When positive electricity is required, a wire or chain, as represented in the plate (n), connects the rubber with the table or the floor. When negative electricity is wanted, that wire is connected with another conductor, such as that represented in fig. 1.; where the conductor in fig. 2. is connected with the table by another wire or chain. If the rubber be made tolerably free from points, the negative power will be as strong as the positive.

The machine, represented Plate LXXV. fig. 1., was a contrivance of Dr Watson's, to whirl four large globes at a time, and unite the power of them all. The construction is so simple, that we need not give any particular description of it, especially after having so fully described that of Dr Priestly.

**Of positive and negative Electricity, and the Leyden Phial.**

Dr Watson and Dr Franklin first suggested the notion of positive and negative, or plus and minus electricity; several experiments led them to conclude, that every body in nature, and particularly all conducting bodies, possessed a certain quantity of electric matter, and that this natural quantity might be augmented or diminished by being placed in particular circumstances. When a body receives a larger quantity than the natural one, it is said to be electrified plus, or positively; when the natural quantity is diminished, it is said to be electrified minus, or negatively. The following experiments will shew the different circumstances requisite to produce these two kinds of electricity.

1. A person standing on wax, and rubbing the tube, and another person on wax drawing the fire, they will both appear to be electrified by a person standing on the floor; that is, he will perceive a spark on approaching each of them with his knuckle.

2. But, if the persons on wax touch one another during the exciting of the tube, neither of them will appear to be electrified.

3. If they touch one another after exciting the tube, and drawing the fire as before, there will be a stronger spark between them, than happens between either of them and the person on the floor.

4. After such strong spark, neither of them discover any electricity.

These appearances are explained in the following manner: the electrical fire is supposed to be a common element, of which each of the three persons above-mentioned has his equal share, before any operation is begun with the tube. A, who stands on wax and rubs the tube, collects the electrical fire from himself into the glass; and his communication with all conductors being cut off by the wax, his body is not again immediately supplied. B, who stands likewise on wax, pulling his knuckle along near the tube, receives the fire which was collected by the glass from A; and his communication with conductors, or the common flock of electrical matter, being likewise cut off, he retains the additional quantity received. To C, standing on the floor, both appear to be electrified: for he having only the middle quantity of electrical fire, receives a spark upon approaching B who has an over quantity, but gives one to A who has an under quantity. If A and B approach to touch each other, the spark is stronger, because the distance betwixt them is greater: after such touch, there is no spark between either of them and C, because the electrical fire in all is reduced to the original equality. If they touch while electrifying, the equality is never destroyed, the fire only circulating. Hence we say, B is electrified positively, A negatively; or rather B is electrified plus, A minus: and in experimenting, it is common to electrify bodies plus or minus at pleasure. To electrify plus or minus, it is sufficient to know, that the parts of the tube or sphere that are rubbed, do, in the instant of the friction, attract the electrical fire, and therefore take it from the thing rubbing; the same parts immediately, as the friction upon them ceases, are disposed to give the fire they have received to any body that has left. Thus you may circulate it or accumulate it upon, or subtract it from any body, as you connect that body with the rubber, or the receiver, the communication in the common flock being cut off.

The great shock from what is called the Leyden Phial, was first discovered by Mr Connes, a native of Leyden; but was never so thoroughly understood till Dr Franklin published his experiments with regard to it. A glass phial or jar, filled, till within an inch of the top, with water, brass dult, or other non-conducting substances, was first used; but coating the vessel with tin-foil, or
or brass-dust, as mentioned above in the section concerning the electrical apparatus, was found to answer better.

We shall here give Dr Franklin’s account of this phial nearly in his own words, together with the experiments confirming it.

1. While the wire and inside of the bottle are electrified positively or plus, the outside of the bottle is electrified negatively or minus, in exact proportion; i.e., whatever quantity of electrical fire is thrown into the inside, an equal quantity goes out of the outside. To understand this, suppose the natural quantity of electricity in the whole bottle, before the operation begins, is equal to 20; and, at every stroke of the tube, or turn of the globe, suppose a quantity equal to 1 is thrown in; then, after the first stroke, the quantity contained in the wire and inside of the bottle will be 21, and in the outside 19; after the second stroke, the inside will have 22, and the outside 18; and so on, till, after 20 strokes, the inside will have a quantity of electrical fire equal to 40, and the outside none at all; and then the operation ends: for no more can be thrown into the inside, when no more can be driven out of the outside. If more is attempted to be thrown in, it is fpun back through the wire, or flies out in loud cracks through the sides of the bottle.

2. The equilibrium of electric matter in the bottle being thus lost, it cannot be restored by any inward communication or contact of the parts: but this must be done by a communication formed without the bottle between the inside and the outside, by some conductor touching or approaching both sides at the same time; in which case the equilibrium is restored with an inexpressible violence and quickness; or, it may be done by touching each side alternately; in which case, the equilibrium is restored by degrees.

3. As no more electrical fire can be thrown into the inside of the bottle, when all is driven from the outside; so, in a bottle not yet electrified, none can be thrown into the inside, when none can get out at the outside; which happens, either when the glass is too thick, or when the bottle is placed in a non-conductor. Again, when the bottle is electrified, but little of the electrical fire can be drawn out from the inside by touching the wire, unless an equal quantity can, at the same time, get in at the outside. Thus, place an electrified bottle on clean glass, or dry wax, and you will not, by touching the wire, get out the fire from the inside: place it on a conductor, and touch the wire, then you will get it out in a short time; but soonest when you form a direct communication as above.

4. The shock to the nerves, or rather convulsion, is occasioned by the sudden passage of the fire through the body, in its way from the inside to the outside of the bottle. The fire takes the shortest course; but it does not appear, that, in order to receive a shock, a communication with the floor is necessary: for he that holds the bottle with one hand, and touches the wire with the other, will be shocked as much, though his shoes be dry, or even standing on wax. And on the touch of the wire (or of the prime conductor, which is the same thing,) the fire does not proceed from the touching finger to the wire, but from the wire to the finger, and passes through the body to the other hand, and so into the outside of the bottle.

The following experiments will confirm this account of the Leyden phial.

1. Place an electrified phial on wax, a small cork-ball held in your hand, suspended by a dry silk thread, and brought near to the wire, will first be attracted and then repelled: When in a repelled state, flink your hand, that the ball may be brought towards the outside of the bottle; it will be instantly attracted till it has parted with its fire.

If the outside of the bottle had a positive electrical atmosphere, as well as the inside and the wire, an electrified cork would be repelled from the one as well as the other.

2. From a bent wire flicking in the table, let a small linen thread hang down within half an inch of the electrified phial; touch the wire of the phial repeatedly with your finger; and, at every touch, you will see the thread instantly attracted by the outside of the bottle. As soon as you draw any fire from the inside by touching the wire, the outside draws in an equal quantity by the thread.

3. Fix a wire in the outside coating of the bottle, so as that bending upwards its ring-end may be level with the top or ring-end of the wire in the cork of the bottle, and at three or four inches distance. Then electrify the bottle, and place it on wax. If a cork, suspended by a silk thread, hang between these two wires, it will play incessantly from the one to the other, till the equilibrium between the inside and the outside of the bottle is restored.

4. Place a man on a cake of wax, and present him the wire of the electrified phial to touch, you standing on the floor and holding it in your hand. As often as he touches it, he will be electrified plus; and any one standing on the floor may draw a spark from him. The fire, in this experiment, passes out of the wire into him; and, at the same time, out of your hand into the outside of the bottle. Give him the electrical phial to hold, and touch the wire; as often as you touch it, he will be electrified minus, and may draw a spark from any one standing in the floor. The fire in this case passes from the wire to you, and from him into the outside of the bottle.

5. Lay two books, or two glasses, back to back, two or three inches distant, place the electrified phial; on one of them, and then touch the wire; that book will be electrified minus, the electrical fire being drawn out of it by the outside of the bottle. Take off the bottle, and, holding it in your hand, touch the other with the wire; that book will be electrified plus, the fire passing into it from the wire, and the outside of the bottle is at the same time supplied from your hand.

The same explosion and shock happens, if the electrified phial is held in one hand by the hook of the wire, and the coating touched with the other, as when held by the coating and touched at the hook. To take the charged phial safely by the hook, and not at the same time diminish its force; it must first be set down on a non-conductor. The phial will be electrified as strongly, if held by the hook, and the coating applied to the globe or tube.
When the terms of charging or discharging the phial are used, it is in compliance with custom, and for want of better ones; since there is really no more electrical fire in the phial after what is called its charging than before, nor left after its discharging. Besides, the phial will not suffer what is called a charging, unless as much fire can go out of it one way as is thrown in by another. A phial cannot be charged standing on wax or glass, or hanging on the prime conductor, unless a communication be formed between its coating and the floor. But suspend two or more phials on the prime conductor, one hanging to the tail of the other, and a wire from the last to the floor, an equal number of turns of the wheel will charge them all equally, and each as strongly as a single one would have been.

When a bottle is charged in the common way, its inside and outside surfaces stand ready, the one to give fire by the hook, the other to receive it by the coating: yet as the first will not give out, unless the other can at the same instant receive in; so neither will the latter receive in, unless the first can at the same instant give out. When both can be done at once, it is done with inconceivable quickness and violence.

Glass has within its substance the same quantity of electrical fire at all times, and that quantity is very great in proportion to the mass of glass. This quantity it obstinately retains; and will have neither more nor less, though it will allow a change to be made in its parts and situation; that is, we may take away part from one of the sides, provided we throw an equal quantity into the other. Yet when the situation of the electrical fire is thus altered in the glass, it will not be at rest, or in its natural state, till it be restored to its original equality; and this restitution cannot be made through the substance of the glass, but must be done by a conducting communication formed without from surface to surface. Thus the whole force of the bottle, and power of giving a shock, resides in the glass itself; the coatings, or conducting substances in contact with the two surfaces, furnishing only to give and receive to and from the several parts of the glass; that is, to give in one side, and take away from the other. This was discovered by Dr. Franklin, and proved by the following experiment: Purposing, (says he,) to analyze the electrified bottle, in order to find wherein its strength lay, we placed it on glass; and drew out the cork and wire, which for that purpose had been loosely put in. Then taking the bottle in one hand, and bringing a finger of the other near its mouth, a strong spark came from the water, and the shock was as violent as if the wire had remained in it, which showed that the force did not lie in the wire. Then to find if it refided in the water, being crowded into and condensed in it, as confined by the glass, which had been our former opinion, we electrified the bottle again, and placing it on glass drew out the wire and cork as before; then taking up the bottle, we decanted all its water into an empty bottle, which likewise flood on glass; and taking up that other bottle, we expected, if the force refided in the water, to find a shock from it; but there was none. We judged then that it must either be lost in decanting, or remain in the first bottle. The latter we found to be true; for that bottle on trial gave the shock, though filled up as it stood with fresh un-electrified water from a tea-pot.—To find, then, whether glass had this property merely as glass, or whether the form contributed any thing to it; we took a pane of thin glass, and laying it on the hand, placed a plate of lead on its upper surface; then electrified that plate, and bringing a finger to it, there was a spark and shock. We then took two plates of lead of equal dimensions, but less than the glass by two inches every way, and electrified the glass between them, by electrifying the uppermost lead; then separated the glass from the lead; in doing which, what little fire might be in the lead was taken out, and the glass being touched in the electrified parts with a finger, afforded only very small pricking sparks, but a great number of them might be taken from different places. Then dexterously placing it again between the leaden plates, and completing a circle between the two surfaces, a violent shock ensued.—Which demonstrated the power to reside in glasses as glass; and that the non-electrics in contact served only, like the armature of a loadstone, to unite the force of the several parts, and bring them to once to any point defined: it being the property of a non-electric, that the whole body instantly receives or gives what electrical fire is given to or taken from any one of its parts.

It is amazing to observe how small a portion of glass a great electrical force may lie. A thin glass bubble about an inch diameter, weighing only 6 or 8 grains, being half filled with water, partly gilt on the outside, and furnished with a wire hook, gives, when electrified, as great a shock as a man can well bear. As the glass is thickest near the orifice, I suppose the lower half, which being gilt was electrified and gave the shock, did not exceed two grains; for it appeared, when broke, much thinner than the upper half.—If one of these thin bottles be electrified by the coating, and the spark taken
495 ELECTRICITY.

1. Lightning strikes the highest and most pointed objects in its way preferable to others, as high hills, and trees, towers, spires, masts of ships, points of spears, &c. In like manner, all pointed conductors receive or throw off the electric fluid more readily than those which are terminated by flat surfaces.

2. Lightning is observed to take the readiest and best direction when it is drawn from an irregular body at some distance, or through a space in which the best conductors are disposed in an irregular manner, which is always the case in the heterogeneous atmosphere of our globe.

3. Lightning is observed to take the readiest and best direction when it is drawn from an irregular body at some distance, or through a space in which the best conductors are disposed in an irregular manner, which is always the case in the heterogeneous atmosphere of our globe.

4. Lightning burns. So does electricity. It will kindle hard dry rosin, spirits unwarmed, and even wood. It will fire gunpowder, by only ramming it hard in a cartridge, into each end of which pointed wires are introduced, and brought within half an inch of one another, and discharging a shock through them.

5. Lightning sometimes dissolves metals. So does electricity. The method in which Dr Franklin made electricity melt metals, was by putting thin pieces of them between two panes of glass, bound fast together, and sending an electric shock through them. Sometimes the pieces of glass, by which they were confined, would be shattered to pieces by the discharge, and be broken into a kind of coarse sand, which once happened with pieces of thick looking-glasses; but if they remained whole, the pieces of metal would be milled in several places where it had lain between them, and instead of it a metallic fluid would be seen on both the glassess, the slips or the under and upper glasses being exactly similar in the minutest stroke.

6. Lightning rends some bodies. So does electricity. The electric spark will strike a hole through a quire of paper. When wood, bricks, stone, &c. are rent by lightning, the splinters will fly off on that side where there is the least resistance. In like manner, when a hole is struck through a piece of pasteboard by an electrified jar, if the surfaces of the pasteboard are not confined and compressed, there will be a bur raised all round the hole on both sides of the pasteboard; but if one side be confined, so that the bur cannot be raised on that side, it will all be raised on the other side, which way ever the fluid was directed. For the bur round the outside of the hole is the effect of the explosion, which is made every way from the center of the electric stream, and not an effect of its direction.

7. Lightning has long been known to strike people blind. And a pigeon, after a violent shock of electricity, by which it was intended to be killed, was struck blind likewise.

8. In a thunder-storm at Streatham, described by Dr Miles, the lightning stripped off some paint which had covered a gilded moulding of a panel of wainscot, without hurting the rest of the paint. Dr Franklin imitated this, by pasting a slip of paper over the gilt of gold on the cover of a book, and sending an electric fluid through it. The paper was torn off from end to end, with such force, that it was broken in several places; and in others there was brought away part of the grain of the Turkey leather in which the book was bound. This convinced the doctor, that if it had been paint, it would have been stripped off in the same manner with that on the wainscot at Streatham.

9. Lightning destroys animal-life. Animals have like wise been killed by the shock of electricity. The largest animals which Dr Franklin and his friends had been able to kill were a hen, and a turkey which weighed about ten pounds.

10. Magnets have been observed to lose their virtue, or to have their poles reversed, by lightning. Dr Franklin did the same by electricity. By electricity he frequently gave polarity to needles, and reversed them at pleasure. A shock from four large jars, sent through a fine sewing needle, gave it polarity, so that it would traverse when laid on water. What is most remarkable in these electrical experiments upon magnets is, that if the needle, when it was struck, lay east and west, the end which was entered by the electric blast pointed north; but that if it lay north and south, the end which lay towards the north would continue to point north, whether the fire entered at that end or the contrary. He also observed, that the polarity was strongest when the needle was struck lying north and south, and weakest when it lay east and west. He takes notice, that in these experiments, the needle, in some cases, would be finely bluer, like the spring of a watch, by the electric flame; in which case the colour given by a flash from two jars only might be wiped off, but that a flash from four jars fixed it, and frequently melted the needles. The jars which the doctor used held seven or eight gallons, and were coated and lined with tinfoil.

To demonstrate, in the completest manner possible, the sameness of the electric fluid with the matter of lightning, Dr Franklin contrived to bring lightning from the heavens, by means of an electrical kite, which he raised when a form of thunder was perceived to be coming on. This kite
E L E C T R I C I T Y.

Great? it commonly bails. Is feen to dart from one part of it to another, and often its branches over a large tract of country, the lightning oufly; at the fame time that a number of small adscititious clouds, the vapours in the atmofphere forming into the higher regions of the air. The lower surface is black, and nearly level; but the upper finely arched, and well defined. Many of these clouds often seem piled upon one another, all arched in the fame manner; but they keep continually uniting, swelling, and extending their arches.

At the time of the rifing of this cloud, the atmofphere is generally full of a great number of separate clouds, motionless, and of odd and whimsical shapes. All thefe, upon the appearance of the thunder-cloud, draw towards it, and become more uniform in their shapes as they approach; till, coming very near the thunder cloud, their limbs mutually flretch towards one another; they immediately coalesce, and together make one uniform mafs. These are called adscititious clouds, from their coming in, to enlarge the fize of the thunder-cloud. But, fometimes the thunder-cloud will fwell, and increafe very faft without the conjunction of any adscititious clouds, the vapours in the atmofphere forming themselves into clouds where-ever it paffes. Some of the adscititious clouds appear like white fringes, at the flirts of the thunder-cloud, or under the body of it; but they keep continually growing darker and darker, as they approach to unite with it.

When the thunder-cloud is grown to a great fize, its lower surface is often ragged, particular parts being detached towards the earth, but still connected with the reft. Sometimes the lower surface fwell into various large protuberances, bending uniformly towards the earth. And fometimes one whole fide of the cloud will have an inclination to the earth, and the extremity of it will nearly touch the earth. When the eye is under the thunder-cloud, after it is grown large, and well formed, it is feen to sink lower, and to darken prodigiously; at the fame time that a number of small adscititious clouds (the origin of which can never be perceived) are feen in a rapid motion, driving about in very uncertain directions under it. While these clouds are agitated with the moft rapid motions, the rain generally falls in the greatest plenty; and if the agitation be exceeding great, it commonly fails.

When the thunder-cloud is swelling, and extending its branches over a large tract of country, the lightning is feen to dart from one part of it to another, and often to illuminate its whole mafs. When the cloud has acquired a sufficient extent, the lightning strikes between the cloud and the earth, in two oppofite places, the path of the lightning lying through the whole body of the cloud and its branches. The longer this lightning continues, the rarer does the cloud grow, and the lefs dark is its appearance; till, at length, it breaks in different places, and shows a clear sky. When the thunder-cloud is thus difpersed, thofe parts which occupy the upper regions of the atmofphere are equally spread, and very thin; and thofe that are underneath are black, but thin too; and they vanifh gradually, without being driven away with any wind.

That thunder-clouds were sometimes in a poftive as well as negative flate of electricity, Signior Beccaria had difcovered, before he heard of its having been observed by Dr Franklin or any other perfon. The fame cloud, in paffing over his obfervatory, electrified his apparatus fometimes poftively, and sometimes negativelv. The electricity continued longer of the fame kind, in proportion as the thunder-cloud was pimple, and uniform in its direftion; but when the lightning changed its place, there commonly happened a change in the electricity of his apparatus. It would change suddenly after a very violent fhock of lightning, but the change would be gradual when the lightning was moderate, and the progress of the thunder-cloud slow.

It was an immediate inference from his obfervations of the lightning abroad, and his apparatus within, that the quantity of electric matter, in an ufual form of thunder, is almofit inconceivably great; confequently how many pointed bodies, as trees, fpires, &c. are perpetually drawing it off, and what a prodigious quantity is repeatedly difcharged to or from the earth.

Confidering the vaft quantity of electric fire that appears in the moft pimple thunder-forms, he thinks it impossible that any cloud, or number of clouds, should ever contain it all, fo as either to difcharge or receive it. Besides, during the progress and increafe of the form, though the lightning frequently struck to the earth, the fame clouds were the next moment ready to make a fmall greater difcharge, and his apparatus continued to be as much affected as ever. The clouds muft, confequently, have received at one place, the moment that a difcharge was made from them in another. In many cases, the electricity of his apparatus, and confequently of the clouds, would instantly change from one kind to another feveral times; an effect which cannot be accounted for by any fimple difcharge or recruit. Both muft have taken place in a very quick fecution.

The extent of the clouds doth not lessen this difficulty; for, be it ever fo great, fmall the quantity ought to be leffened by every difcharge: and besides, the points by which the filent difcharges are made are in proportion to the extent of the clouds. Nor is the difficulty leffened by fupposing that ftrength clouds bring recruits; for besides that the clouds are not ripe for the principal form, till all the clouds, to a great distance, have actually coalesced, and formed one uniform mafs, thofe recruits bear no fhort of proportion to the difcharge, and whatever it was, it would soon be exhausted.
The fact, therefore, must be, that the electric matter is continually darting from the clouds in one place, at the same time that it is discharged from the earth in another. And it is a necessary consequence from the whole, that the clouds serve as conductors to convey the electric fluid from those places of the earth which are overloaded with it, to those which are exhausted of it.

That great quantities of electric matter do sometimes rush out of particular parts of the earth, and rife through the air into the higher regions of the atmosphere, he thinks is evident from the great quantities of sand, ashes, and other light substances, which have often been carried up into the air, and scattered uniformly over a large tract of country. No other known efficient cause of this phenomenon can be assigned, except the wind; and it has been observed when there was no wind stirring; and the light bodies have even been carried against the wind. He supposes, therefore, that these light bodies are raised by a large quantity of electric matter, issuing out of the earth, where it was overcharged with it, and attracting and carrying with it every substance that could serve as a conductor in its passage. All these bodies, being possessed of an equal quantity of the electric fluid, will be dispersed equally in the air, and consequently over that part of the earth where the fluid was wanting, and whither they serve to convey it. Had these bodies been raised by the wind, they would have been dispersed at random, and in heaps.

This comparatively rare phenomenon, he thinks, exhibits both a perfect image, and demonstration, of the manner in which the vapours of the atmosphere are raised to form thunder-clouds. The same electric matter, wherever it issues, attracts to it, and carries up into the higher regions of the air, the watery particles that are dispersed in the atmosphere. The electric matter ascends to the higher regions of the atmosphere, being solicited by the less resistance it finds there than in the common mass of the earth; which, at those times, is generally very dry, and consequently highly electric. The uniformity with which thunder-clouds spread themselves, and swell into arches, must be owing to their being affected by some cause which, like the electric matter, diffuses itself uniformly wherever it acts, and to the resistance they meet with in ascending through the air. As a proof of this, steam, rising from an electrified eolipile, diffuses itself with the same uniformity, and in similar arches, extending itself towards any conducting substance.

The same cause which first raised a cloud, from vapours dispersed in the atmosphere, draws it to those that are already formed, and continues to form new ones; till the whole collected mass extends so far, as to reach a part of the earth where there is a deficiency of the electric fluid. Thither too, will these clouds, replete with electricity, be strongly attracted, and there will the electric matter discharge itself upon the earth. A channel of communication being, in this manner, found, a fresh supply of electric matter will be raised from the overloaded part, and will continue to be conveyed by the medium of the clouds, till the equilibrium of the fluid, between the two places of the earth be restored. When the clouds are attracted in their passage by those parts of the earth where there is a deficiency of the fluid, those detached fragments are formed, and also those uniform depending protuberances, which, in some cases, are the cause of water-spouts, and hurricanes.

That the electric matter, which forms and animates the thunder-clouds, issues from places far below the surface of the earth; and that it buries itself there, is probable from the deep holes that have, in many places, been made by lightning. Flashes of lightning have, also, been seen to arise from subterraneous cavities, and from wells. Violent inundations have accompanied thunderstorms, not occasioned by rain, but by water burbling from the bowels of the earth, from which it must have been dislodged by some internal concussion. Deep wells have been known to fill faster in thunder-storms, and others have constantly grown concave at the approach of thunder.

This very rife, as well as the whole progress of thunder-clouds, has sometimes been in a manner visible. Exhalations have been frequently seen to rise from particular caverns, attended with a rumbling noise, and to ascend into the higher regions of the air, with all the phenomena of thunder-storms described above, according to the description of persons who lived long before the connection between electricity and lightning was suspected.

The greatest difficulty attending this theory of the origin of thunder-storms relates to the collection and inflation of electric matter within the body of the earth. With respect to the former, he has nothing particular to say. Some operations in nature are certainly attended with a loss of the equilibrium in the electric fluid, but no person has yet assigned a more probable cause of the redundancy of electric matter which, in fact, often abounds in the clouds, than what we may suppose possible to take place in the bowels of the earth. And supposing the loss of the equilibrium possible, the same cause that produced the effect would prevent the restoring of it; so that not being able to force a way, at least one sufficiently ready, through the body of the earth, it would issue at the most convenient vent into the higher regions of the air, as the better passage. His electrical apparatus, though communicating with the earth, has frequently, in violent thunder-storms, given evident sparks to his finger.

In the enumeration of the effects of thunder-storms, he observes that a wind always blows from the place from which the thunder-cloud proceeds; that this is agreeable to the observations of all mariners, and that the wind is more or less violent in proportion to the suddenness of the appearance of the thunder-cloud, the rapidity of its expansion, and the velocity with which the adjectitious clouds join it. The sudden condensation of such a prodigious quantity of vapours must displace the air, and repel it on all sides.

He, in a some measure, imitated even this effect of thunder, at least produced a circulation of all the air in his room, by the continued electrification of his chain.

Among other effects of lightning, he mentions the case of a man rendered exceeding stiff, presently after he was struck dead in a storm of thunder. But the most remarkable circumstance, in this case, was the lightning (chasing
ning the best conductor) having struck one particular vein, near his neck, and followed it through its minutest ramifications: so that the figure of it appeared through the skin, finer than any pencil could have drawn it.

He cautions persons not to depend upon the neighbourhood of a higher, or, in all cases, a better conductor than their own body; since, according to his repeated observations, the lightning by no means descends in one undivided track, but bodies of various kinds conduct their share of it, at the same time, in proportion to their quantity and conducting power.

A great number of observations, relating to the descent of lightning, confirm his theory of the manner of its ascent: for, in many cases, it throws before it the parts of conducting bodies, and distributes them along the refilling medium through which it must force its passage.

Upon this principle it is, that the longest flashes of lightning seem to be made by its forcing into its way part of the vapours in the air. One of the principal reasons why those flashes make so long a rumbling, is their being occasioned by the vast length of a vacuum, made by the passage of the electric matter. Though the air collapses the moment after it has passed, and the vibrations (on which the sound depends) commences at the same moment, through the whole length of the track; yet, if the flash was directed towards the person who hears the report, the vibrations excited at the nearer end of the track will reach his ear much sooner than those excited at the more remote end; and the sound will, without any repercussion or echo, continue till all the vibrations have successively reached him.

He thinks that the Aurora Borealis may be this electric matter performing its circulation, in such a state of the atmosphere as renders it visible, or approaching nearer to the earth than usual.

Stones and bricks struck by lightning are often vitriified. He supposes that some stones in the earth having been struck in this manner first gave occasion to the vulgar opinion of the thunder-bolt.

Signior Beccaria was very sensible that heat contributes much to the phenomena of thunder, lightning, and rain; but he could not find, by any experiment, that it tended to promote electricity. He therefore rather thought that heat operated, in this case, by exhalation the moisture of the air, and thereby cutting off the communication of the electric fluid between one place and another, particularly between the earth and the higher regions of the air, whereby its effects were more visible.

Method of securing buildings and persons from the effects of lightning.

Experiments made in electricity first gave philosophers a suspicion that the matter of lightning was the same with the electric matter. Experiments afterwards made on lightning obtained from the clouds by pointed rods, received into bottles, and subjected to every trial, have since proved this suspicion to be perfectly well founded; and that whatever properties we find in electricity, are also the properties of lightning.

This matter of lightning, or of electricity, is an extreme subtile fluid, penetrating other bodies, and subsisting in them equally diffused.

When by any operation of art or nature, there happens to be a greater proportion of this fluid in one body than in another, the body which has most, will communicate to that which has least, till the proportion becomes equal; provided the distance between them be not too great; or, if it is too great, till there be proper conductors to convey it from one to the other.

If the communication be through the air without any conductor, a bright light is seen between the bodies, and a sound is heard. In our small experiments we call this light and found the electric spark and snap; but in the great operations of nature, the light is what we call lightning, and the sound (produced at the same time, though generally arriving later at our ears than the light does to our eyes) is, with its echoes, called thunder.

If the communication of this fluid is by a conductor, it may be without either light or sound, the subtile fluid passing in the substance of the conductor.

If the conductor be good and of sufficient bigness, the fluid passes through it without hurting it. If otherwise, it is damaged or destroyed.

All metals, and water, are good conductors.—Other bodies may become conductors by having some quantity of water in them, as wood, and other materials used in building, but not having much water in them, they are not good conductors, and therefore are often damaged in the operation by lightning.

Glafs, wax, silk, wool, hair, feathers, and even wood, perfectly dry, are non-conductors: that is, they reflect instead of facilitating the passage of this subtile fluid.

When this fluid has an opportunity of passing through two conductors, one good and sufficient, as of metal, the other not so good, it passes in the best, and will follow it in any direction.

The distance at which a body charged with this fluid will discharge itself suddenly, striking through the air into another body that is not charged, or not so highly charged, is different according to the quantity of the fluid, the dimensions and form of the bodies themselves, and the state of the air between them. This distance, whatever it happens to be, may be between any two bodies, is called their striking distance, as till they come within that distance of each other, no stroke will be made.

The clouds have often more of this fluid in proportion than the earth; in which case as soon as they come near enough (that is, within the striking distance) or meet with a conductor, the fluid quits them and strikes into the earth. A cloud fully charged with this fluid, if too high as to be beyond the striking distance from the earth, passes quietly without making any noise or giving light; unless it meets with other clouds that have lefts.

Tall trees, and lofty buildings, as the towers and spires of churches, become sometimes conductors between the clouds and the earth; but not being good ones, that is, not conveying the fluid freely, they are often damaged.

Buildings that have their roofs covered with lead, or other metal, and spouts of metal continued from the roof
in to the ground to carry off the water, are never hurt by lightning, as whenever it falls on such a building, it passes in the metals and not in the walls.

When other buildings happen to be within the striking distance from such clouds, the fluid passes in the walls, whether of wood, brick or stone, quitting the walls only when it can find better conductors near them, as metal rods, bolts, and hinges of windows or doors, gilding on wainscots, or frames of pictures; the silvering on the backs of looking-glasses; the wires for bells; and the bodies of animals, as containing watry fluids. And in passing thro’ the house it follows the direction of these conductors, taking as many in its way as can assist it in its passage, whether in a straight or crooked line, leaping from one to the other, if not far distant from each other, only rending the wall in the spaces where the partial good conductors are too distant from each other.

An iron rod being placed on the outside of a building, from the highest part continued down into the moist earth, in any direction straight or crooked, following the form of the roof or other parts of the building, will receive the lightning at its upper end, attracting it so as to prevent its striking any other part; and, affording it a good conveyance into the earth, will prevent its damaging any part of the building.

A small quantity of metal is found able to conduct a great quantity of this fluid. A wire no bigger than a goose quill has been known to conduct (with safety to the building as far as the wire was continued) a quantity of lightning that did prodigious damage both above and below it; and probably larger rods are not necessary, tho’ it is common to make them of half an inch, some of three quarters, or an inch diameter.

The rod may be fastened to the wall, chimney, &c. with staples of iron.—The lightning will not leave the rod (a good conductor) to pass into the wall (a bad conductor) through those staples.—It would rather, if any were in the wall, pass out of it into the rod to get more readily by that conductor into the earth.

If the building be very large and extensive, two or more rods may be placed at different parts, for greater security.

Small ragged parts of clouds suspended in the air between the great body of clouds and the earth (like leaf-gold in electrical experiments), often serve as partial conductors for the lightning, which proceeds from one of them to another, and by their help comes within the striking distance to the earth or a building. It therefore strikes through those conductors a building that would otherwise be out of the striking distance.

Long sharp points communicating with the earth, and presented to such parts of clouds, drawing silently from them the fluid they are charged with, they are then attracted to the cloud, and may leave the distance so great as to be beyond the reach of striking.

It is therefore that we elevate the upper end of the rod fix or eight feet above the highest part of the building, tapering it gradually to a fine sharp point, which is gilt to prevent its rusting.

Thus the pointed rod either prevents a stroke from the cloud, or, if a stroke is made, conducts it to the earth with safety to the building.

The lower end of the rod should enter the earth so deep as to come at the moist part, perhaps two or three feet; and if bent when under the surface so as to go in a horizontal line six or eight feet from the wall, and then bent again downwards three or four feet, it will prevent damage to any of the stones of the foundation.

A person apprehensive of danger from lightning, happening during the time of thunder to be in a house not so secured, will do well to avoid sitting near the chimney, near a looking-glass, or any gilt pictures or wainscot; the safest place is in the middle of the room, (so it be not under a metal lustre suspended by a chain), sitting in one chair and lying the feet up in another. It is still safer to bring two or three mattresses or beds into the middle of the room, and folding them up double, place the chair upon them; for they not being so good conductors as the walls, the lightning will not chafe an interrupted course through the air of the room and the bedding, when it can go through a continued better conductor, the wall. But where it can be had, a hammock or swinging bed, suspended by silk cords equally distant from the walls on every side, and from the ceiling and floor above and below, affords the safest situation a person can have in any room whatever; and what indeed may be deemed quite free from danger of any stroke by lightning.

In order to secure ships from sustaining damage by lightning, a copper road, about the thickness of a goose quill, should be connected with the spindles and iron work of the masts continued down to the deck, and from thence, in the most convenient direction, till the end of the rod be always in contact with the sea-water.

With regard to powder-mills and magazines, the apparatus to conduct the lightning from them should be detached from the buildings themselves, and conveyed to the nearest water.

Of Medical Electricity.

The first application of electricity to the cure of diseases was made by M. Jallabet, professor of philosophy at Geneva, on a locksmith whose right arm had been paralytic fifteen years. He was brought to M. Jallabet on the 26th of December 1747, and was completely cured by the 28th of February 1748. In this interval he was frequently electrified, sparks being taken from the arm, and sometimes the electrical shock sent through it.

The report of this cure at Geneva, engaged Mr Sauvages of the academy in Montpelier to attempt the cure of paralytics, in which he had considerable success.

In the year 1757, Mr Patrick Bryden, in a few days, performed a complete cure of a hemiplegia, and indeed an almost universal paralytic affection of two years continuance.

Dr Hart, Dr Wilfon, Mr Lovet, Mr Weley, and many others, relate a number of cases wherein the palsy was either cured or mitigated by electricity.

Dr Watfon cured an universal tetanus, in the year 1762, by electrifying the patient, at proper intervals, for three months.
Dr Franklin and others mention some paralytic cases, in which electricity seemed rather to make the patient worse than better.

Mr Wilton cured a woman of a deafness of seventeen years standing.—And Mr Lovet considers electricity as a specific in all cases of violent pains, oblique headaches, the sciaticas, and the cramp. The toothache, he says, is generally cured by it in an infant. He relates a case, from Mr Floyer surgeon at Dorchester, of a complete cure of a gutta perennis; and another of obstinate obstructions in two young women.

De Haen says, that he never failed to cure St Vitus's dance by electricity; and found it of use in some cases of deafness.

Electricity has been generally applied to the human body either in the method of drawing sparks, as it is called, or of giving shocks. But these operations are both violent, and though the strong concussion may suit some cases, it may be of difference in others, where a moderate simple electrification might have been of use.

The great objection to this method is the tediousness and expense of the application. But an electrical machine might be contrived to go by wind or water, and a convenient room might be annexed to it; in which a floor might be raised upon elcetricis, a person might sit down, read, sleep, or even walk about during the electrification. It were to be wished, that some physician of understanding and spirit would provide himself with such a machine and room. No harm could possibly be apprehended from electricity, applied in this gentle and inoffensive manner, and good effects are at least possible, if not highly probable.

**ELECTRICITY.**

**ELECTRUM,** in natural history. See Amber.

**ELECTUARY,** in pharmacy, a form in which both official and extemporaneous medicines are frequently made.

It may be considered as a number of bolus united together, and is made somewhat softer by an addition of a due proportion of preserves or syrups. When the confidence is very soft, it is called sometimes by the name of opiate.

The principal consideration in prescribing official electuaries is, that such things only be put together as will not, by any opposite qualities, deftroy one another, or lose their natural properties by lying long in this manner; and likewise that the whole be of a confidence that will hold ingredients of different gravities in equal mixture.

**ELEMSYNÆ, and Eleemosynarius.** See Alms, and Almoner.

**ELEGANCE,** or Elegancy, an ornament of polite-ness and agreeableness shown in any discourse, with such a choice of rich and happy expressions, as to rife politely above the common manners, so as to strike people of a delicate taste.

It is observed that elegance, though irregular, is preferable to regularity without elegance; that is, by being so scrupulous of grammatical construction, we lose certain licences wherein the elegance of language consists.

**ELEGY,** in ancient poetry, anything belonging to elegy. See Elegy.

Élegiac verses are alternately hexameter and pentameter, as in the following verses of Ovid. See Hexameter.

**Felix est ignotis, elegia, solve capillos:**

*Ab nimis ex voto sanctis tibi nonnun erit.*

Who was the inventor of elegiac poetry is not known. Horace professes himself quite ignorant of it. The principal writers of elegiac verse, among the Latins, were Properius, Ovid, and Tibullus, the latter whereof Quintilian esteemeth the best elegiac poet; but Pliny the younger gives the preference to the first: the

**ELEGIAC,** in ancient poetry, anything belonging to elegy. See Elegy.

**ELEGIUM,** in the materia medica, a kind of resin, very improperly called gum elemi. There are two sorts of it kept in the shops; the one genuine, and brought from Ethiopia; the other spurious, and the

**ELEMI, or Elemis.** See Alum, and Almoner.

The elephant is the largest of all land-animals. From the front to the origin of the tail he is generally about 16 feet long, from the end of the trunk 25 feet, and about 14 feet high. The circumference of the neck is 17 feet, and the circumference of the body at the girthest part 25 feet 10 inches; the tail is about 6 feet long, and 2½ inches in circumference. The circumference of the legs is about 6 feet. The eyes are small in proportion to the size of the animal. The muzzle is very different from that of any other quadruped; it is nothing but the origin of a long trunk which hangs between the two large tusks; the mouth appears behind the trunk, which serves in place of an upper lip and the under lip terminates in a point. The tail is short, and small in comparison of the trunk, which has the appearance of a long thick tail placed before. The feet are short, round, clumsy, and only distin-
guishable by the toes. The trunk is, properly speaking, the nose extended, and terminated by a couple of nostrils. But, besides serving as an organ of smell, the trunk performs all the functions of a strong and dextrous arm. The trunk of an elephant is about 8 feet long, 5½ feet in circumference near the mouth, and one foot and a half near the extremity: It is a pipe of an irregular conical figure, and widened at the end: The superior side of the trunk is convex, and furrowed transversely; and the inferior side is flat, and has two longitudinal rows of small protuberances re-
sembling the tentacula of the silk-worm and most other caterpillars. The upper part of the trunk correspons with the extremity of the nose in other quadrupeds, and answers the same intention; the inferior part serves as an upper lip, including the nostrils at the same time; for the trunk is a continued canal, divided into two cavities by a longitudinal partition: these cavities ac-
fend along the forepart of the upper jaw, where they make a turn inward and descend into the palate, and then terminate in two separate orifices; they have like-
wise each a separate orifice at the end of the trunk. At the place where these cavities make a turn, and before they enter into the bones of the head, there is a moveable cartilaginous plate situate in such a manner as enables the elephant to shut the canal, and to pre-
vent the water with which it occasionally fills the trunk from entering into the passage of the nose where the organs serving for the sensation of smell are placed. The elephant can move the trunk in all directions; he can extend or shorten it at pleasure, without altering the diameters of the two canals within. By this means respiration is not interrupted, whatever be the situation of the trunk; and the water is allowed to remain till the animal chuses to throw it out by an expiration. Each canal is lined with a smooth strong membrane, and the surface of the trunk is covered with another strong membrane or skin. The substance contained between the exterior and interior membranes, is a com-
position of longitudinal and transverse muscles, which serve to extend and contract the length of the trunk. At the extremity of the trunk there is a concave pro-
tuberance, in the bottom of which are the two passages of the nostrils. The inferior part of the protuberance is thicker than the sides, and the superior part is stretched out like a finger about five inches long; which, together with the edges of the whole extremity of the trunk, takes on different figures according to the necessities of the animal. It is by this organ that the animal lays hold of food, or other substances, which he manages with as much dexterity as a man does his hand, taking up grains of corn, or the smallest piles of grass, and conveying them to his mouth. When he drinks he thrusts his trunk into the water, and fills it by drawing in his breath, and exhausting the air:
When the trunk is thus filled with water, he can either throw it out to a great distance, or drink it by putting the end of the trunk in his mouth.

The two large tusks, which some call the horns of the elephant, are of a yellowish colour, and extremely hard. The bony substance of which they are composed is known by the name of ivory, and much used in different branches of manufacture.

The ears are very large, and resemble those of an ape. The skin of the elephant has but few hairs on it, and placed at great distances from each other. It is full of wrinkles, like those on the palm of a man's hand, besides many chaped and greatly ridges. The female has two dugs, one on each side of the breast. The parts of generation are small in proportion to those of other animals. The penis resembles that of a horse. The female organ is situated near the middle of the belly, more than two feet distant from the usual situation in other quadrupeds. When they copulate, the female lies down on her back.

Elephants, even in a savage state, are peaceable and gentle creatures. They never use their weapons but in defence of themselves or companions. Their social dispositions are so strong, that they are seldom found alone, but always in large troops; the oldest and most experienced lead the van; the younger, or tame ones, keep in the middle; and those of a second rate, as to age, walk in the rear. The females carry their young on their tusks, embracing them at the same time with their trunk. They seldom march in this regular order but when they reckon the journey dangerous, such as an expedition to cultivated lands, where they expect to meet with resistance. On other occasions they are less cautious, some of them falling behind or separating from the rest, but seldom so far as to be without the reach of assistance by alarming and assembling their companions. It is only these wanderers that the hunters dare attack; for it would require a whole army to afford a troop of them, and even an army would be unable to conquer them without losing a number of lives. It is dangerous to offer them the least injury; for they run straight upon the offender; and, although the weight of their body be great, their steps are so large, that they easily outrun the swiftest man, whom they either pierce with their tusks or seize with their trunk, dart him in the air like a stone, and then trample him under their feet. But they never attack any person, unless when provoked. However, as they are extremely sensible and delicate with regard to injuries, it is always prudent to keep out of their way. Travellers who frequent these countries kindle large fires, and beat drums during the night, in order to prevent their approach. After being once attacked by men, or falling into any ambush, they are said never to forget the injury, but search for every opportunity of getting revenge. As they are endowed perhaps with a more exquisite sensation of smell than any other animal, owing to the great extent of their nose, they can scent a man at a very great distance, and trace him by his footprints.

Elephants are peculiarly fond of the banks of rivers, deep valleys, and marshy grounds, especially when well shaded with trees. They delight in drawing up water into their trunks, even when they do not drink it, and amuse themselves in dashing the water around. They cannot endure cold, and are equally averse to an excess of heat: In order to avoid the scorching heat of the sun, they retire to the thickest and moist shady parts of the forest. The bulk of their bodies is so enormous, that they do not choose to go into deep waters so frequently as some other quadrupeds; although the length of their trunk, which they raise straight up, and by which they respire, is a great advantage in swimming.

The ordinary food of elephants is roots, herbs, leaves, the tender branches of trees, fruits, and grains; but they abhor flesh or fish. When any of them discovers a fine pasture, he immediately calls and invites his companions to come and eat with him. As they devour a large quantity of food in a short time, they are always shifting their pasture; when they meet with cultivated grounds, they make a prodigious defolation, and destroy more plants by their feet than they use for nourishment, which is very considerable, amounting to 150 pounds of herbage every day; by this means, as they constantly graze in large troops, they lay waste whole fields in an hour. The Indians and negroes employ every art to prevent them from visiting their cultivated lands, making great noise, and burning large fires round their fields. However, these precautions are not always sufficient to prevent the elephants from visiting them. They chase away the domestic animals, put the men to flight, and sometimes even throw down their timber huts. Elephants are hardly susceptible of fear; the only things which can surmise them, or stop their course, are artificial fires, such as fquibs, crackers, &c. the effects of which are so sudden and repeated, that the elephants frequently turn back; and when one runs, all the rest instantly follow his example.

Although the social disposition in the elephant be exceeding strong; yet whenever the females come in season, it immediately gives place to the stronger and more interesting passion of love. They observe the greatest delicacy in their amours, abhorring nothing so much as to be seen by their companions. The troop divide themselves into couples, steal off into the most secret places of the forest, and there give way to all the impulses of nature, which are lively and lasting in proportion to the long period of abstinence; for the female goes with young two years, and it is only once in three years that the season of love returns. They bring forth but one at a time; which, as soon as it comes into the world, is as large as a wild boar, and is furnished with teeth; however, the large tusks do not make their appearance till some time after, and at the age of six months they are several inches long. Elephants of this age are as large as an ox, when in a natural state. But it is incredible how they degenerate when inflamed and under the management of men. Their dignit and chagrin for the loss of liberty seems never to depart from their minds. In this state, though they feel, at the proper seasons, the
the strongest desires for the sex, no art can allure them to copulate: but the natural passion, restrained by an excess of modesty, bursts out into such violent fits of fury and resentment, that the strongest chains are hardly sufficient to command them. This is a striking difference betwixt the elephant and most other tamed animals. It is only the individual that we can enslave; the species, in spite of all our endeavours, still retain their original freedom and independence.

The manner of taking and taming the elephant, therefore, merits our attention. In forests and such places as are frequented by elephants, the Indians choose a spot and inclose it with strong palisades; they use the largest trees as the principal stakes, to which are fixed smaller ones in a transverse direction. These cross-trees are fixed so as to allow a man to pass easily through. There is likewise a large port left for the elephant, over which is suspended a strong barrier; they use the largest trees as the principal stakes, to which are fixed smaller ones in a transverse direction. These cross-trees are fixed so as to allow a man to pass easily through. There is likewise a large port left for the elephant, over which is suspended a strong barrier, which is let down as soon as he enters. In order to decoy him into the inclosure, the hunters take along with them a tame female in cachet, and travel about till they come so near as that the cry of the female can reach a male, whom they previously observe in the forest; then the guide of the female makes her give the cry peculiar to the season of love: the male instantly replies, and sets out in quest of her. The guide then makes the female proceed toward the artificial inclosure, repeating her cries from time to time as she goes along. She enters into the inclosure, the male follows her, and the Indians immediately shut the port behind him. He no sooner discovers the hunters, and that he is inclosed, than his passion for the sex is converted into rage and fury. The hunters entangle him with strong ropes; they fetter his legs and trunk; they bring two or three tame elephants in order to pacify and reconcile him to his condition. In a word, they reduce them to obedience in a few days, by a proper application of torture, and carelessness. There are many other methods of catching elephants. Instead of making large inclosures with palisades, like the kings of Siam, and other monarchs, the poor Indians content themselves with a very simple apparatus: they dig deep pits in the roads frequented by elephants, covering them over with branches of trees, turf, &c. When an elephant falls into one of these pits, he is unable to get out again.

The elephant, when tamed, is the most friendly and obedient of all animals: he is entirely attached to the person who feeds and takes care of him. In a short time he understands signs, and the sound of his master's voice. He distinguishes the language of passion, of command, of satisfaction, and acts accordingly. He receives his orders with attention, and executes them with prudence and alacrity, but without precipitation. He easily learns to bow his knees and lower his body, for the convenience of those who mount him. He cares for his friends with his trunk. He lifts burdens with his trunk, and assists those who are loading him in laying them on his back. He delights in shining harness and trappings. When yoked in a cart or wagon, he pulls equally and cheerfully, unless he be abused by injudicious chastisements. His guide is generally mounted on his neck, with a small rod of iron sharp at the point in his hand; he directs his motion by prickling him on the ears and head; but, for the most part, a word is sufficient.

A tame elephant will do more labour than six horses; but then he requires a proportional quantity of food. They are the principal beasts of burden in many parts of Africa and the East Indies. They carry facks and bundles of all kinds on their neck, back, and tibles. They never lose or damage any thing committed to their care: They will stand on the edge of a river, take bundles off their necks and tibles, lay them carefully in a boat wherever they are desired, and try with their trunk whether they are properly situated; if they are loaded with casks, they go in quest of stones to prop them and prevent them from rolling.

From the earliest accounts in history, the eastern nations have employed elephants in war; Alexander the Great was the first European who ever mounted an elephant. He carried a number of them into Greece, which Pyrrhus employed some years after against the Romans at the battle of Tarentum. Both the Greeks and Romans soon learnt to get the better of these monstrous animals, they opened their ranks and allowed them to pass through; neither did they attempt to hurt them, but threw darts, &c. at their guides. Now that fire-arms are the principal instruments of war, elephants, who are terrified at the noise and flame, instead of being useful, would only tend to embarrass and confound an army. However, in Cochin and other parts of Malabar, as also in Tonquin, Siam, and Pegu, where fire-arms are little understood, they are still used in battle. The guide sits astride upon the neck, and the combatants sit or stand upon the other parts of the body.

When the elephant is properly managed, he lives very long even in a state of slavery and labour. That some have lived in this state 130 years, is pretty well authenticated. In a natural state, they often exceed 200 years, and propagate their species till they be 120: It is 30 years before they come to their full growth.

[Plate LXXIV. fig. 3.]

ELEVATION, the same with altitude or height. See ALTITUDE.

ELEVATION of the host, in the church of Rome, that part of the mafs where the priest raises the host above his head for the people to adore. See MASS and HOST.

ELEVATOR, in anatomy, the name of several muscles, so called from their serving to raise the parts of the body to which they belong. See ANATOMY, Part II.

ELEVATORY, in surgery, an instrument for raising depressed or fractured parts of the skull, to be applied after the intemments and periosteum are removed. See SURGERY.

ELEUSINIA, in Grecian antiquity, a festival kept in honour of Ceres, every fourth year by some states, but by others every fifth. The Athenians celebrated it at Eleusis, a town of Attica, whence the name.

It was celebrated with a world of ceremony, and persons of both sexes were initiated in it; it being deemed...
ELF, a term now almost obsolete, formerly used to denote a fairy, or hobgoblin, an imaginary being, the creature of ignorance, superstition, and craft. See FAIRY.

ELF-ARROWS, in natural history, a name given to the darts, anciently fashioned into arrow-heads, and still found fothile in Scotland, America, and several other parts of the world; they are believed by the vulgar to be shot by fairies, and that cattle are sometimes killed by them.

ELGIN, the capital of the county of Murray, in Scotland, the ell contains 37 1/2 English inches.

ELL, a measure of length, different in different countries; but those most used, are the English and Flemish ells; whereof the former is three feet nine inches, or one yard and a quarter; and the latter only twenty-seven inches, or three quarters of a yard. In Scotland, the ell contains 37 1/2 English inches.

ELLERENA, a town of Huesca, in Spain, fifty miles south-east of Merida.

ELLIPSIS, in geometry. See CONIC SECTIONS.

ELLIPSIS, in grammar, a figure of syntax, wherein one or more words are not expressed; and from this deficiency, it has got the name ellipsis.

The ellipsis, properly so called, is when the deficient word or words must be supplied from elsewhere; as Hec toris Andromache, where usor is under foot; that is, Andromache, Hector's wife.

ELLPTIC, or ELLPTICAL, something belonging to an ellipse.

ELLIPOPACHYSTYLA, in natural history, a genus of imperfect crysals, with single pyramids; one end of their column being affixed to some solid body. They are dodecahedral, with thinner hexagonal columns and hexagonal pyramids.

Of these crystals, authors enumerate a great many species; among which are the whitest pellucid spig crystal, a bright brown kind, a dull brown kind, and a bright yellow kind, all which are farther distinguished according to the different lengths of their pyramids.

ELLIPOOLACHYSTYLA, in natural history, a genus of imperfect crystals, composed of twelve planes, in an hexagonal column, terminated by an hexagonal pyramid at one end, and irregularly affixed to some other body at the other, with shorter columns.

There are two species of these crystals, one short, bright and colourles, found in great plenty in New Spain and other parts of America; the other, a short, dull, and dulky brown one, found in Germany, and sometimes in England.

ELM, in botany. See ULMUS.

ELNA, a town of Catalonia in Spain, but subject to France, situated ten miles south of Perpignan.

ELOCUTION, in rhetoric, the adapting words and sentences to the things or sentiments to be expressed. It consists of elegance, composition, and dignity. The first comprehending the purity and perspicuity of a language, is the foundation of elocution; the second ranges the words in proper order; and the last adds the ornament of tropes and figures to give strength and dignity to the whole.

ELODES, in botany. See HYPERICUM.

ELOGY, a praise or panegyric bestowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Eloquiums should not have so much as one epithet, properly so called, nor two words synonymous; they should strictly adhere to truth; for extravagant and improbable elogies rather leffen the character of the person or thing they would extol.

ELOINED, in law, signifies restrained or hindered from doing something; thus it is said, that if those within age be elioned, so that they cannot sue personally, their next friend shall sue for them.

ELONGATION, in astronomy, the digression or recefs of a planet from the sun, with respect to an eye placed on our earth. See ASTRONOMY.

ELONGATION, in surgery, is an imperfect luxation, occasioned by the stretching or lengthening of the ligaments of any joint.

ELOPEMENT, in law, is where a married woman de-
ELYSIUM, or Elysian fields, in heathen mythology, the habitation of heroes and good men after death. They were, without any change in their size, features, or complexions. The Egyptians also embalmed birds, &c. The prices for embalming were different; the highest was a talent, the next twenty minae, and so decreasing to a very small matter: but they who had not wherewithal to answer this expense, contented themselves with infusing, by means of a syringe, the fundamental, a certain liquor extracted from the cedar, and leaving it there wrapped up the body in salt of nitre: the oil thus preyed upon the intestines, so that when they took it out, the intestines came away, and the body being inclosed in nitre, grew dry, and nothing remained but the skin glued upon the bones.

EMBARGO, in commerce, in arrest on ships, or merchandise,
chandile, by public authority; or a prohibition of
flate, commonly on foreign ships, in time of war, to
prevent their going out of port, sometimes to prevent
their coming in, and sometimes both, for a limited time.

The king may lay embargoes on ships, or employ
thos of his subjects, in time of danger, for service
and defence of the nation; but they must not be for
the private advantage of a particular trader, or com-
pany; and therefore a warrant to slay a single ship is
no legal embargo. No inference can be made from
embargoes which are only in war-time; and are a pro-
hibition by advice of council, and not at prosecution
of parties. If goods be laden on board, and after an
embargo or restraint from the prince or state comes
forth, and then the master of the ship breaks ground,
or endeavours to fail, if any damage accrues, he must
be responsible for the same; the reason is, because his
freight is due, and must be paid, nay though the goods
be seized as contraband.

Embargo differs from quarantine, infomuch as this laft
is always for the term of forty days, in which persons
from foreign parts, infected with the plague, are not
permitted to come on shore. See Quarantine.

EMBASSADOR, or Ambassador, a public minister
sent from one sovereign prince, as a representative of
his person, to another.

Embassadors are either ordinary or extraordinary.
Embassador in ordinary, is he who constantly resides
in the court of another prince, to maintain a good un-
derstanding, and look to the interest of his master.
Till about two hundred years ago, embassadors in or-
dinary were not heard of; all, till then, were embas-
assadors extraordinary, that is, such as are sent on fome
particular occasion, and who retire as soon as the af-
sadors extraordinary, that is, fuch as are fent on fome

Some ordination-facts are observed four times in the
year, viz. the Wednesday, Friday, and Saturday af-
fter the first Sunday in Lent, after Whittunday, after
the fourteenth of September and the thirteenth of
December, it being enjoined, by a canon of the
church, that deacons and ministers be ordained, or
made, only upon the Sundays immediately following
these ember-faits.

EMBERIZA, in ornithology, a genus of birds, belong-
ing to the order of passeris. The bill is conical, and
the mandibles recede from each other towards the
base; the inferior mandible has the fides narrowed in-
wards, but the upper one is still narrower. There are
twenty-four species, viz. The nivalis, or great pyed
mountain-finch of Ray, and the snow-bird of Ed-
wards, has white-wings; but the outer edge of the
prime-feathers are black; the tail is black, with three
white feathers on each fide, They inhabit Lapland
and Hudson's bay, and in hard winters they come into
Sweden, when they are totally white. 2. The hyema-
lis, or snow-sparrow of Cateby, is black above, and
the belly is white. It is a native of North America.

3. The miliaris, or grey emberiza, is of a greyish co-
lour, spotted with black in the belly, and the orb
are reddish. It is the bunting of English authors, and
a bird of Europe. 4. The hortulana, or ortolan, has
black wings; the first three feathers on the tail are
white on the edges, only the two lateral are black out-
wardly. The orbits of the eyes are naked and yel-
low; the head is greenish, and yellow towards the in-
ferior mandible. It feeds principally upon the panick-
grass; grows very fat, and is reckoned a delicate
morfel by certain epicures. It is a bird of Europe.

5. The citrinella, or yellow hammer, has a blackish
tail, only the two outward side-feathers are marked
on the inner edge with a sharp white spot. It is a
bird of Europe, and comes about houfes in winter:
it builds its nest on the ground in meadows. 6. The
olivacea, or olive emberiza, is of an olive colour a-
bove, whiter below; the neck of the neck is orange-
coloured, and it has a black belt across the breast. It
is a native of Dominica. 7. The orix, or grenadier
of

EMBENTEN, a port-town and city of Germany, capital
of a county of the same name, now in possession of the
king of Prussia; it is situated at the mouth of the river
Ems: E. long. 6° 45', and N. lat. 53° 50'.

tail, only the two outward side-feathers are marked
on the inner edge with a sharp white spot. It is a
bird of Europe, and comes about houfes in winter:
it builds its nest on the ground in meadows. 6. The
olivacea, or olive emberiza, is of an olive colour a-
bove, whiter below; the neck of the neck is orange-
coloured, and it has a black belt across the breast. It
is a native of Dominica. 7. The orix, or grenadier
of
of Edwards, is greyish, with the front and belly black, a tawny neck and rump, and a black bill. It is a native of Africa. 8. The quela, has a grey back, a black front, and a red bill. It is a native of Africa. 9. The capensis, or ortolon of the Cape of Good Hope, is greyish, with a white nape of the neck, and a black belt round the orbits and mandibles. It inhabits the Cape of Good Hope. 10. The ludovicus is greyish above, and pale below; the breast is reddish, and there is a black circle on the head. 11. The cia, is reddish, with white eye-brows, and black lines on the head. It is a bird of Europe. 12. The cirius, is a bird of Europe; it has a greyish back, a spotted breast, and yellowish eye-brows. 13. The familiaris is greyish and spotted; the tips of the tail-feathers are white, and hind part of the back yellow. It is a native of Asia. 14. The flavola, is greyish, with a yellow face; it is about the size of a sparrow, and is a native of warm countries. 15. The amazons is of a tawny colour, with the crown of the head yellow, and the base of the wings white underneath. It is a native of Surinam. 16. The orizivora, or ortolan of Carolina, is brownish, with a tawny head, and a black belly. It is properly a native of Cuba, but migrates to Carolina about the autumn after the rice is reaped. 17. The schoeniclas, or reed-sparrow, has a black head, a blackish-grey body, and a white spot on the quill-feathers. It is a bird of Europe. 18. The pittacus, is of a tawny ash-colour, with yellow wings, and two of the tail-feathers remarkably long. 19. The paradisea is brownish, with a red breast, and two long sharp-pointed feathers in the tail, and a black bill. It is a native of Africa, and theds the long feathers of the tail every year, like the peacock. 20. The fera, has a red bill, a black fillet, a red vertex, and a wedge-shaped tail. 21. The vidua, or Indian sparrow of Aldrovandus, is blackish above, and white below, with four very long feathers in the tail, and a red bill. It is a native of India. 22. The principalis, is spotted, with the breast, bill, and legs red. It is a bird of Angola. 23. The regia, has a red bill, four long equal feathers in the tail, and red legs. It is a native of Africa. 24. The ciris, has a blueish head, a yellow belly, and a green back. It is a native of North America.

EMBLEM, a kind of painted enigma, or certain figures painted or cut, metaphorically expressing some action, with reflections underneath, which in some measure explain the sense of the device, and at the same time instruct us in some moral truth, or other matter of knowledge.

EMBLEMETS, among lawyers, denote the profits of town lands; but are sometimes used, more largely, for any products that naturally arise from the ground.

EMBOLISMIC, or INTERCALARY. See Intercalary.

EMBOLUS, the moveable part of a pump, or syringe, called also the pillow, or sucker.

EMBOSSED, or IMBOSSED, in architecture and sculpture, the forming or fashioning works in relief, whether cut with a chisel or otherwise.

EMBOSURE, in architecture, the enlargement made of the aperture of a door or window, on the inside of the wall; its use being to give the greater play for the opening of the door or casement, or to admit the more light.

EMBROCATION, in surgery and pharmacy, an external kind of remedy, which conflits in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c. by means of a woollen or linen cloth, or a sponge, dipped in the same.

EMBROIDERY, a work in gold, or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked. As to muslin, they spread it upon a pattern ready designed; and sometimes, before it is stretched upon the pattern, it is stretched, to make it more easy to handle. Embroidery on the loom is less tedious than the other, in which, while they work flowers, all the threads of the muslin, both lengthwise and breadthwise, must be continually counted; but, on the other hand, this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarce susceptible of this ornament, and in effect we seldom see them embroidered. The thinnest muslins are left for this purpose; and they are embroidered to the greatest perfection in Saxony; in other parts of Europe, however, they embroider very prettily, and especially in France.

There are several kinds of embroidery; as, 1. Embroidery on the flamp, where the figures are raised and rounded, having cotton or parchment put under them to support them. 2. Low embroidery, where the gold and silver lie low upon the sketch, and are fitted with silk of the same colour. 3. Gimped embroidery; this is performed either in gold or silver; they first make a sketch upon the cloth, then put on cut vellum, and afterwards bow on the gold and silver with silk thread: in this kind of embroidery they often put gold and silver cord, tinsel, and spangles. 4. Embroidery on both sides, that which appears on both sides of the stuff. 5. Plain embroidery, where the figures are flat and even, without cords, spangles, or other ornaments.

EMBRUN, or AMBRUN, a city of Dauphiny, in France, near the confines of Piedmont: E. long. 6° 6', and N. lat. 44° 35'.

EMBRIOTOMY, the cutting a foetus to pieces wild in difficult labours. See MIDWIFERY.

EMBRYOBLASTES, in midwifery, an instrument contrived for breaking the bones, for the more easy extraction of the fetus in difficult labours.

EMBRYOLOGY, the cutting a fetus to pieces whilst in the womb, practised in cases of necessity, when there is no other way of saving the mother.

EMBRYULCUS, a hook for extracting the child in difficult labours. See MIDWIFERY.

EMERALD, in natural history, a genus of precious stones, of a green colour, and next in hardness to the ruby. Our jewelers distinguish emeralds into two kinds, the oriental
The opinion among naturalists, there has grown an opinion among the lapidaries, that the emerald is no harder than the crystal; because what they take to be emeralds, are in general only crystals.

The genuine emerald, in its most perfect state, is perhaps the most beautiful of all the gems; it is found of various sizes, but usually small; a great number of them are met with of about the sixteenth part of an inch in diameter, and they are found from this to the size of a walnut.

The emerald is of different figures like the diamond and many of the other gems, being sometimes found in a roundish or pebble-like form, but much more frequently in a columnar one, resembling common crystal; the pebble-emeralds are always the hardiest and brightest, but are seldom found exceeding the size of a pea: the crystal forms grow very large together, and are often larger: the pebble-kind are found loose in the earths of mountains, and sands of rivers; the columnar are found usually bedded in, or adhering to, a white, opaque, and coarse crystalline mass, and sometimes to the Jasper, or the Opal.

The oriental emerald is of the hardness of the fapphire and ruby, and is second only to the diamond in lustre and brightness: the American is of the hardness of the garnet, and the European somewhat softer than that: yet considerably harder than crystal: It loses its colour in the fire, and becomes undistinguishable from the white fapphire.

The oriental emeralds are very scarce, and at present found only in the kingdom of Cambay; very few of them have of late been imported into Europe, in much that it has been supposed there were no oriental emeralds; but within these ten years, some few have been brought from Cambay into Italy, that greatly excel the American ones. The American, being found only in the kingdom of Cambay; very few of them have of late been imported into Europe, in much that it has been supposed there were no oriental emeralds; but within these ten years, some few have been brought from Cambay into Italy, that greatly excel the American ones. The American, being

To counterfeit Emeralds: Take of natural crystal, four ounces; of red-lead, four ounces; verdigris, forty-eight grains; crocus maris, prepared with vinegar, eight grains; let the whole be finely pulverized and sifted; put this into a crucible, leaving one inch empty: lute it well, and put it into a potter's furnace, and let it stand there as long as they do their pots. When cold, break the crucible, and you will find a matter of a fine emerald colour, which, after it is cut and set in gold, will surpass in beauty an oriental emerald.

Emery in natural history, a rich iron ore found in large masses of no determinate shape or size, extremely hard, and very heavy. It is usually of a dusky brownish red on the surface; but when broken, is of a fine bright iron-grey, but not without some tinge of red-

EMETRIC, a medicine which induces vomiting.

EMINENCE, a title of honour peculiar to cardinals. See Cardinal.

EMIR, a title of dignity among the Turks, signifying a prince.

This title was first given to the caliphs; but when they assumed the title of sultans, that of emir remained to their children; as the of Cesar among the Romans. At length the title became attributed to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban instead of the white. The Turks make an observation, that the emirs, before their fortieth year, are men of the greatest gravity, learning and wildness; but after this, if they are not great fools, they discover some signs of levity and stupidity. This is interpreted by the Turks as a sort of divine impulse in token of their birth and facility. The Turks also call the vizirs, bashaws, or governors of provinces, by this name.

EMISSARY, in a political sense, a person employed by another to found the opinions of people, to spread certain reports, or act as a spy over other peoples actions.

EMMENAGOGUES, in pharmacy, medicines which promote the menfes, either by giving a greater force to the blood in its circulation, whereby its momentum against the vessels is increased; or by making it thinner, whereby it will more easily pass through any outlet.

EMMER, a city of Westphalia, in Germany, subject to Prussia: E. long. 5° 45', N. lat. 51° 48'.

EMOLLIENTS, in medicine and pharmacy, are such remedies as heal and soften the aperity of the humours, and relax and supple the solids at the same time.

EMPALEMENT, an ancient kind of punishment, which consisted in thursting a stake up the fundament. See Calix.

EMPEROR, a title of honour among the ancient Romans, conferred on a general who had been victorious, and now made to signify a sovereign prince, or supreme ruler of an empire.

The title of emperor adds nothing to the rights of sovereignty: it only gives preeminence above other sovereigns. The emperors, however, pretend, that the imperial dignity is more eminent than the regal. It is disputed whether emperors have the power of disposing of the regal title; however this may be, they have sometimes taken upon them to erect kingdoms: thus it is that Bohemia, Prussia, and Poland, are said to have been raised to that dignity. In the east, the title of emperor is more frequent than with us; thus the sovereign princes of China, Mogul, are called em-
EMPERORS. In the west, the title has been a long time rehained to the emperors of Germany. The first who bore it was Charlemagne, who was crowned by Pope Leo III. in 800. And it is to be observed, that there was not a foot of land or territory annexed to the emperor's title.

In the year 1723, the Czar of Muscovy assumed the title of emperor of all the Russians. The kings of France were also called emperors, when they reigned with their sons, whom they associated in the crown: thus Hugh Caput was called emperor, and his son Robert king. The kings of England were anciently styled emperors, as appears from a charter of king Edgar.

The emperor of Germany is a limited monarch in regard to the empire, though he is an absolute sovereign in most of his hereditary dominions; the late emperors of the Austrian family, having hereditary dominions, enumerated all of them in their title. Charles VI. was styled emperor of the Romans, always august, king Bohemian and Hungary, archduke of Austria, &c.; but the present empress inheriting those countries, her consort enjoys only the title of emperor of the Romans, duke of Lorraine and Tuscany. The emperor creates dukes, marquesses, and other noblemen; and he appoints most of the officers, civil and military, in the empire: he is elected by the nine electors; and he summons the general diet of the empire.

EMPEROR is a large extent of land, under the jurisdiction or government of an emperor. See EMPEROR.

EMPIRIC is an appellation given to those physicians who conduct themselves wholly by their own experience, without studying physic in a regular way. Some even use the term, in a still worse sense, for a quack who prescribes at random, without being at all acquainted with the principles of the art.

EMPIS, in zoology, a genus of insects belonging to the order of diptera. The beak is horny, inflested, consists of two valves, and is longer than the thorax. There are five species, principally distinguished by their colour.

EMPERESS, the spouse of an emperor, or a woman who governs an empire. See EMPEROR.

EMPROSTHOTONOS, a species of convulsion, wherein the head bends forward. See Medicine.

EMPYREMA, in medicine, a disorder wherein purulent matten is contained in the thorax or breast, after an inflammation and suppuration of the lungs and pleura. See Medicine, and Surgery.

EMPYREUM, a term used by divines for the highest heaven, where the blessed enjoy the beatific vision. See Chemistry.

EMPYREUMA, among chemists and physicians, the fiery tait or offensive smell which brandishes, and other bodies prepared by fire, are impregnated with. See Chemistry.

EMROS. See Haemorrhoids.

EMULGENT, or Renal arteries. See Anatomy, Part III.

EMULSION, a soft liquid remedy, of a colour and consistence resembling milk. See Chemistry.

EMUNCORY, in anatomy, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such more especially are the kidneys, bladder, and mott of the glands. See Anatomy.

ENÆMON, in medicine, an epithet often applied by Hippocrates and Galen, to such topical medicines as are appropriated to a wound newly inflicted, before the blood be stopped.

ENÆOREMA, in medicine, that pendulous sub stance which floats in the urine. It is also called sublimatum and nubecula, from its resemblance to little clouds.

ENALLAGE, in grammar, is when one word is substituted for another of the same part of speech: a substantive for an adjective, as exercitus victor, for victorius; felus, for felinus.

ENAMEL, a kind of coloured glass, used in enamelling and painting in enamel.

Enamels have for their basis a pure crystalline glass or frit, ground up with a fine calx of lead and tin prepared for the purpose, with the addition usually of white salt of tartar. These ingredients baked together, are the matter of all enamels, which are made by adding colours of this or that kind to powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri (De Arte Vitriar.) directs only manganese to be added to the matter which constitutes the basins. For azure, zaffer mixed with calx of brass. For green, calx of brasses with scales of iron, or with crocus martis. For black, zaffer with manganese, or with crocus martis; or manganese with tartar. For red, manganese, or calx of copper and red tartar. For purple, manganese with calx of brasses. For yellow, tartar and manganese. And for violet-coloured enamel, manganese with thrice-calcinated brasses.

In making these enamels, the following general cautions are necessary to be observed. 1. That the pots must be glazed with white glafs, and must be such as will bear the fire. 2. That the matter of enamels must be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it must be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamel is this: powder, sift, and grind all the colours very nicely, and sift mix them, one another, and then with the common matter of enamels; then let them in pots in a furnace, and when they are well mixed and incorporated;
ENAMELING, the art of laying enamel upon metals, is not as
imaginable, come not to your colours while you are prepared by the workmen themſelves, who are employ-

ENAMELLING, the art of laying enamel upon metals,
as gold, silver, copper, &c. and of melting it at the the fire, or of making divers curious works in it at a lamp. It ſignifies alſo to paint in enamel.

The method of painting in Enamel. This is performed on plates of gold or filver, and moft commonly of copper, enamelled with the white enamel; whereon they paint with colours which are melted in the fire, where they take a brightness and luſtre like that of glafs. This painting is the moſt prized of all for its peculiar brightness and vivacity, which is very permanent, the force of its colours not being effaced or fullied with time, as in other painting, and continuing always as fresh as when it came out of the workman's hands. It is ufual in miniature, it being the more difficult the larger it is; becauſe of certain accidents it is liable to in the operation. Enamelling ſhould only be prac-
tified on plates of gold, the other metals being leſs pure: copper, for inſtance, ſcales with the application, and yields fumes; and ſilver turns the yellows white. Nor muſt the plate be made flat: for in ſuch cafe, the enamel cracks; to avoid which, they uſuallſy forge them a little round or oval, and not too thick. The plate being well and evenly forged, they uſually begin the operation by laying on a couch of white enamel (as we obſerved above) on both fides, which prevents the metal from ſwellings and bliftering; and this firſt lay serves for the ground of all the other colours. The plate being thus prepared, they begin at firſt by draw-
ing out exactly the ſubjeqt to be painted with red vitriol, mixed with oil of ſpike, marking all parts of the deſign very lightly with a small pencil. After this, the colours (which are to be before ground with water in a mortar of agate extremely fine, and mixed with oil of ſpike ſomewhat thick) are to be laid on, obſerving the mixtures and colours that agree to the different parts of the ſubjeqt; for which it is neceſsary to underſand painting in miniature. But here, the workman muſt be very cautious of the good or bad qualities of the oil of ſpike he employs to mix his colours with, for it is very ſubjeqt to adulterations. See Oil.

Great care muſt likewiſe be taken, that the leaſt duff imaginable come not to your colours while you are either painting or grinding them; for the leaſt speck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red hot, will leave a hole, and fo deface the work.

When the colours are all laid, the painting muſt be gently dried over a ſlow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red hot in a fire like what the enamellers uſe. Afterwards that part of the painting muſt be paſſed over again which the fire hath any thing effaced, ſtrengthening the ſhades and colours, and committing it again to the fire, obſerving the fame method as before, which is to be repeated till the work be ſhinifhed.

Method of Enamelling by the lamp. Moft enamelled works are wrought at the ſire of a lamp, in which, in-

Great care muſt likewiſe be taken, that the leaſt duff imaginable come not to your colours while you are either painting or grinding them; for the leaſt speck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red hot, will leave a hole, and so deface the work.

Great care muſt likewiſe be taken, that the leaſt duff imaginable come not to your colours while you are
cold, are cut into what lengths the workman thinks fit, but commonly from ten to twelve inches; and as they are all round, if they are required to be flat, they must be drawn through a pair of pincers while yet hot. They have also another iron instrument in form of pincers, to draw out the enamel by the lamp when it is to be worked and disposed in figures. Lastly, they have glass-tubes of various sizes, serving to blow the enamel into various figures, and preserve the necessary vacancies therein; as also to spare the stuff, and form the contours. When the enameller is at work, he fits before his lamp with his foot on the step that moves on the bellows; and holding in his left hand the work to be enamelled, or the brass or iron-wires the figures are to be formed on, he directs with his right the enamel thread, which he holds to the flame with a management and patience equally surprising. There are few things they cannot make or represent with enamel; and some figures are as well finished, as if done by the most skilful carvers.

ENARTHROSIS, in anatomy, a species of diarthrosis. See Anatomy, Part I.

ENCEPHALIS, in surgery, a tubercle arising either from the caruncula lacrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lacrymalia, but also part of the sight, or pupil itself. See Surgery.

ENCAUSTIC and Encaustum, the same with enema. See Enema.

ENEMY, in law, an alien or foreigner, who publicly invades the kingdom. See Enemy.

ENGUMENS, in church history, persons supposed to be possessed by the devil, concerning whom there were many regulations among the primitive Christians. They were denied baptism, and the eucharist; at last, this was the practice of some churches; and though they were under the care of exorcists, yet it was thought

ENCYPLOPAEDIA, in medicine, the same with enema. See Enema.

ENCLITICA, in grammar, particles which are so closely united with other words, as to seem part of them, as in virgule, &c.

ENCLITIC A, in grammar, particles which are so closely united with other words, as to seem part of them, as in virgule, &c.

ENCAMPMENT, the pitching of a camp. See Camp.

ENCEMENIA, the name of three several feasts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabæus, Solomon, and Zorobabel.

This term is likewise used in church-history for the dedication of Christian churches.

ENCANTHIS, in surgery, a tubercle arising either from the caruncula lacrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lacrymalia, but also part of the sight, or pupil itself. See Surgery.

ENCEASTE and Encastum, the same with enamelling and enamel. See Enamelling, and Enamel.

ENCEINTE, in fortification, is the wall or rampart which surrounds a place, sometimes composed of battlements or curtains, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a Roman wall.

ENCEPHALI, in medicine, worms generated in the head, where they cause so great a pain, as sometimes to occasion distraction.

ENCEPEE, in heraldry, denotes fettered, chained, or girt about the middle, as is usual with monkeys.

ENCHAMTER, a person supposed to practise enchantment or fascination. See Fascination, Witchcraft, &c.

ENCHAMERS NIGHTSHADE, in botany. See Circe.

ENCHASING, Inchasins, or Chasing, the art of enriching and b-futifying gold, silver, and other metal-work, by some design of figures or representations thereon in low relief.

Enchasing is practised only on hollow thin works, as watch-cases, cane heads, tweazer cafes, or the like. It is performed by punching or driving out the metal, to form a figure, from within-out, so as to stand out prominent from the plane or surface of the metal. In order to this, they provide a number of fine steel blocks, or punchers, of divers sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tops of these blocks, directly under the lines or parts of the figures; then, with a fine hammer, striking on the metal, sustained by the block, the metal yields, and the block makes an indentation or cavity on the inside, corresponding to which there is a prominence on the outside, which is to stand for that part of the figure.

Thus the workmen proceeds to chase and finish all the parts by successive application of the block and hammer to the several parts of the design. And it is wonderful to consider with what beauty and justness, by this simple piece of mechanism, the artists in this kind will represent foliage, grotesques, animals, histories, &c.

ENCHYSMA, in medicine, the same with enema. See Enema.

ENCLITICA, in grammar, particles which are so closely united with other words, as to seem part of them, as in virgule, &c.

There are three enclitic particles in Latin, viz. que, me, te.

ENCRAITITES, in church history, heretics who appeared towards the end of the second century: they were called Encratites, or Continentes, because they gloried in abstaining from marriage and the use of wine and animal-food.

ENCYCLOPAEDIA, See Cyclopedia, and Dictionary.

ENDECERIS, in antiquity, denotes a vessel or galley with eleven tires of oars.

ENDEMIC, or Endemical diseases, those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living.

ENDIVE, in botany. See Chicorium.

ENDLESS, something without an end: thus authors mention endless rolls, the endless screw, &c.

ENDORSE, in heraldry, an ordinary, containing the said, ve.

ENDORSE, in heraldry, an ordinary, containing the said, ve.

ENDLESS, something without an end: thus authors mention endless rolls, the endless screw, &c.

ENDIVIAE, in botany. See Chicorium.

ENDOWMENT, in law, denotes the setting a dower on a woman; though sometimes it is used figuratively, for setting a provision upon a parson, on the building of a church; or the giving a sufficient portion of tithes for a vicar, when the benefice is appropriated.

ENEMA, in medicine. See Clyster.

ENEM, in law, an alien or foreigner, who publicly invades the kingdom.

ENERGUMENS, in church history, persons supposed to be possessed by the devil, concerning whom there were many regulations among the primitive Christians. They were denied baptism, and the eucharist; at least, this was the practice of some churches; and though they were under the care of exorcists, yet it was thought
thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present. See EXORCISM.

