absence of some process of brain substance. He spoke of the absence of any perceptible differences in the earliest life and development of man and the lower animals; and of the horror felt by some people in the fact that our life in any portion of it should be like the life of any, the lowest, organism.

In conclusion, he insisted upon the necessity that students should have some enthusiasm for their work; and that the lazy contentment with the needs of an examination, and indifference to higher standards of knowledge, should give way to a full development of their faculties and a due sense of their responsibility. "By these means only—as night and day press upon you with their recurring anxieties, their seemingly monotonous round of work—will you succeed in this profession; till, as we hope, in no long time after leaving us, your

"'prosperous labour fills
The lips of men with honest praise.'"

QUEEN'S COLLEGE, BIRMINGHAM.

The Introductory Address was delivered on October 1 at the Midland Institute, Birmingham, on the opening of the session of Queen's College, by John Clay, Professor of Midwifery, etc.

After acknowledging the honour conferred upon him, and giving a hearty welcome to all present, he referred to the prosperous financial condition of the College and to the success of the medical teaching, illustrating the latter by the fact that eighteen out of nineteen students obtained the diploma of the Royal College of Surgeons of England during the past year. He mentioned in feeling terms the loss the College had sustained by the resignation of the Warden, the Rev. T. E. Espin (now Chancellor of Chester), and spoke of the great advance made in regard to the education of medical students in this town by the consolidation of the medical schools and the union of the medical staff of the General and Queen's Hospitals into one clinical board; and after giving some excellent advice to the new students and referring in suitable terms to the founder of the College, Mr. W. Sands-Cox, whose name is worthily perpetuated in the Sands-Cox Prize (which was awarded to Mr. Dodson), he proposed to survey generally the subject of public health—to show the agencies at work in relation to it, to trace their operation, and to indicate their probable results.

"Public health is the science which has for its object the study of the laws of health, with a view to applying the knowledge thus obtained to the prevention of disease. It is a question vitally important to the community, individually and collectively, and of primary importance to the profession. The three general elements which are subservient to the nourishment and sustenance of human and generally of animal life are air, water, and food." The speaker pointed out how each of these are necessary for the existence of life; the manner in which they became vitiated and poisonous to life by noxious vapours mingling with the atmosphere and organic and chemical agents dissolved by water as it percolates the earth; how, in thickly populated districts, they become still more intermixed with injurious materials; and how requisite it is that food should be maintained in a pure and unadulterated state. The persistent and laudable efforts of Mr. Postgate, of Birmingham, in obtaining the Adulteration Act were here incidentally adverted to. He then proceeded: "The maintenance in a state of purity of these three great factors of animal life constitutes the chief aim and purpose of the legislation on public health, the regulation of which lengthens life, lessens disease, and increases vital force and productive vigour. To the medical profession the cultivation of sanitary science is of special interest and importance. Medical men have ever been foremost in the advocacy of sanitary improvements, many of which have been carried out regardless of self-interest by distinguished members of the profession. The leading features of preventive medicine, as vaccination, the prevention of scurvy and ague, and the diminution of epidemic diseases by isolation, and other hygienic measures, may be cited as illustrations. But new channels of usefulness are opened to us: the promotion of inquiry into the laws of health, the collection of facts bearing on health and disease, and the control of a vast network of official sanitary agency, created by recent legislation, fall necessarily within our province—the reward, as it were, of the foresight, public spirit, and self-abnegation which dictated to the profession the disinterested advocacy of measures affecting the improvement of the health of the community. There are many individuals, and some few corporations, who are unwilling to recognise the truth that there is a vast amount of preventable misery, disease, and mortality at present existing in this country, and who fail to appreciate the economic value of measures calculated to secure health. Sanitary science is looked upon by them as of special and professional rather than of general value. They ignore the fact that sound legislation, if actively carried into effect, is certain to raise the standard of public health. There is a sublime disregard of consequences on their part, and the problem of how little to expend on sanitary reforms and preventive measures is approached with a determination not to tolerate any sufficient expenditure, however eminent the danger, until serious mischief occurs, and then some tentative measures alone are adopted. It is too much the fashion in the present day to take for granted that all schemes involving public outlay are necessarily objectionable, and that a petty saving, regardless of consequences, is a powerful necessity to those who are in favour of public frugality. The increased longevity of human life, as shown by the report of the Registrar-General on the census returns, by more than one-third, was justly attributed to sanitary reforms." The lecturer then briefly reviewed the history of public health legislation from the time of Richard II. to the present day, and referred to the penalty imposed on Shakespeare's father on two occasions for depositing filth in the public-street, and for not keeping his gutter clean, as an example of salutary punishment. He continued: "The first real attempt to create a national system of public health was made by the Act of 1872, which called into existence the Local Government Board. This Act, the result of the recommendations of the Royal Sanitary Commission, he regarded as a sort of Magna Charta of public health; and curiously enough it brings us back an 'old foe with a new face,' for the sanitary problem of 1873, as in the reign of Richard II., is how to keep our rivers from being polluted." The various kinds of machinery created by recent legislation for the regulation of public health, and the powers given to local authorities under the supervision of a Government department, were dwelt upon. Everywhere medical officers of health and inspectors of nuisances are to be compulsorily appointed, so that, whether in thickly or thinly populated districts, the health of the whole community will be placed under medical inspection. But medical officers of health need fuller powers for initiating reforms, either alone or with the sanction of a central authority, and this was illustrated by what the lecturer termed a discreditable event in our local history, when about twenty years back the Birmingham Town Council appointed the late Mr. Townsend as medical officer of health, and dismissed him when he recommended certain much needed sanitary reforms. The grave responsibilities of medical officers of health were referred to in suitable terms. The preventive arrangements—comprising factory legislation, inspection of graveyards, of manufactories, mines, and vessels, and the Contagious Diseases Acts, and the registration of marriages, births, and deaths—were each pointed out as showing the progress made in sanitary science; and the

different modes of granting medical relief under the Poor-law system were held out as important agencies in dealing with disease and promoting restoration to health. The parochial system was referred to as working very satisfactorily where established, and the speaker regretted that it had not been made compulsory. The voluntary agencies—comprising hospitals, dispensaries, maternity charities, sick clubs, and friendly societies—were spoken of as exercising a powerful influence on the health of a certain class of the public, and their claims for greater encouragement and protection from Government were strongly urged. After referring to vaccination as perhaps the most powerful agency in preventing disease and prolonging life, and contrasting the success of legislation on this matter with the apathy and irresolution shown in carrying into effect other provisions bearing on public health, the lecturer said: "From the rapid survey already taken it will be seen that the ground is now pretty well covered by one or other of these three great divisions of machinery for administering the public health—namely, the powers entrusted to local authorities, Government agencies of a preventive kind, and voluntary restorative agencies. There is great need, however, for these to be strengthened by being placed entirely under one Government department, directed by a Minister of Health, instead of, as now, being divided between the Local Government Board, the Home Office, and the Privy Council. The principle is no doubt sound, that sanitary work, to be effective, must be to a considerable extent a matter of central administration, and rendered independent of local interests, prejudices, and influences; and it may be hoped that the beginning made by recent legislation may soon lead to the constitution of a real Minister of Health, having charge of all agencies and some control over voluntary as well as compulsory machinery. The increasing knowledge and interest displayed on the part of the public in sanitary matters must tend to stimulate and strengthen the action of the Government, which has hitherto fallen behind rather than been in advance of the requirements of the country. This want of skill and strength is strikingly displayed in regard to a part of the subject which just now interests us very deeply in Birmingham—the treatment of sewage and the disposal of the refuse of great towns. The sewage committee of this borough, under the able presidency of Alderman Avery, in the Bill which they presented to Parliament, came to a very fair solution of the difficulties which beset the consideration of the sewage question, and if the measure had not received an ignominious rejection by Parliament, it would have been a safe guide to the central authority as to what should be undertaken by urban governing bodies under such circumstances. Here Government should have stepped in, either by rendering efficient assistance to the local scheme, or by laying down the principles of some general plan for meeting the difficulty and overcoming the opposition of individual landowners." The Professor proceeded to point out how Government should prevent such hindrances to the effectual carrying out of sanitary legislation, how a considerable amount of organic refuse might be systematically destroyed by fire in individual households, and concluded his address by calling on the members of the profession to instruct the heads of families and individuals in the science of preventing disease in their own households, showing how the health of the community depends upon individual action, pointing out to the profession the important, honourable, and responsible positions held out to them, and how by conscientiously and fearlessly discharging these duties they may become public benefactors, strengthening vital force and prolonging human life under the conditions of health and vigour which make life worth having.

LEEDS SCHOOL OF MEDICINE.

Mr. Scattergood said he regarded the presence there of many not directly concerned in the work of the School of Medicine as an evidence that its existence for considerably more than a generation had attached them to it by ties of friendly interest and sympathy; and the assurance of this afforded unfeigned satisfaction. A successful career of two-and-forty years sufficiently justified the wisdom of the eminent and sagacious men who founded the school. In reviewing the changes which had taken place in the methods of medical education in that period (during half of which he had had the honour of being a teacher in that school), the principal one seemed to be the greater attention paid to "practical instruction." The modern education required from the student not perhaps less reading, but more doing, more employment for his hands and his five senses in proportion to that for his memory. The student had not got less to do with written books, but he was more constantly referred to the great book of nature, with which he was to compare them, thus beneficially becoming more of an active seeker after knowledge, and less of a passive recipient of information. This gave him more of the *locus standi* of an original observer. Every student, for instance, who dissected his parts carefully and conscientiously, might be said in a sense to rediscover for himself the facts of human anatomy. With this assumption of the character and spirit of original inquiry there came some of the pleasure attaching to it, as well as still greater benefit in the discipline it gave to the mind. The exercise of the faculty of observation was an excellent antidote to the lethargy which was apt to creep upon the mind by cramming book-knowledge into the memory with too hungry haste. Turning then from medical education to the remarkable progress of the medical sciences, the lecturer said: Forty-two years ago the necessity which was urgently felt in the medical profession for the study of descriptive anatomy was painfully brought before the public mind by the revolting means by which the dissecting-rooms were in some instances supplied. The issue of it all was, however, the passing of the Anatomy Act, which, though by no means free from defects, by securing a better supply of subjects put an end to the disgusting proceedings of the "resurrectionist," and allowed the general antipathy against dissection to subside under the influence of time and of improving general education. But though descriptive anatomy was at that time earnestly cultivated as of the utmost importance to the surgeon, and also for its own sake as a part of comparative anatomy, yet very little indeed was known of the minute structure of tissues: the word "cell" had no very definite meaning, and "histology" did not exist. It could only exist, indeed, when the microscope was used; and with the increased employment and improved character of this instrument the knowledge of tissue has kept steady pace. In physiology a splendid prospect had been opened by the great discoveries of Sir Charles Bell, and the experiments of Magendie and some others. But the questions involved in the relations of vital to chemical changes had scarcely been touched. We cannot now congratulate ourselves upon either certainty or completeness in our knowledge of the chemistry of digestion, the nature of secretion, and the mode of tissue change; but at that time the very conditions and terms of the problems we are now seeking to solve were not stated. After noticing how advance was indicated by numerous new names and headings in modern medical treatises, Mr. Scattergood pointed out that, over and above the improvements in therapeutics, induced by new pathological views or by the introduction of more powerful remedial agents, there had been during the last forty years a gradual change in treatment, indicated by the disuse of bloodletting and of "heroic remedies." He proceeded to show that the field of research constantly enlarged, that the workers in it increased in numbers and in intellectual activity; also that great improvements were made in the number and character of the instruments now employed. Let it not be supposed, however, that the greater exactitude of such improved methods of research would put an end to theory and speculation. The use of instruments of precision in scientific inquiry will no more, he said, put an end to speculation than the use of weapons of precision will put an end to war. By our instruments we ascertain facts; but every fact we discover is the germ and starting-point of new hypothesis and theory; and every fact sown in the soil of the human mind springs up again a whole army of ingenious speculations and inquiries. If we turn now from the internal development and improvement of our science and art to the relations which the individual medical practitioner and the profession in general sustain towards the community, we shall find that the last forty years, and especially the latter part of it, have seen great alterations in this matter. There have long been signs of an increasing appreciation by the public generally of the value of our profession, and a greater and fairer recognition of the service it does to the community. This has been shown not merely by the "reception" of the British Medical Association by a hospitable Lord Mayor, the attendance of a busy and distinguished Prime Minister at its dinner, and the notice taken of its proceedings by the metropolitan press—signs as these are of the way in which the current of opinion is flowing,—but it has been shown in a much

more satisfactory way, namely, by a call to new duties and enlarged responsibilities; by a discovery on the part of the public that besides the Cure of disease we should undertake the Care of health. Rightly to understand our position, it is well to remember that this idea was not of spontaneous growth in the public mind; it was a sentiment implanted there by our profession itself, and the growth of which it has assiduously promoted. In the first year of the present century, not to go farther back, the late Professor Gregory, the author of the "Conspectus," said in his lectures at Edinburgh, "By the practice of physic we mean the art of *preventing* and curing disease." And seventy years later we find Sir William Jenner writing, "I have always taught that the highest branch of medicine is preventive medicine." And in this key have written all the masters of our art. Is it not the usual course with every practitioner, that, when he has treated a patient for disease, he advises him how he may escape the disease for the future? One of the first and one of the noblest measures of preventive medicine was the introduction of vaccination at the end of the last century; and from that time to the present the profession has promoted others, some of greater and some of less importance. Means to arrest the spread of epidemics, to improve the conditions of quarantine, to remove the causes of preventable diseases as they exist in the impure atmosphere, the polluted water supply, the inefficient drainage, the badly constructed dwelling, the food, the clothing, the employments, the recreations of the people—these have been earnestly inquired into and enforced by us, often against much opposition and amid much obloquy. To some branches of the profession the opportunity has been afforded of more direct action than to others. The Poor-law medical officer, the certifying factory surgeon, the surgeons of the army, and especially of the Indian army, have had a more open field for direct work in preventing disease than perhaps most of their brethren, and they will be unanimous in telling us of the difficulties that crass ignorance and official red-tape have too often placed in their way. But we may go a step further. Let us watch the general practical tendency of all scientific research in medical sciences, and we shall find that all points in the same direction. If enlarged knowledge of diseased processes and greater acquaintance with the action of remedies lead to improved curative treatment, this improvement consists in the more speedy arrest of disease, in lessening its disabling or destructive action, in a more perfect restoration of the body to the normal state—that state in which it most strongly resists morbific agencies. In other words improvements in treatment have a preventive effect. But going parallel with the growth of a true pathology and therapeutics, the discoveries in other fields of research have had a more direct bearing on preventive medicine. Take physiology; the more we know of normal cell-growth, are we not the more likely to be able to prevent degeneration of tissue? If we learn that activity of the brain must be sustained by vigour of the heart—that the maintenance of the chemical activity of the blood depends upon the due oxidation of its hæmoglobin, and this on a proper percentage of oxygen in the inspired air—that all intellectual work and all muscular work cause a certain amount of tissue change which must be made up by a proper supply of food, and that different kinds of food have a different nutritive equivalency, are we not learning directly how to promote health? In other words, the practical side of physiology is hygiene. The idea of preventive medicine originated in the mind of our profession, and has there been fostered and nourished. Fed by all the stream of new discovery and enlarging thought, and by all the warmth of devotion to a cherished purpose of philanthropy, it has grown and developed into many branches of practical application. To those which I have already indicated might be added all that relates to the hours of labour, the unhealthiness of certain occupations, and many others. On all such points we have endeavoured to inform the intelligence and to stimulate the conscience of the country; raising the old adage that "Prevention is better than cure" from a dead proverb in the mouth into a living conviction in the thought. And now that this has taken form and action in the shape of an Act of Parliament, and that the people of this country say to us, "You have taught us our need, and we look to you to satisfy it," the serious question meets us, "Is our profession equal to the emergency, and can it fulfil the duties demanded from it?" "Is the wide appointment of officers of health to mark an epoch in the social and sanitary condition of the people?" "Will the field of research thus opened be cultivated by earnest workers with the best implements of thought and knowledge?" "Will the grave questions relating to public health be henceforth dealt with by their administrators in a large and earnest and scientific spirit?" Now, in the first place, it must be admitted that among medical officers of health there will certainly be instances of want of competency: for this holds in all the positions that human beings can fill, from Imperial Majesties down to nursery-maids. In the next place, it may be found that many of those most highly qualified do not feel it to be their duty to devote themselves to the work, in consequence of the remuneration offered them being less than it ought to be—a condition of things which is pretty sure to be the case in places where the convictions of the community are not ripe for the action which the Legislature has forced upon them. It happens also that the very difficulty which many persons of weak brain, imperfect education, or doubtful character find in earning their living, drives them in shoals to seek for appointments and posts of all kinds for which, whether they know it or not, they are absolutely unfitted. And then, if we could suppose (by a somewhat wide exercise of charity) that those who have the responsibility of appointing the medical officers of health were in all cases men of ability and judgment, it must still be allowed that in very many cases the data have been wanting which would enable them to form a correct notion of the qualifications of the candidates. But, while admitting this, I make bold to assert that the country is now provided with, or is being provided with, an army of health officers who will fulfil the task entrusted to them with intelligence, zeal, and even enthusiasm, and with a success which may be expected to increase year by year. None the less true is it that after the first posts are filled a higher standard of qualification will of necessity be imposed. By the general consent of all who are competent to judge, the medical officer of health (unless in the case which ought but rarely to exist, of a very limited area or a very small population) should be unfettered by private practice. He will thus need to be more adequately remunerated for his services; and this being done, candidates for the post will feel the necessity of qualifying themselves by a special course of training, which it now therefore becomes the governing bodies of the profession to provide, or to encourage and direct; and further, to furnish, by means of some diploma or certificate, a guarantee of individual fitness, and a warrant for public confidence. The University of Dublin has already instituted a "qualification in State medicine." The examinations which candidates for this qualification are required to undergo embraces a limited course of the following subjects:—Law, engineering, pathology, vital and sanitary statistics, chemistry, meteorology, and medical jurisprudence. The papers that were set in the last examination were wide in their scope, and of a very searching character, and it is evident that this examination is adapted to maintain a very high standard for State medicine—as high, in fact, as that which in the ordinary branches of education is maintained by the London University for its medical graduates. The qualification is only offered, however, to Doctors in Medicine of the Dublin University, or of Oxford or Cambridge. These latter Universities have also moved in the direction of specifying State medicine as a subject to be studied by the candidates for these medical degrees. The most important movement, however, is that which is being taken by the General Medical Council, and in the initiation of which a committee of the British Medical Association has taken a helpful part. What has been done—slowly, it must be confessed, as this subject has been before the Medical Council for about five years—has been to take evidence from various authorities, both medical, legal, and others, both at home and abroad, as to the need for the study of State medicine, its scope and limitations, and the constitution of an examining authority. The next step is to get clauses, intended to be of a permissive or enabling nature, inserted in an amended Medical Act, by virtue of which examinations may be held and diplomas conferred. It is hoped that this may be done in the next session of Parliament. State medicine may be considered to include preventive medicine, forensic or legal medicine, and from these some would separate a third division, psychological medicine or mental diseases. Upon the point whether these should be included in one certificate, or whether the duties implied in them should be relegated to different classes of persons, the eminent authorities who have given evidence to the committee are not agreed. But it seems to be generally accepted that (1), a diploma in State medicine should not be given except to persons who shall be on the Medical Register;

(2), that the studies qualifying for this shall not be undertaken until after the ordinary diploma has been obtained; it being considered that in the average students' curriculum there is no room for the introduction of many of the subjects which the special diploma would require to be studied; and (3), that all students ought to pay a certain amount of attention to most of these subjects, and to acquire a certain acquaintance with them. After some judicious words of advice to the students present, the lecturer concluded as follows:—"To revert once more to the considerations which I laid before you in an earlier part of this address: is their interest confined merely to us who are practitioners, or who are only outside observers? So far is this from being the case, that it is the students of to-day, and even the youngest of them, whom the present position of scientific research and progress in medicine most concerns. Is the field of observation widening every day? It is to you that its cultivation will be entrusted in the future. See to it that you appreciate its extent, and that you now prepare yourselves for the labour which the coming age demands of you. Every man is a debtor to his art; and what he has received from the past generation he is bound to repay with usury to the generation which will follow him. Have the last few years seen a greatly increased number of workers and an intensely quickened condition of mental activity? Then remember, that with the increasing spread of knowledge and of education the tension will constantly increase, and the competition become keener year by year. None will be able to take a worthy part in the future who do not now assiduously cultivate every faculty of mind which they possess; and no less needful is it that you should miss no opportunity of acquiring the command of all those instrumental appliances by which the power of the senses is so largely extended in range and precision. With the increasing demands of the age upon our profession, its responsibilities will admit of no slackening of the high tone of morality and the noble spirit of self-sacrifice which have always characterised it. The student's career will afford him abundant opportunities of exercising these. And thus acting, in proportion to your diligence will be the consciousness you will feel of frequent failure; in proportion to the amount of knowledge you acquire will be your sense of how little it is in comparison with the great world of thought and experience beyond you; in proportion to the extent to which you exercise your powers and discipline your mental faculties will be your feeling of their weakness and imperfection; and thus to earnest work and devoted sacrifice of self to duty will be added that humility which is the crown of them both."

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

Dr. Caton delivered the Introductory Address. After referring to the changes and improvements made in the Liverpool Medical School, and to the opening of the new buildings which had just taken place, Dr. Caton proceeded:—

The few remarks I have to offer to you to-day are on the following subject:—Physiology in relation to the Health of the Community, and the Advance of Medicine. Physiology, as we are all aware, is the science of animal life. It inquires into the nature of life, and into the modes in which the functions of the body are carried on. I shall here employ the term in its most comprehensive sense. I wish first to point out the importance of physiological science as the foundation of medicine and hygiene, and the desirability of a knowledge of its elements being more widely diffused, as a means of averting disease and death; here it will be necessary for me to glance briefly at the present state of public health. And next, I have a few words to say about the great results likely to be obtained in the future from physiological research, and the desirability of fostering and aiding it as much as possible.

After briefly describing the slow progress of physiology, and consequently of medicine, in ancient times, and the greater advances of medicine and of hygiene which have more recently followed on the establishment of a sound basis of physiological science, the speaker proceeded to answer the question, How far has this progress of physiology and medicine influenced on a large scale the health and life of the community, the benefit of which is the aim and purpose of our profession? Having stated a few facts which proved great saving of life to have been effected in recent compared with former times, Dr. Caton proceeded:—

Still the state of public health is far from what it ought to be. The average duration of life in this country is only forty years—not much more than half of the whole natural term. Among the lower classes particularly the duration of life is much less than it ought to be. How is it that the improvement in the health of the community has not been greater? The answer is this. There are causes connected with the general condition of the people, in our state of civilisation, which have a progressively injurious effect on life and health; so that while medical science is, as it were, continually lengthening life on the one hand, these causes are continually cutting it short on the other. Both these agencies—the beneficial and the destructive alike—are increasing in activity, and it is now a very serious question which of them is to prevail.

Overcrowding, intemperance, etc., tend to shorten life in all town populations. Hence, in large towns, we find an average mortality of one in thirty-seven annually, compared with one in sixty in the country; while the rapid growth of our large towns, the greater increase of town than of country population, makes the evil a growing one. There is also another cause at work among the people, the importance of which I think has not been fully recognised—viz., the interference with the great law of natural selection as regards human life. In an uncivilised state of society the strongest and most healthy alone survive, and become the parents of the succeeding generation; whereas in civilised communities abounding in conveniences and resources, feebleness of constitution or tendency to disease, which would otherwise be weeded out, survive, and give rise to a predisposition sure to develope in bad hygienic conditions. Thus, while nature would destroy the individual, but benefit the race, medical science saves the individual, but (unless the tendency to disease be counteracted by good hygienic conditions) may endanger the vigour and vitality of coming generations.

Sanitary legislation and improvement in the habits of the people are the only remedies for these evils and dangers.

The knowledge we have acquired of physiology, of the conditions affecting life favourably or unfavourably, is now being applied. A good beginning is being made in sanitary legislation. The appointment of medical officers of health throughout the country is important, as also are the efforts made to prevent the fraudulent adulteration of food, to insure sufficient drainage, good water supply, the due regulation of building in towns, the prohibition of nuisances, etc. All these agencies will be beneficial, and have been so already. Many, however, of the causes at work in producing disease are such as no legislation can ever directly reach—they are within the control of individuals only; you cannot by legislation make the people keep their windows open, or feed and clothe their children properly.

Are there no other means of still further bringing our knowledge to bear practically on the welfare of the lower classes? I confess it appears to me there is a method which has not yet been tried—a method which is rendered possible by the establishment of our system of national education. It is this: teaching the people the rudiments of physiology and hygiene. Let the simple rules of health be strongly impressed upon them—such, for example as the following:—The importance of fresh air; the danger of sleeping in close, crowded bedrooms; the danger of inhaling sewage gas; the value of sunshine, of exercise, of the abundant use of pure water; the main rules of diet; a knowledge of the different kinds of nourishment necessary for health, and the forms in which they can best be obtained; the proper diet and bringing up of children; the effects and dangers of intemperance on the individual and on his offspring; simple rules as to clothing; the dangers of unhealthy occupations, and the modes of escaping their injurious effects. These and other simple practical points might readily be taught to the older pupils in all Government schools. If the objection of education be to prepare for *life*, I cannot conceive anything more essential for benefiting the people. To know how to live must surely be as important as how to read, write, and count.