ENERGY, a term of Greek origin, signifying the power, virtue, or efficacy of a thing. It is also used, figuratively, to denote emphasis of speech.

ENFILADE, in the art of war, is used in speaking of trenches, or other places, which may be scourged by the enemy's shot along their whole length. In conducting the approaches at a siege, care must be taken that the trenches be not enfiladed from any work of the place. See Trenches.

ENFRANCHISEMENT, in law, the incorporating a person into any society or body politic.

ENGASTRIMYTHI, in Pagan theology, the Pythians, or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

The ancient philosophers, &c. are divided upon the subject of the engastrimythi. Hippocrates mentions it as a disease. Others will have it as a kind of divination. Others attribute it to the operation or possession of an evil spirit. And others to art and mechanism. M. Scottus maintains that the engastrimythi of the ancients were poets, who, when the priestess could not speak, supplied the defect by explaining in verse what Apollo dictated in the cavity of the bason on the sacred tripod.

ENGENDERING, a term sometimes used for the act of producing or forming anything: thus meteors are said to be engendered in the middle region of the atmosphere, and worms in the belly. See Generation.

ENGERS, the capital of a county of the same name, in Germany, situated on the river Rhine, about seven miles north of Coblenz.

ENGHEN, a city of Hainault, about fourteen miles south-west of Brussels.

ENGINE, an island on the north-east of the Morea, about fifty miles east of Corinth.

ENGINE, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. See Mechanics.

Engine for extinguishing fires. See HYDROSTATICS, and HYDRAULICS.

Pile-Engine, one contrived for driving piles. See Mechanics.

Steam-Engine, a machine to raise water by fire, or rather by the force of water turned into steam. See HYDROSTATICS, and HYDRAULICS.

ENGINEER, in the military art, an able expert man, who, by a perfect knowledge in mathematics, delineates upon paper, or marks upon the ground, all forts of forts, and other works proper for offence and defence. He should understand the art of fortification, so as to be able, not only to discover the defects of a place, but to find a remedy proper for them; as also how to make an attack upon, as well as to defend, the place. Engineers are extremely necessary for these purposes: wherefore it is requisite that, besides being ingenious, they should be brave in proportion. When at a siege the engineers have narrowly surveyed the place, they are to make their report to the general, by acquainting him which part they judge the weakest, and where approaches may be made with most success. Their business is also to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries, and lodgments, taking care that none of their works be flanked or discovered from the place. After making a faithful report to the general of what is a-doing, the engineers are to demand a sufficient number of workmen and utensils, and whatever else is necessary.

ENGLAND, the southern division of Great Britain, situated in the Atlantic ocean, between 2° E. and 6° W. longitude, and between 49° 55' and 55° 55' N. latitude.

There are in England, including Wales, fifty-two counties, two archbishoprics, twenty-four bishoprics, two universities, twenty-nine cities, upwards of eight hundred towns, and near ten thousand parishes; supposing to contain about 7,000,000 of people.

New England, comprehending the colonies of Massachusetts, New Hampshire, Connecticut, Rhode-Island, and Providence-Plantation, is situated between 67° and 73° W. longitude, and between 41° and 45° N. latitude.

ENGLISH, or the English tongue, the language spoken by the people of England, and, with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The ancient language of Britain is generally allowed to have been the same with the Gaulic, or French; this island, in all probability, having been first peopled from Gallia, as both Cæsar and Tacitus affirm, and prove by many strong and conclusive arguments, as by their religion, manners, customs, and the nearness of their situation. But now we have very small remains of the ancient British tongue, except in Wales, Cornwall, the islands and highlands of Scotland, part of Ireland, and some provinces of France; which will not appear strange, when what follows is considered.

Julius Cæsar, some time before the birth of our Saviour, made a descent upon Britain, though he may be said rather to have discovered than conquered it; but, about the year of Christ 45, in the time of Claudius, Aulus Plautius was sent over with some Roman forces, by whom two kings of the Britons, Cogidunus and Caractacus, were both overcome in battle: whereupon a Roman colony was planted at Maldon in Essex, and the southern parts of the island were reduced to the form of a Roman province: after that, the island was conquered as far north as the frithe of Dumfri-
mixed with the provincial Latin, till, the Roman legions being called home, the Scots and Picts took the opportunity to attack and harass England: upon which, K. Vortigen, about the year 440, called the Saxons to his assistance, who came over with several of their neighbours, and having repulsed the Scots and Picts, were rewarded for their services with the isle of Thanet, and the whole county of Kent; but growing too powerful, and not being contented with their allotment, disposed of the inhabitants of all the country on this side of the Severn: thus the British tongue was in a great measure destroyed, and the Saxon introduced in its stead.

What the Saxon tongue was long before the conquest, about the year 700, we may observe in the most ancient manuscripts of that language, which is a gloss on the Evangelists, by bishop Edfrid, in which the three first articles of the Lord's prayer runs thus:

"Thou, father thine art in heaven, holy,..."

In the beginning of the ninth century the Danes invaded England; and getting a footing in the northern and eastern part of the country, their power gradually increased, and they became sole masters of it in about two hundred years. By this means the ancient British obtained a tincture of the Danish language: but their government being of no long continuance, did not make so great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, A.D. 1067, was subdued by William the Conqueror, duke of Normandy in France: for the Normans, as a monument of their conquest, endeavoured to make their language as generally received as their commands, and thereby rendered the British language an entire medley.

About the year 900, the Lord's prayer, in the ancient Anglo-Saxon, ran thus:

"Thou ur fader the eart on heofenum, fith..."

About the year 1160, under Henry II. it was rendered thus by pope Adrian, an Englishman, in rhyme:

"Uere fader in heaven riche..."

Dr Hicks gives us an extraordinary specimen of the English, as spoken in the year 1385, upon the very subject of the English tongue:

"As it is knowe how many maner peple beeth in this lond; ther beeth also so many dymes longages and tonges. Notheles fome the thermales and Scots that beeth nought medled with other nation, holdeth wel..."

Having
Having thus shewn how the ancient British language was in a manner extirpated by the Romans, Danes, and Saxons, and succeeded by the Saxons, and after that the Saxon blended with the Norman-French, we shall now mention two other causes of change in the language: the first of these is owing to the Britons having been a long time a trading nation, whereby offices, dignities, names of wares, and terms of traffic are introduced, which we take with the wares from the persons of whom we have them, and form them anew, according to the genius of our own tongue; and besides this change in the language, arising from commerce, Britain's having been a considerable time subject to the see of Rome, in ecclesiastical affairs, must unavoidably introduce some Italian words among us. Secondly, as to the particular properties of a language, our tongue has undergone no small mutation, or rather has received no small improvement upon that account: for, as to the Greek and Latin, the learned have, together with the arts and sciences now rendered familiar among us, introduced abundance; nay, almost all the terms of art in the mathematics, philosophy, physic, and anatomy; and we have entertained many more from the Latin, French, &c. for the sake of neatness and elegance: so that, at this day, our language, which about 1800 years ago, was the ancient British, or Welch, &c. is now a mixture of Saxon, Teutonic, Dutch, Danish, Norman, and modern French, embellished with the Greek and Latin. Yet this, in our opinion, is so far from being a disadvantage to the English tongue, as now spoke (for all languages have undergone changes, and do continually participate with each other) that it has so enriched it, as now to become the most copious, significant, fluent, courteous, and masculine language in Europe, if not in the world.

ENGRAFTING, or Grafting, in gardening. See Gardening.

ENGRAILED, or Ingrailed, in heraldry, a term derived from the French greJJy, hail; and signifying a thing the hail has fallen upon and broke off the edges, leaving them ragged, or with half-rounds, or semicircles, struck out of their edges.

ENGRAVING, the art of cutting metals and precious stones, and representing thereon figures, letters, or whatever device, or design, the artist fancies. Engraving, properly a branch of sculpture, must remember, that as statues, &c. are either after paintings, or designs for that purpose.

It is performed with the graver on a plate of copper, which, being well polished, is covered over thinly with virgin-wax, and then smoothed, or warmed, with a feather, so that the wax be of an equal thickness on the plate; and on this the draught or design, done in black lead, red chalk, or ungummed ink, is laid with the face of the drawing on the wax: then they rub the backside, which will cause the whole design of the drawing to appear on the wax. The design, thus transferred, is traced through on the copper, with a point, or needle; then heating the plate, and taking off the wax, the strokes remain to be followed, heightened, &c. according to the tenor of the design, with the graver, which must be very sharp and well pointed.

In the conduct of the graver consists almost all the art, which depends not so much upon rules as upon practice, the habit, disposition, and genius of the artist, the principles of engraving being the same with those of painting; for if an engraver be not a perfect master of design, he can never hope to arrive at a degree of perfection in this art. In conducting the strokes, or cuts, of the graver, he must observe the action of the fingers, and of all their parts, with their outlines; and remark how they advance towards, or fall back from his sight, and then conduct his graver according to the risings or cavities of the muscles, or folds, widening the strokes in the light, and contracting them in the shades; as also at the extremity of the outlines, to which he ought to conduct the cuts of the graver, that the figures or objects represented may not appear as if they grown; and lightening his hand, that the outlines may be perfectly found, without appearing cut or slit: and, although his strokes necessarily break off where a muscle begins, yet they ought always to have a certain connection with each other, so that the first stroke should often serve to make the second, because this will throw the freedom of the graver.

If hair be the subject, let the engraver begin his work by making the outlines of the principal locks, and sketch them out in a careless manner, which may be finished, at leisfure, with finer and thinner strokes to the very extremities.

The engraver must avoid making very acute angles, especially in representing flesh, when he crosses the first strokes with the second, because it will form a very disagreeable piece of tabby-like lattice-work, except in the representation of some clouds, in tempefts, the waves of the sea, and in representations of skins of hairy animals, and leaves of trees. So that the medium between square and acute seems to be the best and most agreeable to the eye. He that would represent sculpture, must remember, that as statues, &c. are most commonly made of white marble, or stone, whose colour does not produce such dark shades as other matters do, they have no black to their eyes, nor hair of the head and beard flying in the air. If the engraver would...
Engraving precious stones, they use either the diamond, or the emery. The diamond, which is the hardest of all stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving, is to cement two rough diamonds to the face of any tool, as a graver, a cushion, or sand-bag, made of leather, to lay the plate on, in order to give it the necessary turns and motions; a burnisher made of iron, or steel, round at one end, and usually flattened at the other, to rub out slips and failures, soften the strokes, &c.; a scraper, to pare off the surface, on occasion; and a rubber, of a black hat, or cloth rolled up, to fill up the strokes that may appear the more visible.

In engraving precious stones, they use either the diamond, or the emery. The diamond, which is the hardest of all stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving, is to cement two rough diamonds to the face of any tool, as a graver, a cushion, or sand-bag, made of leather, to lay the plate on, in order to give it the necessary turns and motions; a burnisher made of iron, or steel, round at one end, and usually flattened at the other, to rub out slips and failures, soften the strokes, &c.; a scraper, to pare off the surface, on occasion; and a rubber, of a black hat, or cloth rolled up, to fill up the strokes that may appear the more visible.

ENGRAVING, or marking, is chiefly employed in cutting seals, punches, matrices, and dyes proper for striking coins, medals, and counters. The method of engraving with the instruments, &c. is the same for coins as for medals and counters: All the difference consists in their greater or less relief, the relief of coins being much less considerable than that of medals, and that of counters still less than that of coins.

Engravers in steel commonly begin with punches, which are in relief, and serve for making the creux, or cavities, of the matrices and dyes: though sometimes they begin with the creux, or hollows, but then it is only when the intended work is to be cut very shallow. The first thing done, is that of defining the figures; the next is the moulding them in wax, of the size and depth they are to lie, and from this wax the punch is engraved. When the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer with which it is struck to give the impression to the matrix.

The figure being thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engraved ring, letters, &c. with little steel punches, well tempered, and very sharp.

ENGUICHE', in heraldry, is said of the great mouth of a hunting horn, when its rim is of a different colour from that of the horn itself.

ENGYSCOPE, the same with microscope. See Microscope.

ENHARMONIC, in the ancient music, one of their genera or kinds of music, so called from its superior excellence; though wherein it consisted, says Mr Malcom, is hard to say: it was allowed by all to be so very difficult, that few could ever practise it.

ENHYDRUS, in natural history, a genus of fiderochita or crustated ferruginous bodies, formed in large and in great part empty caves, including a small quantity of an aqueous fluid.

Of this genus there are only two species: 1. The thick-shelled enhydrus, with black, reddish-brown, and yellow crusts. 2. The thinner shelled kind, with yellowish-brown and purple crusts; neither of which ferments with aqua fortis, or gives fire with steel.

ENIXUM, among chemists, a kind of neutral salt, generated of an acid and an alkali.

The sal enixum of Paracelsus, is the caput mortuum of spirits of nitre with oil of vitriol, or what remains in the retort after the distillation of this spirit; being of a white colour, and pleasing acid taste.

ENMANCHE', in heraldry, is when lines are drawn from the centre of the upper edge of the chief to the sides, to about half the breadth of the chief; signifying...
ENTELECHIA, a word used by Aristotle to express

ENTE', in heraldry, a method of marshalling, more frequent abroad than with us, and signifying a sleeve, from the French manche.

ENNEAGON, in geometry, a polygon with nine sides.

See Polygon

ENNEAHEDRIA, in natural history, a genus of columnar, crystalliform, and double-pointed spars, composed of a trigonal column, terminated at each end by a trigonal pyramid.

Of this genus there are several species, distinguished by the length or shortness of the column and pyramids, none of which will give fire with steel, but all of them ferment with aqua fortis. See Spar.

ENNEANDRIA, in botany. See Botany, p. 635.

ENS, among metaphysicians, denotes entity, being, or existence: this the schools call ens reals, and ens positivum, to distinguish it from their ens rationis, which is only an imaginary thing, or exilis only in the imagination.

ENS, among chemists, imports the power, virtue, and efficacy which certain substances exert upon our bodies.

ENS, in geography, a city of Germany, situated at the confluence of the Danube and the river Ens, about eighty miles south of Vienna: E. long. 14° 20', N. lat. 48° 16'.

ENSEELED, in falconry, is said of a hawk that has a thread drawn through her upper eye-lid, and made fast under her beak, to take away the sight.

ENSIGN, in the military art, a banner under which the soldiers are ranged according to the different companies or parties they belong to.

ENSIGN is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordinate to the captain and lieutenant.

ENSISHEIM, a town of Germany, in the landgraviate of Alzey, about fifty miles south of Strasbourg: E. long. 7° 30', N. lat. 47° 50'.

ENSKIRKEN, a town of Germany, fifteen miles south-west of Cologn.

ENTABLATURE, or Entablement, in architecture, is that part of an order of a column which is over the capital, and comprehends the architrave, frieze, and corniche. See Architecture.

ENTABLED, in architecture, a kind of little story, that is neither walk nor trot, but has somewhat of an amble.

This is a pace or gait of such horses as have no reins or back, and go upon their shoulders; or, of such as are spoiled in their limbs.

ENTRELLADERS, in a ship, are of two sorts; one used by the vessel's sides, in a harbour, or in fair weather, for persons to go in and out of the ship: the other is made of ropes, with small staves for steps; and is hung out of the gallery to enter into the boat, or to come aboard the ship, when the sea runs so high that they dare not bring the boat to the ship's side. See Acuer.

ENTRY, in commerce. See Bill.

Bills of Entry, in commerce. See Bill.

In making entries inwards, it is usual for merchants to include all the goods they have on board the same ship in one bill, though sometimes they may happen to be upwards of twenty several kinds; and in case the goods are short entered, additional or poll entries are now allowed; though formerly the goods, so entered, were forfeited. As to bills of entry outwards, or including goods to be exported, upon delivering them, and paying the customs, you will receive a small piece
of parchment called a cocket, which testifies your payment thereof, and all duties for such goods. If several sorts of goods are exported at once, of which some are free, and others pay customs; the exporter must have two cocketts, and therefore must make two entries; one for the goods that pay, and the other for the goods that do not pay custom.

Entries of goods, on which a drawback is allowed, must likewise contain the name of the ship in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken that the cocketts for those goods were paid as the law directs, you must carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant warrant, which must be given to the surveyor, searchers, or land-waiters, for them to certify the quantity of goods; after which the certificate must be brought back to the collector and comptroller, or their deputies, and oath made that the said goods are really shipped, and not landed again in any part of Great Britain.

ENVELOPE, in fortification, a work of earth, some times in form of a small rampart with a parapet: it is raised sometimes on the ditch, and sometimes beyond it.

ENVIRONNE', in heraldry, signifies surrounded with

ENVOY, a person deputed to negociate some affair with any foreign prince or state. Thos sent from the courts of France, Britain, Spain, &c to any petty prince or state, as such as the princes of Germany, the republics of Venice, Genoa, &c. go in quality of envoys, not ambassadors; and such a character only do those personifies bear, who go from any of the principal courts of Europe to another, when the affair they go upon is not very solemn or important. There are envoys ordinary and extraordinary, as well as ambassadors; they are equally the fame under the protection of the law of nations, and enjoy all the privileges of embassdors, only differing from them in this, that the same ceremonies are not performed to them.

ENVY, in ethics, an uneasiness of the mind, caused by the consideration of a good we desire, obtained by one we think less worthy of it than ourselves. See Passion, and Morals.

EPACT. See Astronomy, Of the Division of Time.

EPANORTIIOSEIS, in rhetoric, a figure by which a person corrects, or ingeniously revokes, what he jut before alluded, as being too weakly expressed, in order to add something stronger, and more conformable to the passion with which he is agitated.

The epanorthosis is distinguished into two kinds. The one is when we correct or revoke the word, as in the following example of the apostle, But I laboured more abundantly than they all: yet not I, but the grace of God, which was with me, 1 Cor. xiv. 10. where, what he first attributed to his own merit, he changes afterwards to call the work of grace, as being the principal cause. The second kind of epanorthosis, is when we correct or revoke the dentiment, as in the following of Cicero: Italianum ornare, quam domum fum, maluit: quamquam, Italiam ornament, donum ipsa mihi videretur ornatum.

EPAKER, in the menace, signifies the flinging of a horfe, or his yarking and striking with his hind-legs.

EPAULEMENT, in fortification, a work raised to cover fide-wise, is either of earth, gabions, or fascines loaded with earth. The epaulements of the places of arms for the cavalry, at the entrance of the trenches, are generally of fascines mixed with earth.

EPENTHESIS, in grammar, the interpolation or insertion of a letter or syllable in the middle of a word; as alitum, for altum; religio, for religio; indepector, for imperator, &c.

EPERLANUS, in ichthyology. See Salmo.

EPHA, or Epah, in Jewish antiquity, a measure for things dry, containing 1.0961 of a bushel.

EPHÆUM, in botany. See Ranunculus.

EPHEDRA, the sea-grape, or shrub horse tail, in botany, a genus of the dioecia monadelphia class. The calix of the amentum of the male and female is divided into segments; the corolla is wanting in both; the stamens are few; there are two pistils, and two seeds covered with a kind of cup-berry. There are two species, none of them natives of Britain.

EPHEMERY, in medicine, the name of a species of fever continuing the space of one day, or sometimes more; for the medical writers express themselves by ephemera simplex, vel plurium die. See Medicine.

EPHEMERA, the day fly, in zoology, a genus belonging to the order of neuroptera. It has no teeth or palps; there are two large protuberances above the eyes; the wings are ereg, the two hind ones being largest; and the tail is brilly. There are eleven species, distinguished by their colour and the number of bristles in their tail. This fly derives its name from the circumstance of its living but one day.

EPHEMAIDES, in literary history, an appellation given to those books or journals, which shew the motions and places of the planets for every day of the year.

It is from the tables contained in these ephemeredes, that eclipses, and all the variety of aspects of the planets, are found.

EPHEMERUM, in botany. See Tradescantia.

EPHALTES, in medicine, the same with the incubus, and the same ceremonies are not performed to them.

EPHIPPUIM, in anatomy. See Anatomy, Part I.

EPHOD, in Jewish antiquity, one part of the priestly vestments, aVe found.

EPHORI, in Grecian antiquity, magistrates established in
in ancient Sparta to balance the regal power. The authority of the ephori was very great. They sometimes expelled and even put to death the kings, and abolished or suspended the power of the other magistrates, calling them to account at pleasure. There were five of them, others say nine. They presided in the public fests and festivals. They were entrusted with the public treasury, made war and peace, and were so absolute, that Aristotle makes their government equal to the prerogative of a monarchy. They were established by Lycurgus.

EPHYDRUM in botany. See Equisetum.

EPIC, or Heroic poem. See Composition.

EPIC DEDIM in ancient poetry, a poem rehearsed during the funeral solemnity of persons of distinction.

EPICOENE, in grammar, a term applied to nouns.

EPICYCLOID, in geometry, a curve generated by the revolution of the periphery of a circle, along the convex or concave side of the periphery of another circle.

EPICYCLE, in the ancient astronomy, a little circle whose centre is in the circumference of a greater circle; or it is a small orb, or sphere, which being fixed in the deferent of a planet, is carried along with it; and yet, by its own peculiar motion, carries the planet fastened to it round its proper centre.

It was by means of epicycles, that Ptolemy and his followers solved the various phenomena of the planets, but more especially their stations and retrogradations.

EPICYCLOID, in geometry, a curve generated by the revolution of the periphery of a circle, along the convex or concave side of the periphery of another circle.

EPICYEMA, among physicians, denotes a superfluous growth, being a false conception or mole happening after the birth of a regular foetus.

EPIDERMIS, in anatomy. See Anatomy, p. 256.

EPIDEMIA, in Grecian antiquity, festivities kept in honour of Apollo and Diana, at the stated seasons when these deities, who could not be present every where, were supposed to visit different places, in order to receive the vows of their adorers.

EPIDEMIC, among physicians, an epithet of diseases which at certain times are popular, attacking great numbers at or near the same time. See Medicine.

EPIDENDRUM, in botany, a genus of the gynandria class. The nectarium is oblique, reflected, and shaped like a turban. There are thirty species, none of them natives of Britain.

EPIDERMIS, in anatomy. See Anatomy, p. 255.

EPIDIDYMIS, in anatomy. See Anatomy, p. 171.

EPIGASTRIC region, a part or subdivision of the abdomen. See Anatomy, p. 256.

EPIGLOTTIS, in anatomy, one of the cartilages of the larynx, or wind-pipe. See Anatomy, p. 281.

EPICLITIS, in anatomy, one of the cartilages of the larynx, or wind-pipe. See Anatomy, p. 281.

EPIDERMIS, in anatomy. See Anatomy, p. 256.

EPIDIDYMIS, in anatomy. See Anatomy, p. 171.

EPIGASTRIC region, a part or subdivision of the abdomen. See Anatomy, p. 256.

EPILLOBIUM, in botany, the willow herb, a genus of the angustifolium, or rolebay
rofebay willow-herb; the hirfutum, or small-flowered hairy willow herb; the ramifcum, great flowered willow herb, or codlings and cream; the montanum, or smooth-leaved willow herb; the tetragonum, or narrow-leaved willow herb; the palnure, or marl willow herb; and the alpinum, or mountain willow herb.

EPILOGUE, in oratory, the end or conclusion of a discourse, ordinarily containing a recapitulation of the principal matters delivered.

EPILOGUE, in dramatic poetry, a speech addressed to the audience after the play is over, by one of the principal actors therein, usually containing some reflections on certain incidents in the play, especially those in the part of the person that speaks it.

EPIMEDIUM, barren wort, in botany, a genus of the tetrandria monogynia class. It has four cap-shaped pectoral lying upon the petals; the corolla consists of four petals; and the calyx is caducous. There is but one species, a native of Germany.

EPIPHANY, a Christian festival, otherwise called the Manifestation of Christ to the Gentiles, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi, or wise-men, who came to adore him and bring him presents. The feast of epiphany was not originally a distinct festival, but made a part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were of solemnity, either of these might properly be called epiphany, as that word signifies the appearance of Christ in the world.

EPIPHONEMA, in rhetoric, a sententious exclamation containing a lively remark placed at the end of a discourse or narration.

EPIPHORA, in medicine, a preternatural defluxion of the eyes, when they continually discharge a sharp serous humour, which excoriates the cheeks. See Medicine.

EPIPHYSIS, in anatomy. See Anatomy, Part I.

EPIPLOCELE, in medicine, is a kind of hernia, or rupture, in which the omentum subides into the scrotum.

EPISCHOPAL, something belonging to bishops.

EPISCHOPALIANS, in church history, an appellation given to those who prefer the episcopal government and discipline to all others. By the suffix, none but episcopalians, or members of the church of England, are qualified to enjoy any office civil or military.

EPISCHOPUS. See Bishop.

EPISODE, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events; though, in a more limited sense, all the particular incidents whereof the action or narration is compounded, are called episodes. See Composition.

EPISPIASTIC, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part.

EPISTATES, in the Athenian government, was the president of the proedri. See Proedri.

EPISTEMONARCH, in the ancient Greek church, an officer of great dignity, who had the care of every thing relating to faith, in the quality of cenfor. His office answered pretty nearly to that of matter of the sacred palace at Rome.

EPISTILE, denotes the fame with a missive letter; but is now chiefly used in speaking of ancient writings, as the epistles of St Paul, epistles of Cicero, epistles of Pliny, &c.

EPISTOLARY, something belonging to an epistle. See Epistle.

EPISTROPHE, in rhetoric, a figure, wherein that which is supposed of one thing, is strongly affirmed of another: thus, *Are they Hebrews? so am I.* *Are they Israelites? so am I.* *Are they of the seed of Abraham? so am I,* &c.

EPISTYLE, in the ancient architecture, a term used by the Greeks for what we call architrave, viz. a massive piece of stone or wood, laid immediately over the capital of a column.

EPITAPH, a monumental inscription in honour or memory of a person dead, or an inscription engraved or cut on a tomb, to mark the time of a person’s decease, his name, family; and, usually, some eulogy of his virtues, or good qualities.

EPITASIS, in ancient poetry, the second part or division of a dramatic poem, wherein the plot, entered upon in the first part, or protasis, was carried on, heightened, and worked up, till it arrived at its state, or height, called catalepsis.

EPITASIS, in medicine, the increase of a disease, or beginning of a paroxysm, particularly in a fever.

EPITHELALIUM, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

Among the Greeks, the married couple were no sooner bedded, than the young men and maidens gathered round the door, dancing and singing the epithalamium, shouting and stamping with their feet, with intention to drown the maid’s cries.

EPITHEM, in pharmacy, a kind of fomentation, or remedy of a spiritual or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the fame, or to correct some intemperature thereof. See Fomentation.

EPITHET, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description. Nothing, says Aristotle, tires the reader more than too great a redundency of epithets, or epithets placed improperly; and yet nothing
nothing is so essential in poetry as a proper use of them.
The writings of the best poets are full of them, espe-
cially Virgil.

EPITOME, in literary history. See ABRIDGEMENT.

EPITRITUS, in profody, a foot consisting of three
long syllables and one short.

EPIZEUXIS, in rhetoric, a figure which repeats the
same word, without any other intervening; such is
that of Virgil, Nunc, nunc, insurgeris remis.

EPOCHA, in chronology, a term or fixed point of time,
whence the succeeding years are numbered or account-
ed. See ASTRONOMY, p. 487.

EPODE, in lyric poetry, the third or last part of the
ode; the ancient ode being divided into strophe, anti-
strophe, and epode. See ODE.

EPOPOEIA, in poetry, the story, fable, or fubje<ct treat-
ed of in an epic poem.

EPOTIDES, in the naval architecture of the ancients,
two thick blocks of wood, one on each side the prow
of a galley, for warding off the blows of the rostra
of the enemy's vessels.

EPPINGEN, a town of Germany, situated about ten
miles north of Halibron.

EPSOM, a town of Surry, about fifteen miles south-west
of London; much resort ed to on account of its medi-
cinal waters; from which the bitter purging salt being
first extracted, got the name of Epom-salt. At pre-
fent, however, the bitter purging salt is procured from
the bittern, remaining after the crystallization of com-
mon salt; and this is found to answer all the purpofes
of that first obtained from Epom-waters, and goes by
its name. See CHEMISTRY.

EPULONES, in Roman antiquity, ministers who asfrift-
ed at the sacrifices, and had the care of the sacred ban-
quett committed to them.

EQUABLE, an appellation given to such motions as al-
ways continue the fame in degree of velocity, without
being either accelerated or retarded. See MECHA-

EQUAL, a term of relation between two or more things
of the fame magnitude, quantity, or quality.

Mathematicians speak of equal lines, angles, figures,
circles, ratios, solids.

EQUALITY, that agreement between two or more things,
whereby they are denomimated equal.

EQUANIMITY, in ethics, denotes that even and calm
frame of mind and temper, under good or bad fortune,
whereby a man appears to be neither puffed up nor o-
verjoyed with prosperity, nor dispirited, foured, or
rendered uncafly by adversity.

EQUATION, in algebra. See ALGEBRA, p. 100.

EQUATION of time, in algebra and chronology, the
reduction of the apparent time or motion of the sun,
to equable, mean, or true time. See ASTRONOMY,
P. 459.

EQUATOR, in geography, a great circle of the terres-
trial globe, equidistant from its poles, and dividing it
into two equal hemispheres; one north, and the other
south. See GEOGRAPHY.

EQUETRY, in the British customs, an officer of state,
under the master of the horse.

There are five equerries, who ride abroad with his
majesty; for which purpofe they give their attendance
monthly, one at a time; and are allowed a table.

As to the equerries of the crown stable, they have
this diffident appellation, as being employed in mounting,
managing, and breaking the saddle-horses for his
majesty's ufe, and holding his stirrup.

EQUES AURATUS, is used for a knight bachelor, cal-
ded auratus; q. d. gilt, because anciently none but
knights were allowed to beautify their armour, or oth-
er habiliments for war, with gold.

EQUESTRIAN STATUE, signifies the statue of a per-
on mounted on horseback.

EQUESTRIAN ORDER, among the Romans, signified their
knights, or equites; as also their troopers, or horfe-
men in the field; the firft of which orders stood in con-
tradifinction to the senators, as the laft did to the foot,
military, or infantry: each of these diftinctions was
introduced into the state by Romulus.

EQUINOCTIAL, in astronomy, a great circle of the
equino&ial points, where the ecliptic interfefts the e-
quino&ial. See ASTRONOMY.

EQUINOCTIAL, in geography, a great circle of the
celestial globe, whose poles are the poles of the world.
See ASTRONOMY, and GEOGRAPHY.

EQUINOX, the time when the fun enters either of the
equino<ial points, where the ecliptic intersects the e-
quino<ial. See ASTRONOMY.

Preception of the EQUINOXES. See ASTRONOMY.

EQUISETUM, or HORSE-TAIL, in botany, a genus of the
cryptogamae filices clafs. The frutification is dis-
pofed on an oblong spike, and of an orbicular fhape.
There are feven fpecies, five of which are natives of
Britain, viz. the faisvaricum, or wood horfe-tail; the
arvenfe, or corn horfe-tail; the palufter, or marth
horfe-tail; the fluvialre, or river horfe-tail; the li-
mofum, or smooth horfe-tail; and the hyemale, or
rough horfe-tail.

EQUITY, in a general fenfe, the virtue of treating all
other men according to common reafon and juftice, or
as we would be gladly treated ourselves, when we un-
derstand aright what is our due. See JUSTICE.

EQUIVALENT, an appellation given to things which
agree
agree in nature, or other circumstances, as force, virtue, &c.

EQUIVOCAL TERMS OR WORDS, among logicians, are those which have a doubtful or double meaning.

According to Mr Locke, the doubtfulness and uncertainty of words has its cause more in the ideas themselves, than in any incapacity of the words to signify them; and might be avoided, would people always use the same term to denote the same idea, or collection of ideas: but, adds he, it is hard to find a discourse on any subject where this is the case; a practice which can only be imputed to folly, or great dishonesty; since a man, in making up his accounts, might with as much fairness use the numeral characters sometimes for one, sometimes for another collection of unities.

EQUIVOCAL GENERATION, the production of animals, without the intercourse between the sexes, by the influence of the sun or stars, &c.

This kind of generation is now quite exploded by the learned.

EQUULEUS, or Eculeus, in antiquity, a kind of rack used for extorting a confession, at first chiefly practised on slaves, but afterwards made use of against the Christians.

The equuleus was made of wood, having holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth, or fifth holes, his arms and legs being fastened on the equuleus with cords; and thus was hoisted aloft, and extended in such a manner, that all his bones were dislocated. In this state red-hot plates were applied to his body, and he was goaded in the sides with an instrument called ungula.

EQUUS, the horse, in zoology, a genus of quadrupeds belonging to the order of bellum. This genus comprehends the horse, the ass, and the zebra; they have six erect and parallel fore-teeth in the upper jaw, and six somewhat prominent ones in the under jaw; the dog-teeth are solitary, and at a considerable distance from the rest; and the feet consist of an undivided hoof. The horse is a domestic animal, and the figure and dimensions of his body are so well known, that a general description is altogether unnecessary. We shall therefore confine ourselves to the natural history of this noble animal.

The horse, in a domestic state, is a bold and fiery animal; equally intrepid as his master, he faces danger and death with ardour and magnanimity. He delights in the noise and tumult of arms, and seems to feel the glory of victory: he exults in the chase; his eyes sparkle with emulation in the course. But though bold and intrepid, he is docile and tractable: he knows how to govern and check the natural vivacity and fire of his temper. He not only yields to the hand, but seems to concur the inclination of his rider. Constantly obedient to the impressions he receives, his motions are entirely regulated by the will of his master. He in some measure reigns his very existence to the pleasure of man. He delivers up his whole powers; he reserves nothing; he will rather die than disobey. Who could endure to see a character so noble abused! Who could be guilty of such gross barbarity!

This character, though natural to the animal, is in some measure the effect of education. His education commences with the loss of liberty, and it is finished by contraint. The slavery of the horse is so ancient and so universal, that he is but rarely seen in a natural state. Several ancient writers talk of wild horses, and even mention the places where they were to be found. Herodotus takes notice of white savage horses in Scythia; Aristotle says, they are to be found in Syria; Pliny, in the northern regions; and Strabo, in Spain and the Alps. Among the moderns, Leardon says, that wild horses are to be found in the Highlands of Scotland, and the Orkney Isles; Olaus, in Muscovy; Dapper, in the island of Cyprus; Leo and Marmol, in Arabia and Africa, &c. But, as Europe is almost equally inhabited, wild horses are not to be met with in any part of it; and those of America were originally transported from Europe by the Spaniards; for this species of animals did not exist in the new world. The Spaniards carried over a great number of horses, left them in different islands, &c. with a view to propagate that useful animal in their colonies. These have multiplied incredibly in the vast deserts of those thinly populated countries, where they roam at large, without any restraint. M. de Salle relates, that he saw, in the year 1685, horses feeding in the meadows of North America, near the bay of St Louis, which were so ferocious that nobody durst come near them. Oesmolin says, that he has seen large troops of them in St Domingo running in the valleys; that when any person approached, they all stood; and one of them would advance till within a certain distance, then snort with his nose, take to his heels, and the whole troop after him. Every author who takes notice of these horses of America, agree that they are smaller and less handsome than those of Europe. These relations sufficiently prove, that the horse, when at full liberty, though not a fierce or dangerous animal, has no inclination to associate with mankind; that all the softness and dulness of his temper proceeds entirely from the culture and polish he receives in his domestic education, which in some measure commences as soon as he is brought forth.

The motions of the horse are chiefly regulated by the bit and the spur; the bit informs him how to direct his course, and the spur quickens his pace. The mouth of the horse is endowed with an amazing sensibility: the slightest motion or preffure of the bit gives him warning, and instantly determines his course. The horse has not only a grandeur in his general appearance, but there is the greatest symmetry and proportion in the different parts of his body. The regularity and proportion of the different parts of the head gives him an air of lightness, which is well supported by the strength and beauty of his chest. He erects his head, as if willing to exalt himself above the condition of other quadrupeds: his eyes are open and lively;
his ears are handsome, and of a proper height; his main adorns his neck, and gives him the appearance of strength and boldness.

At the age of two years, or two years and a half, the horse is in a condition to propagate; and the mare, like most other females, is ready to receive him still sooner. But the foals produced by such early embraces are generally ill made and weakly. The horse should never be admitted to the mare till he is four or four and a half; this is only meant with regard to draught-horses. Fine horses should not be admitted to the mare before they be six years old; and Spanish stallions not till seven. The mares are generally in season from the beginning of April to the end of March; but their chief ardour for the horse lasts but about 15 or 20 days, and this critical season should always be embraced. The stallions of Italy, and especially the Neapolitans, are very good. The best stallions for draught or carriage horses, are those of Naples, Denmark, Holstein, and Frieseland. The stallions for saddle-horses should be from 14 to 15 hands high, and for draught-horses at least 15 hands. Neither ought the colour of stallions to be overlooked; as a fine black, grey, bay, roan, &c. Besides these external qualities, a stallion ought to have courage, tractability, spirit, agility, a sensible mouth, sure limbs. &c. These precautions in the choice of a stallion are the more necessary, because he has been found by experience to communicate to his offspring almost all his good or bad qualities, whether natural or acquired.

The mare contributes less to the beauty of her offspring than the stallion; but the contributes perhaps more to their constitution and stature: for these reasons, it is necessary that the mares for breed be perfectly found, and make good nurses. For elegant horses, the Spanish and Italian mares are best; but, for draught-horses, those of Britain and Normandy are preferable. However, when the stallions are good, the mares of any country will produce fine horses, provided they be well made and of a good breed.

Mares go with young eleven months and some days. They bring forth foaling; contrary to the course of most other quadrupeds, who lie during this operation. They continue to bring forth till the age of 16 or 18 years; and both horses and mares live between 25 and 30 years. Horses castr the hair once a year. Generally in the spring, but sometimes in the autumn. At this time they are weak, and require to be better fed and taken care of than at any other season.

In Persia, Arabia, and most eastern countries, they never geld their horses, as is done in Europe and China. This operation greatly diminishes their strength, courage, and spirit; but it makes them good humour- ed, gentle, and tractable. With regard to the time of performing this operation, the practice of different countries is different; some geld their horses when a year old, and others at 18 months. But the best and most general practice is to delay the operation till they be two years old at least; because, when the gelding is delayed for two years or more, the animals retain more of the strength and other qualities which naturally belong to the male.

The utility of horses surpasses that of all other domestic animals, it may be of use to subjoin some marks by which the age and other properties of horses may be distinguished.

The first teeth that appear are four, two above and two below, which are called foal-teeth, and may be easily distinguished from the others by their whiteness. The rest come out afterwards till they are twelve in number, six above and six below. When a colt is between two years and a half and three years old, he calls four of these teeth, two above and two below. These we call nippers or gatherers, and are much longer and larger than the fore teeth; with these he nips off the grass, and pulls the hay from the rack. When these are complete, the horse will be three years old, or somewhat more.

When he is about four, he calls again two above and two below, one on each side the nippers; so that now there are no fore teeth remaining but the corner-teeth; and hence it may be concluded that he is about four years old. The tulips appear next after these, and are a little crooked. Those below come out before those on the upper jaw; and at four years old they are very small. When all the colt-teeth are cast, and the corner-teeth begin to show themselves, then the horse comes five.

From five to five and a half the corner teeth remain hollow within, and are not quite filled up till the horse is six. At five and a half they are about a quarter of an inch high, and when he is full six near half an inch. Everything that is to be examined at six years old, are the corner-teeth and the tulips. That part of the corner-teeth that had flesh in it first turns to a brownish spot, like the eye of a garden-bean. At seven the mark or spot becomes faint, and the tooth more even. At eight it quite disappears. Though it possibly may remain in a very small degree for two or three years more, which has deceived many. The longer the corner teeth are, the older is the horse; and they are apt to grow foul and turn yellow. When the mark is gone, if you touch the tulips on the upper jaw with your finger, and find it worn away and equal with the palate, you may certainly judge that the horse is ten years old at least. Lastly, when the flanks of a horse are much funk, the feet broken and spoiled, the pace bad, and the eye-pits very yellow, you may certainly conclude the horse is considerably advanced in years.

When the horse is without blemish, the legs and thighs are clean, the knees straight, the skin and thigh thin, and the back fine, strong and well braced. The fins and the bones should be so distinct, as to make the legs appear thin and lathy, not full and round. The pattern joints should never be large and round.
nor must there be any swelling near the coronet. The
hocks should be lean and dry, not puffed up with wind.
With regard to the hoof, the coronet should be equal-
ly thick, and the horn shining and greyish. A white horn is a sign of a bad foot, for it will wear
out in a short time; and likewise when the horn is thin,
it is liable to be spoiled in shoeing, and by travelling
hard on stony grounds. This is best known when the
shoe is taken off; for then the verge all round the
sole will appear thin, and the horse will wince at the
least touch of the pincers.

A strong foot has the fibres of the hoof very distinct
running in a direct line from the coronet to the toe, like
the grain of wood. In this case care must be taken to
keep the foot moist and pliable. The greatest incon-
venience attending a hard strong foot, is its being sub-
ject to rifts and fissures, which cleave the hoof quite
through sometimes from the coronet down to the bot-
 trom.

A narrow heel is likewise a defect; and when it is
not above two fingers in breadth the foot is bad. A
high heel causes a horse to trip and stumble often; and
the low one, with long yielding patterns, is very apt
to be worn quite away on a journey. Too large a foot
onset, that the horse may have sufficient room to carry
through sometimes from the coronet down to the bot-

The head of a horse should be small, and rather
than sleek; the ears should be small, erect,
thin, sprightly, and pointed. The forehead, or brow,
should be neither too broad nor too flat, and should
have a star or snip thereon. The nose should rise a
little, and the nostrils should be wide that he may
breath more freely. The muzzle should be small, and
the mouth neither too deep nor too shallow. The
jaws should be thin, and not approach too near near
gether at the throat, nor too high upwards towards the
onset, that the horse may have sufficient room to carry
his head in an easy graceful posture. The eyes should
be of a middle size, bright, lively, and full of fire.
The tongue should be small, that it may not be too
much pressed by the bit; and it is a good sign when
his mouth is full of white froth, for it shews that he
will not soon be overheated.

The neck should be arched towards the middle,
growing fuller by degrees from the breast and shoul-
ders to the head. The hair of the main should be
long, fine, and fine; and if it be a little frizzled, so
much the better. The shoulders should be pretty
long, the withers thin, and enlarge gradually from
there downwards; but so as to render his breast nei-
ter too narrow nor too grofs. A thick-shouldered
horse soon tires, and trips and stumbles every minute;
especially if he has a thick large neck at the same
time. When the breast is so narrow that the fore-
thighs almost touch, they are never good for much.
A horse of a middle size should have the distance of
five or six inches between his fore-thighs, and there
should be less distance between his feet than his thighs
near the shoulders when he stands upright.

The body or carcase of a horse should be of a
middling size in proportion to his bulk, and the back
should sink a little below the withers; but the other
parts should be straight, and no higher behind than be-
fore. He should also be home-ribbed; but the short
ribs should not approach too near the haunches, and
then he will have room to fetch his breath. When a
horse's back is short in proportion to his bulk, and yet
otherwise well limbed, he will hold out a journey the
he will travel slow. When he is tall, at the same
time with very long legs, he is but of little value.

The wind should never be overlooked in the choice
of a horse; and it may easily be known by his flanks,
if he is broken-winded; when he stands quiet in the
stable; because he always pinches them in with a very
slow motion, and drops them suddenly. A thick-
winded horse fetches his breath often, and sometimes
rattles and wheezes. This may be always discovered
when he is put to brisk exercizes.

The temper of a horse should always be observed;
and it may easily be known by his flanks,
if he is broken-winded; when he stands quiet in the
stable; because he always pinches them in with a very
slow motion, and drops them suddenly. A thick-
winded horse fetches his breath often, and sometimes
rattles and wheezes. This may be always discovered
when he is put to brisk exercizes.

The Spanifh horses are very well made, and handsome, long course; they never do well in a colder climate. They have handsome legs and heads, and are easily managed; as well as very active and nimble; they have good eyes, handfome legs and heads, and are easily managed; they are also good for racing if they are well kept; however, they are not so good in northern climates as in their own country. The Turkish horses are of different shapes; but they are generally swift, though their mouths are bad. Most of them are white; those there are other colours; and they are large, hardy, strong, and fit for the road.

The horses of Barbary, commonly called barbs, have strong hoofs, and are more proper for racing than any others whatever; some have laid they never grow old, because they prefer the vigour to the luff. They are excellent stallions; and some of them are used as such in Britain; however, the Arabian horses are not quite so good as the Barbary, though some think they are both of the same kind; only those that are used to the defects of Arabia are always in action. The horses of the gold-coast of Guinea are very few in number, and in other parts of that coast there are none at all; for many of the negroes, when they have been first brought over to our American plantations, have expressed great admiration at the sight of a horse, and even been afraid to come near one.

The horses of the Cape of Good Hope were originally brought from Persia; and they are generally small and of a chestnut colour; for those that are natives of that country are all wild, and could never yet be tamed. The horses of China are good, and more particularly those in the province Yun Nan, for they are very vigorous, though a little low. The horses of the Eluth Tartars are good and full of fire; and their size is much the same as the Polish horses; they are afraid of nothing, not even of lions and tigers; but perhaps this may be owing to use. In the country of the Mogul they are very numerous, and of all colours: they are generally of the middle size, but there are some large and as handfome as those in Europe. The wild horses of Tartary differ little from the tame; but they are so swift, that they avoid the arrows of the moft skilful hunters. [Plate LXXV. fig. 1.] For the method of training and managing horses, see Horsemanship; and for their diseases and cure, see Farriery.

2. The as is likewise a domestic animal, and easily distinguished from the horse at first fight; we never confound these two animals, even though they should happen to be of the same colour and figure; however, when we view the different parts of the as, whether the external or internal, and compare them with the corresponding parts of the horse, the resemblance of these parts is so perfect, that we are surpriz'd to find the individuals so different and so easily distinguishable by the eye. From this circumstance, some naturalists have considered the as and the horse to be the same species of animals; and that the small differences between them are accidental, or owing to the influence of climate, culture, &c. Linnaeus's specific mark of the horfe is, that the whole tail is covered with long hair; and his specific mark of the as is, that the tail has long hair only towards the point, and a black cross over the shoulders. On the other hand, when we consider the differences in the temper, the manners and dispositions of these two animals, and, above all, the...
impossibility of mixing them so as to produce a common or intermediate species capable of propagating, and tranmitting in the same manner as other distinct species, the notion that the horse and the ass are the same species will appear to be without any solid foundation. Besides, the ass differs materially from the horse in the thickness of the head, the length of the ears, the hardness of the skin, and in the voice, the dispositions, the manner of drinking, etc. With regard to animals, there is perhaps but one permanent and uniform specific distinction in nature: a male and female of different species may copulate; may produce a third animal resembling both, but very different from either; but here nature has put a final stop to all further procreation: the third animal, although it be seemingly furnished with every thing necessary for propagating, remains for ever barren. Now, the horse may be made to copulate with the ass; a mule, or mixture of the two, is the fruit of the unnatural embrace: but the impregnation of a mule is found by experience to be altogether impossible.

The ass, therefore, is a distinct species, and his race as ancient as that of the horse. Why then should this useful, patient, sober animal be so much despised? We are apt to compare him, on every occasion, with the horse, and from this comparison are led to certain false and unfavourable conclusions. The horse is educated with great care and expense; while the poor ass, abandoned to the abuse of the meanest servants or the buffets of every rustic, who beat and overload him, is often rolled on the ground, and covered with hair; he is never troubled with lice, probably owing to the hardness and dryness of his skin; and it is probably for the same reason, that he is less sensible to the whip and spur than the horse.

The teeth of the ass fall out and grow at the same age and in the same manner as those of the horse; and he has nearly the same marks in his mouth. Asses are capable of propagating when two years old. The females are in season during the months of May and June. The milk appears in the dung ten months after impregnation; it brings forth in the twelfth month, and always one at a time. After the birth, the season of the female returns, and she is again in a condition to receive the male. The colt should be taken from her at the end of five or six months, that the growth and nourishment of the fetus may not be obstructed. The stallion or jake-ass should be the largest and strongest that can be found; he should be at least three years old, and never ought to exceed ten.

The ass, like the horse, takes three or four years in growing; and lives till he be 25 or 30: he sleeps less than the horse, and never lies down to sleep but when excessively fatigued. He is more robust, and less subject to diseases than the horse.

Travellers inform us that there are two sorts of asses in Persia; one of which is used for burdens, they being strong and heavy; and the other is kept like horses for the saddle, for they have smooth hair, carry their head well, and are much quicker in their motion; but when they ride them, they fit nearer their buttocks than when on a horse: they are dexterous like horses, and are taught to amble like them; but they generally cleave their nostrils to give them more room for breathing. Dr. Russell likewise tells us they have two sorts in Syria, one of which is like ours, and the other very large, with remarkable long ears; but they are both put to the same use, which is to carry burdens.

The

The
The onager, or wild ass, has, by some authors, been confounded with the zebra; but very improperly, for this last is a distinct species; for the onager is not streaked like this, nor is his shape so beautiful. Wild asses are said to be very swift of course; and when they see a man, they make a bound, and immediately fly away; in fine, that there is no taming of them, but by traps and gins. They have much the same shape as common asses; but they are of a brighter colour, and there runs a white lift from the head to the tail. Of the hide of these asses, and particularly of that part next the rump, they make that excellent leather which we call flagreen, and which is put to so many curious uses.

In America they have no asses at all, nor yet horses; but they have been carried thither long ago, at first by the Spaniards, and afterwards by other nations, where they have multiplied greatly; in fine, that, in some places, there are whole droves of them that run wild, and are very hard to be caught. Ases in general carry the heaviest burdens in proportion to their bulk; and, as their keeping costs little or nothing, it is a great wonder they are not put to more uses than they generally are among us.

The flesh of the common ass is never eaten in these parts of the world; though some pretend their colts are tender, and not disagreeable. [Plate LXXV. fig. 2.]

3. The zebra.—This animal has the figure and gracesfulness of the horse, joined to the swiftness of the flag. He is about 7 feet long, from the point of the muzzle to the origin of the tail, and about 4 feet high. The colour of his skin is beautiful and uniform, consisting of alternate parallel rings of black and white disposed in the most regular manner, as represented in the plate. [LXXV. fig. 3.] He is generally less than the horse, and larger than the ass.

The Zebra is found nowhere but in the eastern and southern provinces of Africa, from Ethiopia to the Cape of Good Hope, and from the Cape of Good Hope to Congo. The Dutch have been at great pains to tame and use them for domestic purposes, but with little success. He is hard-mouthed, and kicks when any person attempts to touch or come near him. He is restless and obstinate as a mule: but perhaps the wild horse is naturally as untractable as the Zebra; for, it is probable, if he were early accustomed to obedience and a domestic life, he would become as docile as the horse.

ERANARCHA, a public officer among the ancient Greeks, whose business was to preside over and direct the alms and provisions made for the poor. Cornelius Nepos, in his life of Epaminondas, describes his office thus: when any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. the eranarcha called an assembly of friends and neighbours, and taxed each according to his means and eilate, to contribute towards his relief.

ERANTHEMUM, in botany, a genus of the diandria monogynia class. The calix is divided into five segments; the tube is diliform; and the stigma is simple. There is but one species, a native of Ethiopia.

ERASED, in heraldry. See Arrache.

ERATION, in a general sense, the art of raising or elevating any thing, as the erection of perpendiculars, &c. It is also used in a figurative sense, as the erection of a bishopric, marquise, &c.

ERECTOR CLITORIS. See clitoris.

ERECTOR PENIS. See Penis.

EREMIT. See Hermit.

EREMITA, in zoology. See Scarabaeus.

ERFURT, a large and beautiful city of Upper Saxony in Germany, capital of Thuringia, and subject to the election of Mentz: E. long. 11° 6', N. lat. 51°.

ERGOT, in farriery, is a stub, like a piece of soft horn, about the bigness of a chesnut, placed behind and below the pattern-joint, and commonly hid under the tuft of the fetlock.

ERICA, or Heath, in botany. A genus of the ostan- dria monogynia clafs. The calix consists of four leaves, and the corolla of four segments; the filaments are inserted into the receptacle; the anthers are bifid; and the capsule has four cells. There are thirty-eight species, five of which are natives of Britain, viz the vulgaris, or common heath; the cinerea, or fine-leaved heath; the tetralix, or crofs-leaved heath; the cilia- ris, or rough-leaved heath; and the multiflor, or fir- leaved heath.

ERIE, a vast lake to the westward of Pennsylvania, in North America, situated between 80° and 87° W. long. and between 41° and 42° N. lat.

ERIGERON, or Sweet fleabane, in botany, a genus of the lyengenia polygamia superflua class. The receptacle is naked; the pappus is hairy; and the radii of the corolla are linear and very narrow. There are sixteen species, two of which are natives of Britain, viz the acre, or blue-flowered fleabane; and the canadense, or Canada fleabane.

ERINACEUS, or Hedge-hog, in zoology, a genus of quadrupeds belonging to the order of feræ, the characters of which are these: they have two foreteeth in the upper-jaw, at a considerable distance from one another, and two in the under jaw, less distant; and they have two recumbent dog-teeth, one on each side. There are three species, viz. 1. The europæus, or common hedge-hog, with round ears, and crested no- strils. It is about nine inches long; the upper part of the body is totally covered with sharp prickles, and the under part is covered with hair. The hedge-hog, even when standing on his legs, has a very sharp aspect. His body is an oblong mass, convex above, terminated on the fore-part by a very sharp muzzle, and mounted on four short legs, of which nothing appears but the feet, and the tail is not discernible. His ears are broad, round, and short; and his eyes are small and protuberant. The length of his body, from the point of the muzzle to the anus, is about nine inches.

The hedge-hog has a very uncommon method of defending himself from the attacks of other animals: being poffesed of little strength or agility, he does not attempt to fly from or affail his enemies; but erects his bristles, and rolls himself up like a ball, expelling no part...
part of his body that is not furnished with sharp weapons of defence; he will not unfold himself, unless thrown into water: the more he is frightened or harrowed, the closer he shuts himself up, and frequently discharges his urine, which has a very fetid and lothsome smell. While in this state, most dogs, instead of biting him, stand off and bark, not daring to seize him; or, if they attempt it once, their mouths are so pricked with his bristles, that they cannot be prevailed on to attempt it a second time. Both the male and female are covered with bristles from the head to the tail. These bristles are of great use in defending them from other animals; but must be very inconvenient when they incline to copulate. This operation they cannot perform in the manner of other quadrupeds; but do it face to face, either lying on end, or the female lying on her back. The females come in season in the spring, and bring forth their young in the beginning of summer. They commonly bring forth three or four, and sometimes five, at a time. The young ones are of a whitish colour, and only the points of the bristles appear above the skin. It is impossible to tame them: the mother and her young have frequently been confined together, and furnished with plenty of provisions: but, instead of nourishing them, she uniformly devoured them one after another. Males and females have likewise been kept in one apartment, where they lived, but never copulated. Hedge-hogs are very fond of flesh-meat, whether raw or roasted. They frequent woods, and live under the trunks of old trees, in the chinks of rocks, or under large stones. Naturalists allege that they go into gardens, mount old trees, in the chinks of rocks, or under large stones. There are two species, neither of them natives of Britain.

ERION, in botany. See ERYNGIUM.

ERIOCEPHALUS, in botany, a genus of the syngenesia polygynia class. The receptacle is somewhat hairy; it has no pappus; the calyx consists of six equal petals; and there are five floccules in the radius. There are two species, none of them natives of Britain.

ERIOPHORUM, in botany, a genus of the triandria monogyyna class. The gluma is paleaceous, and imbricated on each side; the corolla is wanting; and there is but one seed, surrounded by long down.

ERITHACUS, in ornithology. See Motacilla.

ERIVAN, a city of Persia, on the frontiers of Turkey, situated on the south end of a lake of the same name: E. long. 45°; N. lat. 40° 16'.

ERKELENS, a city of Westphalia, in Germany, ten miles north of Juliers: E. long. 6°; N. lat. 51°.

ERMINE, or Ears of corn, an order of knights in France, instituted by Francis the last of that name, duke of Brittany.

This order was so called on account that the collar of it was made up of ears of corn, lying athwart one another, in saltier, bound together, both above and below, each ear being crossed twice, the whole of gold. To this collar there hung a little white beaft, called an ermine, running over a bank of grass diversified with flowers.

ERMINE', or Cross ermine', is one composed of four ermin spots, placed as represented in Plate LXXIV. fig. 8.

It is to be observed, that the colours in these arms are not to be expressed, because neither this cross nor these arms can be of any other colour but white and black.

ERMINITES should signify little ermines, but it is otherwise: for it expreftes a white field powdered with black, only that every such spot hath a little red hair on each.

Erminites also signify a yellow field powdered with black, which the French express much better by or femee d'ermine de fable.

EROSION, among physicians, denotes much the same with corrosion, only in a stronger degree. See Corrosion, and Corrosives.

EROTIC, in general, any thing relating to the paffion of love.

ERRATIC, in general, something that wanders, or is not regular: hence it is the planets are called erratic stars.

ERRHINES, in pharmacy, medicines which, when snuffed up the nofe, promote a discharge of mucus from that part.

ERROUR, Error, a mistake of our judgment, giving affent to that which is not true.

Mr. Locke reduces the causes of error to these four;
Fig. 1. Equus Caballus
or Horse.

Fig. 2. Equus Asinus
or Ass.

Fig. 3. Equus Zebra.
ERYTHROPHTHALMUS, in ichthyology, a species of Sparus. See Sparus.

ERYTHROIDES, in anatomy, the first of the proper species of Salmo. See Salmo.

ERYTHRINUS, in ichthyology, a species of Sparus. See Sparus.

ERYTHRINA, in botany, a genus of the diadelphia decandria class. The calyx consists of five segments of an equal length with the corolla. There are six species, three of which are natives of Britain, viz. the foloncifera, or spring tare; the tetrapermum, or smooth tare; and the hirfutum, or hairy tare.

ERINGIUM, Eringo, in botany, a genus of the penandria class. There are three species, none of them natives of Britain, viz. the officinale, or hedge-mustard; the cheiranthoides, or treacle worm-feed; and the alliaria, Jack-by-the-hedge, or sawce-alone. The leaves of the hedge-mustard are said to promote expectoration, and to excite urine and other excretions.

ERUPTION, in medicine, a hidden and copious excretion of humours, as pus or blood: it signifies also the same with exanthema, any breaking out, as the pustules of the plague, small-pox, measles, &c. See Medicine.

ERVUM, in botany, a genus of the diadelphia decandria class. The calyx consists of five segments of an equal length with the corolla. There are six species, three of which are natives of Britain, viz. the officinale, or hedge-mustard; the cheiranthoides, or treacle worm-feed; the barbara, rocket, or winter-crefies; and the alliaria, Jack-by-the-hedge, or fawce-alone. The leaves of the hedge-mustard are said to promote expectoration, and to excite urine and other excretions.

ERYSIPELAS, in medicine, an eruption of a fiery or acrid humour, from which no part of the body is exempted, though it chiefly attacks the face. See Medicine.

ERYTHRHINUS, in ichthyology, a species of Sparus. See Sparus.

ERYTHROIDES, in anatomy, the first of the proper species of Salmo. See Salmo.

ERYTHRINUS, in ichthyology, a species of Sparus. See Sparus.

ERYTHRINA, in botany, a genus of the diadelphia decandria class. The calyx is bilabiated; and the corolla consists of a long lanceolated vexillum. There are three species, none of them natives of Britain.

ERYTHRINUS, in ichthyology, a species of Sparus. See Sparus.

ERYTHROIDES, in anatomy, the first of the proper species of Salmo. See Salmo.

ERYTHRIONIUM, Dog’s-tooth violet, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped, and consists of five petals; there are two nectariferous tubercles at the base of every second petal. There is but one species, a native of Germany.

ERYTHROPHTHALMUS, in ichthyology, a species of cyprinus. See Cyprinus.

Vol. II. No. 47.

ERZERUM, the capital of the province of Turcomania, or Armenia: E. long. 41°, N. lat. 49°. It is a great thoroughfare from Persia and Ionia to Constantinople, by the way of Trebisonde and the Black-sea.

ESCHAR, in surgery, the crust or scab occasioned by burns or caustic medicines.

ESCHAROTICS, in pharmacy, medicines which produce eschars. See Eschar.

ESCHEAT, in Scots law, is that forfeiture which is incurred upon a person’s being denounced rebel. It is either single or lertent: single escheat is the forfeiture of the rebel’s moveable estate; lertent escheat is the forfeiture of the rents of his heritable estate, during his life. See Scots Law, title 12.

ESCHRAKITES, in matters of religion, a sect of Mahometans, who believe that man’s sovereign good consists in the contemplation of God. They avoid all manner of vice, and appear always in good humour, despising the sensual parasite of Mahomet. The most able preachers, in the royal mosques, are of this sect.

ESCLATTE’, in heraldry, signifies a thing forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCUCAGE, in our old customs, a kind of knight service, called service of the shield, by which the tenant was bound to follow his lord to the wars at his own charge.

ESCULENT, an appellation given to such plants as may be eaten. See Botany, p. 628.

ESCLUSUS, in botany. See Quercus.

ESCURIAL, a palace of the king of Spain, twenty one miles from north-east to south-west, falls into the Solway firth: it gives name to the country of Eskdale. See Naturae History, Of insects.

ESK, a river which forms part of the boundary between England and Scotland; and, running from north-east to south-west, falls into the Solway firth: it gives name to the country of Eskdale. See Naturae History, Of insects.

ERYSIMUM, in botany, a genus of the tetradynamia class. The pod is four-sided, divided into two cells. There are six species, four of which are natives of Britain, viz. the officinale, or hedge-mustard; the cheiranthoides, or treacle worm-feed; the barbara, rocket, or winter-crefies; and the alliaria, Jack-by-the-hedge, or fawce-alone. The leaves of the hedge-mustard are said to promote expectoration, and to excite urine and other excretions.

ESCUTCHEON, or Scutcheon, in heraldry, is derived from the French escuison, and that from the Latin feutum, and signifies the shield whereon coats of arms are represented.

Most nations, of the remotest antiquity, were wont to have their shields distinguished by certain marks painted on them; and to have such on their shields was a token of honour, none being permitted to have them till they had performed some honourable action.

The escutcheon, as used at present, is square, only rounded off at the bottom.

ESDRAS, the name of two apocryphal books, usually bound up with the scriptures. They were always excluded the Jewish canon, and are not admitted as canonical by the papists themselves.

ESSENS, a town of Welfphalia, twenty-five miles north of Embden.

ESKIMAUX,
ESKIMAUX, sometimes called New Britain, and Terra de Labrador, is an extensive country of North America, situated between 59° and 80° W. long., and between 50° and 64° N. lat.

It is bounded by Hudson's straits, which separate it from Greenland, on the north; by the Atlantic ocean, on the east; by the river and bay of St. Laurence, on the south-east; and by Hudson's bay, on the west.

ESLINGEN, an imperial city of Swabia in Germany, seven miles south-east of Stuttgart.

ESOX, in ichthyology, a genus belonging to the order of abdominals. The body is elongated; the head is plainish above; the upper jaw is plain, and shorter than the under one, which is dotted; and the branchiosteg membrane has from seven to twelve rays. There are nine species.

ESPALIERS, in gardening, are rows of trees planted about a whole garden or plantation, or in hedges, so as to inclose quarters or separate parts of a garden; and are trained up regularly to a lattice of wood work in a clofe hedge; for the defence of tender plants against the injuries of wind and weather.

The trees chiefly planted for espaliers, are apples, pears, and some plumbs. See Gardening.

ESPERIE, a city of Hungary, forty miles north of Tocz-kay; it is remarkable for its salt mines.

ESPINAL, a town of Lorrain on the Moselle, thirty-five miles south-east of Nancy.

ESPLANADE, in fortification, the sloping of the covered way towards the campaign.

ESPLEES, in law, the general products which lands yield, or the profit or commodity that is to be taken or made of a thing.

ESPOUSALS, in law, signify a contract or promise made between a man and a woman, to marry each other; and in cases where marriage may be consummated, espousals go before. Marriage is termed an espousal de present.

ESQUIRE was anciently the person that attended a knight in time of war, and carried his shield.

This title has not for a long time, had any relation to the office of the person, as to carry arms, &c. Tho' to whom the title of esquire is now of right due, are all noblemens younger sons, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons; the officers of the king's courts, and of his household; counsellors at law, justices of the peace, &c. Tho' though those latter are only esquires in reputation: besides, a justice of the peace holds this title no longer than he is in commission, in case he is not otherwise qualified to bear it: but a sheriff of a county, who is a superior officer, retains the title of esquire during life, in consequence of the trust once reposed in him: the heads of some ancient families are said to be esquires by prescription.

ESQUIRES of the king, are such as have that title by creation, wherein there is some formality used, as the putting about their necks a collar of SS, and bellowing on them a pair of silver-spyrs, &c.

ESSAY, a trial or experiment for proving the quality of any thing; or an attempt to learn, whether or no any invention will succeed.

ESSAY, in literature, a peculiar kind of composition, the character whereof is to be free, easy, and natural; not tied to strict order or method, nor worked up and finished like a formal system.

ESSAY HATCH is the miner's term for a little trench or hole, which they dig to search for lead or ore.

ESSEX, a town of Hungary, near the confluence of the rivers Drave and Danube, with a bridge five miles over: it lies about eighty miles north-west of Belgrade.

ESSEN, a city of Weftphalia, about ten miles north-east of Duffeldorp.

ESSENCE, in metaphysics, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others; being nothing but that abstract idea to which this name is affixed; so that every thing contained in it, is essential to that particular kind.

ESSENES, or ESSOLIANS, in Jewish antiquity, one of the three ancient sects among that people. They allowed a future state, but denied a resurrection from the dead. Their way of life was very singular: they did not marry, but adopted the children of others, whom they bred up in the institutions of their sect: they despised riches, and had all things in common, and never changed their clothes till they were entirely worn out. When initiated, they were strictly bound not to communicate the mysteries of their sect to others; and if any of their members were found guilty of enormous crimes, they were expelled.

Pliny tells us, that they dwelt on the west side of the lake of Athalites; and that they were a solitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree: he adds, that they were constantly recruited by new-comers, whom the furies of ill fortune had made weary of the world; in which manner the sect was kept up for several thousands of years, without any being born among them. This reason why we find no mention made of them in the New Testament, may be their recluse and retired way of life, no less than their great simplicity and honesty, whereby they lay open to no cenfure or reproof.

ESSENTIAL, something necessarily belonging to a thing, from which it cannot be conceived distinct: thus the primary qualities of bodies, as extension, figure, number, &c. are essential or inseparable from them in all their changes and alterations.

ESSENTIAL OIL. See Chemistry, p. 93.

ESSEX, a county of England, bounded by Suffolk, on the north; by the German sea, on the east; by the river Thames, which divides it from Kent, on the south; and by Middlesex and Hertfordshire, on the west.

ESSOIN, in law, an excuse for a person summoned to appear and answer to an action, on account of the sickness or other just cause of his absence.

ESSORANT, in heraldry, denotes a bird flanding on the
the ground with its wings expanded, as if it had been
wet, and were drying itself.

ESTE, in law, signifies the title or interest that a
person has in lands, tenements, or other effects.

ESTATES, in a political sense, is used either to de-
ote the dominions of some prince, or the general clas-
tes into which the people are divided.

In Britain, the estates are the king, lords, and com-
munes; or rather the lords and commons, who meet the
king in parliament, for reforming abuses, and enacting
good and wholesome laws.

ELSETE, in heraldry, denotes the heads of hearts
torn off by main force. See Arche and Erased.

ESTHER, a canonical book of the Old Testament,
containing the history of a Jewish virgin, dwelling with
her uncle Mordecai at Shushan, in the reign of Ahasu-
erus, one of the kings of Persia.

ESTOITLE, or Cross Estoille, in heraldry, a
star with only four long rays in form of a cross; and,
accordingly, broad in the centre, and terminating in
sharp points.

ESTONIA, a province subject to Russia, on the north of
Livonia.

ESTRAY, in law, any beast not wild that is found with-
in a lordship, and owned by nobody.

ESTREMADURA, a province of Spain, bounded by
Leon, on the north; by the two Cafilles, on the east;
by Andalusia, on the south; and by the province of
Alentejo, in Portugal, on the west.

ESTREMADURA is also a province of Portugal, lying
north of Alentejo, and westward of Spanish Estrema-
dura. Lisbon is its capital, as also of the kingdom.

ESTREMOs, a town of Alentejo, in Portugal, eighty-
five miles south east of Lisbon.

ETCHING, a method of engraving on copper, in which
the lines or strokes, instead of being cut with a tool or
graver, are eaten in with aquafortis.

ETCHING is done with more ease and expedition than
engraving: it requires fewer instruments, and repre-
sents more kind of subjects better and more agreeable
to nature, as landscapes, ruins, grounds, and all small,
fruits, flowers, remote objects, buildings, &c. See En-
graving.

The method of etching is as follows: Choose the
cooperplate as directed for engraving, and furnish your-
self with a piece of ground, tied up in a bit of thin
filk, kept very clean. To be laid upon the plate, when
both have been warmed; proper needles, to hatch with
on the ground; a pencil or brush, to wipe away the
bits of ground which rise after hatching; a polisher;
two or three gravers; a pair of compasses. To measure
distances and draw circles; a ruler, to hatch right lines;
green wax, to make the wall round the edges of the
plate, to contain the aquafortis; an oilstone; a bottle of
aquafortis; some red lead, to colour the back side of the
copy; a flift, and a hand-vice, to hold the plate over the
candle. See Needle, Graver, Polisher, Compass, &c.

To make the ground, take three ounces of asphaltum,
two ounces of clean rosin, half an ounce of Burg-
gundy-pitch, three ounces of black wax, and three
ounces of virgin-wax: let all these be melted in a
clean earthen pipkin over a slow fire, stirring it all the
time with a small stick; if it burn to the bottom, it is
spoiled. After the ingredients are well melted, and it
boils up, put it into a pan of fair water; and before it
be quite cold, take it out, and roll it into small lumps
to be kept from dust: this ground is what others call
the varnish. The next thing is to clean the plate to re-
cieve the ground: take a piece of lifting, roll it up as
big as an egg, tie it very tight, so as to make it a rub-
ber; and having dropped a small quantity of sweet oil,
and added a little powder of rotten stone on the plate,
rub it with this ball, till it will almost swell your face.
Then wipe it all off with a clean rag; and after that,
make it quite dry with another clean rag and a little
fine whitening.

The next thing is to lay on the varnish; to do which
right you must take a hand-vice, and fix it at the
middle of one part of the plate, with a piece of paper
between the teeth of the hand-vice and the plate, to
prevent the marks of the teeth: then laying the plate
on a chaffing-dish, with a small charcoal fire in it, till
the plate be so hot, that, by spitting on the back-side of
the wet will fly off; rub the plate with the ground tied
up in silk, till it be covered all over; and after that
daub the plate with a piece of cotton wrapped up in
silk, till the ground be quite smooth, keeping the plate
a little warm all the time. The varnish being thus
smoothed upon the plate, it must be blacked in the fol-
lowing manner: take a thick tallow candle that burns
clear, with a short snuff; and having driven two nails
into the wall, to let it rest upon, place the plate against
the wall with the varnish side down, and take care
to touch the ground with your fingers: then tak-
ing the candle, apply the flame to the varnish as close
as possible, without touching the varnish with the snuff
of the candle, and guide the flame all over it, till it be-
come perfectly black. After this is done, and the plate
dry, the design is traced with a needle through the
varnish, and a rim or border of wax is raised round
the circumference of the plate; and then the artist has
a composition of common varnish and lamp-black: made
very thin, wherewith he covers the parts that are not
to be bitten, by means of a hair-pencil. And he is ey-
evry now and then covering or uncovering this or that
part of the design, as occasion may require; the con-
duct of the aquafortis being the principal concern, on
which the effect of the print very much depends. The
operator must be attentive to the ground, that it does
not fail in any part, and where it does to stop up the
place with the above composition. The plate is defended
from the aquafortis every where, but in the lines or
hatches cut through it with the needle, through which
the water eats into the copper to the depth re-
quired; remembering to keep it flirring with a feather
all the while; which done, it is to be poured off
again.

Single aquafortis is most commonly used; and if it
be too strong, mix it with vinegar; otherwise it will
make the work very hard, and sometimes break up
the ground: the aquafortis having done its part, the
ground
EVAPORATION, in chemistry, the setting a liquor in
a gentle heat to discharge its superfluous humidity, re-
duce it to a proper consistence, or obtain its dry re-
mainder. See CHEMISTRY.

EVATES, a branch or division of the druids, or ancient
Celtic philosophers. Strabo divides the British and
Gaulish philosophers into three sects; bards, evates, and
druids. He adds, that the bards were the poets
and musicians; the evates, the priests and naturalists;
and the druids were moralists as well as naturalists:
But Marcellus and Hormus reduce them all to two
sects, viz. the bards and druids.

EUBACES, an order of priests, or philosophers, a-
mong the ancient Celts, or Gauls; some will have
the eubages to be the same with the druids and faro-
nidæ of Diodorus; and others, that they were the
same with what Strabo calls evates.

Eucharist, the sacrament of the Lord's supper, proper-
ly signifies giving thanks.

This sacrament was instituted by Christ himself, and
the participation of it called communion.

As to the manner of celebrating the eucharist a-
mong the ancient Christian, after the customary obla-
tions were made, the deacon brought water to the bi-
shop and presbyters, standing round the table, to
wash their hands, according to that of the psalmist,
“ I will wash my hands in innocency, and so will I
“compass thy altar, O Lord.” Then the deacon
cried out aloud, “Mutually embrace and kiss each
“other,” which being done, the whole congregation
prayed for the universal peace and welfare of the
church, for the tranquility and repose of the world,
for the prosperity of the age, for wholesome weather,
and for all ranks and degrees of men. After this fol-
lowed mutual salutations of the minister and people;
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
and for all ranks and degrees of men. After this fol-
followed mutual salutations of the minister and people;
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the
elements by a solemn benediction, he brake the bread,
and then the bishop or presbyter having sanctified the

EVIDENCE, that perception of truth which arises either from the testimony of the senses, or from an induction of reason. See Metaphysics, and Morals.

EVIDENCE, in law, any proof, whether it be by testimony of men on oath, or by writings and records so called, because hereby the point in issue is made evident by a jury.

EVIL. See Morals.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preserve a post, or occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better.

EUONYMOIDES, in botany. See Celastrus.

EUONYMUS, the spindle-tree, in botany, a genus of the pentandria monogynia class. The corolla consists of five petals; the capsule is five-sided, and has five coloured cells; and the seeds are calyptra. There are two species, one of which, *viz.* the europaeus, spindle-tree, or prickwood, is a native of Britain.

EVAR, a city of Normandy in France, twenty-five miles south-east of Rouen.

EUROPA, or Ebora, a city of Portugal, seventy miles south-east of Lisbon.

EUROPA, a town of Savoy, situated twenty-five miles north-east of Geneva, on the south side of the lake of Geneva.

EVORNA, or Ebora, a city of Portugal, seventy miles south-east of Lisbon.

EUPATORIOPHALACRON, in botany. See Veratrum.

EUPATORIUM, Hemp-agrimony, in botany, a genus of the syngenesia polygamy aquilífls class. The receptacle is naked; the pappus is plumose; the calyx is oblong and imbricated; and the stylos is long and semi-bifid. There are twenty-one species, only one of which is a native of Britain, *viz.* the cannabinum, hemp-agrimony, or Dutch agrimony. The leaves are said to strengthen the stomach.

EUPHRASIA, in botany, a genus of the didynamia angiospermia class. The calyx is cylindrical, and consists of four segments; and the capsule is oblong and bilocular. There are nine species, two of which are natives of Britain, *viz.* the officinalis, or eye-bright; and the odontites, or red eye bright. The eye-bright was formerly celebrated as an ophthalmic, but is now totally disregarded.

EUPHRATES, the finest river in Turky in Asia, has two sources, northward of the city of Erzerum, in 40° N. lat. After passing through Armenia, it divides Syria from Diarbec or Assyria, runs through Eyracka or Chaldea; and uniting with the Tygris, it passes by the city of Baspora, fifty miles below which it falls into the gulf of Peria.

EUPHORBIA, in botany, a genus of the dodecandria trigynia class. The corolla consists of four or five petals; and the calyx has but one leaf. There are sixty-two species, twelve of which are natives of Britain, *viz.* the peplus, or small purple sea-spurge; the peplus, or petty spurge; the exigua, or dwarf-spurge; the vegetalis, or corn-spurge; the helioscopium, fun-spurge, or wart-wort; the portlandica, or Portland spurge; the paralias, or sea-spurge; the verrucosa, or rough-fruit spurge; the platysiphlysum, or broad-leaved spurge; the amygualoides, or wood-spurge; the characias, or red spurge; and the hybrena, or knotty-rooted spurge. The spurges are exceedingly acrid, and are now rejected both by the Edinburgh and London dispensatories.

EUPHORBIUM, in pharmacy, a gum resin brought us always in loose, smooth, and glossy gold-coloured drops or granules. It is the produce of the euphorbium antiquorum verum, which grows to ten or twelve feet high. Its principal use is externally in sinapisms, and plasters applied to the feet, which are intended to stimulate, but not absolutely to raise blisters: for it is observed by Avifenna, that when taken internally in large doses, it has been found to excoriate the integuments, and bring on death itself, after the most terrible symptoms.

EUPHRASIA, in botany, a genus of the didynamia angiospermia class. The calyx is cylindrical, and consists of four segments; and the capsule is oblong and bilocular. There are nine species, two of which are natives of Britain, *viz.* the officinalis, or eye-bright; and the odontites, or red eye bright. The eye-bright was formerly celebrated as an ophthalmic, but is now totally disregarded.

EUPHRATES, the finest river in Turky in Asia, has two sources, northward of the city of Erzerum, in 40° N. lat. After passing through Armenia, it divides Syria from Diarbec or Assyria, runs through Eyracka or Chaldea; and uniting with the Tygris, it passes by the city of Baspora, fifty miles below which it falls into the gulf of Peria.

EUREUX, a city of Normandy in France, twenty-five miles south of Rouen.

EURIPUS, a strait between the island of Negropont, and the continent of Greece, remarkable for its irregular tides.

The term *eupirus* is sometimes used, in a more general
EUROPE, the Raft of the four grand divifions of the
earth, is situated between 36° and 72° N. lat.; and
between 10° degrees W. long. and 65° E. long, be-
ing about 5000 miles long from north to south, and
2500 miles broad from eaf: to west. It is bounded by
the frozen ocean on the north, by Asia on the eaf:, by
the Mediterranean, which separates it from Afri-
ca, on the south, and by the Atlantic ocean on the west.

Europe is commonly fubdivided into three grand di-
visions, north, middle, and south. The north or up-
per divifion comprehends Russia, or Mulcovy, Sweden,
Denmark, and Norway, and the islands of Britain,
Iceland, Greenland, and thofe of the Baltic. The
middle divifion contains Poland, Germany, and the
hereditary dominions of the house of Austria, the Low
Countries, or Netherlands, and France. The sou-
thern division comprehends Turkey in Europe, the an-
cient Greece chiefly, Switzerland, Italy, Spain and
Portugal, and the islands of Sicily, Sardinia, Corfica,
Majorca, Minorca, Iwica, and thofe of the Archipe-
lago.

EURYTHMY, in architecture, painting, and sculpture,
is a certain ******, elegance, and elegance, appearing
in the composition of divers members, or parts of a
body, painting, or sculpture, and refulting from the
fine proportion of it.

EUSTACE, or EUSTATIA, one of the Caribbee islands,
four miles west of St Christopher's, and subject to the
Dutch.

EUSTYLE, in architecture, a fort of building in which
the pillars are placed at the moft convenient distance
one from another, the intercolumniations being juft
two diameters and a quarter of the column, except
thofe in the middle of the face, before and behind,
which are three diameters dijam.

EUTYCHIANS, in church-hiftory, heretics in the Vth
century, who embraced the errors of the monk Eu-
tyches, maintaining that there was only one nature in
Jefus Chrift.

EUXINE, the fame with the Black Sea. See BLACK
SEA.

EWAGE, a toll paid for the paffage of water, and o-
therwise called aquage.

EWE, the English name of a female sheep. See OVIS.

EWRY, in the British cuftoms, an office in the king's
houffhold, which has the care of the table-linen, of
laying the cloth, and ferving up water in silver ewers
after dinner.

EXACERBATION. See Paroxysm.

EXACUM, in botany, a genus of the tetrandria mono-
gynia clafs. The calix confifts of four leaves, and
the corolla of four segments, with a roundifh tube;
the capsule is bifolcated, and has two cells containing
many feeds. There are two species, none of them
native of Britain.

EXACTIS, in surgery, the operation of extracting or
taking away something that is hurtful to the human
bed.

EXAGGERATION, in rhetoric, a kind of hyperbole,
bill of exchange, or a note of hand; these are looked upon as payment.

The punctuality of acquitting those obligations is essential to commerce: and no sooner is a merchant's accepted bill protested, than he is considered as a bankrupt. For this reason, the laws of most nations have given very extraordinary privileges to bills of exchange. The security of trade is essential to every society, and were the claims of merchants to linger under the formalities of courts of law when liquidated by bills of exchange, faith, confidence, and punctuality would quickly disappear, and the great engine of commerce would be totally destroyed.

A regular bill of exchange is a mercantile contract, in which four persons are concerned, viz. 1. The drawer, who receives the value; 2. His debtor in a distant place, upon whom the bill is drawn, and who must accept and pay it; 3. The person who gives value for the bill, to whom it is ordered to be paid, creditor to the third.

By this operation, reciprocal debts, due in two distant parts, are paid by a sort of transfer, or permutation of debtors and creditors.

(A) in London is creditor to (B) in Paris, value 100l. (C) again in London is debtor to (D) in Paris for a like sum. By the operation of the bill of exchange, the London creditor is paid by the London debtor, and the Paris creditor is paid by the Paris debtor; consequently, the two debts are paid, and no money is sent from London to Paris, nor from Paris to London.

In this example, (A) is the drawer, (B) is the acceptor, (C) is the purchaser of the bill, and (D) receives the money. Two persons here receive the money, (A) and (D), and two pay the money, (B) and (C); which is just what must be done when two debtors and two creditors clear accounts.

This is the plain principle of a bill of exchange. From which it appears, that reciprocal and equal debts only can be acquitted by them.

When it therefore happens that the reciprocal debts of London and Paris (to use the same example) are not equal, there arises a balance on one side. Suppose London to owe Paris a balance, value 100l. How can this be paid? Answer, It may either be done with or without the intervention of a bill.

With a bill, if an exchanger finds a demand for a bill upon Paris for the value of 100l., when Paris owes no more to London, lends 100l. to his correspondent at Paris in coin, at the expense (suppose) of 1/4, and then, having become creditor on Paris, he can give a bill for the value of 100l. upon his being repaid his expense, and paid for his risk and trouble.

Or it may be paid without a bill, if the London debtor sends the coin himself to his Paris creditor, without employing an exchanger.

This last example shews of what little use bills are in the payment of balances. As far as the debts are equal, nothing can be more useful than bills of exchange; but the more they are useful in this easy way of business, the less profit there is to any person to make a trade of exchange, when he is not himself concerned either as debtor or creditor.

When merchants have occasion to draw and remit bills for the liquidation of their own debts, active and passive, in distant parts, they meet upon change; where, to pursue the former example, the creditors upon Paris, when they want money for bills, look out for those who are debtors to it. The debtors to Paris again, when they want bills for money, seek for those who are creditors upon it.

This market is constantly attended by brokers, who relieve the merchant of the trouble of searching for those he wants. To the broker every one communicates his wants, so far as he finds it prudent; and by going about among all the merchants, the broker discovers the side on which the greater demand lies, for money, or for bills.

He who is the demander in any bargain, has constantly the disadvantage in dealing with him of whom he demands. This is no where so much the case as in exchange, and renders secrecy very essential to individuals among the merchants. If the London merchants want to pay their debts to Paris, when there is a balance against London, it is their interest to conceal their debts, and especially the necessity they may be under to pay them; from the fear that those who are creditors upon Paris would demand too high a price for the exchange over and above par.

On the other hand, those who are creditors upon Paris, when Paris owes a balance to London, are as careful in concealing what is owing to them by Paris, from the fear that those who are debtors to Paris would avail themselves of the competition among the Paris creditors, in order to obtain bills for their money, below the value of them, when at par. A creditor upon Paris, who is greatly pressed for money at London, will willingly abate something of his debt, in order to get one who will give him money for it.

From the operation carried on among merchants upon change, we may discover the consequence of their separate and jarring interests. They are constantly interested in the flate of the balance. Those who are creditors on Paris, fear the balance due to London; those who are debtors to Paris, dread a balance due to Paris. The interest of the first is to diffamble what they fear; that of the last, to exaggerate what they wish. The brokers are those who determine the course of the day: and the most intelligent merchants are those who dispatch their busines before the fact is known.

Now, how is trade in general interested in the question, Who shall outwit, and who shall be outwitted, in this complicated operation of exchange among merchants?

The interest of trade and of the nation is principally concerned in the proper method of paying and receiving the balances. It is also concerned in preserving a just equality of profit and loss among all the merchants, relative to the real state of the balance. Unequal competition among men engaged in the same pursuit, constantly draws along with it bad consequences to the general undertaking; and secrecy in trade will be found, upon examination, to be much more useful to merchants in their private
private capacity, than to the trade they are carrying on.

Merchants endeavour to simplify their business as much as possible; and commit to brokers many operations which require no peculiar talents to execute. This of exchange is of such a nature, that it is hardly possible for a merchant to carry on the business of his bills, without their assistance, upon many occasions. When merchants come upon change, they are so full of fears and jealousies, that they will not open themselves to one another, lest they should discover what they want to conceal. The broker is a confidential man, in some degree, between parties, and brings them together.

Besides the merchants who circulate among themselves their reciprocal debts and credits arising from their importation and exportation of goods, there is another set of merchants who deal in exchange; which is the importation and exportation of money and bills.

Were there never any balance on the trade of nations, exchangers and brokers would find little employment: reciprocal and equal debts would easily be transferred openly between the parties themselves. No man feigns and disembles, except when he thinks he has an interest in so doing.

But when balances come to be paid, exchange becomes intricate; and merchants are so much employed in particular branches of business, that they are obliged to leave the liquidation of their debts to a particular set of men, who make it turn out to the best advantage to themselves.

Whenever a balance is to be paid, that payment costs, as we have seen, an additional expense to those of the place who owe it, over and above the value of the debt.

If, therefore, this expence be a loss to the trading man, he must either be repaid this loss by those whom he serves, that is, by the nation; or the trade he carries on will become less profitable.

Every one will agree, that the expense of high exchange upon paying a balance, is a loss to a people, no way to be compensated by the advantages they reap from enriching the few individuals among them who gain by contriving methods to pay it off: and if an argument is necessary to prove this proposition, it may be drawn from this principle, to wit, whatever renders the profit upon trade precarious or uncertain, is a loss to trade in general: this loss is the consequence of high exchange; and although a profit does result from it upon one branch of trade, the exchange-business, yet that cannot compensate the loss upon every other.

We may, therefore, here repeat what we have said above, that the more difficulty is found in paying a balance, the greater is the loss to the nation.

The course of Exchange.

The course of exchange is the current price between two places, which is always fluctuating and unsettled, being sometimes above and sometimes below par, according to the circumstances of trade.

When the course of exchange rises above par, the country where it rises may conclude for certain, that the balance of trade runs against them. The truth of this will appear, if we suppose Britain to import from any foreign place goods to the value of 100,000l. at par, and export only to the value of 80,000l.; in this case, bills on the said foreign place will be scarce in Britain, and consequently will rise in value; and after the 80,000l. is paid, bills must be procured from other places at a high rate to pay the remainder, so that perhaps 120,000l. may be paid for bills to discharge a debt of 100,000l.

Though the course of exchange be in a perpetual flux, and rises or falls according to the circumstances of trade, yet the exchanges of London, Holland, Hamburg, and Venice, in a great measure regulate those of all other places in Europe.

1. Exchange with Holland.

In Holland there are two sorts of money, bank and current. The bank is reckoned good security; demands on the bank are readily answered; and hence bank-money is generally rated from 3 to 6 per cent. better than the current. The difference between the bank and current money is called the agio.

Bills on Holland are always drawn in bank-money; and if accounts be sent over from Holland to Britain in current money, the British merchant pays these accounts by bills, and in this case has the benefit of the agio.

Prob. I. To reduce bank money to current money.

Rule. As 100 to 100+agio, so the given guilders to the answer.

Example. What will 2210 guilders in bank money amount to in Holland currency, the agio being 3½ per cent.?

GUILD.
Britain gives 11. Sterling for an uncertain number of shillings and pence Flemish. The par is 11. Sterling for 36.59 s. Flemish; that is, 11. 16 s. 7.08 d. Flemish.

When the Flemish rate rises above par, Britain gains and Holland loses by the exchange, and vice versa.

Sterling money is changed into Flemish, by saying,

As 11. Sterling to the given rate,
So is the given Sterling to the Flemish sought.

Or, the Flemish-money may be cast up by practice.

Dutch money, whether pounds, shillings, pence Flemish, or guilders, flivers, pennings, may be changed into Sterling, by saying,

As the given rate to 11. Sterling,
So the given Dutch to the Sterling sought.

Example. 1. A merchant in Britain draws on Amsterdam for 7821. Sterling: How many pounds Flemish, and how many guilders will that amount to, exchange at 34s. 8d. per pound Sterling?

Multiply the Flemish pounds and shillings by 6, and the product will be guilders and flivers; and if there be any pence, multiply them by 8 for pennings; or, divide the Flemish pence by 40, and the quot will be guilders, and the half of the remainder, if there be any, will be flivers, and 1 penny odd will be half a fliver, or 8 pennings, as follows.

2. Change 591 l. 5 s. Flemish into Sterling money, exchange at 37 s. 6 d. Flemish per l. Sterling?
Exchange with Hamburgh.

Books and accounts are kept at the bank, and by most people in the city, in marks, schilling-lubs, and phennings; but some keep them in pounds, schillings, and groots Flemish.

The agio at Hamburgh runs between 20 and 40 per cent. All bills are paid in bank-money.

Hamburgh exchanges with Britain by giving an uncertain number of schillings and groots Flemish for the pound Sterling. The groot or penny Flemish here, as also at Antwerp, is worth ¾ of a penny Sterling; and so something better than in Holland, where it is only ¼ of a penny Sterling.

### Examples.

**Money Table.**

**Par in Ster.**

| 12 deniers | = 0 0 ½ |
| 20 fols    | = 0 1 ½ |
| 3 livres   | = 1 crown |

At Paris, Rouen, Lyons, &c. books and accounts are kept in livres, fols, and deniers; and the exchange with Britain is on the crown, or ecus, of 3 livres, or 60 fols Tournois. Britain gives for the crown an uncertain number of pence, commonly between 30 and 34, the par, as mentioned above, being 29½d.
IV. Exchange with Portugal.

MONEY-TABLE.

In Lisbon, Oporto, &c. books and accounts are generally kept in rees and millrees; and the millrees are distinguished from the rees by a mark set between them thus, 495 ¥ 372; that is, 485 millrees and 372 rees.

Britain, as well as other nations, exchanges with Portugal on the millree, the par, as in the table, being 67₄ d. Sterling. The course with Britain runs from 63 d. to 68 d. Sterling per millree.

**Example. 1.** How much Sterling money will pay a bill of 827 ¥ 160 rees, exchange at 63½ d. Sterling per millree?

Rees. | d. | Rees.
---|---|---
If 1000 = 68½ : 827.160 = 507
8000 507 579012
413800 Rem.
8000, 413870.120 = 2
12) 52421 = 5 d.
20) 4368 = 8 s.

In Madrid, Bilboa, Cadiz, Malaga, Seville, and most of the principal places, books and accounts are kept in millrees, called also dollars, rials, and mervadies; and they exchange with Britain generally on the piafortre, and sometimes on the ducat. The course runs from 35 d. to 45 d. Sterling for a piafortre or dollar of 8 rials.

**Example. 2.** London imports from Cadiz, goods to the value of 2163 rials and 4 rials: How much Spanish money will this amount to, exchange at 38½ d. Sterling per piafortre?

The money of Venice is of three sorts, viz., two of bank money, and the picoli money. One of the banks deals in banco money, and the other in banco current. The bank money is 20 per cent. better than the banco current, and the banco current 20 per cent. better than the picoli money. Exchanges are always negotiated by the ducat banco, the par being 4s. 2½d. Sterling, as in the table.

Though the ducat be commonly divided into 24 gros, yet bankers and negotiators, for facility of computation, usually divide it as follows, and keep their books and accounts accordingly.

12 Deniers d'or = 5½ sols d'or = 1 ducat banco = 139½ florins
20 Soldi make 1 pezzo = 77 crowns

The course of exchange runs from 47 d. to 58 d. Sterling per ducat.

**Example 1.** How much Sterling money is equal to 1459 ducats 18 sols 1 denier, bank money of Venice, exchange at 52½ d. Sterling per ducat?

**Exchange money is reduced to lire money, by allowing for the agio, as was done in exchange with Holland; viz., say, as 100 to 120, or as 10 to 12, or as 5 to 6, to the given bank money to the current fought. And current money is reduced to bank money by reverting the operation. And in like manner may picoli money be reduced to current or to bank money, and the contrary.**

100 ducats banco of Venice.

In Leghorn = 93 pezzos
In Lucca = 77 crowns
In Rome = 68¾ crowns
In Frangfort = 139½ florins

**Decimal.**

160 = 16954 0
160 = 237356
160 = 169540

Lires 19497 2

And lire money is reduced to exchange money by dividing it by 54.

**Soldi of Genoa.**

| In Milan, 1 crown | = 80 |
| In Naples, 1 ducat | = 86 |
| In Leghorn, 1 piastra | = 20 |
| In Sicily, 1 crown | = 127½ |

**VIII.**
VIII. Exchange with Leghorn.

**Money Table.**

12 Denari = 1 soldi 
20 Soldi = 1 piastre = 4 6 Ster.

Books and accounts are kept in piastres, soldi, and denari. The piastre here contains 6 lires, and the lire contains 20 soldi, and the soldi 12 denari, and consequently exchange money is 6 times better than lire money. The course of exchange is from 47 d. to 58 d. Sterling per piastre.

*Example.* What is the Sterling value of 731 piastres, at 55½d. each.

<table>
<thead>
<tr>
<th>731 piastres, at 55½d.</th>
<th>4 or 48 = 146 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 = 18 5 6</td>
<td>4 11 4²</td>
</tr>
</tbody>
</table>

L. 169 0 10½ **Ans.**

Sterling money is reduced to money of Leghorn, by reversing the former operation; and exchange money is reduced to lire money by multiplying by 6, and lire money to exchange money by dividing by 6.

100 piastres of Leghorn are

In Naples = 134 ducats. | In Geneva = 185 ½ crowns.

**Soldi of Leghorn.**

In Sicily, 1 crown = 133¼ 
In Sardinia, 1 dollar = 95⅛.

The above are the chief places in Europe with which Britain exchanges directly; the exchanges with other places are generally made by bills on Hamburg, Holland, or Venice. We shall here however subjoin the par of exchange between Britain and most of the other places in Europe, with which we have any commercial intercourse.

**Par in Sterling.** L. s. d.

| Rome | 1 crown = 6 1½ |
| Naples, | 1 ducat = 3 4½ |
| Florence, | 1 crown = 5 4½ |
| Milan, | 1 ducat = 4 7 |
| Bologna, | 1 dollar = 4 3 |
| Sicily, | 1 crown = 5 0 |
| Vienna, | 1 rixdollar = 4 8 |
| Aixburg, | 1 florin = 3 1½ |
| Francfort, | 1 florin = 3 0 |
| Bremen, | 1 rixdollar = 3 6 |
| Breslau, | 1 rixdollar = 3 3 |
| Berlin, | 1 rixdollar = 4 0 |
| Stettin, | 1 mark = 1 6 |
| Embden, | 1 rixdollar = 3 6 |
| Bollenna, | 1 rixdollar = 3 8 |
| Dantzig, | 1⅓ florins = 1 0 0 |
| Stockholm, | 34½ dollars = 1 0 0 |
| Russia, | 1 ruble = 4 5 |
| Turkey, | 1 asper = 4 6 |

IX. Exchange with America and the West Indies.

In North America and the West Indies, accounts, as in Britain, are kept in pounds, shillings, and pence. In North America they have few coins circulating among them, and on that account have been obliged to substitute a paper-currency for a medium of their commerce; which having no intrinsic value, is subject to many disadvantages, and generally suffers a great discount. In the West Indies coins are more frequent, owing to their commercial intercourse with the Spanish settlements.

Exchange between Britain and America, or the West Indies, may be computed as in the following examples:

1. The net proceeds of a cargo from Britain to Boston amount to 845 l. 17s. 6d. currency: How much is that in Sterling money, exchange at 80 per cent.?

If 180 : 100

18 : 9 :: 4229 7 6

L. 469 18 7¼ **Ster. Ans.**

2. Boston remits to Britain a bill of 469 l. 18 s. 7¼d. Sterling: How much currency was paid for the bill at Boston, exchange at 80 per cent.?

If 100 : 180

5 : 9 :: 469 18 7¼

L. 4229 7 6

845 17 6 currency. **Ans.**

3. How much Sterling money will 1780 l. Jamaica currency amount to, exchange at 40 per cent.?

If 140 : 100

7 : 5 :: 1780

L. 1271 8 6¼ **Ster. Ans.**

Bills of exchange from America, the rate being high, is an expensive way of remitting money to Britain; and therefore merchants in Britain generally chuse to have the debts due to them remitted home in sugar, rum, or other produce.

X. Exchange with Ireland.

At Dublin, and all over Ireland, books and accounts are kept in pounds, shillings, and pence, as in Britain; and they exchange on the 100 l. Sterling.
The par of one shilling Sterling is one shilling and one penny Irish; and so the par of 1001. Sterling is 108L 6s. 8d. Irish. The course of exchange runs from 6 to 15 per cent.

Examp. I. London remits to Dublin 586L 10s. Sterling: How much Irish money will that amount to, exchange at 9\(^\frac{1}{4}\) per cent.?

\[
\begin{align*}
\text{If} & \quad 100 : 109\frac{1}{4} :: 586.5 \\
\text{8} & \quad 877 \\
800 : 877 & \quad 41055 \\
41055 & \quad 46920 \\
800)514360.5 & \\
\hline
542,950,625 & \\
\text{Ans.} 642L 193. Irish.
\end{align*}
\]

By practice.

\[
\begin{align*}
p. \text{cent.} & \quad 586.5 \\
10 & = \frac{1}{10} & \quad 58.65 \\
2 & = \frac{1}{2} & \quad 11.73 \text{sub.} \\
8 & = 46.92 & \\
1 & = \frac{1}{2} & \quad 5.805 \\
1\frac{1}{2} & = \frac{3}{2} & \quad 2.9225 \\
\frac{2}{3} & = \frac{4}{3} & \quad 1.73125 \\
9\frac{1}{2} & = 56.450625 & \\
800)514360.5 & \\
\hline
542,950,625 & \text{Ans.}
\end{align*}
\]

2. How much Sterling will 6251. Irish amount to, exchange at 10\(^\frac{1}{4}\) per cent.?

\[
\begin{align*}
\text{If} & \quad 110\frac{1}{4} : 100 :: 625 \\
8 & \quad 800 \\
883 & \quad 800 \times 883 = 700000 \times 566.5 = 0.6 \text{Ster. Ans.}
\end{align*}
\]

XI. Exchange betwixt London and other places in Britain.

The several towns in Britain exchange with London for a small premium in favour of London; such as, 1, 1\(^\frac{1}{4}\), &c. per cent. The premium is more or less according to the demand for bills.

Examp. Edinburgh draws on London for 8601. exchange at 1\(^\frac{1}{4}\) per cent.: How much money must be paid at Edinburgh for the bill?

\[
\begin{align*}
\text{L.} & \quad 860 \\
\text{per cent.} & \quad 10 \quad 1 \quad 1\frac{1}{2} \\
8 & = 12 \\
2 & = 1 \\
1 & = 6 \\
\hline
11 & 16 & 6 \text{ premium.} \\
871 & 16 & 6 \text{ paid for the bill.}
\end{align*}
\]

To avoid paying the premium, it is an usual practice to take the bill payable at London a certain number of days after date; and in this way of doing, 73 days is equivalent to 1 per cent.

XII. Arbitration of Exchanges.

The course of exchange betwixt nation and nation naturally rises or falls according as the circumstances and balance of trade happen to vary. Now to draw upon and remit to foreign places, in this fluctuating state of exchange, in the way that will turn out most profitable, is the design of arbitration. Which is either simple or compound.

I. Simple Arbitration.

In simple arbitration the rates or prices of exchange from one place to other two are given; whereby is found the correspondent price between the said two places, called the arbitrated price, or par of arbitration: and hence is derived a method of drawing and remitting to the best advantage.

Examp. I. If exchange from London to Amsterdam be 33 s. 9 d. per l. Sterling; and if exchange from London to Paris be 326. per crown; what must be the rate of exchange from Amsterdam to Paris, in order to be on a par with the other two?

\[
\begin{align*}
\text{Ster. Flem. Ster.} \\
\text{s.} & \quad 1 \quad \text{d.} \quad \text{d.} \\
\text{If} & \quad 20 : 33 \quad 9 :: 32 \\
12 & \quad 12 \\
\hline
240 & \quad 405 \\
32 & \\
810 & \quad 1215
\end{align*}
\]

240\times 12560\times 54 \text{ d. Flem. per crown. Ans.}

2. If exchange from Paris to London be 32 d. Sterling per crown; and if exchange from Paris to Amsterdam be 54 d. Flemish per crown; what must be the rate of exchange between London and Amsterdam, in order to be on a par with the other two?

\[
\begin{align*}
\text{Ster. Flem. Ster.} \\
\text{d.} & \quad \text{d.} \quad \text{d.} \\
\text{If} & \quad 32 : 54 :: 240 \\
240 & \\
\hline
216 & \\
108 & \quad \underline{12} \quad \text{i. d.} \\
32\times 12960\times 405 \text{ (33 9 Flem. per l. Ster. Ans.)}
\end{align*}
\]

From these operations it appears, that if any sum of money be remitted, at the rates of exchange mentioned, from any one of the three places to the fecond, and from the fecond to the third, and again from the third to the firft, the sum so remitted will come home entire, without increase or diminution.
From the par of arbitration thus found, and the course of exchange given, is deduced a method of drawing and remitting to advantage, as in the following example.

3. If exchange from London to Paris be 32 d. Sterling per crown, and to Amsterdam 405 d. Flemish per l. Sterling; and if, by advice from Holland or France, the course of exchange between Paris and Amsterdam is fallen to 52 d. Flemish per crown; what may be gained per cent. by drawing on Paris, and remitting to Amsterdam?

The par of arbitration between Paris and Amsterdam in this case, by Ex. 1. is 36 d. Flemish per crown. Work as under.

\[
\begin{array}{c|c|c|c|c|c}
\text{d. St.} & \text{L. St.} & \text{Cr.} \\
32 & : & 1 & :: & 100 & : & 750 \\
\hline
\text{Cr. d. Fl.} & \text{Cr. d. Fl.} \\
52 & : & 1 & :: & 39000 & : & 100 \\
\hline
\text{d. Fl. L. St. d. Fl.} & \text{L. s. d. Ster.} \\
405 & : & 1 & :: & 965 & : & 6.5 \\
\hline
\end{array}
\]

But if the course of exchange between Paris and Amsterdam, instead of falling below, rise above the par of arbitration, suppose to 56 d. Flemish per crown; in this case, if you propose to gain by the negotiation, you must draw on Amsterdam, and remit to Paris. The computation follows.

\[
\begin{array}{c|c|c|c|c|c}
\text{L. St. d. Fl.} & \text{L. St.} & \text{d. Fl.} \\
100 & : & 420 & :: & 100 & : & 420000 \\
\hline
\text{d. Fl. Cr.} & \text{d. Fl. Cr.} \\
29 & : & 1 & :: & 724 & : & 100 \\
\hline
\text{L. s. d. Ster.} \\
34 & : & 1 & :: & 56 & : & 420000 \\
\hline
\end{array}
\]

In negotiations of this sort, a fund for remittance is afforded out of the sum you receive for the draught; and your credit at the one foreign place pays your debit at the other.

II. Compound Arbitration.

In compound arbitration the rate or price of exchange between three, four, or more places, is given, in order to find how much a remittance passing through them all will amount to at the last place; or to find the arbitrated price, or par of arbitration, between the first place and the last. And this may be done by the following

Rules. I. Distinguish the given rates or prices into antecedents and consequents; place the antecedents in one column, and the consequents in another on the right, fronting one another by way of equation.

II. The first antecedent, and the last consequent to which an antecedent is required, must always be of the same kind.

III. The second antecedent must be of the same kind with the first consequent, and the third antecedent of the same kind with the second consequent, &c.

IV. If to any of the numbers a fraction be annexed, both the antecedent and its consequent must be multiplied into the denominator.

V. To facilitate the operation, terms that happen to be equal or the same in both columns, may be dropped or rejected, and other terms may be abridged.

VI. Multiply the antecedents continually for a divisor, and the consequents continually for a dividend, and the quot will be the answer or antecedent required.

Example. 1. If London remit 1000 l. Sterling to Spain, by way of Holland, at 35 s. Flemish per l. Sterling; thence to France, at 38 d. Flemish per crown; thence to Venice, at 100 crowns per 60 ducats; and thence to Spain, at 360 meravides per ducat; how many piastras, of 272 meravides, will the 1000 l. Sterling amount to in Spain?

\[
\begin{array}{c|c|c|c|c|c}
\text{Antecedents.} & \text{Consequents.} & \text{Abridged.} \\
1000 & : & 420000 & : & 724 & : & 1000 \\
35 & : & 38 & :: & 1 & :: & 100 \\
100 & :: & 60 & :: & 1 & :: & 272 \\
1 & :: & 360 & :: & 1 & :: & 272 \\
272 & :: & 1 & :: & 100 & :: & 493 \\
\hline
\text{Aft.} & & & & & & \\
\end{array}
\]

In order to abridge the terms, divide 58 and 420 by 2, and you have the new antecedent 29, and the new consequent 210; reject two ciphers in 100 and 1000; divide 272 and 360 by 8, and you have 34 and 45; divide 34 and 60 by 2, and you have 17 and 30; and the whole will stand abridged as above.

Then, 29 \times 17 = 493 divisor; and, 210 \times 30 \times 45 \times 10 = 2835000 dividend; and, 493 \times 2835000(5750\frac{1}{2} piastras. Aft.

Or, the consequents may be connected with the sign of multiplication, and placed over a line by way of numerator; and the antecedents, connected in the same manner, may be placed under the line, by way of denominator; and then abridged, as follows:

\[
\begin{align*}
420 \times 60 \times 360 & \times 100 = 210 \times 60 = 360 \times 10 \\
58 \times 100 \times 272 & = 29 \times 10 \times 272 \\
210 \times 60 \times 45 & \times 100 = 210 \times 20 \times 45 \times 10 \\
29 \times 34 & = 29 \times 17 \\
\hline
2835000 & = 493 \\
493 & = 493 \\
\text{And, 493} & \times 2835000(5750\frac{1}{2} \text{ piastras. Aft.}
\end{align*}
\]

The placing the terms by way of antecedent and consequent, and working as the rules direct, save so many statedings of the rule of three, and greatly shortens the operation. The proportions at large for the above question would stand as under.

\[
\begin{array}{c|c|c|c|c|c|c}
\text{L. St. d. Fl.} & \text{L. St.} & \text{d. Fl.} \\
1000 & : & 420000 & : & 724 & : & 1000 \\
\hline
\text{d. Fl. Cr.} & \text{d. Fl. Cr.} \\
29 & : & 1 & :: & 17 & : & 1000 \\
\hline
\text{Cr.} & & & & & & \\
\end{array}
\]
If we suppose the course of direct exchange to Spain to be 42½ d. Sterling per piaffe, the 1001. remitted would only amount to 5647½ piaffres; and, consequently, 103 piaffres are gained by the negotiation; that is, about 2 per cent.

2. A banker in Amsterdam remits to London 400 l. Flemish; first to France at 56 d. Flemish per crown; from France to Venice at 100 crowns per 60 ducats; from Venice to Hamburg at 100 d. Flemish per ducat; from Hamburg to Lisbon at 100 d. Flemish per cruade of 400 rees; and, lastly, from Lisbon to London at 64 d. Sterling per milree. How much Sterling money will the remittance amount to? and how much will be gained or saved, supposing the direct exchange from Holland to London at 36s. 10 d. Sterling?

\[
\begin{align*}
\text{Antecedents} & \quad \text{Consequents} \\
56 \text{ d. Flem.} & = 1 \text{ crown} \\
100 \text{ crowns} & = 60 \text{ ducats} \\
1 \text{ ducat} & = 100 \text{ d. Flem.} \\
50 \text{ d. Flem.} & = 400 \text{ rees} \\
1000 \text{ rees} & = 64 \text{ d. Sterling}
\end{align*}
\]

How many d. Ster = 400l. or 96000 d. Flemish?

This, in the fractional form, will stand as follows.

\[
\frac{60 \times 100 \times 400 \times 64 \times 96000}{56 \times 100 \times 50 \times 100} = \frac{368640}{7}
\]

\(7)368640(52662\frac{1}{2} \text{ d. Ster.} = 219l. 8. s. 6\frac{1}{2} \text{ d. St. Anf.}\)

To find how much the exchange from Amsterdam directly to London, at 36s. 10 d. Flemish per l. Sterling, will amount to, say,

\[
\begin{align*}
\text{d. d.} & \quad \text{d. Fl. L. d. Fl. L. i. d. St.} \\
36 \text{ 10} & \quad 1442 \quad 442 \\
12 & \quad 219 \quad 8 \quad 6\frac{1}{2}
\end{align*}
\]

Gained or saved, \(2 \quad 4 \quad 8\frac{1}{2}\)

In the above example, the par of arbitration, or the arbitrated price, between London and Amsterdam, viz. the number of Flemish pence given for 1 l. Sterling, may be found thus:

Make 64 d. Sterling, the price of the milree, the first antecedent; then all the former consequents will become antecedents, and all the antecedents will become consequents. Place 240, the pence in 1 l. Sterling, as the last consequent, and then proceed as taught above, viz.

Vol. II. No 48.

EXCHEQUER, in the British jurisprudence, an ancient court of record, in which all causes concerning the revenues and rights of the crown are heard and determined, and where the crown-revenues are received. It took this name from the cloth that covered the table of the court, which was party-coloured, or chequered. This court is said to have been erected by William the conqueror, its model being taken from a like court established in Normandy long before that time. Anciently its authority was so great, that it was held in the king's presence, and the acts thereof were not to be examined or controlled in any other of the king's courts; but, at present, it is the last of the four courts at Westminster.

EXCHANGE signifies also a place in most considerable trading cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet on certain days, and at certain times thereof, to confer and treat together of matters relating to exchanges, remittances, payments, adventures, assurances, freightments, and other mercantile negociations, both by sea and land.
In the exchequer, some reckon seven courts, viz. the office of pleas, accounts, receipts, exchequer-chamber, (which is an assembly of all the judges on difficult matters in law) errors in the exchequer, errors in the king's bench, and, lastly, the court of equity in the exchequer.

But the exchequer, for dispatch of business, is generally divided into two parts; one of which is chiefly conversant in the judicial hearing and deciding of all causes relating to the king's coffers, formerly termed the exchequer of accounts; the other is called the receipt of the exchequer, as being principally employed in receiving and payment of money.

Officers of the receipt may take one penny in the pound, as their fee for sums issued out; and they are obliged, without delay, to receive the money brought thither; and the money received is to be put in chests under three different locks and keys, kept by three several officers. All sheriffs, bailiffs, &c. are to account in the exchequer; and in the lower part, termed the receipt, the debtors of the king, and persons in debt to them, the king's tenants, and the officers and ministers of the court, are privileged to sue one another, or any stranger, and to be sued in the like actions as are brought in the courts of king's bench and common pleas.

The judicial part of the exchequer, is a court both of law and equity. The court of law is held in the office of pleas, according to the course of common law, before the barons: in this court, the plaintiff ought to be a debtor or accountant to the king; and the leading process is either a writ of subpœna, or quo minus, which last goes into Wales, where no process out of our courts of law ought to run, except a capias utulagatum.

The court of equity is held in the exchequer-chamber before the treasurer, chancellor, and barons; but, generally, before the barons only; the lord chief baron being the chief judge to hear and determine all causes. The proceedings in this part of the exchequer, are by English bill and answcr, according to the practice of the court of chancery; with this difference, that the plaintiff here must likewise set forth that he is a debtor to the king, whether he be fo or not. It is in this court of equity that the clergy exhibit bills for the recovery of their tythes, &c. Here too the attorney-general exhibits bills for any matters concerning the crown; and a bill may be exhibited against the king's attorney by any person aggrieved in any cause prosecuted against him on behalf of the king, to be relieved therein: in which case, the plaintiff is to attend on the attorney-general with a copy of the bill, and procure him to give in an answer thereto; in the making of which he may call in any person interested in the cause, or any officer, or others, to instruct him, that the king be not prejudiced thereby, and his answer is to be put in without oath.

But besides the business relating to debtors, farmers, receivers, accountants, &c. all penalty punishments, intrufion, and forfeitures upon popular actions; are matters likewise cognizable by this court; where there also sits a puisne-baron, who administers the oaths to high-sheriffs, bailiffs, auditors, receivers, collectors, comptrollers, surveyors and searchers of all the customs, &c.

The exchequer in Scotland, has the same privileges and jurisdiction as that of England; and all matters competent to the one, are likewise competent to the other.

**Black book of the Exchequer.** A book containing a description of the court of England in 1755, and its officers, with their ranks, wages, privileges, perquisites, &c. also the revenues of the crown, both in money and cattle.

**EXCIPIENT, in pharmacy, denotes the ingredient, which, in compound medicines, receives all the rest; as the conserve in electuaries, the syrup in balsues, &c.**

**EXCISE, a certain duty or imposts charged upon liquors, as beer, ale, cider, &c. malt, and several other commodities, within the kingdom of Great Britain, and town of Berwick upon Tweed.**

The excise is one of the most considerable branches of the king's revenue. It was formerly farmed out, but is now managed for the king by commissioners in both kingdoms, who receive the whole product of the excise, and pay it into the exchequer. These commissioners are nine in number in England; and four in Scotland. The former have a salary of 1000l. a year, the latter 500l. They are obliged by oath to take no fee or reward but from the king himself; and from them there lies an appeal to five other commissioners called commissioners of appeals.

The duty of excise was first granted to king Charles II. by act of parliament in the year 1660, during the life of that monarch. 1. It was 3d. per barrel upon every barrel of beer or ale above 6s. the barrel, and 3d. per barrel for every barrel of 6s. s. or under, brewed for retail; 15d. for every hoghead of cyder or perry fold by retail; 1d. for every gallon of strong water, aqua vitae, &c. 2. A new excise was granted for ever by the fifth money-act of William and Mary, being for every barrel of beer or ale above 6s. the barrel, 9d.; and for every barrel of 6s. or under, 3d.; for every hoghead of cyder or perry, 1s. per hoghead. In the excise, the price of the liquor is to be reckoned exclusive of the duty. 3. An excise was granted of 6d. a barrel on malt in the reign of king William, which by subsequent statutes has been continued yearly ever since. But such malt as shall be made for exportation, and be not entered and kept separate from other malt, is exempted from the payment of this duty. 4. Another new excise upon home-made liquors was granted in queen Anne's reign; being an additional excise upon every barrel of beer or ale brewed for sale above 6s. the barrel, 3d. exclusive of the duties; and for every barrel at 6s. or under, 1d.; for every hoghead of cyder or perry, 5d.; for every gallon of strong waters or aqua vitae, 1d. This excise was not laid upon any such liquors imported. 5. An excise on candles was first granted in the reign of queen Anne, and continued for ever, being a duty of 4d. a pound on wax, and a halfpenny the pound on tallow candles, made in Great Britain for sale or not for sale; but makers for their own use may compound for 1s. a head for every person in their family. An additional excise on candles was afterwards granted.
granted, being the same with the former in every respect.

6. An excise upon hides and skins tanned in Britain, first granted in queen Anne's reign, was an excise of seventeen different kinds, upon so many different kinds of hides and skins particularly named, and upon all others not named, 131 per cent. ad valorem. An additional excise was afterwards granted, being an additional duty of different kinds, upon so many different sorts of hides and skins particularly named, and on all others not named, 151 per cent. on the value. 7. An excise on home-made vellum and parchment, first granted by the same act, being 1 s. per dozen on vellum, and 6 d. the dozen on parchment. And afterwards an additional excise on vellum, &c. was granted, being an additional duty of 25 s. the dozen on vellum, and 1 s. the dozen on parchment. 8. An excise on hops of home growth was first granted in queen Anne's reign, being 1 d. per pound. 9. An excise on paper, pale-boards, milled-boards, and scale-boards, was first granted in the reign of queen Anne, being a duty of eleven different kinds on so many different sorts of paper particularly named, made in Great Britain; on pale-boards, &c. 3 s. the hundred weight, and on all sorts of paper not named, 121 3. per cent. on the value. An additional duty on paper, &c. was granted of eleven different kinds, &c. on pale-boards, 1 s. 6 d. the hundred weight, and on all sorts of paper not named, 61. per cent. on the value; and on painted paper for hangings, a half-penny the yard square. 10. An excise of 1 d. per pound on soap made in Great Britain, was granted by the same act; to which an additional excise has been added of a halfpenny per pound. 11. An excise upon printed silks, callicoes, linens and stuffs made in Great Britain, and printed, painted, stained or dyed here, was first granted in queen Anne's reign, being a duty of 3 d. on silks and callicoes, and 14 d. on linen and stuffs the yard square, excepting silk handkerchiefs, linens and fullfains dyed of one colour, and stuffs made of woolen, or the greatest part in value of woolen. And an additional excise was granted of 6 d. the yard of half-yard broad silks; 1 d. the yard square of silk handkerchiefs; 3 d. the yard square of callicoes, and 1 d. the yard square of linens and stuffs, excepting, as before, callicoes, &c. dyed of one colour, and woolen stuffs. 12. An excise on itch on itch first granted for 1 d. the pound; and afterwards an additional excise of 1 d. the pound. 13. The excise on gilt and silver wire made in Great Britain, is 8 d. the ounce on gilt wire, and 6 d. the ounce on silver wire.

If any brewers do not make true entries of their liquors brewed, once a-week at the excise-office, they forfeit 10 l. but this is subject to mitigation, so as not to be less than double the duty; and the retailers of beer and ale and strong waters, neglecting to make their entries once a-month of what liquors they retail, are liable to 40 s. penalty. In cafe any brewer erects or alters any back, copper, cooler, &c. or keeps a private flour-house, or if any maltier keeps any private vehicles for steeping barley, without giving proper notice to the officers of excise, such brewer or maltier forfeit 50 l. and where they bribe a gauger, it is 10 l. The officers of excise may go on board ships, and search for any excisable liquors, as officers of the customs do, and seize commodities forfeited, &c. and complaints made at the chief-office of excise are to be heard by three or more commissioner; but two justices of the peace have the power to determine in seizures out of the limits of the excise-office in London.

EXCLAMATION, in rhetoric, a figure that expresses the violent and sudden breaking out, and vehemence of any passion.

EXCOMMUNICATION, an ecclesiastical penalty or censure, whereby such persons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication among the Jews, according to Elias, a German rabbin, was distinguished into three kinds: 1. Niddui, which was a separation of but a few days; 2. Cherem, a separation attended with execration and malediction; and, 3. Shammatha, which was the last and greater excommunication. But Selden says, that Niddui and Shammatha are the same thing; and therefore that there were but two kinds of excommunication among the Jews, viz. the greater and the lesser. They made also another distinction in excommunication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular person in conversation might excommunicate another, and himself likewise; and this excommunication, if well grounded, was of force: nay, if a man dreamed that he was excommunicated by himself or by another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.

As to the effects of the Jewish excommunication, the lesser excluded the excommunicated person from the society of men; that is, he was not to come nearer than four cubits, neither he, his wife, children, or domestics, according to Buxtorf. The greater absolutely sequestered the person from the conversation of others; and sometimes he was shut up in a small chamber or prison, where he lived alone. Baronius and Beza pretend, that the greater excommunication was the same thing; and before, callicoes, &c. dyed of one colour, and woolen stuffs. 12. An excise on itch on itch first granted for 1 d. the pound; and afterwards an additional excise of 1 d. the pound. 13. The excise on gilt and silver wire made in Great Britain, is 8 d. the ounce on gilt wire, and 6 d. the ounce on silver wire.

If any brewers do not make true entries of their liquors brewed, once a-week at the excise-office, they forfeit 10 l. but this is subject to mitigation, so as not to be less than double the duty; and the retailers of beer and ale and strong waters, neglecting to make their entries once a-month of what liquors they retail, are liable to 40 s. penalty. In cafe any brewer erects or alters any back, copper, cooler, &c. or keeps a private flour-house, or if any maltier keeps any private vehicles for steeping barley, without giving proper notice to the officers of excise, such brewer or maltier forfeit 50 l. and where they bribe a gauger, it is 10 l. The officers of excise may go on board ships, and search for any excisable liquors, as officers of the customs do, and seize commodities forfeited, &c. and complaints made at the chief-office of excise are to be heard by three or more commissioner; but two justices of the peace have the power to determine in seizures out of the limits of the excise-office in London.

EXCLAMATION, in rhetoric, a figure that expresses the violent and sudden breaking out, and vehemence of any passion.

EXCOMMUNICATION, an ecclesiastical penalty or censure, whereby such persons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication among the Jews, according to Elias, a German rabbin, was distinguished into three kinds: 1. Niddui, which was a separation of but a few days; 2. Cherem, a separation attended with execration and malediction; and, 3. Shammatha, which was the last and greater excommunication. But Selden says, that Niddui and Shammatha are the same thing; and therefore that there were but two kinds of excommunication among the Jews, viz. the greater and the lesser. They made also another distinction in excommunication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular person in conversation might excommunicate another, and himself likewise; and this excommunication, if well grounded, was of force: nay, if a man dreamed that he was excommunicated by himself or by another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.

As to the effects of the Jewish excommunication, the lesser excluded the excommunicated person from the society of men; that is, he was not to come nearer than four cubits, neither he, his wife, children, or domestics, according to Buxtorf. The greater absolutely sequestered the person from the conversation of others; and sometimes he was shut up in a small chamber or prison, where he lived alone. Baronius and Beza pretend, that the greater excommunication was the same thing; and therefore that there were but two kinds of excommunication among the Jews, viz. the greater and the lesser. They made also another distinction in excommunication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular person in conversation might excommunicate another, and himself likewise; and this excommunication, if well grounded, was of force: nay, if a man dreamed that he was excommunicated by himself or by another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.
earth, and God is besought that a whirlwind may dash him to pieces. He is pelted with stones if he appear in the streets; and if he obtain an absolution, it is upon the most mortifying conditions; for he is publicly tied to a post and whipped, after which he lays himself down at the door of the synagogue, and all those who go out pass over him. This was the very case of the famous Jew Acosta.

In the ancient Christian church, the power of excommunication, as well as other acts of ecclesiastical discipline, was lodged in the hands of the clergy, who distinguished it into the greater and lesser. The lesser excommunication, simply called *aphorismos*, separation or excommunication, consisted in excluding men from the participation of the eucharist, and the prayers of the faithful. But they were not expelled the church; for they had the privilege of being present at the reading of the scriptures, the sermons, and the prayers of the catechumens and penitents. This excommunication was inflicted for lesser crimes, such as neglecting to attend the service of the church, misbehaviour in it, and the like.

The greater excommunication, called *panteles aphorismos*, total separation and anathema, consisted in an absolute and intire exclusion from the church and the participation of all its rites. When any person was thus excommunicated, notice was given of it by circular letters to the most eminent churches all over the world, that they might all conform to the discipline, and the prayers of the faithful. But they were not expelled the church; for they had the privilege of being present at the reading of the scriptures, the sermons, and the prayers of the catechumens and penitents. This excommunication was inflicted for lesser crimes, such as neglecting to attend the service of the church, misbehaviour in it, and the like.

The minor, incurred by those who have any correspondence with an excommunicated person. 2. The major, which falls upon those who disobey the commands of the holy see, or refuse to submit to certain points of discipline; in consequence of which they are excluded from the church militant and triumphant, and delivered over to the devil and his angels. 3. Anathema, which is properly that pronounced by the pope against heretical princes and countries. In former ages, these papal fulminations were most terrible things; but at present, they are formidable to none but a few petty states of Italy.

Excommunication in the Greek church, cuts the offender off from all communion with the 318 fathers of the first council of Nice, and with the saints; confines him over to the devil, and the traitor Judas; and condemns his body to remain after death as hard as a flint or piece of steel, unless he humbles himself and makes atonement for his sins by a sincere repentance. The form abounds with dreadful imprecations; and the Greeks assert, that if a person dies excommunicated, the devil enters into the lifeless corpse; and therefore, in order to prevent it, the relations of the deceased cut his body in pieces, and boil them in wine. It is a custom for the patriarch of Jerusalem annually to excommunicate the pope and the church of Rome; on which occasion, together with a great deal of idle ceremony, he drives a nail into the ground with a hammer, as a mark of malediction.

The form of excommunication in the church of England was to contain thus: “By the authority of God the Father Almighty, the Son and Holy Ghost, and of Mary the blessed mother of God, we excommunicate, anathematize, and sequestrate from the pale of holy mother church,” &c. The causes of excommunication in England are, contempt of the bishop's court, heresy, neglect of public worship and the sacraments, incontinency, adultery, simony, &c. It is published in the church; and if the offender does not submit in forty days, the civil magistrate interposes, and the excommunicated person is imprisoned till he submits and obtains absolution. Excommunication disables a person from doing any judicial act, as suing in an action at law, being a witness, &c.

Excommunication, among the Pagans, excluded the person from the sacrifices and the temples, and delivered him over to the furies, which was called *excrucia*, and *diris devovere*. When Marcus Crassus set out on his expedition against the Parthians, Atteius, tribune of the people, not being able to prevent him, ran to the gate of the city through which the general was to pass, and setting a chaffing-dish in the middle of the way with fire in it, when Crassus drew near, he threw some perfumes into the chaffing-dish, and pronounced curses against Crassus with great exclamation, and thus excommunicated him.

**EXCORIATION**, in medicine and surgery, the galing or rubbing off of the cuticle, especially of the parts between the thighs, and about the anus.

**EXCREMENT**, whatever is discharged out of the body of animals after digestion, or the fibrous parts of the aliment, mixed with the bile, saliva, and other fluids. Urine and the feces are the gross excrements that are discharged out of the bladder or belly. Other excrements are the various humours that are secreted from the blood through the various Skinner in the body, and which serve for several uses, such as the saliva, sweat, bile, the pancreatic juice, lymph, the semen, nails, the hair, the horns and hoofs of animals.

**EXCRESCENCE**, in surgery, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or tubercle. If they are born in a person, as they frequently are, they are called *nodi mutati*, or marks from the mother; but if the tumour is large, so as to depend from the skin like a fleshy mass, it is then called a farcoma.

**EXCRETION**, or *secretion*, in medicine, a separation of some fluid, mixed with the blood, by means of the...
EXEMPLAR, denotes much the same with model. See Model.

EXE (533) EXO

EXEMPLEIFICATION of letters patent, a transcript or duplicate of them, made from the enrollment there of, and sealed with the great seal.

EXEMPTION, in law, a privilege to be free from some service or appearance: thus, barons and peers of the realm are, on account of their dignity, exempted from being sworn upon inquests; and knights, clergymen, and others, from appearing at the sheriff's turn. Persons of seventy years of age, apothecaries, &c. are also by law exempted from serving on juries; and justices of the peace, attorneys, &c. from parochial offices.

EXERCISE, among physicians, such an agitation of the body, as produces salutary effects in the animal economy. See Medicine.

EXERCISE, in military affairs, is the ranging a body of soldiers in form of battle, and making them perform the several motions and military evolutions with different management of their arms, in order to make them expert therein.

EXERCITOR, in Scots law, he who employs a ship in trade, whether he be owner, or only freights her from the owner.

EXERGUM, among antiquarians, a little space around or without the figures of a medal, left for the inscription, cypher, device, date, &c.

EXETER, the capital city of Devonshire, situated on the river Ex, ten miles north of the British channel: W. long. 3° 40', N. lat. 50° 44'.

EXFOLIATION, a term used by surgeons for the skinning or peeling of a bone, or its rising and separating into thin lamina or scales.

EXHALATION, a general term for all effluvia or streams raised from the surface of the earth in form of vapour.

EXHIBIT, in law, is where a deed, or other writing, being produced in a chancery suit, to be proved by witnesses, the examiner, or commissioner appointed for the examination of any such, certifies on the back of the deed or writing, that the same was shown to the witness at the time of his examination, and by him sworn to.

EXHORTATION, in rhetoric, differs only from suasion, as being more directly addressed to the passions.

EXIGENT, in law, a writ which lies where the defendant is found, nor any effects of his within the county, by which he may be attached or disfrained.

EXIGENT, among lawyers, the same with an executory writ, and no longer in use.

EXIGENT, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or disfrained.

EXIGENT, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or disfrained.

EXIGENT, four officers in the court of common pleas, who make all exigents and proclamations, in all actions where proces of outlawry lies. Writs of supercédas, as well as the prothonotaries upon exigents, were likewise drawn up in their office.

EXILE. See Banishment.

EXISTENCE, that whereby any thing has an actual existence, or is said to be. See Metaphysics.

EXIT, in a theatrical sense, the action of a player in going off the stage, after he has played his part.

EXLEGALITUS, among lawyers, the same with an outlawed perfon.

EXOCOETUS, the Flying-fish, in ichthyology, a genus belonging to the order of abdominales. The head is scaly, and it has no teeth; it has ten radii in the branchiophge membrane; the body is whitish, and the glands. Excretions, by which we mean those that evacuate superfluous and heterogeneous humours, purify the mals of blood: the humours which are generated in the blood are excreted by the glands, and are replaced by a sufficient quantity of aliment.

EXCRETORY, in anatomy, a term applied to certain little ducts or vesicles, destined for the reception of a fluid, secreted in certain glandules, and other viscera, for the excretion of it in the appropriated places.

EXECUTION of summons or letters, in Scots law, see Execution of Testaments; see tit. 28.

EXECUTION, in military affairs, is the ranging a body of soldiers in form of battle, and making them perform the several motions and military evolutions with different management of their arms, in order to make them expert therein.

EXECUTOR, in Scots law, signifies either the person intitled to succeed to the moveable estate of one deceased, or who by law or special appointment is intrusted with the administration of it. See tit. 28.

EXECUTOR, in Scots law, is the moveable estate falling to the executor. Under executory, or moveables, is comprehended every thing that moves itself, or can be moved; such as corn, cattle, furniture, ready money, &c. See tit. 9. and 28.

EXECUTRY, in Scots law, signifies either the person intitled to succeed to the moveable estate of one deceased, or who by law or special appointment is intrusted with the administration of it. See tit. 28.

EXECUTION, in a general sense, the act of accomplishing, finishing, orachieving any thing.

EXECUTION of summons or letters, in Scots law, see Execution of Testaments; see tit. 28.

EXECUTION of civil sentences and decrees; see tit. 32.

EXECUTION of criminal sentences; see tit. 33.

EXECUTORS, among antiquaries, a general name for such buildings as were distant from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the executors the chief was the baptistory. See Baptistery.

EXEDRÆ, in antiquity, a general name for such buildings as were distant from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the executors the chief was the baptistory. See Baptistery.

EXEGESIS, a discourse by way of explanation or comment upon any subject. In the Scotch universities, there is an exercice among the students in divinity, called an exegesis, in which a question is flated by the respondent, who is then opposed by two or three other students in their turns; during which time the profefsor for moderates, and sovles the difficulties which the respondent cannot overcome.
EX OFFICIO, among lawyers, signifies the power a per
son has, by virtue of his office, to do certain acts without being applied to.

EXORCISM, among ecclesiastical writers, the expelling of a person who, after the drama or play was ended, sung the exodium. See EXODIUM.

EXODIUM, in the ancient Greek drama, one of the four parts or divisions of tragedy, being so much of the piece as included the catastrophe and unravelling of the plot, and answering nearly to our fourth and fifth acts.

EXODIUM, among the Romans, consisted of certain humorous verses rehearsed by the exodiary at the end of the Fabula Atellane.

EXODIUM, in the Septuagint, signifies the end or conclusion of a feast. Particularly it is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the exodus, or departure out of Egypt.

EXODUS, a canonical book of the Old Testament; being the second of the pentateuch, or five books of Moses.

EXPERIMENTAL philosophy, that philosophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to inquire into, and to investigate the reasons and causes of, the various appearances and phenomena of nature; and to make the truth or probability thereof obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature. See Mechanics, Hydrostatics, Optics, and the other branches of Natural Philosophy.

EXPIATION, a religious act, by which satisfaction, atonement, or amends, is made for the commission of some crime, the guilt done away, and the obligation to punishment cancelled.

The ceremony is performed at the lower end of the church, towards the door. The exorcist first signs the poisselled person with the sign of the cross, makes him kneel, and sprinkles him with holy water. Then follow the litanies, psalms, and prayer; after which the exorcist asks the devil his name, and adjures him by the mysteries of the Christian religion not to afflict the person any more: then, laying his right hand on the sinner's head, he repeats the form of exorcism, which is this: "I exorcise thee, unclean spirit, in the name of Jesus Christ: tremble, O Satan! thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who haft deprived men of life, and haft rebelled against justice; thou seducer of mankind, thou root of evil, thou source of avarice, discord, and envy.

EXPERIENCE, a kind of knowledge acquired by long use, without any teacher. Mr Locke says, that men derive all the materials of knowledge from experience and observation.

EXPERIMENT, in philosopshy, is the trial of the result or effect of the applications and motions of certain natural bodies, in order to discover something of their motions and relations, whereby to ascertain some of their phenomena, or causes.

EXPERIMENTAL PHILOSOPHY, that philosophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to inquire into, and to investigate the reasons and causes of, the various appearances and phenomena of nature; and to make the truth or probability thereof obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature. See Mechanics, Hydrostatics, Optics, and the other branches of Natural Philosophy.

EXPIATION, a religious act, by which satisfaction, atonement, or amends, is made for the commission of some crime, the guilt done away, and the obligation to punishment cancelled.

The method of expiation among the Jews was chiefly by sacrifice, whether for sins of ignorance, or to purify themselves from certain pollutions.

Great day of Expiation, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answers to our September. On this occasion the high-priest laid aside his breast-plate and embroidered ephod, as being a day of humiliation. He first offered a bullock and a ram for his own sins, and those of the priests;
pries; then he received from the heads of the people two goats for a sin-offering, and a ram for a burnt-offering, to be offered in the name of the whole multitude. It was determined by lot which of the goats should be sacrificed, and which left at liberty. After this he perfumed the sanctuary with incense, and sprinkled it with blood; then, coming out, he sacrificed the goat upon which the lot had fallen. This done, the goat which was to be left at liberty being brought to him, he laid his hands upon its head, confessed his sins, and the sins of the people, and then sent him away into some defart place: it was called azazel, or the scape-goat.

As to the expiations among the heathens, they were of several kinds, as sacrifices, and religious washings.

**Expiation**, in a figurative sense, is applied by divines to the pardon procured to men's sins, by the merits of Christ's death.

**Expiration**, in phyic, that part of respiration whereby the air is expelled, or driven out of the lungs.

**Explicit**, in the schools, something clear, distinct, formal, and unfolded.

**Explosion**, in physics, is properly applied to the going off of gun powder and the report made thereby. Hence, it is used to express such sudden actions of bodies as generate air instantaneously.

**Exponent**, in algebra. See Algebra.

**Exponent** is also used in arithmetic, in the same sense as index or logarithm.

**Exportation**, the shipping and carrying out of the kingdom wares and commodities for other countries. See Commerce.

**Exposition**, in general, denotes the setting a thing open to public view: thus it is the Romanists say, the host is exposed, when shewn to the people.

**Exposition**, in a literary sense, the explaining an author, passage, writing, or the like, and setting their meaning in an obvious and clear light.

**Expositor**, or Expository, a title given to small dictionaries, serving to explain the hard words of a language.

**Expostulation**, in rhetoric, a warm address to a person, who has done another some injury, representing the wrong in the strongest terms, and demanding redress.

**Exposure**, in gardening, the situation of a garden, wall, or the like, with respect to the points of the compass, as south or east.

**Express**, something that is determinate or precise, or in such formal terms as leaves no room for doubt.

**Express** also denotes a courier. See Courier.

**Expression**, in rhetoric, the elocution, diction, or choice of words in a discourse. See Composition.

**Expression**, in painting, a natural and lively representation of the subject, or of the several objects intended to be shewn.

The expression consists chiefly in representing the human body and all its parts, in the action suitable to it: in exhibiting in the face the several passions proper to the figures, and observing the motions they impress on the external parts.

**Expulsion**, in a general sense, the act of violently driving a person out of any city, society, &c.

**Expulsion**, in medicine, the act whereby any thing is forcibly driven out of the place in which it is: thus we say, the expulsion of the fetus in delivery.

**Extasy**, a transport which surpasses the function of the senses, by the intense contemplation of some extraordinary or supernatural object.

**Extasy**, in medicine, a species of catalepsy, when a person perfectly remembers, after the paroxysm is over, the ideas he conceived during the time it lasted.

**Extension**, in philosophy, one of the common and essential properties of body, or that by which it poiffeles or takes up some part of universal space, which is called the place of that body. See Metaphysics.

**Extensor**, an appellation given to several muscles, from their extending or stretching the parts to which they belong. See Anatomy, Part II.

**Old and new Extent**, in Scots law. The old extent was a valuation or effimate of the annual value of all the lands in Scotland, taken (it is thought before the reign of Alexander III.) for the purpose of proportionating the public subsidies, and ascertaining the rates of certain feudal casualties. By improvement, and the alteration in the nominal value of money, this valuation, or old extent, became, in length of time, too low a standard for computing their feudal casualties; wherefore, about the reign of Robert I. all iniquels for serving heirs were ordained to take proof alfo of the present value of the lands contained in the brief. This last was called the new extent. See Scots Law, title 12.---None of these extents is the rule by which the land-tax is now proportioned in Scotland. See Valuation, or Valued Rent.

**Exterior**, or External. See External.

**Extermination**, in general, the extirpating or destroying something.

**Extermination**, in Algebra. See Algebra, p. 104.

**External**, a term of relation applied to the surface or outside of a body; or that part which appears or presents itself to the eye, touch, &c. in contradistinction to internal.

**External** is also used to signify any thing that is without a man, or that is not within himself, particularly in his mind, in which sense we may say external objects, &c.

**Extinction**, in general, denotes the putting out or destroying something.

**Extinguishment**, in law, is a confolidation or union, as where one has due to him a yearly rent out of lands, and afterwards purchases the lands out of which the rent arises: in this case, both the property and the rent being united in one possessor, the rent is said to be extinguished.

**Extrication**, the same with extermination. See Extinction.

**Exstitipex**, in antiquity, the person who drew prelages from viewing the intrails of animals offered in sacrifice.
EXT (556) EZR

EXTRINSIC, among metaphysicians, is taken in various senses: sometimes it signifies a thing's not belonging to the essence of another; in which sense, the efficient cause and end of a thing are said to be extrinsic. Sometimes it signifies a thing's not being contained within the capacity of another; in which sense, these causes are called extrinsic which introduce something into a subject from without, as when a fire introduces heat. Sometimes it signifies a thing added or applied to another; in which sense accidents and adherents are said to be extrinsic to the subjects to which they adhere. Sometimes the vision is said to be extrinsic from some form which does not exist in that thing, but is adjacent to it, or by some means or other without it.

EXTRAVAGANTES, those decretal epistles, which were published after the clementines. See Clementines.

They were so called because, at first, they were not digested, or ranged, with the other papal constitutions, but seemed to be, as it were, detached from the canon law. They continued to be called by the same name when they were afterwards inserted in the body of the canon law. The first extravagantes are those of John XXII. successor of Clement V. The last collection was brought down to the year 1483, and was called the common extravagantes, notwithstanding that they were likewise incorporated with the rest of the canon law.

EXTRAVERSATION, in surgery. See Ulcer.

EXVULPE, among naturalists, denote the cast-off parts or coverings of animals, as the skins of serpents, caterpillars, and other insects.

EYE, in anatomy. See Anatomy, p. 289.

EYE-Glass, in the microscope. See Microscope and Optics.

EYEMOUTH, or AYMOOUTH, a port-town of Scotland, about six miles north of Berwick.

EYRAC, or Izaca-arabic, a province of Asia. Turky, situated on the river Euphrates, being the ancient Chaldea or Babylon.

EYRAE, or IRAC-AEEN, the ancient Parthia, now the principal province of Persia, is situated almost in the centre of that kingdom, its capital city being Isphahan, the metropolis of the whole kingdom.

EYRE, or EIRE, in law, the court of itinerant justices. See Justices.

EYSENACH, a city of Germany, in the circle of Upper Saxony: E. long. 10° 12' and N. lat. 51°.

EZEKIEL, a canonical book of the Old Testament, referring chiefly to the degenerate manners and corruptions of the Jews of those times.

It abounds with fine sentences and rich comparisons, and discovers a good deal of learning in profane matters.

Ezekiel was carried captive to Babylon with Jehoiakim, and began his prophecies in the fifth year of the captivity. He was cotemporary with Jeremiah, who prophesied at the same time in Judea. He foretold many events, particularly the destruction of the temple, the fatal catastrophe of those who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

EZRA, a canonical book of the Old Testament, comprehending the history of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. It specifies the number of Jews who returned, and Cyrus's proclamation for the rebuilding the temple, together with the laying its foundation, the obstructions it met with, and the finishing thereof in the reign of Darius.

The illustrious author of this book, was also the refiner and publisher of the canon of the Old Testament.
FACTITIOUS, any thing made by art, in opposition to native, or natural, from which the word is derived.

FACTOR, in commerce, is an agent or correspondent.

FABLE, a tale, or feigned narration, designed either to instruct or divert, disguised under the allegory of an action, &c.

Fables were the first pieces of wit that made their appearance in the world, and have been still highly valued, not only in times of the greatest simplicity, but among the most polite ages of the world. Joatham's fable of the trees is the oldest that is extant, and as beautiful as any that have been made since. Nathan's fable of the poor man is next in antiquity. We find Aesop, in the most distant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeased by the fable of the belly and the members. As fables had their rise in the very infancy of learning, they never flourished more than when learning was at its greatest height; witness Horace, Boileau, and Fontaine.

FABLE, also used for the plot of an epic or dramatic poem; and is, according to Aristotle, the principal part, and, as it were, the soul of a poem. See Composition.

FACE, in anatomy, comprehends all that part of the head which is not covered with the common hair. See Anatomy, Part I. II. and VI.

FACE, in the military art, a word of command, intimately to turn about: thus, face to the right, is to turn upon the left heel a quarter-round to the right; and, face to the left, is to turn upon the right heel a quarter-round to the left.

FACE, or Facette, among jewellers, is the name of the little faces or planes to be found in brilliant and rose diamonds.

FACTION, a cabal or party formed in a state, city, or company.

FACTION, in antiquity, a name given to the different companies of combatants in the circus. They were four, viz. the white, the red, the green, and the blue; to which Domitian added another of purple colour. They were so denominated from the colour of the liversies they wore, and were dedicated, according to M. Aurelius. Callidius, to the four feasons of the year, the green being consecrated to spring, the blue to winter, the red to summer, and the white to autumn. It appears from ancient inscriptions, that each faction had its procurators and physician; and from history, that party rage ran so high among them, that in a diffusion between two factions, in the time of Julianus, almost forty thousand men lost their lives in the quarrel.

FACTITIOUS, anything made by art, in opposition to what is the produce of nature. Thus, factitious cinnambar is opposed to native cinnambar.

FACTOR, in commerce, is an agent or correspondent.

A factor receives from the merchants, his constituents, in lieu of wages, a commissione or factorage, according to the usage of the place where he resides, or in the business he transacts, this being various in different countries, on the purchases and sales of different commodities. He ought to keep strictly to the tenor of his orders; as a deviation from them, even in the most minute particular, exposes him to make ample satisfaction for any loss that may accrue from his non-ob servance of them. When unlimited orders are given to factors, and they are left to sell or buy on the best conditions they can, whatever detriment occurs to their constituents, they are excused, as it is to be presumed they acted for the belt, and were governed by the dictates of prudence. But a bare commissione to sell is not sufficient authority for the factor to trust any person, wherefore he ought to receive the money on the delivery of the goods; and, by the general power, he may not trust beyond one, two, or three months, &c. the usual time allowed for sales, otherwise he shall be answerable out of his own estate. If a factor sells on the usual trust to a person of good credit, who afterwards becomes insolvent, he is discharged; but not if the man's credit was bad at the time of sale. If a factor gives a man time for payment of money contracted on sale of his principal's goods, and, after that time is elapsed, sells him goods of his own for ready money, and the man becomes insolvent, the factor in equity ought to indemnify his principal; but he is not compellable by the common law. A factor should always be punctual in the advices of his transactions, in sales, purchases, freights, and more especially in draughts by exchange. If he purchases goods for another at a price limited, and afterwards they rise, and he fraudulently takes them for his own account, and sells them to another part, in order to secure an advantage that seemingly offers, he will, on proof, be obliged, by the custom of merchants, to satisfy his principal for damages. If a factor, in conformity with a merchant's orders, buys with his money, or on his credit, a commodity he shall be directed to purchase; and, without giving advice of the transaction, sells it again to profit, and appropriate to himself the advantage, the merchant shall recover it from him, and besides have him amerced for his fraud. When factors have obtained a profit for their principal, they must be cautious how they dispose of it; for, if they act without commissione, they are responsible; and if a merchant remits goods to his factor, and about a month after draws a bill on him, the factor, having effects in his hands, accepts the bill, then the principal breaks, and the goods are seized in the factor's hands.
for the behalf of the creditors, it has been conceived the factor must answer the bill notwithstanding, and come in a creditor for so much as he was obliged, by reason of his acceptance, to pay. A factor who enters into a charter-party with a master for freight, is obliged by the contract; but if he loads aboard generally, the principal and the lading are liable for the freightment, and not the factor. If a factor, having money in his hands belonging to his principal, neglects to insure a ship and goods, according to order; if the ship miscarries, the factor, by the custom of merchants, shall make good the damage; and if he make any composition with the insurers after insurance, without orders so to do, he is answerable for the whole insurance.

As fidelity and diligence are expected from the factor, so the law requires the like from the principal: if, therefore, a merchant remits counterfeit jewels to his factor, who sells them as if true; if he receive loss or prejudice by imprisonment or other punishment, the principal shall not only make full satisfaction to the factor, but to the party who bought the jewels.

What is here said of factors, is meant of such as reside abroad to act for merchants, and may be applied to supercargoes, who go a voyage to dispose of a cargo, and afterwards return with another to their principals: but it is also the custom of the merchants of the highest credit throughout the world, to act mutually in the capacity of factors for each other. The business so executed is called commissio busines, and is generally desirable by all merchants, provided they have always effects in their hands, as a security for all the affairs which they transact for the account of others. And this class of traders of established reputation, have current as well as commission account, confiantly between them, and draw on, remit to, and send commissions to each other only by the intercourse of letters, which, among men of honour, are as obligatory and authoritative as all the bonds and ties of law. FACTOR, in arithmetic. See ARITHMETICK, p. 371.

FACTORAGE, called also commissio, is the allowance given to factors by the merchant who employs them. The gain of factorage is certain, however the voyage or sale prove to the merchant: but the commissions vary; at Jamaica, Barbadoes, Virginia, and most of the western parts of the world, the commissio runs at 8 per cent. generally through Italy, 2½; in France, Spain, and Portugal, &c. 2; and in Holland and other places near home, 1½ per cent.

FACTORY is a place where a considerable number of factors reside, to negotiate for their masters or employers. See FACTOR.

The most considerable factories belonging to the Britifh are those established in the East-Indies, Portugal, Turkey, &c.

FACTUM, in arithmetic, the product of two quantities multiplied by each other.

FACTULAE, in astrononomy, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed upon or about the surface of the sun: they are but very seldom seen.

FACULTY, in law, a privilege granted to a person, by favour and indulgence, of doing what, by law, he ought not to do.

For granting these privileges, there is a court under the archbishop of Canterbury, called the court of the faculties, the chief officer whereof is styled master of the faculties; who has a power of granting dispensations in divers cases, as to marry without the bans being first published; to eat flesh on days prohibited; to ordain a deacon under age; for a ton to succeed his father in his benefice; a clerk to hold two or more livings, &c.

FACULTY, in the schools, a term applied to the different members of an university, divided according to the arts and sciences taught there: thus in most universities there are four faculties, viz. 1. Of arts, which include humanity and philosophy. 2. Of theology. 3. Of physics. And 4. Of civil law.

FACULTY of Advocates. See Advocates.

FAELLENT, in chemistry, the gross matter, or sediment, that settles at the bottom after distillation, fermentation, and the like.

FACES, in medicine, the excrescences voided by fcurf.

FACELENT, in general, is applied to things abounding with faces, or dregs: thus the blood and other humours of the human body, are said to be fcurful, when without that purity which is necessary to health.

FAENSA, a city and bishop's fee of Italy, situated in the pope's territories, about thirty miles east of Bologna: E. long. 12° 38', and N. lat. 44° 30'.

FAGARA, in botany, a genus of the tetrandria monoclia clas. The calix consists of four segments, and the corolla of four petals; and the capsule has four cells, two valves, and contains one seed. There are three species, none of them natives of Britain.

FAGGOT, in times of popery here, was a badge worn on the sleeve of the upper garment of such persons as had recanted, or abjured what was then termed heresy; being put on after the person had carried a faggot, by way of penance, to some appointed place of solemnity. The leaving off the wear of this badge was sometimes interpreted a sign of apostacy.

FAGGOTS, among military men, persons hired by officers, whose companies are not full, to muster and hide the deficiencies of the company; by which means they cheat the king of so much money.

FAGONIA, in botany, a genus of the decandria monogynia clas. The calix consists of five leaves, and the corolla of four petals; and the capsule has five cells with one seed in each, and ten valves. There are three species, none of them natives of Britain.

FAGOPYRUM. See Polygonum.

FAGUS, the beech, in botany, a genus of the monocla clas. The calix is bell-shaped, and consists of five segments; it has no corolla, but twelve flames: the calyx of the female consists of four teeth; it has no corolla; the stamens are three; and the capsule is mucronated, has four cells and two seeds. There are three species, two of them natives of Britain, viz. the caiffanes, or chestnut-tree; and the fylvatica, or beech-tree.

FAINTING.
FAINTING. See LIPOTHYMIA.

FAIR, a greater kind of market, granted to a town, by privilege, for the more speedy and commodious providing of such things as the place stands in need of. See MARKET.

It is incident to a fair, that persons shall be free from being arrested in it for any other debt contracted than was contracted in the same; or, at least, promised to be paid there. These fairs are generally kept once or twice a year, and, by statute, they shall not be held longer than they ought, by the lords thereof, on pain of their being feized into the king's hands, &c. Also proclamation is to be made how long they are to continue; and no person shall sell any goods after the time of the fair is ended, on forfeiture of double the value, one fourth to the professor, and the rest to the king. There is a toll usually paid in fairs, on the sale of things, and for stallage, picage, &c. See TOLL.

FAIRFIELD, a town of New England, in the province of Connecticut, about an hundred miles south-west of Boston: W. long. 74°, and N. lat. 41°.

FAIRFORD, a market-town about nineteen miles south-east of Glocefter.

FAIRY, in ancient traditions and romances, signifies a sort of deity, or imaginary genius, conversant on earth, and distinguished by a variety of fantastical actions, either good or bad.

The fairies are a peculiar species of divinities, that have but little relation to any of thofe of the ancient Greeks or Romans, unless perhaps to the larve: the others, with great reason, will not have them ranked among gods, but suppose them an intermediate kind of beings, neither gods, angels, men, or devils. They are of oriental extradiation, and seem to have been invented by the Persians and Arabs, whose religion and history abound with relations concerning them: these have a particular country which they suppose the fairies to inhabit, called Fairy-land.

Spencer's Fairy Queen is an epic poem, under the persons and characters of fairies. In this sort of writing the poet lofes sight of nature, and entertains the reader's imagination with the characters of fairies, witches, magicians, demons, and departed spirits. It requires an odd turn of thought, and a peculiar cast of fancy, with an imagination naturally fruitful and superstitious.

This sort of poetry raises a pleasing kind of horror in the mind of the reader, and amuses his imagination with the strangeness and novelty of the persons who are represented in it; but the judicious object to it, as not having probability enough to affect the imagination.

FAIRY CIRCLE OR RING, a phenomenon pretty frequent in the fields, &c. supposing by the vulgar to be traced by the fairies in their dances: there are two kinds of it, one of about seven yards in diameter, containing a round bare path, a foot broad, with green grass in the middle of it. The other is of different bignefs, encompassed with a circumference of grafs. Meff. Jeffop and Walker, in the Philosophical Transact.
black eagle of Ray, has yellowish-wax on the beak; the legs are half covered with feathers; and the body is ash-coloured and streaked with yellow. It is a native of Europe. 3. The leucocephalus, or white-headed eagle of Catesby, is ash coloured, with the head and tail white; the iris of the eye is white, over which is a prominence covered with a yellow skin; the bill and the fear or wax are yellow, as are likewise the legs and feet; and the talons are black. Though it is an eagle of small size, it weighs nine pounds, is strong and full of spirit, preying on lambs, pigs, and fawns. They always make their nests near the sea, or great rivers, and usually upon old, dead pine or cypress trees, continuing to build annually on the same tree till it falls. Tho' he is so formidable to all birds; yet he suffers them to build near his royal nest without molestation; particularly the fishing hawks, herons, &c. which all build on high-trees, and in some places are so near one another that they appear like a rookery. It is a native both of Europe and America. PI. 76. fig. 1. 4. The offragus, with yellow wax, and half-feathered legs; it is about the size of a peacock; the feathers are white at the base, iron-coloured in the middle, and black at the points; and the legs are yellow; it is a native of Europe. 5. The chrysaetos, or golden eagle, has yellow wax on the beak, and feathered legs; the body is variegated with a brown and iron colour; and the base of the tail is undulated with an ash-colour: it is a bird of Europe. 6. The fulvus, with yellow wax, feathered legs, a brown back, and a white streak on the tail; the face is bare between the eyes and nostrils: it is a native of Europe and Canada. 7. The ruficolus, with a yellow wax, yellow ring round the eyes, and yellow legs; the body is ash-coloured undulated with white, and a white ring round the neck: it is a native of Sweden. 8. The barbarus, with yellow wax, and yellow legs; the body is blueish, and spotted with brown: it is a native of Barbary. 9. The caruleifrons, with yellow wax, a yellow ring round the eyes, and the feet yellow underneath; the back is of a blackish blue colour; and the temples are surrounded with a white line. This is the smallest bird of the genus, and is a native of Asia. 10. The cyanus, with white wax, yellow legs, a whitish blue body, and a white ring round the eyes and throat. It is the blue hawk of Edwards, and is a native of Europe and Africa. 11. The pyrgus, with yellow wax and legs; the body is ash-coloured, with pale red spots along the belly, and white orbits. It is a bird of Europe. 12. The milvus, or kite, with yellow wax on the back, a forked tail, and iron-coloured bill, and the head of a lighter colour. It is a bird of Europe, Asia, and Africa. Bellonius relates, that, about the end of April, in less than fourteen days, incredible numbers of them are seen flying over the Black Sea into Asia. They feed upon offals, young-birds, &c. Like all the species of this genus, they fly remarkably high, and are endowed with uncommon acuteness of vision. 13. The gentils, with yellow wax and legs; the body is ash-coloured, with brown spots; and the tail has four blackish streaks. It is a native of the Alps, and is peculiarly fond of larks. 14. The subbuto, with yellow wax and legs; the back is brown, the nape of the neck white, and the belly is pale, with oblong brown spots. It is called the hobby by English authors, and is a native of Europe. 15. The buteo, with yellowish wax and legs; a brown body, and a pale belly, with brown spots. He feeds upon rabbits, toads, &c. and is a bird of Europe. 16. The tinunculus, with yellow wax and legs; the back is reddish, and spotted with black; it has brownish feathers on the breast, and a roundish tail. It inhabits old buildings, and lives upon small birds and mice. 17. The fulflator, with yellowish wax and legs; the body is of a brownish white colour; and the covers of the eyes are bony. He has a filthy lobe between the nostrils, which, when angry or terrified, he inflates till his head becomes as large as his whole body. He is a native of Surinam. 18. The cachinnans, or laughing hawk, has yellowish legs and wax, and white eye-brows; the body is variegated with brown and white; and it has a black ring round the top of the head. It makes a laughing kind of noise when it observes any person, and is a native of America. 19. The hudsonius, has yellow wax, and yellow legs, a brown back, and white eye-brows. It is found at Hudson's bay. 20. The sparverius, has yellow wax, a brown head, a red belly, and blueish wings. It is a native of America. 21. The columbarius, or pigeon-hawk of Catesby, weighs about six ounces. The bill is black at the point, and whitish at the base; the iris of the eye is yellow; the base of the upper mandible is covered with a yellow fear or wax; all the upper part of the body, wings, and tail, are brown. The interior vanes of the quill-feathers have large red spots. The tail is marked with four regular transverse white lines; the throat, breast, and belly are white, mixed with brown; the small feathers that cover the thighs reach within half an inch of the feet, and are white, with a tincture of red, befet with long spots of brown; the legs and feet are yellow. It is a very swift and bold hawk, preying on pigeons, young turkeys, &c. and is a native of Carolina. PI. 76. fig. 22. The superciliosus has yellow legs and wax, and yellow eye-brows; and the body is brown, waved with white. It is a native of Surinam. 23. The vespertinus, is about the size of a pigeon; the body is of a blueish brown colour; and the bill is yellow, and brown at the point. It is a native of Ingria, and flies both in the day and in the night. 24. The lanarius, has yellowish wax, and the bill and legs, which are short, are blueish. It is a native of Europe. 25. The furcatus, or swallow-tailed hawk, weighs about fourteen ounces; the bill is black; the eyes are large and black, with a red iris; the head, neck, breast, and belly are white; the upper part of the back and wings a dark purple; but more dusky towards the lower parts, with a tincture of green. The wings are long in proportion to the body, and, when extended, are four feet. The tail is dark purple mixed with green, and remarkably forked. Like swallows, they continue long on the wing, catching, as they fly, beetles, flies, and other insects. They are said to prey upon lizards and serpents, and are found in America. PI. 76. fig. 26. Flatturus, or file-hawk of Catesby, weighs three pounds and a quarter; it measures, from one end of the wing to the other, five feet and a half. The bill is black, with a blue fear or wax; the iris of the eye is yellow, and the crown of the head brown, with a mixture of white feathers; from each eye, backwards, runs a brown stripe: the
Fig. 1.