It would certainly seem evident that whatever the people are taught, they ought at least to learn to care intelligently for their own lives, and for those of their offspring. In the words of Professor Huxley, "Were mankind deserving of the title 'rational,' which they arrogate to themselves, there can be no question that they would consider, as the most necessary of all branches of instruction for themselves and for their children, that which professes to acquaint them with the conditions of the existence they prize so highly—which teaches

them to avoid disease, and to cherish health in themselves and those who are dear to them."

In addition to applying and diffusing the practical parts of the physiological knowledge we have at the present time, it is highly desirable that we should extend our knowledge, and that we should attain to more precise acquaintance with the laws of life, for such knowledge would probably lead to great results. The science is making great and rapid progress; its prospects were never so bright and encouraging as at the present time. In this country, and still more on the Continent, many highly trained workers are engaged in research, employing the most exact and scientific methods.

After describing some of the more recent advances made in physiology, Dr. Caton proceeded:—The time will doubtless come when our Government will recognise the importance of aiding this department of science. When we consider the scores of thousands of pounds expended on scientific experiments for the perfecting of weapons, for the discovery of the best mode of defence and attack in warfare, to say nothing of the millions spent in carrying out such results, the ultimate object of which, of course, is the defence and preservation of national life and property; when we consider the vast sums thus spent, it would not appear unreasonable to expend a few thousands—a more fraction in comparison—in aid of the investigation of other modes of saving life—life which is in much greater actual peril in another way. There are other foes besides military invaders. We have enemies at work amongst us at the present time causing as many deaths, and perhaps as much poverty and distress, as any invading army, and we believe we have only to learn more to be able to expel them. For example, 100,000 deaths occur in England and Wales annually from febrile diseases alone (diseases of the zymotic class), and it is not at all unlikely that further knowledge will enable us in time to prevent all or most of these; if so, how desirable to find out the means as soon as possible!

The work of investigation, as I have said, is difficult, laborious, and often expensive. At present it is carried on mainly by medical practitioners, who earn their bread by the practice of their profession, and who gain little or nothing by their scientific work, except the esteem of the few who are able to understand the subject. The public in general know nothing about it. The science is thus at a disadvantage, depending too much on the efforts of isolated men who can only give up a small part of their time. The gain to the science, and the ultimate benefit to the country, would probably be great if one or more Government-supported laboratories were established, and some of the more eminent physiologists paid to devote their entire time to the work.

It is not at all unreasonable to believe that sooner or later a profound acquaintance with the laws of animal life will enable the medical profession to be of many-fold greater service than at present.

We may fairly look forward to a period when, by the aid of science, whole classes of existing diseases will have been swept away entirely, such as the infectious fevers. By further carrying out of sanitary laws, and by improvements in the habits of the people, constitutional diseases may be rendered far less frequent; while a more exact knowledge of the nature of disease, together with advances in therapeutics and surgery, will enable the medical man to give relief and avert death much more speedily and certainly than can be done now. In fact, it is quite reasonable to expect a time when natural death—death at the full term of years, unhastened by any form of disease—shall be the rule, and not as now, the exception, and when the great majority of men may enjoy seventy or eighty years of vigorous life.

Dr. Caton concluded by a few remarks addressed specially to the students in reference to the work of the session about to commence.

NEWCASTLE-UPON-TYNE COLLEGE OF MEDICINE.

The Introductory Address was delivered by Dr. Armstrong, who began by addressing the younger students, assuming that they recognised the importance of the step they were about to take, and at the same time forewarning them that theirs was to be no life of luxury, but one of toil, care, and anxiety. He urged them by the duty they owed to their parents and guardians, as well as by their hopes of success, so to conduct themselves as students that they might in after-life look back upon October 1, 1873, not only as a commencement of a college curriculum, but as the inauguration of an honourable career. Dr. Armstrong cautioned the first year's men against idleness, as the first downward step, and advised them to adhere to a systematic course of study. He also recommended them when in doubt to consult their lecturers, in their general conduct to follow the example of the medallists of their class, and above all to shun the "chronic student" as one who, though not naturally vicious, was certain to exert an influence for evil on new students. The speaker drew attention to the importance of the work of first year's men in the duty of after life; and to excite their interest in these studies he used a simple illustration—"You strike your funny-bone at the elbow so as to feel intense tingling in your little finger, and, if the blow has been severe, in part of the adjoining finger. On studying your anatomy you will find you had not struck a bone at all; it was a nerve. Physiology will teach you why you had the pain in your finger." From this instance the speaker generalised the paramount importance of anatomy and physiology, stating that many examples might be given where ignorance of matters apparently simple might cost them the life of their patient. What would be their feelings if they ever came to reflect that through their negligence as students of anatomy and physiology a wife had been left a widow and children penniless?

In addition to the need for reading and attendance at lectures, the speaker showed the urgent necessity for practice in the dissecting-room and laboratory. Chemistry might appear of less direct importance than the two foregoing subjects in the practice of medicine; it was, however, indirectly of the highest value—such as they could not understand until they came to study subjects allied to it. It behoved them, therefore, to labour diligently to obtain thorough mastery over this branch.

To the men of the second year Dr. Armstrong earnestly recommended diligence, not only on the ground of duty, but as an example to their juniors. He reminded them that they were expected to pass their anatomical and physiological examinations next spring. They were not, through fear of the result, to become nervous, but to think of the cost in time alone of a rejection.

"What," said he, "will be your feelings next inaugural address if from negligence you allow yourselves to be rejected whilst others no more gifted than you pass? What will be the feelings of those whose every hope you are—those who have for years lavished on you their love and care? These motives should incite you to redouble your efforts," etc.

To the third and fourth year students, in addition to the recommendation to work until the goal towards which they were pressing was passed, the speaker gave important practical and general advice for their guidance in after-life. He cautioned them against the idea that they had nothing to learn after they had obtained their diploma—a time when their ignorance would become most palpable to them. He advised them, when questioned by friends as to the state of their patient, to steer between the two extremes of offending friends by reticence and hurting patients by gossip.

The speaker also alluded to several matters of interest of an ethical nature, and cautioned those for whom his remarks were intended, in case a fellow-practitioner were guilty of a breach of etiquette towards them, never to retaliate, but to remember that "Two blacks do not make a white." Behaviour at coroners' inquests and in courts of law, the disastrous effects following want of care in the ordering of alcoholic stimulants, fashion in medicine, hospital practice and its abuses, afforded the speaker fruitful themes for practical advice to those about to enter the profession. There was one matter, he said, to which he would draw their serious attention, the more so that it was a subject not hitherto publicly discussed. Sick benefit societies, so long as they were properly used, were undoubtedly a great blessing to the working man; but, as medical officers of those societies, many of his hearers would think it a very suspicious circumstance that one person should be in four or five different societies. This was sufficiently demoralising, but unfortunately this was not all. A sum of money for funeral expenses, etc., is usually allowed on the death of any member of the family. This multiplied four or five times gives the parent an interest in the death of his offspring, the effect of which is more terrible than can be conceived. The speaker gave examples from his own experience of the sad results of this system, and called upon his hearers to exert their utmost influence to check it.

ORIGINAL COMMUNICATIONS.

ON LUMBAR COLOTOMY.

By C. F. MAUNDER,
Surgeon to the London Hospital.

Having already recorded in the pages of this journal half a dozen instances in which the above operation was performed, I now add three more, the limit to my personal experience.

Case 7.—Scirrhus of the Rectum—Partial Obstruction.

A male adult, whose chief symptom, of about six months' duration, was frequent diarrhœa. He has lost flesh somewhat; his appetite is bad; he is very anæmic and debilitated. Latterly incontinence of fæces has been added to his ailment. During the last forty-eight hours constant vomiting has prostrated him very seriously. At my request Dr. Down examined the patient very carefully, and detected no evidence of any malignant disease of the important viscera. The question of colotomy was put to the patient, and its probabilities and possibilities having been thoroughly explained, he accepted the operation as the alternative. It was performed in the left loin by the transverse incision, and the bowel found and the operation completed with the greatest ease. Vomiting did not recur, but the patient died after the lapse of forty-eight hours from asthenia.

Case 8.—Tertiary Syphilitic Ulceration of the Rectum.

Female adult, about twenty-eight years of age, married, had been under my care at intervals during two years. Varied treatment—on one occasion locking up of the bowels for a fortnight with opium; country and seaside air—failed to relieve her. A frequent desire to evacuate the rectum (a copious flow of highly sanguineous muco-purulent discharge being the general result) greatly distressed and debilitated her. Colotomy seemed to offer the only chance of relief from her sufferings, and to this she readily consented. She was not an absolute stranger to the operation, having on one occasion occupied a bed adjacent to a patient who had been similarly treated. The operation was performed by the transverse incision, but the bowel was found with difficulty. There was no lack of fat, and her muscles were very well developed.

In undertaking the operation, I hoped that by diverting the flow of fæces the ulceration would heal, and though with a tendency to strictnre, this latter could be controlled by the use of the bougie. In this I was disappointed; she could not bear the introduction of the bougie. Fæces passed at the artificial anus, and with this latter, after some months' sojourn in hospital, she left for America. The above patients were submitted to operation within a very few days of each other, and the facility in the one case, and the difficulty in the other, with which the bowel was reached, were well contrasted.

Case 9.—Incomplete Obstruction.

Mrs. —, about sixty years of age, extremely stout, and the mother of a very large family, had been for many years the subject of umbilical and inguinal hernia of the right side. During the last five years she has been liable to frequent attacks of constipation, associated with vomiting of a most alarming character. By treatment for two or three weeks with emollient enemata, opium, and the avoidance of purgatives, these symptoms would yield, a very large quantity of accumulated fæces having come away. About two years since she complained of constant dragging and sense of weight in the left side. On examination, a thickening could be felt on a level with the crest of the ilium. This induration gradually became an appreciable swelling, pain augmented, and some sanguineous mucus had passed. In April, 1871, this lady sustained another severe attack of constipation and vomiting, which was overcome as on former occasions. The bowels now acted fairly every day, and continued to do so until the fatal illness. During at least a week previous to my seeing her a great distaste for food existed—very little was taken, and nearly all returned. This state of things persisted, and on June 7 violent attacks of vomiting, with faintness, came on, although large quantities of fæces passed with and without injections. On June 8 violent sickness and stercoraceous vomit recurred. I saw her, in consultation with Drs. Stilwell and P. Jackson, when she was easier and sickness quiet. It was agreed to give a copious enema under chloroform, with a view to unload the cæcum and ascending colon, and to administer the watery extract of aloes and nux vomica by the mouth. The injection came away untinged, and in the evening another fit of vomiting occurred.

June 9.—10 a.m.: In consultation with Drs. Stilwell, Jackson, and Brown, it was agreed that I should perform colotomy under chloroform, after all the circumstances had been fully explained to the patient and her relatives. I selected the right loin in this instance, lest the tumour should be found to involve the descending colon. The transverse incision was made, and the bowel reached and opened at a depth of from three to four inches of fat. The adipose tissue present was almost incredible, being separated into two chief layers by the broad muscles, which had almost disappeared. On recovering consciousness the patient was greatly exhausted, and it was thought chloroform had not improved her condition. On the following morning fæces passed by the wound, and in the afternoon she died—about twenty-six hours subsequent to the operation.

It is easy to be wise after the event, and under the circumstances we regretted that the operation was not performed earlier. Still, under corresponding conditions a similar line of treatment would probably be adopted, on the ground that the patient, having already recovered from several like alarming attacks, might again do so.

A post-mortem examination disclosed all the organs smothered in fat. At the junction of the descending colon with the sigmoid flexure was an annular stricture, occupying some three inches in length of the intestine. The coats of the bowel were infiltrated and thickened, and adherent in one-half its circumference to the abdominal wall by scirrhous cancer, and the mucous surface was uneven and slightly abraded. A portion of the bowel indicated being the seat of deposit; its original power of contraction, with a view to propel towards the anus fæces travelling thither, was lost. Its calibre also was greatly diminished, and incapable of enlargement. The bowels above this were therefore never emptied by natural means; but when accumulation to a certain degree occurred, regurgitation and vomiting set in, and the life of the patient depended upon the unloading of the bowels before exhaustion had time to kill. The post-mortem also showed the descending colon to be empty, and the day previous to operation we believed the transverse colon to be empty, and the ascending colon to be loaded. At the time of operation we believed the ascending colon had been emptying itself during the night into the transverse, and the post-mortem appearances supported that belief, as the latter bowel then contained masses of fæces.

It has been said that the use of an enema will materially aid the diagnosis in cases of obstruction—a remark which only holds good in cases of complete occlusion of the large gut. The passage of the tube through the stricture was appreciated by the manipulator in this instance, and very large enemata had been employed.

Queen Anne-street, W.

A CASE OF COBRA POISONING

TREATED BY INCISION, AND LIQUOR POTASSÆ LOCALLY AND INTERNALLY, TERMINATING FATALLY IN ONE HOUR AND TWENTY-FIVE MINUTES.

By H. P. ESMONDE WHITE,
Triplicane Hospital.

C., aged 14, male, Gentoo, admitted into the Triplicane Hospital on August 5, 1873, at 8.45 a.m. His friends stated that he had been bitten by a cobra about half an hour previously when attempting to take some young birds from a crevice in a wall. Nothing had been done for him beyond applying some white-looking stuff to the wound. He was driven to the Hospital, and when admitted was in a drowsy state, appearing weak and fainting. A ligature of cord was immediately applied round the forearm, and afterwards replaced by a double roller. On examining the parts a small punctured wound was seen on the internal side of the middle finger of the left hand, just above the articulation of the first and second phalanges. An incision one inch in length was made over the puncture, but no blood came. Some cold water was dashed over the face, and this at once had the effect of producing a large flow of both arterial and venous blood, a small vessel being divided. His pulse was now 68 beats per minute; respirations 29. Eyes closed, but pupils normal. A solution of liquor potassæ and

water was prepared, and the whole hand kept immersed in it, pressure by an assistant's finger being used to arrest the flow from the small artery. Half a drachm of liquor potassæ in an ounce of brandy was then offered him; but although it was greatly diluted with water and given in a feeding-cup, he refused to swallow it. This was twice repeated, with the same result. Each time he vomited, so that he probably took one-half drachm of the liquor potassæ. The pulse now rose to 102. He continued in this state for some minutes, the pulse falling to 96, and the pupils being dilated; but it was impossible to count the respirations, as he lay in a doubled-up position, and moved continually, frequently putting his right hand to his head as if in pain. Two ounces of brandy and one drachm of liquor potassæ were thrown up the rectum. It was not retained, and was immediately repeated—this time with success. Pulse continued to fall, numbering 90; breathing quiet; jugular veins distended; and visible pulsation of the right carotid artery. He remained in this state some minutes, vomiting some slimy and frothy fluid. A strong convulsive movement of the whole body ensued. Pulse fell to 76, and became weak. He now fell into a semi-comatose state, breathing easily. Pulse became very weak, and only 68. From this time he continued to sink, until his pulse numbered only 35, became intermittent, but full at times, and finally flickering so that it could not be counted; and he died at 90.40 a.m., having been in the Hospital fifty-five minutes—the entire time which elapsed from his being bitten to his death being one hour and twenty-five minutes. In this case the wound had not been sucked, as there was no volunteer for so dangerous a duty, and the boy was unable to do so himself when admitted. Everything else was done in accordance with the instructions issued for Dr. Shortt's plan of treatment; but no good effect followed. The treatment got a fair trial, and did not succeed, which at least shows it is not infallible. The snake was a hooded cobra over three feet long.

SATURDAY, OCTOBER 11, 1873.

THE INTRODUCTORIES.—No. II.

At Charing-cross Hospital Mr. Bellamy well pointed out to the students that, besides the study of their profession during their working years at the hospital school, they would have ample opportunities for another and most important study—that of the different tempers, habits, and manners of those with whom they would be brought into contact. In our "Address to Students" we spoke of the special importance of this study of mankind to the medical student, and we are always glad to see it referred to, and its immense value to the medical practitioner somewhat dwelt on. Mr. Bellamy reviewed the various scientific subjects which the medical curriculum obliges the students to work at, and warned them against working at anything merely with the view of being able to pass an examination in it; they must work for the sake of knowledge and the power it gives; and when they should come to the practical part of the curriculum they should "live in the wards and the post-mortem theatre"; no *cramming* would serve to give them an insight into disease. In one part of his lecture Mr. Bellamy spoke of the "Hospital Sunday" movement as a great boon. We trust it may prove to be one, but we confess to some misgivings as to its being an unmixed good. We know that already it has been found that when aid for one of our London hospitals has been asked, "Hospital Sunday" has been made the excuse for refusing to give help at any other time, and we fear that this excuse will be made no little use of. We shall, we need not say, be glad indeed should it turn out that we are mistaken, but at present at any rate our fears are not without foundation.

The address delivered by Mr. Henry Morris at the Middlesex Hospital is an especially thoughtful and able production. Having first drawn the attention of his hearers to the complexity of composition of man, whose individual and social well-being will be their care, he shows that this necessitates their studying chemistry and natural philosophy, human and comparative anatomy, botany and physiology, morbid anatomy and pathology, and psychology, as the means of gaining a thorough knowledge of the "subject matter" of their work. And then, in order to know how to influence and act upon it, they must study—"first, materia medica, which gives a descriptive account of drugs, and of their effects upon the human system; second, the art of therapeutics, which instructs how to substitute physiological for pathological actions otherwise than by the agency of drugs; third, the various kinds of surgical instruments and appliances." And then he points out that there are "two offshoots from this great tree of medicine to which attention must be especially drawn"—medical jurisprudence, a knowledge of which may be "but rarely demanded, yet is absolutely requisite, because the committal of any error therein will be very damaging to reputation, both on account of the gravity and the publicity of such a mistake"; and State medicine, or the science of public health, "one of the very corner-stones of the social safety of mankind." While on this subject the lecturer was naturally led to observe on the present most unsatisfactory state of things in which "medical officers of health are subject to the opinions of lay inspectors who are unacquainted with the fundamental principles of sanitary science," and to lament that preventive medicine should be "groaning under an Act of Parliament which has excited surprise, dissatisfaction, and indignation."

Mr. Morris next discussed the kind of education best suited for those destined to recruit the ranks of medicine, and then the best method of studying the chosen profession; and, quoting a well-known aphorism from the "Novum Organon," he showed how "we must neither do as the ants, which only lay up and then use their store, nor as the spiders, which spin all out of themselves; but as the bee, which takes the middle course, and, after gathering from abroad, digests and arranges by its own faculty all that it has gathered. We must avoid the mistakes of the 'doctrinaires' and of the self-styled 'practical men.' We must avoid both false theory and blind empiricism." We especially commend to the study of our readers that part of Mr. Morris's address which treats of the faculty of observation. After commenting on assisted and unassisted, unintentional and intentional observation, he summed up thus:—"To observe well we must educate thoroughly our

organs of sense. As we have ears to hear, eyes to see, and hands to touch, we ought so to train and discipline them that they reach the highest possible degree of perfection. But we must not only see sights, hear sounds, and touch surfaces; we must, in addition, perform all kinds of mental analysis and synthesis of the facts we observe, treating them as words and letters, resolving the former into their component letters and building up the latter into words. To do all this requires great sagacity and sound judgment, and good powers of reasoning and paying attention." To know how to observe is of such paramount importance to the medical man that Mr. Morris deserves great credit for the fulness with which he treated this part of his subject; the whole of his address, indeed, is admirable for both knowledge and style.

Dr. Shepherd, at St. Mary's Hospital, took for the especial subject of his lecture—the "Relation of the Medical Man to Society," and as a kind of text quoted the following sentence from No. 21 of the *Spectator*:—"If . . we look into the profession of physic, we shall find a most formidable body of men. The sight of them is enough to make a man serious, for we may lay it down as a maxim that when a nation abounds in physicians, it grows thin of people." Dr. Shepherd expressed an opinion that this maxim has not much truth nowadays; but we remember hearing not very long ago of a lady who, on inquiring of some village crone if any medical man lived in or near the village, was answered, "No, ma'am, we mostly dies a nat'ral death." However, it is quite certain that, as Dr. Shepherd said, whatever truth the maxim had or has "should become less with each succeeding year, as the real science of medicine makes more ground among ourselves, and through us bears more upon those whose advisers, in all relating to their health, we are." He dwelt upon the work of medicine in the prevention of disease; upon the danger of an undue respect for authority; upon the evils of pretension and quackery; and on the duties of loyalty between members of the profession, and the necessity of provision for accident or disease; and insisted that the type of our mind ought to react on the mind of the people; and that our science ought to be brought home to them; that we are very much to blame if the nation is not bettered physically, intellectually, and morally by the existence in it of a well-educated body of medical men.

At St. George's Hospital, the Introductory Address was delivered by Mr. Brudenell Carter, who treated of medical education according to the definition which Paley gave of education in general, as the process of preparing in every possible way, during our youth, for the sequel of our lives. He pointed out to his student-hearers the many advantages that they possess over the students of former days, the greatest advantage of all being that they are compelled, by the requirements of the preliminary examination, to come to their work with minds exercised and strengthened by a liberal education; and at the same time warned them against setting too great store by the knowledge already gained and the training already gone through. "Much of the school teaching of the present day," he observed, "seemed to be guided by a belief that the introduction of compressed facts would mechanically expand the intellect"—instruction by "cram," that is, instead of true education; and he not unhappily compared the "show pupils of the period" with the wooden cannon known as "quakers": these "require for their production in unlimited numbers, besides the blocks of wood, only a turning-lathe and a paint-brush, and then are placed, to deceive an enemy, in embrasures which would otherwise be vacant." "Only," as he observed, "there is one grievous flaw in the analogy, for our English 'competition wallahs,' instead of being used to deceive an enemy, are used only to deceive ourselves." The qualities of mind most useful to the student, and therefore the qualities that we should seek especially to develope and strengthen by preliminary education, are—"First, the power of observation—the power of searching out and recognising facts, so as to obtain materials for the operations of the judgment; secondly, the faculty of imagination, by which to link together the known with the unknown; thirdly, the power of maintaining a suspended judgment whenever certainty is unattainable; fourthly, the love of truth." And he well remarked that strict truthfulness is not an easy or natural thing, but "in fact, and in its widest sense, one of the last attainments of the disciplined and cultivated intellect." When speaking with grateful pride of the high character of our brethren in general, he reminded his hearers that Mr. Prescott Hewett had, on a similar occasion, well told them that "It is not enough for a doctor to be honest, he must be chivalrous"; and he concluded an able address (which was delivered without the aid of notes) by quoting from "Bleak House" the charming description given by the doctor's wife of the riches her husband had acquired for them.

Dr. Prosser James, at the London Hospital, took for his subject the advances made in his days in the medical sciences and the art of applying them; and illustrated his subject by reference to the work done by London Hospital men. He drew attention especially to Dr. Herbert Davies's contributions to the comprehension of the circulation, and his law of the series and shapes of the several cardiac orifices; to Dr. Andrew Clark's researches into the nature of tubercle and phthisis; and to Dr. Hughlings-Jackson's eminent services in the elucidation of the functions of the brain and the study of its diseases. He treated also of the value of the laryngoscope and the clinical thermometer, and of the advances made in the treatment of disease by means of cool baths in pyrexia, by electrolysis, and by the introduction of new drugs, foremost among which he placed the chloral hydrate.

We cannot do more than direct attention also to the Introductories given at the provincial schools of medicine, though we are very glad to be able to find space in our pages for short summaries of some of them. It will be observed that Dr. Armstrong, in his address at Newcastle-upon-Tyne, besides the more usual topics, drew attention to the way in which the blessings of sick benefit societies may be turned, and are turned, into curses. By abuse of them a "parent's interest in the death of his offspring may be multiplied four or five times"; and he gave from his own experience examples of the evils of this system, and rightly called on his hearers to exert their utmost influence to check it.

It will be noticed that in all the other provincial Introductories sanitary medicine was the chief topic. At Queen's College, Birmingham, Professor John Clay gave an interesting review of the history of public health legislation from the time of Richard II. to the present day, and pointed to the Act of 1872, which he looks on as "a sort of Magna Charta of public health," as "the first real attempt to create a national system of public health." And he concluded by calling on all members of the profession to become instructors in the science of preventing disease, and pointed out "the important, honourable, and responsible positions held out to them, and how, by conscientiously and fearlessly discharging these duties, they may become public benefactors, strengthening vital force and prolonging human life under the conditions of health and vigour which made life worth having."

Dr. Caton, at the Liverpool Royal Infirmary School of Medicine, took "Physiology in relation to the Health of the Community, and the Advance of Medicine," as his chief subjects, and insisted on the importance of educating the people in a knowledge of the rudiments of physiology and hygiene, quoting in this connexion the words of Professor Huxley, "Were mankind deserving of the title 'rational,' which they

arrogate to themselves, there can be no question that they would consider, as the most necessary of all branches of instruction for themselves and for their children, that which professes to acquaint them with the conditions of the existence they prize so highly—which teaches them to avoid disease, and to cherish health in themselves and those who are dear to them."

And Mr. Scattergood, in his able address, at the Leeds School of Medicine, enlarged, *inter alias*, on the great importance of the art of preventing, as well as that of curing, disease.