Fig. 3. 
Falco Columbarius
or
Pigeon Hawk
the back, wings, and tail, are of a dark brown; the throat, neck, and belly white; the legs and feet are rough and scaly, and of a pale blue colour; the talons are black, and nearly of an equal size; the feathers of the thighs are short, and adhere close to them, contrary to others of the hawk-kind, which nature seems to have designed for their more easy penetrating the water. Their manner of fishing is, after hovering a while over the water, to precipitate into it with prodigious swiftness, where they remain for some minutes, and seldom rise without a fish. The white-headed eagle, who is generally on the back, wings, and tail, are of a dark brown; the of the head, nape of the neck, and legs, are yellowish. It is of rusty, with greenish wax, a greyish body; and the top and creeks near the sea in America, abound with those eagles. It is the gyrfalcon of Ray, lives upon cranes, pigeons, &c. and is a native of Europe. 28. The aviporus, with green wax, yellow legs, and a white belly under-neath, and the sides of the tail white. It is the gyrfalcon of Ray, lives upon cranes, pigeons, &c. and is a native of Europe. 29. The servulus, being about the size of a thrush, and is found in the nort

FALCIRK, a town of Scotland: W. long. 3° 48', N. lat. 56° 20'. FALLOWS, a pale red colour, like that of brick half burnt: such is that of a fallow-deer. FALLOW FIELD, or FALLOW GROUND, land laid up, or that has lain untillled for a considerable time. FALLOWING OF LAND, a particular method of improving land. See AGRICULTURE.

FALMOUTH, a port-town of Cornwall, in England, situated in W. long. 5° 30', N. lat. 50° 15', on a fine bay of the English channel, the entrance whereof is guarded by two forts.

FALSE, in general, something contrary to truth, or not what it ought to be; thus we say, a false witnes, false weight, &c. and yet strict enough beneath, that it may fall upon her head without hurting her; and her back and talons must be a little copied, but not too near as to make them bleed.

FALKIRK, a town of Scotland: W. long. 3° 48', N. lat. 56° 20'. FALLOUT, a pale red colour, like that of brick half burnt: such is that of a fallow-deer.

FALLOUT, a pale red colour, like that of brick half burnt: such is that of a fallow-deer. FALLOW FIELD, or FALLOW GROUND, land laid up, or that has lain untillled for a considerable time. FALLOWING OF LAND, a particular method of improving land. See AGRICULTURE.

FALMOUTH, a port-town of Cornwall, in England, situated in W. long. 5° 30', N. lat. 50° 15', on a fine bay of the English channel, the entrance whereof is guarded by two forts.

FALSE, in general, something contrary to truth, or not what it ought to be; thus we say, a false witnes,

FALCO, in anatomy. See ANATOMY, p. 284.

FAN, a machine used to raise wind and cool the air by agitating it. The custom which now prevails of wearing fans, was borrowed from the East, where they are almost indispensably necessary for keeping off the sun and the flies. Fans are made of a thin slin or piece of paper, cut semicircularly, and mounted on several little sticks of wood, ivory, tortos-shell, or the like. The paper, &c. is usually painted, and in mounting is plaited in such a manner, as that the ribs may be alternately inward and outward. Fan is also an instrument used in winnowing corn.

FANS for corn pay on importation, 1 s. 3 d. and FANS pay on exportation, 1 s. 4 d. in India. Fans pay for every 100 l. gross value at the fable 26 l. 14 s. 2 d., the draw-back on exportation is 25 l. 28 s. 5 d. 100
FANATICS, wild, enthusiastic, visionary persons, who pretend to revelation and inspiration.

FANCY, or Imagination. See Imagination.

FANIONS, in the military art, small flags carried along with the baggage.

FANO, a bishop's see and port-town of Italy, situated on the gulph of Venice, in 44° E. long., and 44° N. lat.

FAR, in horsemanship, an appellation given to any part of a horse's right side: thus the far foot, far shoulder, &c. is the same with the right foot, right shoulder, &c.

FARCE, was originally a droll or petty shew exhibited for the entertainment of a polite audience. Poets have reformed the wildness of the primitive farces, and brought them to the taste and manner of comedy. The difference between the two on our stage is, that comedy keeps to nature and probability, and therefore is confined to certain laws prescribed by ancient critics; whereas farce disallows of all laws, or rather sets them aside on occasion. Its end is purely to make merry; and it ficks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is usually low, the persons of inferior rank, the fable or action trivial or ridiculous, and nature and truth every where heightened and exaggerated to afford the more palpable ridicule.

FARCIN, Farcy, or Fashions, in farriery, a creeping ulcer, and the most loathsome, stinking, and filthy disease that a horse can be affected with.

For the cure, first bleed the horse well; then take oil of bay and euphorbium mixed together, and anoint the knots with it; or bathe the place with the flate of tar, two penny worth of white mercury, and two handfuls of pigeon's dung.

FARDING-deal, the fourth part of an acre of land. See Acre.

FAREWELL cape, the most southerly promontory of Greenland, in 50° W. long. and 60° N. lat.

FARO, a sea-port town of Portugal, in the province of Algarva: W. long. 9°, N. lat. 36° 50'.

 Farewell, a mountain in the county of Surry, ten miles east of Southampton.

FAREWELL, a market town of Hampshire, ten miles east of Southampton.

FAREWELL, a market town of Hampshire, ten miles east of Southampton.

FARNHAM, a market-town in the county of Surry, ten miles north-west of Reading.

FARM, or farm, signifies the chief messuage in a village; or any large messuage, whereunto belongs land, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

FARNHAM, a market-town in the county of Surry, ten miles west of Guildford, remarkable for its large plantations of hops.

FARO, a sea-port town of Portugal, in the province of Algarva: W. long. 9°, N. lat. 36° 50'.

FARRINGTOWN, a market town of Berkshire, twenty-five miles north-west of Reading.

FARMER, or farmer, signifies the chief messuage in a village; or any large messuage, whereunto belongs land, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

FARMER, or farmer, signifies the chief messuage in a village; or any large messuage, whereunto belongs land, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

FARMER, or farmer, signifies the chief messuage in a village; or any large messuage, whereunto belongs land, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

FARMER, one whose emloyment is to shoe horses, and cure them when diseased or lame.

FARRIERY. The miserable state of this useful art, especially in this country, has determined us to select, from the best authors, such a system of practice as seemed to be formed on rational principles; this, we hope, will be a sufficient apology for being so full upon this article.

General Directions with regard to the Management of Horses.

It ought to be laid down as a general rule, to give horses as few medicines as possible; and by no means to comply with the ridiculous custom of some, who are frequently bleeding, purging, and giving balls, though their horses be in perfect health, and have no indication that requires such treatment.

Proper management in their feeding, exercise, and dresting, will alone cure many disorders, and prevent most...
Horses may be kept abroad all the year, where they have a proper stable or field, to shelter them from the weather, and hay at all times to come to. So treated, they are seldom sick, their limbs are always clean and dry; and, with the allowance of corn, will hunt, and do more business than horses keptconfiantly within doors.

If horses, when taken from grases, should grow hot and collyive, mix bran and chopt hay with their corn; and give them sometimes a feed of scalded bran for a fortnight, or longer: let their exercise and diet be moderate for some time, and increase both by degrees.

When horses are foiled in the stable, care should be taken that the herbage is young, tender, and full of sap; whether it be green barley, tares, clover, or any thing else the seafon produces, and that it be cut fresh once every day at least, if not oftener.

When horses lose their flesh much in foiling, they should in time be taken to a more solid diet; for it is not in foiling as in grazing; where, though a horse loses his flesh at first, yet, after the grases has purged him, he soon grows fat.

Young horses who have not done growing, must be indulged more in their feeding, than those come to their maturity; -but if their exercise is so little, as to make it necessary to abridge their allowance of hay, a little fresh straw should constantly be put in their racks, to prevent their nibbling the manger, and turning cribsitters; they should also sometimes be strapped back in order to cure them of this habit.

It is obvious to every one, what care should be taken of a horse after violent exercise, that he cools not too fast, and drinks no cold water, &c. for which reason we shall wave particular directions.

Most horses fed for sale, have the interlacies of their muscles so filled with fat, that their true shapes are hardly known. For which reason, a horse just out of the dealer's hands, should at first be gently used. He ought to lose blood, and have his diet lowered, though not too much: walking exercise is most proper at first, two hours in a day; in a week or fortnight two hours at a time, twice a day; after this usage for a month, bleed him again, and give him two or three times a week scalded bran, which will prepare him for purging physic, that may now be given safely, and repeated at the usual intervals.

When a horse comes out of a dealer's hands, his clothing must be abated by degrees, and care taken to put him in a moderately warm stable; otherwise the sudden transition would be attended with the worst consequences.

Some General Directions in regard to Bleeding, Purging, &c.

Horses who stand much in stable, and are full fed, require bleeding now and then, especially when their eyes look heavy, dull, red, and inflamed; as also, when they feel hotter than usual, and mangle their hay.

Young horses should be bled when they are shedding their teeth, as it takes off those feverish heats they are then subject to. But the cases that chiefly require bleeding, are colds, fevers of most kinds, falls, bruises, hurts of the eyes, strains, and all inflammatory disorders, &c.

It is right to bleed a horse, when he begins to grow febby.
iely at grafts, or at any other time when he looks heavy: and it is generally proper to bleed before purging.

Let your horse always be bled by measure, that you may know what quantity you take away: two or three allow for the disorder, and the horse's constitution.

Let the blood, when cold, be carefully examined, both to colour and consistence, whether black, florid, fizey, &c.

Purging is often necessary in gross full horses, in some disorders of the stomach, liver, &c. but should be directed with caution. Before a purge is given to any horse, it is necessary some preparation should be made for it, in order to render the operation more safe and efficacious; thus a horse that is full of flesh should first be bled, and at the same time have his diet lowered for a week, especially those that have been pampered for sale; several mash of scalded bran should also previously be given, in order to open the bowels, and unload them of any indurated excrement; which sometimes proves an obstacle to the working of the physic, by creating great sickness and griping.

Let it be remembered, that a horse is purged with difficulty; that the physic generally lies twenty-four hours in the guts before it works; and, that the tract of bowels it has to pass through, is above thirty yards; and lying horizontally, consequently resinosus and other improper drugs may, and often do, by their violent irritations, occasion excessive gripings and cold sweats, have off the very mucus or lining of the guts, and bring on inflammations, which often terminate in mortifications, and death.

It is remarkable too, that the stomach and guts of a horse are but thin, compared to some other animals of the same bulk, and therefore must be more liable to inflammation and irritation.

Horses kept much in the stable, who have not the proper benefit of air, and exercise, in proportion to their food, should in spring have a mild purge or two, after a previous preparation by bleeding, lowering their diet, and scalded mash.

Horses that fall off in their stomach, whether it proceeds from too full feeding, or ingendering crudities and indigested matter, should have a mild purge or two.

Horses of a hot temperament, will not bear the common aloeotic purges; their physic therefore should be mild and cooling.

Purging is always found very beneficial in stubborn dry coughs; but mild mercurials joined with them, make them yet more efficacious.

Horses of a watery constitution, who are subject to swelled legs, that run a sharp briny ichor, cannot have the causes removed any way so effectually as by purging.

The first purge you give to a horse should be mild, in order to know his constitution.

It is a mistaken notion, that if a proper prepared purge does not work to expectation, the horse will be injured by it; for though it does not pass by stool, its operation may be more efficacious, as an alternative to purify the blood, and it may pass by urine, or other secretions.

Purging medicines are very successfully given in small quantities, mixed with others; and act then as alternatives.

If mercurial physic is given, care should be taken that it be well prepared; and warmer clothing, and greater circumspection is then required.

Purges should be given early in the morning upon an empty stomach: about three or four hours after the horse has taken it, he should have a feed of scalded bran; and a lock or two of hay may then be put into his rack. The same day give him two more mash; but should he refuse warm meat, he may be allowed raw bran.

All his water should be milk warm, and have a handful of bran squeezed in it; but if he refuses to drink white water, give it him without bran.

Early the next morning, give him another mash; but if he refuses to eat it, give him as much warm water as he will drink: let him be properly cloathed, and rode gently about. This should be done two or three times a day, unless he purges violently, once or twice will then be sufficient: at night give him a feed of oats mixed with bran.

During the working, a horse should drink plentifully; but, if he will not drink warm water, he must be indulged with cold, rather than not drink at all.

We shall here insert some general forms of purges.

Take succotrine aloes ten drams, jallap and salt of tartar each two drams, grated ginger one dram, oil of cloves thirty drops; make them into a ball with syrup of buckthorn.

Or,

Take aloes and cream of tartar each one ounce, jallap two drams, cloves powdered one dram, syrup of buckthorn a sufficient quantity.

Or,

The following, which has an established character among sportsmen.

Take aloes, from ten drams to an ounce and a half, myrrh and ginger powdered each half an ounce, saffron and oil of annis each half a dram.

Mr Gibbon recommends the following,

Take succotrine aloes ten drams, myrrh finely powdered half an ounce, saffron and fresh jallap in powder of each a dram, make them into a stiff ball with syrup of roses, then add a small spoonful of rectified oil of amber.

The succotrine aloes should always be preferred to the Barbadoes or plantation aloes; though the latter may be given to robust strong horses, but even then should always be prepared with the salt, or cream of tartar; which by opening its parts, prevents its adhesion to the coats of the stomach, and bowels; from whence horrid gripings, and even death itself has often ensued. This caution is well worth remarking, as many a horse hath fallen a sacrifice to the neglect of it.

Half an ounce of Caffile soap, to a horse of a gross constitution, may be added to any of the above; and the proportions may be increased for strong horses.

When mercurial physic is intended, give two drams of calomel overnight, mixed up with half an ounce of a diapente and a little honey, and the purging ball the next morning.
The following, when it can be afforded, is a very gentle and effective purge, particularly for fine delicate horses; and if prepared with the Indian rhubarb, will not be expensive.

Take of the finest succotrine aloes one ounce, rhubarb powdered half an ounce or six drams, ginger grated one dram; make into a ball with syrup of roes.

The following purging drink may be given with the utmost safety; it may be quickened, or made stronger, by adding an ounce more fenna, or two drams of jalap.

Take fenna two ounces, infuse it in a pint of boiling water two hours, with three drams of salt of tartar; pour off, and dissolve in it four ounces of Glauber's salts, and two or three of cream of tartar.

This laft physic is cooling, easy, and quick in its operation; and greatly preferable in all inflammatory cases to any other purge, as it passes into the blood, and operates also by urine.

When horses lose their appetites after purging, it is necessary to give them a warm stomach drink, made of an infusion of chamomile flowers, annifeed and saffron; or the cordial ball may be given for that purpose.

Should the purging continue too long, give an ounce of diofocridium in an English pint of Port wine, and repeat it once in twelve hours, if the purging continues.

Plenty of gum arabic water should also be given; and in case of violent gripes, fat broth glysters, or tripe liquor, should be often thrown up, with an hundred drops of laudanum in each.

The arabic solution may be thus prepared.

Take of gum arabic and tragacanth of each four ounces. Juniper-berries and carraway-seeds of each an ounce, cloves bruised half an ounce; simmer gently in a gallon of water, till the gums are dissolved: give a quart at a time in half a pail of water; but if he will not take it freely this way, give it him often in a horn.

When a purge does not work, but makes the horse swell, and refuse his food and water, which is sometimes the effect of bad drugs, or catching cold, warm diuretics are the only remedy; of which the following are recommended.

Take a pint of white wine, nitre one ounce; mix with it a dram of campiphire, dissolved in a little rectified spirit of wine; then add two drams of oil of juniper, and the same quantity of unrectified oil of amber, and four ounces of honey, or syrup of marshmallows.

When a horse swells much with physic, do not suffer him to be rode about till he has some vent; but rather lead him gently in hand, till some evacuation is obtained.

As it is observed, that horses more willingly take sweet and palatable things, than those that are bitter and of an ill taste; care should be taken, that the latter are given in balls; and that their drinks are always contrived to be as little nauseous as possible, and sweetened either with honey or liquorice.

Those that are prepared with gross powders are by no means so agreeable to a horse, as those made by infusion; as the former often clam the mouth, irritate the membranes about the palate and throat, and frequently occasion the cough they are intended to prevent.

Balls should be of an oval shape, and not exceed the size of a pullet's egg; when the dose is larger, it should be divided into two; and they should be dip in oil, to make them slip down the easier.

As we have given some general forms of purges, we shall observe the same rule in regard to glysters, with some few cautions and remarks.

Let it be observed then, that, before the administering emollient glysters in colicive disorders, a small hand, well oiled, should be passed up the horse's fundament, in order to bring away any hardened dung, which otherwise would be an obstacle to the glyster's passage.

A bag and pipe of a proper form, is to be preferred to a syringe, which throws up the glyster with so much force, that it often surprises a horse, and makes him reject it as faft as it goes in; whereas the liquor, when pressed gently from the bag, gives him no surprize or uneasiness, but paffes easily up into the bowels, where it will sometimes remain a long time, and be extremely useful, by cooling and relaxing them; and will sometimes incorporate so with the dung, as not easily to be distinguished from the other contents of the guts. These emollient glysters are extremely serviceable in most fevers, and greatly preferable to purging tunes; which in general are too pungent, and stimulate too much, especially if aloes are a part of the composition.

Emollient glysters are very necessary, and often save a horse from starving, when his jaws are so locked up by convulsions that nothing can be conveyed by the mouth.

They should not exceed a quart or three pints at a time, but be often repeated; nor should they be too fat; but made of sheep's heads, trotters, or any other meatbroths, milk potage, rice-milk strained, and many other such nourishing things. For an emollient glyster, take the following.

Take marshmallows and chamomile flowers each a large handful, bay berries and sweet fennel seeds bruised each an ounce; boil in a gallon of water to three quarts, pour off into a pan, and dissolve in it half a pound of treacle, and a pint of lint-feed oil, or any common oil.

To make it more laxative, add four ounces of lenitive elecuary, or the same quantity of cream of tartar, or common purging salts.

Purging Glyster.

Take two or three handful of marshmallows, senna one ounce, bitter apple half an ounce, bay berries and annifeed bruised each an ounce, salt of tartar half an ounce; boil a quarter of an hour in three quarts of water; pour off, and add four ounces of syrup of buckthorn, and half a pint of oil.

This glyster will purge a horse pretty briskly; and may be given successfully, when an immediate discharge is wanting; especially in some fevers with inflamed lungs, or other disorders, which require speedy relief.

But it is necessary to caution against a solution of course aloes for this purpose, as it has been found to grieve horses violently, and excite feverish, and sometimes convulsive
convulsive symptoms; and indeed all pungent and stimulating medicines, as the stronger purgatives generally are, should be given in this form with great caution.

But the generality of emollient glysters, may be prepared with much less trouble: as two quarts of water-gruel, with a half a pound of treacle, a pint of oil, and a handful of common salt, will as effectually answer every purpose. The following is a restraining glyster.

Take pomegranate-bark or oak-bark two ounces, red rofe-leaves fresh or dry a handful, balaulines an ounce; boil in two quarts of water, till one is near confumed; pour off and dissolve in it four ounces of diafordinium; to which may be added a pint of Port wine.

This will answer in all common cases, where restrin-
gents are necessary, but should never be given in larger quantities; for the longer glysters of this kind lie in the bowels, the more efficacious they are.

Of Colds.

By taking cold, we mean that the pores and outlets of the skin (which in a natural healthy state of body are continually breathing out a fine fluid, like the stream arling from hot water, or smoke from fire) are so far shut up, that these streams, or perfpirable matter, not having a free passage through them, are hindered from going off in the usual manner; the consequence of which is, their recoiling on the blood, vitiating its quality, of the principal parts.

To enumerate the various causes of colds would be endless; the most usual are, riding horses till they are hot, and suffering them to stand in that condition where the air is cold and piercing; removing a horse from a stable to a cold one, and too suddenly changing its clothing; hence it is, that horses often catch such fevers, after going off in the usual manner; the consequence of which is, the body should be kept open by emollient glysters, or cream of tartar dissolved in his water, to the quantity of three or four ounces a-day.

Of Fevers in general.

The symptoms of a fever are great restlessness, the horfe ranging from one end of his rack to the other; his eyes are red and inflamed; his tongue parched and dry; his breath is hot, and smells strong; he refuse his meat, bleed him, if strong, two quarts more; and if you are not satisfied, without giving medicines, avoid, as you would poison, a farrier's drench; (which is generally composed of some hot, maufeous powders, given in a quantity of ale; which too often encreases the fever, by overheating the blood, and pulls the horse's stomach by its loathomnens :) and instead of it, infuce two ounces of anniseeds, with a dram of saffron, in a pint and a half of boiling water; pour off the clear, and dissolve in it four ounces of honey; to which may be added four spoonfuls of fallad oil: this drink may be given every night; or one of the following balls, provided there is no fever; in which case, it always will be more eligible to give two or three ounces of nitre or salt prnella every day in his feeds, or water, till it is removed; but should the horse be inclined to coltivenes, remember that his body should be kept open by emollient glysters, or cream of tartar dissolved in his water, to the quantity of three or four ounces a-day.

Pectoral Horse-ball.

Take of the fresh powders of annifeed, cicampane, carraway, liquorice, turmeric, and flour of brimstone, each three ounces; juice of liquorice four ounces, dissolved in a sufficient quantity of mountain; saffron powdered half an ounce, fallad oil and honey half a pound, oil of anniseed one ounce; mix together with wheat flour enough to make them into a paffle.

Or, the following from Dr Bracken.

Take anniseed, carraway seed, and greater carda-
mons, finely powdered, of each one ounce, flour of brimstone two ounces, turmeric in fine powder one ounce and a half, saffron two grams, Spaniffi juice dissolved in water two ounces, oil of anniseed half an ounce, liquorice powder one ounce and a half, wheat-flower a sufficient quantity to make into a stiff paffle, by beating all the ingredients well in a mortar.

These balls consist of warm opening ingredients; and, given in small quantities, about the size of a pullet's egg, will encourage a free perfpiration; but in case of a fever, should be cautiously continued. They are much more ef-
ficacious, and in all cases superior to the farrier's drenches, if dissolved in a pint of warm ale.

This simple method, with good nursing and hot mashes, warm water and cloathing, especially about the head and throat, which promotes the running at the noftrils, will answer the most sudden colds; and when the horfe feeds heartily, and snorts after coughing, moderate exercise every day will hasten his recovery.

To a horfe loaded with feffi, a rowel may sometimes be necessary, as may also a gentle purge or two, to some, when the distemper is gone off.

The symptoms of a fever are great restlessness, the horse ranging from one end of his rack to the other; his flanks beat; his eyes are red and inflamed; his tongue parched and dry; his breath is hot, and smells strong; he
be loses his appetite, and nibbles his hay, but does not chew it, and is frequently frothing to the ground; the whole body is hotter than ordinary, (though not parched, as in some inflammatory disorders;) he dung often, little at a time, usually hard, and in small bits; he sometimes flutes with difficulty, and his urine is high-coloured; his flanks beat; and he seems to thirst, but drinks little at a time, and often; his pulse beats full and hard, to fifty strokes and upwards in a minute.

The first intention of cure is bleeding, to the quantity of two or three quarts, if the horse is strong and in good condition; then give him a pint of the following drink, four times a-day; or an ounce of nitre, mixed up into a ball with honey, may be given thrice a-day, instead of the drink, and walked down with three or four horns of any small liquor.

Take of baum, sage and chamomile flowers, each a handful; liquorice root sliced half an ounce, salt prunel or nitre three ounces; infuse in two quarts of boiling water; when cold, strain off, and squeeze into it the juice of two or three lemons, and sweeten with honey.

As the chief ingredient to be depended on in this drink is the nitre; it may perhaps be as well given in water alone; but as a horse’s stomack is soon palled, and he requires palatable medicines, the other ingredients may in that respect have their use. Söylefel for this purpose advices two ounces of salt of tartar, and one of salt armoniac to be dissolved in two quarts of water, and mixed with a pail of common water, adding a handful of bran or barley-flour to qualify the unpleasant taste: this may be given every day, and is a useful medicine.

His diet should be scalded bran, given in small quantities; which, if he refuses, let him have dry bran sprinkled with water: put a handful of picked hay into the rack, which a horse will often eat, when he will touch nothing else; his water need not be much warmed, but should be given often, and in small quantities: his clothing should be moderate; too much heat and weight on a horse being improper in a fever; which scarce ever goes off in critical sweats (as those in the human body terminate) but by strong perspiration.

If in a day or two he begins to eat his bran, and pick a little hay, this method with good nursing will answer: but if he refuses to feed, more blood should be taken away, and the drinks continued; to which may be added two or three drams of saffron, avoiding at this time all hotter medicines; the following glyster should be given, which may be repeated every day, especially if his dung is knotty or dry.

Take two handfuls of marshmallows, and one of chamomile flowers; fennel feed an ounce; boil in three quarts of water to two; strain off, and add four ounces of treacle, and a pint of linseed oil, or any common oil.

Two quarts of water gruel, fat broth, or pot liquor, with the treacle and oil, will answer this purpose; to which may be added a handful of salt. These sort of glysters are properer than those with purging ingredients.

The following opening drink is very effectual in these fevers, and may be given every other day, when the glysters should be omitted; but the nitre-balls or drink may be continued, except on those days these are taken.

Take of cream of tartar and Glauber’s salts, each four ounces; dissolve in barley water, or any other liquor: an ounce or two of lenitive electuary may be added, or a dram or two of powder of jallap, to quicken the operation in some horses.

Four ounces of Glauber’s fafts, or cream of tartar, with the same quantity of lenitive electuary, may be given for the same purpose, if the former should not open the body sufficiently.

In four or five days the horse generally begins to pick his hay, and has a seeming relish to food; though his flanks will heave pretty much for a fortnight: yet the temper of his body and return of appetite shew that nothing more is requisite to complete his recovery, than walking him abroad in the air, and allowing plenty of clean litter to retch him in the stable.

This method of treating a fever is simple, according to the laws of nature; and is confirmed by long experience, to be infinitely preferable to the hot method.

The intention here is to leffen the quantity of blood; promote the secretion of urine and perspiration, and cool and dilute the fluids in general.

There is another sort of fever that horses are subject to, of a more complicate and irregular nature than the former; which if not properly treated, often proves fatal.

The signs are a slow fever with languishing, and great depressions; the horse is sometimes inwardly hot, and outwardly cold; at other times hot all over, but not to any extreme; his eyes look moist and languid; he has a continual moisture in his mouth, which is the reason he seldom cares to drink, and when he does it is but little at a time. He feeds but little, and leaves off as soon as he has eat a mouthful or two; he moves his jaws in a feeble, loose manner, with an unpleasant grating of his teeth; his body is commonly open; his dung soft and moist, but seldom greasy; his fluting is often irregular, sometimes little, at other times profuse. Seldom high-coloured, but rather pale, with little or no sediment.

When a horse’s appetite declines daily, till he refuses all meat, it is a bad sign. When the fever doth not diminish, or keep at a stand, but increases, the case is then dangerous. But when it sensibly abates, and his mouth grows drier, the grating of his teeth ceases, his appetite mends, and he takes to lay down (which perhaps he has not done for a fortnight) these are promising signs. A horse in these fevers always runs at the nose, but not the kindly white discharge, as in the breaking of a cold, but of a reddish or greenish dusky colour, and of a confluence like glue, and sticks like turpentine to the hair on the inside of the nostrils: If this turns to a gleet of clear thin water, the horse’s hide keeps open, and he mends in his appetite; these are certain signs of recovery.

The various and irregular symptoms that attend this slow fever, require great skill to direct the cure, and more knowledge of the symptoms of horses diseases, than the generality of gentlemen are acquainted with. The experienced
experienced farrier should therefore be consulted and attend- to, in regard to the symptoms; but very seldom as to the application of the remedy, which is generally above their comprehension; though it may be readily selected, by duly attending to the observations here inculcated.

First then, a moderate quantity of blood, not exceeding three pints, may be taken away, and repeated in pro portion to his strength, fullness, inward soreness, cough, or any tendency to inflammation. After this, the fever-drink, (p. 457. col. r. parag. 5.) may be given, with the addition of an ounce of snake-root, and three drams of saffron and camphor dissolved in a little spirit of wine; the quantity of the nitre may be lessened; and these in created, as the symptoms indicate.

The diet should be regular; no oats given, but scalded, or raw bran sprinkled; the best flavoured hay should be given by handfuls, and often by hand, as the horse sometimes cannot lift up his head to the rack.

As drinking is so absolutely necessary to dilute the blood, if the horse refuses to drink freely of warm water or gruel, he must be indulged with having the chill only taken off, by standing in the flable; nor will any inconvenience ensue, but oftener an advantage; for the naufeous warmth of water, forced on horses for a time, or gruel, he must be indulged with having the chill

Should the fever after this treatment increase, the horse feed little; it often, his urine being thin and pale, and his dung sometimes loose, and at other times hard: should the moisture in his mouth continue, his skin being sometimes dry, and at others moist, with his coat looking starting, and surfeited: upon these irregular symptoms, which denote great danger, give the following balls, or drink; for in these cafes there is no time to be lost.

Take of contrayerva-root, myrrh, and snake-root powdered, each two drams, saffron one dram, mithridate or Venice treacle half an ounce; make into a ball with oil of amber.

Should these balls not prove successful, add to each a dram of camphor, and where it can be afforded, to a half an ounce of camphor, as if a horse must be harved in a few days, if he

Dilute

DRINKS, instead of the mithridate; if it increases, give more potent remedies.

Let it be remembered, that camphor is a very powerful and effectual medicine in these kinds of putrid fevers; being both active and attenuating, and particularly calculated to promote the secretions of urine and perspiration.

Regard should also be had to its staling; which, if in too great quantities, so as manifestly to depress his spirits, should be controuled by proper reftringents, or by preparing his drinks with lime-water. If, on the contrary, it happens that he is too remiss this way, and stales so little as to occasion a fullness, and swelling of the body and legs, recourse may be had to the following drink:

Take of salt prunella, or nitre, one ounce; juniper-berries, and Venice turpentine, of each half an ounce; make into a ball with oil of amber.

Give him two or three of these balls, at proper intervals, with a decoction of marsh-mallows, sweetened with honey.

But if, notwithstanding the method we have laid down, a greenish or reddish gleet is discharged from his nostrils, with a frequent freezing; if he continues to lose his flesh, and becomes hide bound; if he altogether forfakes his meat, and daily grows weaker; if he swells about the joints, and his eyes look fixed and dead; if the kernels under his jaws swell, and feel loofe; if his tail is raifed and quivers; if his breath smelis frong, and a purging enfues with a discharge of fetid dark-coloured matter, his cafe may then be looked on as desperate, and all future attempts to save him will be fruitless.

The signs of a horse's recovery are known by his hide keeping open, and his skin feeling kindly; his ears and feet will be of a moderate warmth, and his eyes bright and lively; his nofe grows clean and dry; his apetite mends, he lays down well, and both stales and dungs regularly.

Be careful not to overfeed him on his recovery; let his diet be light, feeds small, and increased by degrees as he gains strength; for by overfeeding, horses have frequent relapses, or great surfeits, which are always difficult of cure.

If this fever should be brought to intermit, or prove of the intermitting kind, immediately after the fit is over, give an ounce of Jesuit's bark, and repeat it every six hours, till the horse has taken four or six ounces; should eruptions or swellings appear, they ought to be encouraged, for they are good symptoms at the decline of a fever, denote a termination of the distemper, and that no further medicines are wanted.

The true reasons perhaps why so many horses miscalcas in fevers, are, that their munders, or doctors, will not wait with patience, and let nature have fair play; that they generally neglect bleeding sufficiently at first; and are constantly forcing down sugar sops, or other food is ahoorn, as if a horse must be starved in a few days, if he did not eat: then they ply him twice or thrice a day with hot medicines and spiritous drinks, which (excepting a very few cafes) must be extremely pernicious to a horse, whose diet is naturally simple, and whose stomach and blood, unaccustomed to such heating medicines, must be greatly injured, and without doubt are often inflamed by such treatment.
Dilute the blood with plenty of water, or white drink; let his diet be warm bran mashies, and his hay sprinkled. Should the fever rise, which will be known by the symptoms above described, give him an ounce of nitre thrice a-day in his water, or made up in a ball with honey. Let his body be kept cool and open, with the opening drink, given twice or thrice a-week; or an ounce of salt of tar- tar may be given every day, diffolved in his water, for that purpose, omitting then the nitre. After a week's treatment in this manner, the cordial ball may be given once or twice a-day, with an infusion of liquorice-root sweetened with honey; to which may be added, when the phlegm is tough, or cough dry and husky, a quarter of a pint of linseed or safflower oil, and the same quantity of oxymel squills.

The following cooling purge is very proper to give at the decline of the distemper, and may be repeated three or four times.

Take two ounces of fennon; anniseed and fennel bruised, each half an ounce; salt of tartar three drams; let them infuse two hours in a pint of boiling water; strain off, and diffolve in it three ounces of Glauber's salt, and two of cream of tartar; give for a dose in the morning.

This purge generally works before night very gently; and in fevers, and all inflammatory disorders, is infinitely preferable to any other physic.

Before we close this chapter on fevers, it may be no improper hint to the curious, to take notice that a horse's pulse should more particularly be attended to than is customary, as a proper estimate may thereby be made both of the degree and violence of the fever present, by observing the rapidity of the blood's motion, and the force that the heart and arteries labour with to propitiate it. The niggert calculation that has been made of the quickness of the pulse in a healthy horse, is, that it beats about forty strokes in a minute; so that in proportion to the increase above this number, the fever is rising, and if farther increased to above fifty, the fever is very high.

How often the pulse beats in a minute may easily be discovered by measuring the time with a stop-watch, or minute sand-glass, while your hand is laid on the horse's near side, or your fingers pit any artery; those which run up on each side the neck, are generally to be seen beating the quickness of the pulse in a healthy horse, is, that it beats a

How often the pulse beats in a minute may easily be discovered by measuring the time with a stop-watch, or minute sand-glass, while your hand is laid on the horse's near side, or your fingers pit any artery; those which run up on each side the neck, are generally to be seen beating as well as felt a little above the cheek; and one withinside each leg may be traced with the finger.

A due attention to the pulse is so important an article, in order to form a proper judgment in fevers, that it would appear amazing it has so much been neglected, if one did not recoiled, that the generality of farriers are so egregiously ignorant, that they have no manner of conception of the blood's circulation, nor in general have they ability enough to distinguish the difference between an artery and a vein.—With such pretty guardians do we intrust the healths and lives of the most valuable of animals!

Of a Pleurisy, and Inflammation of the Lungs, &c.

These disorders have scarce been mentioned by any writer in farriery before Mr Gibfon; who, by frequent-
The diet and medicines should be both cooling, attenuating, relaxing, and diluting; and the horse should have warm mashes, and plenty of water or gruel. The following balls may be given thrice a-day.

Take of spermaceti and nitre, of each one ounce; oil of annieeed, thirty drops; honey enough to make a ball.

A pint of barley-water, in which figs and liquorice-root have been boiled, should be given after each ball; to which the juice of lemons may be added; and if the lungs are greatly oppressed by a dry short cough, two or three horns full of the decoction may be given three or four times a-day, with four spoonfuls of honey and linseed oil. A strong decoction of the rattlesnake-root is also much recommended in pleuritic disorders, and may be given to the quantity of two quarts a day, sweetened with honey.

It remarkably attenuates the blood, and disperses the inflammation, and in some parts is deemed a specific for this complaint.

An emollient glyster should be injected once a day, to which may be added two ounces of nitre or cream of tartar.

In two or three days he will probably run at the nose, and begin to feed; but should he not, and continue hot and short-breathed, you must bleed him again, and give the following glyster.

Take senna and marshmallows, of each two ounces; fennel and bay-berries, each one ounce; boil in five pints of clear water, to two quarts; pour off the clear, and add four ounces of purging salts, two or three of syrup of buckthorn, and half a pint of linseed, or any common oil.

If by these means he grows cooler, and his pain moderates, repeat the glyster the next day, unless it worked too much; then intermit a day; and when he comes to eat scalded bran and picked hay, leave off the balls, and continue only the decoction, with now and then a glyster.

But let it be observed, that a horse seldom gets the better of these disorders, unless he has relief in a few days; for if the inflammation is not checked in that time, it usually terminates in a gangrene, or collection of matter, which, for want of expectoration, soon suffocates him.

But as pleuritic disorders are apt to leave a taunt on the lungs, great care should be taken of the horse's exercise and feeding, which should be light and open for two or three weeks.

There is also an external pleurisy, or inflammation of the muscles between the ribs, which, when not properly treated, proves the foundation of that disorder called the chest-founder; for if the inflammation is not dispersed in time, and the viscid blood and juices so attenuated by internal medicines, that a free circulation is obtained; such stiffness and inactivity will remain on these parts, as will not easily be removed, and which is generally known by the name of chest-founder.

The signs of this inflammation, or external pleurisy, are a stiffness of the body, shoulders, and fore-legs; attended sometimes with a short dry cough, and a shrinking when handled in those parts.

Bleeding, soft pectorals, attenuants, and gentle purges are the internal remedies; and externally, the parts affected may be bathed with equal parts of spirit of salt armoniac, and ointment of marshmallows, or oil of chamomile.

These outward inflammations frequently fall into the inside of the fore-leg, and sometimes near the shoulder; forming abscesses, which terminate the disorder.

The membrane which separates the lungs, and more particularly the diaphragm or midriff, is often also inflamed; which is scarce to be distinguished from the pleurisy, only in this, that when the midriff is greatly inflamed, the horse will sometimes be jaw set, and his mouth so much closed that nothing can be got in; but the method of cure is the same.

Of a Cough, and Asthma.

The consequence often of the preceding disorders injudiciously treated, are settled habitual coughs; which frequently degenerate into asthmatic, and broken-wind.

Nothing has more perplexed practitioners than the cure of settled coughs; the cause of which, perhaps, has been their want of attention to the different symptoms which distinguish one cough from another; for without strict observance thereof, it is impossible to find out the true method of cure.

Thus, if a horse's cough is of long standing, attended with loss of appetite, wasting of flesh, and weakness, it denotes a consumption; and that the lungs are full of knotty, hard substances, called tubercles, which have often been discovered on dissection.

The following signs denote when the cough proceeds from phlegm, and slimy matter, that float up the vesicles of the lungs.

The horse's flanks have a sudden quick motion; he breathes thick, but not with his nostrils open, like a horse in a fever, or that is broken-winded; his cough is sometimes dry and husky, sometimes moist, before which he wheezes, rattles in the throat, and sometimes throws out of his nose and mouth great gobs of white phlegm, especially after drinking, or when he begins or ends his exercise, which discharges commonly gives great relief. Some such horses wheeze and rattle to such a degree, and are so thick winded, that they can scarce move on, till they have been out some time in the air; though then they will perform beyond expectation.

The above asthmatic case proves often very obstinate; but, if it happens to a young horse, and the cough is not of long standing, it is greatly relieved, if not totally cured, by the following method.

If the horse is full of flesh, bleed him plentifully; if low in flesh, more sparingly; which may occasionally be repeated, on very great oppressions and difficulty of breathing, in proportionate quantities.

As mercurial medicines are found remarkably useful in these cases, give a mercurial ball (with two drams of calomel) over night, and a common purge next morning.

The following, which is recommended by Mr Gibson.

Take gum-galbanum, ammoniacum, and ala feris,
of each two drams, fine aloes one ounce, saffron one dram, oil of annaeed two drams, oil of amber one dram; with honey enough to form into a ball.

They may be repeated at proper intervals, with the usual cautions. In the intermediate days, and for some time after, one of the following balls may be given every morning.

Taste cinnabar of antimony, finely levigated, six ounces; gum ammoniacum, galbanum, and a squills, of each two ounces; garlick four ounces; saffron half an ounce; make into a paste for balls, with a proper quantity of honey.

Take of the peocoral or cordial ball one pound, balsam of Peru half an ounce, balsam of sulphur annized one ounce, flowers of Benjamin half an ounce, honey as much as is sufficient to form them into a paste; give the size of a pigeon’s egg every morning.

Exercise in a free open air is very serviceable, and the diet should be moderate.

The following are the symptoms of a dry cough, or asthma.

The horse affected with this cough eats heartily, hunts and goes through his business with alacrity, appears well coated, and has all the signs of perfect health; yet he coughs at particular times almost incessantly, without throwing up any thing, except that the violence of the cough will cause a little clear water to distill from his nose. Though this cough is not periodical, yet some of these horses cough most in a morning, after drinking.

This may properly be styled a nervous asthma in a horse; as probably it chiefly affects the nerves in the membranous parts of the lungs and heart; and is as a cause very doubtful at least, if not incurable; but when the horse is young, the following method may be successful.

Take away first a moderate quantity of blood; then give him two doses of calomel, mixed up with an ounce of diapente, for two nights; and the next morning a purging ball. Keep him well clothed and littered, and feed him with scalded bran and warm water.

Once in eight or ten days this purge may be repeated, with one mercurial ball only, given over night.

The following balls may then be taken, one every day, about the size of a pullet’s egg, the horse falling two hours afterwards; and should be continued two months, or longer, to be of real service.

Take native cinnabar, or cinnabar of antimony, half a pound; gum guaiacum four ounces; myrrh, and gum ammoniac, of each two ounces; Venice soap half a pound; the cinnabar must be finely levigated, as before observed, and the whole mixed up with honey, or oxymel squills.

The following also will be found a useful remedy in obstinate dry coughs.

Take gum ammoniacum, squills, and Venice soap, of each four ounces, balsam of sulphur with annized one ounce; beat up into a mass, and give as the former.

Before we close this section, it may be necessary to observe here, that some young horses are subject to coughs on cutting their teeth; their eyes also are affected from the same cause. In these cases, always bleed; and if the cough is obstinate, repeat it, and give warm mashes; which, in general, are alone sufficient to remove this complaint.

Of a Broken wind.

This disorder hitherto seems to have been little understood; but Mr. Giffon is inclined to think, that the source of it is frequently owing to injudicious or hasty feeding young horses for sale; by which means the growth of the lungs, and all the contents within the chest, are so increased, and in a few years so preternaturally enlarged, that the cavity of the chest is not capacious enough for them to expand themselves in, and perform their functions.

A narrow contracted chest with large lungs may sometimes naturally be the cause of this disorder; and it has been observed, that horses rising eight years old are as liable to this distemper, as, at a certain period of life, men fall into asthmatics, consumptions, and other chronic dis eases.

The reason why this disorder becomes more apparent at this age, may be, that a horse comes to his full strength and maturity at this time; at six he commonly finishes his growth in height; after that time he eats down his belly, and spreads, and all his parts are grown to their full extent; so that the pressure on the lungs and midriff is now more increased.

But how little weight soever these reasons may have, repeated dissections have given ocular proofs of a preternatural largeness, not only of the lungs of broken-winded horses, but of their heart and its bag, and of the membrane which divides the chest; as well as of a remarkable thinness in the diaphragm, or midriff.

This disproportion has been observed to be so great, that the heart and lungs have been almost of twice their natural size, perfectly found, and without any ulceration whatever; or any defect in the wind-pipe, or its glands. Hence it appears, that this enormous size of the lungs, and the space they occupy, by hindering the free action of the midriff, is the chief cause of this disorder; and as the substance of the lungs was found more fliehy than usual, they of course must lose a great deal of their spring and tone.

Whoever considers a broken-wind in this light, must own that it may be reckoned among the incurable distempers of horses; and that all the boasted pretensions to cure are vain and frivolous, since the utmost skill can amount to no more than now and then palliating the symptoms, and mitigating their violence.

We shall therefore only lay down such methods as may probably prevent this disorder, when pursued in time. But if they should not succeed, we shall offer some remedies and rules to mitigate its force, and to make a horse as useful as possible under this malady.

It is usual, before a broken wind appears, for a horse to have a dry obstinate cough, without any visible sickness or loss of appetite; but, on the contrary, a disposition to foul feeding, eating the litter, and drinking much water.
In order then to prevent, as much as possible, this disorder, bleed him, and give him the mercurial physic above preferred, which should be repeated two or three times.

The following balls are then to be taken for some time, which have been found extremely efficacious in removing obstinate coughs.

Take aurum mosaicum, finely powdered, eight ounces; myrrh and elicampane, powdered, each four ounces; anniseeds and bay-berries, each an ounce; saffron, half an ounce; make into balls with oxymel squills.

The aurum mosaicum is made of equal parts of quicksilver, tin, gallic acid, and sulphur. We give this medicine as strongly recommended by Mr. Gibson; but how far the aurum mosaicum may contribute to its efficacy, may perhaps justly be doubted: as a substitute in its room, therefore, for this purpose, we recommend the same quantity of powdered squills, or gum ammoniacum, or equal parts of each.

Broken-winded horses should eat sparingly of hay, which as well as their corn may be watered with chamber lye, or fair water; as this will make them less craving after water.

The volatile salts in the urine may make it preferable to water, and may be the reason why garlic is found so efficacious in these cases; two or three cloves given at a time in a feed, or three ounces of garlic bruised, and boiled in a quart of milk and water, and given every other morning for a fortnight, having been found very serviceable; for by warming and stimulating the solids, and dissolving the tenacious juices, which choke up the vellums of the lungs, these complaints are greatly relieved.

Careful feeding, and moderate exercise has greatly relieved broken-winded horses.

Horses sent to graze in order to be cured of an obstinate cough, have often returned completely broken-winded, where the pasture has been rich and succulent, so that they have had their bellies constantly full. As the ill consequence therefore is obvious, where you have not the conveniency of turning your horse for a confinement, you may foil him for a month or two with young green barley, tares, or any other young herbage.

To purgative thick-winded horses, Barbadoes and common tar have often been given with success, to the quantity of two spoonfuls mixed with the yolk of an egg, dissolved in warm ale, and given fasting or two or three times a week, especially those days you hunt or travel.

But in order to make all these sorts of horses of any real service to you, the grand point is to have a particular regard to their diet, observing a just economy both in that and their exercise; giving but a moderate quantity of hay, corn, or water, at a time, and moistening the former, to prevent their requiring too much of the latter, and never exercising them but with moderation, as has before been observed. The following alternative ball may be given once a fortnight or three weeks; and as it operates very gently, and requires no confinement but those days it is given (when warm meat and water are necessary), it may be continued for two or three months.

Take succus tridenti aloes, fix drams; myrrh, galbanum, and ammoniacum, of each two drams; bay-berries half an ounce: make into a ball with a spoonful of oil of amber, and a sufficient quantity of syrup of buckthorn.

Of a Consumption.

When a consumption proceeds from a defect in a horse's lungs, or any principal bowel; the eyes look dull; the ears and feet are mostly hot; he coughs sharply by fits; sneezes much, and frequently groans with it; his flanks have a quick motion; he glets often at the nose, and sometimes throws out a yellowish curdled matter; and he has little appetite to hay, but will eat corn, after which he generally grows hot.

As to the cure, one of the principal things is bleeding in small quantities (a pint, or pint and half, from some horses is sufficient) which should be repeated as often as the breath is more than ordinarily oppressed. Pectorals may be given to palliate present symptoms; but as defections have discovered both the glands of the lungs and mefentery to be swollen, and often indurated, the whole stress lies on mercurial purges, and the following ponderous alteratives, given intermediately.

Take native cinnabar, or cinnabar of antimony, one pound, powdered very fine, and add the same quantity of gum guaiacum and nitre; give the horse an ounce of this powder twice a-day, wetting his feeds.

The spring grass is often extremely serviceable, but the salt marshes are to be preferred, and to be more depended on than medicines; for great alterations are thereby made in the blood and juices, and no small benefit arises from open air and proper exercise.

Of an Apoplexy or Staggers, Convulsive Disorders, Lethargy, Epilepsy, and Palsy.

Farriers generally include all distempers of the head under two denominations, viz. staggers and convulsions; wherein they always suppose the head primarily affected. But in treating these disorders, we will distinguish between those that are peculiar to the head, as having their source originally thence; and those that are only concomitants of some other disease.

In an apoplexy a horse drops down suddenly, without other sense or motion than a working at his flanks.

The previous symptoms are, drowsines; watery eyes, somewhat full and inflamed; a disposition to reel, feebleness, a bad appetite; the head almost constantly hanging, or reeling on the manger; sometimes with little or no fever, and scarce any alteration in the dung or urine: the horse is sometimes disposed to rear up, and apt to fall back when handled about the head; which is often the cafe with young horses, to which it does not prove suddenly mortal; but with proper help they may sometimes recover. If the apoplexy proceeds from wounds, or blows on the head, or matter on the brain; besides the above symptoms, the horse will be frantic by fits, especially after his feeds, so as to start and fly at every thing. These cafes seldom admit of a perfect recovery; and when horses fall down suddenly, and work violently at their flanks, without any ability to rise after a plentiful bleeding, they seldom recover.

All
All that can be done is to empty the vessels as speedily as possible, by striking the veins in several parts at once, bleeding to four or five quarts, and to raise up the horse's head and shoulders, supporting them with plenty of straw. If he survives, cut several rowsels; give him night and morning glysters prepared with a strong decoclio of fenna and salt, or the purging glyster mentioned in the direction; blow once a day up his nostrils a dram of powder of affarabacca, which will promote a great discharge; afterwards two or three aloeic purges should be given; and to secure him from a relapse, by attenuating and thinning his blood, give him an ounce of equal parts of antimony and crocus metallorum for a month; or, which is preferable, the same quantity of cinnabar of antimony and gum guaiacum.

If the fit proceeds only from fulnefs of blood, high feeding, and want of sufficient exercife, or a fify blood (which is often the cafe with young horses, who though they reel, stagger, and sometimes suddenly fall down, yet are easily cured by the above method), an opening diet with scalded bran and barley will be necessary for fome time; and the bleeding may be repeated in small quantities.

As to the other disorders of the head, fuch as lethargy or sleeping evil, epilefy or falling-ficknfs, vertigo, frenzy, and madnefs, convulsions, and paralytic disorders, as they are moft of them to be treated as the apoplexy and epilefy, by bleeding and evacuations with the alteratives there directed, we shall wave treating of them separafely, but mention fome particular rules to diftinguish them, according to the plan we laid down, and then offer fome general remedies for the feveral purpofes.

In an epilefy, or falling ficknfs, the horse reeds and flaggers, his eyes are fixed in his head, he has no fene of what he is doing, he ftales and dungs infenfibly, he runs round and falls suddenly; fometimes he is inmoveable, with his legs fretched out as if he was dead, except only a quick motion of his heart and lungs, which caufes a violent working of his flanks; fometimes he has involuntary motions, and shaking of his limbs, fo strong, that he has not only beat and fpurned his litter, but the pavement with it; and with these alternate symptoms a horse continued more than three hours, and then he has as surprifingly recovered; at the going off of the fit, he generally foams at the mouth, the foam being white and dry, like what comes from a healthful horse when he champs on the bit. But in all kinds of grifes, whether they proceed from disorders in the guts, or retention of urine, a horse is often up and down, rolls and tumbles about; and when he goes to lie down, generally makes feveral motions with great feeming carefulness, which fhews he has a fenfe of his pain; and if he lays flretched out for any time, it generally but for a fhort space.

Epilepsies and convulsions may arife from blows on the head, too violent exercife, and hard ftraining; and from a fulnefs of blood, or impoverished blood, and furfeits; which are fome of the caufes that denote the original disorder.

In lethargic disorders, the horse generally reeds his head with his mouth in the manger, and his pole often reclined.
walk, he is ready to fall at every step, unless he be carefully supported; his eyes are so fixed with the infatiation of the muscles, as give him a deadness in his looks; he starts and freezes often, pants continually with shortness of breath; and this symptom increases continually till he drops down dead; which generally happens in a few days, unless some sudden and very effectual turn can be given to the distemper.

In all these cases the horse should first be bled plentifully, unless he is low in flesh, old, or lately come off any hard continued duty, then you must be more sparing the medicines, as give him a deadness in his looks; he

This may be given twice a day at first; and then once, washed down with a decoction of mistletoe or valerian sweetened with liquorice or honey: an ounce of affa foetida may be tied up in a piece of strong coarse linen rag, and put behind his grinders to champ on.

This ball may be given twice a day at first; and then once, washed down with a decoction of mistletoe or valerian sweetened with liquorice or honey: an ounce of affa foetida may be tied up in a piece of strong coarse linen rag, and put behind his grinders to champ on.

This is the most effectual method of treating these disorders; but when they are suspected to arise from bots, and worms, which is generally the case, mercurial medicines must lead the way, thus:

The laxative purges and emollient gysters should be given immediately to keep the body open; but when the former balls have been taken a week or ten days, the following may be given once a day with the valerian decoction.

Take cinnabar of antimony six drams, affa foetida half an ounce, aritoblochia myrrh and bay-berries of each two drams; make into a ball with treacle and oil of amber.

This ball may be given twice a day at first; and then once, washed down with a decoction of mistletoe or valerian sweetened with liquorice or honey: an ounce of affa foetida may be tied up in a piece of strong coarse linen rag, and put behind his grinders to champ on.

The laxative purges and emollient gysters should be given immediately to keep the body open; but when the former balls have been taken a week or ten days, the following may be given once a day with the valerian decoction.

Take cinnabar of antimony six drams, affa foetida half an ounce, aritoblochia myrrh and bay-berries of each two drams; make into a ball with treacle and oil of amber.

This is the most effectual method of treating these disorders; but when they are suspected to arise from bots, and worms, which is generally the case, mercurial medicines must lead the way, thus:

Take mercurius dulcis and philonium of each half an ounce; make into a ball with conserve of roses, and give the horse immediately; half the quantity may be repeated in four or five days.

The following infusion should then be given, to the quantity of three or four horns, three or four times a day, till the symptoms abate; when the above nervous balls may be continued till they are removed.

Take penny-royal and rue of each two large handfuls, chamomile flowers one handful, affa foetida and caflor of each half an ounce, saffron and liquorice-root sliced of each two drams; infuse in two quarts of boiling water; pour off from the ingredients as wanted.

If the caflor is omitted, add an ounce of affa foetida. The following ointment may be rubbed into the cheeks, temples, neck, shoulders, spines of the back and loins, and where ever there is the greatest contractions and stiffness.

Take nerve and marshmallow ointment of each four ounces, oil of amber two ounces, with a sufficient quantity of camphorate spirit of wine; make a liniment.

When the jaws are so locked up that medicines cannot be given by the mouth, it is more eligible to give them by way of gyster; for forcing open the jaws by violence often puts a horse into such agonics, that the symptoms are thereby increased.

In this case also he must be supported by nourishing gysters, made of milk-pottage, broths, &c. which must be given to the quantity of three or four quarts a day; gysters of this kind will be retained, and absorbed into the blood; and there have been instances of horses thus supported for three weeks together, who must otherwise have perished.

Mr Gibbon mentions some extraordinary instances of success in cases of this sort by these methods, and repeated frictions, which are extremely serviceable in all convulsive disorders, and often prevent their being jaw-set; they should be applied with unwearied diligence every two or three hours, where ever any stiffness or contractions in the muscles appear; for a horse in this condition never lies down till they are in some measure removed.

The use of rowels in these cases is generally unsuccessful, the skin being so tense and tight, that they seldom digest kindly, and sometimes mortify; so that if they are applied, they should be put under the jaws, and in the breast.

The red-hot iron so frequently run through the fontop and mane, near the occipital bone, for this purpose, has often been found to have destroyed the cervical ligament.

In paralytic disorders, where the use of a limb or limbs is taken away, the internals above recommended should be given, in order to warm, invigorate, and attenuate the blood; and the following stimulating embrocation should be rubbed into the parts affected.

Take oil of turpentine four ounces, nerve ointment and oil of bays of each two ounces, camphor rubbed fine one ounce, rectified oil of amber three ounces, tincture of cantharides one ounce.

With this liniment the parts affected should be well bathed for a considerable time, to make it penetrate; and when the hind parts chiefly are lame, the back and loins should be well rubbed with the same. To the nervous medicines above recommended, may be added snakeroot, contrayerva, mustard-seed, horse-raddish root steeped in strong beer, or wine where it can be afforded. Take the following for an example, which may be given to the quantity of three pints a day alone, or two horns full may be taken after the nervous balls.

Take snakeroot, contrayerva, and valerian, of each half an ounce; mustard-seed and horseraddish root scraped, of each two ounces; long pepper two drams: infuse in three pints of strong wine.

When the horse is recovering from any of the above disorders, the following alterative purge may be repeated two or three times, as it operates very gently.

Take succotrine aloes one ounce, myrrh half an ounce, affa foetida and gum ammoniacum of each two drams, saffron one dram; make into a ball with treacle.

When a retention of dung is the cause of this disorder, the great gut should first be raked thoroughly with a small hand, after which plenty of emollient oily gysters should be thrown up, and the opening drink given, till the bowels are thoroughly emptied of their imprisoned dung. Their diet should for some days be opening, and consist...
THE STRANGLES, AND VIVES.

The strangles is a distemper to which colts and young horses are very subject; and begins with a swelling between the jaw bones, which sometimes extends to the muscles of the tongue; and is attended with so great heat, pain, and inflammation, that sometimes, till matter is formed, the horse swallows with the utmost difficulty. The symptoms are extraordinary heat and feverishness, with a painful cough, and a great inclination to drink without being able; some horses losing their appetite entirely, others eating but little, by reason of the pain which chewing and swallowing occasions: when the swelling begins on the inside of the jaw bones, it is much longer en coming to matter than when more to the middle; when it arises among the glands, and divides into several tumours, the cure is generally tedious, as it breaks in different places; and when it forms upwards on the wind-pipe and gullet, there is sometimes danger of suffocation, unless the swelling soon breaks. But the most dangerous kind is, when, besides the above symptoms, the horfe runs at the nose; this is by some called the beftrard strangler.

As this disorder seems to be critical, the most approved method is to assist nature in bringing the swellings to maturity, by keeping them constantly moist with ointment. When the swelling is formed, the horse swallows with the utmost difficulty. The symptoms are extraordinary heat and feverishness, that sometimes, till matter is formed, the horse swallows with the utmost difficulty. The running at the nose which often attends the strangles is dangerous, especially if it continues after they have ripened and broke, as the horse will be greatly weakened thereby. To prevent this waste and decay, give him every day for some time an ounce of Jesuit's bark; or a strong decoction of guaiacum shavings, which hath been found extremely beneficial in restraining these glandular discharges when too liberal, and in drying up ulcers of all kinds in horses.

If a hardness remains after the sores are healed up, they may be anointed with the mercurial ointment; and when the horse has recovered his strength, purging will be necessary. The vives or ives differ from the strangles only in this; that the swellings of the kernels, under the ears of the horse, (which are the parts at first chiefly affected), seldom gather, or come to matter, but by degrees perspire off and disperse by warm clothing, anointing with the marshmallow ointment, and a moderate bleeding or two. But should the inflammation continue notwithstanding these means, a suppuration must be promoted by the methods above recommended in the strangles.

When these swellings appear in an old or full-aged horse, they are signs of great malignity, and often of an inward decay, as well as forerunners of the glanders. The mercurial ointment above mentioned, may be prepared thus:

Take of crude mercury or quicksilver one ounce, Venice turpentine half an ounce; rub together in a mortar till the globules of the quicksilver are no longer visible; then add two ounces of hogs-lard;

The mercurial ointment above mentioned, may be prepared thus:

Take of crude mercury or quicksilver one ounce, Venice turpentine half an ounce; rub together in a mortar till the globules of the quicksilver are no longer visible; then add two ounces of hogs-lard.

Of the Disorders of the Eyes.

In order to make the disorders of the eyes well understood, we shall consider them as arising from different causes; external injuries affecting the globe of the eye; and from internal causes affecting the humours within the globe. We shall consider also the eye as naturally weak from a bad conformation, which possibly may often be hereditary.

In all recent disorders of the eye from external injuries, such as blows, bites, &c. attended with a swelling of the lid, and a running from the eye, you must first sponge the part often with cold spring-water and vinegar; and if much swelled, bleed immediately, and apply over it a poultice made of the pulps of roasted or boiled apples, cleared from their seeds and hulls; or of conserve of rose and vinegar, with a little bole, and the white of an egg. When the swelling is abated, either of the following washes will complete the cure:

Take white vitriol half an ounce, sugar of lead two drams; dissolve in a pint of spring-water; to which may occasionally be added, when the rheum is very great, and inflammation removed, half an ounce of tarry, or compound powder cerus.

Let the eye and eyelid be bathed three or four times a-day with a clean sponge dipped in this wash; or it may be applied with a feather, leaving a few drops on the eye. When the veins under the eye have been turgid, opening them with a lancet has often been found successful.
Mr. Gibson, from his own experience, recommends the following, with which alone he has succeeded in most common cases.

**Take two drams of rose-buds, infuse them in half a pint of boiling water; when cold, pour off the infusion, and add to it twenty grains of sugar of lead.**

This is to be used as the former; but the quantity of sugar of lead may occasionally be increased.

Sometimes from the violence of the inflammation, succeeding blows, and external injuries, the coats of the eye shall lose their transparency, thicken, and turn white, or pearl-colour; in the latter case, the horse has some glimmering of light; in the former, he is blind while the eye continues in this state.

If the horse be sleek and of a gross constitution, bleeding may be repeated, and a rowel will be necessary: let his diet be scarred bran or barley; avoiding for some days oats, beans, or any thing hard to chew.

The cooling opening drink, (p. 547. col. 1. par. 1.) should be given every other day, which will answer better than aloeetic purges.

If the eye-lids continue swollen and moist, and the under side of the eye inflamed, an ounce of honey may be added to four ounces of the above waters, or the part of sugar of lead in three ounces of spring-water: to which may be added, when the eye is very watery, a spoonful or two of red wine, which will help to thicken the matter and dry it up.

If a film or thick slough should remain, it may be taken off, by blowing into the eye equal parts of white vitriol and sugar-candy finely powdered.

Glass finely powdered, mixed up with honey and a little fresh butter, is much recommended by Dr. Bracken for this purpose; as also the following ointment.

**Take ointment of tarry one ounce, honey of roses two drams, white vitriol burnt one scruple; this, with a feather, may be smeared over the eye twice a day.**

Let it be remembered, that it has long been observed in practice, that the eye in its first state of inflammation is so very tender, that the eye-waters prepared with tarry and other powders aggravate the disorder; consequently, during this state, the tinctures of vegetables and solutions of salts are greatly preferable.

Wounds of the eye may be dressed with honey of roses alone, or with a little sugar of lead mixed with it, adding thereto, after a few days, an eighth part of tincture of myrrh; all the preceding directions in regard to inflammation being attended to, especially bleeding, rowels, and gentle cooling physic.

When the humors of the eye are thickened, and the disorder is within the globe, sharp external applications are not only useless, but extremely detrimental, by the irritation they occasion, and consequently should be avoided.

In all cases of this sort, whether moon-eyes, which are only cataracts forming, or in confirmed ones attended with a weeping; general evacuations, with internal alteratives, can only take place.

These generally make their appearance, when a horse is turned five, coming fix; at which time one eye becomes clouded, the eye lids being swelled, and very often shut up; and a thin water generally runs from the diseased eye down the cheek, so sharp as sometimes to excoriate the skin; the veins of the temple, under the eye, and along the nose, are turgid and full: though sometimes it happens that the eye runs but little.

This disorder comes and goes till the cataract is ripe; then all pain and running disappears, and the horse becomes totally blind, which is generally in about two years. During this time some horses have more frequent returns than others, which continue in some a week or more, in others three or four; returning once in two or three months, and they are seldom so long as five without a relapse.

There is another kind of moon-blindness, which is also the forerunner of cataracts, where no humour or weeping attends. The eye is never shut up or closed here, but will now and then look thick and troubled, at which time the horse sees nothing, diffusely: when the eyes appear sunk and perishing, the cataracts are longer coming to maturity; and it is not unfrequent in this case for one eye to escape.

These cases generally end in blindness of one, if not of both eyes; the most promising signs of recovery are when the attacks come more seldom, and their continuance grows shorter, and that they leave the cornea clear and transparent, and the globe plump and full.

The attempts to cure cataracts have hitherto been only palliative and mitigating the symptoms; yet early care has sometimes been successful. To this end the horse should be rowelled and bled at proper intervals; except where the eyes appear sunk and perishing, where it is often pernicious. During the violence of the symptoms, observe the cooling treatment above recommended, giving him two ounces of nitre every day mixed into a ball with honey, and bathe the parts above the eye with verjuice, or vinegar, wherein rose-leaves are infused; to four ounces of which, half a dram of sugar of lead may be added.

The swelling on the lid may afterwards be bathed with a sponge dipped in equal parts of lime and Hungary water, mixed together: the cooling physic, (p. 545 col. 1. par. 4.) should be given every fourth day, till the eye becomes clear, and recovers its usual brightness. The following also is very proper physic for this purpose.

**Take lenitive electuary and cream of tartar of each four ounces, Glauuber's salts three ounces, syrup of buckthorn two ounces.**

When the weeping is by these means removed, the alterative powders (See the section, Of Alterative Medicines) should be given every day, till two or three pounds are taken, and after an interval of three months, the same course should be repeated. This method has often been attended with good success, where the eyes have been full, and no way perished; in that case, bathe or foment the same with the following, twice a day.

**Take crude sal ammoniac two drams, diffolve in a pint of lime-water, and add to it four ounces of brandy, or Hungary water.**

This will act as a stimulus, and may help to thin and clarify
satisfy the gummy juices, and bring new supplies of nourishment to the periling eyes.

This course not succeeding, in order more powerfully to open the vessels of the chrysaline humour, (which in these cases is always found opaque, and, when the cataract is confirmed, entirely loses its transparency,) and hinder as much as possible the forming of obstructions, mercurials are chiefly to be depended on: thus give every other day, for three or four mornings, two drams of calomel, mixed up with conserve of roses; and then purge off with the common ball.

During this course, particular care should be taken of the horse: after repeating this, the alterative powders before-mentioned should be given for some weeks or months, if you expect any benefit from them; or they may be heat up into a ball with live millipedes, and an ounce and a half given, every day: if these should not succeed, and the horse is a valuable one, the turblind course recommended in the fiction on alteratives, seems to be the most promising method left. But, to horses that are not so, an ounce of antimony, ground into an impalpable powder, may be given every day in one of his feeds for three months or longer; or a strong decoction of guaiacum shavings may be given for some time, to which crude antimony may be given in the following manner.

Take guaiacum shavings one pound, crude antimony tied in a rag the same quantity; boil in two gallons of forge-water to one, and give a quart a-day, either alone, or mixed with his water.

The haws is a swelling and sponginess that grows in the inner corner of the eye, so large sometimes as to cover a part of the eye. The operation here is easily performed by cutting part of it away; but the farriers are apt to cut away too much; the wound may be dressed with honey of roses; and if a fungus or spongy flesh arises, it should be sprinkled with burnt alum, or touched with blue vitriol.

Of the Glanders.

The cause and seat of the glanders has till lately been so imperfectly handled, and so little understood by the writers of this distemper, that it is no wonder it should be ranked among the incurables: but a new light having been thrown on this whole affair by the study of M. La Foffe, the king of France's farrier, who has been at the pains to trace out, and discover, by dissections, the source and caufe of this disorder; we hope the method he has propounded, with some further experiments and improvements, will soon bring to a certainty of cure (in most cases at least) a distemper so dangerous to our horses, and that hitherto has eluded the forces of art.

M. de la Foffe has distinguished seven different kinds of glanders, four of which are incurable.

The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, sometimes appearing in lumps and grumes: in this distemper, though the matter is discharged from the nostrils, yet the malady is solely in the lungs.

The second is a watery humour, which usually seizes horses at the decline of a disease, caused by too hard labour; this defluxion also proceeds from the lungs.

The third is a malignant discharge, which attends the strangles sometimes, and falls upon the lungs, which runs off by the nostrils.

The fourth is, when an acrimonious humour in the farcy seizes these parts, where it soon makes terrible havoc.

The fifth kind we shall describe by and by, as arising from taking cold.

The sixth kind is a discharge from the strangles, which sometimes vents itself at the nostrils.

These are the various disorders which have been observed sometimes to throw matter out from the nostrils; let us now describe the real glanders.

The matter, then, discharged from the nostrils of a glandered horse, is either white, yellow, or greenish, sometimes streaked, or tinged with blood: when the discharge is of long standing, and the bones are fouled, the matter turns blackish, and becomes very putrid; and is always attended with a swelling of the kernels or glands under the jaws; in every other respect the horse is generally healthy and sound, till the distemper has been of some continuance.

It is always a bad sign, when the matter sticks to the inside of the nostrils, like glue or stiff paste; when the inside of the nose is raw, and looks of a livid or lead-like colour; when the matter becomes bloody, and flakes, and when it looks of an ah-colour. But when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw not increasing, and the disorder of no long continuance, we may expect a speedy care; for in this case, which arises from taking cold, after a horse has been overheated, the putrifying membrane is but slightly inflamed, the lymph in the small vessels congealed, and the glands overloaded, but not yet ulcerated.

From these symptoms, and some observations made both by Bracken and Gibbon, it is plain they were not absolute strangers to the feat of this disorder, though they neglected pushing their inquiries to the fountain-head, and consequently were at a loss to know how to apply the remedy to the parts affected.

But our author, after examining by dissection the carcases of glandered horses, and making a strict scrutiny into the state of the viscera, allotted for that purpose by ingenious and expert anatomists, for ten years together, affirms this distemper to be altogether local; and that the true seat of it is in the putrifying membrane which lines the partition along the inside of the nose, the maxillary sinuses or cavities of the cheek-bones on each side the nose, and the frontal sinuses or cavities above the orbits of the eyes; that the viscera, as liver, lungs, &c. of glandered horses are in general exceeding found; and consequently that the seat of this disorder is not in those parts, as has been asserted by most authors; nor indeed is it probable it should: for how could such horses preserve their appetite, their good appearance, sleek and shining coats? in a word, all the signs of health for many years together (which many glandered horses are known to enjoy) with such distempered bowels.

But on nicely examining the heads of such horses, he found the cavities above-mentioned more or less filled with a viscid limy matter, the membrane which lines both them and the nostrils inflamed, thickened, and corroded...
with fistulous ulcers, which in some cases had eaten into the bones.

He observes, that when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found disinterred.

It is a curious remark of our author, that the sublingual glands, or the kernels situated under the jaw-bone, which are always swelled in this distemper, do not discharge their lymph into the mouth, as in man, but into the nostrils; and that he constantly found their obstruction agreed with the discharge; if one gland only was affected, then the horse discharged from one nostril only; but if both were, then the discharge was from both.

The seat of this disorder thus discovered, our author with great ingenuity has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection, and in fine the ulcers deterged, healed, and dried up.

But as from the observations since made by this gentleman, there are different species of the glands, so the cure of the milder kinds may first be attempted by injections and fumigations: thus after taking cold, should a horse for fifteen or twenty days discharge a limpid fluid or whitish matter from one or both nostrils, the glands under the jaw rather growing harder than diminishing, we may expect it will degenerate into a true glanders.

To prevent which, after first bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with the powders of frankincense, mastich, amber, and repeated three times a-day: should the running not lessen, be thrown up as far as possible with a strong syringe, and dried up.

But the chief of this disorder thus discovered, our author with great ingenuity has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection, and in fine the ulcers deterged, healed, and dried up.

The seat of this disorder thus discovered, our author with great ingenuity has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection, and in fine the ulcers deterged, healed, and dried up.
ment. when to control or encourage a looseness, but these appearances of horses that die of this disorder, whose blood, and inflaming the bowels, till a mortification is brought on them. These are, in general, the constant medicines should in every species of this disorder be guarded against, and given with great caution and discretion. It is sometimes a nice matter to form a proper judgment when to control or encourage a looseness, but these general rules may be a direction: If a healthy full horse, on taking cold, or upon hard riding, overfeeding, eating unwholesome food, or with a flight fever, should have a moderate purging, by no means think of stopping it; but rather encourage it with an open diet, and plenty of warm gruel: but if it continues long, with gripings, the mucus of the bowels coming away, and the horse losing his appetite and flesh, it is then high time to give him proper medicines; if he voids great quantities of lime and greyish matter, give him the following drench, and repeat it every other day for three times.

Take lenitive electuary and cream of tartar of each four ounces, yellow rosin finely powdered one ounce, and four ounces of sweet oil; mix with a pint of water gruel.

The following alternative ball alone has been found successful for this purpose, when given twice a-week, with scalded bran and warm gruel.

Take luccotrine aloes half an ounce, diapente one ounce; make into a ball with the juice of Spanish liquorice dissolved in water, and a spoonful of oil of amber. To this may be added two drams of myrrh, and a dram of saffron, and (where it can be afforded) half an ounce of rhubarb.

When the purging is attended with a fever, rhubarb should first be given to the quantity of half an ounce, with an ounce and half of lenitive electuary; at night after the working, give half an ounce or more of diascordium in a pint of red wine mulled with cinnamon, and repeat it every day, and the rhubarb ball once in two or three.

But if the distemper increases, the horse's flanks and belly look full and distended, and he appears griped and in pain, let this glyster be given, and the quantity of diascordium increased an ounce in his night-drink.

Take chamomile flowers one handful, red roses half a handful, pomegranate and bauatsines of each an ounce; boil in two quarts of water to one; strain off, and dissolve in it two or three ounces of diascordium, and one of mithridate; to which may be added a pint of port wine: repeat it once a-day.

If the flux continues violent, give an ounce of rock-alum, with an ounce and a half of bole, twice a-day; or, dissolve double this quantity with two ounces of diascordium, and the cordial ball, in two quarts of harts-horn drink; to which may be added a pint of port; and give the horfe, three or four times a-day, a pint of this drink. For this purpose also a strong decoction of oak-bark may be given, with either of the above remedies, and to the same quantity; even by itself, it will be found on trial a no incon siderable remedy.

When the discharge is attended with an acrid mucus or slime, the griping and pains are very severe, the common lining of the bowels coming washed away; in this case, the following glyster should frequently be injected warm.

Take of tripe-liquor or thin starch two quarts, oil of olives half a pint, the yolk of six eggs well broke, and two or three ounces of course sugar. Some horses having naturally weak stomachs and bowels,
bowels, throw out their aliment undigested; their dung
is habitually soft, and of a pale colour; they feed poorly,
and get no flesh: to remedy this complaint, give the fol-
lowing purge two or three times; and then the infusion
to the quantity of a pint every morning.

Take succotrme aloe six drams, rhubarb powdered
drugs, myrrh and faffron each a dram; make
into a ball with syrup of ginger.

Infusion.—Take zedoary, gentian, winters bark, and
orange peel, of each two ounces; pomegranate-bark
and balsamint, each of an ounce; chamomile-flowers
and centaury, each a handful; cinnamon and cloves,
each an ounce: infuse in a gallon of port or strong
beer.

The bloody flux is a distemper horses are not very lub-
ject to; however, as it sometimes does occur, whenever
blood is discharged, attended with gripings, and great
pain in the bowels, if the flux is not speedily restrained,
the horse probably may be soon lost: we recommend there-
fore the following glyster and drink for that purpose.

Take oak bark four ounces, tormentil-root two ounces,
burnt hornthorn three ounces; boil in three
quarters of forge water to two; strain off, and add
two ounces of disaccordium, four ounces of flarch,
and half a dram of opium.

A glyster may also be prepared with the same quantity of
fat broth, flarch and opium, in order to plufier over the
cists of the bowels, and abate their violent irritations.
Also,

Take soft chalk two ounces, mithridate or diaforium
one ounce, powder of Indian-root half a dram,
liquid laudanum fifty or sixty drops; disfolve in a
pint of hornthorn drink, and add to it four ounces
of cinnamon-water or red wine: give it twice a-
day.

Gum arabic dissolved in hornthorn drink, or in common
water, should be the horse's usual drink.

When horses are apt to be coltive, from whatever
cause it arises, gentle openers should be given; such as
cream of tartar, Chabers's salts, and lenitive elecutary;
four ounces of any two of these dissolved in warm ale,
whey, or water, given every other morning for two or
two thirds, will answer this purpose; especially if affifted
by an oily emollient glyster, prepared with a handful
of salt. Sacked bran or barely, with an ounce of fenugreek
and lafiest, occasionally given, will prevent this com-
plaint: but where it is constitutional, and proceeds from
the power and force of digestion in the stomach and guts,
as sometimes happens, and the horse is otherwise in per-
fecft health, no inconvenience will arise from it; and it is
observed that such horses are able to endure great fa-
tigue and labour.

Of Worms and Bots.

Authors have described three different sorts of
worms that affect horses, etc. Bots, which young horses
are often troubled with in the spring; the Rotundi, or
those resembling earth worms; and the Ascarides, or
those about the size of the largest sewing needle, with flat
heads.

The bots which breed in the stomachs of horses, and
are sometimes the cause of convulsions, appear to be very
large maggots, composed of circular rings, with little
sharp prickly feet along the sides of their bellies (like the
feet of hog-lice), which by their shapness (like the
points of the finest needles) seem to be of use to feten
them to the part where they breed and draw their
nourishment, and to prevent their being loofered from
such adherence before they come to maturity. The eggs
from whence these bots are produced, are differfered into
clusters all round the lower orifice of the stomach, and
are laid under the inner coat or thin membrane of the
stomach; so that when the animals come to form and life,
they burst through this inner coat with their breech and tail
straight outwards, and their trunks fo fixed into the muf-
cular or fleny coat of the stomach, that it sometimes re-
quires a good pull to disengage them; from the blood of
this last coat they draw their nourishment, which they
suck like fo many leeches, every one ulcerating and pur-
sing up the part where it fixes like a honey comb; and
they often make such quick havoc, as to destroy the
horse.

The symptoms of worms are various. The bots that
many horses are troubled with in the beginning of the
summer, are always seen sticking on the strut gut, and
are often thrust out with the dung, with a yellowish co-
oured matter like melted sulphur; they are nowadays
dangerous there, but are apt to make a horse reflefs and
uneasv, and rub his breech against the post. The feafon
of their coming is usually in the months of May and
June, after which they are seldom to be seen, and rarely
continue in any one horse above a fortnight or three
weeks. Thofe that take their lodgment in the stomach,
are extremely dangerous by causing convulsions; and are
feldom discovered by any previous signs before they come
to life, when they throw a horse into violent agonies.
The other kinds are more troublesome than dangerous;
but are known by the following signs: The horfe looks
lean and jaded, his hair flares as if he was surfeited, and
nothing he eats makes him thrive; he often strikes his
hind feet againft his belly, is fometimes griped, but with-
out the violent fymptoms that attend a cholic or strangu-
ary; for he never rolls and tumbles, but only flews un-
cafnifs, and generally lays himself down quietly on his
belly for a little while, and then gets up and falls a feed-
ing; but the fureft sign is when he voids them with his
dung.

For the cure of bots in the stomach, we have already
taken notice that aloes ftiouid firft be given in large
quantities, and repeated at proper intervals, (fee p. 554.
col. 1.) £Ethiops mineral, or fome of the under men-
powdered, of each two drams; oil of savin and amber, of each one dram; syrup of buckthorn enough to form into a ball.

But as the source of worms in general proceeds from a vitiated appetite and a weak digestion, recourse must first be had to mercurials, and afterwards to such things as are proper to strengthen the stomach, promote digestion, and, by destroying the supposed ova, prevent the regeneration of these animals. Thus, two drams of calomel may be given with half an ounce of diapente, and mixed up with conserve of wormwood, over night; and the next morning the above purge; these may be repeated six or eight days. Or the following mercurial purge may be given, which will be less troublesome, and no less efficacious.

Take crude quicksilver two drams; Venice turpentine half an ounce; rub the quicksilver till no glistering appears; then add an ounce of aloes, a dram of grated ginger, thirty drops of oil of savin, and a sufficient quantity of syrup of buckthorn to make a ball.

One of these balls may be given every six days, with the usual precautions in regard to mercurial physic; and these powders interchangeably.

Take powdered tin and Ethiopia mineral of each half an ounce; give every night in a mahl, or among his corn.

The various preparations of antimony and mercury must be given several weeks together, in order to get entire riddance of these vermin. The Ethiopia mineral may be given to the quantity of half an ounce a day; the mercurius alkalifatus to two drams a day, incorporated with a bit of cordial ball. The cinnabar powders, as directed in the farcy, are no less effectual: and when worms are bred from high feeding, or unwholesome food; rue, garlic, tansy, savin, box, and many other simples, may be given successfully; being for that purpose mixed with their food; as also cut tobacco, from half an ounce to an ounce a day.

Of the Yellows, or Jaundice.

Horses are frequently subject to this distemper; which is known by a dulky yellowness of the eyes; the inside of the mouth and lips, the tongue and bars of the roof of the mouth, looking also yellow. The horse is dull, and refuses all manner of food; the fever is slow, yet both that and the yellowness increase together. The dung is often hard and dry, of a pale yellow, or light pale green. His urine is commonly of a dark dirty brown colour; and when it has settled some time on the pavement, it looks red like blood. He flagles with some pain and difficulty; and if the distemper is not checked soon, grows delirious and frantic. The off-side of the belly is sometimes hard and distended; and in old horses, when the liver has been long diseased, the cure is not practicable, and ends fatally with a wafting diarrhoea: but when the distemper is recent, and in young horses, there is no fear of a recovery, if the following directions are observed.

First of all bleed plentifully; and give the laxative glyster (p. 547, col. 1, par. 2, from the bottom) as hors:Vol. II. No. 50. 2 are apt to be very collique in this distemper; and the next day give him this purge.

Take of Indian rhubarb powdered one ounce and a half, saffron two drams, succotrine aloes six drams, syrup of buckthorn a sufficient quantity. If the rhubarb should be found too expensive, omit it, and add the same quantity of cream of tartar, and half an ounce of Caffile soap, with four drams more of aloes. This may be repeated two or three times, giving immediately the following balls and drink.

Take of Ethiopia mineral half an ounce, millepedes the same quantity, Caffile soap one ounce; make into a ball, and give one every day, and wash it down with a pint of this decoction.

Take madder-root and turmeric of each four ounces, burdock root sliced half a pound, Monk's rhubarb four ounces, liquorice sliced two ounces; boil in a gallon of forge-water to three quarts; strain off, and sweeten with honey.

Balls of Caffile soap and turmeric may be given also for this purpose, to the quantity of three or four ounces a day; and will in most recent cases succeed.

By these means the distemper generally abates in a week, which may be discovered by an alteration in the horse's eyes and mouth; but the medicines must be continued till the yellowness is entirely removed. Should the distemper prove obdurate, and not submit to this treatment, you must try more potent remedies, viz. mercurial physic, repeated two or three times at proper intervals; and then the following balls.

Take salt of tartar two ounces, cinnabar of antimony four ounces, live millepedes and filings of steel of each three ounces, saffron half an ounce, Caffile or Venice soap half a pound: make into balls, the size of a pullet's egg, with honey; and give one, night and morning, with a pint of the above drink.

It will be proper, on his recovery, to give two or three mild purges; and if a fat full horse, to put in a rowel.

Of the Disorders of the Kidneys and Bladder.

The signs of the kidneys being hurt or affected are, a weakness of the back and loins, difficulty of itching, faintness, loss of appetite, and deadness in the eyes; the urine is thick, foul, and sometimes bloody, especially after a violent strain. A horse diseased in his kidneys can seldom back, that is, move strait backwards without pain, which is visible as often as he is put to the trial; the same thing is observable indeed in horses, whose backs have been wrung and wrenched; but with this difference, that in the latter there is seldom any defect or alteration in the urine, except that it is higher coloured.

Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more so, if a fever attends a difficulty in haling, for then we may suspect the kidneys already inflamed. A rowel in the belly has been found useful; and the following balls may be given twice or thrice a day, with a pint of marshmallow decoction, in which half an ounce of gum arabic is dissolved, with an ounce of honey.

Take lucatellus-balfam one ounce, spermaceti six drams,
urine from the blood: in this latter cafe, the bladder is
flammation of the kidney; for at others, from a paralytic
fluence of the blood—either from any purulent fettlement.

If the urine passes with difficulty and pain, notwithstanding thefe means, give this ball, and repeat it twice
or thrice a-day till the horfe flales freer and without
pain, his urine become of a right confidence, and free
from any purulent fettlement.

Take balfam of copivi or Stralburgh turpentine, and
Venice soap, of each one ounce, nitre six drams, myrrh powdered two drams; make into a ball with
honey, and wash it down with the marshmallow de-
cotion.

As a fuppression of urine arises sometimes from an in-
flammation of the kidney: so at others, from a paralytic
difforder, disabling them in their office of separating the
urine from the blood: in this latter cafe, the bladder is
usually empty, so that a horfe will make no motion to
flale; and if he continues a few days in this condition,
his body will swel to a great degree, breaking out in
blotches all over, and death will foon clofe the fcene.

If it arises from inflammation, bleed largely, and treat
the horfe as above recommended; but if not, give stimu-
lating glyfters, and ftrong diuretics, fuch as the follow-
ing, once in four hours: for if a horfe flales not in
thirty hours, his danger muft be great.

Take juniper-berries powdered one ounce, fal pru-
nella six drams, ethereal oil of turpentine half an
ounce, camphor one dram, oil of juniper two drams;
make into a ball with honey, and give after it three
or four horns of the marshmallow decoction and
honey.

Or, take squills powdered two or three drams, nitre half
an ounce or six drams; make into a ball with
honey.

If the complaint is not removed by these means, rub
the horfe's reins well with two parts of oil of turpentine,
and one of oil of amber; and apply a poultice of garlick,
horfe raddish, muftard feed, camphor, and green soap,
spread on thick cloth, over them. Give the horfe alfo two
drops of calomel over night, and a moderate purge the
next morning. These perhaps are the chief and beft re-
medies that can be given in this generally fatal diforder.

When the strangury in a horfe does not arife from
wind, or dung preffing on the neck of the bladder (as
was obferved in the Section on Cholicks) the caufe is
from inflammation, or too long a retention of the urine.
Such horfes make frequent motions to flale, fland wide
and flraddling, are full, and have their flanks diftended.
In this cafe bleed largely; give the following drink, and
repeat it every two hours, for two or three times, till
the horfe is relieved.

Take Venice turpentine, broke with the yolk of an
egg, one ounce, nitre or fal prunella six drams,
half a pint of fweet oil, and a pint of white wine.
If this drink should not have the defired effeft, the di-
uretic ball above mentioned may be given in the fame man-
er, omitting the myrrh.

Give the horfe plenty of the marshmallow decoction, in
a quart of which difsolve an ounce of nitre and gum arab-
ic, and two of honey.

Horfes subject to a diabetes, or profufe flaling, if old,
or of a weak conftitution, are feldom cured; they foon lofe
their flefh and appetite, grow feeble, their coat flaring,
and they die rotten. Of a young horfe there are more
hopes; but he muft not be indulged with too much wa-
ter, or moif food. Give him the following:

Take jefuit's bark four ounces, bitof and tormentil-
root of each two ounces; boi in two gallons of
lime-water to the confumption of half, and give a
pint three times a-day.

As this diforder generally proceeds from too violent
exercife, over-flaining, &c. repeated bleedings in small
quantities are absolutely neceffary, till the mouths of the
veffels clofe up.

Of Molten-grease.

By molten greafe is meant a fat or oily discharge
with the dunge, and arises from a colliquation, or melt-
ing down of the fat of a horfe's body by violent exer-
cife in very hot weather. It is always attended with a
fever, heat, reftlefsnefs, flarting and trembling, great
inward ficknefs, throatnefs of breath, and fometimes with
the symptoms of a pleurify. His dunge will be extreme-
ly greasy, and he will fall into a fcoriing; his blood will
have a thick skin or fat over it when cold, of a white or
yellow hue, but chiefly the latter; the congealed part or
feditement is commonly a mixture of size and greafe, which
makes it fo extremely flippery, that it will not adhere to
the fingers, and the small portion of ferum feels also flip-
pery and clammy. The horfe foon lofes his flefh and fat,
which probably is difsolve and abforbed into blood;
and thofe that survive this flock, commonly grow hide-
ous; and if this is not done effectually, the far-
cey, or fome obftinate furfeit, generally follows, very
difficult to remove.

In the firft place bleed plentifully, and repeat it for
two or three days succifively in smaller quantities; two or
three rowels fhould alfo be immediately put in, and the
cooking emollient glyfters (p. 547. col. 1. par. 2. from the
bottom) daily thrown up to abate the fever, and drain off
the greatly matter from the intefines. By the mouth give
plenty of warm water or gruel, with cream of tartar or
nitre, to dilute and attenuate the blood, which in this
cafe is greatly difposed to run into grumes, and endanger
a total flagnation.

When the fever is quite gone off, and the horfe has
recovered his appetite, gentle aloetic purges fhould alfo be
immediately put in, and the cooling emollient glyfters (p. 547, col. 1. par. 3.) till it abates.
powdered half an ounce, of diaphoretic antimony and powder of myrrh of each two drams; make into a ball with syrup of buckthorn.

These will seldom take a horse from his prudent above two or three days in a week; neither will he lose his flesh or appetite with them, but on the contrary mend in both; which can not be obtained by any other method of purging, and gives this greatly the preference in many cases.

Of Surfeits, Mange, and Hide-bound.

Surfeits arise from various causes; but are commonly the effects of some diseases not attended to, or that have been ill cured.

A horse is said to be surfeited, when his coat flares, and looks ruly and dirty, though proper means has not been wanting to keep him clean. The skin is full of scales and dander, that lies thick and meally among the hair, and is constantly supplied with a fresh succession of the same, for want of due transpiration. Some horses have hurls of various sizes like peas or tares; some have dry fixed fisbs all over their limbs and bodies; others a moisture, attended with heat and inflammation; the humours being so sharp, and violently itching, that the horses rub so incessantly, as to make themselves raw. Some have no eruptions at all, but an unwholesome look, and are dull, sluggish and lazy; some appear only lean and hide-bound: others have flying pains and lameness, resembling a rheumatism; so that in the surfeits of horses, we have almost all the different species of the scurvy and other chronic delicacies.

The following method is usually attended with success in the dry species. First take away about three or four pounds of blood, and then give the following mild purge, which will work as an alternative, and should be repeated once a-week, or ten days, for some time.

Take succotrine aloes six drams or one ounce, gum guaiacum half an ounce, diaphoretic antimony and powder of myrrh of each two drams; make into a ball with syrup of buckthorn.

In the intermediate days, an ounce of the following powder should be given, morning and evening, in his feeds.

Take native cinnabar, or cinnabar of antimony, finely powdered, half a pound; crude antimony, in fine powder, four ounces; gum guaiacum, also in powder, four ounces: make into sixteen doûses for eight days.

This medicine must be repeated till the horse coasts well, and all the symptoms of surfeit disappear.

The wet surfeit, which is no more than a moist running scurvy, appears on different parts of the body of a horse, attended sometimes with great heat and inflammation; the neck oftentimes swells so in one night's time, that great quantities of a hot briny humour issues forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll evil or fiftula. This disease also frequently attacks the limbs, where it proves obstinate and hard to cure: and in some horses shews itself spring and fall.

In this case bleed plentifully, avoid externally all repellers, and give cooling physic twice a-week; as, four ounces of lenitive elecuuary, with the same quantity of cream of tartar; or the latter, with four ounces of Glauber's salts, quicked, if thought proper, with two or three drams of powder of jallap, dissolved in water-gruel, and given in a morning fasting.

After three or four of these purges, two ounces of nitre made into a ball with honey may be given every morning for a fortnight; and if attended with success, repeated for a fortnight longer.

The powders above-mentioned may be also given with the horse's corn; or a strong decoction of guaiacum savings or logwood may be given alone to the quantity of two quarts a-day. These, and indeed all-alterative medicines, must be continued for a long time, where the disorder proves obstinate.

The diet should be cool and opening, as scalded bran or barley; and if the horse is hide-bound, an ounce of fenugreek seeds should be given in his feeds for a month or longer; and, as this disorder often proceeds from worms, give the mercurial physic too, and afterwards the cinnabar powders, as above directed; but as in general, it is not an original disease, but a symptom only of many, in the cure regard must be had to the first caufe: thus, as it is an attendant on surfeits, fevers, worms, &c. the removal of this complaint must be variously effected.

In a mangy horse the skin is generally tawny, thick, and full of wrinkles, especially about the mane, the loins and tail; and the little hair that remains in those parts stands almost always strait out or briftly: the ears are commonly naked and without hair, the eye and eyebrows the same; and when it affects the limbs, it gives them the same aspect; yet the skin is not raw, nor peels off, as in the hot inflamed surfeit.

Where this disorder is caught by infection, if taken in time it is very easily cured; and we would recommend a sulphur ointment as most effectual for that purpose, rubbed in every day. To purify and cleanse the blood, give antimony and sulphur for some weeks after. There are a great variety of external remedies for this purpose, such as train-oil and gun-powder, tobacco steeped in chamber-lye, &c. Solleyboul recommends the following.

Take burnt alum and borax in fine powder of each two ounces, white vitriol and verdigeaue powdered of each four ounces; put them into a clean pot, with two pounds of honey, stirring till they are incorporated; when cold, add two ounces of strong aqua-fortis. But when this disorder is contracted by low feeding, and poverty of blood, the diet must be mended, and the horse properly indulged with hay and corn. The following ointments are effectually used for this disorder, rubbed into the parts affected every day.

Take powdered brimstone, train-oil, and tar, of each equal quantities; to which may be added ginger, or white hellocbore.

Or,

Take sulphur vivum half a pound; crude sal ammoniac one ounce, hogs lard or oil a sufficient quantity to form into an ointment.

These
These are both very powerful remedies for this disorder, and can scarce fail of success.

Of the Farcin or Farcy.

The true farcy is properly a distemper of the blood-vessels, which generally follows the tract of the veins, and, when invertebrate, thickens their coats and intumeguments, so that they become like so many chords. We shall not describe the different sorts of farcies, seeing they are only degrees of one and the same distemper; but proceed to paint the distemper by its symptoms, which are pretty manifest to the eye.

At first, one or more small swellings, or round buds like grapes or berries, springing over the veins, and are often exquisitely painful to the touch; in the beginning they are hard, but soon turn into soft blisters, which when broke discharge an oily or bloody ichor, and turn into very foul and ill-disposed ulcers. In some horses it appears on the head only; in some on the external jugular; in others on the plate-vein, and runs downwards on the inside of the fore-arm towards the knee, and very often upwards towards the brisket; in some the farcy spreads itself on the hind-parts, about the patterns, and along the large veins on the inside of the thigh, rising upwards into the groin, and towards the sheath; and sometimes the farcy makes its appearance on the flanks, and spreads by degrees towards the lower belly, where it often becomes very troublesome.

When the farcy appears on the head only, it is easily cured; especially when it is felt in the cheeks and forehead, the blood-vessels being there small; but it is more difficult when it affects the lips, the nostrils, the eyes, the kernels under the jaws, and other soft and loose parts, especially if the neck-vein becomes chorded. When it begins on the outside of the shoulder or hips, the cure is seldom difficult; but when the farcy arises on the plate-vein, and that vein swells much, and turns chorded, and the glands or kernels under the arm-pit are affected, it is hard to cure; but more so when the cranial veins within side of the thigh are chorded, and beset with buds, which affects the kernels of the groin and the cavernous body of the yard. When the farcy begins on the patterns or lower limbs, it often becomes very uncertain, unless a timely stop is put to it; for the swelling in those dependant parts grows so excessively large in some constitutions, and the limbs so much disfigured thereby with foul sores and callous ulcerations, that such a horsey is seldom fit for anything afterwards but the meaneft drudgery: therefore on the plate, thigh, or neck veins appearing chorded, bleed immediately on the opposite side, and apply the following to the chorded vein.

Take ointment of elder four ounces, oil of turpentine two ounces, sugar of lead half an ounce, white vitriol powdered two drams; mix together in a gally-pot.

The buds sometimes by this method are dispersed, leaving only little bald spots, which the hair soon covers again. When they break and run, if the matter be thick and well digested, they will soon be well; but in order to confirm the cure, and to disperse some little lumps which often remain for some time on the skin without hair, give the liver of antimony for a month; two ounces a day for a fortnight, and then one ounce a day for the other fortnight; by following this method, a farcy which affects only the small vessels, may be stopped in a week or ten days, and soon after totally eradicated.

When the farcin affects the larger blood-vessels, the cure is more difficult; but let it always be attempted early: therefore on the plate, thigh, or neck veins appearing chorded, bleed immediately on the opposite side, and apply the following to the chorded vein.

Take oil of turpentine in a pint bottle six ounces, oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by little at a time, otherwife the bottle will burst; when it has done smoking, drop in more oil of vitriol, and so on till all is mixed.

This mixture is one of the best univerfals in a beginning farcy; but where it is felt in loose fleshly parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are necessary.

Rub the parts first with a woollen cloth; and then apply some of the mixture over the buds, and where-ever there is any swelling, twice a day. Give the cooling phycic every other day, and then three ounces of nitre every day for some time.

When the farcy begins on the flanks, or towards the lower belly, it often takes its rise from a single puncture of
of a sharp spur. The pain and smarting is one sure sign to distinguish the farcy from common accidents; the flaring of the hair, which stands up like a tuft all round the buds or blisters, and the matter that issues from the buds, which is always purulent and of a clammy greasy consistence, are other certain signs. After bathing with the mixture above mentioned till the ulcers are smooth and healing, should the swelling not subside, to prevent the spreading of the buds, and to disperse them, bathe with either of these mixtures as far as the centre of the belly; and at the same time give a course of antimonials, as will presently be prescribed.

Take spirits of wine four ounces, oil of vitriol and turpentine, of each two ounces, white-wine vinegar, or verjuice, six ounces

Or the following:

Take spirits of wine rectified four ounces, camphor half an ounce, vinegar or verjuice six ounces, white vitriol, dissolved in four ounces of spring water, one ounce; mix together.

In the lower limbs the farcy lies sometimes concealed for a great while, and makes slow progress, that it is often mistaken for grease, or for a blow or kick, and goes by the general appellation of a humour settled there. In order to distinguish the one from the other, we shall observe that a kick, or bruise, is generally attended with a sudden swelling, or a contused wound, which for the most part digests easily; the grease is also a smooth swelling that breaks out above the bending of the patterns backwards; but the farcy begins on the pattern joint unius with one bud, and runs upwards like a knotty crab-tree.

Very simple means have sometimes stopped it, before it has begun to spread; a poultice with bran and verjuice bound round the part, and renewed once a-day, will often alone succeed; and if proud flesh should arise, touch it with oil of vitriol, or aqua fortis, an hour before you apply the poultice; for when the distemper is local, as we suppose it here, it is to be conquered by outward applications.

When the distemper grows inveterate, and resists the above method, and the vesicles continue chorded, Gibbon recommends the following mixture.

Take linseed oil half a pint; oil of turpentine and salpetre, of each three ounces; tincture of euphorbium and hellebore, of each two drams; the soldiers ointment two ounces; or oil of bays, or oil of origanum, half an ounce; double aqua fortis half an ounce; after the ebullition is over, add two ounces of Barbadoes tar.

Rub this into the chorded veins, and where-ever there is a swelling, once in two or three days; but if the orifices are choked up with proud flesh, or the skin so much thickened over the ulcers as to confine the matter, in either case it is necessary to make an open passage with a small hot iron, and destroy the proud flesh, after which it may be kept down by touching with oil of vitriol, aqua fortis, or butter of antimony. A false may also be prepared with quicksilver and aqua fortis, rubbing any quantity of the former with enough of the latter, to the consistence of a liniment; linear the ulcers with this when they appear foul, and you will find it preferable to most other external medicines.

Our farriers, after opening the buds, put in usually a small quantity of corrosive sublimate or arsenic, which they call coring out the farcy; this may answer where the buds are few, and not situated near large blood-veins, joints, or tendons; others use Roman vitriol, or sublimate and vitriol, in equal quantities: but let it be remembereed, that many a horse has been poisoned by these medicines ignorantly used, and in too large quantities.

The following balls are proper in every stage of the farcy; and when the distemper has been in its infancy, before the skin was much defaced, has often cured it in a week or two, by giving them only once or twice a-day: but in an old farcy they should be given for two or three months together.

Take of native cinnabar, or cinnabar of antimony, eight ounces; long bithwart and gum guaiacum powdered, of each four ounces: make into a paste with honey, and form into balls of the size of a large walnut, and roll them into liquorice powder.

The tediumness of this course has encouraged the giving of mercurials; and indeed where they are directed with skill, they must be attended with success: the strongest preparations, as the red and white precipitates, and tumbir, being combined with sharp saline parts, may be hazardous and injurious; but the latter given in small quantities have been found very successful in such kind of inveterate disorders. Mr Gibbon says, he has given it to a horse at a doze, where the limbs have been greatly swelled; that in forty-eight hours the fores were all dried up, and the limbs reduced; but that it made the horse so violently sick for several days, and scourcd him to such a degree, that it could not be repeated.

One would have thought that the success attending this medicine so suddenly, might have encouraged Gibbon to have made further trials in smaller quantities; which had he done, it is more than probable he would not have been disappointed: for the grand secret in giving mercurials as alteratives, is the introducing them into the blood, without operating on the stomach and bowels; and to do this effectually, they must be given in small quantities, and so bridled as to control their force on the first passages; taken in this manner, they will mix gradually with the blood and juices, and operate both effectually and safely.

Dr Bracken recommends the knots and chords to be rubbed with the mercurial ointment before they break, in order to disperse them; and after breaking, to dress the sores with equal parts of Venice turpentine and quicksilver: if by these means the mouth should become sore, treat as above.—This method seems to be effectual with proper care.

The following is also recommended by the same gentleman:

Take butter of antimony and bezooz, mineral, of each one ounce; beat up with half a pound of cordial ball, and give the bigness of a walnut, or three quarters of an ounce, every day for two or three weeks, falling two or three hours after it.
We shall here take notice of what is called the water-
farcy, which has no resemblance to a true farcy, either
in its cause, symptoms, or effects, but has only obtained
this name through custom and ignorance.

This water farcy then is of two kinds; one the pro-
duct of a feverish disposition, terminating on the skin, as
often happens in epidemical colds; the other is drophical,
where the water is not confined to the belly and limbs,
b ut flows itself in several parts of the body by soft
swellings yielding to the pressure of the finger. This laft
kind usually proceeds from foul feeding, or from the lat-
ter grass and fog, that often comes up in great plenty
with continued cold rains, and breeds a sluggish viscid
blood. In the former case, we have seen the limbs and
whole body enormously swelled, and very hard, the bel-
ly and sheath greatly distended; which were as surprizing-
ly reduced in four and twenty hours, by flight scarificati-
ons within side the leg and thigh, with a sharp penknife,
and three or four strokes on the skin of the belly on each
side the sheath; from these scarifications there was a con-
stant and surprising large dripping of water, which soon
relieved the horse; when a few purges completed his
recovery.

In the other species of dropfy the curative intentions
are to discharge the water, recover the crazis or strength
of the blood, and brace up the relaxed fibres throughout
the whole body. To this end, purge once a-week or ten
days; and give immediately either of the following.

Take black hellebore freh gathered, two pounds;
wash, bruife, and boil in fix quarts of water, to
four; and then strain out the liquor, and put two
quarts of white-wine on the remaining hellebore,
and let it infuse warm forty-eight hours; then strain
off, mix both together, and give the horse a pint
night and morning.

Take nitre two ounces, squills powdered three drams
or half an ounce, camphor one dram, honey enough
to form into a ball, to be given once a-day alone, or
washed down with a horn or two of the above drink.

Before we clofe this fection, it is proper to lay
down the symptoms of an incurable farcy, that the own-
ers of such horses may fave themselves unnecessary ex-
rence and trouble in their endeavours to obtain a cure.

When a farcy, by improper applications, or by neglect,
has spread and increafed, or after long continuance refil-
ted the medicines above recommended; if freh buds are
continually fprooting forth, while the old ones remain
foul and ill conditioned; if they rife on the spines of the
back and loins; if the horfe grows hide-bound, and runs
at the nofe; if abfcffes are formed in the flefty parts
between the interficles of the large muscles; if his eyes
look dead and lifelefs; if he forfakes his food, and fcurfs
often, and his excrements appear thin and of a blackinf
colour; if the plate or thigh vein continues large and
chorded after firing, and other proper applications: thefe
symptoms denote the diftemper to have penetrated in-
ternally, and that it will degenerate into an incurable con-
sumption; it is moft probable also, that the whole mafs
of fluids are tainted, and become irremediable by art.

Of Alteotive Medicines.

By alteratives, or altering medicines, are to be under-
flood fuch as, having no immediate fenfible operation, gra-
dually gain upon the conftitution, by changing the hu-
mours or juices from a slate of diftemperature to health.
This intention in fome cases may perhaps be effected by
correcting the acrimony of the juices, and accelerating
the blood’s motion; and in others by attenuating, or
breaking its particles, and dividing thofe cohefions which
obiurft the capillaries or finer veffels; and fomote the
due secretions of the various fluids. It is certain, that
many have but an indifferent opinion of a medicine that
does not operate exterally, and gratify their fcenes with
a quantity of imagined humourse ejefted from the body:
but let fuch people remember, that there are good hu-
mours as well as bad, which are thrown off together;
that no evacuating medicine has a power of felecting, or
feparating the bad from the good, and consequently that
they are thrown out only in a proportionate quantity.
These few hints may be fufficient to convince the judici-
ouff reader of the great advantages arifing from altera-
tives, and the preference due to them in moft cafes over
purgatives; unlefs it could be proved, as already mention-
ed, that the latter could pull out and feparate from the
blood the bad humour solely, leaving the good behind;
but this felective power has long been juflly exploded as
ridiculous and uncertain, fince it is plain, that all kinds
of purging medicines differ only in degree of strength,
and operate no otherwife upon different humours than as
they illuftrate more or lefs.

We fhall therefore take this opportunity of recom-
mending fome alterative medicines, which are not fo ge-
erally known as they ought to be; and that too on the
fureft grounds, a proper experience of their good effects in
repeated trials. The firft then is nitre or purified falt-
petre, which has long been in great efleem, and perhaps
is more to be depended on in all inflammatory fevers than
any other medicine whatever: but besides this extensive
power of efllaying inflammatory diforders, it is now offer-
ed as a remedy, taken in proper quantities, as an alte-
rate for fefurfs, molten-greafe, hide-bound, greafe-
heels, &c. And as it has been known to fucceed even in
the cure of the farcy, what other diftempers in horfes,
arife from vitiated fluids, may it not be tried on, with a
strong probability of success? This great advantage will
arife from the ufe of this medicine over moft others,
that, as its operation is chiefly by urine, it requires no
confinement or cloathing; but the horfe may be worked
moderately throughout the whole courfe. This medi-
cine has been found equally efficacious (by many trials
made in one of our hofpitals) in correfting the acrimony
of the juices, and difpofing the moft obstinate and inve-
terate fores to heal up; and hence probably it came re-
commended as an alterative to our horfes.

The quantity of nitre given at a time should be from
two to three ounces a-day; let it be finely powdered, and
then mix with it by little at a time as much honev as
will form it into a ball; give it every morning fasting for a month; or it may be given at first for a fortnight only, intermitting a fortnight, and then repeat it. If it be observed that the horse shows an uneasiness at the stomach after taking it, a horn or two of any liquor should be given after it, or it may be dissolved at first in his water, or mixed with his corn; though the belly, where it agrees, is the easiest method of giving.

When horses take drinks with great reluctance, powders must be given in their feeds; thus crude antimony, or liver of antimony finely powdered, may be given to the quantity of half an ounce, night and morning; but in all surfeits, gum guaiacum mixed with antimony is found more efficacious. Thus,

Take of crude antimony finely powdered, or, where it can be afforded, cinnabar of antimony, and gum guaiacum, of each a pound: mix together with an oily pestle to prevent the gum's caking; divide the whole into thirty-two dozes, viz. an ounce each doze; let one be given every day in the evening feed.

Or,

Take of cinnabar of antimony, gum guaiacum, and Castile or Venice soap, of each half a pound, half of tartar four ounces; beat them up into a mass, and give an ounce every day. To these may be added very advantageously, an ounce and a half of camphor.

Æthiops mineral given to the quantity of half an ounce a-day, is a very good sweetener and corrector of the blood and juices; but it has been observed, after having been taken a week or ten days, to make some horses flabb, and unable to chew their hay and oats; and the same symptoms have arose, where only two drams of crude mercury has been given, and continued about the same space of time.

Diet Drinks.—1. A decoction of logwood, prepared like that of guaiacum, is also successfully given in surfeits.

2. Lime-water, prepared with shavings of saffapharas and liquorice, is a good diet-drink, to sweeten and correct a horse's blood; and may be given with the nitre balls for that purpose.

3. Tar-water also, as has before been hinted, may in many cases be well worth trial: but let it be remembered, that all medicines of this kind should be continued a considerable time in obstinate cases.

Of Rowelling.

There seems to be no remedy so much made use of, and so little understood by farriers in general, as rowels; for which reason we shall endeavour to let the whole affair in a clearer light, than hitherto it has appeared in.

We shall begin then by describing rowelling, which is an artificial vent made between the skin and flesh, in order to unload and empty the vessels in general, and thereby relieve particular parts, when too much oppressed by a fulness or redundancy.

The general and absurd reasoning of farriers on the effects and use of rowelling, in some measure makes this fiction the more necessary, as it is too notorious how impertinently they talk on this subject: for in short, with them, a rowel is to draw off all the bad and corrupt humours from the blood by a sort of magic.

It is necessary to observe, that the matter generally discharged by a rowel, is nothing more than an ouzing from the extremities of the vessels divided in the making of it; in fact then, it is blood, which loses its colour, by being fled out of the vessels, the warmth of the part, and its confinement.

If this is granted, it will evidently appear, that the good effects ensuing this operation, must be owing to a gradual depletion or emptying of the vessels in general; by which means the surcharge or load on a particular part, is taken off and removed, and impurities or bad juices (generally called humours) run off with the good in proportion to their quantity in the blood.

Thus, to lean hide-bound horses, and those of a dry hot constitution, the discharge, by depriving the constitution of too much blood and fluids, is daily exhausting the strength of the animal; and may be productive of bad consequences, by depraving the constitution of a necessary fluid.

But in distorders from fulness, attended with acrimony, or sharpness of the juices, and with des Excellions on the eyes, lungs, or any part of consequence; the gradual discharge, brought on by these means, will contribute to lessen the fulness on the parts affected, and give the vessels an opportunity of recovering their tone, while evacuating and alterative medicines are doing their office.

It may be necessary, however, to observe, that there is a wonderful communication between the vessels of the cellular membrane under the skin, which remarkably appears, by inflating those of sheep, calves, &c by the butchers; hence probably it is that some disorders of this integument, are so apparently relieved by issues, or rowels, without our having any recourse to that general depletion of the vessels, we have just observed, to account for it; and hence also may be deduced their utility, sometimes in draining off any extravasated fluids, which may lodge between the interstices of the muscles, after violent strains of the shoulder; also in discharging such vitious or sharp fluids as are thrown on the membranes, and occasion those flying pains and lamenesses, which we find are often removed by this local remedy.

Of Strains in Various Parts.

It is necessary to observe, that in all strains, the muscular or tendinous fibres are overstretched; and sometimes ruptured, or broke. To form therefore a true idea of these disorders, let us first consider every muscle and tendon as composed of springy elastic fibres, which have a proper power of their own to contract and extend themselves; or, to make their action more familiar, let us compare them to a piece of catgut, that we may the better judge with what propriety oily medicines are directed for their cure. Thus then, if by a violent extension of this catgut, you had so overstrained it as to destroy its springiness or elasticity, and was inclined to recover its lost tone; would you for that purpose think of soaking it in oil? And is not the method of treating strains, or overstrained...
stretched muscles and tendons, full as preposterous, when you bathe or soak them in oily medicines, at a time that they want reftringents to brace them up? Yet custom has so established this practice, and fallacious experience seemingly confirmed it, that it would be a difficult task to convince the illiterate and prejudiced of the absurdity, who, by ascribing effects to wrong causes, are led into this error, and the oils usurp the reputation that is due only to rest and quiet: they seem, however, to be aware of the ill consequences, by their adding the hot oils, as spike, turpentine, and origanum; which, though they in some measure guard against the too suppling quality of the other oils, yet the treatment is still too relaxing to be of real service.

And indeed, in all violent strains of either tendons or muscles, whatever opinion we may entertain of bathing and anointing with favourite nostrums, which often succeed in flight cures, where perhaps bandage alone would have done; yet it is the latter, with proper refting the relaxed fibres, till they have thoroughly recovered their tone, that are the chief things to be depended on; and frequently some months are necessary for effecting the cure.

All violent strains of the ligaments, which connect the bones together, especially those of the thigh, require time, and turning out to grafs, to a perfect recovery. External applications can avail but little here, the parts affected lying too deep, and so surrounded with muscles that medicine cannot penetrate to them. The sooner, in these cases, a horse is turned out to grafs, the better; as the gentle motion in the field will prevent the ligaments from thickening, and of course the joint itself from growing stiff.

When a horse's shoulder is overdrained, he does not put out that leg as the other; but to prevent pain, sets the sound foot hardly on the ground to save the other; even though he be turned short on the lame side, which motion tries him the most of any. When trotted in hand, instead of putting his leg forward in a right line, he forms a circle with the lame leg; and when he stands in the stable, that leg is advanced before the other.

In order to cure this lameness, first bleed him, and let the whole shoulder be well bathed three times a day with hot verjuice or vinegar, in which may be dissolved a piece of soap; but if the lameness continues without swelling, or inflammation, after refting two or three days, let the muscles be well rubbed for a considerable time, to make them penetrate, with good opodeldoc, or either of the following mixtures:

**Take camphorated spirit of wine, two ounces; oil of turpentine, one ounce; this proportion will prevent the hair coming off.**

Or,

**Take the belt vinegar, half a pint; spirit of vitriol, and camphorated spirit of wine, of each two ounces.**

When the shoulder is very much swelled, it should be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice and spirit of wine; or a fomentation prepared with a strong decoction of wormwood, bay-leaves, and rosemerry, to a quart of which may be added half a pint of spirit of wine.

A rowel in the point of the shoulder in this case often does great service; especially if the strain has been very violent, and the swelling very large: but as to boring up the shoulder with a hot iron, and afterwards inflating it, is both a cruel and absurd treatment; and the pegging up the sound foot, or setting on a patten-shoe, to bring the lame shoulder on a stretch, is a most preposterous practice, and directly calculated to render a horse incurably lame; for it can only be necessary in cases the very opposite to this, where the muscles have been long contracted, and we want to stretch them out.

Where poultices can be applied, they are at first undoubtedly very effectual, after bathing with hot vinegar or verjuice, and are to be preferred greatly to cold charges, which, by drying to soon on the part, keep it stiff and uncasy: let them be prepared with oat meal, rye flour, or bran boiled up in vinegar, strong beer or red wine lees, with lard enough to prevent their growing stiff; and when by these means the inflammation and swelling is brought down, bathe the part twice a day with either of the above mixtures, opodeldoc, or camphorated spirit of wine; and roll the part three or four inches, both above and below, with a strong linen roller, of about two fingers width; which contributes not a little to the recovery, by bracing up the relaxed tendon; and perhaps is more to be depended on than the applications themselves.

In strains of the e. fin joint, that have not been discovered in time, there will grow such a stiffness in the joint, that the horse will only touch the ground with his toe; and the joint cannot be played with the hand; the only method here is repeated blistering, and then firing supericularly.

Strains of the b. c. kneews are very common, and are easily discovered by the swelling, which extends sometimes from the back-side of the knee down to the heel, but for the most part the horse sets that leg before the other. The tendon should be well bathed three or four times a day with hot vinegar; and if much swelled, apply the poultices above recommended; and when the swelling is down, bathe with the mixtures above, or with camphorated spirit of wine and oil of amber, in which is dissolved as much camphor as the spirits will take up, and roll up the tendon with a proper bandage, or laced stocking; which last, properly fitted to the limb, might be wore to great advantage, not only in these sort of injuries, but in most others, where there is a disposition to the grousse, or other swellings of the limbs, from weak and relaxed fibres. Curriers' Savings wetted with vinegar have been found useful for this purpose: as has also tar and spirit of wine: but where the tendons have suffered by repeated injuries of this kind, the cafe will demand blistering, firing, and proper reft.

Strains of the knees and patte neis arise frequently from kicks or blows; if they are much swelled, apply all the poultices; and when the swelling is abated, bathe with the above, or the following.

**Take vinegar, one pint; camphorated spirits of wine, four ounces; white vitriol, dissolved in a little water, two drams.**

Or,

**Take the white of three or four eggs, beat them into a froth with a spoon; to which add an ounce of**

---
rock allum, finely powdered; spirit of turpentine, and wine, of each half an ounce; mix them well together.

As great weakness remains in the patterns after violent strains, the best method is to turn the horse out to graze till he is perfectly recovered; when this cannot be complied with, the general way is to blister and fire.

When a horse is lame in the stifle, he generally treads on his toe, and cannot set the heel to the ground. Treat him at first with the vinegar and cooling rettirgents; but if a large swelling, with puffines, ensues, foment it well with the disinfectant fomentation till it disperses; and then bathe the part with any of the above medicines.

A lameness in the subiel-bone and hip, is discovered by the horse dragging his leg after him, and dropping backward on his heel when he trots. If the muscles of the hip are only injured, this kind of lameness is cured easily; but when the ligaments of the joint are affected, the cure is often very difficult, tedious, and uncertain. In either case, at first bathe the parts well with the cooling medicines, four or five times a-day; in the muscular strain, this method alone may succeed; but in the ligamentous, it is rest and time only can restore the injured parts to their proper tone.

Strains in the back are to be treated by soaking the parts with coolers and repellers; but when the ligaments are hurt, and they are attended with great weakness and pain, use the fomentation. If a hardness should remain on the outside, it may be removed by repeated blistering; if within, it may be out of the power of any external applications to remove; however, the joint should be fired gently with small rases or lines pretty close together, and then covered with a mercurial piafier. To the disinfectant fomentation above mentioned may be added crude sal armoniac, with a handful of wood-atties boiled in it.

The blistering ointment for the above purposes may be found in the Section of Bone-spavin; but the sublimate should be omitted.

The firing, used for the strengthening relaxed sinews or tendons, should act only on the skin, which, by contracting and hardening it round all the sinews, compresses them more firmly like a bandage. The bow-men of old submitted to this operation, in order to give strength to the muscles and tendons of their arms. A proper degree of skill is very requisite to perform it effectually on a horse; for a due medium should be observed, and the instrument neither too slightly applied, as to scarify the skin only superficially, nor so deep as to wound or cauterize the sinew or its sheath. The lines should be drawn pretty close together, on each side of the joint or sienew, following the course of the hair; no cross lines should be made, as they but disfigure the horse afterwards, without any real use. The firing instrument, or knife, ought to be a little rounded on the edge, gradually thickening to the back, that it may retain the heat for some time, but should not be applied till the flaming redness is partly gone off. The cauterized parts may be bathed with spirit of wine at first, and anointed afterwards with beeswax and oil, which alone is sufficient to complete the cure.

Tumours, or swellings, arise either from external injuries, or internal causes.

Swellings, caused by external accidents, as blows and bruises, should at first be treated with rettingents; thus, let the part be bathed frequently with hot vinegar or verjuice, and, where it will admit of bandage, let a flannel wetted with the same be rolled on: if by this method the swelling does not subside, apply, especially on the legs, a poultice with red-wine lees, strong-beer grounds, and oatmeal, or with vinegar, oil, and oatmeal; either of these may be continued twice a-day, after bathing, till the swelling abates; when, in order to disperse it entirely, the vinegar should be changed for camphorated spirit of wine, to four ounces of which may be added one of spirit of sal armoniac; or it may be bathed with a mixture of two ounces of crude sal armoniac boiled in a quart of chamber-lye, twice a-day, and rags dipped in the same may be rolled on.

Fomentation made by boiling worm-wood, bay-leaves, and roemary, and adding a proper quantity of spirits, are often of great service to thin the juices, and fit them for transpiration; especially if the injury has affected the joints.

But in bruises, where the extravasated blood will not by these means be dispersed, the shortest way is to open the skin, and let out the grumes.

Critical tumours, or swellings, which terminate fevers, should by no means be dispersed; except when they fall on the pattern or coffin-joint, so as to endanger them: in this case the disinfectant fomentation, (p. 568. col. 1. bottom) should be applied three or four times a-day, and a cloth or flannel frequently wrung out of the same should be bound on, in order to keep the joint continually breathing.

But if the swelling fixes under the jaws, behind the ears, on the poll, withers, or in the groins and sheath, &c. it should be encouraged and forwarded by ripening poultices where-ever they can be applied; oatmeal boiled soft in milk, to which a proper quantity of oil and lard is added, may answer this purpose; or the poultice recommended in the Section of Strangles: these must be applied twice a-day, till the matter is perceived to fluctuate under the fingers, when it ought to be let out; for which purpose, let the tumour be opened with a knife or strong lancet, the whole length of the swelling, if it can be done safely; for nothing contributes so much to a kind healing, as the matter's having a free discharge, and the openings being big enough to drees to the bottom.

Pledgets of tow, spread with black or yellow basilicon (or the wound ointment) and dipped in the same, melted down with a fifth part of oil of turpentine, should be applied to the bottom of the fore, and filled up lightly with the same, without crammint; it may be thus dressed once or twice a-day, if the discharge is great, till a proper digestion is procured, when it should be changed for pledgets spread with the red precipitate ointment, applied in the same manner.
Should the wound not digest kindly, but run a thin water and look pale, foment, as often as you dress, with the above fomentation; and apply over your dressing the strong-beer poultice, and continue this method till the matter grows thick, and the fore flour.

The following ointments will generally anfwer your expectations in all common cafes, and may be prepared without, as well as with, the verdigrase.

Take Venice turpentine and bees-wax of each a pound, oil of roses one pound and a half, yellow rosin twelvetwelve ounces; when melted together, two or three ounces of verdigrase, finely powdered, may be stirred in, and kept so till cold, to prevent its spreading.

Take of yellow basilicon, or the above ointment, without verdigrase, four ounces; red precipitate, finely powdered, half an ounce; mix them together cold with a knife or spatula.

This last, applied early, will prevent a fungus, or proud flesh, from shooting out; for if you dress too long with the above digestive, the fungus will rife half, and give some trouble to suppress it; when it will be necessary to wash the fore as often as you dress, with a solution of blue vitriol in water, or to sprinkle it with burnt alum and precipitate. If these should not be powerful enough, touch with a caustic, or wash with the sublimate water, made by dissolving half an ounce of corrosive sublimate in a pint of lime-water.

But this trouble may in a great measure be prevented, if the fore is on a part where bandages can be applied with compresses of linen cloth: for even when these excrescences regenerate, as it were under the knife, and spring up in spite of the caustics above mentioned, they are to be subdued by moderate compression made on the sprouting fibres, by these means.

Authors on farriery have given in general very proper receipts to answer every intention of this kind by medicines; but as they have not laid down sufficient rules for their application in those cafes where they are most wanted, the following general directions will not be unacceptuable; as the difficulty in healing some kinds of fores arises frequently from the unskilful manner of dressing them.

It may be necessary then to observe here, once for all, that the cures of most fores are affected by the simplest methods, and that it is often of much more consequence to know how to dress a sore, than what to dress it with; and in this contest indeed the chief art of this branch of surgery; for the most eminent in that profession have long since discovered, that variety of ointments and salves are unnecessary in the cure of most wounds and fores, and they have accordingly discarded the greatest part, formerly in repute for that purpose; repeated observations having taught them, that after the digestion, nature is generally disposed to heal up the wound foot enough herself, and that the surgeon's chief care is to prevent a luxuriancy, commonly called proud flesh; which all ointments, wherein lard or oil enters, are but too prone to encourage, as they keep the fibres too lax and supple; and which dry lint alone, early applied, as easily prevents, by its absorbing quality, and light compression on the sprouting fibres.

Thus, if a hollow wound or sore is crammed with tents, or the dressings are applied too hard, the tender shoots of flesh from the bottom are prevented from pushing up; and the edges of the sore in time from this detension may grow horny, and turn fistulous; nor has the matter by this method a free discharge.

On the other hand, if sores of any depth are dressed superficially, the external parts being more disposed to heal and come together than the internal, they will fall into contact, or heal too soon; and the sore, not filling up properly from the bottom, will break out afeath.

Hence we may truly conceive how little stress is to be laid on famous ointments, or family salves, unskillfully applied; for unless this due medium is observed, or obtained in the dressing, no hollow sore can heal up properly.

As soon as a good digestion is procured (which is known by the thickness and whiteness of the matter discharged, and the florid red colour at the bottom of the sore) let the dressings be changed for the precipitate medicine; or the sore may be filled up with dry lint alone, or dipped in lime-water with a little honey and timure of myrrh, or brandy, about a fifth part of the latter to one of the former; a pledge of lint dipped in this mixture should also be applied to the bottom of the sore, which should be filled up with others to the surface or edges, but not trammed in too hard, as before observed, nor yet applied too loosely.

By this method, the sore would incarn, or heal up properly, and soft spongy flesh would be prevented, or suppressed in time; whereas when ointments or salves are too long continued, a fungus, or proud flesh, is thereby encouraged in its growth, that it requires some time to destroy and eat it down again; a proper compress of cloth, and a linen roller, is absolutely necessary both for this purpose, and to secure on the dressings, where ever they can conveniently be applied.

Of Wounds in General.

In all fresh wounds made by cutting instruments, there is nothing more required than bringing the lips of the wound into contact by future or bandage, provided the part will allow of it; for on wounds of the hips, or other prominent parts, and across some of the large muscles, the stiches are apt to burst on the horse's lying down and rising up in the stall; in such cases the lips should not be brought close together: one stitch is sufficient for a wound two inches long; but in large wounds, they should be at an inch or more distance; and if the wound is deep in the muscles, care should be taken to pass the needles proportionably deep, otherwise the wound will not unite properly from the bottom.

Should the wound bleed much from an artery divided, the first step should be to secure it, by passing a crooked needle underneath, and tying it up with a waxed thread; if the artery cannot be got at this way, apply a button of lint or tow to the mouth of the bleeding vessel, dipped in a strong solution of blue vitriol, typhitic water, oil of vitriol, or hot oil of turpentine, powdered vitriol, or colochtar, &c. and remember always to apply it close to the mouth of the bleeding vessels.
A famous old surgeon in Germany; but he does not seem it up, till a grume of blood is formed internally, which by constringing the extremity of the vesel, or choking to have a thought of trusting to it in such considerable medicines, before a good foundation for healing can be laid of healing, it must be rectified by proper internal medicines, as will appear from the aspect of the wound, and its manner, and the blood is deprived of its balsamic gate, which is so often attributed to the medicine; when it is furnished the best balsam, and performs herself the cure, well assured, that in a healthy sound constitution, nature wounds, whether ointments, or Fryar's balsams, being where it can be retained by a proper bandage.

The first intention in the cure of ulcers is bringing them to digest, or discharge a thick matter; which will, in general, be effect'd by the green ointment, or that with precipitate; but should the fore not digest kindly by these means, but discharge a gleetie thin matter, and look pale, you must then have recourse to warmer dressings, such as balsam, or oil of turpentine, melted down with your common digestive, and the strong beer poultice over them; it is proper also in these kind of sores where the circulation is languid, and the natural heat abated, to warm the part, and quicken the motion of the blood, by fomenting it well at the time of dressing; which method will thicken the matter, and roufe the native heat of the part, and then the former dressings may be re-applied.

If the lips of the ulcer grow hard or callous, they must be pared down with a knife, and afterwards rubbed with the caustic.

Where soft fungous flesh begins to rise, it should carefully be suppressed in time, otherwise the cure will go on but slowly; if it has already sprouted above the surface, pare it down with a knife, and rub the remainder with a bit of caustic; and, to prevent its rising again, sprinkle the fore with equal parts of burnt alum, and red precipitate; or wash with the sublimate water, and drefs with dry lint even to the surface, and then roll over a compress of linen as tight as can be borne; for a proper degree of preasure,
prefure, with mild applications, will always oblige these
spumy excremences to subside, but without bandage the
strongest will not so well succeed.

All sinuses, or cavities, should be laid open as soon as
discovered, after bandages have been ineffectually tried;
but where the cavity penetrates deep into the muscles, and
a counter opening is impracticable or hazardous; where,
by a continuance, the integuments of the muscles are
constantly dripping and melting down; in these cases in-
jections may be used, and will frequently be attended
with success. A decoction of colostrum boiled in forge-
water; or solution of lapis medicamentosus in lime wa-
ter, with a fifth part of honey and tincture of myrrh,
may be first tried, injected, three or four ounces twice a-
day; or some refined melted down with oil of turpentine,
may be used for this purpose; if these should not succeed,
the following, which is of a hard and caustic nature, is
recommended on Mr. Gibbon's experience.

Take of Roman vitriol half an ounce; dissolve in a
pint of water, then decant and pour off gently into a
large quart-bottle: add half a pint of camphorated
spirit of wine, the same quantity of the beef vinegar,
and two ounces of Aegyptiacum.

This mixture is also very successfully applied to ulce-
lated greasy heels, which it will both cleanse and dry up.

These sinuses, or cavities, frequently degenerate into
fistulae, that is, grow pipey, having the inside thickened,
and lined, as it were, with a hollow callous substance.
In order to their cure, they must be laid open, and the
hard substance all cut away; where this is impracticable,
scarify them well, and trust to the precipitate medicine
made strong, rubbing now and then with caustic, butter
of antimony, or equal parts of quicksilver and aqua-
fortis.

When a rotten or foul bone is an attendant on an ulcer,
the flesh is generally loose and flabby, the discharge oily,
thin, and thinning, and the bone discovered to be curious,
by its feeling rough to the probe passed through the
flesh for that purpose. In order to a cure, the bone
must be laid bare, that the rotten part of it be removed;
for which purpose, destroy the loose flesh, and dress with
dry lint; or the dollars may be pressed out of tincture of
myrrh or euphorbium: the throwing off the scale is gen-
erally a work of nature, which is effected in more or
less time, and in proportion to the depth the bone is af-
fected; though burning the foul bone is thought by some
to hasten its separation.

Where the cure does not properly succeed, mercurial
phyllic should be given, and repeated at proper intervals;
and to correct and mend the blood and juices, the anti-
ominal and alterative powders, with a decoction of guai-
acum and lime-waters, are proper for that purpose.

Of a Bone-Spavin.

Without entering at all into the cause of this disorder,
which is a bony excrecence, or hard swelling, growing
on the inside of the hock of a horse's leg, we shall con-
tent ourselves with describing the different kinds thereof,
by their symptoms; and then enter on their cure.

A spavin, that begins on the lower part of the hock,
to the growth of the spavin, and is apt to leave both a
blemish and fistness behind; besides the great risk run
(by applications of these fiery and caustic medicines to the
nervous and tendinous parts about the joints) of exciting
violent pain and anguish, and destroying the limb.

The best and safest way therefore, is to make trial of
the blistering ointment above, and to continue it according
to the directions there laid down, for some months,
if found necessary; the horses in the intervals working
moderately: the hardness will thus be dissolved by de-
grees, and wear away insensibly.

Where the spavin lies deep, and runs so far into the
hollow of the joint, that no application can reach it, nei-
ther firing nor medicines can avail, for the reasons above-
mentioned; though bold ignorant fellows have sometimes
succeeded in cases of this sort (by men of judgment deem-
ed incurable) by the application of caustic ointments with
sublimate, which act very forcibly, enter deep, and make
a large discharge, and by that means destroy a great part
of the substance, and dissolve away the remainder: Tho',
whoever is at all acquainted with the nature of these
medicines, must know how dangerous in general their
operation is on these occasions; and that a proper pre-
pared cautery made like a stream, under the direction of
a skilful hand, may be applied with less danger of inju-
ing either tendons or ligaments. After the substance
of the swelling has been properly penetrated by the instru-
ment, it must be kept running by the precipitate medicine,
or mild blistering ointment. Where the spavin lies not
depth in the joint, and the blistering method will not suc-
ceed, the swelling may be safely fired with a thin iron
forced pretty deep into the substance, and then should be
dressed, as is above directed.

**Of a Curb and Ring-bone.**

As a spavin rises among the bones on the fore-part of
the hock, so a curb takes its origin from the junctures of the
same bones, and rises on the hind part, forming a pretty
large tumour over the back part of the hind-leg, attended
with stiffness, and sometimes with pain and lameness.

A curb proceeds from the same causes that produce
spavins; viz. hard riding, strains, blows, or kicks. The
cure at first is generally easy enough effected by blistersing,
repeated two or three times, and oftener. If it does not
submit to this treatment, but grows excessively hard, the
quickeft and surest way is to fire with a thin iron, mak-
ing a line down the middle from top to bottom, and
drawing several lines in a penniform manner pretty deep;
and then to apply a mild blistering plaster or ointment o-
ver it.—This method will entirely remove it.

There is another swelling taken notice of on the out-
side of the hock, which is called a jordon. This com-
monly proceeds from blows and kicks of other horses;
but frequently happens to maneged horses, by setting
them on their haunches: it is seldom attended with much
lameness, unless it has been neglected, or some little pro-
cesses of the bone be broke. It should first be treated
with the coolers and repellers in (p. 574, and 575); but
if any swelling continues hard, and insenfible, the
best way is to blister or fire; but the mild blisters alone
generally succeed.

**Of Splents.**

These are hard excrecences that grow on the Shank-
bone, and are of various shapes and sizes. Some horses
are more subject to splents than others; but young hor-
se are most liable to these infirmities, which often wear
off and disappear of themselves. Few horses put out
splents after they are seven or eight years old, unless they
meet with blows or accidents.

A splent that arises in the middle of the shank-bone is
no ways dangerous; but those that arise on the back part
of this bone, when they grow large and press against the
back finew, always cause lameness or fistness, by rub-
bing against it; the others, except they are situated near
the joints, seldom occasion lameness.

As to the cure of splents, the best way is not to meddle
with them, unless they are so large as to disfigure a hor-
se, or are so situated as to endanger his going lame.

Splents in their infancy, and on their first appearance,
should be well bathed with vinegar, or old verjuice;
which, by strengthing the fibres, often put a stop to
their growth: for the membrane covering the bone, and
not the bone itself, is here thickened: and in some con-
itutions purging, and afterwards diuretic drinks, will be
a great means to remove the humidity and moisture about
the limbs, which is what often gives rise to such excre-
cences.

Various are the remedies prescribed for this disorder;
the usual way is to rub the splent with a round fiek or
the handle of a hammer, till it is almost raw, and then
touch it with oil of origanum. Others lay on a pitch-

Vol. II. No. 50. 2
plasterer, with a little sublimate, or arsenic, to destroy the
substance: some use oil of vitriol; some tincture of can-
tharides: all which methods have at times succeeded;
only they are apt to leave a scar with the loss of hair.
These applications that are of a more caustic nature, of-
ten do more hurt than good, especially when the splent
is grown very hard. As they produce a rottenness, which
keeps running several months before the ulcer can be heal-
ed, and then leaves an ugly scar.

Mild blisters often repeated, as recommended in the sec-
tion upon the Bone Spavin, should first be tried as the mo-
st eligible method, and will generally succeed, even beyond
expectation: but if they fail, and the splent be near the
knee or joints, you must fire and blister in the same man-
ner as for the bone-splavin.

Splents on the back part of the shank-bone are difficult
to cure, by reason of the back fineews covering them:
the best way is to bore the splent in several places with
an iron not very hot; and then to fire in the common
way, not making the lines too deep, but very close to-
gether.

Of the Poll-evil.

The poll-evil is an abscess near the poll of a horse,
formed in the sinuses between the poll-bone, and the up-
permost vertebrae of the neck.

If it proceeds from blows, bruises, or any external vio-
lence, at first bathe the swelling often with hot vinegar;
and if the hair be fretted off with an ouzing through the
skin, make use of two parts of vinegar, and one of spirit
of wine; but if there be an itching, with heat and in-
flammation, the safest way is to bleed, and apply poultices
in several places with hot vinegar three or four times a day; if that does not suc-
cede alone, an ounce of oil of vitriol may be put to a
foot, and when it is made scalding hot, pour it into the
abscess, and close the lips together with one or more
stitches. This is to remain in several days; and if good
matter appears, and not in an over great quantity, it will
do well without any other dressing, but bathing with spi-
rit of wine; if the matter flows in great abundance, and,
of a thin consistence, it must be scalded again, and re-
peated till the matter lessens and thickens.

Of a Fistula, and Bruises on the Withers;
Wandles on the Back, and Sit-fasts.

Bruises on the withers frequently impothismulate, and
for want of care turn fistulous. They arise often from
pinches of the saddle, and should be treated with repel-
lers: for this purpose bathe the tumour well with hot
vinegar three or four times a day; if that does not suc-
cede alone, an ounce of oil of vitriol may be put to a
foot, and when it is made scalding hot, pour it into the
abscess, and close the lips together with one or more
stitches. This is to remain in several days; and if good
matter appears, and not in an over great quantity, it will
do well without any other dressing, but bathing with spi-
rit of wine; if the matter flows in great abundance, and,
of a thin consistence, it must be scalded again, and re-
peated till the matter lessens and thickens.

Of a Fistula, and Bruises on the Withers;
Wandles on the Back, and Sit-fasts.

Take two ounces of crude salt ammoniac, boiled in a
quart of lime-water; where that cannot be had, a
handful of pearl or wood-ashes may be boiled in
common water: pour off the decoction when settled,
and mix with it half a pint of spirit of wine: anoint
the part afterwards with linseed oil, or elder oint-
ment, to soften and smooth the skin.

But when the swellings are critical, the consequence of
a fever settled on this part, you must avoid the repelling
method, and assist in bringing the swelling to matter, by
means of fuppurating poultices: experienced farriers ad-
vise, never to open these tumours till they break of
themselves: for if they are opened before they are ripe,
the whole fore will be spongy, and discharge a bloody in-
chor, which soon degenerates into a fordid ulcer. But
take care to enlarge the openings and pare away the lips,
that your dressings may be applied easily; and avoid the
ligament which runs along the neck to the withers: if a
gathering forms on the opposite side, open it in the same
manner, but take care they incline downwards, for the
fake of depending orifices, and letting the matter flow
of
off easily. For the method of dressing, we must refer to
the preceding Section; and if the bones should be found
soul, they must be dressed with tincture of myrrh till they
scale off: if the fungus is very troublesome, and the dis-
charge oily, yellow and viscid, pledge soaked in the
following, made hot, have been found very effectual,
bathing the swelling round with spirit of wine and vi-

Take half an ounce of blue vitriol diffolvo in a pint
of water; oil of turpentine, and rectified spirit of
wine, of each four ounces; white-wine vinegar, six
ounces; oil of vitriol and Egyptianum, of each two
ounces.

When the cavities are truly fistulous, the callous
must be cut out, where it can be done, with a knife; and
the remainder destroyed by corrosives, viz. precipi-
tate, burnt alum, and white vitriol, as we have already
observed in the Section on Ulcers.

Warbles are small hard tumours under the saddle-part
of the horse’s back, occasioned by the heat of the saddle
in travelling, or its uneasy situation. A hot greasy difh-

Of wind-galls, blood and bog spavins.

A wind-gall is a flatulent swelling, which yields to
the pressure of the finger, and recovers its shape on
the removal thereof: the tumour is visible to the eye,
and often seated on both sides of the back finew, above
the fetlocks, on the fore legs, but most frequently on the
hind-legs; though they are met with in various parts of
the body, wherever membranes can be separated, that
a quantity of air and serofities may be included within
their duplicatures.

When they appear near the joints and tendons, they
are generally called by trains, or bruises on the finews,
or the sheath that covers them; which, by being over-
art, have some of their fibres ruptured; whence
or the sheath that covers them; which, by being over-

A blood-spavin is a swelling and dilatation of the vein
that runs along the inside of the hock, forming a little
soft swelling in the hollow part, and is often attended
with a weaknefs and lameness of the hock.

The cure should be first attempted with the refringing
and bandage above recommended, which will contribute
greatly to strengthen all weakness of the joints, and
frequently will remove this disorder, if early applied:
but if by these means the vein is not reduced to its usual
dimensions, the skin should be opened, and the vein tied
with a crooked needle and wax-thread passed underneath
it, both above and below the swelling, and the turgid
part suffered to digest away with the ligatures: for this
purpose, the wound may be daily dressed with turpentine,
honey, and spirit of wine, incorporated together.

A bog-spavin is an encysted tumour on the inside the
hough; or, according to Dr. Bracken, a collection of
brownish gelatinous matter, contained in a bag, or cyst,
which he thinks to be the lubricating matter of the joint
altered, the common membrane that incloses it forming
the cyst. This case he has taken pains to illustrate in
a young colt of his own, where he says, When the spa-
vin was pressed hard on the inside the hough, there was a
small tumour on the outside, which convinced him the
fluid was within the joint: he accordingly cut into it,
discharged a large quantity of this gelatinous matter, dre-
sed the fore with诋s dipped in oil of turpentine, put-
ting into it, once in three or four days, a powder made
of calcined vitriol, alum, and bole: by this method of
dressing, the bag sloughed off, and came away, and the
cure was successfully compleated without any visible fear.

This disorder, according to the above description, will
scarcely submit to any other method, except firing, when
the cyst ought to be penetrated to make it effectual: but
in all obstinate cases that have refisted the above methods,
both the cure of this and of the swellings called wind-galls
should be attempted in this manner. If, through the
pain attending the operation or dressings, the joint should
swell and inflame, foment it twice a-day, and apply a
poulterice over the dressings till it is reduced.

Of mallenders and sallenders.

Mallenders are cracks in the bend of the horse’s
knee, that discharge a sharp indigestif matter; they are
often the occasion of lameness, stiffness, and the horse’s
tumbling.

Sallenders are the same disease, situate on the bend-
ing of the hough, and occasion a lameness behind.

They are both cured by washing the parts with a lather
of soap warmed, or old chamber-lye; and then apply o-

VEER.
over the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off; if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it.

Take hogs lard, two ounces; sublimate mercury, two drams.

Or,

Take hogs lard, two ounces; oil of vitriol, two drams.

Take the next from Gibson, which is to be depended on:

Æthiops mineral, half an ounce; white vitriol, one dram; soft green soap, six ounces.

Anoint with this often; but first clip away the hair, and clear the scabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre balls may be taken advantageously, for a fortnight or three weeks.

Of Lampas, Barns, and Wolves Teeth.

The lampas is an excrecence in the roof of the horse's mouth, which is sometimes so luxuriant, that it grows above the teeth, and hinders his feeding. The cure is in lightly cauterizing the flesh with a hot iron, taking care that it does not penetrate too deep, so as to scale off the thin bone that lies under the upper bars; the part may be anointed with burnt alum and honey, which is proper for moat fores in the mouth.

This operation is by some thought to be entirely unnecessary; it being a general observation with them, that all young horses have their mouths more or less full of what are called lampas; and that sometimes they rise higher than the fore-teeth; but they further observe, in proportion as a horse grows older, the roof flattens of itself, and the teeth then appear to rise. We are obliged to the ingenious M. La Foffe for this remark, and hope it will be the means of abolishing this cruel and unnecessary operation.

Barbs are small excrescences under the tongue, which may be discovered by drawing it aside, and are cured by cutting close off, and washing with brandy or salt and water.

A horse is said to have wolves teeth, when the teeth grow in such a manner, that their points prick, or wound either the tongue, or gums, in eating. Old horses are most liable to this infirmity, and whole upper over shoot the under teeth in a great degree.

To remedy this evil, you may either chop off the superfluous parts of the teeth with a chizzel and mallet, or file them down, which is the better way, till you have sufficiently waited them.

Of the Grease.

In order to treat this disorder with some propriety; we shall consider it as arising from two different causes; a fault or relaxation in the vessels, or a bad disposition in the blood and juices. We must here observe, that the blood and juices (or humours, for there are always some in the best state of blood) are brought to the extreme parts by the arteries, and returned by the veins; in which latter, the blood is to rise in perpendicular columns, to return the circulating fluids from the extremities: hence swellings in the legs of horses may easily be accounted for, from a partial stagnation of the blood and juices in the finer vessels, where the circulation is molten languid; and especially when there is want of due exercise, and a proper muscular compulsion on the vessels, to push forward the returning blood, and propel the inert and half stagnating fluids through their vessels; in short, the blood in such cases cannot so readily ascend as descend, or a greater quantity is brought by the arteries than can be returned by the veins.

The grease then, confidered in this light, must be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted, and in good condition; or as a disorder where they are both complicated: but when it is an attendant on some other distemper, as the farcy, yellow, dropsey, etc., such diseases must first be cured before the grease can be removed. In the former case, moderate exercise, proper dressing, cleanliness, and external application, will answer the purpose; in the latter, internals must be called in to our assistance, with proper evacuations.

When a horse's heels are first observed to swell in the flable, and subside or go down on exercise, let care be taken to wash them very clean every time he comes in, with soap-fuds, chamber-lye, or vinegar and water, which, with proper rubbing, will frequently prevent, or remove this complaint: or let them be well bathed twice a-day with old verjuice, or the following mixture, which will brace up the relaxed vessels; and if rags dipped in the same are rolled on, with a proper bandage, for a few days, it is most likely the swellings will soon be removed by this method only, as the bandage will support the vessels, till they have recovered their tone. To answer this end also, a laced stocking made of strong canvas or coarse cloth, neatly fitted to the part, would be found extremely serviceable, and might easily be contrived by an ingenious mechanic.

Take rectified spirit of wine, four ounces; dissolve in it half an ounce of camphor; to which add wine-vinegar, or old verjuice, six ounces; white vitriol, disdolved in a gill of water, one ounce; mix together, and thake the phial when used.

But if cracks or scratches are observed, which ouze and run, let the hair be clipped away, as well to prevent a lodgment (which becomes flinking and offensive by its flay) as to give room for washing out dirt or gravel, which, if suffered to remain there, would greatly aggravate the disorder.

When this is the case, or the heels are full of hard scabs, it is necessary to begin the cure with poultices, made either of boiled turnips and lard, with a handful of linseed powdered; or oatmeal and rye flour, with a little common turpentine and hogs lard, boiled up with strong-beer grounds or red-wine lees. The digestive ointment being applied to the fores for two or three days, with either of these poultices over it, will, by softening them, promote a discharge, unload the vessels, and take down the swelling; when they may be dried up with the following:

Take hogs lard, two ounces; oil of vitriol, two drams.
Take white vitriol and burnt alum, of each two ounces; Ægyptiacum, one ounce; lime-water, a quart or three pints: wash the sores with a sponge dipped in this, three times a-day, and apply the common white ointment spread on tow; to an ounce of which may be added two drams of sugar of lead.

This method is generally very successful, when the distemper is only local, and requires no internal medicines; but if the horse be full and gross, his legs greatly gorged, so that the hair flares up, and is what some term pen-feathered, and has a large flinking discharge from deep foul sores, you may expect to meet with great trouble, as these disorders are very obstinate to remove, being often occasioned by a poor dropstall of blood, or a general bad disposition in the blood and juices.

The cure in such cases, if the horse is full and feathery, must be begun by bleeding, rowels, and repeated purging; after which, diuretic medicines are frequently given with success. Thus,

Take four ounces of yellow rosin, one of sal prunelle; grind them together with an oiled pestle, add a dram of oil of amber, and give a quart of forge-water every morning, falling two hours before and after taking, and ride moderately.

As this drink is found very disagreeable to some horses, I would recommend the nitre-balls in its stead, given to the quantity of two ounces a day, for a month or six weeks, mixed up with honey, or in his feeds; take the following also for that purpose.

Yellow rosin, four ounces; salt of tartar, and sal prunelle, of each two ounces; Venice soap, half a pound; oil of juniper, half an ounce; make into balls of two ounce weight, and give one every morning.

The legs, in this case, should be bathed or fomented, in order to breathe out the flagrant juices, or to thin them, so that they may be able to circulate freely in the common current. For this purpose, foment twice a day with the diffusive fomentation, p. 569. col. 2. par. 3. in which a handful or two of wood-ashes has been boiled; apply then the above poultices, or the following, till the swelling has subsided, when the legs may be dried with the green ointment till they are properly digested, and then dried up with the water and ointment above recommended.

Take honey, one pound; turpentine, six ounces; incorporate with a spoon; and add of the meal of sesamum and linseed, each four ounces; boil in three quarts of red-wine lees to the confidence of a poultice; to which add, when taken from the fire, two ounces of camphor in powder; spread it on thick cloths, and apply warm to the legs, securing it on with a strong roller.

If the sores are very foul, dress them with two parts of the wound-ointment, and one of Ægyptiacum; and apply the following, spread on thick cloths, and rolled on.

Take of black soap, one pound; honey, half a pound; burnt alum, four ounces; verdigrise powdered, two ounces; wheat flour, a sufficient quantity.

If the diuretic balls should not succeed, they must be changed for the antimonial and mercurial alternatives, already mentioned; but turning a horse out in a field, where he has a hovel or shed to run to at pleasure, would greatly contribute to quicken the cure, and indeed would in general effect it alone; but if this cannot be complied with, let him be turned out in the day-time.

If the horse is not turned out, a large and convenient stall is absolutely necessary, with good dressing and care.

The last thing we shall recommend, is a method to oblige a horse to lie down in the stable. This undoubtedly is of the utmost consequence, as it will not a little contribute to the removal and cure of this disorder; for by only changing the position of his legs, a freer circulation would be obtained, and the swelling taken down: whereas in general it is greatly aggravated by the obstinacy of the horse, who refuses to lie down at all (probably from the pain it gives him to bend his legs for that purpose) by which means the thickness and swelling increases, till the over-gorged and distended vessels are obliged to give way, and by bursting, discharge the fluids, which should circulate through them.

Of Scratches, Crown-Scabs, Rat-Tails, and Capellets.

Scratches in the heels have so much affinity with the greafe, and are so often concomitants of that distemper, that the method of treating them may be selected chiefly from the preceding section; which at first should be by the linseed and turnip poultice, with a little common turpentine to soften them, and relax the vessels; the green ointment may then be applied for a few days to promote a discharge, when they may be dried up with the ointments and washes recommended in the above section. It is best afterwards to keep the heels supple, and softened with currier's dubbing, which is made of oil and tallow. This will keep the hide from cracking, and be as good a preservative as it is to leather; and by using it often before exercise, will prevent the scratches, if care is taken to wash the heels with warm water, when the horse comes in. When they prove obstinate, and the sores are deep, use the following: but if any cavities or hollow places are formed, they should first be laid open; for no foundation can be laid for healing, till you can dress to the bottom.

Take Venice turpentine, four ounces; quicksilver, one ounce; incorporate well together by rubbing some time, and then add honey and sheeps' feet, of each two ounces.

Anoint with this once or twice a day; and if the horse is full or feathery, you must bleed and purge; and if the blood is in a bad state, the alternatives must be given to rectify it.

The crown-scab is an humour that breaks out round the coronet, which is very sharp and itching, and attended with a scurifnes: sharp waters prepared with vitriol are generally used for the cure; but the safest way is first to mix marshmallow and yellow basilicon, or the wound ointment, equal parts, and to spread them on tow, and lay all round the coronet. A dozen or two of physic may be very proper, with the diuretic medicines, (par. 4. 5. 6. of the preced. col. and the alternatives above recommended)
Of the Diseases of the Feet.

Of Narrow Heels, and Binding of the Hoof, &c.

Though narrow heels in general arise from a natural defect, yet they are often rendered incurable by bad shoeing; for some farriers hollow the quarters so deep and thin, that they may be pinched in with the fingers, and think by that method to widen them out, by a strong broad webbed shoe; but this turns them narrow above, wires their heels, and dries, or rots the frog. The best way in all such cases is not to hollow the foot in shoeing, and to pare nothing out but what is rotten or foul; if the foot be hard and dry, or inclined to be rotten, bathe it often with chamber-lye, or boil two pounds of linseed bruised in two quarts of the same, to the consistence of a poultice, then add fix ounces of soft green soap, and anoint the foot with it every day, rubbing a little of it upon the sole.

Or, take bees-wax two ounces; fresh butter or lard, fix ounces; tar, one ounce; as much linseed, or nearest foot oil, as will make it the consistence of a smooth ointment.

The hoofs, if too dry, may be anointed with the above, or with lard only; some for this purpose use tars, tallow, and honey, but most greasy and unctuous applications will answer this intention; the feet also, if too dry, may be stuffed with bran and lard heated, or worked up together in the hand, which is very proper also to apply every night, when your horse is travelling in hot weather on roads that are dry and hard; cow-dung likewise is a proper stuffing for the feet, but vinegar should cautiously be mixed with it; for though it is a known cooler, it is a remarkable restringent, which in this case would be extremely prejudicial, instead of which, a print of fresh butter may be first applied to the sole, and the cow-dung laid over it.

There is another disorder the hoofs are subject to, which is their being too soft and moist; this may be constitutional, or proceed from going much in wet and marshy grounds, standing constantly on wet litter, or any infirmity that may bring too much moisture into the feet. In this case the horse’s hoofs may be bathed every night with warm vinegar, verjuice, copperas-water, and such like restringents; to which may be added galls, alum, &c. remembering to let the horse stand constantly dry.

We say a horse is hoof-bound, when the hoof is so tight round the inletp, that it turns the foot somewhat into the shape of a bell. This is caused sometimes by shoeing as above, to widen the heel, and sometimes by cutting the toes down too much, which gives that shape to the foot, and causes the horse to go lame.

To remedy this disorder, Mr Gibbon recommends the following method: let the foot be drawn down from the coronet almost to the toe with a drawing knife, making seven or eight lines or razes through the hoof, almost to the quick; afterwards keep it charged with pitch rosin, till the lines are wore out in shoeing, which will require several months.

Of Sand Cracks and Quittors.

What is called a sand-crack, is a little cleft on the outside of the hoof: if it runs in a straight line downwards, and penetrates through the bony part of the hoof, it often proves troublesome to cure; but if it passes through the ligament that unites the hoof with the coronet, it is then apt to breed a quittor, or false quarter, which is dangerous.

When the crack only penetrates through the hoof, without touching the ligament, unless the hoof be hollow, it may easily be cured, by rasping only the edges smooth, and applying thick pledgets of basilicon, and binding them down with a piece of soft lint; if some precipitate be added to it, this medicine will be improved thereby, and in general answers the end, without any other application. But if you perceive any hollownesses under the hoof, and that the cleft has a tendency to penetrate through the gristle or ligament, the bell method, in that case, is to fire out of hand with irons that are not made
made too hot, first rasping very thin and wide from both sides of the cleft; the horse must not carry any weight for some time, but be turned out to graze, or wintered in a good farm-yard.

A quittor is an ulcer formed between the hair and hoof, usually the inside quarter of a horse’s foot; it arises often from treads and bruises, sometimes from gravel, which, by working its way upwards, lodges about the coronet: if it is only superficial, it may be cured with cleaning dressings, bathing the coronet every day with spirit of wine, and dressing the fore with the precipitate medicine.

But if the matter forms itself a lodgment under the hoof, there is no way then to come at the ulcer, but by taking off part of the hoof; and if this be done artfully and well, the cure may be affected without danger.

When the matter happens to be lodged near the quarter, the farrier is sometimes obliged to take off the quarter of the hoof, and the cure is then, for the most part, but palliative; for when the quarter grows up, it leaves a pretty large seam, which weakens the foot; this is what is called a false quarter, and a horse with this defect seldom gets quite found.

If the matter, by its confinement, has rotted the coffin-bone, which is of so soft and spongy a nature, that it soon becomes so, you must enlarge the opening, cut away the rotten flesh, and apply the actual cautery, or hot iron pointed pyramidically, and draw the bone with doses of lint, dipped in tincture of myrrh, and the wound with the green or precipitate ointment. When the fore is not enlarged by the knife, which is the best, and least painful method, pieces of sublimate are generally applied, which bring out with them cores, or lumps of flesh; blue vitriol powdered, and mixed with a few drops of the oil, is used also for this purpose, and is said to act as effectually, and with less pain and danger; during the operation of these medicines, the foot should be kept in some soft poultice, and care should be taken, during the whole dressing, to prevent proud flesh rising, which otherwise will not only retard the cure, but prevent a firm and sound healing.

Of Wounds in the Feet, from Nails, Gravel, &c.

Accidents of this sort are very common, and sometimes for want of early care, prove of bad consequence; for the parts, being naturally tender, are very susceptible of inflammation; and when matter is once formed, if a free discharge is not procured, the bone, which is spongy, soon becomes affected, and the whole foot is then in danger.

When any extraneous bodies, such as nails, flubs, thorns, &c. have paffed into the horse’s foot, you should endeavour to get them out as soon as possible; and after washing the part with oil of turpentine, drefs the hole with lint dipped in the same, melted down with a little tar; the foot may be flopped up with bran and hogs-lard heated together, or put it into the turnip, or any soft poultice; this method is generally successful, when the nail, &c. is entirely removed; but if any piece, or particle, should remain behind, which may be suspected by the degree of pain, and discharge of matter; after parting away the sole as thin as possible, introduce a bit of sponge tent, in order to enlarge the hole, that it may be drawn out by a small pair of forceps, or brought away by digestion: if this method should not succeed, but the lamenefs continues, with a discharge of a thin bloody, or slimy matter, you must no longer delay opening the wound with a drawing-knife to the bottom, and then dress as above directed, or with the turpentine digestive, divided with the yolk of an egg, and a little tincture of myrrh; afterwards with the precipitate medicine.

If the lamenefs proceeds from pricking in shoeing, the foot should be pared thin on the wound side, and after dressing with the tar and turpentine, let it be flopped with the poultices above mentioned, or with two ounces of common turpentine, melted down with four of lard; should this method not succeed, follow the above directions.

If the nail has paffed to the nut-bone, it is incurable, because this little bone cannot exfoliate, and because the cartilaginous part of it is destroyed, as soon as injured.

If the nail has not paffed to the tendon, the horse will do well, without a necessity for drawing the sole; but if the tendon is wounded, the sole must be carefully drawn, because a sinova and gleet is discharged.