It must be acknowledged that the Introductory Lectures of this season more than justify the continued observance of the old custom of in this way opening the winter session at the various medical schools. And it is to remembered that these addresses may have an influence over a much wider circle of readers than the profession. The daily press makes the gist of many, if not of all of them, known to the public at large, and no little good may be done by this means in awakening public interest in, and sowing seeds of knowledge of, the subjects spoken of.

HOSPITAL REFORM.

Whilst we here in London have been busy talking on hospital reform, our brethren in Birmingham have undertaken the matter in earnest, and have been able to produce a fairly good working scheme. The first step has been taken by the Queen's Hospital there, whose authorities, through the agency of the Charity Organisation and Mendicity Society, early this year undertook an investigation into the conditions of a certain number of persons who presented themselves as out-patients, whilst a certain number of the patients in the wards were examined as to their condition in life, and their statements carefully inquired into. The plan adopted was this:—The officer of the Charity Organisation and Mendicity Society attended at the Hospital on certain mornings, to take down names, addresses, and other particulars of persons who applied at the out-patient department. These persons were then visited at their own homes by an agent appointed for the purpose—a man of considerable penetration and of reliable character. It was his business to verify the statements they had made at the Hospital, and to ascertain their circumstances as accurately as possible. A circular was then sent, where necessary, to the employers, asking for the average wages, and a printed form, together with stamped and directed envelope enclosed for reply. Some of the patients lived at too great a distance to be visited, and in their cases information was sought from the clergy of the parish or the relieving officers. The nature of the disease from which each patient suffered was obtained from the Hospital registers. As regards in-patients, particulars were obtained from the Hospital of the patients who were in the wards on May 19, and the cases were followed out as above.

The result, as regards the out-patients, was that out of 366 cases investigated, information was refused in 2 and false addresses given in 34 instances, 6 were parish cases, 64 were unsuitable, and 260 legitimate. In certain instances the case was considered suitable, independently of means, the disease being of an unusually serious or prolonged character, especially where the patients' means had been exhausted in paying for medical attendance. Parish cases, too, were justly considered unsuitable when the Poor-law medical officer had not been seen; but when the patient had been treated for some time by this official without relief, and a better opinion was wanted, they were held to be suitable. The unsuitable cases were classed in two divisions, the first including those who were able to pay for medical advice; but many circumstances were taken into account, no rigid rule being adopted, and each was judged on its own merits. The following examples will show that the special circumstances of each case were allowed full weight:—

"No. 44.—Passed as legitimate because the husband's earnings were stopped by reason of his poisoned hand.

"No. 146.—Single man, wages 18s.; passed because consumptive.

"No. 189.—Young woman, whose family earn good wages; passed because she had been ill a long time.

"No. 224.—Child; parents earn good wages, but had provided medical advice for six months, and wanted a higher opinion. Passed.

"No. 260.—Young man, wages 22s.; passed because he and his brother support their aged parents."

The second division included such as were unsuitable from idleness, drunkenness, and otherwise dissolute character. From the experience thus gained the committee found themselves in a position to suggest a scheme for carrying out a systematic examination of all who present themselves, which as their experience showed was greatly required. This scheme we cannot but think fair, and it certainly is well worthy of consideration. It has been well worked out, and we would, without pledging ourselves to it in any way, earnestly bespeak it all due consideration.

"*Out-Patient Department.*

"1st.—Rules to be drawn up, by which the fitness or otherwise of applicants for hospital treatment shall be determined.

"2nd.—The Charity Organisation and Mendicity Society to be asked to undertake the investigation into the circumstances of the applicants at the hospital at a fee of .... per head. In case of their refusal the hospital to appoint its own inspectors for the purpose.

"3rd. A sub-committee, hereafter called the Revising Committee, to be appointed for the purpose of deciding upon the fitness or otherwise of the persons whose cases have been previously investigated. It is of great importance that this committee should be so constituted as to inspire the working-classes with confidence that the rules will be judiciously and impartially applied.

"4th. Every applicant who *appears* to come within the rules to receive medical treatment *on the day that he applies;* subsequent admission to benefit of hospital to be determined by the Revising Committee. Each person to be charged a registration fee of sixpence on his *first* application. This fee to be again paid whenever a month elapses between the attendances of the patient.

"5th. Any applicant who does *not* come within the rules to be referred to the medical staff, that they may decide whether the disease is of a grave order, or one calculated to conduce to the educational efficiency of the institution as a clinical hospital. If so, the applicant to be received.

"*In-Patient Department.*

"6th. Persons to be admitted as in-patients upon satisfying the Revising Committee that they are proper objects of hospital charity.

"All cases of accidents and extreme urgency to be immediately admitted, upon the general understanding that, if their means allow, they shall subsequently give a donation to the hospital.

"In order to meet the cases which (as this inquiry shows) arise from time to time of persons who are not strictly objects of charity, but whose maladies require professional skill or surgical appliances *beyond their means*, the Revising Committee to have the power of admitting such on the recommendation of the honorary medical or surgical officer, and of requiring such payment for their maintenance as, with regard to their means, may be determined upon by the said committee.

"7th.—In order to secure the clinical efficiency of the hospital, the honorary staff to have the power of directing the admission into the wards of any *special* case, each admission to be entered in a register, and subsequently laid before the Revising Committee."

We confess that the arrangements for seeing each apparently suitable case on the days when presented, and the power granted to medical officers to admit special cases on their own authority, obviate very serious objections to most ordinary

schemes; but, on the other hand, the payment of a registration fee of sixpence, though a trifle to most, would be a difficulty to some of the most deserving without a previous visit to the poor man's banker—the pawnbroker.

THE WAR ON THE GOLD COAST.

If the axiom that "in the multitude of counsellors there is wisdom" be true, the Government should have derived a vast amount of benefit from the advice which has been heaped upon it from all quarters on the subject of the conduct of the war on the Gold Coast. It is somewhat amusing to contrast the free and open-handed method of discussing our fighting difficulties of the present day with the reserve and taciturnity which distinguished the commencement of hostile operations in former times. It must be admitted, however, that if the method which now obtains is the better of the two, it is open to some few objections which did not exist under the older system. One of these to which we more particularly allude is the eager anxiety exhibited by the proprietors of every known nostrum and patent appliance to force their wares upon the unfortunate and bewildered authorities. No sooner has the first whisper of aggressive tactics obtained credence, than applications are showered upon the heads of departments soliciting orders for every description of the most anomalous products. Every inventor emphatically asserts that without a supply of his invaluable medicine or remedial agent the most unheard-of catastrophes are absolutely certain to follow, and the extra-taxed time of the offices is wasted in replying to individuals who seek to render their patriotism a means of extending their profits.

Amongst the later suggestions for the equipment of the expeditionary force which is shortly to leave this country for the West Coast of Africa, is one to provide our soldiers with respirators and mosquito-nettings. These articles would doubtless be of use, the former for modifying to some extent the inhalation of malarious and pestiferous exhalations, and the latter for protecting the slumbers of the men at night; but we almost fear their perfect applicability to the case of soldiers, who, we imagine, would be inclined to regard them rather in the light of incumbrances, and—certainly as regards the respirators—as an approach to molly-coddling.

There is a decided lull in the more active preparations for the coming campaign, not attributable in any degree to supineness on the part of the authorities, but referable, as we last week explained, to the necessity for awaiting Sir Garnet Wolseley's report. The Government, we believe, are fully alive to the importance of rapidity in action when the proper instructions from the seat of the forthcoming operations have been received; meanwhile, to prepare heaps of material which after all might not be required would only entail useless expense upon the country, and in no way facilitate the supply of what will turn out to be actually necessary.

A further contingent of army medical officers who had volunteered for service on the Coast embarked last week at Liverpool for Cape Coast Castle, and this included Surgeons R. Bennett, W. F. Bennett, D. Thornton, and W. McNalty. The Medical Department has, up to the present time, been enabled to provide officers for the peculiar service now required entirely from volunteers, and has not yet been compelled to place any others under orders; indeed, it would appear that in all branches of the service, combatant and non-combatant, there is a universal desire to take part in the forthcoming proceedings. An ample staff of willing and experienced medical officers is above all things to be desired, and we may congratulate ourselves upon possessing a large body of brave and skilful men who are anxious to place themselves at the disposal of their chief in the present emergency.

THE WEEK.

TOPICS OF THE DAY.

An exhibition of sanitary, educational, and domestic appliances in connexion with the meeting of the Social Science Congress was opened on October 2 by Dr. Bateman, Sheriff of Norwich and Physician to the Norwich and Norfolk Hospital. In opening the exhibition, Dr. Bateman delivered an address upon subjects connected with hygiene. He drew a picture of the time when, some diseases having disappeared and others becoming much less formidable, the *rôle* of the physician will become a passive one, and the hygieist will take the place of the therapeutist. Such a sanitary millennium is not yet; although when we find that by good drainage and water supply the death-rate of Salisbury, which twenty years ago used to be over twenty-six in the 1000, during the last quarter was only ten per 1000, it may be argued that it is nearer than some people suppose. England will, perhaps, some day answer to the satirist's description of Scotland and Ireland a hundred years ago, when all whom hunger spared with age decayed. At present, however, our prospects are not bright. The high price of fuel and of provisions cannot but have its influence on the health of London and the great towns during the coming winter. A scarcity of fuel always encourages overcrowding and neglect of ventilation. Dear food and coal and overcrowded dwellings are the necessary factors in the production and spread of typhus and relapsing fever, and it will be a marvel if they do not bear their accustomed fruits. Already an outbreak of typhus is reported in Drury-lane, which is supposed to have been caused by the removal of an accumulation of filth in clearing away the *débris* of a fire in Lincoln-court, Little Wild-street, or by the breaking open of coffins which were being removed from a cellar under an old Baptist Chapel in the same locality, and the consequent escape of offensive gases. This removal has been stopped by the order of Dr. Ross, the Medical Officer of Health for St. Giles's. But the seeds of typhus are probably never entirely wanting in densely populated metropolitan districts, and it only requires starvation, filth, and overcrowding to develope them into activity.

No fresh cholera cases have been reported from Liverpool; but on Tuesday last the captain of the schooner *Juliana* from Caen, an infected port, was found on board his ship, which had passed Gravesend and been hauled into the Surrey Commercial Docks, prostrate with cholera. Mr. Harry Leach, the officer of the port, had the ship taken to the isolated moorings granted by the Thames Conservators, where she will be kept with her crew in quarantine until disinfection has been properly instituted. The sick man was taken to the Seamen's Hospital.

Mr. Disraeli's celebrated letter which charges the present Government with having "worried every profession" is now matter of history. The medical profession, we suppose, is included as affording ground for the stinging censure. We believe a good many of our army medical brethren would agree as to its justice, but with regard to certain other sections of the medical world it may be a matter of dispute on which side most worry was inflicted. We should think Lord de Grey and Ripon cannot have a very pleasant recollection of his venture in medical politics during his term of office.

CHOLERA IN HOLLAND.

Our Rotterdam correspondent writes that the *Staatsblad* (official journal) of October 7 states that from September 21 to 22 three cases of cholera occurred in Bergen-op-Zoom, a town in the vicinity of the river Scheldt. From September 28 to October 4 three cases of cholera (Asiatic) occurred in Dordrecht (a seaport). No other cases had occurred in the country, or at least had been officially acknowledged as cholera.

AN IMPORTANT JUDGMENT.

THERE is, we believe, but one court of judicial inquiry in this country at which accusations of the gravest character can be brought against a prisoner in his absence: this court is the coroner's. The injustice of this is manifest, and has on many occasions been noticed by the presiding judge. With the view of remedying this abuse, coroners have frequently, particularly in the county of Middlesex, made strenuous efforts to have the prisoner before them. The magistrates in whose custody the prisoner has been have invariably refused to comply with this requisition. The Home Secretary has been appealed to, but, with a solitary exception, this official has endorsed the conduct of the magistrates. It appears that magistrates and Home Secretaries, in this obstruction, have acted in violation of the law. At least, that is the case if the decision recently given by one of the Irish judges remains a sound one. We cannot give a better summary of the proceedings before Mr. Justice Fitzgerald on Saturday last than the following extract from the *Times*:—

"A blacksmith named Reardon has been arrested by the police and brought before the magistrates, who have remanded him, on a charge of causing the death of a young woman by throwing her into the Liffey. At the coroner's inquest, which is still pending, the police authorities refused to direct that the prisoner should be in attendance, and the coroner declined to proceed in his absence. An application was made on the prisoner's part for a *habeas corpus* to have him tendered for examination, and the law officers of the Crown opposed it on the ground that there were no special circumstances to call for the issue of the writ. There had been a usage in Dublin of obtaining a warrant from the magistrates for the attendance of a prisoner, but there was no legal authority for it. Counsel on behalf of Reardon, contended that great injustice might be done if the inquest proceeded in his absence, because the result might be a finding of "wilful murder" upon which he could be indicted. In these respects the current jurisdiction of the coroner was greater than the magistrate. Mr. Justice Fitzgerald held that the applicant was entitled to be present at the inquest, in order to give evidence or put such questions on cross-examination as might tend to exonerate him, and that it would not be right to have evidence given behind his back upon which he might be indicted. He therefore granted the writ, subject to the filing of a proper affidavit setting forth that he was advised that the attendance at the inquest was necessary. A similar conflict of authority between the coroner and the police occurred recently in Belfast in a murder case.

"Subsequently, at the inquest held in presence of the prisoner Reardon, it was clearly proved that the deceased committed suicide. Reardon is still in custody under remand of the police magistrates."

It is difficult to understand, after this verdict, upon what ground Reardon remains in custody. It may possibly be solved by the obstinacy of the magistrates, who it seems are not satisfied with evidence which appears to a common jury to be perfectly conclusive and incontrovertible. We trust that this case will form a precedent of which coroners in the future will take advantage, and thereby give an importance to the coroner's court to which its usefulness clearly entitles it. A writ of *habeas corpus* over-rules not only the dicta of magistrates, but the decision of a Home Secretary.

DEATH FROM AN ANÆSTHETIC AGENT.

AN inquest was held at Southampton on Saturday last on the body of a boy aged fourteen, who died from the effects of ether administered to him at the South Hants Infirmary. It had been decided to perform an operation on deceased, for which purpose he was placed under the influence of ether. The jury, having heard all the facts of the case, at once returned a verdict of accidental death. The foregoing is reported to be the first fatal case of the kind which has taken place at the South Hants Infirmary for a period of twenty-four years.

DR. WHITMORE'S REPORT ON TYPHOID FEVER.

A LONG and animated discussion took place on the report of the Medical Officer of Health for the parish at the meeting of the Marylebone Vestry last week. The adoption of his report was proposed and seconded; but Mr. Emery, a member of the Sanitary Committee, moved an amendment, on the ground that the report was one-sided, and did not contain all the facts. He did not believe in the milk theory at all, and thought it was more likely that Dr. Murchison, being himself, as he (Mr. Emery) believed, attached to a fever hospital, might have carried the fever home to his family, and also to the houses of patients he visited. This amendment was seconded by Mr. Stevens, who objected to Dr. Whitmore having given a certificate in favour of a particular farm being free from contamination, and it was held that, as Medical Officer of that Board, he had no business to do so. Dr. Whitmore defended his right, and stated that he had not only the support of Dr. Murchison, but that he had also consulted Sir William Jenner, who had taken a deep interest in the matter, and had largely assisted him in its solution, and was of the same opinion as Dr. Murchison. Ultimately the report was adopted by a majority of 44 to 7. A vote of thanks was also carried to Dr. Whitmore for his energetic action in reference to the recent outbreak of typhoid fever, and for his valuable report thereon; to Dr. Murchison, for the zeal and scientific skill he had brought to bear in his assistance to the Medical Officer of Health in the conduct of his inquiries; and to Sir William Jenner for the assistance he had also afforded in pursuing the investigation. Dr. Whitmore, in suitable terms, thanked the Vestry on the part of himself and his medical colleagues for this expression of its approbation. It is due to Dr. Whitmore to state that he has carried on the inquiry respecting the outbreak of typhoid fever with great ability and judgment, and he was fully entitled to the gratitude of his fellow-parishioners.

SANITARY AND ADULTERATION ACTS.

WITH the view of meeting some of the difficulties which our medical and sanitary officers have had to contend against to secure a proper removal of dust, Dr. Meymott Tidy, the Medical Officer of Health for Islington, has proposed a new plan, the principal feature of which is that the contractor should only be paid for the quantity removed. In reference to the enforcing the Adulteration of Food Act in the parish of Islington, Dr. Tidy reports to the vestry that, as a proof that the prosecutions in milk cases have been of very considerable benefit, the last twenty samples of milk he examined proved to be very superior in quality to those he previously analysed. He had also examined twenty samples of bread, and it was a matter for congratulation that only in four cases did he find alum. The amount in these was small, and therefore no action was taken. He had also examined two samples of tea, both of which were pure.

CHOLERA IN NAPLES.

"THE cases of cholera," observes the Naples correspondent of the *Times*, writing on the 28th ult., "up to this day may be put down as being nearly 300, many of which have proved fatal. On the 24th inst. there were 12 cases and 9 deaths; on the 25th, 22 cases and 19 deaths; on the 26th, 11 cases and 7 deaths. For the last two days we have had a cold north wind blowing, and there has been an evident decrease in the number of those who are said to have been attacked. It is supposed that the real extent of the malady is not declared. Making allowances, however, for concealment, the cholera of this year is by no means so formidable as it was on its former visitations. The proportion of deaths is larger, but the malady does not spread so rapidly; it is better understood, and sanitary regulations are more attentively observed."

THE LONDON HOSPITAL MEDICAL COLLEGE.

After the Introductory Lecture, the following prizes were distributed by Edmund Hay Currie, Esq., Chairman of the House Committee of the Hospital. Clinical Medicine: £20 Scholarship, given jointly by the House Committee and the Medical Council—Mr. R. Kershaw. Clinical Surgery: £20 Scholarship, given jointly by the House Committee and the Medical Council—Mr. T. D. Watson; Honorarium £15—Mr. W. Lang. Clinical Obstetrics: £20 Scholarship, given jointly by the House Committee and the Medical Council—Mr. T. D. Watson; Honorary Certificate—Mr. R. R. Llewellyn. Dressers' Prizes for zeal, efficiency, and knowledge of Minor Surgery, given by the House Committee: £15 Prizes—F. B. Collenette, S. D. Clippingdale, A. Brandum; £5 Prizes—H. E. Price, E. G. C. Snell, J. Needham. Buxton Scholarships, given for proficiency in the subjects required for the Preliminary Examinations: £30 Scholarship—Mr. W. P. Mears; £20 Scholarship—Mr. S. H. Fisher; Honorary Certificate—Mr. E. Brumwell. Human Anatomy: £20 Scholarship, given by the Medical Council—Mr. John Neylan; Honorary Certificate—Mr. H. T. Batchelor. Anatomy, Physiology, Chemistry: £25 Scholarship, given by the Medical Council—Mr. R. H. Fox; Honorary Certificate—Mr. H. Habgood. Special Certificates awarded to Medical Assistants for three months' service—J. Blunson, H. T. Shapley, C. W. Drew, F. E. Pocock, R. R. Llewellyn, R. Kershaw, W. Porter, H. M. Leckler, W. H. Todd, B. Crawshaw, R. D. Smith, C. A. Low, E. O. Bark, J. H. Allden.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

A conversazione was held in the board-room at St. Mary's Hospital at the conclusion of the Introductory Address by Dr. Shepherd. Both the address and the social gathering afterwards were attended by a very numerous company of past and present students, members of the staff, and medical men and others residing in the neighbourhood. Amongst them were Dr. Sibson, F.R.S., Mr. Spencer Smith, Dr. Handfield Jones, F.R.S., Mr. Gascoyen, Dr. Meadows, Mr. W. B. Owen, Dr. Leadam, Dr. Norton, Dr. T. King Chambers, and many others of well-known name and reputation.

THE ATCHINESE EXPEDITION.

A convoy of 250 Dutch troops sailed on Monday last for Java and Sumatra from Nieuwe Diep, at the entrance of the Zuyder Zee, in the steamship *Celebes*. These are the last who will reach the islands in time for the expedition against Atchin. There are two English doctors on board—Dr. Mayo and Mr. Galton,—who go with the expedition. The arrangements made by the company to which the ship belongs for the treatment of any sickness that may make its appearance among the troops or passengers were of the most moderate kind. There were plenty of drugs, and a ship's doctor; but the doctor had no place given him to put his drugs in, and was obliged to put them in his berth, in a very small cabin which he shared with another passenger, the fact being that the company had simply put passengers into the cabin which ought to be the doctor's. Some improvement was insisted on and enforced before the ship sailed, but everything had to be done in a hurry and imperfectly. Very contradictory reports are given of the climate of Java and Sumatra. Some represent it as most deadly, especially on the low ground near the coasts; others, and the majority of those who have much to do with the islands, take the climate as a matter of course, and do not seem at all afraid of it. On the other hand, several Javanese ayahs, or "baboos," on board the *Celebes* wear the same light clothing that they would use in their own country with apparent impunity, though the weather has been by no means warm at night and in the morning.

A LIBERAL BOARD OF GUARDIANS AND OVER-PAID DOCTORS.

On the proposal of a motion to increase the medical officer's salary, the following discussion occurred at the last meeting of the Wakefield Board of Guardians. The pecuniary value at which they estimate the services of gentlemen in our profession is amusing and characteristic. Mr. Oliver moved that the salary of Mr. J. Heaps, the Medical Officer for Lofthouse-with-Carlton, be increased from £10 to £15. He said the rateable value of the township had been nearly doubled and the population increased by a thousand since the appointment at £10 was made. Mr. Marshall said the rateable value of Shaulston was nearly as much as that of Lofthouse-with-Carlton, and yet their officer only received £5. Mr. Oliver urged that they could not estimate a doctor's work by the rateable value; it was the population they had to go by. Mr. Marshall's impression was that he (the doctor) was well paid. The Chairman explained that the township paid half the salary and Government the other. Mr. Connor reminded the board that the application had been strongly recommended by the ratepayers of the township. The resolution was thereupon put and carried. Mr. Heaps was then formally reappointed at the salary named.

A BAVARIAN HOSPITAL.

The correspondent of a contemporary gives the following interesting particulars from Wurzburg of the Julius-Spital (or hospital), founded in 1576 by the Prince-Bishop Julius, whose statue, by the celebrated Schwanthaler, of Munich, fronts the building. Notwithstanding the disastrous effects of war and other misfortunes the revenues of this beneficent establishment remain intact, and its capital is at the present time over five millions of florins. It has also an enormous estate, consisting of arable land, forests, and vineyards. In the hospital are forty-six wards, capable of accommodating 350 patients, and there are also twenty rooms appropriated to 200 pensioners, who, however, must be of the Catholic religion and natives of the *ci devant* dukedom of Franconia.

HEALTH OF KENSINGTON.

In his annual report on the health of the Kensington district, comprising Kensington Town and Brompton, Dr. Orme Dudfield seates that the mortality during the year was 17·17 per 1000, and was lower than the rate in Dover, Hastings, Brighton, Bath, and Cheltenham. Compared with Hastings, which stood at 17·80, and Cheltenham at 17·60, Kensington may well be called a health-resort of high character.

ROYAL INFIRMARY, LIVERPOOL.

The new buildings which have recently been added to the School of Medicine in Dover-street, Liverpool, were formally opened by Mr. John Torr, M.P., on the 1st inst. The opening ceremony was well attended by members of the medical profession, and a large number of the students of the school were also present. Dr. Waters, the treasurer of the fund which had been subscribed for the extension and improvement of the School of Medicine, read an address to the meeting.

GLASGOW SOUTHERN MEDICAL SOCIETY.

At the thirtieth annual meeting of this Society, held on the 2nd inst., the following office-bearers were elected for the session 1873-74:—*President:* James Dunlop, M.D. *Vice-President:* John White, M.D. *Treasurer:* Edward Macmillan, L.R.C.S.E. *Secretary:* John Dougall, M.D. *Seal-Keeper:* Robert T. Paton, M.D. *Court-Medical:* Eben. Duncan, M.D. (convener); Robert W. Forrest, M.D.; David Tindal, L.F.P.S.G.; William Rice, M.D.; and J. H. Menzies, M.D.

FROM ABROAD.—THE FACULTY OF MEDICINE AT KIEL—BELLADONNA PLASTERS IN VOMITING.

Dr. D'Espine furnishes to the *Gazette Hebdomadaire* (No. 37) some interesting particulars concerning a visit he has recently paid to the Faculty of Medicine at Kiel. Among 250 students at this University from sixty to seventy are medical. The Faculty enjoyed a great reputation when Kiel was the capital of the Duchy of Holstein, such names as those of Stromeyer and Langenbeck in surgery, Griesinger and Frerichs in medicine, and Michaelis in midwifery, show that this was well deserved. Its fame seems likely to continue since the annexation. Its present Professor of Clinical Surgery, Esmarch, is well known by his operation in constriction of the jaws, and by numerous publications. Among these his recent treatise on nervous affections of the joints (*Gelenkneurosen*) is highly esteemed, relating as it does to a portion of the domain of surgery that has been but little explored. Stromeyer also has quite lately published a *brochure* on the same subject, recalling the well-known researches of Brodie, and communicating a series of corroborative cases that he has met with in his own private practice. The professor of clinical medicine, Dr. Bartels, who like Esmarch is a Schleswig-Holsteinian, is a good *eliniciens*, professing a great admiration of Trousseau, many of whose views he has adopted. What is rare for a German practitioner, he admits no distinction between croup and diphtheria, and has resorted to tracheotomy on a large scale. His paper in the *Deutsch. Arch. f. Klin. Med.*, Band ii., is an interesting monograph on the cases of diphtheria observed at Kiel. Among other important contributions is one of the earliest papers on catarrhal pneumonia (*Virchow's Arch.*, B. xxi.); another on the treatment of pleurisy by paracentesis; and a very lucid exposition of recent investigations on diseases of the kidney, contained in Volkmann's *Vorträge*. The professor of gynæcology and obstetrics, Dr. Litzmann, is a worthy successor of Michaelis, and like him is known on account of his researches on contraction of the pelvis.

"The hospital is the centre of the medical life of Kiel, all the lectures, except those on anatomy and physiology, being given within its walls, either at the bedside or in theatres adjacent to the wards. Nothing can be more pleasing than the park well shaded with trees in which it is placed, situated on a hill outside the town, with a view of the magnificent harbour. Here are all the university buildings, and the sick are lodged, as it were, like princes. The buildings are recent and well-arranged in their hygienic relations; and, while there is great simplicity in its beds and other furniture, there is an ample supply of air and water, and the greatest cleanliness prevails. There are many small rooms and few large wards, allowing of bed-curtains being dispensed with, and securing sufficient isolation. The maternity is in a separate building, and small-pox patients are strictly isolated in separate pavilions. Croup, which is of frequent occurrence at Kiel, is treated in the ordinary wards, and measles and scarlatina have never prevailed sufficiently to call for isolation. In the surgical wards, hospital gangrene is the only disease treated separately, separation having been tried in vain for erysipelas. The park also contains sheds for surgical affections, a small but well-appointed pathological institute, an ophthalmological clinic, and the residences of the professors."

The writer gives, as an example of the mode of procedure, an account of one of his fully employed days at the Faculty.

It commenced at seven with the *Demonstrations-Kurs* at the pathological institute. At this, Professor Heller describes various of the pathological specimens, illustrating them by plates and microscopical preparations. In reference to each lesion he gives a short account of the state of that portion of pathology. The students are divided into several groups, so that each is enabled to see and touch the parts; and while the Professor repeats his demonstration to some of them, others are examining the microscopical preparations. At nine the obstetric clinic commences, the system being the same as that observed at Paris. The patients are examined in their beds, or, if they are easily transportable and their cases very remarkable, in the theatre. It is in this department that the advantages of small hospitals for teaching come out. *Das Material*, as the cases are called, is not very abundant, but each pupil superintends a delivery and reports the case in full next morning at the clinic. Puerperal fever is very rare, and almost always sporadic. Great precautions are also taken, no student being allowed to touch a woman without having washed his hands in permanganate, while the autopsies are always performed by the professor of pathological anatomy, and never by the students. Each woman, too, has a syringe or other apparatus to herself. The student-midwives, who are usually women from the country, do all the duties of the wards, and take, three or four times a day, under the direction of the *Assistent-Arzt*, the temperature of the women who have been delivered. In attendance on each woman in labour are a student-midwife and a medical student, a pelvis with the head of a fœtus and a midwifery manual being always close at hand. Crédé's method of expelling the placenta by expression is always followed.

At ten the medical clinic commences, the patients having been first passed in review by the *Assistenten*. The most interesting cases are picked out for the clinic, and are interrogated in turn by the senior students (termed *Practikanten*), the professor discoursing to the class on their diagnosis and treatment. After this the patients are visited in their beds, and then the class adjourns to the dead-house to witness with their professor the autopsies of cases that have proved fatal, these being performed by the professor of pathological anatomy. At midday, Professor Esmarch's surgical clinic commences, and the observer is at once struck with the numerous examples of the various forms of scrofula that are presented. Lupus, necrosis, and white-swelling constitute more than half of the whole material. The treatment adopted, designated as *Abkratzen*, is quite peculiar. It may be translated as *abrasion* or scraping, and is a modification of Sédillot's *évidement*. Esmarch does not perform excision in the regular manner, but, with the object of saving as much of the bone as possible, scoops away all carious portions, breaks off carious protuberances by Liston's forceps, and bores here and there, if required, the carious extremity, leaving in the track one of Lister's drains. These operations are very long and laborious, and the Professor has of late employed, during their performance, the compressive caoutchouc bands lately described in our columns, which entirely prevent bleeding, and allow him to pursue his dissection as on the dead body. This complete compression is sometimes continued for almost an hour without any ill effect. Lupus has also for some time past been successfully treated by abrasion, all the diseased portions of skin or mucous membrane being scraped away by means of the acorn-cup-shaped gouge of Bruns. The bleeding parts are then covered by wadding soaked in perchloride of iron, giving the patient a most hideous appearance, due to the mixture of black, yellow, and red which covers his face. Cicatrisation is completed at the end of some weeks, the treatment being repeated if relapse takes place, until the extinction of the disease is attained. All wounds are dressed with what is called Bruns' wound-dressing cotton, which is brought in bales from Schaffhausen, small slips of muslin soaked in phenic acid being laid beneath it, and the whole covered by impermeable varnished paper. This dressing remains three days *in situ*. Cataplasms are rarely used, bladders with ice being substituted. For wounds that bleed much after indispensable ligatures or torsions have been employed, gauze bags containing perchlorated wadding are introduced. Irrigation, which had long been employed, has been reduced to within the limits of strict necessity, as Professor Esmarch has met with bad results from its continuance. In the evening the Pro-

fessor delivers a course of lectures on surgery, which he illustrates by drawings of cases that have occurred in his wards.

At a recent meeting of the Paris Therapeutical Society, Dr. Guéneau de Mussy read a communication on the good effects of belladonna plaster in the symptom of vomiting, whatever the nature of this may be. Bretonneau, whose name is so familiar in modern therapeutics, paid great attention to the action of belladonna, and strongly recommended it in the incoercible vomiting of pregnancy. He prescribed frictions of the extract diluted with water, which was rubbed into the hypogastrium during several minutes two or three times a day. In many instances this treatment succeeded in relieving vomiting in pregnancy when all other means failed. As belladonna absorbed by the skin will thus relieve the morbid irritation of the uterus which is the cause of the vomiting, so will it also modify that of the stomach itself; and for more than twenty-five years Dr. Guéneau de Mussy has extended Bretonneau's treatment to all descriptions of vomiting, whatever the cause of this may be; but he has found that a plaster is a better excipient of the extract, allowing of its continuous application being conveniently made. It consists of diachylon plaster and theriac plaster of each two parts, and extract of belladonna one part, the plaster being twelve centimeters in diameter. It may remain applied to the epigastrium for twelve or fifteen days without being renewed; and out of the thousands which he has employed the author has only met with one case in which an idiosyncracy caused some ill effects to result. It is not meant to be asserted that this means always succeeds, but it has succeeded in a very great number of cases, either in entirely relieving vomiting or greatly mitigating it, some remarkable examples of which are alluded to in the paper. This success has encouraged Dr. Guéneau de Mussy to try the effect of the plaster as a prophylactic and curative in sea-sickness, and although as yet he has only tried it in four cases, he entertains great hopes of the benefit to be derived, and at all events thinks that so simple a remedy deserves further trial in so extremely painful an affection which has hitherto resisted all measures of relief. The first of these four cases occurred in the person of a young married lady, who never could place foot on a vessel without being tortured by sea-sickness, and who always landed in a state of exhaustion and semi-syncope. Having to make a voyage to Australia, she was advised to try the belladonna plaster, and after having had some vomiting on the first day, she, when last heard of, had traversed the Red Sea without sickness and in good health. A Brazilian physician, who had made several visits to Europe, and every time had been tormented by repeated and obstinate vomiting, and suffered greatly from this, eagerly adopted the plaster, and although in his last voyage the passage was a very bad one, he only felt slight nausea. A great personage of the same country was also a constant victim of sea-sickness, but on the last occasion he made the passage without any attack, and was able to walk the deck, which he had never done on any of the other passages. On board the same vessel was a lady in whom sea-sickness had produced, if not alarming, yet very distressing symptoms. One of the plasters was applied, and in the course of a few hours the vomiting, which had been incessant, completely ceased, so that the patient was enabled to join the other passengers on deck. These observations are given only for what they are worth, wanting as they are in exact details; but they may serve to draw further attention to the means employed.

In reference to the cholera at Liverpool it has been officially stated that there was already sufficient hospital accommodation for any cases of cholera which might arrive suddenly, and that in twenty-four hours additional accommodation could be provided to a much larger extent.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Forty-third Meeting.

(*From our Special Correspondent.*)

Of the Action of Light on the Retina and other Tissues.

Dr. McKendrick gave an account of the observations made by Mr. Dewar and himself on the physiological action of light. He described the method employed. They succeeded in the first instance with the eye of the frog. The eye was placed on an apparatus in connexion with a delicate galvanometer, and the electro-motive force determined. It was then observed that the electro-motive force was affected by light. On the impact of light there is an increase; during the continuance a diminution; and on its removal there is another increase. They have found the same results in the eye of the living cat, pigeon, owl, serpent, frog, toad, newt, stickleback, goldfish, rockling, crab, lobster, hermit crab, and swimming crab. They have also observed the effects of the various colours of the spectrum, and found that those rays which to our consciousness are the most luminous produce the greatest amount of change in the electro-motive force.

Physiological Researches on the Nature of Cholera.

This was a paper by Dr. Brunton. The search after a true remedy for cholera, the author thought, had hitherto been fruitless. The cause of the disease was now generally admitted to be a poison of some sort which could be transmitted from one person to another, but there must also be a proper soil for the development of the poison—in other words, the blood and tissues must be in such a state that it can act upon them. In the state of collapse there was constant vomiting and purging, and the intestinal canal was speedily washed clean out, the stools consisting of the secretion alone; the blood stagnated in the great veins of the thorax and abdomen, and left the skin shrunken, pale, and cold, the interior of the body being hotter even than in a state of high fever. The blood which filled the small cutaneous veins, being no longer driven forward by fresh supplies from the arteries, became completely deoxidised and black, imparting to the surface a livid hue. It still retained its power to take up oxygen and give off carbonic acid; but notwithstanding this, it passed so slowly through the pulmonary vessels that only about one-third of the usual quantity of carbonic acid was given off from the lungs, and little oxygen being taken in, there was a distressing feeling of want of breath. At the same time the voice was hoarse, low, and weak; but this seemed to be simply a consequence of the general exhaustion of the patient. The symptoms of cholera all arose from disturbance of the circulation and the altered intestinal secretion, and it might be thought that the only way to remove those conditions would be to eliminate from the body the poison which was producing these effects, and that so long as it was still circulating in the blood any remedy which was simply intended to counteract it would be administered in vain. But the researches of Fraser and others on antagonism had shown that the elimination of a poison was not required in order to prevent its injurious or fatal action. The administration of an antidote would deprive it of its hurtful power; and as it was with other poisons so might it be with that of cholera. It occurred to Dr. Bruton that, if any poison should possess actions similar to those of the cholera poison, an antidote to it might possibly prove to be a remedy for cholera. He therefore began to look for a drug which would produce the same changes in the circulation which occurred in cholera. These were, he believed, first attributed by Dr. Parkes to spasmodic contraction of the vessels in the lung, which prevented the blood from passing through them; and this opinion found a warm supporter in Dr. George Johnson. Most of the symptoms, though not all, could be explained on this hypothesis. Professor Schmiedeberg, in investigating the physiological action of a poisonous mushroom, the *Amanita muscaria* or *Agaricus muscarius*, noticed that when given to animals it caused great dyspnœa, and at the same time the arteries became empty, so that when cut across hardly a drop of blood issued from them, this being the condition which existed in cholera. Administering atropia to the warm-blooded animals suffering from these symptoms, Professor Schmiedeberg found that they at once recovered; but he had not thought at all of contraction of the pulmonary vessels as a cause of dyspnœa. He attributed it rather to excitement

of the nervous centre in the medulla oblongata, which regulates the respiratory movements; and the effect of atropia itself being to excite this nervous centre, it ought, according to his supposition, to have increased instead of removing the breathlessness. When the idea that the dyspnœa was due to contraction of the pulmonary capillaries suggested itself to Dr. Brunton, he proceeded to test it by experiment. He first gave a rabbit such a dose of chloral hydrate as to deprive it of all sensibility, then put a tube into the windpipe, and connected it with a pair of bellows. He was thus able to inflate the animal's lungs at regular intervals and keep up respiration artificially when the animal could no longer breathe itself. He next opened the thoracic cavity so as to observe the slightest change in the lungs or heart. He injected a little muscarin into the jugular vein, when the lungs which had been previously rosy became blanched; the right side of the heart swelled up, the veins passing to it became enormously distended, and the left side of the heart became almost empty. Shortly afterwards he injected a little atropia into the jugular vein. At once the effects of the muscarin disappeared, and everything assumed its normal appearance. From the want of muscarin he had not pursued his investigations, but hoped shortly to do so. Hitherto he had proceeded on the assumption that Drs. Parkes' and Johnson's theory of cholera was correct, and that the stoppage of the circulation is due in cholera, as in muscarin poisoning, to contraction of the arteries of the lungs. In poisoning by muscarin the great veins of the thorax and abdomen and the right side of the heart seemed to be almost equally distended, and exactly the same condition was found in persons who had died of cholera. But it was not certain that the right side of the heart was always so much distended during life, even when the symptoms of cholera were present in their most pronounced form. It would almost seem that the veins dilated still more in cholera collapse than they did in muscarin poisoning. Nitrite of amyl has the power of dilating the arteries throughout the body, and those of the lungs also. But it was found practically to be of no use in cholera. The pulse might become a little stronger and the surface a little warmer, but the improvement was so slight that it was hardly worth mentioning, and the patient felt no better for the medicine either when inhaled or when injected subcutaneously. If the weakness of the pulse depended only on contraction of the vessels in the lungs, this result would be astonishing; but if they supposed it to be caused by dilatation of the great veins, it was just what they would expect. From these and other facts Dr. Brunton concluded that the veins were dilated, and that, therefore, some remedy must be employed which would make them contract. There had been few experiments on the contractility of the veins, but in the condition of depression or shock following severe injuries in which the veins were much dilated, digitalis had been found useful, and it might be found useful in cholera also. Atropia had been lately tried in cholera by an American practitioner with considerable success, and it seemed deserving of more extensive trial. It would not do, however, to consider the action of any proposed remedy for cholera on the circulation alone, and to leave out of account its effect upon the intestinal secretions. He therefore set to work to discover the action of atropia upon those secretions. Since the effect of cholera upon the intestine was the same as that of division of the nerves, which was one cause of secretion, they were justified in believing that if any drug could stop the secretion in the experiment of dividing the nerves it was likely to have a similar effect on cholera. Now, atropia had a remarkable power to stop secretion from the salivary and sweat glands when their nerves were irritated, rendering the mouth and skin quite dry. What its effect on paralytic secretion in the salivary glands might be he did not know, but thinking that it might arrest the flow of fluid into the intestine he repeated Moreau's experiment, and injected some solution of atropia into the veins of an animal. The result was disappointing, and rendered the use of atropia in cholera somewhat doubtful. It was, however, difficult to foretell the effect of any drug under particular circumstances, and he should therefore continue his experiments. The points to which he wished to direct particular attention were these: —(1) That, assuming Parkes' and Johnson's theory to be correct, and the impeded circulation in cholera to be due to obstruction in the pulmonary vessels, atropia was likely to prove beneficial to a certain extent; and since it had been empirically found to be useful in the disease, it ought to receive a fair trial at the hands of the medical profession. (2) The fact that the right side of the heart was not dilated during life in cholera patients, as well as the uselessness of nitrite of amyl, which dilated the pulmonary vessels, showed that Parkes' and Johnson's theory, if not erroneous, was at least imperfect, and that one of the most important pathological conditions in cholera collapse consisted in an active dilatation of the thoracic and abdominal veins. Any remedy, to be useful in cholera, must have the power of counteracting this condition; and the administration of digitalis in cholera collapse might be useful. (3) The profuse secretion from the bowels in cholera was due to paralysis of some of the intestinal nerves; and a remedy which will arrest it is still a desideratum.

GERMAN ASSOCIATION FOR THE ADVANCEMENT OF NATURAL SCIENCE AND MEDICINE.

(*From our Special Correspondent.*)

WIESBADEN MEETING, SEPTEMBER, 1873.

(*Continued from page* 395.)

Abstracts of some of the most important Papers:—Dr. Köhler on the Physiological Action of Bitter Principles—Professor Kollmann on the Influence of Water on the Red Corpuscles of the Blood—Dr. Ponfick on the Pathological Changes in Relapsing Fever—Professor Eberth on Embolism by Fat—Professor Jürgensen on a Mild Form of Typhoid.

IN the Section of Anatomy and Physiology, Dr. Köhler, of Halle, related the results of his experiments on the physiological action of bitter principles on the circulation and blood-pressure. When cetrarin, columbin (and probably other bitter principles), are injected into the veins, they cause first a diminution, and thereafter a gradual elevation of the arterial pressure. The fall of the pressure also occurs after division of the spinal cord and vagus, and its cause is to be found in the heart itself. It occurs as well after the terminal branches of the vagus in the heart have been paralysed. The rise of the blood-pressure on the other hand, which is observed as the second effect of the injection of columbin, etc., must be referred to the irritation of the vaso-motor centre, for it does not occur after section of the spinal cord. The frequency of the heart in these experiments is not altered until shortly before death.

In the same section, Professor Kollmann, of Munich, described certain observations which he had made upon the effect of water on the red corpuscles of the blood. If the blood of a decapitated frog be allowed to flow into water, and a drop examined after a quarter of an hour, the coloured corpuscles are found—not swollen, as one might expect—but shrunken, with an irregular surface and outline and a stellate nucleus. This condition lasts for days, and cannot therefore be due to a "vital" contraction. Kollmann would refer it to a coagulation of the stroma of the corpuscle, as described by Brücke, Stricker, and Rollett.

In the discussion on this subject, Professor Gerlach, of Erlangen, confirmed the observation of Kollmann: the condition described he has seen last for fourteen days. He could positively say that the same effect never follows the addition of a drop of water to a drop of blood, and he confessed that no explanation can be given at present of these remarkable phenomena.

In the section of Pathological Anatomy, Dr. Ponfick, of Berlin, assistant to Professor Virchow, read a description of the pathological changes in Relapsing Fever. A very large number of post-mortem examinations were made in the Pathological Institute at Berlin during the late severe epidemic of the disease, but only a few of the most striking changes would be described on this occasion. Most of the patients died of pneumonia, with abundant exudation. This was a mere complication, but remarkable nevertheless from its frequency, and from the disease having been usually developed in the hospital without evident external cause. The spleen presented at times very considerable alterations. In about a half of the cases it was swollen, sometimes extremely so. In other cases there was infarction of the organ, very much as in endocarditis, the form and true characters of the infarct being present, without any alteration in the heart or thrombus in the veins, except in a single case. Ponfick would refer this infarction, therefore, to a local cause. The condition may advance, adhesions form, ulceration take place, and even perforation of the diaphragm may be found. In one case the splenic swelling ended in rupture and fatal hæmorrhage. A third alteration

found in the spleen in some of the cases was the appearance of a number of small yellowish-white points and streaks—altered Malpighian bodies. In these spleens there were found with the microscope enormous granular cells, as in other diseases of the same organ. They could also be discovered in the bloodvessels throughout the body, sometimes in great numbers, as very large nucleated cells. Some of these were probably endothelial cells, but others were so characteristic that there could be no question of their splenic origin. Besides these cells, the bodies discovered and described by Obermeier were found in the blood. The medulla of the bones was examined in fifteen cases, and in four of these definite appearances were observed—namely, hæmorrhagic infarcts passing into yellow masses.

In the same section, Professor Eberth, of Zürich, made a short but important communication on Embolism by Fat, which has lately excited fresh interest among pathologists. Eberth finds a source of the fatty-embolus in breaking down coagula in the heart. If the coagula occur in the right side of the heart, embolism of the pulmonary capillaries results, and severe dyspnœa should the condition be at all extensively distributed. Fresh coagula form upon the broken surfaces of the older ones in the heart, and these undergoing in their turn fatty degeneration, a great part of the pulmonary capillaries are filled with fatty emboli.

In the section of Medicine, Professor Jürgensen, of Tübingen, described what he designated a "Mild Form of Typhoid Fever." He had observed over a hundred cases, of the specific nature of which there could be no doubt. The following are the principal characteristics of this form of the disease:—1. The infection seems to be sudden: 57 per cent. could give an account of their being suddenly taken ill. 2. Pyrexia lasts from ten to sixteen days. 3. The absolute temperature varies much: in some it reaches even 42° C., in others it is low; but it is more steady, and less affected by quinine, etc. 4. The spleen is nearly always enlarged. 5. The eruption occurs in about one-half of the cases. 6. Bronchitis occurs in about 28 per cent., and is mild. 7. Diarrhœa is present in but 16 per cent. 8. There is a frequent and early alteration of the urine. Jürgensen believes that these cases may develope into ambulant typhoid fever. There is nothing new to be said in regard to treatment. Of the etiology of these cases—especially in regard to infection by milk—he could say nothing. A full description of this form of typhoid fever will shortly appear in Volkmann's *Klinische Vorträge*.

REVIEWS.

The Microscope and Microscopical Technology: a Text-Book for Physicians and Students. By Dr. Heinrich Frey, Professor of Medicine in Zurich, Switzerland. Translated from the German and edited by George R. Cutter, M.D., Clinical Assistant to the New York Eye and Ear Infirmary. New York: William Wood and Co. 1872. Pp. 627.

It may be taken as characteristic of the German mind, rather than as any pretence at modesty, when Dr. Frey, in his introduction, speaks of this thick, large octavo volume as his "little work." It is, in reality, a very complete and full treatise on the employment of the microscope in medicine, giving a description of the mechanism of the instrument, and of using its several parts; of the various methods of investigation now in use; and directions for the examination of the various tissues and parts of the body in their normal and pathological conditions.

The work is divided into twenty-two sections, and the best way, perhaps, of showing the fulness of the treatment of the subject will be to name the subjects of the several sections. The first treats of the "Theory of the Microscope"; the second, of "Apparatus for Measuring and Drawing"; the third, of "The Binocular, the Stereoscopic, and the Polarising Microscope"; the fourth, fifth, and sixth, of "Testing the Microscope," of the "Use of the Microscope," and of "The Preparation of Microscopic Objects"; the seventh, eighth, ninth, and tenth deal with "Fluid Media and Chemical Reagents," with "Methods of Staining, Impregnation with Metals, and the Drying and Freezing Processes," with "Methods of Injecting," and with "The Mounting and Arrangement of Microscopic Objects"; and the rest of the sections, from the eleventh to the twenty-second, both inclusive, describe the various fluids and tissues of the body, from "Blood, Lymph, Chyle, Mucus, and Pus," through "Epithelium, Nails, and Hair," the "Connective Tissue and Cartilage," the "Bones and Teeth," "Muscles and Nerves," and so on, down to the last two sections, which are devoted to the "Sexual Organs," and the "Organs of Sense."

The sections on "Testing the Microscope" and the "Use of the Microscope" strike us as being particularly good, and we are pleased to see that the author insists especially on the value of low powers. At page 74 he says—"We would here call to mind what we have previously said with regard to the great value of weaker powers. They should never be wanting. At least one objective of medium strength is also a valuable additiou. Finally, a stronger objective, which with a weak eye-piece magnifies from 200 to 250 times, and with a stronger one affords a good and thoroughly serviceable magnifying power of 300 to 350, should not be wanting on any microscope." And he shows "that he who can obtain about the same magnifying power in a double manner—that is, by means of a weak objective and a strong eye-piece, or by means of a strong objective and a weak eye-piece—should always have recourse to the latter." But though the clearness, preciseness, and fulness of this part of the work have seemed to us especially praiseworthy, the rest is also excellently done. The microscopical appearances of diseased tissues is not very fully treated of; but Dr. Frey, in his introduction, gives a good reason for this. "Possibly," he says, "in the department of pathology we have been too concise for a portion of our readers. The investigation of sputum, pus, urinary sediment, and tumour usually occupies a much larger space in books on this subject. But, true to our maxim that the most accurate knowledge of the normal relations should precede every investigation of their pathological condition, we endeavour, first of all, to make the former clear, and then join the latter supplementarily. As every pathological new formation repeats, more or less, the type of the normal structure, so are the methods of investigating diseased conditions and portions of the body almost the same." Most of the author's readers certainly will, we suspect, think that he has been "too concise" in the department of pathology when he treats of the nervous system. "We have already noticed above," he observes, "the great difficulties which the investigation of the normal textural conditions of the central organs of the nervous system still present. Hence we shall comprehend that their numerous pathological alterations are still very inadequately known, and can only be assailed histologically with slight results. It is usually accepted that the nervous elements indeed undergo numerous secondary processes of degeneration, such especially as the fatty, and also amyloid and colloid transformations, but that the true new formations proceed from the connective-tissue framework and from the vessels. The correctness of the former doctrine has more recently, however, become doubtful, and the lymphoid migratory cells exert at present a deep and disagreeable influence on the latter. The finer textural conditions of the framework substance are also uncommonly difficult to follow, as the very methods of hardening which are customary for the normal structure frequently render very little service in the domain of pathology, so that often one is able to examine only fresh objects." And that is almost all that he says on the subject.