When gravel is the caufe, it for the moft part follows the nail-holes, and if it gets to the quick cannot return, unless it is scraped out; for the make of the hoof, which is spiral like an ear of corn, favours its ascent, so that the gravel continues working upwards towards the coronet, and forms what the farriers call a quittor-bone.

The nature of this disorder points out the method of cure, which is to be as expeditious and careful as possible, in getting out the gravel; if it is found difficult to effect this, let the sole or hoof be pared thin, and, if necessary, the wound enlarged to the bottom, and then dressed up as usual. Should the coffin-bone be affected, you must follow the directions laid down in the preceding section, remembering always to bathe the hoof with vinegar, or repellers, in order to allay the heat and inflammation, which often happen on such occasions; and should the pain and anguish affect the legs, treat them in the same manner, or charge the leg and pattern with a mixture of wine-lees and vinegar.

Figs are spongy swellings on the bottom of horses feet, generally on the sides of the flesh. These, or any other kind of excrescences, such as warts, corns, grapes, &c. are best removed by the knife; and if any part of them be left behind, or should shoot up afreafi, touch them with the caufts, or oil of vitriol, and drefs with Aegypticum; to which may be added, when they are very rebellious, a small quantity of sublimate; when the roots are quite destroyed, you may incarn with the precipitate medicines, and dry up the fore with the following wafh.

Take of white vitriol, alum, and galls in powder, of each two ounces; disolve them by boiling a little in two quarts of lime-water, and keep in a bottle for use, which should be shook when used.
Of the Running Thrush, Canker, and Loss of Hoof.

The thrush or fresh is an imposthume that sometimes gathers in the frog; or a scabby and ulcerous disposition, which sometimes causes it to fall off: when the discharge is natural, the feet should be kept clean, but no drying washes made use of, it being thought as unsafe to repel some of these discharges, as to cure some sweaty feet.

When an imposthume, or gathering appears, the safest way is to pare out the hard part of the frog, or whatever appears rotten; and wash the bottom of the foot two or three times a-day with old chamber-lye; this is the safest and best way of treating them. But when a horse has been neglected, and there is is a strong flux to the part, it is apt to degenerate into a canker; to prevent which, use the following wash.

Take spirit of wine and vinegar of each two ounces, tincture of myrrh and aloes one ounce, Egyptia-cum half an ounce; mix together.

Bathe the thrush with this, where ever there appears a more than ordinary moisture, and lay over the ulcer a little tow dipped in the same. The purges and diuretics recommended in the grease, should be given at this time, to prevent the inconveniences that the drying up these discharges frequently occasion.

A canker in the foot proceeds, for the most part, from thrushes, when they prove rotten and putrid, though many other causes may produce this disorder. The method used by farriers for the cure is generally with hot oils, such as virgul, aqua-fortis, and butter of antimony, which are very proper to keep down the rising flesh, and should be used daily, till the fungus is suppressed, when once in two days will be sufficient, stirring fine precipitate powder over the new-grown flesh, till the sole begins to grow.

There is one great error committed often in this cure, that is, in not having sufficient regard to the hoof; for it should not only be cut off, where-ever it presses on the tender parts, but should be kept soft with linseed oil; and as often as it is dressed, bathe the hoof all round the coronet with chamber-lye. Purging is very proper to complete the cure.

The loss of the hoof may be occasioned by whatever accident may bring an impolthumation in the feet, whereby the whole hoof becomes loosened, and falls off from the bone. If the coffin-bone remains uninjured, a new hoof should by no means be pulled off, unless some accident happens that requires its removal; for it serves as a defense to the new one, and makes it grow more smooth and even; and indeed nature will generally do this office at her own proper time.—On the removal of the hoof, a boot of leather, with a strong sole, should be laced about the pattern, bolstering and stopping the foot with soft flux, that the treads may be easy: dress the fore with the wound ointment, to which should be added the fine powders of myrrh, maitlich, and oilba-num. If this medicine should not be sufficient to prevent a fungus, burnt alun or precipitate may be added to it, and the luxuriant flesh may be daily washed with the sublimate water.

Of Ruptures, Anticor, Colt-evil or Gonorrhoea, and Diseases of the Mouth.

In regard to ruptures, though they are generally divided into particular classes, we shall only observe, that by violent efforts of the horse, or other accidents, the guts or caul may be forced between the muscles of the belly at the navel, and through the rings of the muscles into the forotum or cod. The swellings are generally about the size of a man's fist, sometimes much larger, descending to the very hock; they are frequently soft, and yield to the pressure of the hand, when they will return into the cavity of the belly with a rumbling noise; and, in moff, the vacuity may be felt through which they passed.

On their first appearance, endeavors should be made to return them by the hand; but if the swelling should be hard and painful, in order to relieve the torture, and relax the parts, through which the gut or caul has passed, let a large quantity of blood be immediately taken away, and the part fomented twice or thrice a-day, applying over it a poultice made with oatmeal, oil and vinegar, which should be continued till the swelling grows soft and easier, or the gut is returned. In the mean time it would be proper to throw up emollient oily glysters twice a-day, and to let the horse's chief diet be boiled barley, scalded malt, or bran.

Should the swelling afterwards return, we apprehend the refrigent applications, usually recommended on these occasions, will avail little without a sulfenporous bandage; so that an ingenious mechanic in that art is chiefly to be relied on for any future assistance; though it has been observed, that with moderate feeding, and gentle exercise, some horses have continued to be very useful under this complaint.

The anticor is a disorder not very common among our horses, or those in northern climates; but particular-ly taken notice of by the French, Spanish, and Italian writers; who describe it a malignant swelling in the breast, which extends sometimes to the very sheath under the belly; it is attended with a fever, great depressions, and weakens, and a total loss of appetite.

The cure should first be attempted by large and repeated bleedings, to abate the inflammation; emollient glysters should be injected twice or thrice a-day, with an ounce of sal prunella in each, and the cooling drink in the section on fevers should be given inwardly; the swelling should be bathed with the marshmallow ointment, and a ripening poultice, with onions boiled in it, should be daily applied over it. If by this method, continued four or five days, the inflammation in the throat and gullet is removed, our attention should more particularly turn to encourage the swelling at the breast, and bring it, if possible, to matter: to which end, continue the poultice, and give two ounces of Venice treacle dissolved in a pint of beer every night; when the swelling is grown soft, it must be opened with the knife, and dressed with turpentine digestive, the danger now being over.
But should it be found impracticable to bring the swelling to matter, and it increases upwards, so as to endanger suffocation; authors have advised to pierce the tumour with a hot pointed cauter, and promote a greater discharge, to add to it a small quantity of Spanish flies and euphorion in powder; fomenting at the same time, and basting the circumjacent parts with ointment of marshmallows. M. Guerinier, as well as Soleyfell, have advised opening the skin, when the tumour cannot be brought to matter, in order to introduce a piece of black hellebore-root steeped in vinegar, and to confine it there for twenty-four hours; this also is intended as a stimulant, and is said to answer the intention, by occasioning sometimes a swelling as big as a man's head.

Besides the disorders of the mouth, which we have already animadverted on, there are frequently observed on the inside the lips and palate, little swellings or bladders called giggs: futting them open with a knife, or lancet, and washing them afterwards with salt and vinegar, is in general their cure; but when they degenerate into what are called cankers, which are known by little white specks, that spread and occasion irregular ulcers, the best method then is to touch them daily with a small flat cautery, moderately heated, till the spreading is stopped, and to rob the fores three or four times a-day with Aegyptiacum, and tincture of myrrh, sharpened with oil, or spirit of vitriol; when by this dressing the floughs are separated, they may be washed frequently with a sponge dipped in copperas, or sublimate water, if they continue to spread; or a tincture made by dissolving half an ounce of burnt alum, and two ounces of honey, in a pint of tincture of roses. Either of these will dry them up, and are very useful in most disorders of the mouth.

A relaxation and swelling of the palate sometimes happens to horses on catching cold. To remedy this disorder, blow pepper on the part, or anoint it with the same mixed up with honey. The tincture above-mentioned may be used for this purpose, to which may be added half an ounce of spirit of sal armoniac.

The colt-evil is supposed to arise from stoned colts having full liberty with mares, before they are able to cover them; whence frequently ensues an excoriation or fretting on the glands, and a swelling on the sheath; this last disorder frequently proceeds too from dirt, or filth lodging there, and is often removed by washing the part clean with butter and beer: but when the yard itself is swelled, foment it twice a-day with marshmallows boiled in milk, to which may be added a little spirit of wine; anoint the excoriation with the white ointment, or wash it with a sponge dipped in lime, to a pint of which may be added two drams of sugar of lead; the yard should be suspended up to the belly; and if the swelling should increase with the inflammation, bleed, and give the cooling physic, anoint with ointment of elder, and apply the bread and milk poultice.

If a simple gonorrhoea or seminal gleet is observed to drip from the yard, (which is often the case in high-fed young horses, where a relaxation of the glands and seminal vesicles has been brought on by frequent emissions) let the horse be plunged every day into a river or pond; give him two or three rhubarb purges, at proper distances; and immediately the following balls.

Take of balsam of copivi, or Venice turpentine, olibanum, and malitch powdered, of each two drams; bole armoniac half an ounce: mix up into a ball with honey, and give it night and morning, till the discharge lessens, and then every night, till it goes off.

Balls prepared with rhubarb and turpentine may also be given for this purpose: two drams of the former, with half an ounce of the latter.

FASCINES, in fortification, faggots of small wood, of about a foot diameter and six feet long, bound in the middle and at both ends. They are used in raising batteries, making chandeliers, in filling up the moat to facilitate the passage to the wall, in binding the ramparts where the earth is bad, and in making parapets of trenches to screen the men.

FASHION-PIECES, in the sea-language, are two compartmented pieces of timber, into which is fixed one on each side the tranom. See Transom.

FASHION, in general, denotes the abstinence from food; but is more particularly used for such abstinence on a religious account.

FASTERMANS, among our Saxon ancestors, were pledges or bondsmen, who were answerable for each other's good behaviour.

FASTI, in Roman antiquity, the calendar wherein were secreted the several days of the year, with their feasts, games, and other ceremonies.

FAT, in anatomy, an oleaginous or butyraceous matter, secreted from the blood, and filling up the cavity of the adipose cells. Fat, properly and distinctly so call-
F A W

F A W W ( 582 )

ed, is not secreted from glandules, but from the little arteries of the adipose membrane. Authors distinguish it into two kinds, which they express by the words *secum* or *adips*, and *pinguedo*. According to this distinction, there is no such thing as *secum* or hard fat in the human body, its fat being all of that soft expressed by pinguedo, or soft and oily. That this oleaginous matter has a circulatory motion, or an egress into the veins, is very evident from the sudden consumption of it in many diseases, and from its vast diminution by exercise or labour.

Fat, in the feast language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the bottom in or tuck of her quarter be deep.

Fat likewife denotes an uncertain measure of capacity. Thus a fat of large glass contains from 3½ hundred weight to 4 hundred weight; a fat of unbound books, half a maund or four bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

FATE, denotes an inevitable necessity depending upon a superior cause. It is also used to express a certain unavoidable designation of things, by which all agents, both necessary and involuntary, are swayed and directed to their ends.

FATES, in mythology. See PARCE.

FATHOM, a long measure containing six feet; used chiefly at sea for measuring the length of cables and cordage.

FATUUS ignis, in physiology, a meteor otherwise called Will-with-a-wilm. See WILL.

FAVIFORM, in general, something resembling a honeycomb. Surgeons give this appellation to certain ulcers, which emit a fpecies through little holes, especially in the head.

FAVIISE, in antiquity, were, according to Festus and Gallus, cisterns to keep water in: but the favilfae in the Capitol at Rome were dry cisterns or subterraneous cellars, where they laid up the old statues, broken vessels, and other things used in the temple. These were much the same with what, in some of the modern churches, are called the archives and treasury.

FAUNALIA, in Roman antiquity, three annual festivities in honour of the god Faunus; the first of which was observed on the 1st of February, the second on the 16th of the calendar of March, and the third on the nones of December. The principal sacrifices on this occasion were lambs and kids. Faunus was a deity of the Romans only, being wholly unknown to the Greeks.

FAUNS, a kind of rural deities, among the ancient Romans, represented with horns on their heads, sharp-pointed ears, and the rest of their bodies like goats.

FAWN, among sportsmen, a buck or doe of the first year; or the young one of the buck's breed in its first year.

FE, or St Fe, the capital of New Mexico: W. long. 100°, N. lat. 36°.

St Fe de Bajada, the capital of the kingdom of New Granada: W. long. 73°, N. lat. 4°. It is an archbishopric and the seat of the governor of the province, &c.

St Fe is also a town of Spain, in the province of Granada, situated on the river Xemil: W. long. 3° 45', N. lat. 37° 20'.

FEALTY, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land.

FEAST, or Festival, in a religious sense, is a day of feasting and thanksgiving.

Among the ancients, feasts were instituted upon various accounts, but especially in memory of some favourable interposition of Providence. Thus, the Jews had their feast of passover, pentecost, and tabernacles; the Greeks their cerealia, pahathena, &c. and the Romans their saturnalia, ambarvalia, &c. See Passover, CEREAAL.

FEATHER, in physiology, a general name for the covering of birds; it being common to all the animals of this class to have their whole body, or at least the greatest part of it, covered with feathers or plumage.

FEBRIFUGE, in medicine, an appellation given to such medicines as mitigate, or remove a fever.

FEBRIS, fever, in medicine. See Fever.

FEBRUARY, in chronology, the second month of the year, reckoning from January, first added to the calendar of Romulus by Numa Pompilius.

February derives its name from Februa, a feast held by the Romans in this month, in behalf of the manes of the deceased; at which ceremony sacrifices were performed, and the laws were made for the shades of the dead.

February, in a common year, consists only of twenty-eight days; but in the bisextile year, it has twenty-nine, on account of the intercalary day, added that year.

FECALES, or Fœciales, a college of priests instituted at Rome by Numa, consisting of twenty persons, selected out of the best families. Their business was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith.

FEES, in Scots law, signifies a complete feudal property. See Scots Law, title 10. Hence, where the bare lifierent of any feudal subject is meant to be conveyed to A, and the absolute property to B; that meaning is expressed thus, to A in derriferent, and to B in fee.

FEELERS, in natural history, a name used by some for the horns of insects.

FEELING, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities.

FEINT, in fencing, a shew of making a thrust at one part
FELLS, the Cat, a genus of quadrupeds belonging to
FELIN, a town of Livonia, about an hundred miles
FELAPTON, in logic, one of the six first modes of
nifh of saily. The Romans, says Mr. Shaw, brought
travellers, and the scourge of the neighboring pro-
fometimes covered with snow, are neither so strong or
hot and barren deserts, that the lion is the dread of
sun of Africa or the Indies, are the most formidable, and
the climate. The lions nourished under the scorching
hausted or lowered according to the good or bad suc-
the length of the claws is about an inch and a quarter,
bead to below the shoulders, and hangs down to his
knees; the belly and breast are likewise covered with
northeast of Riga.

The fore teeth are equal; the molares or grinders have
three points; the tongue is furnished with rough sharp
prickles, and pointing backwards; and the claws are
sheathed, and retractile. This genus comprehends
seven genera, viz.

1. The LEOPARD. The largest lions are from eight
to nine feet in length, and from four to eight feet high:
those of a smaller size are generally about 5 1/2 feet
long, and about 3 1/2 high. His head is very thick, and
his face is befeet on all sides with long bulky yellowish
hair; this shaggy hair extends from the top of the
head to below the shoulders, and hangs down to his
knees: the belly and breast are likewise covered with
long hair. The rest of the body is covered with very
short hair, excepting a bush at the point of the tail.
The ears are roundish, short, and almost entirely con-
cealed under the hair of his front. The shagginess of
the fore-part of his body makes the hinder part have a
naked appearance. The tail is long and very strong;
the legs are thick and heavy; and the feet are short;
the length of the claws is about an inch and a quarter,
are of a whitish colour, very crooked, and can be ex-
tended or retracted into the membranous sheath at
pleasure: Their points are seldom blunted, as they are
never extended but when he seizes his prey.

The female, or lioness, has no mane, or long hair a-
about her head or shoulders; in her we see distinctly the
whole face, head, ears, neck, shoulders, breast, &c.
all these parts being in some measure concealed un-
der the long hair of the male, give the female a very
different appearance: besides, she is considerably les-
than the male. The hair of both male and female is
of a yellowish colour, and whiten on the sides and
belly.

In warm countries, quadrupeds in general are lar-
ger and stronger than in the cold or temperate climates.
They are likewise more fierce and hardy; all their na-
tural qualities seem to correspond with the ardour of
the climate. The lions nourished under the scorching
sun of Africa or the Indies, are the most strong, fierce,
and terrible. Those of mount Atlas, whose top is
sometimes covered with snow, are neither so strong or
so ferocious as those of Biledulgerid or Zaara, whose
plains are covered with burning sand. It is in those
hot and barren deserts, that the lion is the dread of
travellers, and the scourge of the neighbouring pro-
vinces. But it is a happy circumstance, that the spe-
cies is not very numerous: they even appear to dimin-
ish daily. The Romans, says Mr. Shaw, brought
many more lions out of Libya for their public shews,
than are now to be found in that country. It is like-
wise remarked, that the lions in Turkey, Perhia, and
the Indies are less numerous than formerly. As this
formidable and courageous animal makes a prey of
most other animals, and is himself a prey to none,
this diminution in the number of the species can be
owing to nothing but an increase in the number of man-
kinds: for it must be acknowledged, that the strength
of this king of animals is not a match for the dexter-
ity and address of a Negro or hottentot, who will
often dare to attack him face to face, and with very
light weapons.

The ingenuity of mankind augments with their num-
ber; that of other animals continues always the same.
All the noxious animals, as the lion, are reduced to
a small number, not only because mankind become
more numerous, but likewise because they have become
more ingenious, and have invented weapons which no-
thing can resist. This superiority in the numbers and
inability of mankind, at the same time that it has broke
the vigour of the lion, appears like wise to have encrea-
ted his courage. This quality, though natural, is ex-
alted or lowered according to the good or bad success
with which any animal has been accustomed to employ
his force. In the vast deserts of Zaara; in those
which seem to separate two very different races of men,
the Negroes and Moors, between Senegal and the
boundaries of Mauritania; in those uninhabited regions
above the country of the Hottentots; and, in general,
in all the meridional parts of Africa and Asia, where
mankind have disdained to dwell, lions are still as nu-
merous, and as fierce as ever. Accustomed to
measure their strength by that of all other animals
which they encounter, the habit of conquering renders
them haughty and intrepid. Having never experienced
the strength of man, or the power of his arms, instead
of discovering any signs of fear, they disdain and set
him at defiance. Wounds irritate, but do not terrify
them: they are not even disconcerted at the sight of
numbers. A single lion of the desert has been known
to attack a whole caravan; and if, after a violent and
obstinate engagement, he found himself weakened, he
retreats fighting, always keeping his face to the enemy.
On the other hand, the lions which live near the vil-
lages or huts of the Indians or Africans, being ac-
cquainted with man and the force of his arms, are fo
dacrately as to fly and leave their prey at the sight of
women or children.

This softening in the temper and disposition of the lion,
shows that he is capable of culture, and susceptible,
at least to a certain degree, of the impressions that he re-
ceives: accordingly, history informs us of lions yoked in
triumpal chariots, trained to war, or the chase; and
that, faithful to their masters, they never employed
their strength or courage against their enemies. It is,
however, certain, that a lion taken young and brought
up among domestic animals, will easily be accustomed
to live and sport with them; that he is mild and ca-
refling to his master, especially when he is young; and
that, if his natural ferocity sometimes breaks out, it
is rarely turned against those who have been kind to him. But, as his passions are impetuous and vehement, it is not to be expected that the impressions of education will at all times be sufficient to balance them: for this reason it is dangerous to let him suffer hunger long, or to vex him by ill-timed teazings: bad treatment not only irritates him, but he remembers it long, and meditates revenge. On the other hand, he is exceedingly grateful, and seldom forgets benefits received. He has been often observed to disdain weak or insignificant enemies, to despise their insults, and to pardon their offensive liberties. When led into captivity, he will discover symptoms of uneasiness, without anger or peevishness; on the contrary, his natural temper sofens, he obeys his master, cares for the hand that gives him food, and sometimes gives life to such animals as are thrown to him alive for prey; by this act of generosity he seems to consider himself as for ever bound to protect them; he lives peaceably with them, allows them a part, and sometimes the whole of his food, and will rather submit to the pangs of hunger than fill his stomach with the fruit of his beneficence. We may likewise observe, that the lion is not a cruel animal; he kills rather from necessity than choice, never destroying more than he eats, and whenever his appetite is satisfied he is mild and peaceable.

The aspect of the lion does not detract from the noble and generous qualities of his mind. His figure is respectable; his looks are determined; his gate is stately; and his voice is tremendous. In a word, the body of the lion appears to be the best model of strength joined to agility. The force of his muscles is expressed by his prodigious leaps and bounds, often 20 feet at once; by the brisk motion of his tail, a single sweep of which is sufficient to throw a man to the ground; by the eafe with which he moves the skin of his face, and particularly of his forehead; and, lastly, by the faculty of erecting and agitating the hair of his main when irritated.

Lions are very ardent in their amours: when the female is in season, she is often followed by eight or ten males, who roar incessantly, and enter into furious engagements, till one of them completely overcomes the rival, takes peaceable possession of the female, and carries her off to some secret recess. The lioness brings forth her young in the spring, and produces but once every year. All the passions of the lion, the soft passion of love not excepted, are excessive; the love of offspring is extreme: the lioness is naturally weaker, less bold, and more gentle than the lion; but she becomes perfectly rapacious and terrible when she has young. Then she exhibits more courage than the male; she knows no danger; she attacks indiscriminately men and all other animals, kills them, and carries them to her young ones, whom she thus early instructs to suck their blood and tear their flesh. She generally brings forth in the most secret and inaccessible places; and, when afraid of a discovery, she endeavours to conceal the traces of her feet, by returning frequently on her fleps, or rather by effacing them with her tail; and, when the danger is great, she carries off her young and conceals them some where else. But, when an actual attempt is made to deprive her of her young, she becomes perfectly furious, and defends them till she be torn to pieces.

The lion seldom goes abroad in the middle of the day; he goes round in the evening and night, in quest of prey. He is afraid of fire, never approaches the artificial fires made by the shepherds for the protection of their flocks; he does not trace other animals by the scent, but is obliged to trust to his eyes. Many historians have even misrepresented him as incapable of finding out his prey; but that he is obliged to the jackal, an animal of exquisite scent, in order to provide for him, and that this animal either accompanies or goes before him for this purpose. The jackal is a native of Arabia, Lybia, &c. and, like the lion, lives upon prey; perhaps sometimes he follows the lion, but it is with a view to pick up what he leaves behind, not to provide for him; for, being a small and feeble animal, he ought rather to fly than to serve the lion.

The lion, when hungry, will attack any animal that presents itself: but he is so very formidable, that all endeavour to avoid his rencontre; this circumstance often obliges him to conceal himself, and lie in wait till some animal chances to pass. He lies squat on his belly in a thicker; from which he springs with such force and velocity, that he often seizes them at the first bound. He endures hunger longer than thirst; he seldom paces water without drinking, which he does by lapping like a dog. For his ordinary subsistence, he requires about 15 pounds of raw flesh each day.

The roaring of the lion is so strong and loud, that it resembles the rumbling of distant thunder. His roaring is his ordinary voice: but when he is irritated, his cry is shorter, repeated more suddenly, and is still more terrible than the roaring: besides he beats his sides with his tail, flamps with his feet, erects and agitates the hair of his head and main, moves the skin of his face, shows his angry teeth, and lolls out his tongue.

The gait of the lion is stately, grave, and slow, though always in an oblique direction. His movements are not equal or measured, but consist of leaps and bounds; which prevents him from toppling suddenly, and makes him often over-leaf his mark. When he leaps upon his prey, he makes a bound of 12 or 15 feet, falls above it, seizes it with his fore-feets, tears the flesh with his claws, and then devours it with his teeth.

The lion, however terrible, is hunted by large dogs, well supported by men on horseback: they divide him, and oblige him to retire. But it is necessary that both the dogs and horses be trained beforehand; for almost every animal flees and flies as soon as he feels the very smell of a lion. His skin, although hard and firm, does not reful either a ball or a javelin: however, he is seldom killed by a single stroke; and is more frequently taken by address than force. They put a live animal above a deep pit covered with light substances, and thus decoy him into the snare.

2. The Tiger. The size of this animal, according to some authors, is larger, and, according to others, somewhat less than the lion. M. de la Landemaron assures us, that he has seen a tiger in the East Indies 15 feet long, including undoubtedly the length of

the tail, which, supposing it to be four feet, makes the body of the tiger about 10 feet in length. The skeleton preserved in the cabinet of the French king, indicates that the animal was about 7 feet long from the point of the muzzle to the origin of the tail; but then it must be considered that he was caught young, and lived all his days in confinement. The head of the tiger is large and roundish; and the ears are short, and at a great distance from each other. The form of the body has a great resemblance to that of the panther. The skin is of a darkish yellow colour, striped with long black streaks; the hair is short, excepting on the sides of the head, where it is about four inches long. The point of the tail is black, and the rest of it is interpersed with black rings. His legs and claws resemble those of the lion, only the legs are much shorter in proportion to the size of the animal.

The tiger is more ferocious, cruel, and savage than the lion. Although gorged with carnage, his thirst for blood is not appeased; he seizes and tears in pieces a new prey with equal fury and rapacity, the very moment after devouring a former one; he lays waste the country he inhabits; he neither dreads the aspect nor the weapons of men; puts to death whole troops of domestic animals; and attacks young elephants, rhinoceroses, and sometimes even braves the lion himself. The tiger seems to have no other instinct but a constant thirst after blood, a blind fury which knows no bounds or distinction, and which often stimulates him to devour his own young, and to tear the mother in pieces for endeavouring to defend them. He lies in wait at the banks of rivers, &c. where the heat of the climate obliges the other animals to repair for drink. Here he seizes his prey, or rather multiplies his massacres; for he no sooner kills one animal, than he flies with equal fury upon the next, with no other view but to plunge in his head into their bodies and drink their blood. However, when he kills a large animal, as a horse or a buffalo, he sometimes does not tear out the entrails on the spot; but, to prevent any interruption, he drags them off to the wood, which he executes with incredible swiftness. This is a sufficient specimen of the strength of this rapacious animal.

Neither force, restraint, or violence can tame the tiger. He is equally irritated with good as with bad treatment: he tears the hand which affrights him with equal fury as that which administers blows; he roars, and is enraged at the sight of every living creature. Almost every natural historian agrees in this horrible character. When viewing the beautiful tiger which is at present exhibiting in the city of Edinburgh, we at first suspected that his character was not so bad or ferocious as represented by historians: he allowed the keeper not only to come near him, but to stroke his head and take his paw in his hand. However, this appeared to be only a forced complaisance; he was chained so close to the floor, that he had only just room to stand; he snarled and roared when his master troubled him more than he inclined; and, upon throwing him a piece of flesh, his eyes instantly sparkled with rage; he put himself in a posture of defence, set up the moit horrible roarings, and made several bounds to get at the keeper as well as the spectators.

Vol. II. No. 51.

It is happy for other animals, that the species of the tiger is not numerous, and that they are confined to the warm climates. They are found in Malabar, Siam, Bengal, the interior parts of Africa, and, in general, in all the regions that are inhabited by the elephant and rhinoceros.

The tiger has always been a more rare animal than the lion, and yet brings forth an equal number of young, namely, four or five at a litter. The female is furious at all times; but, when her young are attempted to be taken from her, her rage is redoubled: she braves every danger; she pursues the ravishers, who are obliged, when hard pressed, to drop one of the young in order to retard her motion; she stops, takes it up, and carries it into some secret part of the forest; but the infantly returns and pursues the hunters into their villages or boats.

The tiger moves the skin of his face, grinds his teeth, and roars, like the lion; but the sound of his voice is different.

3. The Panther.—It is about the size of a large dog, and has a great resemblance to a domestic cat. The tongue is rough and remarkably red; the teeth are strong and sharp; the skin is exceedingly beautiful, being of a yellow colour, variegated with roundish black spots, and the hair is short.

The panther has a cruel and ferocious aspect; his motions are brisk and lively; his cry resembles that of an enraged dog, but more fierce and rough. He is not so perfectly unapproachable as the tiger; but, notwithstanding all attempts to render him obedient and tractable, he may rather be said to be tamed than tamed; for he never entirely loses his natural ferocity. Accordingly, when kept with a view to hunting bucks, goats, or other animals, great care is necessary in training him, and still greater in conducting him. When leading out to the field, they put him in a cage and carry him on a cart. When the game is sprung, they open the door of the cage; he instantly springs towards the animal, often seizes him in a few bounds. He throws him to the ground, and drags him. But, if he happens to miss his aim, he becomes mad with rage, and sometimes falls upon his master, who, in order to prevent accidents of this kind, generally carries with him pieces of flesh, or perhaps a lamb or a kid, which he throws to him in order to appease his fury.

The panther is no where to be found but in Africa, and the regions of the Indies.

4. The Onca or Once, is less than the panther; the tail is longer; the hair is likewise longer; and of a whitish grey colour. The once is easily tamed; and is employed in hunting in several parts of Asia, where dogs are very scarce. He has not the delicate scent of a dog; does not trace other animals by the smell; neither can he run them down in a fair chase; but lies in wait for their approach, and then darts upon them unawares. He leaps so nimbly, that he easily clears a ditch or a wall several feet high: besides, he often climbs trees, waits till some animal passes, and instantly leaps down upon them. This method of catching their prey, is practised by the panther and leopard, as well as the once.

5. The Leopard differs from the panther and the once in the beauty of his colour, which is a lively yellow, with smaller spots than those of the two latter, and
disposed in groups. He is larger than the once, and less than the panther. The manners and disposition of the leopard are nearly the same with those of the panther. He is never tamed or employed in hunting. The panther, once, and leopard, are inhabitants of Africa and the warmer regions of Asia. In general, these animals delight in thick forests, and frequent the banks of rivers, and the neighbourhood of solitary villages, where they lie in wait to surprize domestic animals and the wild beasts that come in quest of water. They seldom attack men, even when provoked. With regard to their skins, they are all valuable, and make excellent furs.

6. The Lynx is about 2½ feet long and 1½ inches high. He has a great resemblance to the cat; but his ears are longer, and his tail is much shorter; his hair is streaked with yellow, white, and black colours. The lynx is an inhabitant of Muscovy, Poland, Canada, &c. His eyes are brilliant, his aspect is soft, and his air is gay and sprightly; like the cat, he covers his urine with earth; he howls something like the wolf, and is heard at a considerable distance; he does not run like the dog or wolf, but walks and leaps like a cat; he pursues his prey even to the tops of trees; neither wild-cats nor squirrels can escape him; he lies in wait for flags, goats, hares, &c. and darts suddenly upon them; he seizes them by the throat and sucks their blood, then opens the head and eats the brain; after this, he frequently leaves them and goes in quest of fresh prey; the colour of his skin changes according to the season or the climate; the winter furs are more beautiful than those of summer.

7. The Cat, is a well-known domestic animal, and therefore requires no particular description. The wild-cat, the cat of Angora, &c. differ only in the length of their hair, and some small varieties arising from climate and their manner of living.

Of all domestic animals, the character of the cat is the most equivocal and fupicious. He is kept, not for any amiable qualities, but purely with a view to banish rats, mice, and other noxious animals from our houses, granaries, &c. Although cats, when young, are playful and gay, they possess at the same time an innate malice and perverse disposition, which increaseth as they grow up, and which education learns them to conceal, but never to subdue. Constantly bent upon theft and rapine, though in a domestic state, they are full of cunning and dissimulation; they conceal all their designs; seize every opportunity of doing mischief, and then fly from punishment. They easily take on the habits of society, but never its manners; for they have only the appearance of friendship and attachment. This disingenuiness of character is betrayed by the obliquity of their movements, and the ambiguity of their looks. In a word, the cat is totally delusive of friendship; he thinks and acts for himself alone. He loves ease, searches for the softest and warmest places to repose himself. The cat is likewise extremely amorous; and, which is very singular, the female is more ardent than the male; she not only invites, but searches after and calls upon him to satisfy the fury of her desires; and, if the male disdains or flies from her, she pursues, bites, and in a manner compels him. This heat of passion in females lasts but nine or ten days, and happens twice in the year, namely in the spring and autumn; however, in some it happens three or four times in the year. The female goes with young 55 or 56 days, and generally produces four or five at a litter. As the male has an inclination to destroy the young, the female takes care to conceal them from him; and, when she is apprehensive of a discovery, she takes them up in her mouth one by one, and hides them in holes or inaccessible places. When she has nursed a few weeks, she brings them mice, small birds, &c. in order to learn them to eat flesh. But, it is worth notice, that these careful and tender mothers sometimes become unnaturally cruel, and devour their own offspring.

The cat is incapable of restraint, and consequently of being educated to any extent. However, we are told, that the Greeks in the island of Cyprus trained this animal to catch and devour serpents, with which that island was greatly infested. This however was not the effect of obedience, but of a general taste for slaughter; for he delights in watching, attacking, and devouring all kinds of weak animals indiscriminately. He has no delicacy of scent, like the dog; he hunts only by the eye: neither does he properly pursue; he only lies in wait, and attacks animals by surprize: and after he has caught them, he sports with and tormenteth them a long time, and at last kills them (when his belly is full) purely to gratify his sanguinary appetite.

The eye of the cat differs greatly from that of most other animals. The pupil is capable of a great degree of contraction and dilatation; it is narrow and contracted like a line during the day, round and wide in the dark; it is from this conformation of the eye that the cat sees at night, which gives him a great advantage in discovering and seizing his prey.

Although cats live in our houses, they can hardly be called domestic animals; they may rather be said to enjoy full liberty; for they never act but according to their own inclination. Besides, the greatest part of them are half wild; they do not know their masters, and frequent only the barns, out-houses, &c. unless when pressed with hunger.

Cats have a natural antipathy at water, cold, and bad smells. They love to bask in the sun, and lie in warm places. They likewise have a affection for certain aromatic smells; they are transported with the root of the valerian.

Cats take about eighteen months before they come to their full growth; but they are capable of propagation in twelve months, and retain this faculty all their life, which generally extends to nine or ten years. They eat chiefly, and are peculiarly fond of fishes. They drink frequently; their sleep is light; and they often assume the appearance of sleeping, when in reality they are meditating mischief. They walk softly, and without making any noise. As their hair is always dry, it easily gives out an electrical fire, which becomes visible when rubbed across in the dark. Their eyes likewise sparkle in the dark like diamonds.

The wild, or savage cat, couples with the domestic one, and is consequently the same species. It is not unusual for domestic cats, both male and female, when stimulated by love, to repair to the woods in quest of these savage
The feminine gender serves to intimate that the noun feminine, a place overflowed with water, or abounding with water. In grammar, one of the genders of nouns. Female, a term peculiar to animals, signifying that which conceives and generates its young within itself.

FELT, in commerce, a sort of stuff deriving all its character, that its helm may be applied either in the head or to the sword. Felt is made either of wool alone, or of wool and hair. Thole of French make, 32 yards long, and 14 broad, for cloaks, pay each 21. 14s. 1d. on importation; and draw back 11. 12s. 3d. on exporting them again.

FELTIRE, a town of Italy, subject to Venice, thirty-five miles south-east of Constance.

FELLOWSHIP, or Company, in arithmetic. See Arithmetic. p. 386.

FELICE, in Roman antiquity, holidays, or days upon which the Romans had two kinds of feriae: 1. Stativa; feriae, which were only kept by some private families. 2. The public, which were only kept by some public families. The public feriae were fourfold: 1. Stativa feriae, or feriae, which confisted in making presents at their graves, mar-riages were forbidden, and the temples of the divinities shut up; because they fancied that, during this festival, the ghosts suffered no pains in hell, but were permitted to wander about their graves, and feast upon the meats prepared for them.

FERDE, moulin, milrinde, ink de vtoulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

FERDÉN, or Verden, a city of Germany, subject to Hanover: it is situated in lower Saxony, on the river Aller, twenty-six miles south-east of Bremen: E. lon. 6°, and N. lat. 53° 24'.

FÉREN, or FÉRENTARII, in Roman antiquity, were auxiliary troops, lightly armed; their weapons being a sword, bow, arrows, and a sling.

FÉRETINO, a city and bishop's see of Italy, about fifty miles east of Rome: E. lon. 14° 5', and N. lat. 41° 45'.

FÉRETINO, or Fer de sois, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

FERDE, moulin, milrinde, ink de vtoulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

FERDE, moulin, milrinde, ink de vtoulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

FERDE, moulin, milrinde, ink de vtoulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

FERDE, moulin, milrinde, ink de vtoulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone. See Plate LXXX. fig. 4.

the month, and were marked in the calendar; of
these the chief were the agonalia, carmentalia, and
lupercalia. 2. Concepitae feriae, holidays appointed
every year upon certain or uncertain days by the
magistrates or the pontiff; such were the latinae, paga-
nalia, compitalia, &c. See Paganalia, &c. 3. Imperial
feriae, holidays commanded or appointed by the
authority of the consuls or praetors; of this kind
we may reckon the lectionernium. See Lectisterni-
num. 4. Nundinae, the days for fairs. See Nun-
dine.

Feriae Latinae were instituted by Tarquinus Superbus,
who having overcome the Tuscans, made a league with
the Latins, and proposed to them to build a temple in
common to Jupiter Latialis, in which both nations
might meet, and offer sacrifice for their common safety.
At this festival a white bull was sacrificed; and each
town, both of the Latins and Romans, provided a
certain quantity of meat, wine, and fruits. At first
the solemnity continued but one day; after the expul-
sion of the kings, the senate added a third, a fourth,
and so on to ten days.

Feria, in the Romish breviary, is applied to the seve-
rnal days of the week; thus Monday is the feria secun-
da, Tuesday the feria tercia; though these days are
not working days, but holidays. The occasion of this
was, that the first Christians were used to keep the
caller week holy, calling Sunday the prima feria, &c.
whence the term feria was given to the days of every
week. But besides these, they have extraordinary fe-
rie, viz. the three last days of passion-week, the two
following easter day, and the second feriae of roga-
tion.

Fermanach, a county of Ireland, in the province of
Ulter, the chief town of which is Innilkilling.

Fermount, any body which, being applied to another,
produces fermentation.

Fermentés are either matters already in the act
of fermentation, or that soon run into this act. Of
the first kind are the flowers of wine, yeal! fermenting
beer, or fermenting wine, &c. and of the second are
the new expressed vegetable juices of hummer-fruit.

Among distillers, ferments are all those bodies which,
when added to the liquor, only correct some fault
therein, and, by removing some obstacle to fermenta-
tion, forward it by secondary means; as also such as,
being added in time of fermentation, make the liquor
yield a larger proportion of spirit, and give it a finer
flavour.

Fermentation, may be defined a sensible internal
motion of the constituent particles of a moift, fluid,mixt or compound body; by the continuance of which
motion, these particles are gradually removed from
their former situation or combination, and again, after
some visible separation is made, joined together in a
different order and arrangement. See Chemistry.

FERMO, a port-town of Italy, situated on the gulf of
Venice, about thirty miles south of Ancona. It is an
archbishop's see.
FESSE, in heraldry, one of the nine honourable ordinar- 
ies, consisting of a line drawn directly across the 
shield, from side to side, and containing the third part 
of it, between the honour-point and the nombril. 
It represents a broad girdle or belt of honour, which 
knaves at arms were anciently girded with. See Plate LXXX. fig. 5. 
FESSE-POINT, is the exact centre of the escutcheon. 
See Point.

FESSE-WAYS, or in fesse, denotes any thing borne af- 
ter the manner of a fesse; as is, in a rank across the 
middle of the shield. 
Party per fesse, implies a parting across the middle of 
the shield, from side to side, through the fesse point.

FESTI DIES, in Roman antiquity, certain days in the 
year, devoted to the honour of the gods. 
Numa, when he distributed the year into twelve 
months, divided the fame into the dies fessi, dies pro- 
fessi, and dies intercessi.

The fesse were again divided into days of sacrifices, 
bansquets, games, and feria. See Sacrifices, Eu- 
ple, Ludi, and Feriae.

The professi were those days allowed to men for the 
administration of their affairs, whether of a public or 
private nature: these were divided into鲑物, comitia 
les, comperendini, flati, and privatienses. See Fasti,
Comitiales, &c.

The intercessi were days common both to gods and 
men, some parts of which were allotted to the service 
of the one, and some to that of the other.

FESTINO, in logic, the third mood of the second fi- 
gure of the syllogism, the first proposition whereof is 
an universal negative, the second a particular affirma- 
tive, and the third a particular negative: as in the 
following example:

| FES | No bad man can be happy, |
| NO | Ego, some rich men are not happy.

FESTIVAL, the same with feast. See Feast.

FESTOON, in architecture and sculpture, &c, an or- 
nament in form of a garland of flowers, fruits and 
leaves, intermixed or twilled together.

FESTUCA, in botany, a genus of grasses, belonging to 
the triandria digynia class. The calix has two valves; 
and the epica is oblong and cylindrical. There are sixteen 
fpecies, eleven of which are natives of Britain, viz. the 
ovina, or sheep's fescue-grass; the rubiculca, or hard 
sescue-gras; the rubra, or purple fescue-grass; the bro- 
moides, or barren fescue-grass; the myuros, or wall fescue- 
gras; the pratenitis, or meadow fescue-grass; the elatior, 
or tall fescue-grass; the decumbens, or small fescue-grass; 
the fluitans, or flat fescue-grass; the loliacea, or spiked 
sescue-gras; and the sylvatica, or wood fescue-grass.

FETIPOUR, a city of the hither India, twenty-five 
miles west of Agra: E. long. 78° 40', N. lat. 27°.

FETLOCK, in the menage, a tuft of hair growing be- 
hind the pattern joint of many horses; for those of a 
low size have scarce any such tuft.

FEUD, the same with fee. See Fee.

FEUDAL, or FEODAL, denotes any thing belonging to 
a feet. See Fee.

Vol. II. No. 51.
FIELD, in fortification, are those thrown up by
Field-staff, a weapon carried by the gunners, about
Field-pieces, small cannons, from three to twelve
Field-officers, in the art of war. See Trustee.
FIELD-COLOURS, in war, are small flags of about a foot
FIELD-FARE, in ornithology. See Turdus.
FIELD, in agriculture, a piece of ground inclosed,
FIELD, in heraldry, is the whole surface of the
FIELD, in geography, a county of Scotland bounded by
FIDEI COMMISSUM, in Roman antiquity, an estate left
Field, or Fee. See Fee.
FIELD BOOK, in surveying, that wherein the angles,
FIELD-COLOURS, in war, are small flags of about a foot
Field-staffs are said to be armed.
FILE, among mechanics, a tool used in metal, &c. in
FILE in the art of war, a row of soldiers, standing one
FILE, in geography, a county of Scotland bounded by
FILBERT, or Filberd, the fruit of the Corylus, or hazel.
FILE, in music, one of the harmonical intervals or
FIG, or Fig-tree. See Ficus.
FIFF, or fig-tree. See Ficus.
FIGWORT, a plant called by the botanists Scrophularia.
Field works, in fortification, are those thrown up by
FILED HAMMER, one whole handle is a fidd, or made taper-
FIELD, or Fee. See Fee.
FIELD, in agriculture, a piece of ground inclosed,
FIELD, in heraldry, is the whole surface of the

FIGURE, in painting and designing, denotes the lines and colours which form the representation of any animal, but more particularly of a human personage.
or squadron. The files of a battalion of foot are generally three deep; as are sometimes those of a squadron of horse. The files must be straight, and parallel one to another.

FILIGRANE, or Filigree-work, any piece of gold or silver-work that is curiously done with grains or drops on the surfaces or threads.

FILIPENDULA, in botany. See Spiraea.

FILIX, in botany, an order of the cryptogamia class of plants. See Botany, p. 636.

FILLET, in anatomy. See Froenum.

FILLET, or Filet, in architecture, a little square member, ornament, or moulding, used in divers places, and upon divers occasions, but generally as a crowning over a greater moulding.

FILLET, in heraldry, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common bordure. It is supposed to be withdrawn inwards, and is of a different colour from the field. It runs quite round, near the edge, as a lace over a cloak.

FILLET, in the menage, the loins of an horse, which begin at the place where the hinder part of the saddle rests.

FILLER horse, one yoked immediately to a cart.

FILLY, a term among horse-dealers, to denote the female or mare-colt.

FILM, a thin skin or pellicle. In plants, it is used for that thin, woody skin, which separates the seeds from the pods, and keeps them apart.

FILTER, or Filtre, in chemistry, a strainer composed of fibrous or filtering paper in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid.

FIMBRIÆ, denotes appendages disposed by way of fringe round the border of any thing.

FIMBRIATED, in heraldry, an ordinary with a narrow bordure or hem of another tincture.

FIN, in natural history, a well-known part of fifties, consisting of a membrane supported by rays, or little bony or cartilaginous offices.

FINALS, in general, whatever terminates or concludes a thing.

FINAL LETTERS, among Hebrew grammarians, five letters so called, because they have a different figure at the end of words from what they have in any other situation.

FINAL, in geography, a port town of Italy, to Genoa, and situated on the Mediterranean, about thirty-seven miles south-west of that city.

FINANCES, in the French polity, signify the revenues of the king and state.

FINCH-KIND, in ornithology, an appellation given to a genus of birds, known among authors by the names of fringilla. See Fringilla.

FINE, in law, has divers significations, it being sometimes taken for a sum of money advanced and paid for the income of lands. It is likewise used in another sense, where a sum is paid as an amends, or by way of punishment for an offence committed.

FINERS of gold and silver, are those who separate these metals from coarser ores. See Refiners.

FINERY, in the iron works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar.

FINGERS; in anatomy, the extreme part of the hand divided into five members. See Anatomy, part I. and II.

FINISTERRA, the most westerly cape or promontory of Spain, in 16° 15' W. long, and 43° N. lat. This cape is likewise the most westerly part of the continent of Europe.

FINITE, something bounded or limited, in contradistinction to infinite. See INFINITE.

FINLAND, a province of Sweden, lying northward of the gulph of Finland, and southward of the Bohinick gulph. It is a frontier province, bounded by Russia on the east.

FIR-TREE, in botany. See Pines.

FIRE, a general name, by which men seem to understand a certain sensation or complex notion of light, heat, burning, melting, &c.

The power of fire is so great, its effects so extensive, and the manner of its acting so wonderful, that some of the wisest nations of old revered and worshipped it, as the supreme deity. Some of the chemists also, after they had discovered its surprising operations, suspected it to be an uncreated being; and indeed the most famous of them have acknowledged it as the source of all their knowledge; and hence have professed themselves philosophers by fire, nor thought they could be honoured with a nobler title. Now, amongst all the wonderful properties of fire, there is none more extraordinary than this, that though it is the principal cause of almost all the sensible effects that continually fall under our observation, yet it is itself of so infinitely a subtle nature, that it eludes the most sagacious enquiries, nor ever comes within the cognizance of our senses. Fire is generally divided into three kinds or species, viz. celestial, terraneous, and culinary.

By celestial fire is principally understood that of the sun, without regard to that of the fixed stars, though this perhaps may be of the same nature.

By terraneous fire we understand that which manifests itself in fiery eruptions of the earth, volcanoes, or burning mountains; or by any other effects it produces in mines, or the more central parts of the earth.

By culinary fire we mean that employed in all chemical operations, and the common occasions of life.

The sun's heat appears to be the alluring principle, by which fire is produced in all the above instances. Fire, considered in itself, seems to exist in the greatest purity and perfection in the celestial regions; at least we are insensible of any considerable smoke it yields:
yields: for the rays of light come to us from the sun, 
as mixed with any of that gross, fubtle, or terrestrial 
matter, found in culinary and subterranean fires; but, 
allowing for this difference, the effects of the fo-
lar fire appear the fame as thofe of culinary fire.

If we to examine the effects of subterraneous fires, 
we shall find them the fame with thofe produced 
by culinary fire. Thus, burnt coals, cinders, and 
melted minerals, are thrown up by Vesuvius and other 
burning mountains. Warm nephritic exhalations, 
natural hot fprings, fteams, vapours, fmoke, &c. are 
found in several parts of the globe, rising nearly in 
the fame manner as if they were produced by the heat 
of a furnace. Whence it appears, that subterraneous 
fires are of the fame nature with the culinary.

As men generally affix to the word fire, a complex 
idea of burning, light, heat, melting, &c. this idea 
should be analyfed, in order to fee what parts are ef-
cential, and what precarious or arbitrary.

We frequently find the effects of fire produced 
where no visible fire appeared. Thus the fingers are 
easily burnt by an iron heated below the degree of 
ignition, or fo as to be no ways visibly red-hot or fiery: 
whence it follows, that the eye is no judge of fire.

So likewise the touch gives no positive notice of 
any degree of fire below the natural heat of the body, 
or any fo great as to destroy the organ.

Again, the effects of fire are often produced without 
any manifest figns of burning, melting, &c. as in e-
vaporations, &c. If this method of exclusion and re-
jection were purified to its due length, we should 
perhaps find no criterion, infallible mark, or charac-
teriftic of fire in general, but that of a particular mo-
tion struggling among the minute parts of bodies, and 
tending to throw them off at the surface. If this 
should prove the cafe, then fuch a motion will be the 
form and effence of fire; and which, being prefent, 
makes fire alfo prefent: and, when abfent, makes fire 
alfo abfent: whence to produce fire, and produce this 
motion in bodies, will be one and the fame thing.

The great and fundamental difference in refpect 
to the nature of fire is, whether it be originally fuch, 
formed thus by the Creator himfelf at the beginning 
of things; or whether it be mechanically producible 
from other bodies, by inducing fome alterations in the 
particles thereof. The former opinion is maintained 
by Homberg, Boethaave, the younger Lemery, and 
s’Gravefande; the latter is chiefly supported by the 
English philofophers, lord Bacon, Mr Boyle, and Sir 
Ifaac Newton.

Bacon, in the treatife De Forma Calicli, deduces, 
from a great number of particulars, that heat in bodies 
is no other than motion fo and fo circumfanced; fo 
that to produce heat in a body, nothing is required but 
to excite a certain motion in the parts thereof.

Boyle fects him in an exprès treatife of the me-
chanical origin of heat and cold, and maintains the 
same doctrine with new observations and experiments; 
as a fpecimen of which, we fhall hear give the two 
following.

1. In the production of heat, fays that able philofo-
pher, there appears nothing on the part either of the 
agent or patient, but motion and its natural effects. When 
a smith briskly hammers a piece of iron, the metal 
thereby becomes exceedingly hot; yet there is nothing 
to make it fo, except the forcible motion of the ham-
mer imprefling a vehement and variously determined 
agitation on the small parts of the iron, which, being 
a cold body before, grows, by that fuper-induced 
commotion of its small parts, hot: firft, in a more 
loofe acceptance of the word, with regard to fome o-
 ther bodies, compared with which it was cold before; 
then fensibly hot, because this agitation furpafles that 
of the points of our fingers; and in this infinace ofen-
times the hammer and anvil continue cold after the 
operation; which fhews, that the heat acquired by the 
iron was not communicated by either of thofe imple-
ments, as heat; but produced in it by a motion, great 
 enough strongly to agitate the parts of so small a body 
as the piece of iron, without being able to have the 
like effect upon fo much greater mafles of metal as the 
hammer and the anvil: though if the percufions were 
often and briskly renewed, and the hammer were small, 
this alfo might be heated: whence it is not necefsary 
that a body itself be hot to give heat.

2. If a large nail be driven by a hammer into a plank 
of wood, it will receive feverall frokes on its head 
before it grows hot; but when it is once driven to the 
head, a few frokes fuffice to give it a coniderable 
heat; for while, at every blow of the hammer, the 
nail enters further into the wood, the motion produced 
is chiefly progressive, and is of the whole nail tending 
one way; but when that motion ceaftes, the impulfe 
given by the froke being unable to drive the nail fur-
ther on, or break it, muft be fpent in making a vari-
ous, vehement, and infenfible commotion of the parts 
among themselves, wherein the nature of heat confifts.

Agreeable to this is the opinion of Sir Ifaac New-
ton, who conceives that gros bodies may be converted 
into light, by the agitation of their particles; and light, 
again, into gros bodies, by being fixed therein.

On the other hand, M. Homberg, in his Effai da 
Souffre Principe, holds, that the chemical principle, 
or element sulphur, which is fuppofed one of the fimple, 
primary, pre-existent ingredients of all natural bodies, 
is real fire, and confequently that fire is coeval with 
bodies.

Dr s’Gravefande goes on much the fame principle:
fire, according to him, enters the compofition of all 
bodies, is contained in all bodies, and may be separ-
ated or procured from all bodies, by rubbing them 
against each other; and thus putting their fire in motion: 
but fire, he adds, is by no means generated by fuch 
motion.

Mr Lemery, the younger, agrees with thefe two 
authors in afferting this abfolute and ingenerable 
nature of fire: but he extends it farther. Not content-
ed to confine it as an element to bodies, he endeavours 
to fhew, that it is equally diffufed through all fpace, 
and that it is prefent in all places; in the void fpaces 
between bodies, as well as in the infenfible interflices 
between their parts.

This
This last sentiment falls in with that of Boerhaave and the celebrated M. Muffchenboeck. But notwithstanding what those able philosophers have advanced, it is evident that fire, heat, flame, &c. are only the different modifications of the particles of light, and that the particles of light themselves depend entirely on velocity for their lucid quality; hence, by many experiments, we know, that the particles of bodies become lucid, or particles of light, by only producing in them a requisite degree of velocity: thus the particles in a rod of iron, being hampered very nimbly, shine and become red-hot: thus also the violent stroke of the flint against the steel, in striking fire, puts the particles of the steel, which it takes off, into such a motion as causes them to melt, and become red-hot, which makes the sparks of fire produced by each stroke: as, therefore, fire confinits in the great velocity of the particles, so it may be communicated from one body in which it is, to another in which it is not, after the same manner that one body in motion will communicate motion to another that has got none.

Fire differs from heat only in this, that heat is a motion in the particles of a body, with a lesser degree of velocity; and fire, a motion with a greater degree of velocity, viz. such is sufficient to make the particles shine; though we often call such a flame as will burn, fire, though it does not actually shine; and we seldom call those lucid bodies fires, which only shine, and do not burn. These are a sort of phosphiors, which, though they have no heat, yet seem to owe their lucidity to the motion of their parts.

There seems to be no other difference between fire and flame, than this; that fire consists in a glowing degree of velocity in the parts of a body, while yet suffusing together in the mass; but flame is the same degree of velocity in the particles dissipated and flying off in vapours: or, to use Sir Isaac Newton's expression, flame is nothing else but a red-hot vapour. See Flame.

Fire, in chemistry. See Chemistry, p. 67, and 110.

Vol. II.

Electrical fire. See Electricity.

Walking fire, in meteorology. See Will-with-a whip.

Fire, in theology. See Hell.

We read of the sacred fire in the first temple of Jerusalem, concerning which the Jews have a tradition that it came down from heaven: it was kept with the utmost care, and it was forbidden to carry any strange fire into the temple. This fire is one of the five things which the Jews confinits were wanting in the second temple.

The Pagans had their sacred fires, which they kept in their temples with the most religious care, and which were never to be extinguished. Numa was the first who built a temple to Fire as a goddess, at Rome, and instituted an order of priestesses for the preservation of it. See Vestals.

Fire was the supreme god of the Chaldeans; the magi were worshippers of fire; and the Greeks and Armenians still keep up a ceremony called the Holy Fire, upon a persuasion that every Easter day a miraculous fire descends from heaven into the holy sepulchre, and kindles all the lamps and candles there.

Fire-lock. See Gun, Musquet, &c.

Fire pots, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered; then the pot is covered with a piece of parchment, and two pieces of match across lighted; this pot being thrown by a handle of matches where it is designed, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, to the end its operations may be the quicker.

Fire-works. See Pyrotechnia.

Fire ship, in the navy, a vessel charged with artificial fire-works, which having the wind of an enemy's ship, grapples her, and sets her on fire.

Fire-office, an office of insurance from fire. See Assurance.

Wild-fire, a kind of artificial or fictitious fire, which burns even under water, and that with greater violence than out of it. It is composed of sulphur, naphtha, pitch, gum, and bitumen; and is only extinguisable by vinegar mixed with sand and urine, or by covering it with raw hides. Its motion or tendency is said to be contrary to that of natural fire, and it always follows the direction in which it is thrown, whether it be downwards, sidways, or otherwise.

Firing-iron, in farriery, an instrument not unlike the blade of a knife; which being made red-hot, is applied to a horse's hams, or other places standing in need of it, as in pretreterrestrial dwellings, farcy, knots, &c. in order to cuttis them.

Firkin, an English measure of capacity, for things liquid, being the fourth part of the barrel: it contains 8 gallons of ale, soap, or herrings; and 9 gallons of beer. See Measure and Barrel.

Firlot, a dry measure used in Scotland. The oat-firlot contains 21/3 pints of that country; the barley-firlot contains about 22/11 cubical inches; and the barley-firlot, 31 standard pints. Hence it appears that the Scotch wheat-firlot exceeds the English bushel by 23 cubical inches.

Firmament. In the Ptolemaic astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions: a diurnal motion, given to it by the planets which it surrounds; and another opposite motion from west to east, about the poles of the ecliptic; and another opposite motion from east to west; which last it finishes, according to Tycho, in 25,412 years, according to Ptolemy in 3600, and according to Copernicus in 25,800, in which time the fixed stars return to the same points in which they were at the beginning. This period is commonly called the Platonic year, or the great year.

Firmament is also used in divers places of scripture, to denote the middle region of the air.

Firman is a passport or permit granted by the great mogul to foreign vessels, to trade within the territories of his jurisdiction.

Firmness, denotes the confidence of a body, or that state
Fish, in natural history. See Natural History.

Fish, in a ship, a plank or piece of timber, fastened to the part of the ground, that the trench of the flood-gate or sluice, having a good fall, may not be too long in emptying. The best way of making the head secure, is to drive in two or three rows of flakes above six feet long, at about four feet distance from each other, the whole length of the pond-head, whereof the first row should be rammed at least about four feet deep. If the bottom is false, the foundation may be laid with quicklime; which flacking, will make it as hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and strakes; and when these are well covered, drive in others as they see occasion, ramming in the earth as before, till the pond-head be of the height designed.

The dam should be made flapping on each side, leaving a waite to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed five feet, rising gradually in thoulds towards the sides, for the fish to run themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a half with a white fat water, as the washings of hills, commons, fircets, finks, &c., be best for fattening all sorts of fish. For storing a pond, carp is to be preferred for its goodnefs, quick growth, and great increase, as breeding five or six times a-year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds that have marl or clay bottoms, with plenty of weeds and grass, whereon they feed in hot months.

Your pond should be drained every three or four years, and your fish forsted. If it is a breeding one, the smaller ones are to be taken out, to fole other ponds with; leaving a good flock of females, at least eight or nine years old, as they never breed before that age. In feeding ponds, it is best to keep them pretty near of a size.

Fishery, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring, mackrel, pilchards, &c. are along the coasts of Scotland, England, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West-Indies.

Fishery denotes also the commerce of fish, more particularly the catching them for sale.

Were we to enter into a very minute and particular consideration of fisheries, as at present established in this kingdom, this article would swell beyond its proper bounds; because to do justice to a subject of that concernment to the British nation, requires a very ample and distinct disquisition. We shall, however, observe, that since the Divine Providence has so eminently favoured the coasts of Great Britain and Ireland with the most valuable fish; and since fisheries, if successful, become permanent nurseries for breeding expert fishermen: it is not only a duty we owe to the Supreme Being, not to despise the wonderful plenty he hath afforded us, by neglecting to extend this branch of commerce to the utmost; but it is a duty we owe to our country, for its natural security, which depends upon the strength of our royal navy. No nation can have a navy, where
there is not a fund of business to breed and employ seamen, without any expense to the public; and no trade is so well calculated for training up these useful members of this society, as fisheries.

The situation of the British coasts is the most advantageous for catching fish in the world; the Scottish islands, particularly those to the north and west, lie most commodious for carrying on the fishing trade to perfection; for no country in Europe can pretend to come up to Scotland in the abundance of the finest fish, with which its various creeks, bays, rivers, lakes, and coasts are replenished. King Charles I. was so sensible of the great advantage to be derived from fisheries, that he began the experiment, together with a company of merchants; but the civil wars soon occasioned that project to be set aside. King Charles II. made a like attempt; but his pressing wants made him withdraw what money he had employed that way, whereupon the merchants that joined with him did so too. Since the union, several attempts have been made to retrieve the fisheries, and a corporation settled to that effect, entitled the Royal British Fishery.

In the year 1750, the parliament of Great Britain taking the state of the fisheries into consideration, an act was passed for the encouragement of the white-herring fishery, granting a charter, whereby a corporation is created, to continue twenty one years, by the name of the Society of the Free British Fishery, to be under the direction of a governor, president, vice-president, council, &c. who are to continue in office the space of three years, with power to make bye-laws, &c. and to raise a capital of 500,000l. by way of subscription. And any number of persons, who, in any part of Great Britain, shall subscribe 10,000l. into the flock of this society, under the name of the Fishing Chamber, and carry on the said fishery on their own account of profit and loss, shall be entitled to the same bounty allowed to the society. The bounty is 30s. the tun, to be paid yearly, for fourteen years, besides 3 per cent. for the money advanced by each chamber. The act contains other proper regulations relative to the nets, marks on the herring-barrels, number of hands, and the quantity of salt that is entitled to the bounty, &c. It is then by the encouragement given by this act, that we now see a laudable emulation prevailing all over the two kingdoms, and fishing buffets fitted out from almost every port, in order to repair to the Shetland islands, where the herring fishery is carried on with an ardor becoming so important a branch of trade. Scotland, which suffered incredibly from the neglect of this valuable and natural produce of the seas, has not been backward to join in a scheme that tends so evidently to its own advantage; for the cities of Edinburgh and Glasgow, the towns of Montrose, Dundee, Perth, Inverness, and some other boroughs, have raised the proper sum, and chambers have been erected in each of them; the gentlemen of estates adjoining to the respective places above-mentioned, liberally contributing with merchants, towards the prosecution of an undertaking so visibly tending to the good of their country in general.

**Cod-Fishery.** There are two kinds of cod-fish, the one green or white cod, and the other dried or cured cod; though it is all the same fish differently prepared; the former being sometimes salted and barrelled, then taken out for use; and the latter, having lain some competent time in salt, dried in the sun or smoke. We shall therefore speak of each of these apart; and first of **Green-cod Fishery.** The chief fisheries for green cod are in the bay of Canada, on the great bank of Newfoundland, and on the island of St Peter, and the island of Sable, to which places vessels resort from divers parts both of Europe and America. They are from 100 to 150 tons burden, and will catch between thirty and forty thousand cod each. The most essential part of the fishery is, to have a master who knows how to cut up the cod, one who is skilled to take off the head properly, and above all a good falter, on which the preference of them, and consequently the success of the voyage, depends. The best season is from the beginning of February to the end of April; the fish, which in the winter retire to the deepest water, coming then on the banks, and fattening extremely. What is caught from March to June keeps well; but those taken in July, August, and September, when it is warm on the banks, are apt to spoil soon. Every fisher takes but one at a time: the most expert will take from 350 to 400 in a day; but that is the most, the weight of the fish and the great coldness on the bank-fatiguing very much. As soon as the cod are taken, the head is taken off; they are opened, gutted, and salted; and the falter flows them in the bottom of the hold, head to tail, in beds aathom or two square; laying layers of salt and fish alternately, but never mixing fish caught on different days. When they have lain thus three or four days to drain off the water, they are replaced in another part of the ship, and salted again; where they remain till the vessel is loaded. Sometimes they are cut in thick pieces, and put up in barrels for the convenience of carriage.

**Dry-cod Fishery.** The principal fishery for dry cod is, from Cape Rosco to the Bay des Exports, along the coast of Placentia, in which compas there are divers commodious ports for the fish to be dried in. These, though of the same kind with the fresh cod, are much smaller, and therefore fitter to keep, as the salt penetrates more easily into them. The fishery of both is much alike; only this latter is most expensive, as it takes up more time, and employs more hands, and yet scarce half so much salt is spent in this as in the other. The salt is herring, of which great quantities are taken on the coast of Placentia. When several vessels meet and intend to fish in the same port, he whose hawlop first touches ground, becomes entitled to the quality and privileges of admiral; he has the choice of his station, and the refusal of all the wood on the coast at his arrival. As falt as the masters arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts, and in the mean time the mates provide a tent on shore, covered with branches of trees, and sails over them, with a scaffold of great trunks of pines, twelve, fifteen, sixteen, and often
often twenty feet high, commonly from forty to sixty feet long, and about one third as much in breadth. While the scaffold is preparing, the crew are a fishing; and as fast as they catch, they bring their fish shore; open and salt them upon moveable benches; but the main salting is performed on the scaffold. When the fish have taken salt, they wash and hang them to drain on rails; when drained, they are laid on kinds of slates, which are small pieces of wood and a cross, and covered with branches of trees, having the leaves stripped off for the passage of the air. On these slates, they are disposed, a fish thick, head against tail, with the back uppermost, and are turned carefully four times every twenty four hours. When they begin to dry, they are laid in heaps ten or twelve thick, in order to retain their warmth; and every day the heaps are enlarged, till they become double their first bulk; then two heaps are joined together, which they turn every day as before; lastly, they are salted again, beginning with the first salted; and being laid in huge piles, they remain in that situation till they are carried on board the ships, where they are laid on the branches of trees disposed for that purpose, upon the ballast, and round the ship, with mats to prevent their contracting any moisture.

There are four kinds of commodities drawn from cod, viz. the round, the tongues, the roes, and the oil extracted from the liver. The first is salted at the fishery, together with the fish, and put in barrels from 6 to 700 pound. The tongues are done in like manner, and brought in barrels from 4 to 500 pounds. The roes are also salted in barrels, and serve to cast into the sea to draw fish together, and particularly pilchards. The oil comes in barrels, from 4 to 500 pounds, and is used in dressing leather.—In Scotland, they catch a small kind of cod on the coasts of Buchan, and all along the Murray frith on both sides; as also in the frith of Forth, Clyde, &c. which is much esteemed. They salt and dry them in the sun upon rocks, and sometimes in the chimney. They also cure krait, and other smaller fish in the same manner; but most of these are for home consumption.

Curing Salmon. When the salmon are taken, they open them along the back, take out the guts and gills, and cut out the greatest part of the bones, endeavouring to make the inside as smooth as possible; then salt the fish in large tubs for the purpose, where they lie a considerable time soaking in brine; and about October, they are packed close up in barrels, and sent to London, or exported up the Mediterranean. They have also in Scotland, a great deal of salmon salted in the common way, which after soaking in brine a competent time, is well pressed, and then dried in smoke: this is called kipper, and is chiefly made for home consumption, and, if properly cured and prepared, is reckoned very delicious.
Sturgeon-Fishery. The greatest sturgeon-fishery is in the mouth of the Volga, on the Caspian sea, where the Muscovites employ a great number of hands, and catch them in a kind of inclosure formed by huge flakes representing the letter Z, repeated several times. These fisheries are open on the side next the sea, and close on the other; by which means the fish ascending in its season up the river, is embarrassed in its narrow angular retreats, and so is easily killed with a harpining-iron. Sturgeons, when fresh, eat deliciously; and in order to make them keep, they are salted or pickled in large pieces, and put up in casks from thirty to fifty pounds. But the great object of this fishery is the roe, of which the Muscovites are extremely fond, and of which is made the caviar, or kavia, so much esteemed by the Italians. See Caviar.

Whale-Fishery. Whales are chiefly caught in the north sea: the largest sort are found about Greenland, or Spitzbergen. At the first discovery of this country, whales not being used to be disturbed, frequently came into the very bays, and were accordingly killed almost close to the shore, so that the blubber being cut off was immediately boiled into oil on the spot. The ships in these times took in nothing but the pure oil and the fins, and all the business was executed in the country, by which means a ship could bring home the produce of many more whales than she could according to the present method of conducting this trade. The fishery also was then so plentyful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the flotation of this country, by which means a ship could bring home the produce of many more whales than she can according to the present method of conducting this trade. The ships coming in such numbers from Holland, Denmark, Hamburg, and other northern countries, ill intruders upon the English, who were the first discoverers of Greenland, the whales were disturbed, and gradually, as other fishes often do, forsaking the place, were not to be killed so near the shore as before; but are now found, and have been so ever since, in the openings and space among the ice, where they have deep water; and where they go sometimes a great many leagues from the shore.

The whale fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away, and get clear of the ice, by the end of August; so that in that month of September at farthest, they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows. As soon as the fishermen hear the whale blow, they cry out, Fall! fall! and every ship gets out its long boat, in each of which there are six or seven men: they row till they come pretty near the whale, then the harpooner strikes it with his harpoon. This requires great dexterity; for through the bone of his head there is no striking, but near his spout there is a soft piece of flesh, into which the iron sinks with ease. As soon as he is struck, they take care to give him rope enough, otherwise, when he goes down, as he frequently does, he would inevitably sink the boat: this rope he draws with such violence, that, if it were not well watered, it would, by its friction against the sides of the boat, be soon set on fire. The line fastened to the harpoon is six or seven fathom long, and is called the fore-runner; it is made of the finest and softest hemp, that it may slip the easier: to this they join a heap of lines of 60 or 100 fathoms each: and when there are not enough in one long boat, they borrow from another. The man at the helm observes which way the rope goes, and steers the boat accordingly, that it may run exactly out before; for the whale runs away with the line with so much rapidity, that he would overheat the boat, if it were not kept thatreight. When the whale is struck, the other long boats row before, and obverse which way the line hangs, and sometimes pull it; if they feel it stiff, it is a sign the whale still pulls in strength; but if it hangs loose, and the boat lies equally high before and behind upon the water, they pull it in gently, but take care to coil it so, that the whale may have it again easily if he recovers strength: they take care, however, not to give him too much line, because he sometimes entangles it about a rock, and pulls out the harpoon. The fat whales do not sink as soon as dead, but the lean one's do, and come up one days afterwards. As long as they see whales, they lose no time in cutting up what they have taken, but keep fishing for others: when they see no more, or have taken enough, they begin with taking off the fat and whilkers in the following manner. The whale being lashed along-side, they lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which, together with the fins, is struck off as soon as he is taken, to keep those extremities above water. On the off-side of the whale are two boats, to receive the pieces of fat, utensils, and men, that might otherwise fall into the water on that side. These precautions being taken, three or four men with irons at their feet, to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick, and eight long, which are hauled up at the capstan or windlass. When the fat is all got off, they cut off the whilkers of the upper jaw with an ax. Before they cut, they are all lathed to keep them firm, which also facilitates the cutting, and prevents them from falling into the sea: when on board, five or six of them are bundled together, and properly flowed; and after all is got off, the carcasse is turned adrift, and devoured by the birds, who are very fond of it. In proportion as the large pieces of fat are cut off, the reel of the crew are employed in slicing them smaller, and picking out all the lean. When this is prepared, they flow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in tubs in the hold, cramming them very full and close. Nothing now remains but to sail homewards, where the fat is to be boiled and melted down into train oil. See Train Oil.

It was in vain to speak in this place of the advantages that may be derived to Great Britain from the whale-fishery. We shall only remark, that the legisla-
tice think that trade of so great importance, as to grant a very considerable bounty for the encouragement of it; for every British vessel of 200 tons or upwards, bound to the Greenland seas on the whale-fisheary, if found to be duly qualified according to the act, obtains a licence from the commissioners of the customs to proceed on such voyage; and on the ship’s return, the master and mate making oath that they proceeded on such voyage and no other, and used all their endeavours to take whales, &c. and that all the whale fins, blubber, oil, &c. imported in their ship, were taken by their crew in those seas, there shall be allowed 40s. for every ton according to the admeasurement of the ship.

Besides these fisheries, there are several others both on the coasts of Great Britain and in the North Seas, which, although not much the subject of merchandise, nevertheless employ great numbers both of ships and men; as, 1. The oyster-fishing at Colchester, Feversham, the Isle of Wight, in the Swales of the Medway, and in all the creeks between Southampton and Chichester, from whence they are carried to be fed in pots about Wevenhoe and other places. See Oyster. 2. The lobster-fishing all along the British Channel, the Frith of Edinburgh, on the coast of Northumberland, and on the coast of Norway, from whence great quantities are brought to London. And lastly, the fishing of the pot-fish, fin-fish, sea-unicorn, sea horse, and the seal, or dog-fish; all which are found in the same seas with the whales, and yield blubber in a certain degree; besides, the horn of the unicorn is as estimable as ivory, and the skins of the seals are particularly useful to trunkmakers.

**Trout Fishing.** The baits for this purpose are either natural or artificial, as earth, worms, minnows, and fishing flies, both natural and artificial. Whatever worms are used, they answer best if kept some time in an earthen pot, with moss often changed in summer. If you fish for trout with hand on the ground, the hook is to be introduced into the worm a little above the middle, coming out again a little below; then draw the worm above the arming of the hook, making your first entrance at the tail-end, that the point of the hook may come out at the head-end. When you fish with minnows, take the whitest and middle sized; and after putting the hook in at the mouth, and out at the gills, and drawing it through about three inches, flip it again into his mouth, so as the point and beard may come out at the tail. This done, tie the hook and tail together with a fine white thread, and let the body of the minnow be almost upright upon the hook.

**Fissure of the Bones, in surgery,** is when they are divided either transversely or longitudinally, not quite through, but cracked after the manner of glass, by any external force. See Surgery.

**Fistula,** in the ancient music, an instrument of the wind-kind, resembling our flute, or flageolet.

The principal wind-instruments of the ancients, were the tibia and fistula. But how they were constituted, wherein they differed, or how they were played on, does not appear.

**Fistula,** in medicine and surgery. See Medicine and Surgery.

**Fistula,** in farriery. See Farriery.

**Fistular,** or *Fistulous,* appellations given by surgeons to wounds and ulcers, which degenerate into fistulas.

**Fit,** in medicine. See Paroxysm.

**Fitche’s,** in heraldry, a term applied to a cross, which, although not much the subject of merchandize, is purely French, and signifies the king’s son.

**Five Churches,** a bishop’s see of Lower Hungary, 76 miles south of Buda.

**Fives, or Vives,** in farriery. See Farriery, p. 555.

**Fixation,** in chemistry, the rendering any volatile substance fixed, so as not to fly off upon being exposed to a great heat; hence, **Fixed Bodies** are those which bear a considerable degree of heat without evaporating, or losing any of their weight.

**Flaccidity,** among physiicians, a disorder of the solids, cured by astringent and cardiac medicines, joined with exercice and good air.

**Flag,** a general name for colours, standards, ancients, banners, ensigns, &c. The fashion of pointed or triangular flags, as now used, Rod. Toletan affures, came from the Mahometan Arabs, or Saracens, upon their seizure of Spain, before which time all the ensigns of war were stretched or extended on crofs pieces of wood, like the banners of a church. The pirates of Algiers, and throughout the coasts of Barbary, bear an hexonal flag. **Flag officer,** he who commands the several squadrons of a fleet, such as the admirals, vice-admirals, and rear-admirals.
The flag officers in our pay, are the admiral, vice-admiral, and rear-admiral of the white, red, and blue. See Admiral.

Flag-ship, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under the command thereof.

Flag-flower, in botany. See Iris.

Flag-flower, in botany. See Gladiolus.

Flag officers in our pay, are the admiral, vice-admiral, and rear-admiral of the white, red, and blue. See Admiral.

Flagship, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under the command thereof.

Flag-flower, in botany. See Iris. Flanders is a perfectly champaign country, with not a rising ground or hill in it, and watered with many fine rivers and canals. Its chief commodities are fine lace, linen, and tapestry.

The brighter in colour, and of the choice of lintfeed. Of the arrangement of the trees from growing to any perfection.

The method of laying it in handfuls across other: Of the arrangement of the trees from growing to any perfection.

If the ground be free and open, it should be but once ploughed, and that as shallow as possible, not deeper than 3/4 inches. It should be laid flat, reduced to a fine garden-mould by much harrowing, and all stones and lods should be carried off.

Except a little pigeon's dung for cold or four ground, no other dung should be used preparatory for lint, because it produces too many weeds, and throws up the lint thin and poor upon the flax.

Before sowing, the bulky clods should be broken, or carried off the ground; and lodes, quickenings, and every other thing that may hinder the growth of the flax, should be removed.

Of the choice of lintfeed. The brighter in colour, and heavier the feed is, so much the better: that which when bruised appears of a light or yellowish green, and fresh in the heart, oily and not dry, and smells and tastes sweet, and not sullen, may be depended upon.

Dutch feed of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than any other foreign feed. Philadelphia feed produces fine lint and few bolls, because fown thick, and answers best in wet cold soils. Riga feed produces coarser lint, and the greatest quantity of feed. Scots feed, when well winned and kept, and changed from one kind of soil to another, sometimes answers pretty well; but should be fown thick, as many of its grains are bad, and fail. It springs well, and its flax is sooner ripe than any other; but its produce afterwards is generally inferior to that from foreign feed.

A kind has been lately imported, called memmel- feed, which looks well, is short and plump, but seldom grows above eight inches, and on that account ought not to be sown.

Of sowing lintfeed. The quantity of lintfeed sown should be proportioned to the condition of the soil; for if the ground be in good heart, and the feed fown thick, the crop will be in danger of falling before it is ready for pulling. From eleven to twelve pecks Lin- lithgow measure of Dutch or Riga feed, is generally sufficient for one Scots acre; and about ten pecks of Philadelphia feed, which being the smallest grained, goes farthest. Riga lintfeed, and the next year's produce of it, is preferred in Lincolnshire.

The time for sowing lintfeed is from the middle of March to the end of April, as the ground and season answers; but the earlier the seed is sown, the less the crop interferes with the corn-harvest.

Late sown lintfeed may grow long, but the flax upon the flax will be thin and poor.

After sowing, the ground ought to be harrowed till the seed is well covered, and then (supposing the soil as before mentioned to be free and reduced to a fine mould) the ground ought to be rolled.

When a farmer sows a large quantity of lintfeed, he may find it proper to sow a part earlier and part later, that in the future operations of weeding, pulling, watering, and gristing, the work may be the easier and more conveniently gone about.

It ought always to be sown on a dry bed.

Of weeding flax. It ought to be weeded when the crop is about four inches long. If longer deferred, the weeds will so much break and crook the flax, that they will never perhaps recover their straightness again; and when the flax grows crooked, it is more liable to be hurt in the rippling and swinging.

Quickening-gras should not be taken up; for, being strongly rooted, the pulling of it always loosens a deal of the lint.

If there is an appearance of a settled drought, it is better to defer the weeding, than by that operation to expose the tender roots of the flax to the drought.

How soon the weeds are got out, they ought to be carried off the field, instead of being laid in the furrows, where they often take root again, and at any rate obstruct the growth of the flax in the furrows.

Of pulling flax. When the crop grows so short and branchy, as to appear more valuable for feed than flax, it ought not to be pulled before it be thoroughly ripe; but if it grows long and not branchy, the feed ought to be disregarded, and all the attention given to the flax.

In the last case it ought to be pulled after the bloom has fallen, when the flax begins to turn yellow, and before the leaves fall, and the bolls turn hard and sharp-pointed.

When the flax is small, and carries few bolls, the flax is fine; but the flax of coarse flax is coarse, rank, branchy, and carries many bolls.