The work is freely and well illustrated; and the illustrations are, we suppose, for the most part original, for, so far as we have observed, but very few are acknowledged to have been taken from other works.

Two faults we will venture to point out. It seems to us that very often, to say the least, it is not mentioned what magnifying power has been used for the illustrations; and the author rarely gives any opportunity of verifying statements that he makes on the authority of other observers.

Dr. Cutter apologises for the literalness of his translation; but it appears to us that he has performed a by no means easy task very well. The book is provided with a good index as well as a table of contents.

An Introduction to the Study of Clinical Medicine: being a Guide to the Investigation of Disease for the use of Students. By Octavius Sturges, M.D. Cantab., F.R.C.P., Assistant-Physician to Westminster Hospital, etc. London: Smith, Elder, and Co. Pp. 131.

About the little volume before us very various opinions have been expressed—it has been highly extolled and sharply

criticised. For our own part, whilst freely admitting the excellent quality of the work in many respects, it seems as if Dr. Sturges had entirely mistaken his auditory—it is a work for teachers, if they want such, rather than for students. It takes for granted a vast deal of knowledge which the student does not possess, and seems to teach the philosophy of the subject before a man knows anything at all about the basis of this philosophy. Students should as far as possible be taught by practical examples, not by didactic discourse, which is the method here pursued; and certainly theory without example is worse than example without theory. It is all very well when a man has acquired a certain skill to philosophise on what he has already acquired, but to begin with the philosophy is a mistake. Nevertheless, the book is justly entitled to favourable notice, for every page of it shows that it is the work of a man well skilled in his profession. Our only regret is that, having done so well, he did not do better. In many respects the work is unequal, the earlier part overbalancing the latter; and though described as a book on clinical medicine, it does not go beyond a critique on the examination of signs and symptoms. Treatment is cursorily dismissed; yet most people practically look upon this as being the most important thing of all. Nevertheless, in the former part there is so much that is good, and so true to nature, that we are sorry there is not more of it. But with all this, dealing as the book does with the philosophy of the thing, there are not a few—indeed, there are very many—passages where we should be prepared to join issue with the author; for such is the difficulty connected with many of the subjects of which he treats that we can easily conceive several explanations, all more or less plausible, of the phenomena; and the final verdict must too often be—"Well, in *my opinion* it is so-and-so." And yet Dr. Sturges has fallen into mistakes—time-honoured fallacies, perhaps, yet palpable mistakes. Thus, he tells us in order to detect fluid in the abdomen to place the two open hands on opposite sides of the abdomen, and gently to tap with the fingers of one of them. Now, this process is all very well if there is a good deal of fluid, but will certainly not succeed when the quantity is small; in point of fact you have to bring the fingers close together as a surgeon does in case of an abscess. Again, in speaking of the detection of sugar in the urine, he mentions the old-fashioned Trommer's test, whereas Fehling's test fluid is now generally employed. Used as recommended, the test for sugar is as full of fallacies as it can well be. This part of the book is decidedly inferior to that which refers to chest diseases.

OBITUARY.

JOHN BISHOP, F.R.S.

The obituary of the *Times* one day last week recorded the death of a man of some note in his time, and who was deservedly well known to the members of two different professions—viz., medicine and music. The gentleman whose name appears at the head of this notice received his professional education at St. Bartholomew's Hospital, and on its completion was admitted a Member of the Royal College of Surgeons, nearly half a century ago—viz., May 21, 1824. Whilst waiting for patients he occupied his leisure time by writing for the medical and other journals. His first paper "Researches into the Pathology and Treatment of Deformities of the Human Body" appeared in the pages of the *Lancet*, and it brought him into favourable notice. These investigations were afterwards collected into a volume, published in 1852, in which the author shows his preference for mechanical over surgical treatment. His earliest public appointment was that of Surgeon to the Islington Dispensary. When the new charter was granted to the College of Surgeons, empowering them to grant the Fellowship to its distinguished Members, Mr. Bishop was one of the first elected—for he received that distinction December 11, 1843; and in 1849 the Fellows returned him a member of the Council, in conjunction with Messrs. Hodgson, Wormald, and Pilcher. His last official connexion with the College was as Hunterian Orator, his address being delivered in 1859. He was exceedingly anxious to be elected an Examiner in Mathematics for the Fellowship of the College, and there is no doubt that his high attainments in mathematical science eminently fitted him for the post. The Council, however, thought otherwise, and elected Professor Stokes. At a succeeding election for Councillors he lost his seat, being displaced by Mr. John Adams, who subsequently became one of the examiners. Elsewhere, however, he was more fortunate, as an admirable paper "On the Physiology of the Human Voice," published in the *Philosophical Transactions*, justly obtained for him the Fellowship of the Royal Society. His articles on the Larynx, Motion, and Voice in the "Cyclopædia of Anatomy and Physiology" greatly added to his literary reputation. Another work, "On Articulate Sounds and the Cause and Cure of Impediments of Speech," brought him a new class of patients; as, with the exception of the late Mr. Poett, no one at that time appeared to devote much attention to this important subject. As a member of the London Medical Society, an institution in which he always took a warm interest, he was appointed Lettsomian Lecturer, and took for his subject the "Physical Constitution, Diseases, and Fractures of the Bones." His other works—"On the Construction of Hearing and Speaking Instruments," "Observations made on the Movements of the Larynx when viewed by the Laryngoscope," and "On the Influence of the Pitch of the Tuning-fork on the Mechanism of the Human Voice"—brought him much in contact with members of the musical profession, who, however, whilst seeking his professional assistance, did not add much to his emoluments. His last work appears to have been "On the Pathology of Tinnitus Aurium, with remarks on the Acoustics of the Sense of Hearing." Latterly he was obliged to throw aside his pen in consequence of failing sight and ultimately of the complete loss of one eye. He left his town residence—Bernard-street, Russell-square—for a short time, to try the effects of his native air, but he gradually sank, and died on the 29th ult., at Strangeways, Marnhull, Dorset, in his seventy-sixth year. The deceased, who was twice married, leaves a widow, but no family.

Mr. Bishop in his early life was a handsome man, with an expressive countenance and a very agreeable manner, and of a somewhat short and slender stature. The list of his published works and the honours he received show him to have been a man of no ordinary acquirements; and his conversation, although far from being pedantic or dictatorial, was most intelligent and instructive. He never made any great effort to obtain an extensive practice, and he lived very quietly but comfortably, having acquired a moderate independence, which rendered it unnecessary for him to continue in later years the struggle for professional gain. He had, indeed, the reputation of being a rich man, which, however, in the ordinary sense, he was not.

JOHN THURNAM, M.D., F.R.C.P.,

Was, we believe, a native of Yorkshire, and pursued his medical studies at Dermott's School of Anatomy in Gerrard-street, Soho, and at the Westminster Hospital. He became a Member of the Royal College of Surgeons of England in 1834, graduated at King's College, Aberdeen, in 1846, and was elected a Fellow of the Royal College of Physicians, England, in 1859. He commenced general practice in Brewer-street, Golden-square, in 1835. Shortly afterwards a vacancy having occurred in the "Retreat," York, he was elected Medical Superintendent of that institution. He was subsequently appointed Medical Superintendent to the Wilts County Asylum, at Devizes, which office he retained until his lamented death a few days since. Dr. Thurnam was a Member of the Society of Friends, and for some years wore the characteristic dress of the disciples of George Fox. He was diligent as a student; most painstaking and industrious as a practitioner. It could not be said that he was brilliant or suggestive, but he had one quality of genius, at least—that of untiring perseverance. His services to the cause of medical science obtained for him the honour of the Fellowship of the College of Physicians, and no man more justly deserved it. He was a man of singularly unobtrusive manners, somewhat reticent and difficult of access. His contributions to medicine were the following:—"The Statistics of Insanity," 1845; "Memoirs on Aneurism of the Heart," 1838; "Spontaneous Varicose Aneurism of the Aorta, etc.," *Medico-Chirurgical Transactions*, 1840; joint author of "Crania Britannica," 1856-65; "On Ancient British and Gaulish Skulls," 1865-69; contribution "On the Weight of the Human Brain," *Journal of Mental Science*, 1866. Dr. Thurnam succumbed to an attack of apoplexy, consequent upon the excitement caused by the escape of a patient from the Asylum. He was found insensible, and never recovered consciousness.

NEW INVENTIONS.

J. & F. ALLEN'S IMPROVED ENEMA AND DOUCHE. This apparatus, which we have already noticed (*Medical Times and Gazette*, November 16, 1872) as likely to be found "most useful for patients suffering from disorders of the rectum and uterus," has been fitted by the inventors in a full-sized *bidêt* on a stand, and in this form must prove a very useful appliance in the sick-room. It can likewise be had packed in a portable tin case for persons travelling. The apparatus seems to us very well suited for the auto-administration of enemata and injections by the patient.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, Oct. 2:—

Chambers, Eber, Ryde, Isle of Wight.
Collinson, Alfred Cockburn, 36, Elgin-road, W.
Vowell, Charles Martin, Cheltenham.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ATTHILL, WILLIAM EYRE BLENNERHASSETT, M.R.C.S. Eng., L.R.C.P. Lond. (late Assistant-Surgeon Prussian Army).—Parochial Medical Officer of the Middlebie Union, Dumfriesshire, N.B., *vice* Mr. Jardine, M.B., M.C. Edin., resigned.

FABER, Dr. CARL (of Freudenstadt, Würtemberg)—Resident Medical Officer at the German Hospital, Dalston, *vice* Dr. Paul Schliep, resigned.

HESSEL, Dr. JULIUS (of Kreuznach)—Resident Medical Officer at the German Hospital, Dalston, *vice* Dr. Adolphus Nieden, resigned.

SYMES, E. WEST, M.B. Edin., M.R.C.S. Eng.—Medical Officer of Health for the Skipton and Settle Rural and Urban Sanitary Districts in the West Riding of Yorkshire.

NAVAL AND MILITARY APPOINTMENTS.

ADMIRALTY.—William H. Patterson, Surgeon to the *Active*.

WAR OFFICE—MEDICAL DEPARTMENT.—Surgeon-Major Alexander Richmond retires upon temporary half-pay; Surgeon-Major Robert Watson is placed upon temporary half-pay; Surgeon-Major William Henry Price is placed upon temporary half-pay; Surgeon-Major Joseph Salkeld Johnston, M.D., retires upon temporary half-pay. Surgeon Francis Edward McFarland to be Surgeon-Major, *vice* George William Powell, who retires upon half-pay; Surgeon John Dallas Edge, M.D., to be Surgeon-Major, in recognition of his gallant services when engaged against the Indians at Orange Walk, British Honduras.

ARMY HOSPITAL CORPS.—The Christian name of Captain of Orderlies Wallis is Llewen, and not Lewin, as stated in the *Gazette* of June 24.

BREVET.—Surgeon-Major George William Powell to have the honorary rank of Deputy Surgeon-General on retiring upon half-pay.

MEMORANDUM.—Staff Assistant-Surgeon James Francis Deakin, M.D., commuted his half-pay.

BIRTHS.

CARTER.—On September 29, at Lichfield, the wife of Graham Atherley Carter, M.D., of a daughter, stillborn.

GRAY.—On October 1, at 45, St. Giles's, Oxford, the wife of Edward B. Gray, M.D., of a son.

HOLMAN.—On October 2, at High Bank, Forde Park, Newton Abbot, Devon, the wife of W. Holman, M.R.C.S. Eng., of a son.

LUBBOCK.—On October 3, at Foulis-terrace, Onslow-square, the wife of M. Lubbock, L.R.C.P., F.R.C.S., of a daughter.

MARRIAGES.

ALLEN—HALL.—On October 7, at Allhallow's Church, Tottenham, Lewis Philip Allen, Esq., of Stoke Newington, to Agnes Millicent, second daughter of William Hall, M.R.C.S. Eng., L.S.A., of Tottenham.

BARTLET—ROSE.—On October 1, at St. George's, Bloomsbury, Alexander Edward Bartlet, Surgeon Royal Artillery, to Alice Harriet, only child of the late Thomas Rose, Esq., of Madeley, co. Salop, and stepdaughter of Borlase Hill Adams, Esq., of 55, Torrington-square.

BARTHOLOMEW—RYE.—On September 22, at the Anglican Collegiate Church of St. Paul, Malta, Charles Eugene, eldest son of Eugene G. Bartholomew, Esq., of Cathcart-hill, Upper Holloway, London, to Edith Annie, third daughter of Arthur B. Rye, F.R.C.S., late of Banbury, Oxon.

DURRANT—COCKBURN.—On October 2, at St. James's, Leith, Christopher Rawes Durrant, Captain 48th (Northamptonshire) Regiment, eldest son of Christopher Mercer Durrant, M.D., Ipswich, to Elizabeth Martin, youngest daughter of the late James Cockburn, Esq., of Ramporc, Baulcah, Bengal, and Trinity-grove, Edinburgh.

JONES—FENTON.—On August 2, at the British Legation House, Yeddo, Japan, Richard Oliver Rymer Jones, son of Professor Rymer Jones, F.R.S., London, to Isabella Mary, daughter of C. D. Fenton, M.D., Doncaster, Yorkshire.

MACKRAY—HENDERSON.—On October 1, at 19, Ainslie-place, Edinburgh, the Rev. Archibald Neilson Mackray, M.A., of St. Andrew's English Presbyterian Church, Torquay, to Anne Emily, second daughter of the late William Henderson, M.D., Professor of Pathology in the University of Edinburgh.

MILLER—MORSE.—On October 4, at St. Philip's Church, Kennington-road, John, youngest son of Charles Miller, Esq., of The Terrace, Kennington-park, to Emily, eldest daughter of Edward Morse, F.R.C.S., L.S.A., of Upper Kennington-lane.

PLAISTER—GREENWAY.—On October 4, at St. John the Evangelist's, Clifton, W. H. Plaister, M.R.C.S., F.R.G.S., of Tottenham, to Alice Emma, daughter of the late Wm. Greenway, Esq., of Bristol.

READ—BENCRAFT.—On September 25, at St. Mary's Church, Southampton, George Read, Esq., of Bridge-street, to Lucy Grace, eldest daughter of Henry Bencraft, M.R.C.S., L.S.A., of St. Mary-street, Southampton.

SPOONER—CASSWELL.—On October 4, at North Ormsby, Louth, Lincolnshire, Edward Monro Spooner, M.R.C.S., of Blandford, Dorset, to Elizabeth, youngest daughter of the late Thomas Casswell, of Pointon, Lincolnshire.

WAILE—NORTON.—On October 2, at Llanon Church, Thomas Waile, son of the late David Waile, Esq., of Crawley, Hants, to Mary (Minnie), second daughter of J. Howard Norton, M.D., of Nantglas, Llanelly.

WHITEHOUSE—MCALPIN.—On September 30, at Stratford, Thomas G. Whitehouse, M.D., to Elizabeth, widow of the late David McAlpin, Esq., formerly of Grenada, West Indies.

DEATHS.

ARMSTRONG, RICHARD LEPPINGS, Captain Madras Staff Corps, attached to 5th M.N.I., youngest son of the late Robert Armstrong, M.D., Inspector-General of Hospitals and Fleets.

BOUSTEAD, MARY JANE, wife of Surgeon-Major R. Boustead, H.M. Bombay Army, at sea, off Gibraltar, on her passage from India, on September 10, aged 36.

CARTER, FRANCIS RODNEY BECHER, son of Robert Brudenell Carter, F.R.C.S. Eng., L.S.A., at 69, Wimpole-street, Cavendish-square, after a few days' illness, on October 8, aged 12.

CRAVEN, JOHN, M.R.C.S., of Dockroyd, near Keighley, Yorkshire, at the Salisbury Hotel, London, in the 47th year of his age.

HUNTER, MARY LUTYEUS, elder daughter of James A. Hunter, M.D., at Edinburgh, on October 3, aged 17 months.

LEDSAM, JOHN JOSEPH, M.D., at 17, Esplanade, Scarborough, on October 2, in his 75th year.

LYON, GILBERT, M.D., L.R.C.S., at 1, Lansdown-place, Clifton, on October 5, aged 70.

MICHELL, DANIEL, M.R.C.S., late of Delaney-street, Gloucester-gate, and of Old Cavendish-street, Cavendish-square, at Launceston, of rapid consumption, on September 30.

SIEVEKING, HENRY DROOP, youngest son of Edward H. Sieveking, M.D., on September 2, aged 13.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ANDOVER UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to T. Lamb, Clerk to the Guardians, on or before October 14.

BIDEFORD UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to Charles W. Hole, Clerk to the Guardians, on or before October 20.

CARLISLE DISPENSARY.—Assistant House-Surgeon. Applications, with testimonials, to J. H. W. Davidson, Esq., Honorary Secretary, 8, Devonshire-street, Carlisle.

CHELTENHAM.—Medical Officer of Health. Candidates must be duly qualified. Applications, with testimonials, to E. T. Brydges, Clerk to the Urban Sanitary Authority, Public Offices, Cheltenham, on or before October 11.

GUEST HOSPITAL, DUDLEY.—Honorary Surgeon. Applications, with testimonials, to Mr. E. Poole, Secretary, on or before October 31.

HOO UNION.—Medical Officer. Candidates must be duly qualified. Applications, with testimonials, to F. Furrell, Clerk, Rochester, on or before October 15.

LIVERPOOL DISPENSARIES.—Assistant House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Secretary, on or before October 29.

MANCHESTER ROYAL EYE HOSPITAL.—Three Honorary Medical Officers. Candidates must be duly qualified. Applications, with testimonials, to P. Goldschmidt, Esq., Chairman of the Board, 100, Albert-square, Manchester, on or before October 15.

ST. PETER'S HOSPITAL.—House-Surgeon. Candidates must attend personally, with their testimonials, on Monday, October 20, at 4 p.m.

TARBUT (PARISH OF), ROSS-SHIRE.—Medical Officer. Applications, with testimonials, to John Ross, Inspector of Poor, Stafford-street, Tain, N.B., on or before October 17.

UNST, SHETLAND.—Medical Officer for the Parochial Board. Applications, with testimonials, to Mr. White, Inspector of Poor, Unst.

WEST HAM, STRATFORD, AND SOUTH ESSEX DISPENSARY.—Resident House-Surgeon. Applications, with testimonials, on or before October 14, care of Mr. T. G. Tonge, 2, St. John's-terrace, Stratford, E.

WEST LONDON HOSPITAL, HAMMERSMITH.—House-Surgeon. Candidates must be duly qualified, and attend at the Hospital on Monday, October 20, at 10.30 a.m.

UNION AND PAROCHIAL MEDICAL SERVICE.

*** The area of each district is stated in acres. The population is computed according to the census of 1861.

VACANCY.

New Winchester Union.—The Twyford District is vacant; area 15,567; population 3911; salary £105 per annum.

APPOINTMENTS.

Alderbury Union.—John R. Perkins, L.R.C.S. Edin., L.S.A., to the Second District.

Bridgnorth Union.—Alfred Bethell, M.R.C.S. Eng., L.S.A., to the Fourth District.

Cheltenham Union.—Charles J. Newton, M.R.C.S. Eng., L.S.A., to the Third District.

Croydon Union.—Thomas H. Barnes, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Fourth District.

Henstead Union.—John B. Pitt, L.R.C.P. Edin., F.R.C.S. Eng., L.S.A., to the Workhouse.

Knighton Union.—Thomas J. E. Brown, M.R.C.S. Eng., L.S.A., to the Llanbister District.

Manchester Township.—William Berry, L.R.C.P. Edin., L.R.C.S. Edin., M.R.C.S. Eng., as Junior Assistant Medical Officer at the Workhouse Hospital.

Newmarket Union.—Clement F. Gray, M.R.C.S. Eng., L.S.A., to the First District.

St. George-in-the-East Parish.—George Levick, M.R.C.S. Eng., L.S.A., to the Schools at Plashet.

Sheffield Union.—Augustus T. V. Packman, M.R.C.S. Eng., L.S.A., to the South-East District.

Strand Union.—Mr. Charles H. Piesse as Analyst for the Strand District.

FORTY-FOUR children out of 472 in the Holborn Union Schools at Mitcham are suffering from ophthalmia.

A RESOLUTION expressing the regret they felt at the loss they have sustained in the death of the late Dr. Donald Dalrymple, M.P., has been passed by the Bath Town Council.

A COTTAGE INFIRMARY has been established at Watlington, and John E. Boyton, M.R.C.S. Eng., L.A.H. Dub., and Henry Dixon, M.R.C.S. Eng., L.S.A. Lond., have been appointed medical officers.

PRESENTATION.—Dr. Justyn Douglas, on resigning the post of Resident Medical Officer to the Bournemouth Dispensary—which he has held for two years—in order to begin private practice, has been presented by the patients who were under his care with a microscope and other valuable apparatus. The amount subscribed for this purpose was £10.

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At a meeting of this Corporation, held on the 6th inst., the following office-bearers were elected for the ensuing year, viz. :—*President :* Eben. Watson, M.D. *Visitor :* Andrew Fergus, M.D. *Treasurer :* John Coats, M.D. *Honorary Librarian :* J. D. Maclaren, M.D. *Vaccinator :* Hugh Thomson, M.D. *Councillors :* The President, *ex officio ;* The Visitor, *ex officio ;* J. G. Fleming, M.D. ; H. R. Howatt, M.D. ; James Steven, M.D. ; James Morton, M.D. ; George Buchanan, M.D. *Board of Examiners :* William Lyon, M.D., Surgery and Surgical Anatomy ; Eben. Watson, M.D., Anatomy and Physiology ; James Morton, M.D., Surgery and Surgical Anatomy ; Robert Perry, M.D., Chemistry ; P. A. Simpson, M.D., Midwifery and Medical Jurisprudence ; James Steven, M.D., Medicine and Materia Medica ; Alexander Lindsay, M.D., Chemistry ; George Buchanan, M.D., Anatomy and Physiology ; R. Scott Orr, M.D., Medicine and Materia Medica ; J. G. Wilson, M.D., Midwifery and Medical Jurisprudence. *Clinical Examiners in Medicine :* The Physicians of the Royal Infirmary. *Clinical Examiners in Surgery :* The Surgeons of the Royal Infirmary. *Clerk :* William Henry Hill. *Librarian and Secretary :* Alexander Duncan, B.A.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The London Medical Record of this week has done us the peculiar honour of reproducing, without one word of acknowledgment, a large portion of one of the letters of our correspondent at Madras on the subject of the "Poisonous Snakes of India," which appeared in the *Medical Times and Gazette* of September 20. The letters of our correspondent bear the well-known signature "R. D.," and although all readers of the *Medical Times and Gazette* are doubtless well aware that these are the initials of our valued *confrère*, Dr. Druitt, it appears that the editor of the *London Medical Record* conceives that his readers require enlightenment on the subject. He therefore commences his excerpt—which plain-spoken people might designate by a harsher term—with the introduction, "Dr. R. Druitt writes from India—". We must leave our readers to form their own opinion of this ingenious, if not ingenuous, mode of appropriating the correspondence of another journal.

J. C., St. Bartholomew's.—Registration is not necessary for the Fellowship of the College, only Membership ; it closes on the 15th inst.

L. D. S., St. Austell.—Only the *examination* for the dental diploma has been altered, not the diploma itself. All candidates have now to undergo a *written*, in addition to an *oral* examination.

N. C. C.—The North Cambridgeshire Cottage Hospital at Wisbeach was opened on the 2nd inst.

Ted O. S.—An International Congress of Oculists met on the 27th and 28th ult., at Heidelberg. England, France, and Russia were represented.

A. B. E.—Professor Tyndall is, we believe, a native of Leighliubridge, near Carlow.

K. W.—The medical staff of the new Temperance Hospital in Gower-street will consist of a House-Surgeon, two Visiting Physicians, and one Visiting Surgeon.

Philip G.—From an official return recently issued it appears there are 1500 private slaughter-houses, and they are distributed generally over the whole metropolitan district.

Dr. Mott.—A portrait of Professor Bumstead, M.D., New York, appeared in the last number of Messrs. Barraud and Jerrard's "Medical Profession in All Countries," and is an admirable likeness.

An Old Subscriber.—The first number of the *Medical Times* appeared on Saturday, September 28, 1839, under the editorship of the late Mr. Frederick Knight Hunt, M.R.C.S., subsequently, and at the time of his early death, chief editor of the *Daily News.*

Gill.—"The Science and Art of Nursing the Sick," by E. Munro, M.D. Glasgow : James Maclehose.

T. C. O. S.—The Board of Trade return recently published of all the railway accidents which have occurred during the year 1872 is the first which has been prepared for an entire twelvemonth, under the regulation of Railways Act, 1871 (34 and 35 Vict., cap. 78), which came into operation on November 1 in that year.

M. A. P.—The Professorship of Experimental Physics in the Royal College of Science for Ireland, Dublin, is in the gift of the Lords of the Committee of Council on Education, South Kensington. It is of the value of £200 per annum, besides a share in the fees paid by the students.

Plica Polonica, Scarborough.—There are specimens in the Museum of the College of Surgeons. The affection is common and endemic in Poland ; hence the term "Polonica" that has been given to it.

In answer to X. B. (see *Medical Times and Gazette*, September 20) we are informed that Mr. Paleologus (not Paliolgus), whose name is referred to, was a Staff-Surgeon in the Army Medical Department. It was understood in the Department that Mr. Paleologus was a descendant of the Emperors of the Eastern Empire, but we are not aware whether this belief is correct. His name was mentioned in one of the English papers at the time of the last election for the Greek throne.