When flax has fallen and lies, such as lies ought to be immediately pulled, whether it has grown enough or not, as otherwise it will rot altogether.

When parts of the same field grow unequally, so that some parts are ready for pulling before other parts; only what is ready should be pulled, and the rest should be suffered to stand till ready.

The flax-ruiser ought to be at pains to pull, and keep by itself, each different kind of lint which he finds in his field; what is both long and fine, by itself; what is both long and coarse, by itself; what is both short and fine, by itself; what is both short and coarse, by itself; and in like manner every other kind by itself that is of the same size and quality. If the different kinds be not thus kept separate, the flax must be much damaged in the watering, and the other succeeding operations.

What is commonly called under growth, may be neglected as useless.

Few persons that have seen flax pulled, are ignorant of the method of laying it in handfuls across other: which gives the flax sufficient air, and keeps the handfuls separate and ready for the rippler.

Of stacking up flax during the winter, and winning

300
The canal ought not to be under any shade; which, besides keeping the sun from softening the water, might make part of the canal cooler than other parts, and so water the flax unequally.

The flax-raiser will observe, when the water is brought to a proper heat, that small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising on the surface. If no such signs appear, the water must not be warm enough, or is otherwise unfit for flax.

Mofs-holes, when neither too deep nor too shallow, frequently answer well for watering flax, when the water is proper, as before described.

The proper season for watering flax is, from the end of July to the end of August.

The advantage of watering flax as soon as possible, after pulling, has been already mentioned.

The flax being forked after rippling, as before mentioned, should next be put in beets, never larger than a man can grasp with both his hands, and tied very flack, with a band of a few stalks. Dried rushes answer exceedingly well for binding flax, as they do not rot in the water, and may be dried and kept for use again.

The beets should be put into the canals slope-ways, or half flanding upon end, the root-end uppermost. Upon the crop-ends, when uppermost, there frequently breeds a deal of vermin, destructive of the flax, which is effectually prevented by putting the crop-end downward.

The whole flax in the canal ought to be carefully covered from the sun with divots; the grassy side of which should be next the flax, to keep it clean. If it is not thus covered, the sun will discolor the flax, though quite covered with water. If the divots are not weighty enough to keep the flax entirely under water, a few stones may be laid above them. But the flax should not be pressed to the bottom.

When the flax is sufficiently watered, it feelst soft to the grip, and the haste parts easily with the bow or flowl, which last is then become brittle, and looks whitish. When these signs are found, the flax should be taken out of the water, beet after beet; each gently rinsed out of the water, beet after beet; each gently rinsed out of the water, each gently rinsed.

When lint taken out of the canal is not found sufficiently watered, it may be laid in a heap, for twelve, eighteen, or twenty-four hours, which will have an effect like more watering; but this operation is nice, and may prove dangerous in unskilful hands.

After the flax is taken out of the canal, fresh lint should not be put a second time into it, until the former water be run off, and the canal cleaned, and supplied with fresh water.

Of grafting flax. Short heath is the best field for grafting flax, as, when wet, it softens to the heat, and is thereby prevented from being blown away by the wind. The heath also keeps it a little above the earth,
earth, and so exposes it the more equally to the weather. When such heath is not to be got, links, or clean old lea-ground is the next bed. Long grass-grounds should be avoided, as the grass growing thro' the lint frequently spots, tenders, or rots it; and grounds exposed to violent winds should also be avoided.

The flax, when taken out of the water, must be spread very thin upon the ground; and being then very tender, it must be gently handled. The thinner it is spread the better, as it is then the more equally exposed to the weather. But it ought never to be spread during a heavy shower, as that would wash and waste the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blister from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better.

If there be little danger of high winds carrying off the flax, it will be much the better of being turned about once a-week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp requires a deal of ground, and enriches it greatly.

The skilful flax-raiser spreads his first row of flax at the end of the field opposite to the point from whence the most violent wind commonly comes, placing the root-ends foremost; he makes the root ends of every other row overlap the crop-ends of the former row three or four inches, and binds down the last row with a rope; by which means the wind does not easily get below the lint to blow it away; and as the crop-ends are seldom so fully watered as the root-ends, the aforesaid overlapping has an effect like giving the crop-ends more watering. Experience only can fully teach a person the signs of flax being sufficiently graffed: then it is of a clearer colour than formerly; the harle is blistered up, and easily parts with the boon, which is then become very brittle. The whole should be sufficiently graffed before any of it is lifted; for if a part be lifted sooner than the rest, that which remains is in great danger from the winds.

A dry day ought to be taken for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grass, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be all equally watered and graffed, and as the different qualities will best appear at lifting the flax off the grass; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and quality.

The smaller the beets lint is made up in, the better for drying, and the more convenient for flacking, houfing, &c. and in making up these beets, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root-ends together, and the crop-ends together.

**Of keeping Flax after it is graffed.** Nothing needs be said here, but that if the flax is to be flacked, it should be set in an airy place, upon a dry foundation, such as poh middings, or the like, and well covered from the weather; and if houfed, the floor must be dry, and the houfe well aired, and water-tight.

*Follows an Estimate of the Expence, Produce, and Profit of a Scots acre of Flax,—supposing the season favourable, that no accidental losses happen, and that the farmer is neither unskilful nor negligent.*

**Ballance for profit**
There is nothing flated here as expence of the ca-
nal in which the flax is watered; because that varies
much according to the conveniences people have for
making it: and a canal once made requires for after-
years only to be repaired and cleaned.
It is a certain fact, that the greater the crop is, the
better is the quality of the fame kind of flax.

The advantage of having both a crop of flax and a
crop of timb in the same year—or of sowing grain
seeds along with the lintseed—and of reducing the
ground to a fine garden mould, free of weeds, ought
to be attended to.

For Cambrick and fine Lawn. The ground must be a
rich light foil, rather sandy, but cannot be too rich.

It ought to be ploughed in September, or the begin-
nings of October, first putting a little hot rotten dung
upon it.

Second ploughing in January after a hard frost; and
when you intend to sow it, plough it a third time, or
rather hoe it, reducing the clods very fine; but make
no furrows: the land must be made level like a garden;
but never work the land when wet.

The seed should be sown the beginning of April,
and about double the quantity that is generally sown by
our farmers; if the land be very rich, it will require
rather more than double.

As soon as sown (if the weather be dry) it will be
necessary to roll the ground.

The lint must be weeded very clean when about
three inches high; directly after which you must set
forked stakes (of about one and half inch thick (which
ought to be prepared before) every four or five feet,
according to the length of the poles you are to lay up-
on them; they should be well fixed in the ground, the
forked part to receive the poles about six or seven
inches above the lint; each row of poles should be
two, three, or four feet aunder, according to the length
of the thuftwood you are to lay upon them.

The poles ought to be from ten to fifteen feet long;
and strong enough to support the thuft across the poles;
take the longest thuftwood you can get, the
more branchy the better, very thick, filling up the va-
cancies with smaller thuft, and any of the branches
that rise higher than eighteen or twenty inches ought
to be lopped off to make the thuft lie as level as possible:
york of thuft will do except oak, as that tinges the
lint.

Your lint must be pulled as soon as the seed is fully
formed, which is a few days after it is out of the
bloom before the lint turn yellow.

It must be pulled above the thuftwood, and every
handful laid upon it as soon as possible: if it is fine
weather, leave it four or five hours in that manner;
then carry it to a freen near a barn, to put it under cover
in case of rain; there it must be spread four or five
days, and always put in the barn at night, or when
it appears to rain: the bundles must be opened in the
barn, or made hollow, to prevent it from heating.

These operations must be performed until the lint is
perfectly dry, and out of danger of heating; taking
care all the time to keep the roots as even as possible,
The great property of this flax is to be fine and long. Thick sowing raises all plants fine and flender, and when the ground is very rich, it forces them to a great length. Pulling green prevents that coarse hardnefs which flax has when let fland till it be full ripe, and gives it the fine flaky property. The brufiwood, when the flax springs up, catches it by the middle, prevents it from lying down and rottmg; infallible consequences of sowing thick upon rich ground. It likewise keeps it flaight, moift, and soft at the roots; and by keeping it warm, and fladed from the fun, greatly promotes its length. The keeping it from rain, heating, taking proper care of your water, prefers the colour, and prevents these bars in cloth fo much complained of by bleachers.

The breaking by rollers is scarcely subject to any objection, but that it is dangerous to workmen not sufficiently on their guard, who fometime$ allow the rollers to take hold of their fingers, and thereby their whole arm is infallibly drawn in: thus many have loft their arms. To avoid this danger, a break upon the general principles of the hand-break before defcribed, has been lately adapted to water machinery, and used in place of rollers. The horizontal froke of the fcutchers was long thought too severe, and wafeful of the flax; but very careful experiments have discovered that the wafle complained of must be charged to the unskilfulnefs or negligence of the workman, as in good hands the mill carries away nothing but what, if not fo fcutched off, mufl be taken off in the heckling with more lofs both of time and flax. But to obviate this objection of the violence of the horizontal fcutcher, an imitation of hand fcutching has lately been applied to water. The fcutchers then project from an horizontal axle, and move like the arms of a check-reel, striking the flax neither across nor perpendicularly down, but floping in upon the parcel exactly as the flax is struck by the hand-fcutcher. This floping froke is got by raising the $cutching$-flock some inches higher than the centre of the axle; and by raising or lowering the flock, over which the flax is held, or resin is nearer to or farther from the fcutchers, the workman can temper or humour the froke almost as he pleafes.

The breaking of the flax by rollers is scarcely suited to the workmen, and more expeditious than the old hand-methods, and more gentle than water-mills, has also been lately invented in Scotland. It is much like the break and fcutcher giving the floping froke laft defcribed, moved by the foot. The treadle is remarkably long, and the fcutchers are fixed upon the rim of a fly-wheel. The foot-break is alfo aflifted in its motion by a fly. These foot-machines are very ufeful where there are no water-mills, but they are far inferior to the mills in point of expedition.—[See plans of the water-mills, and foot-machine, on the unnumbered plates betwixt the LXXXII. and LXXXIII.]

The next operation that flax undergoes after fcutching, is heckling. The heckle (fig. 6. Plate LXXXIII.) is firmly fixed to a bench before the workman, who $ftri$k$es the flax upon the teeth of the heckle, and draws it thro' the teeth. To persons unacquainted with that kind of work this may seem a very fimpie operation; but, in fact, it requires as much practice to acquire the flight of heckling well, and without wafting the flax, as any other operation in the whole manufacture of linen. They use coarser and wider teethed heckles, or finer, according

Plate LXXXII.
ing to the quality of the flax; generally putting the flax thro' two heckles, a coarser one first, and next thro' a fine heckle.

**Flax for cambrick and fine lawn, thread and lace,** is dressed in a manner somewhat different. It is not flutched so thoroughly as common flax; which from the skutch proceeds to the heckle, and from that to the spinner: whereas this fine flax, after a rough flutching, is scraped and cleansed with a blunt knife upon the workman's-knee covered with his leather apron: from the knife it proceeds to the spinner, who, with a brush made for the purpose, straightens and dresses each parcel just before she begins to spin it.

**Read-Flax.** See Linaria.

**Flea-rane,** in botany. See Conyza.

**Flea bitten,** that colour of a horse, which is white or grey, spotted all over with dark redish spots.

**Fleam,** in forgery and farriery, an instrument for let-ting a man or horse blood. A cage of flams, as it is called by farriers, comprehends fix sorts of instruments; two hooked ones, called drawers, and used for cleaning wounds; a pen-knife; a sharp pointed lancet, for making incisions; and two fleams, one sharp and the other broad pointed. These last are somewhat like the point of a lancet, fixed in a flat handle, only no longer than is just necessary to open the vein.

**Fleche,** a town of France, under the meridian of London, twenty miles north-east of Angers.

**Fleche,** the covering of wool, shorn off the bodies of sheep. See Wool.

**Order of the Golden Fleck,** an order of knighthood instituted by Philip II. duke of Burgundy. These knights at first were twenty-four, besides the duke himself, who reserved the nomination of six more: but Charles V. increased them to fifty. He gave the guardianhip of this order to his son Philip king of Spain, since which the Spanish monarchs are chiefs of the order. The knights had three different mantles ordained them at the grand solemnity, the collar and fleec.

**Fleet,** commonly implies a company of ships of war, belonging to any prince or state; but sometimes it denotes any number of trading ships, employed in a particular branch of commerce.

In sailing, a fleet of men of war is usually divided into three squadrons; the admiral's, the vice admiral's, and the rear-admiral's squadron, all which, being distinguished by their flags and pendant, are to put themselves, and, as near as may be, to keep themselves in their customary places, viz. The admiral, with his squadron, to sail in the van, that so he may lead the way to all the rest in the day-time, by the light of his flag in the main top-mast-head; and in the night time, by his lights or lanterns. The vice-admiral and his squadron, is to sail in the centre or middle of the fleet. The rear-admiral, and the ships of his squadron, is to bring up the rear. But sometimes other divisions are made; and those composed of the lighter ships and the best sailors, are placed as wings to the van, centre, and rear.

**Fleet is also a noted prison in London, where persons are committed for contempt of the king and his laws, particularly of his courts of judicature, or for debt, where any person will not, or is unable to pay his creditors.**

There are large rules and a warden belonging to the fleet prison, which had its name from the float or fleet of the river or ditch, on the side whereof it stands.

**FLENSBURGH,** a port town subject to Denmark, sixteen miles north of the city of Slewich.

**Flesh,** in anatomy, a similar, fibrous part of an animal body, soft and bloody, being that whereof most of the other parts are composed, and whereby they are connected together: or more properly, it is such parts of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

**Fleury,** a town of Burgundy, in France, thirty miles north of Chalon.

**Fleurer,** in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

**Flexor,** in anatomy, a name applied to several muscles, which are so called from their office, which is to bend the part to which they belong; in opposition to the extensors, which open or stretch them. See Anatomy, part II.

**Flint,** in natural history, a semipellucid stone, composed of crystal debased with earth, of one uniform substance, and free from veins; but of different degrees of colour, according to the quantity of earth it contains, and naturally surrounded with a whitish crust.

Flint is a stone of an extremely fine, compact, and firm texture, and very various, both in size and figure. It is of all the degrees of grey, from nearly quite black, to almost quite white. It breaks with a fine, even, glossy surface; and is moderately transparent, very hard, and capable of a fine polish. It readily strikes fire with steel, and makes not the least effervescence with aquafortis, and burns to a whitefluff. Its uses in glass-making, &c. are too well known to need a particular rectification.

**Floatages,** all things floating on the top of the sea or any water, a word much used in the commissions of water bailiffs.

**Flood.** See Deluge.

**Florence,** an archbishop's see and city of Italy, situated on the river Arno, in Tuscany, forty-five miles east of Leghorn: E. long. 12° 15', and N. lat. 43° 30'. Florence is one of the most elegant towns in Italy, has an university, and is six miles in circumference. The statues, paintings, and curiosities in the grand duke's palace are the admiration of travellers.

**Florentine,** a town of Champaign in France, twenty-eight miles south-west of Troyes.

**Flores,** in geography, one of the Azores islands, subject to Portugal.

**Florida,** in geography, a name first given by the Spaniards to all that part of North America which lies north of the gulf of Mexico. However, all that retains the name Florida at present, is the peninsula between the British colony of Georgia and cape Florida,
FR CRW Flower. See Xeranthemum.

FLOUR, the meal of wheat-corn, finely ground and flopped.

FLounder, the Englifh name of a fpecies of Pleuronectes.

Flower de luce. See Iris.

Flower Fence. See Poinciana.

Flower de luce. See Iris.

Everlafting Flower. See Graphium.

Sultan-Flower. See Cyarus.

Flux, in metallurgy, whatever can cause a body otherwise hard or solid, but is now reduced by fusion, or fire, into a state of fluidity.

German flute, an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is flopt with a tampion or plug; and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, befitting that for the mouth, the lowest of which is flopt and opened by the little finger’s preffing on a ftraw or formed to a silver key, like thoje in hautboys, faffoons &c. Its found is exceeding sweet and agreeable; and serves as a treble in a concert.

Coarfe flutes, on importation, pay the gros, containing twelve dozen, 3 s. 10 1/2 d, and on exportation draw back 2 s. 3 1/2 d.

Flutes, or Flutings. See Architecture.

Fluvialis, in botany. See Najas.

Flux, in chemistry, an extraordinary issue, or evacuation of some humours of the body. See Medicine.

Flux, in metallurgy, whatever can cause a body otherwise not at all, or hardly, fusible by fire, to melt. See Chemistry.

FLODER. See Colombia.

Fluid, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed.

Laws and properties of Fluids. See Hydraulics and Hydrostatics.

Flower de lis, or Flower de luce, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some more, and spread all over the escutcheons in great numbers.

The arms of France are, three flower de lis or, in a field azure.

Flusion, or Uliing, a port town of Zeeland in Holland, five miles south of Middleburgh: E. long. 3° 25', N. lat. 51° 30'. It is a town of great foreign trade, and has a good secure harbour.

Flute, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side.

German flute, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is flopt with a tampon or plug; and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, befitting that for the mouth, the lowest of which is flopt and opened by the little finger’s pressing on a ftraw or shaped to a silver key, like those in hautboys, faffoons &c. Its sound is exceeding sweet and agreeable; and serves as a treble in a concert.

Coarfe flutes, on importation, pay the gros, containing twelve dozen, 3 s. 10 1/2 d, and on exportation draw back 2 s. 3 1/2 d.

Flutes, or Flutings. See Architecture.

Fluvialis, in botany. See Najas.

Flux, in medicine, an extraordinary issue, or evacuation of some humours of the body. See Medicine.

Flux, in metallurgy, whatever can cause a body otherwise not at all, or hardly, fusible by fire, to melt. See Chemistry.
FLUXIONS.

FLUXIONS, a method of calculation which greatly facilitates computations in the higher parts of mathematics. Sir Isaac Newton and Mr Leibnitz contended for the honour of inventing it. It is probable they had both made progress in the same discovery, unknown to each other, before there was any publication on the subject.

In this branch of mathematics magnitudes of every kind are supposed generated by motion: a line by the motion of a point, a surface by the motion of a line, and a solid by the motion of a surface. And some part of a figure is supposed generated by an uniform motion; in consequence of which the other parts may increase uniformly or with an accelerated or retarded motion, or may decrease in any of these ways; and the computations are made by tracing the comparative velocities with which the parts flow.

Fig. 1. If the parallelogram ABCD be generated by an uniform motion of the line AB toward CD while it moves from FE towards FS, while the line BF receives the increment FB, and the figure will be increased by the parallelogram FB; the line FE in this case undergoes no variation.

The fluxion of any magnitude at any point is the increment that it would receive in any given time, supposing it to increase uniformly from that point; and as the measures will be the same, whatever the time be, we are at liberty to suppose it less than any assigned time.

The first letters in the alphabet are used to represent invariable quantities; the letters x, y, z variable quantities; and the same letters with points over them x, y, z, represent their fluxions.

Therefore if AB=α, and BF=x; FB, the fluxion of BF, will be = x, and FE, the fluxion of AF, = ax.

If the rectangle be supposed generated by the uniform motion of FC toward AD, at the same time HG moves uniformly towards AD, the point G keeping always on the diagonal; the lines FG HG will flow uniformly; for while B receives the increment FB and HB, the increment HK, FG will receive the increment BG and HG the increment AG, and they will receive equal increments in equal successive times. But the parallelogram will flow with an accelerated motion; for while F flows to F and H to K, it is increased by the gnomon KG; but while F and H flow through the equal spaces fml KL it is increased by the gnomon Lgm greater than KG; consequently when fluxions of the sides of a parallelogram are uniform, the fluxion of the parallelogram increases continually.

The fluxion of the parallelogram BHGF is the two parallelograms KG and Gf; for though the parameter receives an increment of the gnomon KG; while its sides flow to F' and K, the part gG is owing to the additional velocity wherewith the parallelogram flows during that time; and therefore is no part of the measure of the fluxion, which must be computed by supposing the parameter to flow uniformly as it did at the beginning, without any acceleration.

Therefore if the sides of a parallelogram be x and y, their fluxions will be x y; and the fluxion of the parallelogram xy+xy; and if x=y, that is, if the figure be a square, the fluxion of x^2 will be 2xx.

Fig. 2. Let the triangle ABC be described by the uniform motion of DE from A towards B, the point E moving in the line DF, so as always to touch the lines AC, CB; while D moves from A to F, DE is uniformly increased, and the increase of the triangle is uniformly accelerated. When DE is in the position FC, it is a maximum. As D moves from F to B, the line FC decreases, and the triangle increases, but with a motion uniformly retarded.

Fig. 3. If the semicircle AFB be generated by the uniform motion of CD from A towards B, while C moves from A to G, the line CD will increase, but with a retarded motion; the circumference also increases with a retarded motion, and the circular space increases with an accelerated motion, but not uniformly, the degrees of acceleration growing less as CD approaches to the position GF. When C moves from G to B, it decreases with a motion continually accelerated, the circumference increases with a motion continually accelerated, and the area increases with a motion continually retarded, and more quickly retarded as CD approaches to B.

The fluxion of a quantity which decreases is to be considered as negative.

When a quantity does not flow uniformly, its fluxion may be represented by a variable quantity, or a line of a variable length; the fluxion of such a line is called the second fluxion of the quantity whose fluxion that line is: and if it be variable, a third fluxion may be deduced from it, and higher orders from these in the same manner: the second fluxion is represented by two points, as x.

The increment a quantity receives by flowing for any given time, contains measures of all the different orders of fluxions; for if it increases uniformly, the whole increment is the first fluxion; and it has no second fluxion. If it increases with a motion uniformly accelerated, the part of the increment occasioned by the first motion measures the first fluxion, and the part occasioned by the acceleration measures the second fluxion. If the motion be not only accelerated, but the degree of acceleration continually increased, the two first fluxions are measured as before; and the part of the increment occasioned by the additional degree of acceleration measures the third; and so on. These measures require to be corrected, and are only mentioned here to illustrate the subject.

DIRECT METHOD.

Any flowing quantity being given, to find its fluxion.

Rule I. To find the fluxion of any power of a quantity
The fluxion of \( x^n \) is \( nx^{n-1} \); for the root of \( x^n \), whose fluxion is \( x \), which multiplied by the exponent \( n \), and by a power of \( x \) left by unity, gives the above fluxion.

If \( x \) receive the increment \( x \); it becomes \( x+x \); raise both to the power of \( n \), and \( x^n \) becomes \( x^{n-1}x^{n+1} \); all the parts of the increment, except the first term, are owing to the accelerated increase of \( x^n \), and form measures of the higher fluxions. The first term only measures the first fluxion; the fluxion of \( x^2 \), which is equal to the proposed fluent, is \( 3x^2 \), for which substituting the values of \( x \) and \( x \), we have \( x=2z \), and the fluxion of \( x^3 \), for which we have \( x=z \), and we have the above fluxion.

Thus the fluxion of \( x \), is \( x^2+y \); that of \( xz \), is \( x^2y+xy \); and that of \( x^2z \), is \( x^2z^2+yz \); for \( x=2z \), and \( x=2z \), for which substituting the values of \( x \) and \( x \), we have \( x=2z \), and we have the above fluxion.

Rule II. To find the fluxion of the product of several variable quantities multiplied together, multiply the fluxion of each by the product of the rest of the quantities, and the sum of the products thus arising will be the fluxion sought.

Thus the fluxion of \( xy \), is \( xy+y \); that of \( xz \), is \( xz \); and that of \( x^2z \), is \( x^2z^2+yz \); for \( x=2z \), and \( x=2z \), for which substituting the values of \( x \) and \( x \), we have \( x=2z \), and we have the above fluxion.

Rule III. To find the fluxion of a fraction. — From the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator.

Thus the fluxion of \( \frac{x}{y} \), is \( \frac{xy-xz}{y^2} \); that of \( \frac{x}{y} \), is \( \frac{x^2y+y^2x^2-x^2y^2}{x^2+yz} \); for the fluxion of \( x^2 \) is \( 2xx \); and of \( y^2 \) is \( y^2 \), by Rule I., and therefore the fluxion of \( x^3 \) (by Rule II) \( 2x^2y+y^2x^2 \); from which, multiplied by \( x \), (by Rule II, and subtracting from it the fluxion of the denominator \( x \), multiplied by the numerator, and dividing the whole by the square of the denominator, gives the above fluxion.

Rule IV. The second fluxion is derived from the first, in the same manner as the first from the flowing quantity.

Thus the fluxion of \( x^2 \), \( 3x^2x \); its second \( 6x^3+3x^2 \) (by Rule II); and so on: but if \( x \) be invariable, \( x=0 \), and the second fluxion of \( x^2=6x^2 \).

Prob. 1. To determine maxima and minima

When a quantity increases, its fluxion is positive; when it decreases, it is negative; therefore when it is just between increasing and decreasing, its fluxion is \( 0 \).

Rule. Find the fluxion, make it \( =0 \), whence an equation will result that will give an answer to the question.

Fig. 4. Example. To determine the dimensions of a cylinder, open at the top, which shall contain a given quantity of liquor, grain, &c. under the least surface possible.

Let the diameter \( AB=x \), and the altitude \( AD=y \); moreover, let \( \rho \) (3.14159, &c.) denote the periphery of the circle whose diameter is unity, and let \( c \) be the given content of the cylinder. Then it will be \( \rho : x : (\rho x) \); the circumference of the base, which, multiplied by the altitude \( y \), gives \( \rho xy \) for the concave superficies of the cylinder. In like manner, the area of the base, by multiplying the same expression into \( \frac{1}{2} \) of the diameter \( x \), will be found \( =\frac{\rho x^2}{4} \); which drawn into the altitude \( y \), gives \( \frac{\rho x^2y}{4} \) for the solid content of the cylinder; which being made \( =c \), the concave surface \( \rho xy \) will be found \( =\frac{c}{x} \), and consequently the whole surface \( =\frac{\rho x^2+y^2}{x} \); whereof the fluxion, which is \( \frac{\rho c}{x} \), being put \( =0 \), we shall get \( 8\rho +\rho x^2=0 \); and therefore \( x=2 \); and \( x=4 \), it follows, that \( x=2 \); whence \( y \) is also known, and from which it appears, that the diameter of the bafe must be just the double of the altitude.

Fig. 5. When the absciss \( x \) of a curve moves uniformly from \( A \) to \( B \), the motion of the curve will be retarded if it be concave, and accelerated if convex towards \( AB \); for a straight line \( TC \) is described by \( x \) uniformly, and the fluxion of the curve at any point is the same as the fluxion of the tangent, because it would describe the tangent if it continued to move equally from that point. Now if \( S \) or \( C \) be the fluxion of the base, \( Cd \) will be the fluxion of the tangent, and \( de \) of the ordinate. And because the triangles \( S \), \( T \), \( C \), \( ed \), are equiangular, \( de : ce :: CS : ST \), wherefore

Rule. Find a fourth proportional to the fluxion of the
the ordinate valued in terms of the abscissa, the fluxion of the abscissa, and the ordinate, and it determines the line ST, which is called the semi-tangent, and TC joined is a tangent to the curve.

Fig. 6. Example. To draw a right line CT, to touch a given circle BCA in a given point C.

Let CS be perpendicular to the diameter AB, and put AB=a, BS=x, and SC=y: Then, by the property of the circle, $y^2 = AB \times SC = ax - x^2$; whereof the fluxion being taken, in order to determine the ratio of $x$ and $y$, we get $2yy = ax - 2xx$; consequently

$\frac{x}{\sqrt{a-x}} = \text{the subtangent ST}$. Whence (O being supposed the centre) we have $OS = \frac{a-x}{y}$: CS (y) :: CS (x) :: ST; which we also know from other principles.

Prob. 3. To determine points of contrary flexure in curves.

Fig. 7. Supposing C to move uniformly from A to B, the curve DEF will be convex towards AB when the celerity of E increases, and concave when it decreases; therefore at the point where it ceases to be convex and begins to be concave, or the opposite way, the celerity of E will be uniform, that is, CE will have no second fluxion. Therefore,

Rule. Find the second fluxion of the ordinate in terms of the abscissa, and make it $= 0$; and from the equation that arises you get a value of the abscissa, which determines the point of contrary flexure.

Ex. Let the nature of the curve ARS be defined by the equation $ay = a^\frac{3}{2}x^2 + xx$, (the abscissa AF and the ordinate FG being, as usual, represented by $x$ and $y$ respectively). Then $y$, expressing the celerity of the point $r$, in the line FH, will be equal to $\frac{a^\frac{3}{2}x^2 + xx}{2a}$. Whole

flution, or that of $\frac{1}{2} a^{\frac{3}{2}} x^2 + 2xx$ (because $a$ and $x$ are constant) must be equal to nothing; that is, $-\frac{1}{2} a^{\frac{3}{2}} x^2 + 2xx = 0$: Whence $a^{\frac{3}{2}} x^2 = 8a^3$, $64x^3 = 3a$, and

$x = \frac{4}{3} a = AF$; therefore FG $= \frac{a^\frac{3}{2}x^2 + xx}{2a}$. From which the position of the point G is given.

Prob. 4. To find the radii of curvature.

The curvature of a circle is uniform in every point, that of every other curve continually varying; and it is measured at any point by that of a circle whose radius is of such a length as to coincide with it in curvature in that point.

All curves that have the same tangent have the same first fluxion, because the fluxion of a curve and its tangent are the same. If it moved uniformly on from the point of contact, it would describe the tangent. And the deflexion from the tangent is owing to the acceleration or retardation of its motion, which is measured by its second fluxion; and consequently two curves which have not only the same tangent, but the same curvature at the point of contact, will have both their first and second fluxions equal. It is easily proven from thence, that the radius of curvature is $= \frac{x^3}{4y^3}$, where $x$, $y$, and $z$ represent the abscissa, ordinate, and curve respectively.

Ex. Let the given curve be the common parabola, whose equation is $y = a^{\frac{1}{3}} x^2$: Then will $y = \frac{1}{3} a^{\frac{1}{3}} x^2 - \frac{1}{2} a^{\frac{1}{3}} x^2$ and (making $x$ constant) $y = \frac{1}{3} a^2 x^2 - \frac{1}{2} a^2 x^2 = \frac{3}{2} a^2 x^2$: Whence $\frac{x}{\sqrt{a^2 x^2 + z}} = \frac{2}{\sqrt{a}}$ and the radius of curvature $= \frac{3}{2} a^{\frac{5}{3}} x^{\frac{1}{3}}$. Which at the vertex, where $x = o$, will be $= \frac{3}{2} a$.

INVERSE METHOD.

From a given fluxion to find a fluent.

This is done by tracing back the steps of the direct method. The fluxion of $x$ is $x$; and therefore the fluent of $x$ is $x$: but as there is no direct method of finding fluents, this branch of the art is imperfect. We can assign the fluxion of every fluent, but we cannot assign the fluent of a fluxion, unless it be such a one as may be produced by some rule in the direct method from a known fluent.

General Rule. Divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased.

For, dividing the fluxion $nx^{n-1} x$ by $x$ (the fluxion of the root $x$) it becomes $nx^{n-1}$; and, adding 1 to the exponent $(n-1)$ we have $nx^n$; which, divided by $n$, gives $x^n$, the true fluent of $nx^{n-1} x$.

Hence (by the same rule) the

Fluent of $x^n y$ will be $= x^n$;

That of $8x^{n-1} y$ will be $= \frac{8x^n}{3}$;

That of $2x^3 y$ will be $\frac{x^n}{3}$;

That of $y^3$ will be $\frac{x^n}{3}$.

Sometimes the fluent so found requires to be corrected. The fluxion of $x$ is $x$, and the fluxion of $a + x$ is also $x$, because $a$ is invariable, and has therefore no fluxion.

Now when the fluent of $x$ is required, it must be determined, from the nature of the problem, whether any invariable part, as $a$, must be added to the variable part $x$.

When fluents cannot be exactly found, they can be approximated by infinite series.

Ex. Let it be required to approximate the fluent of

$$\frac{a^2 - x^2}{c^2 - x^2}$$

in an infinite series.
The value of \( \frac{a^2-x^2}{1+\frac{1}{x}} \), expressed in a series, is
\[
\frac{a}{c} + \frac{1}{2} - \frac{1}{2ac} x^2 - \frac{a}{4ac^2} \frac{1}{x} x^4 + \frac{5a}{16ac} \frac{3}{x^6} + \epsilon c.
\]
Which value being therefore multiplied by \( x^n \), and the fluent taken (by the common method) we get
\[
\frac{a^2-x^n+1}{c} + \frac{1}{2ac} x^2 - \frac{a}{4ac^2} \frac{1}{x} x^4 + \frac{5a}{16ac} \frac{3}{x^6} + \epsilon c.
\]

**Prob. 1. To find the area of any curve.**

**Rule.** Multiply the ordinate by the fluxion of the abscissa, and the product gives the fluxion of the figure, whose fluent is the area of the figure.

**Exampl. 1.** Fig. 8. Let the curve ARMH, whose area you will find, be the common parabola. Let \( u \) represent the area, and \( u \) its fluxion.

In which case the relation of \( AB(x) \) and \( BR(y) \) being expressed by \( y = ax \) (where \( a \) is the parameter) we hence get \( y = a^2x^2 \); and therefore \( u = RwHB (=ux^2) = a^2x^2 \) : whence \( u = \frac{1}{2} a^2x^2 \) : and \( a^2x^2 = \sqrt{\frac{a}{u}} \), because \( \sqrt{a} = \frac{a}{u} \).

**Exampl. 2.** Let the proposed curve CSDR (fig. 9.) be of such a nature, that (supposing \( AB \) unity) the sum of the areas CSTB and CDGB answering to any area CRNB, whose corresponding abscissa \( AN \) is equal to \( 1 \), be of such a nature, that (supposing \( AB \) unity) the sum of a rectangle of the same base and altitude.

\[\begin{align*}
\frac{x}{1+x} + \frac{1}{1+3x} + \frac{1}{1+4x} + \frac{1}{1+5x} + \ldots
\end{align*}\]

The value of \( e^x \), expressed in a series, is
\[
1 + x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \ldots
\]

**Exampl. 3.** Fig. 5. Becaufe \( C^4 \) is a right-angled triangle, \( C^4 \) = \( a^2 + a^2 \); wherefore the fluxions of the abscissa and ordinate being taken in the same terms and squared, their sum gives the square of the fluxion of the curve; whose root being extracted, and the fluent taken, gives the length of the curve.

**Exampl. To find the length of a circle from its tangent.** Make the radius \( AO \) (fig. 5.) = \( a \), and its tangent \( = x \), the curve \( = z \), and its fluxion \( = z \); because the triangles \( T \), \( O \), \( C \), are similar, \( T \) : \( O \) :: \( O \) :: \( O \); whence \( OS = \frac{a}{t} \), and \( SA = a - \frac{a}{t} = a - \sqrt{a^2 + t^2} \). whose

\[\begin{align*}
\text{fluxion is } &\frac{a^2t}{a^2 + t^2} \quad \text{and, because the triangles } \quad \text{OTC, } \quad \text{are similar, } \\
\text{are equal to } &\frac{a^2t}{a^2 + t^2} \quad \text{and, because the triangles } \quad \text{OTC, } \quad \text{are similar, } \\
d^2 = &\frac{a^2t}{a^2 + t^2} \quad \text{fluxion of the curve.}
\end{align*}\]

Now by converting this into an infinite series, we have the fluxion of the curve
\[\begin{align*}
&\frac{a^2t}{a^2 + t^2} + \frac{a^2t}{a^2 + t^2} + \frac{a^2t}{a^2 + t^2} + \ldots
\end{align*}\]

consequently \( z = a - \frac{a}{t} + \frac{a^2}{t^2} + \frac{a^3}{t^3} + \ldots \), \( e^x \) being equal to \( 1 + x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \ldots \).

Where, if (for example) \( AR \) be supposed an arch of 30 degrees, and \( AO \) (to render the operation more easy) be put \( = unity \), we shall have \( t = \sqrt{\frac{a}{2}} = 0.5773502 \) (because \( O \sqrt{\frac{a}{2}} = \frac{BR(\frac{a}{2})}{2} \)).

\[\begin{align*}
&\text{Whence, } \\
&t^3 = \frac{a^2}{t^3} = 0.1924500 \\
&t^5 = \frac{a^4}{t^5} = 0.0641500
\end{align*}\]
And therefore \( AR = \frac{5773502}{3} - \frac{1924500}{3} + \frac{0641500}{3} - \frac{0121833}{3} \times \frac{001277}{3} - \frac{0023759}{3} + \frac{0007919}{3} - \frac{0002639}{3} \).

Other series may be deduced from the versed sine, sine, and secant; and these are of use for finding fluents which cannot be expressed in finite terms. For,

\[
\begin{align*}
\frac{aw}{\sqrt{2a^2 - w^2}} & \quad \text{Verfed-sine} \\
\frac{aw}{\sqrt{a^2 + w^2}} & \quad \text{Right-sine} \\
\frac{aw}{a^2 + w^2} & \quad \text{Tangent} \\
\frac{aw}{\sqrt{a^2 - w^2}} & \quad \text{Secant}
\end{align*}
\]

Prob. 3. To find the contents of a solid.

Let the surface of the generating plane be multiplied by the space it passes through in any time, the product will give a solid which is the fluxion of the solid required; the surface must therefore be computed in terms of \( x \), which represents the line or axis on which it moves, and by its motion on which the fluxion is to be measured, and the fluent found will give the contents of the solid.

FLY in zoology. See Natural History.

FLY, in mechanics, a cross with leaden weights at its ends; or rather a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which the force of the power, whatever it be, is not only preserved, but equally distributed in all parts of the revolution of the machine. See Mechanics.

FLYING, the progressive motion of a bird, or other winged animal, in the air.

The parts of birds chiefly concerned in flying are the wings, by which they are sustained or wafted along. The tail, Mr. Willughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascents and descents in the air; and to obviate the oscillations of the body and wings: for, as to turning to this or that side, it is performed by the wings and inclinations of the body, and but very little by the help of the tail. The flying
flying of a bird, in effect, is quite a different thing from the roiling of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and prepares the same situation what way ever the bird turns.

In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left, so a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclinations of their head and neck, which altering the course of gravity, the bird will proceed in a new direction.

The manner of flying is thus: the bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid reflets those successions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The refi-

ance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this refi-

lance, when the two forces continue to be in equilibrio, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a refi-

lance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no re-

fi-

lance, and consequently the bird can never mount.

Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

Flying fish, a name given by the English writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of water a long time. See Esoxobutus.

Flying pinion, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock’s motion, when the weight descends in the striking part.

Foil, or Colt, the young of the horse kind. The word colt, among dealers, is understood of the male kind. See Equus and Horsemanship.

Fochén, a town of China, capital of the province of Fokein: E. long. 118°, N. lat. 26° 20’.
FONTAINE, a town of Hainalt, fifteen miles east of Mons.

FONTAINEBLEAU, a village of the isle of France, about thirty miles south-east of Paris; remarkable for an elegant royal palace.

FONTANELLA, in anatomy, the quadrangular aperture, between the os frontis and os incisivus, in infants just born.

FONTARA, a port-town of Spain, in the province of Biscay, twenty miles west of Bayonne: W. long. 1° 35'; and N. lat. 43° 20'.

FONTENAYLE, a town of Orleans, in France, about forty-six miles west of Poitiers.

FONTENOY, a town of Hainault, situated three miles south-east of Tournaic.

FONTERAUD, or Order of Fonteraud, a religious order instituted about the latter end of the 13th century. By the rules of this order the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

FONTICULUS, or Fontanella, in surgery, an issue, feton, or small ulcer made in various parts of the body, in order to eliminate the latent corruption out of it.

FONTINALIS, in botany, a genus of the cryptogamia musci class. The anthera is operculated, and the caryopsis is septic. There are four species, all natives of Britain, viz. the antipyretica, or greater water-moss; the minor, or lesser water-moss; the squamosa, or scaly water-moss; and the pennata, or feathered water-moss.

FOOD implies whatever aliments are taken into the body.

FOOT, in the Latin and Greek poetry, a metre or measure of the syllables; others are compound, consisting of four syllables, and therefore called difyllabic or trisyllabic feet. These feet are commonly reckoned twenty-eight, of which some are simple, as confisting of two or three syllables, and therefore called difyllabic or trisyllabic feet; others are compound, consisting of four syllables, and therefore called tetrasyllabic feet.

The difyllabic feet are four in number, viz. the pyrrhichius, spondeus, iambus, and trocheus. See PYRRHICHIUS, &c.

The trisyllabic feet are eight in number, viz. the dactylus, anapæstis, troihychys, mollofas, amphiбраcys, amphimacer, bacchius, and antbacchius. See DACTYLY, &c.

The tetrasyllabic feet are sixteen, viz. the procleusmaticus, dispondeus, choriambus, antispalatus, diambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus secundus, epitritus tertius, epitritus quartus, paeon primus, paeon secundus, paeon tertius, and paeon quartus. See PROCLEUSMATICUS, &c.

FOOT is also a long measure, consisting of 12 inches. Geometricians divide the foot into 10 digits, and the digit into 10 lines.

FOOT square, is the same measure both in breadth and length, containing 144 square or superficial inches.

Cubic or Solid Foot, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

FOOT of a horse, in the menage, the extremity of the leg, from the coronet to the lower part of the hoof.

FOOT LEVEL, among artificers, an instrument that serves as a foot-rule, a square, and a level. See Level, Rule, and Square.

FORAMEN, in anatomy, a name given to several apertures or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina, in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membrane tympani. See Anatomy.

FORCALQUIER, a town of Provence, in France, thirty miles north of Aix.

FORCE, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform or not direct. See Mechanics.

Central Forces. See Mechanics.

FORCE, in law, signifies any unlawful violence offered to things or persons.

FORCEPS, in surgery, &c. a pair of tongs for cutting off, or dividing, the flesh, and serous membraneous parts of the body, as occasion requires. See Surgery.

FORE-Castle of a ship, that part where the foremast stands. It is divided from the rest by a bulkhead.

FOREIGN, some thing extraneous, or that comes from abroad.

FOREIGNER, the natural born subject to some foreign prince.

Foreigners, tho’ made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy-council, or members of parliament, &c. This is by the acts of the settlement of the crown. Such persons are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

FORELOCKS, in the sea language, little flat wedges made with iron, used at the ends of bolts, to keep them from flying out of their holes.

FORELORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or, at a siege, to form the counter-scarpe, mount the breach, or the like.

They are so called from the great danger they are unavoidably expoed to; but the word is old, and begins to be obsolete.
FORE-MAST of a ship, a large round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-sail and fore top-sail yards. Its length is usually \( \frac{2}{3} \) of the main-mast, and the fore top gallant mast is \( \frac{1}{2} \) the length of the fore-top.

FOREMAST-MEN, are those on board a ship that take in the top-sails, fling the yards, fall the sails, bowse, trice, and take their turn at the helm, &c.

FOREST, in general, a great wood, or a large extent of ground covered with trees.

FOREST, in law, is defined by Manwood, a certain territory of woody grounds, and fruitful pastures, privileged for wild beasts and fowls of forest, chase and warren, to rest and abide under the protection of the king, for his princely delight, bounded with unremovable marks, and meres, either known by matter of record or prescription; replenished with wild beasts of venery, or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, with the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of that antiquity in England, that, excepting the new forest in Hampshire erected by William the Conqueror, and Hampton Court erected by Henry VIII. it is said that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers, and in divers of our laws and statutes.

There are sixty-nine forests in England, thirteen chafes, and 800 parks. The four principal forests are New Forest, Sherwood Forest, Dean Forest, and Windsor Forest.

FOREST-TOWNS, in geography, certain towns of Swabia, in Germany, lying along the Rhine and the confines of Switzerland, and subject to the house of Austria. Their names are Rhinefield, Seckingen, Lauingenburg, and Waldhut.

FORE-STAFF, or CROSS-STAFF, an instrument used at sea for taking the altitude of the sun, moon or stars.

FORESTALLER, a person who is guilty of forestalling.

Forests are of that antiquity in England, that, excepting the new forest in Hampshire erected by William the Conqueror, and Hampton Court erected by Henry VIII. it is said that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers, and in divers of our laws and statutes.

There are sixty-nine forests in England, thirteen chafes, and 800 parks. The four principal forests are New Forest, Sherwood Forest, Dean Forest, and Windsor Forest.

There are sixty-nine forests in England, thirteen chafes, and 800 parks. The four principal forests are New Forest, Sherwood Forest, Dean Forest, and Windsor Forest.

FORESTALLER, a person who is guilty of forestalling.

FORESIGHT, or foresight, in Scots law, signifies premeditated murder.

FORFEIT, the capital of the county of Angus, in Scotland: W. long. 2° 32', and N. lat. 56° 25'.

It is a parliament town, classed with Perth, Dundee, Coupar, and St Andrews, which all together send one member.

FORFEITURE, properly signifies the effect of transferring some penal law, and extends to lands or goods.

FORFICULA, the ear-wig, in zoology, a genus of insects belonging to the order of coleoptera. The antennae are bristly; the elytra are dimidiated; the wings are covered; and the tail is forked. There are two species, viz. the auriculata, or common ear-wig, with the tops of the elytra white; and the minor, with telfaceous and unspotted elytra.

FORGE, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red-hot, in order to soften them and render them more malleable and manageable on the anvil.

Forge is also used for a large furnace, wherein iron ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and separated in a former furnace, and then cast into fows and pigs, is heated and fuded over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGER, in law, one guilty of forgery. See the next article.

FORGERY, in a legal sense, is where a person fraudulently makes and publishes false writings to another's prejudice: or, it signifies the writ that lies against him who offends that way.

FORIFSAMIFICATION, in law, when a child, upon receiving a portion from his father, or otherwise renounces his legal title to any further share of his father's succession, he is said to be forisfamiliated. See Scots Law, title 28.

FORLI, a town of Romania, in the pope's territories, fifteen miles south-west of Ravenna.

FORM, in physics, the essential or distinguishing modality of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence; being that which constitutes it such a particular body, and distinguishes it from every other body.

Form is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

FORM, in law, the rules established and requisite to be observed in legal proceedings.

FORM, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars to sit on. At schools, the word form is frequently applied to what is otherwise termed a class. See Class.

FORM also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness.
Form is also used, among mechanics, for a sort of mould whereon any thing is fashioned or wrought: as the hatter's form, the paper-maker's form, &c.

Printer's Form, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every form is inclosed in an iron-chaise, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form confines of more or fewer pages, according to the size of the book.

FORMAL, something belonging to, or constituting the form of a thing. See Form.

FORMICA, or the Ant, in zoology, a genus of insects belonging to the order of hymenoptera, the characters of which are these: There is a small scale between the breast and belly, and the joint is so deep that the animal appears as if it were almost cut through the body. The females, and the neuters or working ants which have no sexual characteristics, are furnished with a hidden wing; and both the males and females have wings, but the neuters have none. There are eighteen species, most of them distinguished by their colours.

These insects keep together in companies like the bees, and maintain a sort of republic. Their nest is not exactly square, but longer one way than the other; and in it there are a sort of paths, which lead to different magazines. Some of the ants are employed in making the ground firm, by mixing it with a sort of glue, for fear it should crumble, and fall down upon their heads. They may be sometimes seen to gather several twigs, which serve them for rafters, which they place over the paths, to support the covering; they lay others across them, and upon them rushes, weeds, and dried graps, which they heap up into a double declivity, which serves to turn off the water from their magazines. Some of these serve to lay up their provisions in, and in others they lay their eggs.

As for the provisions, they lay up everything that is fit for them to eat; and you may often see one loaded with pippin, or grain of fruit, another with a dead fly, and several together with the carcass of a mag-bug, or other insect. If they meet with any they cannot bring away, they eat it upon the spot, or at least so much of it, as may reduce it to a bulk small enough for them to carry. They do not run about where they please, at all adventures: for some of them are sent abroad to make discoveries; and if they bring back news they have met with a pear, or a sugar-loaf, or a pot of sweetmeats, they will run from the bottom of the garden, as high as the third story of a house, to come at it. They all follow each other in the same path, without wandering to the right or the left; but in the fields they are more at their liberty, and are allowed to run about in search of game. There is a sort of green fly, that does a great deal of mischief among the flowers, and which curl up the leaves of peach and pear trees; and these are surrounded with a sort of glue, or honey, which the ants hunt after very greedily; for they touch neither the plant nor the flies themselves.

Next to this, their greatest passion is to lay up hoards of wheat, and other corn; and for fear the corn should sprout by the moisture of the subterraneous cells, they gnaw off the end which would produce the blade. The ants are often seen pulling along grains of wheat, or barley, much larger than themselves.

In Africa, and particularly in Guinea, the ants are exceeding troublesome, and do a great deal of mischief. They make their nests of earth in the fields, twice as high as a man; besides which they build large nests in high trees, from which places they advance in such prodigious swarms to the houses, that they frequently oblige the inhabitants to quit their beds in the night-time. They will sometimes attack a living sheep, which in a night's time they will reduce to a perfect skeleton, leaving not the least thing except the bones. It is common for them to serve domestic fowls in the same manner, and even the rats themselves cannot escape them. If you place a worm or a beetle where only one or two ants are, they will immediately depart, and bring with them above an hundred; after which they seize their prey, and march off with it in good order. These ants are of various sorts, some great, others small, some black, and others red; the fling of this last is very painful, and caueth an inflammation; the white are as transparent as crystal, and have such strong teeth, that in a night's time they will eat their way through a thick wooden chest, and make it as full of holes as if it had been penetrated by hail-shot.

There are also several sorts of ants in the East Indies, whose numbers are prodigious; some of them are exceeding large, and of a reddish colour, inclining to black; and some have wings, but others have none. They are very pernicious to the fruits of the earth, and do a great deal of mischief in houses, unless great care is taken to prevent them. It is remarkable, that if one ant meets another that is loaded, it always gives way to let it pass freely.

The ant lays eggs in the manner of the common flies, and from these eggs are hatched a sort of small maggots or worms without legs: these are sharp at one end and blunt at the other; and are white, but so transparent, that the intedines are seen through the skin. These, after a short time, change into large white aureliae, which are what are usually called ants eggs. That end which is to be the tail is the largest, and that which is the head is somewhat transparent.

The ants move these about at pleasure with their forelegs. It is well known, that when a nest of these creatures is disturbed and the aurelia scattered about, the ants are at infinite pains to get together all that are unhurt, and make a nest for them again: nay, any ants will do this, and those of one nest will often take care of the aurelia of another.

The affection of the ant for its offspring is amazing. They carry the young worms about in their mouths, that nothing may injure them; and when the earth
earth of the nest is dry, they carry them down to a
greater depth, but when wet they bring them to the
surface, that they may not be injured by the damps.

The common ant builds only with small pieces
of dry earth, and there is always found a vast quantity
of dry earth, and there is always found a vast quantity
of the national ant. The ant wears a thin skin;
and when carefully opened, they show the worm per-
fected, and in its several stages of perfection.

The forecast of ants in providing against the winter
is a mistake. They are supposed not to eat in the win-
ter, but to spend that season, like dormice and other
ants, and in its several stages of perfection.

The care these creatures take of their offspring is
remarkable. Whenever a hill is disturbed, all the ants
are found buried in consulting the safety, nor of them-
several of the larger bodies enclosing the maggots or young ant; they carry these down any
way so as to get them out of sight, and will do this
over and over as often as they are disturbed.

They carry away the eggs and vermicles together in
their confusion; but as soon as the danger is over, they
carefully separate them, and place each lot in par-
chelves under shelter of different kinds, and at various depths, according to the different
degrees of warmth and cover up the different lots re-
quire.

In the warm season of the year, they every morn-
ing bring up the eggs, as they are usually called, to
the surface, or nearly so; and from ten in the fore-
noon to five in the afternoon or thereabouts, all these
will be found just under the surface; and if the hills be
examined toward eight in the evening, they will be
found to have carried them all down; and if rainy
weather be coming on, it will be necessary to dig a
foot deep or more, in order to find them.

These little creatures are very troublesome in gar-
dens, and in pastures; as well by feeding on the fruit, as by making up hills for their habitation.

In the hotter countries, as Italy, Spain, and the West
Indies, ants are great pests of the fields. Trees
may be preferred from them by compassing the item,
for four fingers breadth, with a roll of wool, newly
pulled from the sheep's belly; or by laying saw-dust
all round the stump of it. Some anoint the tree with
tar, which has the same effect.

The large, black, winged ants of America, to a-
void the great rains which fall there at particular sea-
s, make to themselves large nests on trees, with
a covered way for them to go up and down on the lee-
side of the tree. These nests are round in the out-
side, made of light brown earth, plastered smooth.

They are larger than a bushel; and in the inside are
many fine cavities or lodgings communicating with
each other. See Plate LXXX. fig. 1. A, The ants
nest; B, The tubular passage, made of the same
materials.

FORMICA, in medicine, a callous sort of wart.
FORMICA-LEO, the Ant-lion, or Ant-eater, in
zoology, an insect so called from its devouring great
numbers of ants. It is the caterpillar or worm of a
fly much resembling the libellae or dragon-flies.

The address of this insect in catching the ant is ad-
mirable; it makes a hole of a conical or funnel shape,
in the loose sand; and is sure to catch all the ants that
come within the verge of this hole, by throwing up
sand on them, whereby they are forcibly carried into
the power of the enemy at the bottom of the hole.

FORMOSA, an island in the pacific ocean, between 119°
and 122° of E. long, and between 22° and 25° N. lat.
about 100 miles of Canton in China. It is sub-
ject to the Chineses.
FORMULA, or Formulary, a rule or model, or cer-
tain terms preferred or decreed by authority, for the
form and manner of an act, instrument, proceeding,
or the like.

FORMULA, in church-history and theology, signifies a
profession of faith.

FORMULA, in medicine, imports the constitution of me-
dicines, either simple or compound, both with respect
to their prescription and consistence.

FORMULARY, a writing containing the form of an
oath, declaration, attestation, abjuration, &c. to be
made on certain occasions.

FORNACALIA, or Fornicalia, in Roman antiqui-
ty, a festival instituted by Numa in honour of For-
ax, the god of ovens; wherein certain cakes were
made, and offered in sacrifice before the ovens.

FORNICATION, the act of incontinency between in-
gle persons; for when either of the parties is married,
such act is adultery. See Adultery.

FORNIx, in anatomy. See Anatomy, p. 285.
FORAGE, in the military art, denotes hay, oats,
barley, wheat, grass, clover, &c. brought into the
for the security of the forragers.

FORRES, a parliament-town of Scotland in the coun-
ty of Murray, about thirteen miles west of Elgin: W.
long. 3° 20', and N. lat. 57° 40'.

It is flcased with Inverness, Fortrose, and Nairn.
FORT, in the military art, a small fortified place, en-
vironed on all sides with a moat, rampart, and para-
pet. Its use is to secure some high ground or the
passage of a river, to make good an advantageous po-
t. It is the business of the quarter-master-general to
appoint the method of forrage, and post proper guards
for the security of the forragers.

FORRES, a parliament-town of Scotland in the coun-
ty of Murray, about thirteen miles west of Elgin: W.
long. 3° 20', and N. lat. 57° 40'.

It is clased with Inverness, Fortrose, and Nairn.
FORT, in the military art, a small fortified place, en-
vironed on all sides with a moat, rampart, and para-
pet. Its use is to secure some high ground or the
passage of a river, to make good an advantageous po-
t, to defend the lines and quarters of a siege, &c.
FORTALICE, in Scots law, signified anciently a small
place of strength, originally built for the defence of the
country; and which on that account was formerly re-
koned inter regalia, and did not go along with the
lands upon which it was situated without a special grant
from the crown. Now, fortalices are carried by a gen-
eral grant of the lands; and the word is become syn-
nonymous with manor-place, messuage, &c.

FORTIFICATION.
FORTIFICATION.

FORTIFICATION, the art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a small number of men within, may be able to defend themselves for a considerable time against the assaults of a numerous army without; so that the enemy in attacking them, must of necessity suffer great losses.

Fortification is either ancient or modern, regular or irregular. Ancient fortification, at first, consisted of walls or defences made of trunks and other branches of trees mixed with earth, to secure them against the attacks of the enemy. This was afterwards altered to stone walls, on which were raised breast-works, behind which they made use of their darts and arrows in security. Modern fortification is that which is flanked and defended by bastions and out works, the ramparts of which are so solid, that they cannot be beat down but by the continual fire of several batteries of cannon. Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

Section I. Of Regular Fortification.

The art of regular fortification may be distinguished into two parts, viz. the elementary or theoretical, and practical.

The elementary part consists in tracing the plans and profiles of a fortification on paper, with scales and compasses; and to examine the systems proposed by different authors, in order to discover their advantages and disadvantages.

And the practical part consists in forming a project of a fortification, according to the nature of the ground and other necessary circumstances, to trace it on the ground, and to execute the project, together with all the military buildings, such as magazines, store-houses, bridges, &c.

Notwithstanding all the improvements which have been made in the art of fortifying since the invention of gunpowder, that of attacking is still superior to it: engineers have tried in vain to render the advantages of a fortification equal to those of the attack; the superiority of the besiegers fire, together with the greater number of men, obliges generally, sooner or later, the besieged to submit.

The greatest improvement made in the art of attacking happened in the year 1697, when M. Vauban made first use of ricochet firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been none; whereas before, they had been secure as long as the parapet was not demolished; and the worst is, that there can be no remedy found to prevent this enfilading without falling into inconveniences almost as bad as those which we endeavour to avoid.

Although authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be both needless and superfluous to treat of all the different methods hitherto proposed, we shall content ourselves with explaining those only, which are most esteemed by the best judges, and have been mostly put in practice.

Construction of M. Vauban's Method.

This method is divided into little, mean, and great; the little is chiefly used in the construction of citadels, the mean in that of all forts of towns, and the great in particular cases only.

We shall give the construction of the mean, as being most useful, and refer the reader to the table hereafter, for those dimensions which are different in these several fortifications.

[Plate LXXXIII. fig. 1.] Incribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let AB be one of the sides of half an exagon, which beight by the perpendicular CD: divide half AC of it into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is fix French feet; and therefore the whole side AB is supposed to be 180 toes.

As the dividing a line into so many equal parts, is troublesome and tedious; it is more convenient to have a scale of equal parts by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toes, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an exagon inscribed; AB being bisected by the perpendicular CD as before, set off 30 toes from C to D, and draw the indefinite lines ADG, BDF, in which take the parts AE, BH, each equal to 50 toes; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal outline of the front.
If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification.

If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts a, b, c, &c. together with these arcs will represent the outline of the ditch.

Thefe arcs will represent the outline of the ditch.

Thefe arcs are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts a, b, c, &c. together with these arcs will represent the outline of the ditch.

The face of the principal or outline, the one at 3 toises distance, and the other at 8 from it; then the space xy included between the principal one and that farthest distant, is called the rampart.

And the space xx, contained by the principal line, and that next to it, and which is generally stained black, is called the parapet.

There is a fine line drawn within four feet of the parapet, which expresses a step called banquette.

N.B. All works have a parapet of three toises thick, and a rampart of 8 to 10, besides its slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular contructions of engineers.

The parapet is a part of the rampart elevated from 6 to 7½ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

The body of the place, is all that which is contained within this first rampart; for which reason, it is often said to construct the body of the place; which means properly, the construction of the battlements and curtains.

All the works which are constructed beyond the ditch before the body of the place are called outworks.

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260.

In the second, the perpendiculars answering to these sides.

In the third, the lengths of the faces of bastions; and in the fourth, the lengths of the capitals of the ravelins.

The forts are mostly, if not always, squares; for which reason, the perpendiculars are made one eighth of the exterior side, and all pentagons ¼th, and in all the rest upwards ⅙th.

3. Construction of Orillons and retired Flanks.

Describe the front MPQRST as before, and divide the flank into three equal parts, of which suppose Sr to be one: from the opposite flanked angle M draw a line Mr, in which take the part Mr of 5 toises; take likewise Rn in the line of defence MR, produced, equal to 5 toises, and join nm, upon which as a base describe the equilateral triangle npm, and from the angle p, opposite to the base as centre, is described the circular flank nm.

And if Sr be bisected by the perpendicular 1, 2, and another be erected upon the face ST, at S; the intersection 2 of these two perpendiculars, will be the centre of the arc which forms the orillon.

The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be, if they were of any other figure.

2. Con-
2. Construction of Ravelins or Half moons.

Fig. 2. Set off 50 toifes, from the re-entering angle O of the countercarp, on the capital OL of the ravelin, or on the perpendicular produced, and from the point L draw lines to the shoulders A B; whose parts LM, LN, terminated by the countercarp, will be the faces MO, ON, the semi-gorges of the ravelin required.

This is M. Vauban's method of constructing ravelins, according to some authors; and others will have the faces of the ravelin to terminate on those of the bastions within 3 toifes of the shoulders; which seems to be the best way, for the ravelins cover the flanks much better than the others.

The ditch before the ravelin is 12 toifes, its countercarp parallel to the faces of the ravelins, and is made in a circular arc, before the salient angle; as likewise all ditches are in general.

When the ravelins are made with flanks, as in fig. 3, the faces should terminate off those of the bastions, at least 5 toifes from the shoulders.

The flanks are made by setting off 10 toifes from the extremities of the faces, from f to h, and from m to l, fig. 3, and from the points h, l, the flanks hk, lp, are drawn parallel to the capital LO of the ravelin.

There are sometimes redoubts made in the ravelin, such as in fig. 2, which is done by setting off 16 toifes from the extremities of the faces on the semi-gorges from N to b, and from M to a; and from the points b, a, the faces are drawn parallel to those of the ravelin: the ditch before this redoubt is 6 toifes, and its countercarp parallel to the faces.

3. Construction of Tenailles.

A tenaill is a work made in the ditch before the curtains, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different forts: the first are those as in fig. 4, which are made in the direction of the lines of defence, leaving a passage of 3 toifes between their extremities and the flanks of the bastions, as likewise another of 2 in the middle for a bridge of communication to the ravelin.

The second fort, are those as in fig. 5. Their faces are in the lines of defence, and 16 toifes long, besides the passage of 3 toifes between them and the flanks of the bastions; their flanks are found by describing arcs from one shoulder of the tenaille as centre thro' the other, on which are set off 10 toifes for the flanks described.

And the third fort, are those as in fig. 6. Their faces are 16 toifes, as in the second fort, and the flanks are parallel to those of the bastions.

The use in general of tenailles, is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the re doubt within the ravelin, which can be defended from no where else so well as from them.

The first fort do not defend the ditch so well as the others, as being too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be seen in the citadel of Lille, at Landau, New-Brifac, and in a great many other places.

The second fort defend the ditch much better than the

Fig. 7. Lunettes are placed on both sides of the ravelin, such as B, to increase the strength of a place: they are constructed, by bisecting the faces of the ravelin with the perpendicular LN; on which is set off 30 toifes from the countercarp of the ditch, for one of its faces; the other face PN, is found by making the semi-gorge TP of 25 toifes; the ditch before the lunettes is 12 toifes, the parapet 3, and the rampart 8; as in the ravelin.

There is sometimes another work made to cover the salient angle of the ravelin; such as A, called Bonnet, whose faces are parallel to those of the ravelin, and when produced bisects those of the lunettes; the ditch before it is 10 toifes.

There are likewise lunettes, such as D, in fig. 8, whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their semi-gorges are only 20 toifes.

These kind of works may make a good defence, and are no very great expense; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

5. Construction of Tenailions.

Fig. 9. Produce the faces of the ravelin beyond the countercarp of the ditch, at a distance MN of 30 toifes, and take on the countercarp of the great ditch 15 toifes from the re entering angle p to q, and draw Nq; then qNMP will be the tenailion required; its ditch is 12 toifes, that is, the same as that of the ravelin. Sometimes there is made a retired battery in the front of the tenailions, as in fig. B; this battery is 10 toifes from the front to which it is parallel, and 15 toifes long.

There are commonly retreatments made in the tenailions, such as O; their parapets are parallel to the

frants.
fortification.

Plate LXXXIV. fig. 1. From the salient angle of the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin produced at C; from the point C, set off the cords CB, CF, each of them equal to 110 toises; and on each of which, as an exterior side, construct a front of a polygon of the same dimensions as in the hornwork; that is, the perpendicular should be 18 toises, the faces 30, and the branches terminate on the faces of the battlements, within 25 toises of the shoulders.

The ditch is 12 toises, the capital of the ravelin 35, and its ditch 8; that is, the same as in the hornwork.

Sometimes the crownwork is made before the baflion, as in fig. 2, the arc is described from the salient angle A of the baflion, with a radius of 120 toises, as before, and the branches terminate on the faces of the adjacent ravelins within 25 toises of their extremities; the rest of the dimensions and constructions are the same as before.

Hornworks, as well as crownworks, are never made but when a large spot of ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town;

Although we have not hitherto mentioned the covert-way, nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking the covert-way, when it is in a good condition and well defended, is generally the most bloody action of the siege.

After having constructed the body of the place, and all the outworks which are thought necessary, lines are drawn parallel to the outmost counterfcarps of the ditches, at 6 toises distant from it; and the space mmnm. included between that line and the counterfcarp, will be the covert-way required.

Fig. 3. There is in every re-entering angle of the counterfcarp a place of arms, m; which is found by setting off 20 toises from the re-entering angle a, on both sides from a to b, and from a to c; and from the points b, c, as centres, arcs are described with a radius of 25 toises, so as to intersect each other in d; then the lines drawn from this intersection to the points b, c, will be the faces of the places of arms.

If lines are drawn, parallel to the lines which terminate the covert-way, and the places of arms, at 20 toises distant from them, the space x, y, z, between these lines and those which terminate the covert-way, will be the glacis.

At the extremities of the places of arms, are traverses made, such as v, v, which serves to inclose them; these traverses are 3 toises thick, and as long as the covert-way is broad; and a paffage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the rest of the covert-way.

There are also traverses of the same dimensions before every salient angle of the baflion and outworks, and are in the same direction of the faces of those works produced; and the thickness lies at the same side as the parapets.

The paffages round these last traverses are likewise from 6 to 8 feet wide.
In each place of arms are two fally ports $z, z$, which are 10 or 12 feet wide, for the troops to fall out; in time of a siege they are shut up, with barriers or gates.

10. Construction of Arrows and Detached Redoubts.

An arrow is a work made before the falient angles of the glacis, such as $A$, fig. 2.; it is composed of a parapet of 3 toises thick, and 40 long; and the ditch before it 5 toises, terminating in a sloop at both ends. The communication from the covert-way into thefe arrows is 4 or 5 toises wide, and there is a traverse $r$ at the entrance of 3 toises thick, with a passage of 6 or 8 feet round it.

A detached redoubt is a kind of work much like a ravelin, with the flanks beyond the glacis; such as fig. B: they are made in order to occupy some spot of ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise.

Their distance from the covert-way ought not to exceed 120 toises, that it may be defended by muskets shot from thence.

The gorge $a b$ is 40 toises, the flanks $a c$, $b f$, which are perpendicular to the gorge $10$, and the faces $c d$, $f d$ 30; the ditch before it is 6 toises, ending in slopes at both ends; the covert-way 4; the branches of the covert-way are 42 toises long, or thereabouts; the faces of the places of arms $y$, $y$, which are perpendicular to the branches, 10; and the other, which is parallel to them, 14.

The communication from the covert-way into the redoubt, is 5 or 6 toises wide; and there is a traverse made just at the entrance; and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis.

If these redoubts are above 50 toises distant from the covert-way, the besiegers carry their trenches round, and enter through the gorge; by which the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent this, some other outerworks should be made to support them.

Fig. 4. When the ground is low, and water to be found, there is often a ditch of about 10 or 12 toises made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch; such as $D$, whose breadth on the counterfcarp of the ditch is 30 toises, from $b$ to $a$, and from $c$ to $d$; and the faces $a l$, $d l$, are parallel to those of the places of arms; the ditch before them is from 8 to ten toises wide.

The second covert-way is 4 toises, the semi-gorges of the places of arms, $m$, about 15, and the faces perpendicular to the counterfcarp; the second glacis is from 15 to 18 toises broad.

This second covert-way has traverses every where, in the same manner as the first.

Plate LXXXV, fig. 1. A profile is the representation of a vertical section of a work; it serves to shew those dimensions which cannot be represented in plans, and are necessary in the building of a fortification; they are generally constructed upon a scale of 30 feet to an inch. It would be needless to describe all their particular dimensions, since they are marked in the schemes; we shall therefore lay down the principal rules only, given by M. Vauban, on this subject.

1. Every work ought to be at least 6 feet higher than that before it, so that it may command those before it; that is, that the garrison may fire from all the works at the same time, with great and small arms, at the besiegers in their approaches; notwithstanding this specious pretence, there are several authors, who object against it. For they say, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries; so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it.

But if all the works were of the same height, those within cannot be destroyed, till such time as those before them are taken; guns might be placed in the covert-way and outworks to obstruct the enemy's approach, and when they come near the place, they might be transported into the inner-works; and as the body of the place would be much lower, the expense would be considerably diminished.

But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees: this might however be partly prevented, by making the parapets near the salient angles, for the space of 8 toises on each side, 5 or 6 feet higher than the rest of the works.

2. The covert-way should be lower than the level-ground, otherwise the body of the place must be raised very high, especially when there are several outworks; this is to be understood only when the works exceed each other in height, otherwise it need not be below the level.

3. The bases of all inward slopes of earth should be at least equal to the height, if not more.

4. The bases of all outward slopes of earth, two thirds of their heights.

5. The slopes of all walls or revetments should be one fifth of their height; but one sixth would be sufficient in our opinion: the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation.

6. The slopes of all parapets and traverses are one fifth of their breadth; that is, 3 feet towards the field, or the inside, where the banquelets should be, 3 feet higher than the outside.

7. When the revetment of a rampart goes quite up to the top, 4 feet of the upper-part is a vertical wall of 3 feet thick, with a square flone at the top of it, projecting 6 inches, and a circular one below, or where the slope begins, of 8 or 10 inches diameter; they go quite round the rampart, and the circular projection is called the cordon.

Where the straight part of the wall ends and the flope begins, the wall is always made 5 feet thick; and the counterforts or buttreffes reach no higher than that place.

7. When the rampart is partly walled, and partly turf-
ed, then one fifth of the height which is turfed must be added to 5 feet, to get the thickness of the wall above.

And having the thickness of any wall above, by adding one fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a fifth part must be added.

For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed; then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 4 added to the thicknesses 7 above, gives 11 for the thickness near the foundation.

Plate LXXXV. fig 1. Represents, in military perspective, the profiles of the body of a place, the ravelin and covert-way; which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived.

Sect. II. Of Irregular Fortification.

The most essential principle in fortification, consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides; this can happen no otherwise but in a regular fortification situated in a plain or even ground; but as there are but few places which are not irregular, either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular, without too great expense; it is much more necessary to shew in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise if such a place is to be attacked, to know which is the strongest or weakest.

1. Construction of an irregular place situated in an open country.

If the place to be fortified is an old town inclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature of the ground, to regulate his plan accordingly, so as to avoid the disadvantages, and gain all the advantages possible; he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place cannot be reduced into a regular figure, or nearly so; for, if that can be done without increasing the expense considerably, it should by no means be omitted; old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and mended when it may be done; if there is a rampart without bastions or towers, it must be well considered, whether bastions may not be added, or if it is not better to make only some outworks; if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions, otherwise ravelins and counterguards must be constructed; special care must be taken, to make all sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of musket-shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest.

If it should happen, that some of the sides are inaccessible or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others, which are of easy access, and the flanks need not be so large as the rest; by so doing, there will be some expenses saved, which may be used in making the other sides stronger by adding more outworks.

There are few situations, but what are more advantageous in some parts than in others; it is therefore the business of an engineer to distinguish them, and to render those sides strong by art, which are not so by nature.

If the situation is low and watery, lunettes or tenaille, and such other small outworks should be constructed, because they are not of any great expense, and may make a very good defence; but if one side of the place is only low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing, that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled, by means of dykes or sluices, so as to overflow the best part of the first glacis, it should be done; for by so doing, these works will be able to make a very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis, which cannot be done but within a few toises of the first covert-way, where the besiegers are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them.

But if the situation is of a dry nature, without any water about it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries raised in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis, so as to afford no cover for the enemy behind them; arrows, and detached redoubts are likewise very proper to be used in such a case, and sometimes horn or crown-works, if it should be thought convenient; but these works should never be constructed, without an absolute necessity, either to occupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance into the town, for they are of so great expense, that their defence seems not to be answerable to it.

Most of the places in Flanders are fortified with horn-works, such as Ipres, Tournay, Lille, and others.

If the place to be fortified is new, and the situation will not admit of a regular construction; particular care must be taken in chusing such a spot of ground as is most advantageous, and least liable to any disadvantages, either in the building or in the maintaining of it; all hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters, for the same reason, excepting a lake is, or may be made navigable: good water should be had either within the place or near it, for it is absolutely necessary for men and cattle.
cattle; the air should be wholesome, otherwise the con-

Bus of sickness that may reign in such a place might pre-

hend people to come and live in it; and the garrison would

not be in a condition to defend themselves as they ought
to do; in short, all the different circumstances attending
such an undertaking should be maturely considered, before
a resolution is taken to fortify any place.

When a situation is pitched upon, the next thing to be
considered is, the bigness of the town and the number of
its outworks, which must absolutely depend upon the
configuration such a place is of to a nation; if it is only to
guard a pass, or entrance into a country, it need not be
so large; but if it is to be a place either to promote or
to protect trade, it should be large and commodious; the
streets should be wide, and the buildings regular and
convenient: as to what regards the fortification, its
construction should depend on the nature of the situation,
and the number of the works on the funds or expence a
prince or a nation will be at; which however ought to
be according to the benefit arising from such a place:
for, as such undertakings are of very great expence, an
engineer cannot be too sparing in his works; on the
contrary, the greatest expense should be used, both in
regard to the number of works, and to their construction.
The body of the place may have * revetements quite up
to the top, or only in part, and the rest turfed; but as
to the outworks, they should have half revetements, or
they may be made with turf only; as being not so neces-
fary to prevent the place from being surpris'd, and may
nevertheless make a good defence.

On Plate LXXXV. fig. 2. is the plan of an octagon,
one half of which is similar and equal to the other half;
it being supposed, that the situation would not admit of
fortification quite regular; and the exterior sides are
each 180 toises, and the works are constructed according
to our method; but because the sides AB, EF, are
weaker than the rest, as has been proved before, we have
added tentailles, redoubts in the ravelins, and lunettes, to
render them nearly equal in strength with the others;
and if counter guards were made before the batters A
and B, it would effectually secure that front. Instead
of lunettes, any other works may be made, as it may be
thought convenient and according to the nature of the
ground. If it should be judged necessary to add other
outworks to the ravelins all round the place, care must be
taken to add likewise more to the fronts AB, EF, in
order to render the advantages and disadvantages of at-
tacking on either side equal.

2. Construction of an irregular place, situated on a
hill or rock.

In the construction of such places, care must be taken
that no neighbouring hill commands any part of the works;
The town should always be built on the highest part; but
if it should be thought more convenient to place it lower,
then the upper part must be fortified with a fort; the
situation should be made level as near as possible, by
removing the earth from some places to fill up others; and

if it cannot well be levelled without extraordinary ex-
pence, works must be made on the highest part, so as to
command and protect the lower; the works ought to oc-
cupy all the upper part of the hill, but if it should be too
extensive to be all inclosed, or so irregular as not to be
fortified without great inconvenience, the parts which fall
without should be fortified with some detached works,
and a communication with the place must be made either
above or under ground. There should be no cavity or
hollow roads, within cannon-shot, round about the place,
where the enemy might be able to approach under cover;
if there should happen to be a spring, near the top of the
hill, it should be inclosed in the fortification, or if that
cannot be done, by some work or other; for there is no
thing more necessary, and at the same time nearer in such
situations than water, for which reason there cannot be
too much care taken in providing it; several cisterns are
to be made to receive the rain-water, and to preferve it;
wells should be dug likewise, though ever so deep, the
water of which will serve for common use.

Places built on hills or rocks, should never be large,
for their use is generally to guard passes or inlets into a
country, and are seldom useful in traffic, and it is a dif-
cult matter to provide for a large garrison in such situa-
tions, neither should any such place be built without
some very material reasons; but when it is absolutely
necessary, great care and precautions should be taken to
render the works as perfect as the situation will admit of,
and at the same time to be as frugal in the expence as
possible.

3. Construction of irregular fortifications, situated near
rivers, lakes, or the sea.

As the intent of building these kind of places is chiefly
to facilitate and protect trade, it is of much more im-
portance than any other kind, especially in maritime
countries, where the principal strength and power depends
on it; for which reason, we shall treat of it more largely
than any other part.

The first thing to be considered is their situations,
which ought to be such as to afford a good harbour for
shipping, or a safe and easy entrance in stormy weather;
but as it is hardly possible to find any, where ships may
go in and lie secure with all winds, care should be taken
to make them safe to enter with those winds which are
most dangerous: but it is not sufficient that the har-
bour be safe against stormy weather, they should likewise
be so against an enemy, both by land and water; for it
often happens, that ships are destroyed where it was ima-
gined they were secure, which is of too great a con-
sequence not to be provided against; for which reason,
forts or batteries must be built in the most convenient
places, to prevent the enemy's ships from coming too
near, fo as to be able to cannonade those in the harbour,
or fling shells amongst them: and if there is any danger
of an enemy's approach by land, high ramparts and edi-
fices must be built, fo as to cover them.

When a river is pretty large, and it is not convenient

* Revetements are chiefly made to prevent a place from being surpris'd; cutworks do not want to be made fo, the
taking them by surprize is of no great consequence, except in a siege, when other cautions are used to prevent it.
for making a harbour without great expence, the ships may ride along the shore, which, for that reason, must be made accessible for ships of burden; this may be done by advancing the quay into the river, if the water is too shallow, or by digging the river sufficiently deep for that purpose.

And to prevent any enemy from coming up the river, forts must be built on both sides, especially when there are any turnings or windings. Antwerp is such a place; for the Scheld is sufficiently deep to carry ships of great burden, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river.

When the river is but small, so that no ships of burden can come through it; it is sufficient to make it run through some of the works, where proper landing places are contrived, from whence the goods may be carried into the place; as at Sarrelouis, where a horn-work is built beyond the Sarre, in the gorge of which the goods are landed.

If the breadth of the river does not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived as that the river passes through the curtain, in order to have a bastion on each side to defend the coming in and going out.

When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others; such is Hunningen on the Rhine, and Sarrelouis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author.

But it is plain, that the sides which terminate at the river, are the weakest; because the besiegers trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side; besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river longer, the angles at its extremities become wider, and consequently the adjacent sides stronger.

There are other advantages, besides these mentioned already, which arise from the lengthening that side; for if the river is very deep, it is not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water-side to any part of the town.

F O R T I S S I M O, in music, sometimes denoted by FFF, or fff, signifies to sing or play very loud or strong.

F O R T - L E W I S, a fortress of Alface, in Germany, situated on the western shore of the Rhine, subject to France: E. long. 8°, and N. lat. 48° 46'.

F O R T U N A T E - I S L A N D S, in ancient geography, certain islands, concerning the situtation of which authors are not agreed, famous for the golden apples of the Hesperides. See Hesperides.

The common opinion is, that they are the same with the Canary islands.

F O R T U N E, a goddess worshipped with great devotion by the ancient Greeks and Romans, who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure.