Statistics.—In England the population is equal to one person to every 7340 square yards, in Wales one person to 18,777 square yards, in England and Wales together one to 7953 square yards, in Scotland one to 28,084 square yards, in Ireland one to 18,621 square yards. In the United Kingdom as a whole the population is one person to every 11,935 square yards, or about 260 persons to the square mile. In the United Kingdom the area of a county averages 1037 square miles, in England 1273 square miles, 1017 in Ireland, 923 in Scotland, and 615 in Wales.

Prizes.—The following are the subjects for the prizes offered by the Council of the Royal College of Surgeons for competition amongst the members—viz., for the Collegial-Triennial Prize, consisting of the John Hunter Medal executed in gold to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of fifty pounds. The subject of this prize is—"The Structure and Functions of the Medulla Oblongata, including the Connexions of the Central Nerve-Roots." The dissertation may be illustrated by preparations and drawings. The Jacksonian Prize is the dividend (between £10 and £11) received from the trust. The subject for the prize for the present year (1873) is—"Ununited Fractures." The dissertation may be illustrated by drawings, preparations, etc. The subject for the prize for the ensuing year (1874) is—"Tracheotomy—with particular reference to the Causes of Death after the operation and the rules for rendering the operation more generally successful." The essays for the Collegial Prizes must be delivered on or before Christmas-day next.

THE ARMY MEDICAL OFFICERS IN INDIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It is stated out here, on good authority, that the numbers of Surgeons-Major in this country is to be considerably increased, and that this cold season some forty or fifty are to be sent out to replace an equal number of Surgeons who go home, and that at the same time they are only to receive the pay of their former rank. Whether this will prove true as regards the new arrivals time will show, but it has already proved to be the case with those out here recently promoted. There are over fifteen Surgeons-Major promoted in the *Gazette* of April 1 at present in this country, who up to date have been refused the pay justly their due, and are obliged to serve on the pay of their former rank. Nay, even more, as I have been informed on good authority, two Surgeons-Major who came out since promotion were informed by the Pay Department on arrival that they could only issue pay to them as Assistant-Surgeons, they being in excess of the fixed establishment. Whether they have been lucky enough to come on the establishment since I cannot say, but being seniors they may have.

Paragraph 5 of the new and much-abused Warrant states :—"The relative rank of these officers shall regulate choice of quarters, rates of lodging-money, servants, fuel and light or allowances in their stead." My object in writing to you is that the Surgeons-Major ordered out may, previous to coming to this country, ascertain by an appeal to those in authority whether Paragraph 5 is to be over-ruled and made a farce of by the Government of India, who appear to be at liberty to play ducks and drakes with Royal Warrants as suits their fancy.

I need scarcely tell men who have served fifteen years that everything in India costs double what it does at home, or treat of the expense entailed by servants in this country (my own cost me 90 rupees per mensem, screw how I will); but at the same time, for the benefit of all, I annex a statement showing how things stand and what they will gain by coming to India. In England a Surgeon-Major over fifteen years' service receives £1 per diem, equal to about 304 rupees per mensem; in addition, he has quarters, fuel, light, servant, and (as a rule) forage for one horse. In India a recently promoted unfortunate receives his old rate of pay as Assistant-Surgeon, 451·14·5 rupees a month, or 148 rupees a month more than his net pay in England: out of this he has to pay house-rent, 40 to 60 rupees per mensem; keep a host of servants, costing from 50 to 90 rupees,—more than the latter if married; keep of a horse, say 30 rupees; provide himself with tents (the Government allowance for which to a Major is 100 rupees); pay all expenses on the line of march, as Indian allowances are supposed to cover cost of carriage, etc.,—though, in fact, he receives no Indian allowances, as the average of the before-mentioned sums exceed the 148 rupees.

I trust you will give this letter a place, and use your influence as one of the leading medical journals to procure for medical officers in India their just rights; and that my brother officers at home will try and bring any Parliamentary influence they may have to bear on the India Office, more particularly the juniors, or else some one of them may find his promotion on April 1 has made of him, like me,

An April Fool.

P.S.—The proper pay of a Surgeon-Major under fifteen years' service is 789 rupees odd per mensem; over fifteen, 825 rupees.

Paypoore, India, August 29.

COMMUNICATIONS have been received from—

Mr. O. R. Thomson; Dr. John Dougall; Mr. Feldman; Dr. Handfield Jones; Mr. Haviland; Mr. Burdett; Dr. E. W. Symes; Mr. John Clay; Dr. Caton; Mr. Scattergood; Mr. J. Chatto; Mr. Brudenell Carter; Dr. Ramskill; Dr. Shepherd; Dr. Prosser James; Dr. Armstrong; Mr. W. E. B. Atthill; Mons. Cowze; Dr. Mayo; Mr. J. W. Groves Blennerhassett.

BOOKS RECEIVED—

Pirrie's Surgery, third edition—De la Régénération des Organes et des Tissus en Physiologie et en Chirurgie, par J. N. Demarquay—Du Traitement des Rétrécissements de l'Urethre par la Dilatation Progressive, par le Dr. T. B. APPOINTMENTS FOR THE WEEK.

October 11. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; King's College, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 9 a.m. and 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

13. *Monday*.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 3 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

14. *Tuesday*.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

Royal Medical and Chirurgical Society, 8½ p.m. Mr. Henry Lee, "Imperfect Development of the Circular Fibres of the Rectum and Vagina." Mr. Spencer Watson, "On Acute Inflammation of the Vitreous Humour of both Eyes."

15. *Wednesday*.

Operations at University College, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2½ p.m.; King's College (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

16. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Opbtbalmic, 1½ p.m.

Harveian Society, 8 p.m. Dr. A. Meadows, "On Pelvic Hæmatocele."

17. *Friday*.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

Medical Microscopical Society, 8 p.m. *Conversazione*, at the residence of the President, 1, Bedford-square, W.C.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 4.

At the Royal Observatory, Greenwich, the mean reading of the barometer last week was 29·84 in. The highest was 30·04 in. on Monday at noon, and the lowest 29·69 in. on Friday afternoon.

* The figures in this column for the English towns are the numbers enumerated in April, 1871, as finally revised at the Census Office, and raised to the middle of 1873 by the addition of two years and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary at the revised number enumerated in April, 1871.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON DUST-INHALATION AS A CAUSE OF LUNG DISEASE.(a)

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

Gentlemen,—It is not my intention to-day to attempt a complete *résumé* of the subject selected, but rather to refer to some of those practical points which have been brought before my notice in the extensive field afforded by the in-patient and out-patient departments of this Hospital. In the out-patient department cases of disease clearly traceable to dust-inhalation are very numerous, and among the in-patients there are always some in whom dust has exercised decided influence in the causation of lung disease. I say *lung* disease, because it is not easy to find a more specific general term which will comprehend the varieties of which I am about to speak. Sometimes the term "asthma" might be appropriate, sometimes "subacute" or "chronic bronchitis," or "bronchorrhœa"; and in other cases, again, the term "phthisis" is quite appropriate, for there is progressive destruction of lung with wasting of the body, a definition of phthisis which appears to me the best that can at present be ventured upon. The destructive disease is accompanied often, though not always, by an extensive deposit of pigment, the lung-substance and the bronchial glands being quite melanotic (as in the diagrams now shown, taken from Carswell and Lebert's works). But to the pathological changes I shall refer presently, when I have described more in detail the conditions met with during life.

I have said that cases due mainly to dust-inhalation are common in London. This is true, but they are still more common in some of those centres of industry in which the chief occupation of the townsfolk is connected with some dust-producing work. First and foremost among these are the metal-grinders—the knife, fork, and needle-makers of Sheffield; next, those employed in the pottery trades of Staffordshire.

My friend Dr. Greenhow, in his laborious and exhaustive Blue-book issued in 1858, gives a comparative statement of the destructive effects of these and other trades. He considers the pottery trade very injurious; that the coal and iron trades are more injurious than the coal or iron alone, but less so than the lead, tin, and copper mines.

As regards lead mines, this interesting generalisation has been made—that when the lead exists in limestone, mining is not hurtful; but when in sandstone, it is very fatal, so much so that at Alston, a place where lead has been extracted from sandstone for centuries, the mortality among men from lung disease is very large, and the proportion of widows is larger than in any other place, being 21·4 per cent. of all the women in the town. The women are healthy and long-lived, but the men die young.

Again, in Dr. Ballard's more recent report (see Appendix to Report on the Staffordshire Potteries, noticed in *Lancet*, May 10, 1873, p. 667), the death-rate in the pottery districts is shown to be less from pulmonary disease between the ages of 15 and 25 than elsewhere, but between 25 and 45 the reverse is the case; and between 45 and 55 the mortality, especially among males, is very large indeed. It is sad to notice that the excessive mortality among the males above 45 years of age is on the increase. Dr. Ballard observes that the pottery manufacture is prominent among dusty occupations which set up lung disease. The effects are slow; health is destroyed and existence rendered miserable for many years before the death-rate is affected. Fewer females are now employed than formerly, and thus the death-rate among women under 55 is reduced; but those above 55 have died in larger proportion of late, because many are included who had been employed in the trade before the recent movement against the employment of women took place. The women of this class are now dying of the chronic lung disease developed during the years of their pottery life. Improvements as to steam power, ventilation, etc., are confined to the new buildings, where the best and oldest hands are employed. Children still work in the old and badly ventilated rooms. The improvements operate but slowly, and do not yet reduce the mortality, for those formerly engaged in bad factories have enough dust in the new ones to keep up and ultimately render fatal the old disease long ago established. It is sad that the children should begin in the worst places, and thus have the seed sown of disease which could only be eradicated by complete removal from the trade. It would be better to kill off the old hands who are already hopelessly diseased, instead of subjecting those at present healthy to conditions which will destroy them like their predecessors.

Dr. Ballard adds that lead-poisoning is still as bad as ever, for the workpeople dip their hands into the glaze and also scatter a preparation of lead on to the coloured wares.

I must be forgiven for referring here to the success which a few years ago attended my efforts to lessen the evil of lead-poisoning arising from dusting on whitelead in the straw hat manufactories. I applied to a practical and scientific chemist (Mr. Tomlinson, the editor of the "Cyclopædia of Arts and Manufactures") to ascertain whether an innocuous white powder might not be found possessing similar qualities as a dressing for white straw hats. He made various experiments, and hit upon two white powders—one oxide of zinc, and the other the insoluble white sulphate of baryta. I was able to induce the chief hat-makers at Luton to try these powders, and they found that the last-named was equal in every way to the lead formerly used, and was not noxious; and, being less expensive, I believe it is coming into general use. Possibly a similar powder might be found equally effective in the pottery trade.

After this digression I pass on to consider the varieties of lung disease dependent on dust as their cause. The nature of the irritant has less to do with the character of the resulting disease than has the constitution and temperament of the patient. The dust given off from horsehair mattresses or highly dried flour sets up ulcerative disease of as destructive a character as that which follows the inhalation of particles of forks, needles, and millstones.

The dust causes first increased secretion from the mucous surfaces. The tubes become narrowed, partly from congestion and secretion, but chiefly from muscular spasm; the respiration is consequently impeded, and dyspnœa occurs. Among persons inheriting asthmatic proclivities, spasmodic dyspnœa is the first and chief ailment; whereas among those subject to winter cough, aggravated and very chronic bronchitis supervenes. In either case a good deal of emphysema is sure to follow, caused possibly by the act of coughing (*vide* Parsons on "Potters' Bronchitis," p. 26). The dyspnœa is often so urgent that expiration and inspiration become intermingled, and it seems as if both were going on together in different parts, or even in the same parts, of the chest. Under such circumstances relief may be sometimes obtained by exercising a voluntary control over the breathing, so as to equalise the length of the expiratory and inspiratory waves. Do not look upon all your cases as alike, unless you desire to be a mere routinist, but in every case seek out the distinguishing features and characteristics, and modify your treatment in accordance with these rather than with the vague general notion that you are dealing with a case of pneumonia, bronchitis, or what not.

In the malady, or rather in the group of maladies, before us the aptness of this remark is well exemplified; for there are cases without perceptible pathological change in which the asthmatic element alone is to be detected, and there are others in which pulmonary disorganisation is so advanced that it is a marvel that life can be prolonged. It is by no means uncommon to meet with instances in which, with the appearance of fair health, the physical signs are indicative of a surprising amount and extent of disease. There are indeed few lung diseases in which the physical signs are more prominent and the auscultatory phenomena more marked. The disease is generally widely diffused, morbid sounds occurring in various parts, with healthy breathing around.

In tubercular disease there is often an amount of constitutional deterioration disproportionate to the lung disorder, whereas in dust bronchitis the reverse is usually the case. The first stages of the former are often independent of the lung; in the latter the pulmonary affection is always primary, and the

(a) Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

general deterioration is secondary and often long delayed. Difficult breathing on exertion, irritation of the larynx and trachea, with cough and frothy mucous expectoration, are the first symptoms, and it is exceptional for grinders suffering thus to apply for treatment in the early stages. The urgency of the dyspnœa—a symptom more marked than in consumption—generally leads the patient to seek medical aid; even in the last stage the pulse may remain quiet, rarely rising above 80 or 85.

Men of feeble constitution are usually the first attacked, but the hale and vigorous do not escape. Those of stunted growth generally die first, while those with sound constitutions live on for years, the body becoming bent as from premature old age. The progress of general constitutional deterioration is slower at first than in ordinary phthisis, but in the advanced stages of the malady there is no difference in this respect. In ordinary bronchitis mischief does not usually spread to the lungs, nor does pneumonia affect the bronchial membrane; but in dust bronchitis the irritant acts both on the lungs and bronchial tubes. In persons of the tubercular diathesis—hereditary or acquired—the symptoms are scarcely to be distinguished from those of ordinary phthisical disease. Our wards afford several examples of this. I may instance the case of

Mary Ann H., aged 15, in the Eldon ward, under Dr. Pollock's care. This child has no hereditary tendency to phthisis. She has been employed in the chignon manufacture, and her branch of the business has been a very dusty one—viz., pulling out the long and short hairs from a dusty mass of unarranged locks. Her cough was first troublesome two years and a half ago, and now it is constant and distressing. The appearance of the child suggests the idea of advanced phthisis, and on physical examination this is confirmed, for she has flattening with dulness at the left apex in front, humid crepitation and gurgling sounds, conducted cardiac sounds, and the impulse, probably of the auricle, is seen in the second and third interspaces. There is no present evidence of bronchitis, and except at the commencement of the attack there does not appear to have been any. The case may be regarded as one of tubercular phthisis early developed in consequence of exposure to a trying and irksome occupation; the dust having a secondary and perhaps not essential relation to the disease.

Another patient, named Thomas G., now in the Paget ward under my care, who has been a baker for years, and exposed to dust, has the appearance and symptoms of ordinary phthisis, the physical signs being dulness with feeble breathing at the left apex, and crackling in the supra-spinous fossa. Notwithstanding what has been said above, I think that a distinction may be drawn between the disease as it affects those who have worked with metal—grinders or drillers, for instance—and those who have worked with a less keen-edged irritant—as bakers or chaff-cutters. In the former case the disease, when once established, is apt to run its course—tedious and protracted though it be—unchecked, even though the occupation be deserted; but in the latter case the disease may be arrested, and, under favourable conditions, life may be prolonged for the natural term. The following cases of Walter B. and of Robert G. illustrate these two positions. I will briefly detail them:—

Walter B., aged 36, engine-fitter, when working in the midst of steel filings, was seized with hæmorrhage to the extent of one or two pints. He was previously quite well, and the hæmorrhage has never returned severely. Three years ago felt pain in the left side, with gradually increasing dyspnœa and cough. Does not inherit chest disease, though his father was short-winded. His wife and child are phthisical.

Physical Signs.—Chest flat, with high, rounded shoulders, cord-like sterno-mastoidei and latissimus dorsi; respiration chiefly diaphragmatic. Right side: Cooing and prolonged expiration, amphoric sound (dilated bronchus) at apex, and diffused crepitation over the upper third. Behind, respiration feeble, with diffused scanty crepitation to base. Left side: Percussion dull; just beneath the sterno-clavicular articulation is a small patch of very superficial fine crepitation. Behind, breathing blowing (compensatory), with sibilant râles. Cough violent, tearing, spasmodic, causing profuse perspiration. Skin greasy. Eight weeks ago, when first examined, the physical signs were the same, but rhonchus and sibilus were diffused throughout. So urgent was the dyspnœa that the patient was confined to bed, though he could not lie down. Expectoration at first scanty, now (under chloric ether and ammonia) copious, frothy, and easy. Respirations 44; pulse 90; weight on admission 9 st. 5½ lb., and has gradually risen to 9 st. 9 lb. Has taken ol. morrh. ℥ij. bis die; bismuth powders; mist. fe. per. c. eth. Hydrate of chloral gr. xv. o. n. in camphor water was useful. Nitric acid and bark mixture disagreed. Iron suits well. Tincture of iodine has been less useful than croton oil liniment.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASES OF HEART DISEASE AFFORDING EVIDENCE RESPECTING THE ACTION OF DIGITALIS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

As in one of the addresses recently delivered at the meeting of the British Medical Association some surprise was expressed by the accomplished speaker that digitalis was stated by M. Loraine to augment the force of the heart's action, it may not be useless to contribute some clinical evidence confirming the above statement. I had, indeed, imagined that this view—long held more or less firmly by many physicians—had been settled by Dr. Fothergill; but in a matter literally so vital as the influence of a powerful drug upon the heart we can scarcely have too much testimony.

Case 1.—*Dilatation and Hypertrophy of Heart—Engorgement of Lungs—Anasarca—Use of Digitalis—Great Improvement.*

A. S., aged 42, cook, admitted November 29, 1872. She had been ailing some time with dyspnœa and anasarca of lower limbs. Her breath was very short. Her urine was scanty, thick, specific gravity 1020, rather highly albuminous. The lower parts (about the half) of both lungs were a good deal engorged and the tubes obstructed. The pulse was small, quick, weak, and irregular. The heart's sounds at mid-sternum were short, the first like the second; at the fifth space, both outside and inside the nipple-line, the first sound was louder, especially its valve element, but there was no bruit. She was ordered at first tinct. digitalis ℥x., liq. ferri muriat. ℥x., inf. calumb. ℥j., t. d.; brandy ℥iij.

From December 4 to 11 she was very ill with constant orthopnœa; could only doze a little in the sitting posture; had bloody muco-purulent expectoration; very small and weak and irregular pulse; signs of much obstruction in more than lower half of both lungs; highly albuminous urine; and diarrhœa. On December 4 the mixture first ordered was replaced by tinct. senegæ ℥ ss., ammon. carb. gr. iv., inf. cascarill. ℥j., quater die. On the 11th, tinct. digitalis ℥xv. was added to each dose.

16th.—Patient was better; sputa less bloody, and appetite improved.

19th.—She was much better; took food better; slept three or four hours at night; urine was much less albuminous, nearly clear and natural.

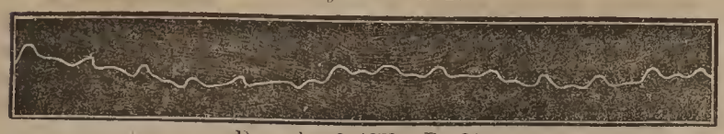
The same treatment was continued till January 9, when she was a great deal better, taking food nicely. She had on December 23 a cough mixture of Indian hemp and squills to take occasionally, to which on February 6 pot. iod. gr. j. was added. The dose of digitalis was now reduced to ℥x.

January 15.—The pulse was much more regular, the backs were fully resonant, and the breathing free—only crepitations were heard in the lower right. The senega was now replaced by ferri ammonio-citrat. gr. viij.

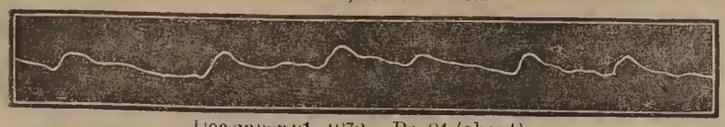
On February 10 she left the hospital, having improved still further: her urine then was not albuminous, neither was it on January 20, or 23, or 30, but was to some extent on February 6.

This patient at one time appeared doomed—with engorged lungs, a feeble and failing heart, albuminuria, insomnia, and anorexia her case seemed hopeless; but after she got the tinct. digitalis ℥xv. quater die she improved in a very remarkable manner, and left the hospital so well that she but half credited, I think, my warnings that she was unfit for any but very light work. The tracing taken December 21 shows a decided improvement in the circulation compared with that of December 3. Digitalis was commenced December 11. It is unfortunate that I omitted to take another tracing at a still later date, when she was further improved.

Tracings in Case 1.



December 3, 1872.—Pr. 84.



December 21, 1872.—Pr. 84 (about).

Case 2.—*Dilatation and Hypertrophy of Heart—Free use of Digitalis—Great Improvement for about Three Months—Relapse—Death—Autopsy.*

W. C., aged 54, coachman, admitted September 25, 1872. Has been ill on and off about six months. Had first pain in left side of abdomen and chest, and some in right side. Has had some palpitation of heart. Never could eat much, and lately has hardly been able to take anything; has had no solid food for some months. No epigastric tenderness; no tumour. Præcordial region is bulged, a slight tremor is perceptible at epigastrium, and a diffused impulse all over præcordial region and lower left front and side. No special apex-beat discoverable; head raised by jog of heart while auscultating. Dulness area appears increased. No murmur; second sound loud at apex and xiphoid. Resonance in both fronts is pretty equal and good; good resonance and breathing in right back. Left back dull in lower half, and breathing much weakened; some crepitation heard in this region. Breathing tolerably good in left supra-spinous fossa, but weaker than in right. At mid-part of left back there is more breathing, mingled with crepitation. Pulse 108, very weak; temperature 100·8°. Vocal fremitus much weaker in left lower back than in right. Breath very short on exertion. Coughs a good deal. Urine full-coloured, clear, notably albuminous, deposits some nearly homogeneous casts. Bowels act twice a day with loose, watery motions. Liver dulness of normal extent. Is made sick by solid food, and even milk if drunk quickly is rejected as large lumps of curd. Feels a heavy weight at epigastrium. Was always a healthy man until this illness; family healthy. Strychniæ gr. $\frac{1}{24}$th, acidi muriat. ℥ij., spt. chloroformi ℥x., aq. ʒj. ter die; brandy ʒij. Spoon diet: beef-tea, pudding.

28th.—Yestermorning the pulse was so weak it could hardly be felt. At 2 p.m. it was more distinct, but extremely frequent. He complained of increased dyspnœa, and of being unable to get any sleep. Tinct. digitalis ℥x., aq. ʒss., 6tis horis.

29th.—He was better for some hours, but this morning became worse again, and appeared almost moribund. Mr. Hickman, the House-Surgeon, with excellent judgment doubled the dose of tincture of digitalis, and increased the brandy to eight ounces.

30th.—Last night was the best he has had yet. To-day the pulse is much more distinct, 108. Says his breath is very much better to-day. Impulse of heart more evident all over præcordia. No distinct murmur to be heard; first sound is weak.

October 2.—Pulse is very large and soft, 120, fairly regular. He lies down well and sleeps well; asks for meat—chop ordered. Extensive dulness and absence of breathing in left back; at scapular spine some breathing and moist râle is heard. Good full breathing in right back. Urine free, cloudy, not albuminous.

On the 3rd the pulse was very irregular, 84. The mixture was ordered to be given only ter die, and he was to take besides vini ferri ʒj. ter die.

On the 5th there was some temporary loss of power in the left thumb and two next fingers. The dose of digitalis was reduced to ℥x. ter die. On the night of the 5th he had much delirium, got frequently out of bed, and went about the ward; had a good deal of diarrhœa also. The flux ceased with astringents and opiates, and on the 24th he was doing very well; the sounds of heart were fairly normal; its impulse was seen at the xiphoid and at the vertical line. Pt. mist. bis die. The steel wine was omitted about the 7th.

31st.—There was some return of delirium on nights of 24th and 25th, but he seems to be going on well. He can walk briskly up and down the long ward where his bed is, and make himself useful in the ward without experiencing any distress. His pulse before walking in the ward was 84, afterwards about 90. Urine very pale, sp. gr. 1008, not albuminous at all. Ferri carb. saech. gr. x., bis die. He continued to do well, and left the Hospital on November 8.

I saw him again January 2, 1873, when he was looking very well, but his appetite was failing. His heart's action was fairly regular; there was no bruit; the sounds and impulse were extensively diffused, the latter rather forcible. He continued the carbonate of iron.

He applied again for admission on February 28, when it was stated by his wife that he had been getting worse for a month, and had been much worse the last ten days. He complained first of loss of appetite, then cough and dyspnœa came on. His hands were cold, and his pulse scarcely to be felt at the wrist. The next day his hands were warmer, and the pulse more perceptible, though still feeble and indistinct. He was very drowsy, his face yellowish, his lips not livid. The drowsiness may have been owing to an enema of liq. opii ℥xv., which he had on admission for diarrhœa. His feet and legs were of a dull red, slightly swollen. The lower right chest expanded in inspiration, the left fell in. He had begun tinct. digitalis ℥xx., aq. ʒss., quater die; and was now ordered besides ammon. carb. gr. v., m. camph. ʒss., 4tis horis.

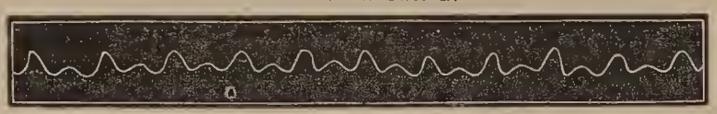
5th.—Had much diarrhœa yesterday; was very delirious in the night, getting out of bed often. He has been wandering and half-conscious, the sister says, ever since his admission. Pulse scarcely to be felt; some rusty mucous expectoration; jugular veins full on both sides. Temperature 99·32°. Takes nourishment well; has six ounces of brandy. The delirium and diarrhœa lessened, but he gradually sank and died on the night of the 7th.

Autopsy.—Heart weighed twenty-one ounces and a half; left ventricle dilated; the cavity contained small masses of old fibrine at the apex entangled among the columnæ. The aortic and right valves were healthy; the mitral flaps moved well, but did not completely prevent regurgitation when water was poured in from the aorta. Right lung healthy, but much congested; left shrunken and congested, and adherent to ribs. Liver nutmeg. Kidneys fairly healthy. The muscular tissue of right and left ventricles was similar; to the naked eye it did not appear abnormal, except that it was very flaccid and flabby. Under the microscope the fibres were well seen; they were not broken up nor atrophied by encroaching fibroid tissue, but they showed no trace of transverse striation, and but little of longitudinal. They seemed to consist of an homogeneous soft material, in which were embedded a few fatty granules, often in streaks, and a good deal of very fine molecular or granulous matter. On the addition of acetic acid very many elongated nuclei came into view, and the tissue became more transparent, but there was not much to be seen of fatty particles. The muscular fibre seemed certainly degenerated, but it could not be properly said to be in a state of fatty degeneration; it was more like the granular degeneration of Ormerod. The masses of fibrine at the apex of the left ventricle consisted of celloid corpuscles, most of them probably nucleated, mingled with a large quantity of coarse granular matter. A section showed grey areas, separated by red lines and streaks or patches. These were full of blood, and seemed to be blood-channels or vessels in an early stage of development.

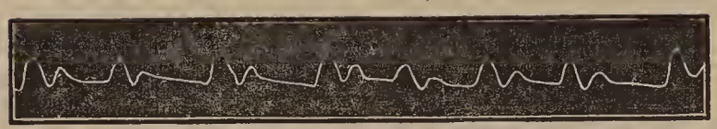
The foregoing case is a simple one: the phenomena during life and the results of dissection are quite intelligible and accordant. One organ alone showed unmistakable signs of failing vital power, and that organ after death is found changed in such a way as to explain readily the symptoms. One remedy on the first occasion is administered in sufficient doses, and recovery immediately commences and goes on satisfactorily. The dyspnœa and consequent insomnia were due to the insufficient propulsion of blood to the lungs by the debilitated right ventricle. The quick, weak, and small pulse, the cold surface, the general debility, and the delirium, showed how feeble was the current sent from the left ventricle. The albuminuria and diarrhœa may be traced to the stagnation of blood in the large veins, depending on defective contraction of the ventricles, causing congestion of the capillaries of the kidneys and intestines. As the heart became able to impel the blood more actively the stagnation was dissipated, and the disorders consequent on it ceased. It is a fact often witnessed in microscopy of the frog's web, as well as at the bedside, that a feeble arterial current gives rise to repletion of the small vessels with stagnant blood. The action of digitalis was, in this instance, as marked as it well could be, and beyond question its effect was to invigorate the heart, and enable it to carry on the circulation more efficiently. As there was no dropsical

accumulation to be removed, the result cannot be attributed to its operation on the kidney. Some consider, I believe, that the remedy acts chiefly on the vessels contracting their vascular coat, and regard the increased vascular pressure observed in experiments on animals as obtained in this way and not by augmentation of cardiac force. However this may be in such experiments, I think it is clear it was otherwise in the instance narrated. Had the drug acted on the vessels, and not on the heart, it must have increased the resistance to the blood-flow, and in so doing must have arrested the already failing play of the ventricles. The evidence afforded by the tracings is to the same effect, for that taken on October 26 is much more ample than that taken on October 1, when the drug had only been given three days. It is not too much to say that this patient's life was prolonged three months by Mr. Hickman's sound knowledge of the use of digitalis, and firmness in acting on it. Had he, seeing the patient *in extremis*, and knowing that he was already taking ℥xl. in the day, vacillated and omitted the remedy from fear that it was doing harm, in all probability he would have sealed his fate. By doubling the dose he saved his life for the time. So it is in medical as well as in military strife, that exigencies occur which show whether a man has true insight or no. The rate of the pulse was reduced under the use of digitalis from probably over 130 to 68; at the same time it became much fuller and more distinct, though it continued irregular or intermittent. It is worth remarking that though vin. ferri appeared to disagree with the patient, yet carbonate of iron suited him very well. Judging from the steady improvement which took place while the patient remained in the hospital, it seems reasonable to think that if the same treatment had been persistently carried out under favourable circumstances life might have been preserved and rendered enjoyable for many years. When he returned to the hospital, the life of the cardiac muscle had died out too far to make restoration possible. All the tracings are markedly dicrotic, the first two eminently so. This is no doubt indicative of the unfilled state of the arteries, and perhaps, also, of the resistance to the onward current occasioned by the semi-stagnation of the blood in the veins. The first tracing is much like one of typhus, where indeed the state of the circulation is very similar, the heart acting quickly and feebly. The pressure employed in the last tracing, when improvement was most advanced, was notably greater than in the two others, yet the rise is considerably higher.

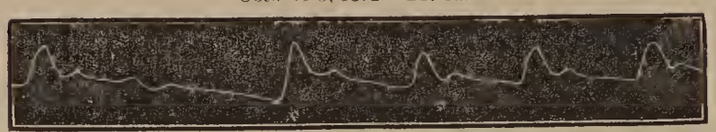
Tracings in Case 2.



October 1, 1872.—Pr. 84; rate 120.



October 5, 1872.—Pr. 84.



October 26, 1872.—Pr. 108; rate 68.

GLEANINGS IN WAR SANITATION

FROM N. PIROGOFF'S "BESICHTIGUNG DER MILITAIR-SANITÄTS-ANSTALTEN IN DEUTSCHLAND, LOTHRINGEN, UND ELSASS."

By NATHANIEL ALCOCK, L.K.Q.C.P., A.M.D.

(*Continued from page* 253.)

Beds.

The most feasible improvement in the various elaborate fracture beds was the division of the mattress into pieces, any one of which could be withdrawn singly from beneath the patient, according to the object in view—whether to use a bed-pan or to dress an ulcer.

Continuous Extension in the Treatment of Compound Thigh Fractures.

For the purpose of counter-extension, the French continued to use the old plans of Desault and Boyer; but the Germans had adopted much later methods. They sometimes allowed the body of the patient to make the counter-extension by giving the pelvis an inclination backwards, so that its weight would counteract the extension made from the foot. Again, they effected the extension by means of a weight attached to a cord which passed over a roller at the bottom of the bed, and to avoid excoriation of the limb by the cord, applied first a plaster-of-Paris bandage. Notwithstanding, however, the various apparatus devised, shortening for the most part followed these fractures. The remaining and more energetic treatment of compound fractures—the resection of the broken ends—was not put in practice, nor is it likely ever to gain a place in conservative surgery.

Neither was resection of the knee-joint for fracture through the femur and patella often used. Only two cases of this operation were seen, and three heard of. Of the former, in one the wound appeared comparatively healthy, but the bones were in a bad position; in the other, pyæmia supervened. Of those reported, all died. Subsequently, thirty cases were reported to have been operated on at Munich, but without success. Just as little satisfactory were the resections of the head of the thigh-bone.

When, on the other hand, the conservative method afforded such brilliant experiences in the treatment of compound thigh and knee fractures, it is no wonder that in shoulder, elbow, and ankle-joint wounds the result should have been still more favourable.

Fifty cases were discovered in which penetrating wounds of these joints had healed without surgical interference beyond the opening of succeeding abscesses; and, if there be such grounds for expecting a successful issue in penetrating joint wounds without resection, wherefore shall it be hastily undertaken? The extent and anatomical peculiarities of each wound must decide the necessity of operation. In elbow-joint wounds it may be desirable to expedite the performance of the operation on the chance of preserving the mobility of the articulation, which by delay will usually be lost in anchylosis. On the other hand, in ankle-joint wounds the probability of subsequent mobility is not so great, and its advantage over anchylosis is very doubtful. Again, where anchylosis of the elbow-joint has taken place with the forearm in the extended position, resection may be employed, but otherwise, after anchylosis is completed, should only be carried out at the entreaty of the patient.

The treatment of joint wounds and of wounds after resection consisted for the most part in the application of an immovable bandage, in swinging the limb, and in local baths. This last is but a process of maceration, and was not often employed.

It is, however, less intelligible why the plaster-of-Paris bandage was not used in all cases of resection. Dr. Pirogoff since 1848 has made its application under these circumstances an invariable rule, and in no instance during twenty years' experience has he observed the supervention of those evils which usually follow undue movement of the limb—viz., pus infiltration and œdema,—and to which those treated with ice compresses, splints, and slings are exposed. In fact, only by the use of this immovable bandage can the dangers of resection be reduced to a minimum, inasmuch as the patient is by this means alone spared the enervating effects of long confinement to bed. In Berlin, resected elbow-joints were laid on Esmarch's splint, and secured by a plaster-of-Paris bandage; but this was removed long before the wound had healed, and the patients were in consequence to be seen lying in bed without any support to the limb. It may be laid down as a first principle that the bandage should be continued till the fragments become covered with callus, and never less than six weeks. During this time the bandage will require to be renewed about three times, and these occasions afford opportunities of giving to the limb the most favourable position.

Of the death-rate after these resections no positive information is attainable.

Among the resources of conservative surgery may be reckoned the operations for the arrest of bleeding, the most important of which is the ligature of arteries. Of seventeen such cases which came under observation three only offered any prospect of success, and even these succumbed at a later period. In every instance had aneurism or secondary hæmorrhage indicated the wounding of the arteries. These cases were universally fatal in the Crimea, and have been so in all wars. Failure seems to be due to two circumstances—to the operation being too long deferred, and then carried out

when the patient had, from loss of blood or extensive suppuration, become weak and anæmic; and to error in selecting the place for ligature. For example, in bleeding from the femoral artery, instead of at once securing the external iliac, the femoral is taken up in its middle or upper third, thus leaving a large, deep branch between the ligature and the heart; so, also, in bleeding at the bend of the elbow, the brachial is obliterated instead of the axillary. Besides this, if the operation be put off too long the aneurismal sac will be found to contain decomposed blood and its walls to have begun to soften; the coats of the artery, also, will be in such a state that they mortify rapidly under the ligature, and not unfrequently the patients are affected with pyæmia even before the operation.

Five instances of successfully treated artery wounds were encountered, but they had been dealt with in a different manner from the foregoing. In one Professor Langenbeck checked bleeding from the "tibialis antica" by cutting down through the muscles and securing the vessel at the seat of injury; in another a traumatic crural aneurism was cured by digital compression; and in the three remaining, hæmorrhage from the carotid, external iliac, and crural was in each case controlled by digital compression kept up in the wound itself. This latter method Professor Simon considers more safe than ligature, but Dr. Pirogoff doubts that it will ever command universal confidence. Success in either case depends on the formation of a clot, and the only objection that can be urged against the ligature is that it crushes and tears the arterial coats. Yet every practical surgeon knows that secondary hæmorrhage can follow only under three conditions—the extension of unhealthy suppurative action from the wound to the walls of the artery, an originally diseased state of those walls, or the application of the ligature at a place too close to the origin of a large arterial branch. Under circumstances where, from the exhaustion of the patient and the evil condition of the wound, ligature offers no promise of success, digital compression may be tried, but even in such cases Dr. Pirogoff would prefer to have recourse to galvano-acupuncture of the main vessel.

It is incomprehensible why the artery is not at once taken up when the position of the wound is diagnosed, without waiting for the occurrence of bleeding or the formation of an aneurism; and it is still less rational to hesitate when strong pulsation, dilatation, or bruit in the vessel indicate the beginning of aneurism. In the cases detailed, ligature was only undertaken when the aneurismal sac was much distended or passing into gangrene: thus, in a case of wounded axillary seen at Karlsruhe, the operation was carried out after the hæmorrhage had recurred three times and the shoulder had become swollen and distended; also at Berlin a ligature was put on the femoral below Poupart's ligament when the patient was pyæmic and the toes of the injured limb had begun to be gangrenous.

Of three cases of varicose aneurism observed, all were situated in the groin, and the wounded, with the exception that they limped when walking, did well. An instance of varicose aneurism in the supra-spinous fossa was mentioned by Professor Langenbeck; ligature of the arteria innominata was contemplated, but the patient died before it could be effected.

In concluding this account of the brightest side of modern war surgery—viz., the conservative plan—but little need be added concerning that method which is opposed thereto, viz., the removal of limbs. As in the Crimea, so in more recent campaigns, it presents a sad chapter. "Death and again death"—such was the result of early, as well as late, amputations during the past war.

In his address delivered at the seventy-fourth anniversary of the Frederick William Medico-Chirurgical Institute of Berlin, 1870, Professor von Langenbeck asserted that "the duties of a field-surgeon can be of practical use to the severely wounded only when they begin immediately after the battle, and cease not later than two days after the same: therefore must all unavoidable amputations be performed and all conservative treatment be commenced in the course of the first twenty-four to forty-eight hours succeeding the engagement, before the sending away of the wounded with the distant transports; for the late and intermediary amputations afford the most unfavourable death-rate." From this expression it follows that the distinguished Berlin surgeon considers it possible within the first twenty-four hours after the battle to make all unavoidable amputations, and to be able to apply permanent bandages on all limbs destined for the conservative mode of treatment; and that he may be reckoned among the supporters of Bouchet's and Larrey's doctrine, since he regards all early amputations without exception as less dangerous than the later. One must now reflect that the Prussian administration did not lack opportunity of testing in practice during the past war these maxims of German surgery. It had at its disposal undoubtedly a sufficient number of surgeons, since, for example's sake, for 1000 amputations and for the application of 1000 permanent bandages, not more than 100 surgeons and some experienced surgeons for classifying the wounded would be necessary; that is, supposing that each one of them carried out about twenty amputations and an equal number of bandagings in the course of one day. But just here lies the difficulty, that neither any administration nor any science can show Professor Langenbeck's convictions to be founded on fact and in truth—firstly, because, owing to the scant supply of sanitary detachments in all European armies, it is impossible, not only to render help within the first twenty-four hours to all the severely wounded, but even to remove them from the scene of action; secondly, because the classification of the wounded in the ambulances is not established, and therefore the indications for amputations and for conservative treatment cannot be recognised immediately after the battle; thirdly (and this is the chief reason), because once the possibility and advantage of conservative treatment be conceded in principle, then also the necessity for late amputations cannot be gainsaid. No surgeon, be he ever so skilled, will be at any time in a position to predict whether he will be able to avoid a late amputation; not unfrequently will circumstances occasion him to desist from the conservative method, which may have in the beginning appeared so very possible and even probable. The conservative treatment and late amputation are so inseparably united that if the possibility of the first be granted the probability of the second must of necessity be admitted. The early doctrine of Bouchet and Larrey was as follows:—They laid down that amputations should be carried out in war as quickly as possible, because they regarded the retaining of a limb as generally more dangerous than amputation, and taught that whoever did not amputate immediately after the wound jeopardised more lives than he saved hands and feet. As soon, however, as modern science had announced the conservative treatment to be, even in war, not only possible, but also in many instances less dangerous, so must it, to be consistent, declare against the pressing necessity of early amputation. To defend conservative surgery, and at the same time to uphold the principle of early amputation, means to prove it in contradiction with itself.

"In order to obviate this contradiction in the words of Professor von Langenbeck cited by me, one must accept it that when he spoke of the necessity of making the unavoidable amputations as early as possible, he only wished to express the universally received rule, not to defer the operation in those cases in which it is obviously unavoidable. Yet the last war showed that even this indisputable axiom could not be observed, partly owing to unforeseen strategical circumstances, partly by reason of the abnormal military medical system, but partly too in consequence of the nature of the wounds themselves, many of which, resulting from large projectiles, were probably accompanied by such torpor and collapse that they would admit of no operative help before thirty-six to forty-eight hours; so was it at least the case with us in the Crimea. But even of those early amputations which were achieved on the field of battle in the first twenty-four hours, it can scarcely be assumed that they were to the advantage of the wounded, who were immediately after the operations despatched to a distance on country carts, were by this exhausted, and arrived at the hospitals with the bones sticking out of the wounds; and even where the indications for unavoidable amputation were unusually evident and very abundant—namely, in siege fights,—the early amputations, according to the independent testimony of the surgeons, gave favourable results only at the beginning of the siege. But as the communications from the theatre of war by 'L. Z.' (who visited the Strasburg hospitals twelve or fourteen days after the capitulation, as I also did) have shown, even there out of 180 early amputations 130 died. Likewise was I astonished that Professor Langenbeck should in general give the preference to all early amputations over the later, since experience with us in the Crimea, as well as in still more recent campaigns, afforded indisputable evidence that early amputation yielded a really good result in the upper extremity only, in which, too, the conservative method is most successful. In wounds of the leg, of the knee, and especially of the thigh-bone, the early as well as the late operations so often

eventuated fatally that neither deserves preference over the other.

"Still more, however, did the circumstance surprise me that Professor von Langenbeck allowed the preference to early amputations; since he in that same address, agreeing with me, showed himself an advocate for late resection of the shoulder, elbow, and ankle joints. Now, any surgeon who has convinced himself of the advantage of late resection must give the preference to late amputation over early, and certainly at once on the ground that in recent wounds the choice between amputation and resection is not unfrequently extremely difficult. In a word, from whichever side we regard these things, we come to the conclusion that the introduction of conservative treatment into modern war surgery is in and by itself already a protest against early amputation, which allows no saving of the limb."

(*To be continued.*)

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

NINE CASES OF FATAL FRACTURE OF THE SKULL, WITH POST-MORTEM REPORTS THEREON.

By Mr. HENRY MORRIS, Senior Assistant-Surgeon to the Hospital.

During the two years 1870 and 1871 there were 170 post-mortem examinations of surgical cases made in the Middlesex Hospital. Among these 170 cases were nine of fatal fracture of the skull, the details of all of which are here given. The object in view in publishing these cases is to show the situations in which the fractures have occurred.

Case 1.—*Fracture of Right Temporal Bone extending vertically downwards through the Squamous Portion nearly to the root of the Petrous Portion, and then backwards at right angles across the root of the Petrous Portion, exposing the Cavity of the Tympanum.*

No. 438.—Henry T., aged 27, was admitted on May 19, 1870, having been struck by a skittle-ball twelve hours before admission. When admitted he was quite unconscious, and breathing stertorously. Neither pupil acted, and the left was widely dilated. There was no scalp wound present, nor could any fracture be detected, but there was a soft tumour felt, which could be pitted on pressure, in the right temporal region. There was no bleeding from the ears, nose, or mouth. He died one hour after admission.

Post-mortem Examination.—A vertical fracture curving at the upper extremity a little forwards was found in the right temporal region, but as the edges were not at all displaced, but perfectly level, it could not have been felt during life. The squamous portion of each temporal bone was remarkably thin, especially the left, which only measured three lines. The fracture extended vertically downwards nearly to the foramen spinosum, and then backwards at right angles across the root of the petrous portion of the temporal. The roof of the tympanic cavity was very thin, and a piece of it as large as a hempseed was detached, so that the small bones of the ear could be seen. Immediately beneath the bone, and between it and the dura mater, was a large clot spread over the whole side of the membrane and compressing the brain so as to form a considerable depression upon the right hemisphere. The weight of the clot was four ounces and three-quarters, its source the posterior branch of the right middle meningeal artery, around the ruptured seat of which some of the clot was very firmly adherent.

Remarks.—Direct violence upon very thin bone, which gave way at the point struck. Meningeal artery ruptured, and a large clot, five inches in antero-posterior measurement, three inches and a quarter in vertical, and one inch and three-quarters in thickness. Fracture extended to, but not across, the base, and to this only by continuity.

Case 2.—*Fracture of the Left Frontal Bone extending along the Roof of the Orbit through the Greater Wing of the Sphenoid to the Petrous Portion of the Temporal Bone.*

No. 472.—Thomas B., aged 9, admitted in March, 1870, having fallen out of a window about ten feet above the ground. When brought in the forehead was much bruised, and his left eyelid was ecchymosed and swollen. There was no coma, and no bleeding from any source whatever. He died twelve hours after admission.

Post-mortem Examination.—A fracture extended through the vertical portion of the frontal bone parallel with the frontal suture, and down to and then along the margin of the orbit; it thence reached backwards along the inner side of the roof of the left orbit, taking a course farther back somewhat, through the small wing of the sphenoid, and then backwards through the greater wing near the foramen in its base. In the centre of the vertical part of the left frontal bone there was a slight depression, and between the dura mater and this part of the bone was a layer of coagulated blood spreading over the bony roof of the left orbit. The periorbital membrane was not ruptured, but a good deal of blood was effused within it amongst the fat and muscle of the space. The brain was contused, and even lacerated, at the base and fore part of the left anterior lobe. There was some extravasation of blood into the arachnoid cavity about the lower part of the pons and the medulla.

Remarks.—History as to exact part of the body which first impinged on ground could not be ascertained. The violence in all probability was over left frontal bone, and the fracture extended from that to the left side of the base of the skull.

Case 3.—*Fracture of the Base of the Skull across the Anterior Fossa—Skull Fractured also on the Right Side through the Frontal and Parietal Bones—The Right Anterior Convolutions of Brain considerably Bruised—Arachnitis.*

No. 457.—George R., aged 10, was admitted on May 26, having shortly before fallen from the top of a baker's van while it was standing still. In his fall he struck the right and front part of his head against both van and ground. There was ecchymosis, with swelling of the eyelids of both eyes, a circular abrasion on the right side of the forehead, and blood of a bright colour was flowing from the mouth. The pupils were equal and acting. He became delirious, with muttering delirium, but could be roused when spoken to in a loud voice. The semi-consciousness rapidly passed into almost complete coma, and he expired on June 2, thus living seven days from the date of injury.

Post-mortem Examination.—Blood extravasation between hairy scalp and frontal and fore part of parietal bones. A fracture extended upwards from the outer angle of the right orbit towards the right frontal eminence. This was joined nearly at right angles by another, which crossed the lower anterior corner of the parietal bone to reach the squamous suture. Another fracture extended vertically from the margin of the right orbit, near the inner angle, upwards to the frontal eminence, but this did not meet the other. Both extended across the roof of the orbit, which was quite detached and separated. There was a double transverse fracture in the base of the anterior fossa of the skull—one was limited to the left half, and was close to the vertical portion of the frontal bone; the second traversed the whole length of the floor immediately in front of the lesser wings of the sphenoid, both of which were, however, fractured, and the left quite detached. The crista galli was also detached. The dura mater over the roof of the orbit was lacerated, and detached by effused blood from the bone. The arachnoid around the optic commissure and covering the pons and cerebellum was thickened, and covered by a firm layer of yellow purulent lymph. This condition was confined to the parts specified. No lymph was seen on parts near the fractures.

Case 4.—*Fracture of the Base of the Skull through the Horizontal Plate of the Frontal Bone and Cribriform Plate of Ethmoid, extending from the Right Side of the Median Line in front to the Optic Foramen of the Left Side, and continuous with an obliquely vertical Fracture of the Frontal Bone—Arachnitis.*

No. 587.—J. S., aged 44, was admitted on July 18, 1870. While at work repairing the outside of a house, he looked up, and, seeing a brick falling, he tried to avoid it striking him; in doing so he slipped and fell from the ladder on which he was standing to the ground, a height of seven feet. He walked to the Hospital between two men immediately afterwards. On admission he was conscious and able to answer questions. His eyelids on both sides and the conjunctiva of the left eye were ecchymosed. No fracture could be detected, although the nose was much distorted and appeared pushed over to the right side. The day after admission he became restless, and turned from side to side constantly, but answered questions rationally. This restlessness increased, but consciousness

when spoken to continued up to the hour of his death, on July 25, the second day after admission.

Post-mortem Examination.—The base of the brain was coated by a thick layer of yellow puriform lymph. This was beneath the arachnoid, and was chiefly marked about the cerebellum, pons, and as far forwards as the circle of Willis. The ventricles were distended with pinkish serum. There was a fracture through the frontal bone near the median line, but bearing to the right side near the orbital ridge. It reached along the horizontal plate of the frontal and obliquely across the ethmoid, just behind the crista galli, and ending at the inner angle of the lesser wing of the left sphenoid bone.

Case 5.—Fracture of the Base of the Skull extending along the Anterior Surface of the Right Petrous Portion of the Temporal Bone. This was continuous with a vertical Fracture through the Squamous Portion of the Bone, which reached upwards and backwards for an inch upon the Parietal Bone.

No. 800.—George B., aged 41. About five hours before admission on October 9—the patient being drunk at the time—he fell down some stone steps, and struck his head against a stone slab. He was picked up insensible, and remained so up to his admission, when he was bleeding from the right ear; he could, however, be roused when spoken to. His pupils were small, but acted to light. His unconsciousness increased, his breathing became stertorous, and he died in a comatose state at seven o'clock on the evening of October 13—the fourth day after his admission.

Post-mortem Examination.—A fracture extended vertically upwards and slightly backwards from just in front of the external meatus to an inch beyond the squamo-parietal suture. Near the ear the bone was splintered into two or three fine spicula nearly an inch long, which were lying loose between the fractured edges. On removing the calvarium a large clot ($3\frac{3}{4}$ oz.) extended itself over the right side of the brain and dura mater. This was firmly adherent to the dura mater, plugs of which were fixed to the ruptured ends of the meningeal artery. The artery in several places was completely torn across.

Case 6.—Fracture of the Base of the Skull—(1) through the Lesser Wings of the Sphenoid; (2) through the Body of the Sphenoid, extending in a curved line across the Middle of the Right Petrous Bone; (3) vertically along the Median Line of the Occipital Bone from the Foramen Magnum to the Occipital Eminence.

No. 988.—James B., aged 40, a cab-driver, was thrown violently from his seat by his cab coming into collision with another cab. On admission, December 16, 1870, he was insensible, and smelt very strongly of spirits. He died two hours after admission.

Post-mortem Examination.—A fracture extended from near the occipital foramen along the median line to the occipital eminence. A large quantity of black clot was lying in the arachnoid space along the whole length of the base of the cerebrum, and over the upper surface, especially over the anterior half of the upper surface. There was more extravasation on the left than on the right side; much of the clot on this side was resting upon the tentorium cerebelli and between this and the under surface of the large brain. Over the front extremities of the anterior lobes the pia mater and arachnoid were ruptured, and the brain substance was bruised, and a considerable quantity of black clot was lying beneath the arachnoid. A crack in the bone extended across the posterior portion of the anterior fossa. Another fracture with much splintering of the bone extended from the sella turcica through the right temporal bone, extending in a curved manner, with the convexity outwards and forwards.

Case 7.—Fracture of the Base of the Skull extending across the Greater Wing of the Sphenoid Bone on the Right Side, from its Superior and Posterior Angle to the Spheno-Maxillary Fissure—Depression of Bone, and Laceration of the Membranes of the Brain at the Upper End of the Fracture.

No. 990.—Lucy H., aged 55, admitted on December 18 at 10 a.m. It was ascertained that the evening before she was passing by an opening in the pavement into a cellar, when she was suddenly frightened and fell through the opening. She lay where she fell, insensible all night, and died on December 20.

Post-mortem Examination.—On removing the right temporal muscle, a fracture was seen running obliquely across the greater wing of the sphenoid to the spheno-maxillary fissure. The bone immediately in front of the line of fracture was slightly depressed and pressing hard against the brain substance at the upper point of the fracture. Here the membranes were ruptured, and a black coagulum in the arachnoid space was spread over the upper and lateral surfaces of the right hemisphere. The anterior extremity of the under surface of the left middle lobe was bruised, and from this spot a layer of partly coagulated blood was spread out. As the fracture was most marked at the superior and posterior angle of the fracture, it would appear that the chief violence fell directly upon the right temporal fossa, and that the bruising and hæmorrhage of the left side, and left side of the base, were probably due to injury by contrecoup.

Case 8.—Fracture of the Base of the Skull in Orbital Plate of the Frontal Bone of the Right Side.

No. 94 R, 1871.—Wm. G., aged 38, a painter, fourteen days before his admission slipped upon a piece of orange-peel, and wounded his scalp behind and above the angle of the right orbit. On January 31, 1871 (the day of his admission), he was brought to the Hospital by a policeman, as he had fallen again just before, and was picked up in a semi-conscious state. He complained of pain in the head, and was vomiting a good deal. His face and right eyelids were swollen, and discharge was flowing from the wound of the scalp.

February 1.—He was trephined at the seat of the wound; but no abscess was found connected with the membranes or brain itself. He died the next day (February 2), the second day after admission.

Post-mortem Examination.—A triangular-shaped piece of the orbital plate of the right frontal bone was quite detached from the rest. The diploë of the frontal bone was infiltrated with pus, and the edges of the fracture presented the appearance of having been fractured some days. At the anterior extremity of the middle lobe the brain was superficially bruised, and covered with a layer of creamy yellow pus, which reached upwards in front and laterally over the right hemisphere between the layers of the arachnoid. Outside the dura mater, in the sella turcica, and along each carotid artery, was some dirty brown pus. On the right side some pus of similar character extended a little way into the orbit, where a thin streak was seen beneath the superior rectus muscle.

Case 9.—Fracture through the Left Occipital Bone and the Squamous and Petrous Portions of the Temporal Bone.

No. 679.—William L., a drayman, fell off the box-seat of the dray. On admission he answered questions slowly and stupidly. There was hæmorrhage from the left ear. Pupils were equal. No fracture could be detected, but there was swelling over the upper portion of the occipital bone.

Post-mortem Examination.—Fracture of the skull, extending through the side of the horizontal portion of the occipital bone and the root of the petrous portion of the temporal bone. The fracture of the petrous bone was bifid—one fissure passing upon its posterior aspect, curved inwards and backwards to end in the foramen lacerum basis cranii; the other passing forwards allowed of the detachment of a considerable portion of the anterior surface of the bone, and the consequent exposure of the cavity of the internal year. The anterior convolutions of the anterior lobes of the brain were much bruised and lacerated, especially on the left side. A quantity of blood-clot, four ounces and three quarters in weight, occupied the right arachnoid cavity, and flattened the left hemisphere of the brain.

Sir James Paget, Bart.—This distinguished surgeon lately placed a memorial window in the Church of St. Nicholas, Great Yarmouth, of which town he is a native. It is very handsome, representing Isaiah, Elisha, and Elijah, with suitable extracts from the Holy Scriptures; and on a brass plate beneath the following inscription:—"To the glory of God. In loving memory of Samuel Paget, a merchant, and Sarah Elizabeth, his wife. They and many of their forefathers dwelt in this town. They were pious, loyal and gentle lovers of their Church and home, bountiful in prosperity, patient in adversity, honoured by friends, reverenced by their children. They lived and died hoping for deathless life through our Lord Jesus Christ. Samuel Paget died in 1857, aged 83; Sarah Elizabeth Paget in 1843, aged 65. Twelve of their children rest with them in and near this church." A modest "J. P." is all to indicate this filial act on the part of our great surgeon, who it is to be hoped may reach the patriarchal age of his sire.

At the meeting of the Wrexham Sanitary Authority last week, it was reported there had been fever in eighty houses at the Rhos and Ponkey, and 204 persons had been attacked, thirty-seven of whom had died.

SATURDAY, OCTOBER 18, 1873.

FEES.

The Medical Season in London may be said to begin with the opening of the schools on October 1. Most of our brethren are returning or have returned from their holidays, and if patients on their way to southern health-resorts require a final opinion in London before leaving, they can be indulged with consultations at a reasonably short notice. Still, London is comparatively empty, and before the whirl and press of business are fairly upon us we invite our *confrères* to consider with us the very important subject of Fees.

We suppose that it will be admitted on all hands that every item of personal and family expense has largely increased since the reign of William and Mary, that the guinea of that period was at least worth three of our present sovereigns, that it represented at least three sovereigns' worth of food, service, and lodging,—and yet the fee of one guinea was paid to Radcliffe and Mead, whilst only the same nominal sum is now given to our leading physicians and surgeons, or one-third of the physician's fee in Queen Anne's time. It is clear that with such a depreciation in the value of money, rise in the price of most necessaries and many of the luxuries of life, and a general increase in the expenditure of all classes of the community, Medicine cannot long continue to hold its place, but must sooner or later descend in the social scale. We know that in thus writing we are treading on delicate ground, but we think it behoves the leaders in London practice to take this matter into their serious consideration. The fact that a leading Fellow of the College of Physicians or of the College of Surgeons can be consulted for the same coin that would be slipped into a friend's gamekeeper's hand on leaving his country house is at least an incongruity. The truth is that in England the sovereign has taken the place of the crown—a coin which, as eighteenth-century novels show, answered many of the purposes to which the modern sovereign is put.

Not to descend, however, to particulars, we may lay down the broad principle that professional charges ought to be regulated by the value of money, the cost of living, and the social condition of a people. In England the value of money has depreciated, but, instead of medical charges rising, they have depreciated with it. Amongst general practitioners the modern plan of charging for visits alone, instead of for medicine and attendance, is found less lucrative. Amongst the consulting class there is, if current reports be true, an increasing readiness to grant more than one interview for the ordinary fee, and to accept smaller emoluments for extraordinary services. We believe, however, that this state of things, which we cannot but regard with extreme dissatisfaction, is to be remedied only by the foremost practitioners of London. Were the few leading surgeons and physicians steadily to refuse to accept any fee less than three guineas for a consultation, we may rest assured that their example would be in their degree imitated by the whole profession. The leaders would reap pecuniary advantages at least equal to those which they at present enjoy, at the expenditure of two-thirds less of physical and mental force, whilst the less prominent and junior members of the consulting ranks would proportionately benefit. The general practitioner would not then have to complain that the physician or surgeon competed with him by multiplying interviews without a proportionate increase of fees, and the general position of the whole profession would be improved. Medicine no longer gives riches. It has been long outstripped in the race for wealth by brewing, banking, stockbroking, and a hundred trading pursuits. The question is not whether medical men as of old should amass princely fortunes—modern sanitary science will answer that in the negative,—but whether medicine shall continue to hold its social position amongst the liberal professions.

THE MEDICAL USES OF ELECTRICITY.—No. V.

Therapeutical Use of Electricity.

In *traumatic* paralysis faradisation is invaluable. Brown-Séquard has proved that even the spinal cord may be perfectly restored after traumatic lesion, and it has long been known that nerves will perfectly reunite after division, and when even considerable portions of them have been excised. But after reunion of a nerve has taken place, the muscles supplied by it will often remain paralysed, and continue to waste, and contract unless faradisation be resorted to. Its value in this form of paralysis was largely tried and well proved in America in cases of men wounded in the Civil War; and in a report on "Gunshot Wounds and other Injuries of Nerves," (a) the surgeons in charge say:—"The only important means in the treatment of paralysis from default of innervation is faradisation by the method of Dr. Duchenne. Most of our cases were from wounds that were of old standing when they came under our care, and localised faradisation proved of the utmost value. In some cases at a single application it restored the power of movement to parts long deprived of it, and we have seen very few instances in which there has not been improved nutrition and greater sensibility and strength when we were able to continue it sufficiently long." The faradisation will, of course, be of no use till after the injured nerve has regained its power of conduction; but in recent cases of injury the interrupted voltaic current should be localised in the affected muscles, and direct faradisation be employed when farado-contractility begins to return.

In cases of *local* paralysis, dependent on cold or on metallic poisoning, as from lead or mercury, or on diphtheria, the employment of electrisation should not be neglected when the affection has resisted other means of treatment. In these cases the faradic and the interrupted voltaic currents, used alternately and localised in the affected muscles, will generally effect a cure. As a rule the farado-contractility is unaltered

(a) By S. Weir Mitchell, G. R. Morehouse, and W. W. Keen. Philadelphia. 1868. See also "Injuries of Nerves and their Consequences," by S. W. Mitchell, M.D. Philadelphia, 1872.

in muscles paralysed by exposure to cold; but this is not the case in facial paralysis from cold. Here the farado-contractility is diminished or quite lost, while the excitability to the interrupted voltaic current is increased; and faradisation may be employed for weeks without effecting any improvement. In this affection, therefore, the interrupted voltaic current must be used and localised in the muscles till the farado-contractility is restored, and then the two forms may be employed alternately; and in this way cases of even years' standing may be cured or greatly benefited. It will be remembered that in speaking of the diagnostic uses of electricity we mentioned it might be employed to distinguish *lead-palsy* from paralysis caused by cold, for in lead-palsy farado-contractility and sensibility are diminished or lost, while they are normal in paralysis from cold. In lead-palsy the interrupted voltaic current should be applied to the affected muscles. As in other forms of paralysis, where this current acts and the faradic current elicits no response, the sensitiveness to the former is abnormally great, and it is found to lessen as the farado-contractility returns, till each becomes normal. The voltaic current employed must be a slowly interrupted current, and may be gradually abandoned for the faradic current as farado-contractility is restored; and whichever of the two currents is used, it must be localised in the muscles—not indirectly applied.

In *aphonia*, whether emotional (or hysterical) or caused by paralysis of the vocal cords, faradisation will effect a cure. In the latter it is best to apply the current to the larynx internally by the catheter-shaped instrument used by Dr. Morell-Mackenzie. In emotional aphonia, faradisation will sometimes fail, when static or frictional electricity, employed by sparks taken from the skin over the larynx, or by a shock from a charged Leyden jar, will at once produce the desired effect; and this form of electrisation is not only more effectual, but also less disagreeable than faradisation.

Other local palsies may be treated with success by electrisation; but the same principles of treatment will apply to them all, and we shall not speak of them in detail. Nor can we treat here of the use and value of faradisation in the constipation and the difficulty of micturition of paraplegia, or in locomotor ataxy, wasting palsy, and many other disorders; but must be content to refer our readers to the English works we have mentioned, and to Duchenne's treatise on "Localised Electrisation."

We must notice, however, the electrical treatment of cases of over-action of muscles. In cases of torticollis, and in long-standing cases of tonic contraction of muscles, as those which may accompany muscular rheumatism, faradisation of the antagonists of the affected muscles is very successful. And "in all cases in which tremor or spasm is a promiuent symptom," the use of the "positive charge" of electricity, of which we will speak directly, combined with faradisation of the antagonisers of the contracting muscle, gives excellent results. In writers' cramp, also, and the analogous affections, the same system should be followed. Dr. G. V. Poore finds that writers' cramp is most successfully treated by allowing a very mild continuous current to pass through the trunk of the nerve supplying the affected muscles, and, *at the same time*, making the patient exercise the muscles. His papers on writers' cramp in the *Practitioner* for this year are well worthy of careful study.

Franklinisation has been but little employed of late, but at the National Hospital for the Paralysed and Epileptic it has been found very useful. We have already mentioned that electrisation by sparks over the larynx often rapidly cures *emotional aphonia;* so effective is it, indeed, that at the above-named hospital it is used in most of these cases before trying faradisation. And Dr. Tibbits tells us that "*facial neuralgia* which has resisted other modes of treatment may occasionally be relieved with rapidity and permanently by drawing sparks along the track of the affected branch or branches of the trifacial nerve." He has also seen obstinate *sciatica* and *facial spasm* partially or altogether removed by this means.

Dr. Radcliffe has originated a special method of electrisation which Dr. Tibbits thus describes in his work. It is a method "in which the patient and the battery must both be insulated, in which the passage of the current must be quite constant, and in which a wire, which Dr. Radcliffe terms a "ground wire," must be carried from the negative pole of the battery, or from the negative rheophore, to the earth. This wire may be conveniently attached to a chandelier or gaspipe, which always gives a direct metallic conduction to the ground. With careful insulation, the negative electricity passes away by this wire, and while the current circulates, the patient continues "*charged*" with positive electricity. A sheet of guttapercha about four feet square by half an inch thick will answer admirably to insulate the patient and the accessories. In speaking of Dr. Radcliffe's theory on the mode in which this acts on the body, into which we cannot enter here, Dr. Tibbits observes, "When a part of the body is included in the voltaic circuit it may be all charged with positive electricity if an earth wire be put to the negative pole, or with negative if an earth wire be put to the positive pole; and the conditions are favourable to irritability in the former case, unfavourable in the latter. This is the fact insisted upon. It is of no moment whether this charge with which the animal Leyden jars are to be charged is from a friction machine, or whether it be from a voltaic battery by running off the opposite electricity by an earth wire. What is wanted is to charge the outsides of the sheaths positively as they are charged internally. What is aimed at is to put the fibres by this means in the condition most favourable to the preservation or recovery of their irritability,—*not to provoke this irritability into existence by shocking it;* and certainly there is much in theory and much in practice to recommend this view as one which opens out quite a new field in electro-therapeutics." We have mentioned that the "positive charge" alternated with faradisation has been found highly beneficial in cases of tremor or spasm. Dr. Tibbits has also found that in wasting palsy this plan of treatment has been followed by an arrest of the disease and a filling out of the wasting muscles. "Localise faradisation," he says, "in the wasted muscles, and vary the treatment on alternate days by the positive charge." In very long-standing cases of facial palsy, also, when there is fibrillation in the muscles, he has found great advantage from daily treatment by the positive charge.

Drs. Beard and Rockwell, of New York,(b) employ very largely a method of general faradisation. They place the patient with naked feet on a sheet of copper connected with one rheophore, while the other pole is connected by means of a moistened sponge with the left hand of the operator, who uses his right hand as a rheophore, passing it over the muscles or even the whole body of the patient. They say that they have used this method more than ten thousand times, and speak very highly of its effects in states of debility. They believe "that electrisation, besides being merely a local stimulant, also exercises an influence over general and local nutrition, at once unique and unrivalled, and that entitles it to the highest rank among constitutional tonics; and that the system of making the application exclusively local is both illogical and inconsistent: that in the use of electricity, as of every other remedy, constitutional diseases should be treated constitutionally." We requote Dr. Tibbits, not having succeeded in seeing the original work.

Electrisation of the brain has been advised in cerebral disease, and it has been shown that the continuous current

(b) "A Practical Treatise on the Medical and Surgical Uses of Electricity," by Drs. Beard and Rockwell. New York, 1871.

can be passed in any direction through that organ; and some experts have recommended "galvanisation of the sympathetic," one electrode being pressed deeply into the auriculo-maxillary fossa, while the other is applied over the sixth or seventh cervical vertebra, or over the top of the sternum close to the edge of the sterno-mastoid. But very little is yet known about these employments of electrisation, and it is certain that their use calls for very great caution. A paper on the "Electric Treatment of the Insane," by Dr. Clifford Allbutt, will be found in the second volume of the "West Riding Lunatic Asylum Medical Reports"; and one, by Dr. Buzzard, in the *Practitioner*.(c)

We have now said as much as we feel justified in saying in these papers on the medical uses of electricity. The subject is one of very great importance in the treatment of disease, and we might very easily have much extended our notice of it, for it is one of constantly widening importance. But, as we said at the outset, we pretend only to treat of the most clearly ascertained uses of electricity in medicine, and leave almost entirely untouched the many conditions in which it may yet be found of service. We venture to hope, however, that we may help a little in stimulating practitioners to the careful study and employment of it, and we will close our brief notices with Dr. Russell Reynolds's words to his readers —"Electricity is one of the most powerful agents that you can employ in the treatment of disease; but it is useful, useless, or mischievous, according to the manner in which it is applied." The Why, When, and How of its application are, each and all, of great importance. Our knowledge should be as exact and precise as possible of the pathological condition to be relieved or removed, of the kind of electricity to be used and the method of its application, of the time when to administer it, and the kind and amount of benefit to be looked for from its employment.

THE WEEK.

TOPICS OF THE DAY.

The General Medical Council cannot remain in Soho-square. The apartments modestly shared with the Dental Hospital will soon no longer be at their disposal, for we understand that the house is let to a "Hospital for Diseases of the Heart," to certain advertisements of which our attention has been on various occasions called, and the dentists have obtained a house in the wilderness of Leicester-square. The General Medical Council, therefore, is threatened with being literally turned into the streets—houseless and homeless. Our readers will remember that in the summer we announced in a spirit of faith and gratitude, which the attitude of the Government towards the Council seemed to warrant, that the Medical Council were to be provided with apartments in a Government building which was being erected at the corner of St. Martin's-lane. "Put not your faith in Cabinets" is a modern rendering of an ancient piece of sound advice. It is now understood that Government will only provide the Council with apartments on the Council agreeing to pay the Government a full rent for the same. Considering that the Government has the nomination of six members of the Council, whom they do not pay, we think this is neither generous nor equitable on the part of Messrs. Lowe and Ayrton. However, time is pressing, and it is understood that there must be an early meeting of the Executive Committee of the Council to take the matter into consideration. The term of office of four of the members nominated by the Crown—Dr. Parkes, Dr. Quain, Sir R. Christison, and Dr. Stokes—expires in the middle of next month. It is probable that one at least of these gentlemen will not desire reappointment.

(c) "Cases Illustrating the Employment of Central Galvanisation in various Sensory Disturbances," by T. Buzzard, M.D. (*Practitioner*, vol. i. 1873, p. 81 *et seq.*).

The visitation of examinations continues. The reports from Ireland are said to be good. Scotland is now receiving the attention of the visitors. From all we hear we believe that the visitation of these examinations is likely to produce most valuable fruit.

The report of the Hospital Sunday Fund Committee has been made public, and shows that the total amount received to September 4 last was £27,700 8s. 1d. This sum was principally made up as follows:—Collections at nearly 1100 places of worship, £25,743; collections at 88 schools, £112 11s. 8d.; from workmen, £244 7s. 6d.; sundry donations, £1489. The expenses included many items which the Committee state are not likely to occur again, and amounted to £750 8s. 10d., being rather more than 2½ per cent. on the sum collected. There is no doubt that some unavoidable outlays were incurred in the inauguration of this undertaking, and it is to be hoped that on future occasions the expenditure will be smaller for the collection of a much larger sum of money. A further report of the Committee of Distribution shows that of the sum collected £24,571 was awarded to general and special hospitals, and £2185 to fifty-three dispensaries and other medical charities. A great deal of care and attention were bestowed by the Committee in adjusting the various donations and selecting the most necessitous and the most deserving charities for the benefits to be conferred, and the public may be very satisfied that the money contributed by them has been equitably and usefully distributed. The Committee recommend the establishment of what they term "provident dispensaries," to be made as near as possible self-supporting, by a monthly payment from a large number of members, thus constituting the medical attendance which they require a right rather than a favour. They imagine that there are many persons in London who now obtain gratuitous medical assistance who would be willing to pay something for their medicine and attendance, but who cannot afford to incur a doctor's bill, and who yet feel much reluctance in accepting charity. This class of persons use the hospital or dispensary solely from their inability to discover any system of medical relief within their means, and in these days of co-operation should be encouraged to extend a feeling of independence which helps them to be provident, and tends to relieve the pressure which at present exists upon the resources of many of our large charities. There is, of course, nothing new in this proposal. The only difficulty is how to prevent the provident dispensary being abused.

GYMNASTICS AND THE ARMY.

Amongst many modern institutions and improvements for the well-being of the British soldier the gymnasia which have been added to most of the large barracks and stations are worthy of special mention. As a means of amusing the men, whilst adding greatly to their muscular development and physique, they are unrivalled; and, wisely recognising the importance of fostering in the ranks a popularity for this species of recreation, the Duke of Cambridge gave his consent to a grand field-day of military athletic sports being carried out at the Crystal Palace on Monday last. In France and Germany so much importance is attached to this branch of a soldier's education, that gymnastics form a part of the regular drill. In this country the advantage of rendering men agile and active has only lately dawned upon the authorities at the War Office. However, upon the occasion in question a very creditable display of stamina and agility was provided, and it is to be hoped that this public encouragement and recognition will be continued. With battalions considerably beneath their proper strength, and a paucity of recruits presenting themselves—to say nothing of the enormous drain brought about by desertions consequent upon the unpopularity of the army

service as it now stands (with its short term of service and want of pensions)—it becomes incumbent upon us not only to show the soldier that even in his amusements the country takes an interest, but also to lead his recreation into such channels that those whom we really do possess may at any rate be made thoroughly effective.

THE MEDICAL SCHOOLS.

The annual registration of gentlemen pursuing their professional studies at the eleven recognised metropolitan hospitals was brought to a close at the Royal College of Surgeons on Wednesday, the 15th inst. It is understood there will be a small addition to the undermentioned, by permission of the President, of gentlemen unable to reach their respective schools from illness and other unavoidable circumstances:—

	Total number registered.		Fresh entries.	
	1873.	1872.	1873.	1872.
Guy's Hospital . . .	304	319	89	83
St. Bartholomew's Hospital .	273	254	100	79
University College ,, .	270	273	63	83
St. Thomas's ,, .	184	156	53	51
King's College ,, .	139	120	45	35
London ,, .	114	91	36	31
St. George's ,, .	114	108	35	47
Middlesex ,, .	80	47	38	22
St. Mary's ,, .	65	61	22	21
Charing-cross ,, .	41	48	13	20
Westminster ,, .	24	19	10	4
Totals	1608	1496	504	476

From the above it will be seen that there is an increase of 112 in the total number, and of twenty-eight in the new entries over the number registered last year.

The following table, showing the fluctuations in the registration during the last ten years, will no doubt be read with some interest by metropolitan teachers and others taking an interest in medical education:—

In 1864 the number of students registered was				. .	995
1865	,,	,,	,,	. .	1013
1866	,,	,,	,,	. .	1027
1867	,,	,,	,,	. .	1125
1868	,,	,,	,,	. .	1194
1869	,,	,,	,,	. .	1241
1870	,,	,,	,,	. .	1298
1871	,,	,,	,,	. .	1475
1872	,,	,,	,,	. .	1496
1873	,,	,,	,,	. .	1608

The returns from the provincial schools have not yet been received. In both returns a margin must be left for several gentlemen still continuing their studies for the Fellowship of the College of Surgeons, which necessitates a more extended curriculum. There is, we are informed, an increase in the number of students pursuing their studies for the diploma in dental surgery.

CHOLERA IN NAPLES.