F O R U M, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.
Fig. 1

Fig. 2

Fig. 3
Forum, was also used for a place of traffic, answering to our market-place: of these there were vast numbers, as the forum piscarium, olitorium, &c. These were generally called fora venalia, in contradistinction to the former, which were called fora civilia. Forum, is also used, among calluits, &c., for jurisdiction; thus they say, In foro legiti, &c.

Foss, or fossa, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

Foss way, one of the four principal highways of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side thereof.

Fossil, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, fossils, earths, and other minerals; or extraneous, deposited in the bowels of the earth by some extraordinary means. See Natural History.

Fossombrone, a city and bishop's see of Italy, ten miles south-east of Urbino.

Foumart, in zoology. See Mustela.

Foundation, in architecture, is that part of a building which is under ground. See Building.

The foundation is properly so much of the masonry as reaches as high as the surface of the ground, and ought always to be proportioned to the load or weight of the building that it is to bear. Sometimes the foundation is massive, and continued under the whole building, as in the antique arches and aqueducts, and some amphitheatres; but it is more usually in spaces or intervals, either to avoid expense, or because the vacuities are at too great a distance, in which latter case they make use of inflated pillars bound together by arches.

Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging; unless there be cellars under ground, in which case he would have it somewhat lower; and as to thickness, double the width of the wall is no bad rule.

Foundation of Bridges, is laid after different manners. The first is by inclosing all round the space of ground you would build upon, by dams made with piles set deep in the ground in double rows, well strengthened and bound together with crofs pieces and cords, and filling the vacant spaces between them with chalk or other earthy matter. This being done, the water must be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be necessary, upon which the walls of the foundation must be laid. But this method is only practicable in building on such rivers, where the water is neither very rapid, nor very deep. The second is by laying the foundation on grate-work, rafts of floate oak well bound together, and made fast at the surface of the water with cables or machines, and building upon them large quarters of floone, cramped together, and joined with good mortar, or cement, and afterwards letting them descend softly by these cables and machines perpendicular to the bottom of the water. This was the method practised in laying the foundation of Wellington Bridge, the grating being made of the bottom of a frame called by the French Caiffon, the sides of which were so contrived, that they might be taken off, after a pier was finished. The third is by drawing off all, or the greatest part of the water of the river into some other place.

Founder, in a general sense, the person who lays a foundation, or endows a church, school, religious-house, or other charitable institution.

Founder also implies an artsit who calls metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c., whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c., See Foundery.

Founder, in the sea language: A ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she cannot steer nor flog, but lie like a log; and not being able to swim long, will at last sink.

Foundery, or Foundry, the art of casting all sorts of metals into different forms. It likewise signifies the work-house or smelting-hut wherein these operations are performed.

Foundery of small-works, or casting in sand. The sand used for casting small works, is, at first, of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a fort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared. This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in full, such another frame, only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and pouring mill-duif over them, dries them in a kind of oven for that purpose.
Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of a press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is worked over again for other castings.

Foudery of Statues. The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with fltone, or brick; or when the figure is very large, they sometimes work on the ground, and raise a proper fence to reftil the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair, and horse dung; or of plaster of Paris mixed with brick-dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is folded up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core; though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick dust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder, when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water, to the consistence of a colour fit for painting; accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whiles. For the second impression, they add horse dung, and natural earth to the former composition. The third impression is only horse dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron girts, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate.

If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed in two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-flone, or brick. At the bottom is made a hole of the same materials with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting-furnace. For the rest, the method is the same in both. The mould being finished, and included as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented, till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they take out the bricks and fill up their place with earth moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen bason, over the mould, into the bottom of which all the big branches of the jets, or caws, which are to convey the metal into all the parts of the mould, are inserted.

These caws, or jets, are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence, may
may not enter any of them, till the basin be full e-
ough of matter to run into them all at once. Upon
which occasion they pull out the plugs, which are long
iron rods with a head at one end, capable of filling the
whole diameter of each tube. The whole of the fur-
nace is opened with a long piece of iron fitted at the
end of each pole, and the mould filled in an instant.
This completes the work in relation to the calling
nace is opened with a long piece of iron fitted at the
whole diameter of each tube. The whole of the fur-
iron rods with a head at one end, capable of filling the
which occasion they pull out the plugs, which are long
part ; the bell being the sculptor's or carver's business,
end of each pole, and the mould filled in an instant.

The dimensions of the core and the wax for bells,
are not left to chance, but must be measured on a scale, or diapason, which gives
the height, aperture, and thickness necessary for the
several tones required. See Diapason.

It is on the wax that the several mouldings and o-
other ornaments are formed to be represented in relieve,
on the outside of the bell.

The business of bell-foundery is reducible to three
particulars. 1. The proportion of a bell. 2. The
forming of the mould; and, 3. The melting of the
metal.

The proportions of our bells differ much from those
of the Chinese: in ours, the modern proportions are,
to make the diameter fifteen times the thickness of the
brim, and twelve times the height.

There are two kinds of preparations, viz. the sim-
ple and the relative: the former are those proportions
only that are between the several parts of a bell, to
render it sonorous; the relative proportions establish
a requisite harmony between several bells.

The particulars necessary for making the mould of
a bell are, 1. The earth; the most cohesive is the
bell: it must be well ground and sifted, to prevent any
chinks. 2. Brick-stone; which must be used for the
mine, mould, or core, and for the furnace. 3. Horse dung, hair, and hemp, mixed with the earth,
to render the cement more binding. 4. The wax for
inscriptions, coats of arms, &c. 5. The tallow equa-
lish mixed with the wax, in order to put a slight
lay of it upon the outer mould, before any letters are
applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold con-
sisting of four boards, ranged upon treffles. Upon
this they carry the earth, grossly diluted, to mix it
with horse-dung, beating the whole with a large spatula.

The compasses of construction is the chief instru-
ment for making the mould, which consists of two
different legs joined by a third piece. And last of all,
the founders fill their, on which are the engravings of
the letters, cartridge, coats of arms, &c.

They first dig a hole of a sufficient depth to contain
the mould of the bell, together with the cafe, or can-
non, under ground; and about six inches lower than
the terreplain, where the work is performed. The
hole must be wide enough for a free passage between
the mould and walls of the hole, or between one
mould and another, when several bells are to be cast.
At the centre of the hole is a stake erected, that is
strongly fastened in the ground. This supports an
iron peg, on which the pivot of the second branch of
the compasses turns. The stake is encompassed with
a solid brick-work, perfectly round, about half a foot
high, and of the proposed bell's diameter. This they
call a mill-stone. The parts of the mould are, the core,
the model of the bell, and the shell. When the outer
surface of the core is formed, they begin to raise the
core, which is made of bricks that are laid in course
equal height upon a layer of plain earth. At the lay-
ing each brick, they bring near it the branch of the
compasses, on which the curve of the core is shaped, so
as that there may remain between it and the curve the
distance of a line, to be afterwards filled up with layers
of cement. The work is continued to the top, only
leaving an opening for the coals to bake the core.
This work is covered with a layer of cement, made
of earth and horse dung, on which they move the
compasses of construction, to make it of an even smooth-
nesses every where.

The first layer being finished, they put the fire to
the core, by filling it half with coals, through an open-
ning that is kept shut, during the baking, with a cake
of earth, that has been separately baked. The first
fire consumes the stake, and the fire is left in the core
half or sometimes a whole day; the first layer being
thoroughly dry, they cover it with a second, third,
and fourth; each being smoothed by the board of the
compasses, and thoroughly dried before they proceed to
another.

The core being completed, they take the compasses
to pieces, with intent to cut off the thickness of the mo-
del, and the compasses are immediately put in their place
to begin a second piece of the mould. It consists of a mix-
ture of earth and hair, applied with the hand on the core,
in several cakes that close together. This work is fi-
nished by several layers of a thinner cement of the
same matter, smoothed by the compasses, and thoroughly
dried, before another is laid on. The first layer of
the model is a mixture of wax and grease spread over
the whole. After which are applied the inscriptions,
coats of arms, &c. beamed with a pencil dipped in
a vessel of wax in a chaffing-dish: this is done for every
letter. Before the shell is begun, the compasses are
taken to pieces, to cut off all the wood that fills the
place of the thickness to be given to the shell.

The first layer is the fame earth with the reft, sifted
very fine; whilst it is tempering in water, it is mixed
with cow's hair, to make it cohere. The whole being
a thin bullis, is gently poured on the model, that fills
exactly all the finuositie of the figures, &c. and this
is repeated till the whole is two lines thick over the
model. When this layer is thoroughly dried, they
cover it with a second of the same matter, but some-
thing thicker: when this second layer becomes of
some consequence, they apply the compasses again, and
light
light a fire in the core, so as to melt off the wax of
the inscriptions, &c.

After this, they go on with other layers of the shell,
by means of the compasses. Here they add to the
cow’s hair a quantity of hemp, spread upon the layers,
and afterwards smoothed by the board of the compasses.
The thickness of the shell comes to four or five
inches lower than the mill stone before observed, and
surrounds it quite close, which prevents the extrava-
ation of the metal. The wax should be taken out be-
fore the melting of the metal.

The ear of the bell requires a separate work, which
is done during the drying of the several incrustations of
the cement. It has seven rings; the seventh is called the
bridge, and unites the others, being a perpendicular sup-
port to strengthen the curves. It has an aperture at the
top, to admit a large iron peg, bent at the bottom;
and this is introduced into two holes in the beam, fast-
ened with two strong iron keys. There are models
made of the rings, with masses of beaten earth, that
are dried in the fire, in order to have the hollow of
them. These rings are gently pressed upon a layer of
earth and cow’s hair, one half of its depth; and then
taken out, without breaking the model. This opera-
tion is repeated twelve times for twelve half moulds,
that two and two united may make the hollows of the
fix rings: the same they do for the hollow of the bridge,
and bake them all, to unite them together.

Upon the open place left for the coals to be put in,
are placed the rings that constitute the ear. They first
put into this open place the iron-ring to support the
clapper of the bell; then they make a round cake of
clay, to fill up the diameter of the thickness of
the core. This cake, after baking, is clapped
upon the opening, and folded with a thin mortar
spread over it, which binds the cover close to the
core.

The hollow of the model is filled with an earth,
sufficiently moist to fix on the place, which is fixed
at several times upon the cover of the core; and they
beat it gently with a pelle, to a proper height; and a
workman smooths the earth at top with a wooden
trowel dipped in water.

Upon this cover, to be taken off afterwards, they
assemble the hollows of the rings. When every thing
is in its proper place, they strengthen the outside of the
hollows with mortar, in order to bind them with the
bridge, and keep them steady at the bottom, by means
of a cake of the same mortar, which fills up the whole
aperture of the shell. This they let dry, that it may
be removed without breaking. To make room for the
metal, they pull off the hollows of the rings, through
which the metal is to pass, before it enters into the va-
cuity of the mould. The shell being unloaded of its
ear, they range under the mill-stone five or six pieces
of wood, about two feet long, and thick enough to
reach almost the lower part of the shell; between these
and the mould they drive in wooden wedges with a
mallet, to shake the shell of the model wherein it rests,
so as to be pulled up, and got out of the pit.

When this and the wax are removed, they break
the model and the layer of earth, through which the
metal must run, from the hollow of the rings, between
the shell and the core. They smoke the inside of the
shell, by burning straw under it, that helps to smooth
the surface of the bell. Then they put the shell in
the place, so as to leave the fame interval between that
and the core; and before the hollows of the rings or
the cap are put on again, they add two vents, that are
united to the rings, and to each other, by a mass of
baked cement. After which they put on this mass of
the cap, the rings, and the vent, over the shell, and
fold it with thin cement, which is dried gradually by
covering it with burning coals. Then they fill up the
pit with earth, beating it strongly all the time, round
the mould.

The furnace has a place for the fire, and another for
the metal. The fire-place has a large chimney with a
spacious ash-hole. The furnace which contains the
metal, is vaulted, whose bottom is made of earth,
rammed down; the rest is built with brick. It has
four apertures; the first, through which the flame re-
vibrates; the second is closed with a stopple that is
opened for the metal to run; the others are to sepa-
rate the drofs, or scorize, of the metal by wooden rakes:
through these last apertures passes the thick smoke.
The ground of the furnace is built sloping, for the
metal to run down.

**Foundery of great guns and mortar pieces.** The meth-
of casting these pieces is little different from that of
bells: they are run maffily, without any core, being
determined by the hollow of the shell; and they are
afterwards bored with a steel trepan, that is worked
either by horses, or a water-mill.

For the metal, parts, proportions, &c. of these
pieces, see Cannon.

**Letter Foundery, or casting of printing letters.** The
first thing requisite is to prepare good steel-punches, on
the face of which is drawn the exact shape of the let-
ter with pen and ink, if the letter be large, or with a
smooth blunted point of a needle, if small; and then,
with proper gravers, the cutter digs deep between the
strokes, letting the marks stand on the punch; the
work of hollowing being generally regulated by the
depth of the counter-punch. Then he files the outside,
till it is fit for the matrice.

They have a mould to justify the matrices by,
which consists of an upper and under part, both which
are alike, except the stool and spring behind, and a
small roundish wire in the upper part, for making the
nick in the flank of the letter. These two parts are
exactly fitted into each other, being a male and female
gage, to slide backwards and forwards. See Gage.

Then they justify the mould, by casting about twenty
samples of letters, which are set in a composing-stick,
with the nicks towards the right hand; and comparing
these every way with the pattern-letters, set up in the
same manner, they find the exact measure of the body
to be cast.

Next they prepare the matrix, which is of brass or
copper, an inch and a half long, and of a proportion-
able thickness to the size of the letter it is to contain.
In this metal is sunk the face of the letter, by striking the letter-punch the depth of an n. After this, the sides and face of the matrice are justified, and cleared, with files, of all bunchedings that have been made by finking the punch.

Then it is brought to the furnace, which is built up-right of brick with four square sides, and a stone at top, in which is a hole for the pan to stand in.

Printing-letters are made of lead, hardened with iron or flub-nails. To make the iron run, they mingle an equal weight of antimony, brozen small in an iron mortar, and flub-nails together. They charge a proper number of earthen pots, that bear the fire, with the two ingredients, as full as they can hold, and melt it in an open furnace, built for that purpose.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compoft is ladled into an iron-pot, wherein is melted lead, that is fixed on a furnace close to the former. 3 lb of melted iron to 25 lb of lead; this they incorporate according to art.

The cafter taking the pan off the stone, and having kindled a good fire, he fets the pan in again, and metal in it to melt. If it be a small-bodied letter, or a thin letter with great bodies, that he intends to cast, his metal must be very hot, and sometimes red hot, to make the letter come. Then taking a ladle, of which he has several forts, that will hold as much as will make the letter and break, he lays it at the hole where the flame burfts out: then he ties a thin leather, cut with its narrow end against the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and softening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice-cheek; and places the foot of the matrice on the floor of the mould, and the broad end of the leather on the wood of the upper haft of the mould, but not tight up, left it hinder the foot of the matrice from finking clofe down upon the floor, in a train of work. Afterwards laying a little rosin on the upper part of the mould, and having his cafting-ladle hot, he, with the boiling fide, melts the rosin, and presses the broad end of the leather hard down on the wood, and so fastens it thereto. Now he comes to cafting, when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the low part of its right hand towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both sides of the mould clofe together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three frokes outwards upon the surface of the melted metal, to clear it of the fume; then he takes up the ladle full, and having the mould in the left hand, turns his left fide a little from the furnace, and brings the gaft of his ladle to the mouth of his mould; and then he takes the upper part of his right hand towards him, to pour the metal into it, while, at the fame instant, he puts the mould in his left hand forward, to receive the metal with a strong shake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the flank. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he taffes the letter, break and all, out upon a fheet of waft paper, laid on a bench, a little beyond his left hand, and then is ready to caft another letter, as before, and likewise the whole number in that matrix.

Then boys, commonly employed for this purpose, separate the breaks from the flanks, and rub them on a stone, and afterwards a man cuts them all of an even height, which finishes the fount for the use of the printer. See next article.

A workman will ordinarily caft 3000 of these letters in a day. The perfection of letters thus caft, conflits in their being all severally square and straight on every side; and all generally of the fame height, and evenly lined, without flopping one way or other; neither too big in the foot, nor the head; well grooved, so as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and scraped, with a fensible notbf, &c. See PRINTING.

FOUNT, or FONT, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. call'd by a letter-founder, and forted.

FOUNTAIN, in philofophy, a spring or fource of wafer rising out of the earth. Among the ancients, fountains were held sacred, and even worfhipped as a kind of divinities. For the phenomena, theory, and origin of fountains, see HYDROSTATICS.

FOUNTAIN, or Artificial Fountain, called also a font d'eau, is a contrivance by which water is violenty foured upwards. See HYDROSTATICS.

FOURCHE'E, or FOURCHY, in heraldry, an appellation given to a crofs forked at the ends. See Plate LXXX. fig. 8.

FOWEY, a borough-town of Cornwall, which fends two members to parliament: W. long. 5°, and N. lat. 50° 26'.

FOWL, among zoologifts, denotes the larger forts of birds, whether domestic or wild: fuch as geele, pheafants, partridges, turkey, ducks, &c.
FOX, in zoology. See Canis.
Fox-glove, in botany. See Digitalis.
FOY, or St Foy, a town in Guienne, in France, thirty-two miles east of Bourdeaux; it is situated under the meridian of London, in 49°, 50', N. lat.

FRACTION, in arithmetic and algebra. See Arithmetics, p. 387, and Algebra, p. 83.
Decimal Fractions. See Arithmetic, p. 395.

FRACTURE, in surgery, a rupture of a bone, or a solution of continuity in a bone, when it is crushed or broken by some external cause. See Surgery.

FRÆNUM, in anatomy, a term applied to some membranous ligaments of the body.

FRÆNÜM LINGUE. See Anatomy, p. 305.
FRÆNÜM PENIS. See Anatomy, p. 274.
FRAGA, a town of Arragon, in Spain, situated under the meridian of London: N. lat. 41° 16'.

FRAGARIA, the Strawberry, in botany, a genus of the icofandria polygynia class. The calix is divided into ten segments; the petals are five; and the receptacle is an oval deciduous berry. There are three species, two of them natives of Britain, viz. the vesca, or common strawberry; and the flexilis, or barren strawberry.

FRANCE, a large kingdom of Europe, situated between 5° W. and 7° E. long. and between 43° and 51° N. lat. being bounded by the English channel and the Aftrian Netherlands, on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and, by the bay of Bifcay, on the west. This kingdom was formerly divided into twelve provinces; but at present it is divided into twenty-five general governments, over every one of which is an officer, called an intendant, appointed by the king, who has a power of controlling the governor, and all other officers of justice; and presides over the receivers-general of his generality.

FRANCÖPOT, a city of Germany, situated on the confines of Hesse and Franconia, on both sides of the river Maine: E. long. 10°, N. lat. 50° 10'.
FRANCÖPORT on the Oder, a city of Germany, in the circle of Upper Saxony, and marquisate of Brandenburg, situated in E. long. 15°, N. lat. 52° 22'.
FRANCHE-COMTE, the same with the county of Burgundy. See Burgundy.
FRANCHE-COMTE, a province of France bounded by Lorraine on the north; by Alsace and Switzerland, on the east; by La Bres and Bugey, on the south; and by the dukedom of Burgundy, on the west.
FRANCHISE, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.
FRANCISCAI MÖNKS, FRIARS MAJOR, or GREY FRIARS, religious of the order of St Francis, founded by him in the year 1209.

The rule of the Franciscans, as established by St Francis himself, is briefly this: they are to live in community, to observe chastity, and to pay obedience to the pope and their superiors.

Before they can be admitted into the order, they are obliged to sell all they have, and give it to the poor; they are to perform a year's noviciate, and when admitted never to quit the order upon any account. They are to fall from the feast of All Saints, to the Nativity. This order has produced four popes, forty-two cardinals, and an infinite number of patriarchs.
FRANCOLIVI, a town of Italy, situated on the river Po, about nine miles north-east of Ferrara.
FRANCONIA, a circle of the German empire, lying between Bohemia on the east, and the electorate of Mentz on the west. Its capital is Nuremberg; and from this country the Franks, who conquered and gave name to the kingdom of France, are said to have come.
FRANGULA, in botany. See Rhamnus.
FRANGULÆ SPECIES, in botany. See MAUCOCE.-

FRANK language, or lingua franca, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

FRANK, or FRANC, an ancient coin, either of gold or silver, struck and current in France. The value of the gold frank was somewhat more than that of the gold crown; the silver frank was a third of the gold one: this coin is long out of use, though the term is still retained as the name of a money of account; in which sense it is equivalent to the livre, or twenty sols.
FRANKENDAL, a city of Germany, in the palatinate of the Rhine, situated on the west side of the river Rhine, in E. long. 8° 15', N. lat. 49° 30'.
FRANCENIA, sea-heath, or sea-chickweed, a genus of the hexandria monogynia class. The calix is tunnel shaped, and divided into five segments; the petals are five; the stigma has six divisions; and the capsule consists of one cell, with three valves. There are three species, two of them natives of Britain, viz. the lasius, or smooth sea-heath; and the pulverulenta, or broad leaved sea-heath.
FRANKENSTEIN, a town of Germany, in the palatinate of the Rhine, and dutchy of Zuebruggen, situated twenty miles north-west of Langau.
FRANKER, a town of the United Provinces in the province of Weft Friesland, nine miles west of Lewarden.
FRANKS, FRANKIS, or FRANQUIS, an appellation given by the Turks, and other nations of Asia, to all the people of the western parts of Europe, to which they give the name of Frankifan.
FRANSTAT, or Fraustat, a town of Silefia, situated twenty-five miles north-east of Glogaw, subject to Prussia.
FRASCATI, or Frescati, a town of Italy, in the campania of Rome, thirteen miles east of that city; near which place is the Tufculum of Cicero, called Grotto Ferrate.
FRATERNITY, in the Roman-catholic countries, signifies
FRAY, among sportsmen. A deer is said to fray its head, when it rubs it against a tree, to cause the pills of the new horns to come off.

FRA ( * 31 ) F II E

FRA ( * 31 ) F II E

FREE, in a general sense, is used in opposition to what- ever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

FREE STONE, a whitish flone, dug up in many parts of Brit- ain, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a kind of the grit done, but finer sanded, and asmooth- er stone; and is called free, from its being of such a constitution as to cut freely in any direction.

FREEZING, in philosophy, the same with congelation.

FREEZE, or Frieze, in commerce, a coarse kind of woolen stuff, or cloth, for winter wear; so called, as being freezed or napped on each side.
articles are nothing else but common air, which entangling itself with the particles of water, prevents their motion. Others will have a kind of nitrous fact to be the cause of congelation, by infusing itself between the particles of water, and fixing them together, like nails. And, indeed, it seems probable that cold and freezing do arise from some substance of a saline nature floating in the air; since all salts, and particularly nitrous ones, when mixed with ice and snow, greatly increase their cold, and even bulk.

Boerhave observes, that it is extremely difficult to exhibit to the eye the precise degree of cold wherein ice begins to form; since heat and cold, once given to a body, adhere long to it before they quit it. When the air, therefore, is in such a state as keeps Fahrenheit's thermometer at 32 degrees, water will not freeze; because water being 800 times denser than air, retains the warmth considerably longer than air. If any person, therefore, is curious to know in what degree of cold water begins to freeze, let him first suspend a thermometer in a free open air on all sides; and then wetting a thin linen cloth with clear water, and hanging it likewise in the open air, it will grow stiff upon the first access of the freezing cold, and thereby show when it is beginning to turn to ice. See Thermometer.

By means of freezing, wine, vinegar, and malt-liquors may be reduced to a fourth part of their quantity, without any considerable loss of their essential parts; since only the aqueous parts freeze, leaving the vinous parts concentrated or brought into a compact, and capable of being transported with less expense, and keeping for several years. Freezing mixture. Mr Boyle shews in his history of cold, that not only all kinds of salts, but likewise spirits, sugar, and saccharum faturi, mixed with snow, are capable of freezing molt fluids; and the same effect was also produced by the mixture of oil of vitriol, or spirit of nitre with snow.

Freight, or Freight, in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel.

French, in general, something that is new, pure, and good; or, that has little or no fault in it.

Fret, or Frette, in architecture, a kind of knot or ornament, consisting of two or more semicircles variously interlaced or interwoven, and running at parallel distances equal to their breadth.

Fret-work, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but is mostly practised in roofs, which are fretted over with plaster work.

Freystatt, a town of Silesia, in Germany, E. long. 17° 55', N. lat. 50°.

Friable, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are the free stone, punice-stone, &c.

Friar, a term common to monks of all orders, founded
ed on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, viz. 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars, or carmelites. From these four the rest of the orders descend. See Franciscans, Augustines, etc.

Friburg, the capital of a canton of the same name in Switzerland, situated eighteen miles south west of Bern: E. long. 60° 55', N. lat. 46° 50'.

Friburgh, a city of Swabia, in Germany, twenty-eight miles south of Strafsburg.

Fricento, a town and bishop's see of Italy, forty-three miles east of the city of Naples.

Fricton, in mechanics, the rubbing of the parts of engines and machines against each other, by which means a great part of their effect is destroyed. See Mechanics.

Friedburg, an imperial city of Bavaria, in Germany, fifteen miles north of Frankfort on the main.

Friedburg, an imperial city of Germany, sixteen miles north of Frankfort on the main.

Friesland, one of the most northern provinces of the united Netherlands, bounded by the German ocean on the north, by Groningen and Overysel on the east, by the Zuyder-see and Overysel on the south, and by the same ocean on the west: its chief town is Leerdam.

East Friesland, a province of Westphalia in Germany, being the north-well part of Germany, bordering on Groningen.

Frieze, freeze, or frise, in architecture, a large flat face, or member, separating the architrave from the cornice, being that part of the entablature between the architrave and the corinice. See Architecture.

Frigat, among seamen, a ship of war, light built, and that is a good faier.

A frigat has commonly two decks; whence that called a light frigat is a frigat with only one deck.

Frigid, is applied to a jeune style, that is unanimated by any ornaments, and consequently without any force or vigour.

Frigorific, in phylology, small particles of matter, which, according to Gaffendus and others, being actually and effentially cold, and penetrating other bodies, produce in them that quality which we call cold.

Frill, in falconry. When a hawk trembles, or answers, they say the frills.

Fringilla, in ornithology, a genus belonging to the order of passerers. The bill is conical, strait, and sharp-pointed. There are no less than thirty species comprehended under this genus, distinguished principally by varieties in their colour.

1. The brown fringilla with a tawny neck, and white spots on the wings and hinder part of the back.

It is the Carolina ortolan of Catelby, and is a bird of the island of Cuba; only the hens pass into Carolina in the autumn. 2. The fringilla with black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It is the chaffinch of English authors, and is a bird of Europe. 3. The fringilla, with the base of the wings underneath of a deep yellow colour. It is the Brambling or mountain finch of English authors, and is a bird of Europe. 4. The brown fringilla, with a reddish breast and shoulders, and the black wings marked with a reddish spot: It is an inhabitant of Sweden. 5. The fringilla with a blackish spotted head, and a white spot behind the eyes. It is the greater chaffinch of Albin, and is found in Lapland. 6. The fringilla with the limbs, wings, and tail black, only the outermost from the middle externally white. It is a bird of Sweden. 7. The grey fringilla, spotted with black, has a space running from the bill to the sides of the neck black. It is the houmburgher, akin to the lark of Edwards, and is a bird of South America. 8. The black fringilla, with a reddish giosis, a reddish belly, with a white spot on the wings, is the American black sparrow with red eyes, of Cateby. 9. The fringilla, with the quill-feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. This is the goldfinch of English authors. 10. The fringilla with a red face and tail, the belly undulated with white and black, and the back green. It is the green goldfinch of Edwards, and is a Chinefe bird. 11. The fringilla with purple tail-feathers, with the hinder halves black. It is the amaduvad of Albin, and an inhabitant of the East Indies. The cock is all over purple; but the hen is ash-coloured, except the bill and tail. 12. The green fringilla with a red head, a yellow collar, and a blue breast. It is the red-headed green finch of Edwards. 13. The fringilla all over red, is the red fly-catcher of Cateby, and is a bird of America. 14. The yellow fringilla, with a black forehead and brown wings, is the American goldfinch of Catelby. 15. The fringilla with a black head, a tawny breast, and a white streak on the wings and above and below the eyes, is the Bahama finch of Catelby. 16. The fringilla with a wedge-like tail, a reddish body, a red bill, and the temples, rump and belly of a violet colour, is the red and blue Brazilian finch of Edwards. 17. The green fringilla, with the supercilia, breast and belly yellow, but the prime feathers of the wings are white on the outer edge. It is the Indian green finch of Edwards, and is found in Madera. 18. The fringilla with a whitish body and bill, and the prime feathers of the wings and tail greenish. This is the Canary bird of English authors, and is found in the Canary islands. 19. The fringilla with the prime feathers of the wings yellow in the middle, and the fore first chief tail-feathers without spots; but they are yellow at the base, and black at the points. It is the fifkin of English authors, and haunts places where juniper-bushes grow. 20. The brown fringilla, with a flame-coloured crest,
is the brown linnet of Klein. 21. The brown fringilla, with a yellowish bill, is an European bird, as are also the two former. 22. The fringilla, with the prime feathers of the wings, and the chief feathers of the tail black, but white on the edges. It is the greater red-headed linnet of Ray, and is a bird of Europe. 24. The fringilla, with a brown back, and a blue belly and tail, is the blue bellied finch of Edwards; and is found in Africa. 25. The violet-coloured fringilla, with the forehead and under part of the body of a deep yellow colour; the back, neck, prime feathers of the wings, and upper part of the tail are of a bluish black colour; but the forehead, breast, belly, and under part of the neck are of a deep yellow. The bill is exceeding short, triangular, black and crooked at the point. 26. The fringilla with the chief feathers of the tail brown, and the outermost marked with a wedge-like spot; the body is variegated with grey and black, and the head is black. It is the reed sparrow of English authors, and is a bird of Europe. 27. The fringilla with the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. This is the house-sparrow of English authors, and is an European bird. 28. The fringilla with the prime feathers of the wings and tail brown, the body variegated with grey and black, and a double white streak on the wings. This is the mountain-sparrow of Ray, and is a bird of Europe. 29. The ferruginous fringilla, with a black head and a blue bill, is the Chinspe sparrow of Edwards. 30. The black fringilla, with a white belly, is the American snow-sparrow of Catesby.

FRINWALT, or Fridland, a town of Brandenburg, sixty miles south-east of Berlin, situated on the west side of the river Oder.

FRIO, a cape or promontory of Brazil: W. long. 44°, and S. lat. 23° 30'.

FRISACH, a town of Bavaria, sixty miles south-east of Salzburg: E. long. 14° 15', and N. lat. 47° 20'.

FRISON, in ornithology. See Loxia.

FRIT, in the glass-manufacture, the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace; or it is the calcined matter to be run into glass. See Glass.

FRITH, in its most usual acceptation, signifies an arm of the sea: such are the frith of Forth or of Edinburgh, the frith of Clyde, Murray frith, &c.

FRITILLARIA, in botany, a genus of the hexandria monogynia class. The corolla consists of six bell-shaped petals, with a hollow nectarium above the unguis of each petal; and the stamina are of an equal length with the petals. There are five species, only one of which is a native of Britain, viz. the melegaris or common checkered daffodil.

FRIUJLI, a province of Italy, subject to Venice, and bounded by Carniola in Germany on the north, by Carniola on the east, by the gulph of Venice on the south, and by the Bellunese and Feltrin on the west.

FRIZING of cloth, a term, in the woollen manufactory, applied to the forming of the nap of a cloth, or fluff, into a number of little hard burrs or prominences, covering almost the whole ground thereof.

Some cloths are only frized on the back side, as black cloths; others on the right side, as coloured and mixed cloths, rateens, bays, freezes, &c.

Frizing may be performed two ways; one with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument.

The other way is by a mill, worked either by water, or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equally and regularly.

FRIBISHER'S STRAITS, in west Greenland, lie a little to the northward of Cape Farewell: W. long. 48°, and N. lat. 63°.

FRODINGHAM, a market-town of Yorkshire, thirty miles east of York.

FRODSHAM, a market-town of Chester, fourteen miles north-east of Chester.

FROG, in zoology. See RANA.

FRONT, in geography. See Geography, p. 152.

FRONTIGNAC, a town of Languedoc in France, situated sixteen miles south-west of Montpelier, and remarkable for producing excellent wine.

FRONTIER, the border, confine, or extremity of a kingdom or province, which the enemies find in front, when they would enter the same: thus we say, a frontier town, a frontier province, &c.

Frontiers were anciently called marches.

FRONTIS, in anatomy. See Anatomy, p. 152.

FRONTIGNIAC, a town of Languedoc in France, situated sixteen miles south-west of Montpelier, and remarkable for producing excellent wine.

FROST, in physiology, such an excessively cold state of the air as converts watery fluids into ice.

In very cold snowy weather, not only water, but urine, beer, ale, milk, vinegar, and even wine, are either wholly or in part converted into ice, though the last but slowly. As to the freezing of expressed oils, a very intense cold may deprive them of their fluidity, so as to be capable of being cut into portions of any figure; but whether they are convertible into real ice, is not yet determined. In Russia oil freezes much harder than with us, but does not even there become perfect ice. Common annised-water, and the like weak spirits, are said to be converted into an imperfect ice in Mufcovy; and the strong spirits into a substance like that of oil. When brandy freezes, a liquid part, much stronger than common brandy, retires to the centre of the vessel.

Even solid bodies are liable to be affected by frost: timber is often apparently frozen, and rendered exceedingly difficult to saw. Marl, chalk, and other sorts solid terrestrial concretions, will be shattered by strong and durable frosts. Metals are contracted by frost: thus, an iron tube, twelve feet long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, it swells or dilates fluids near one tenth of their bulk. Mr. Boyle made several experiments with metalline vessels, exceeding thick and strong; which being filled with water, cold stopped, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently
FROTH, a white, light substance, formed on the surface of fluids, by vehement agitation, consisting of little spherules, or globules.

***FROST***, or Cuckow spit, a name given to a white froth, or spume, very common, in the spring and first months of the summer, on the leaves of certain plants, particularly on those of the common white field lynchnis or catch fly, thence called by some flatting poppy.

All writers on vegetables have taken notice of this froth, though few have understood the cause or origin of it till of late; being formed by a little leaping animal, called by some the flea grafs-hopper, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which containing some air in it is soon elevated into a small bubble: before this is well formed, it depôsites such another drop, and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see.

FRUCTIFEROUS, signifies properly any thing that produces fruit.

FRUCTIFICATION, among botanists, in a mere lax sense, includes the flower and fruit, with their several coverings. See Botany.

FRUIT, in general, includes whatever the earth produces for the nourishment and support of man, and other animals; as herbs, grain, hay, corn, &c.

FRUIT, more properly, signifies the production of a tree, or plant, for the propagation or multiplication of its kind; in which sense the word takes in all kinds of seeds with their furniture. But botanists usually understand by it that part of a plant wherein the seeds are contained.

FRUIT also implies an assemblage of seeds in a head; as in a ranunculus, &c. and all kinds of seeds, or grains, whether inclosed in a cover, capstrule, or pod; and whether bony, fleshy, skinny, membranous, or the like.

See Agriculture, Part I.

FRUMENTACEOUS, a term applied by botanists to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

FRUMENTARII, a kind of soldiers, or archers, under the western empire.

In cold countries, the froth proves often fatal to mankind; not only producing cancers, but even death itself. Those who die of it have their hands and feet first seared, till they grow past feeling it; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, viz. by freezing the abdomen and vifera, which on dissection are found to be mortified and black.

Hoar-Frost, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy crystals of various figures. Hoar-frost therefore is nothing but dew, turned into ice by the coldness of the air.
F U L.

collected all the corn from the several provinces to furnish the common-wealth.

FRUMENTATION, in Roman antiquity, a largesf of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans; and frequently used to sooth the turbulent humour of the populace. At first the number of those to whom this largesse was given, was indeterminate, till Augustus fixed it at two hundred thousand.

FRUFL, or FROG, among farriers, a sort of tender horn which arises in the middle of a horse's sole; and, at some distance from the toe, divides into two branches, running towards the heel in the form of a fork. FRY, in zoology, signifies the spawn, or rather young, of fish.

FUCUS, in botany, a genus of submarine plants, belonging to the cryptogamia class.

The focus consists of a tough matter, formed into a kind of leaves, which are flat and variously divided; and which have some appearance of fructification, in punctuated tubercles, covering oblong vessels, supposed by Linæus to be male flowers; and smooth roundish vessels, hollow and interwoven with filaments, which appear to him to be female flowers. There are thirty-four species of fucus, or sea wrack, many of them to be found on our coasts.

FUEL, whatever is proper to burn or make a fire; as, wood, turfs, peats, bituminous earths, coals, &c.

FULCARE, in Roman antiquity, a feast feepaed by some to be the same with the fugalia was the fame with the feufl, of fugia, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery.

FULGATE, in music, is when different parts of a musical composition follow each other; each repeating what the first had performed.

FULCRUM, in mechanics, the prop or support by which a lever is fulfilled. See MECHANICS.

FULD, a town and abbey of Germany, the abbot of which is a prince of the empire: E. long. 9° 35', N. lat. 50° 34'.

FULICA, the coot, in ornithology, a genus of birds, of the order of gallin. It has a convex bill, with the upper mandible fornicated over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald, and the feet have four toes a little lobated. There are four species.

1. The Fulica with a bald forehead, a black body, and lobated toes. It is the coot of Ray, and an inhabitant of Europe, and feeds upon seeds and herbs, and runs as well as swims upon the water.

2. The fulica with a bald forehead, and toes without webs.

It is the water-hen, or moor-hen of Ray, and is found in Europe. 3. The fulica with a bald forehead, a violet-coloured body, and toes without webs, is the purple water-hen of Edwards, and it inhabits Asia and America. 4. The fulica with a carunculated forehead, a variegated body, spiny shoulders, and toes without webs; but the nail on the hind toe is exceeding long. It is the spur-winged water-hen of Edwards, and is an inhabitant of South America. The nail on the hind toe is strait, and longer than a man's finger. The pollex reaps upon one joint, and the wings are green.

FULIGINOUS, whatever proceeds from a thick, footy smoke, such as litharge and lamp black.

FULIGNO, a city of Italy, in the pope's territories, ten miles north of Spoletto.

FULIGO, in natural history, a species of pumice-stone. See Pumice.

FULLER, a workman employed in the woollen manufactories, to mill or scour cloths, Serges, and other stuffs, in order to render them more thick, compact, and durable. See CLOTH.

FULLER'S EARTH, in natural history, a soft, greyish, brown, dense, and heavy marle: when dry, it is of a greyish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast: it is very hard and firm, of a compact texture, of a rough and somewhat dusty surface that adheres slightly to the tongue: it is very soft to the touch, not flaining the hands, nor breaking easily between the fingers: it has a little harshness between the teeth, and melts freely in the mouth: thrown into water, it makes no effervescence with aqua fortis.

It is of great use in scouring cloths, stuffs, &c. imbuing all the grease and oil used in preparing, dressing, &c. of the wool, for which reason it is made a contraband commodity, and is not to be exported under the penalty of 1 s. for every pound weight. See FULLING.

FULLER'S WOOD, in botany. See Dipsacus.

FULLERY, a place where cloths, &c. are fulled. See the next article.

FULLING, the art or act of scouring and pressling cloths, stuffs, fengers, &c. to cleanse, thicken, and render them more firm and strong, which is done by means of a water mill.

Fuller's earth is used with some proportion of soap; but soap alone would do much better, was it not dearer than fuller's earth.

Fulling of fencers, caps, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or those of horses or bullocks. The ingredients generally used on this occasion are fuller's earth, urine, white soap and green soap. But water sooted with chalk is far preferable.

FULMINATING, something that thunders, or resembles thunder.

FULMINATION, in chemistry, is used in a synonymous sense with detonation.

Fulmination,
Fulmination in the depuration of the more perfect metals, is, when, upon infusing them with lead, a brighter colour succeeds a kind of sulphureous cloud, before appearing in the metals, during the fusion.

Fulmination, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed, that some bull sent from the pope shall be executed.

Fumaria, in botany, a genus of the diadelphia hexandria class. The calix consists of two leaves, and the corolla is ringent. There are 11 species, three of them natives of Britain, viz. the officinalis, or fumitory; the capreolata, or ramping fumitory; and the clavicula, or climbing fumitory.

The whole plant of the officinalis is used in medicine, being accounted good in the scurvy, jaundice, and disorders of the spleen.

Fumigation, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded, or softened, by receiving certain fumes for that purpose.

Fumigation, in medicine, the application of fumes to particular parts of the body; as those of fæctitious cinnabar, to venereal ulcers.

Fumitory, in botany. See Fumaria.

Funchal, the capital of the Madeira islands, subject to Portugal: W. long. 16°, N. lat. 32° 33'.

Function, the act of fulfilling the duties of any employment.

Function, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The vital functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The natural functions are such as it cannot subsist any considerable time without them, as the digestion of the aliment, and its conversion into blood. Under animal functions are included the sense of touching, tasting, &c. memory, judgment, and voluntary motion, without any, or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles, and this action consists chiefly in the shortening the fleshy fibres, which is called contraction, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

In short, all parts of the body have their own functions, or actions peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exercise of them.

Fund, in commerce, signifies the flocks of the great trading and monopoly companies. See Stocks.

Fundament, in anatomy. See Anus.

Fundey Bay, that situated between New England and New Scotland, in which there is said to be an excellent fishery.

Funen, the second island for magnitude belonging to the king of Denmark, situated at the entrance of the Baltic sea, and separated from Jutland by the strait called the lesser Belt, and from the island of Zeland by the strait called the great Belt. Its chief town is Odense.

Vol. II. No. 53.
Funeral games, a part of the ceremony of the ancients, and fatten it in that posture with a firing; because the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a speech to the dead in the following terms: “Blessed be God, who has formed thee, fed thee, maintain thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life, &c.” Then they spoke the eulogium, or funeral oration, of the deceased; after which they paid a prayer, called the righteousness of judgment; then turning the face of the deceased towards heaven, they called out, “Go in peace.”

The ancient Christians testified their abhorrence of the Pagan custom of burning the dead; and always deposited the body entire in the ground: and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral attire. The exportation, or carrying forth of the body, was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of Psalms, was the great ceremony used in all funeral processions among the ancient Christians.

In the Roman church, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the miserere, and some other psalms; and at the end of each psalm a requiem. We learn from AleCio’s ritual, that the feet of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers; after the office for the dead; mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the Greek church, are much the same with those of the Latin. It needs only be observed, that after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased; after which each of the company eats a bit of bread, and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

 Funeral games, a part of the ceremony of the ancient funerals.

It was customary for persons of quality, among the ancient Greeks and Romans, to institute games with all sorts of exercises, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus’s funeral games, take up the greatest part of one of Homer’s Iliads; and Agamemnon’s ghost is introduced by the same poet telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks, mostly consisted of horse-races; the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The garlands, given to victors on this occasion, were usually of purple, which was thought to have some particular relation to the dead.

Those games, among the Romans, consisted chiefly of proceedings; and sometimes of mortal combats of gladiators around the funeral pile. They, as well as the Greeks, had also a cultum, though very ancient, of cutting the throats of a number of captives before the pile, as victims to appease the manes of the deceased. Caesar relates, that the Gauls had this custom.

The funeral games were abolished by the emperor Claudius.

Funeral oration, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

Fungibles, in Scots law, are such things as are estimated by number, weight, or measure; as, coin, butter, ale, &c.

Fungus, in surgery, denotes any spongy excrescence. See Surgery.

Fungus, in botany. See Botany, p. 636.

Furca, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced his servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor, having his head fastened to the furca, was whipped to death.

Furche', in heraldry, a cross forked at the ends.

Furies, in pagan antiquity, certain goddesses whose office it was to punish the guilty after death. These were three in number; Aleöto, Megara, and Tiphophone, who were descried with snakes instead of hair, and eyes like lightening, carrying iron-chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish the guilty; and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tiphophone punished the crimes which sprang from hatred or anger; Megara, those from envy; and Aleöto, those from an inatable pursuit after riches and pleasure. They were worshiped at Caefina in Aecadía, and at Carmia in Peloponnesus.
FUR (39)

FUR, or Boil, in surgery, a small being tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin.

FURZE, in botany. See Ulex.

FUSANUS, in botany. See Euonymus.

FUSAROLE, in architecture, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSEE, in clock-work, is that conical part drawn by the spring, and about which the chain or firing is wound; for the use of which, see Watch.

FUSEE, or Firelock. See Musquet.

FUSIBILITY, in natural philosophy, that quality of bodies which renders them fusible.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as it were whaled on one side.

FUSTICK, or Fustock, a yellow wood, that grows in all the Caribbee islands, used in dying yellow. It pays no duty on importation.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

FUTURE, in general, denotes whatever regards futurity, or the time to come.
are seven cylindrical rays in the branchiostegite membrane; the body is oblong, with deciduous scales; the whole fins are covered with the common skin of the fish; the rays of the back-fins are blunt, and those of the breast are sharp. There are seventeen species, principally distinguished by their cirri, and the number of back-fins.

**GAGE** in the sea-language. When one ship is to windward of another, the is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water, is the ship's gage.

**GAGE** among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, spaces, &c. of the different sorts of letters. See **FOUNDEY**.

**Sliding-Gage**, a tool used by mathematical instrument-makers, for measuring and setting off distances.

**Sea Gage**, an instrument invented by Dr Hales and Dr Defaguilers, for finding the depth of the sea, the description whereof is this. AB (Plate LXXXVI. fig. 1. N° 1.) is the gage bottle, in which is cemented the gage-tube FF in the brass cap at G. The upper end of tube F is hermetically sealed, and the open lower end f is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass HG, pierced with several holes, to admit the water into the bottle AB. The body K is a weight hanging by its shank L, in a socket N, with a notch on one side at m, in which is fixed the catch l of the spring S, and passing through the hole L, in the shank of the weight K, prevents its falling out when once hung on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full-blown bladder I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument, thus constructed, is used in the following manner: The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket N is somewhat longer than the shank L, and therefore, after the weight K comes to the bottom, the gage will continue to descend, till the lower part of the socket strikes against the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K; when this is done, the ball or bladder I, instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube FF, and the height to which it has been forced by the greatest pressure, viz. that at the bottom, will be shewn by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shews into what space the whole air in the tube FF is compressed; and consequently the height or depth of the water, which by its weight produced that compression, is the thing required.

If the gage-tube FF be of glass, a scale might be drawn on it with the point of a diamond, shewing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is no more than 534 feet, which is not half a quarter of a mile.

If, to remedy this, we make use of a tube fifty inches long, which for strength may be a musket-barrel, and suppose the air compressed into an hundredth part of half an inch; then by saying, as 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the Doctor contrived a new form for his sea gage, or rather for the gage-tube in it, as follows: BCDF (ibid. N° 2.) is a hollow metallic globe communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube; therefore, to answer that end; a slender rod of metal or wood, with a knob on top of the tube AB, will receive the mark of the treacle, and shew it, when taken out.

If the tube AB be 50 inches long, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. 2½ inches, which correspond to 6600 which is a mile and a quarter. Again, half that space, or 1½ inch, will shew double the former depth, viz. 73200 feet, or 2½ miles, which is probably very nearly the greatest depth of the sea.

**GAIETA**, a strong fortified town of the kingdom of Naples in Italy, thirty-five miles north-west of the city of Naples: E. long. 14° 30', and N. lat. 41° 20'.

**GAINSBOROUGH**, a market-town of Lincolnshire, fourteen miles north-west of Lincoln; which gives the title of earl to the noble family of Noel.

**GAIOPHRAGMIA**, in natural history, a genus of septrae, divided by septae or partitions of earthy matter, of which there are several species. See **SEP'TARIE**.

**GALACTITES**, in natural history, the name by which the ancients called a smooth, ash-coloured, indurated kind of clay, said to have been used with success for defluxions and ulcers of the eyes, and as an astringent.

**GALANGALS**, in the materia medica, the name of a root.
GALILEANS, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, efferentiating its indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrollment of all the subjects of the Roman empire.

They pretended that God alone should be owned as Master and Lord; and in other respects were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

GALL, in the animal economy. See BILE.

GALL-BLADDER. See Anatomy, p. 269.

Gall, in natural history, denotes any tumour or tumour produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

The general history of galls is this: an insect of the fly kind is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: the for this purpose wounds the leaves or tender branches of a tree; and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The hole in each of these tumours, through which the fly has made its way, may for the most part be found; and when it is not, the maggot inhabitant or its remains are sure to be found within, on breaking the gall. However, it is to be observed, that in those galls which contain several cells, there may be insects found in some of them, though there be a hole by which the inhabitant of another cell has escaped.

Oak galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows stronger, becomes black; and on this property depends the art of making our writing ink, as also a great deal of the dyeing and dressing leather, and other manufactures.

In medicine, galls are found to be very astringent, and good, under proper management, in diarrhoeas, dysenteries, and hemorrhages of all kinds; they have also a very eminent virtue as a febrifuge.

GALLERY, in architecture, a covered place in a house, much longer than broad, and usually in the wings of a building; its use being chiefly to walk in.

GALLERY, in fortification, a covered walk across the ditch of a town, made of strong beams, covered over with planks, and loaded with earth: sometimes it is covered with raw hides to defend it from the artificial fires of the besieged.
Gallery, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

Galley, in naval affairs, a low-built vessel, using both sails and oars, and commonly carrying only a main-mast and fore mast, which may be struck or lowered at pleasure. Such vessels are much used in the Mediterranean, especially by the king of France. See Ship.

Galli, in antiquity, the priests of the goddess Cybele, who were eunuchs, and took their name from Gallus, a river in Phrygia.

When a youth was to be initiated into this order, the custom was to throw off his clothes, to run crying aloud into the midst of the troop, and then drawing a sword to caltrate himself; after this, he ran about the streets, carrying in his hands the marks of his mutilation, which he was to throw into a house, and in that house to put on a woman's dress.

Gallician, any thing belonging to France: thus the term Gallician church denotes the church of France, or the assembly of the clergy of that kingdom.

Gallicism, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages.

Gallinaceus, an appellation given to the birds of the order of the gallinæa.

Gallina, in ornithology. See Scolopax.

Gallion, or Galleon, in naval affairs, a fort of ships employed in the commerce of the West Indies. The Spaniards send annually two fleets: the one for Mexico, which they call the flota, and the other for Peru, which they call the gallions. See Flota.

Gallet, a small galley designed only for chase, carrying only one mast, and two or three patteneroes; it can both sail and row, and has sixteen or twenty oars. All the men on board are soldiers, and each has a musket by him on quitting his oar.

Gallipago-islands, are situated in the Pacific Ocean on both sides the equator, between 85° and 90°. W. long., and about four hundred miles west of Peru.

Gallipoli, a port town of European Turkey, situated at the entrance of the Propontis, or Sea of Marmora, about 100 miles south-west of Constantinople: E. long. 28°, and N. lat. 40° 45'.

Gallipoli is also a port town of the kingdom of Naples, situated on the gulf of Otranto, about twenty-three miles west of that city: E. long. 19°, and N. lat. 40° 25'.

Gallium, ladies-bedstraw, in botany, a genus of the tetrântera monogynia class. The corolla consists of one plane petal; and the seeds are two, and round. There are 23 species, 11 of them natives of Britain, viz. the verum, or yellow ladies-bedstraw; the mollugo, or wild madder; the montanum, or mountain ladies-bedstraw; the uliginosum, or marsh goosef.

Gallo, an island on the Pacific Ocean near the coast of Peru, about 200 miles west of Popayan: W. long. 80°, and N. lat. 2° 15'.

Gallo is also a town of Italy, ten miles south of Ancona.

Gallo, or Punto Gallo, a sea-port of Ceylon, subject to the Dutch: E. long. 78°, and N. lat. 6°.

Gallon, a measure of capacity both for dry and liquid things, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: for instance, the wine gallon contains 231 cubic inches, and holds eight pounds avoirdupois, of pure water: the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter avoirdupois, of water: and the gallon for corn, meal, &c. 2732 cubic inches, and holds nine pounds thirteen ounces of pure water.

Gallopa, in zoology. See Melanagris.

Galloway, a county of Scotland, which gives the title of earl to a branch of the noble family of Stuart.

It is divided into two districts; the western, called Upper Galloway, being the same with Wigtownshire; and the eastern, or stewartry of Kirkudbright, called Lower Galloway.

Galloway is also the capital of a county of the same name, in the province of Connaught, in Ireland: W. long. 6° 12', and N. lat. 53° 12'.

It has a good port, and is advantageously situated for foreign trade.

Gallus, in ornithology. See Phasianus.

Gally, in printing, a frame into which the compositor empties the lines out of his composing flick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom, called a gally-flice.

Gambia, a great river of Africa, which, running from east to west falls into the Atlantic ocean, 14° N. lat. and 15° W. lon.

Gamboge, is a concreted vegetable juice, the produce of two trees, both called by the Indians caracapalli, and is partly of a gummy, and partly of a resinous nature. It is brought to us either in form of orbiculi, or of cylindrical rolls of various sizes; and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambodia, in the East Indies, called also Cambodja, and Cambogia; and from thence it has obtained its names of cambadium, cambogiiam, and gambogium.

It is a very rough and strong purge; it operates both by vomit and flux, and both ways with much violence, almost in the infant in which it is swallowed; but yet without griping. It requires caution and judgment in administering it; but those who know how to give it properly,
GAME, in general, signifies any diversion, or sport, that is performed with regularity, and restrained to certain rules. See Gaming.

Games, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Iphthian, Nemean, &c. games; and, among the Romans, the Apulianarian, Circenian, Capitoline, &c. games. See Olympic, Pythian, &c.

GAME, in law, signifies birds or prey, taken or killed by fowling, or hunting. There are several statutes for punishing offences committed by persons not qualified by law to take or destroy the game.

GAME-COCK, a fighting cock, or one kept for sport; a barbarous practice, which is a disgrace to any civilized nation.

GAMELIA, in Grecian antiquity, a nuptial feast, or solemn occasion. Such, among the Greeks, were presenting their hair to some deity to whom they had particular obligations.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing twenty-nine days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper leaft of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazard, as cards, dice, tables, &c.

Mr de Molure, in a treatise de Mensura Sortis, has computed the variety of chances in several cafes that occur in gaming, the laws of which may be understood by what follows.

Suppose $p$ the number of cases in which an event may happen, and $q$ the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as $p$ to $q$.

If two gamblers, A and B, engage on this footing, that, if the cases $p$ happen, A shall win; but if $q$ happen, B shall win, and the stake be $a$: the chance of A will be $\frac{p}{p+q}$, and that of B $\frac{q}{p+q}$; consequently, if $p+q=b$, they sell the expectancies, they should have that for them respectively.

If $A$ and $B$ play with a single die, on this condition, that, if A throw two or more aces at a sight throws, he shall win; otherwise B shall win: what is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let $a=1$, and $b=5$. And, again, since there are eight throws of the die, let $a=8$; and you will have $a=8^7$, $b=8^8-a=8^7-1$, to $b=8^9-a=8^8-1$: that is, the chance of A will be to that of B, as 662991 to 10156525, or nearly as 2 to 3.

A and B are engaged at single quoits; and, after playing some time, A wants 4 of being up, and B 6; but B is so much the better gamerster, that his chance against A upon a single throw would be as 3 to 2: what is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise $a+b$ to the ninth power, and it will be $a^9 + 9a^8b + 36a^7b^2 + 84a^6b^3 + 126a^5b^4 + 126a^4b^5 + 84a^3b^6 + 36a^2b^7 + 9ab^8 + b^9$; call $a, b, c, d$ the numbers of cases wherein A may happen, and $q$ the number of cases wherein it may not, let $a=3$, and $b=2$, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at single quoits, and A is the best gamerster, so that he can give B 2 in 3, what is the ratio of their chances at a single throw? Suppose the chances as 2 to 1, and raise $z+1$ to its cube, which will be $z^3 + 3z^2 + 3z + 1$. Now since A could give B 2 out of 3, A might undertake to win three throws running; and, consequently, the chances in this case will be as $z^3$ to $z^3 + 3z^2 + 3z + 1$. Hence $z^3 = 3z^2 + 3z + 1$; or, $z^3 = z^3 + 3z^2 + 3z + 1$. And, therefore, $z^3 = z^3 + 3z^2 + 3z + 1$; and, consequently, $z = \frac{1}{\sqrt{2} - 1}$. The chances, therefore, are $\frac{1}{\sqrt{2} - 1}$, and $1$, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4, what is the probability I win both wagers?

1. The probability of winning the first is $\frac{3}{4}$, that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is $\frac{4}{7}$; therefore, multiplying these two fractions together, the product will be $\frac{12}{28}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{16}{28}$, which is the probability I do not win both wagers: therefore the odds against me are 24 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is $\frac{3}{4}$, the probability of losing the second is $\frac{1}{4}$; therefore multiplying these two fractions together, the product $\frac{3}{4} \times \frac{1}{4}$ will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain $\frac{7}{4}$, which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: the probability of winning the second is $\frac{7}{4}$; the probability of losing the first is $\frac{1}{4}$; therefore, multiplying these two fractions together, the product $\frac{7}{4} \times \frac{1}{4}$ is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{3}{4}$, and the probability of losing the second $\frac{4}{7}$; therefore, the probability of losing them both is $\frac{12}{28}$; which being subtracted from 1, there remains $\frac{16}{28}$; therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration.
deration. Thus if I would know what the probability  
of missing an ace four times together with a die, this  
I consider as the failing of four different events. Now  
the probability of missing the first is $\frac{4}{6}$, the second is  
also $\frac{4}{6}$, the third $\frac{4}{6}$, and the fourth $\frac{4}{6}$; therefore the probability of missing it four times together is $\frac{4 \times 4 \times 4 \times 4}{6 \times 6 \times 6 \times 6}$; which being subtracted from 1, there will remain \[ \frac{1}{6^4} \] for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three  
times, the probability of missing it three times would be $\frac{4 \times 4 \times 4}{6 \times 6 \times 6} = \frac{4^3}{6^3}$; which being subtracted from 1, there will remain $\frac{27}{6^3}$, for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is $\frac{4}{6}$, and of missing it the other three times is $\frac{2 \times 2 \times 2}{6 \times 6 \times 6}$, it follows that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{4 \times 2^3}{6^4} = \frac{1}{6^2}$; but because it is possible to hit it every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing the other three, is $4 \times \frac{2^3}{6^4} - \frac{500}{1296}$; which being subtracted from 1, there will remain $\frac{496}{1296}$, for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has  
twice as many chances to come up as the other, what  
is the probability that the event, which has the greater  
number of chances to come up, does not happen twice  
before the other happens once, which is the cafe of  
slinging 7 with two dice before 4 once? Since the  
number of chances are as 2 to 1, the probability of  
of the first happening before the second is $\frac{3}{4}$, but the probability of its happening twice before it is $\frac{3 \times 3}{4^2}$ or $\frac{9}{16}$; therefore it is 5 to 4 even does not come up twice  
before four once.

But, if it were demanded, what must be the proportion  
of the facilities of the coming up of two events, to make that which has the most chances come  
ung twice, before the other comes up once? The answer is 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{4}{7}$, and the probability of throwing it twice is $\frac{4^2}{7^2}$, or $\frac{16}{49}$; therefore the probability of not doing it is $\frac{33}{49}$; therefore the odds against it are as 145 to 44, which comes very near an equality.

Suppose there is a heap of thirteen cards of one  
colour, and another heap of thirteen cards of another  
colour, what is the probability that, taking one card  
at a venture out of each heap, I shall take out the two  
aces?

The probability of taking the ace out of the first  
heap is $\frac{4}{13}$, the probability of taking the ace out of the  
second heap is $\frac{4}{13}$; therefore the probability of taking out both aces is $\frac{4}{13} \times \frac{4}{13} = \frac{16}{169}$, which being subtracted from 1, there will remain $\frac{153}{169}$; therefore the odds against me are 163 to 1.

In cafes where the events depend on one another, the  
manner of arguing is somewhat altered. Thus, suppose  
that out of one single heap of thirteen cards of one  
colour I should undertake to take out first the ace; and,  
secondly, the two: though the probability of taking  
out the ace be $\frac{1}{13}$, and the probability of taking  
out the two be likewise $\frac{1}{13}$; yet, the ace being suppo  
sed as taken out already, there will remain only twelve  
cards in the heap, which will make the probability of  
taking out the two to be $\frac{1}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13} \times \frac{1}{12}$.

In this last question the two events have a dependence  
on each other, which consults in this, that one of the  
events being supposed as having happened, the probabil  
ity of the other's happening is thereby altered. But  
the case is not so in the two heaps of cards.

If the events in question be $n$ in number, and be  
such as have the same number $a$ of chances by which  
they may happen, and likewise the same number $b$ of  
chances by which they may fail, raise $a + b$ to the pow  
er $n$. And if A and B play together, on condition  
that if either one or more of the events in question  
happen, A shall win, and B lose, the probability of  
A's winning will be $\frac{a+b^n}{a+b^n}$; and that of B's  
winning will be $\frac{b^n}{a+b^n}$; for when $a+b$ is actually  
raised to the power $n$, the only term in which $a$ does  
not occur is the last $b^n$: therefore all the terms but  
the last are favourable to A.

Thus if $n=3$, raising $a+b$ to the cube $a^3+3a^2b+3ab^2+b^3$, all the terms but $b^3$ will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3+3a^2b+3ab^2+b^3}{a+b}$; or $\frac{a+b^3}{a+b}$; and the probability  
of B's winning will be $\frac{b^3}{a+b}$.

But if A and B play on condition, that if either two or more of the events in question happen, A shall win; but in case  
one only happen, or none, B shall win; the probability  
of A's winning will be $\frac{a+b^n-na-b^{n-1}}{n+b^n}$; for  
the only two terms in which $aa$ does not occur, are the  
two laft, viz. $na-b^n-1$ and $b^n$.

GAMMUT, in music, a scale wherein we learn to found  
the musical notes, ut, re, mi, fa, sol, la, in their fev  
eral orders and dispositions. See Music.

Gang-way is the several passages or ways from one part  
of the ship to the other; and whatever is said in any  
of those passages, is said to lie in the gang-way.

GANGEA, the capital of a territory in the province of  
'Chirvan, in Persia: E. long. 46°, N. lat. 41°.
GANGES, a large river of the hither India, rises in the mountains which separate India from Tartary; and, running from the north west to the south east near 1500 miles through the Mogul’s dominions, discharges itself by several channels into the bay of Bengal.

GANGI, or Coulor, a town of Golconda, in the hither India: E. long. 70°, and N. lat. 16°.

GANGLIO, or Ganglion, in surgery, a hard tubercle, generally movable, in the external or internal part of the corpus, upon the tendons or ligaments in that part, usually without any pain to the patient.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. See Medicine and Surgery.

GANTLET, or Gauntlet, a large kind of glove, made of iron, and the figures covered with small plates. It was formerly worn by cavaliers, when armed at all points.

GAOL, a prison, or place of legal confinement.

GAOL DELIVERY, is where a commission or patent is granted by the king in the nature of a letter, to certain persons, who are thereby appointed his justices, or to two or three of them, authorizing them to deliver his gaol, at such a place, of the prisoners contained therein; and for that end it commands them to meet at such a place, at the time they themselves shall appoint, when the sheriff of the county is commanded to bring all the prisoners in the gaol before them, &c.

GAP, a city and bishop’s see of Dauphine, in France, sixteen miles west of Embrun: E. long. 5° 46’, N. lat. 44° 32’.

GARBE, in heraldry, a sheaf of any kind of grain, bore in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

GARCINIA, in botany, a genus of the icofandria monogyria clafs. The flower consists of four roundish patent petals; and the fruit is a large unilocular coriaceous berry, containing eight hairy and fleshy seeds, convex on one side, and angular on the other. There are two species, none of them natives of Britain.

GARDA, a town of the Veronese, in Italy, subject to Venice: E. long. 11°, N. lat. 45° 25’.

GARDANT, or Guardant, in heraldry, denotes any beast full faced, and looking right forward. See Plate LXXXVII. fig. 6. which represents a lion gardant.

GARDELBERGEN, a town of Bradenburg, in Germany: E. long. 11° 45’, N. lat. 52° 40’.

GARDENING.

GARDENING, a branch of agriculture, containing the cultivation of gardens.

The simplest idea of a garden, is that of a spot embellished with a number of natural objects, trees, walks, polished parterres, flowers, freams, &c. One more complex comprehends statues and buildings, that nature and art may be mutually ornamental. A third approaching nearer perfection, is of objects assembled together, in order to produce, not only an emotion of beauty, essential to every garden, but also some other particular emotion, grandeur for example, or gaiety. The most perfect idea of a garden is an improvement upon the third, requiring the several parts to be arranged in such a manner, as to inspire all the different emotions that can be raised by gardening. In this idea of a garden, the arrangement is an important circumstance; for some emotions figure best in conjunction, and others ought always to appear in succession and never in conjunction. When the most opposite emotions, such as gloominess and gaiety, stillness and activity, follow each other in succession, the pleasure on the whole will be the greatest; but such emotions ought not to be united, because they produce an unpleasant mixture. For that reason, a ruin, affording a sort of melancholy pleasure, ought not to be seen from a flower-parterre, which is gay and cheerful; but to pass from an exhilarating object to a ruin, has a fine effect: for each of the emotions is the more sensibly felt by being contralled with the other. Similar emotions, on the other hand, such as gaiety and sweetnefs, stillness and gloominess, motion and grandeur, ought to be raised together; for their effects upon the mind are greatly heightened by their conjunction.

Kent’s method of embellishing a field, is admirable; which is, to paint a field with beautiful objects, natural and artificial, disposed like colours upon a canvas. It requires indeed more genius to paint in the gardening way: in forming a landscape upon a canvas, no more is required but to adjust the figures to each other: an artifcl who lays out ground in Kent’s manner, has an additional talk: he ought to adjust his figures to the several varieties of the field.

One garden must be distinguished from a plurality; and yet it is not obvious wherein the unity of a garden consists. A notion of unity is indeed suggested from viewing a garden surrounding a palace, with views from each window, and walks leading to every corner: but there may be a garden without a house; in which case, what makes it one garden, is the unity of design, every single spot appearing part of a whole. The gardens of Versailles, properly expressed in the plural number, being no fewer than sixteen, are indeed all of them connected with the palace, but have scarce any mutual connection: they appear not like parts of one whole, but rather like small gardens in contiguity. Were these gardens at some distance from each other, they would have a better effect: their junction breeds confusion of ideas, and upon the whole gives less pleasure than would be felt in a flower succession.
Regularity is required in that part of a garden which joins the dwelling-houfe; for being considered as a more immediate accoutre, it ought to partake the regularity of the principal object: but in proportion to the distance from the house considered as the centre, regularity ought to be studied; for, in an extensive plan, it hath a fine effect to lead the mind insensibly from regularity to a bold variety. Such arrangement tends to make an impression of grandeur: and grandeur ought to be studied as much as possible, even in a more confined plan, by avoiding a multiplicity of small parts. A small garden, on the other hand, which admits not grandeur, ought to be strictly regular.

Milton, describing the garden of Eden, prefers justly the grand tale to that of regularity:

Flow's worthy of paradise, which not nice art
In beds and curious knots; but Nature boon
Pour'd forth profuse on hill, and dale, and plain;
Both where the morning-run first warmly mote
The open field, and where the unpierc'd shade
Imbrownd the noontide bow'r's. Paradise Lost, b. 4.

An hill, by being covered with trees, appears both more powerful and more lofty: provided no other beauties be hid that might be seen if the hill were naked. To distribute trees in a plain requires more art: near the dwelling-houfe they ought to be fo thin, as not to break the unity of the field; and even at the greatest distance of distinct vision, they ought never to be fo crowded as to hide any beautiful object.

In the manner of planting a wood or thicket, much art may be displayed. A common centre of walks, termed a flar, from whence are seen a number of remarkable objects, appears too artificial, and consequently too fift and formal, to be agreeable: the crowding withal so many objects together, lessens the pleasure that would be felt in a flower succession. Abandoning therefore the star, let us try to substitute some form more natural, that will lay open all the remarkable objects in the neighbourhood. This may be done by various openings in the wood contrived to catch surrounding objects, which in walking bring successively under the eye these objects as by accident; sometimes a single object, sometimes a plurality in a line, and sometimes a rapid succession of them. In this form, the mind at intervals is roused and cheered by agreeable objects; and the scene is greatly heightened by the surprise it occasions when we stumble, as it were, upon objects of which we had no expectation.

An object terminating in a narrow opening in a wood, appears at a double distance. This suggests another rule for distributing trees in some quarter near the dwelling-house; which is, to place a number of thickettes one behind another, with an opening in each directing the eye to the most distant through all the intermediate thickettes; which, by making these thickettes appear more distant from each other than they are in reality, will enlarge in appearance the size of the whole field. To give this plan its utmost effect, the thickettes ought to be at a considerable distance from each other; and, in order that each may be seen distinctly, the opening nearest the eye ought to be wider than the second, the second wider than the third, and so one to the end.

By a judicious distribution of trees, various beauties may be produced, far exceeding what have been mentioned; which will appear as follows. A landscape fo rich as to ingrofs the whole attention, and fo limited as sweetly to be comprehended under a single view, has a much finer effect than the most extensive landscape that requires a wandering of the eye through successive scenes. This consideration suggests a capital rule in laying out a field: which is, never at any one station to admit a larger prospect than can easily be taken in at once. A field so happily situated as to command a great extent of prospect, is a delightful subject for applying this rule: let the prospect be split into proper parts by means of trees; studying at the same time to introduce all the variety possible. A plan of this kind executed with taste will produce charming effects: the beautiful prospects are multiplied: each of them is much more agreeable than the entire prospect was originally: and, to crown the whole, the scenery is greatly diversified.

As gardening is not an invenitive art, but an imitation of nature, or rather nature itself ornamented, it follows necessarily, that every thing unnatural ought to be rejected with disdain. Statues of wild beafts vomiting water, a common ornament in gardens, prevails in those of Versailles. Is this ornament in a good taste? A jet d'eau, being partly artificial, may, without difguise, be tortured into a thousand shapes: but a representation of what really exists in nature, admits not any unnatural circumstance. These flutes therefore of Versailles must be condemned; and yet so inoffensive has the artiff been to justify imitation, as to have displayed his vicious taste without the least colour or difguise: a lifeless statue of an animal pouring out water, may be endured without much difgust; but here the lions and wolves are put in violent action, each has feized its prey, a deer or a lamb, in act to devour; and yet, instead of extended claws and open mouth, the whole, as by a hocus-pocus trick, is converted into a different scene; the lion, forgetting his prey, pours out water plentifully; and the deer, forgetting its danger, performs the fame operation.

In gardening, every lively exhibition of what is beautiful in nature has a fine effect: on the other hand, distant and faint imitations are displeasing to every one of taste. The cutting evergreens in the shape of animals, is a very ancient practice; as appears from the epistles of Pliny, who seems to be a great admirer of this puerile conceit. The propensity to imitation gave birth to this practice: and has supported it wonderfully long, considering how artificial it is. But the vulgar, great and small, devoid of taste, are entertained with the oddness and singularity of a resemblance, however distant, between a tree and an animal. An attempt in gardens of Versailles, to imitate a grove of trees by a group of jets d'eau, appears, for the same reason, not less ridiculous.

In laying out a garden, every thing trivial or whimsical ought to be avoided. Is a labyrinth then to be justified? It is a mere conceit, like that of composing verses in the shape of an ax or an egg: the walks and hedges may be agreeable; but in the form of a labyrinth, they serve to no end but to puzzle; a riddle is a conceit not fo mean; because...
because the solution is a proof of sagacity, which affords no aid in tracing a labyrinth.

The gardens of Verailles, executed with infinite expense by the best artists that could be found, are a lasting monument of a taste the most depraved: the faults above mentioned, instead of being avoided, are chosen as beauties, and multiplied without end. Nature, it would seem, was deemed too vulgar to be imitated in the works of a magnificent monarch; and for that reason preference was given to things unnatural, which probably were mistaken for supernatural.

A straight road is the most agreeable, because it shortens the journey. But in an embellished field, a straight walk has an air of stiffness and confinement: and at any rate is less agreeable than a winding or waving walk; for in surveying the beauties of an ornamented field, we love to roam from place to place at freedom. Winding walks have another advantage: at every step they open new views. In short, the walks in a field intended to please the eye, ought not to have any appearance of a road.

This rule excludes not long straight openings terminating upon distant objects; which openings, beside variety, never fail to raise an emotion of grandeur, by extending in appearance the size of the field: an opening without a terminating object, soon closes upon the eye; but an object, at whatever distance, continues the opening, and seduces the spectator into a conviction, that the trees which confine the view are continued till they join the object: and the object also, as observed above, seems to be at a greater distance than it is in reality. Straight walks also in recesses do extremely well: they vary the scenery, and are favourable to meditation.

An avenue ought not to be directed in a straight line upon a dwelling house: better far an oblique approach in a waving line, with single trees and other scattered objects interposed. In a direct approach, the first appearance continues the same to the end: we see a house at a distance, and we see it all along in the same spot without any variety. In an oblique approach, the interposed objects put the house seemingly in motion: it moves with the passenger, and appears to direct its course so as hospitably to intercept him. An oblique approach contributes also to variety: the house, being seen successively in different directions, takes on at every step a new figure.

A garden on a flat ought to be highly and variously ornamented, in order to occupy the mind, and prevent its regretting the insufficiency of an uniform plan. Artificial mounts in this view are common: but no person has thought of an artificial walk elevated high above the plain. Such a walk is airy, and tends to elevate the mind: it extends and varies the prospect: and it makes the plain, seen from a height, appear more agreeable.

Whether should a ruin be in the Gothic or Grecian form? In the former; because it exhibits the triumph of time over strength, a melancholy but not unpleasant thought: a Grecian ruin suggests rather the triumph of barbarity over taste, a gloomy and discouraging thought.

Fountains are seldom in a good taste. Statues of animals vomiting water, which prevail everywhere, stand condemned. A statue of a whale spouting water upward from its head, is in one sense natural, as whales of a certain species have that power; but it is sufficient to make this design be rejected, that its singularity would make it appear unnatural: there is another reason against it, that the figure of a whale is in itself not agreeable. In the many fountains in and about Rome, statues of fishes are frequently employed to support a large basin of water. This unnatural conceit is not accountable, unless from the connection between water and the fish that swim in it; which, by the way, shows the influence of even the slightest relations.

Hitherto a garden has been treated as a work intended solely for pleasure; or, in other words, for giving impressions of intrinsic beauty. What comes next in order is the beauty of a garden destined for use, termed relative beauty; see Beauty: and this branch shall be dispatched in a few words. In gardening, luckily, relative beauty need never stand in opposition to intrinsic beauty: all the ground that can be requisite for use, makes but a small proportion of an ornamented field; and may be put in any corner without obstruting the disposition of the capital parts. At the same time, a kitchen-garden, or an orchard, is susceptible of intrinsic beauty; and may be so artificially disposed among the other parts, as by variety and contrariety to contribute to the beauty of the whole.

Gardening being in China brought to greater perfection than in any other known country, we shall take a flight view of Chineses gardens, which will be found entirely obsequious to the principles that govern any one of the fine arts. In general, it is an indispensable law there, never to deviate from nature; but in order to produce that degree of variety which is pleasing, every method is used that is consistent with nature. Nature is strictly imitated in the banks of their artificial lakes and rivers; which sometimes are bare and gravelly, sometimes covered with wood quite to the brink of the water. To flat spots adorned with flowers and shrubs are opposed others steep and rocky. We see meadows covered with cattle; rice grounds that run into lakes; groves into which enter navigable creeks and rivulets: these generally conduct to some interesting object, a magnificent building, terraces cut in a mountain, a cascade, a grotto, an artificial rock, or such like. Their artificial rivers are generally serpentine; sometimes narrow, noisy, and rapid; sometimes deep, broad, and slow: and to make the scene still more active, mills and other moving machines are often erected. In the lakes are interperfected islands; some barren, surrounded with rocks and shoals; others enriched with every thing that art and nature can furnish. Even in their cascades they avoid regularity, as forcing nature out of its course: the waters are seen burting from the caverns and windings of the artificial rocks, here an impetuous cataract, there many leffer falls; and the stream often impeded by trees and stones, that seem brought down by the violence of the current. Straight lines are sometimes indulged, in order to take advantage of some interesting object at a distance, by directing openings upon it.

Sensible of the influence of contrast, the Chineses artists deal in sudden transitions, and in opposing to each other, forms, colours, and shades. The eye is conducted from
from limited to extensive views, and from lakes and rivers to plains, hills, and woods: to dark and gloomy colours, are opposed the more brilliant: the different masses of light and shade are disposed in such a manner, as to render the composition distinct in its parts, and striking on the whole. In plantations, the trees are artfully mixed according to their shape and colour; those of spreading branches with the pyramidal, and the light green with the deep green. They even introduce decayed trees, some erect, and some half out of the ground. In order to heighten contrast, much bolder strokes are rifled: they sometimes introduce rough rocks, dark caverns, trees ill formed and seemingly rent by tempests or blasted by lightning, a building in ruins or half consumed by fire. But to relieve the mind from the harshness of such objects, they are always succeeded by the sweetest and most beautiful scenes.

The Chineses study to give play to the imagination. They hide the termination of their lakes: the view of a cascade is frequently interrupted by trees, through which are seen obscurely the waters as they fall. The imagination once roused, is disposed to magnify every object.

Nothing is more studied in Chinese gardens than to raise wonder or surprize. In scenes calculated for that end, every thing appears like fairy-land; a torrent, for example, conveyed under ground, puzzling a stranger by its uncommon found to guess what it may be; and, to multiply such uncommon founds, the rocks and buildings are contrived with cavities and interstices. Sometimes one is led insensibly into a dark cavern, terminating unexpectedly in a landscape inriched with all that nature affords the most delicious. At other times, beautiful walks insensibly conduct us to a rough uncultivated field, where bushes, briars, and stones interrupt the paffage: when we look about for an outlet, some rich prospect unexpectedly opens to view. Another artifice is, to obscure some capital part by trees or other interposed objects: our curiosity is raifed to know what lies beyond; and after a few steps, we are greatly surprized with some scene totally different from what was expected.

These cursory observations upon gardening, shall be clofed with some reflections. Rough uncultivated ground, dismal to the eye, inspirespeevidfulness and discontent: may not this be one cause of the harsh manners of fages? A field richly ornamented, containing beautiful objects of various kinds, displays, in full lufette, the goodnccs of the Deity, and the ample provision he has made for our happiness; which must fill every spectator with gratitude to his Maker, and with benevolence to his fellow-creatures. Other fine arts may be perverted to excite irregular, and even vicious, emotions: but gardening, which inspires the purest and most refined pleasures, cannot but promote every good affection. The gaiety and harmony of mind it produceth, inclining the spectator to communicate his satisfaction to others, and to make them happy as he himself is, tend naturally to establish in him a habit of humanity and benevolence.

Having thus unfolded the general principles of gardening, that have an influence upon taste or manners; we shall now subjoin the practical part, in the form of a calendar.

**January.**

**Flower-Garden.**

This is the proper time for planting roots of the ranunculus; the soil should be rich and sandy, and they should be planted at least three inches deep. By laying a quantity of earth made of old patch or straw, about seven inches beneath the surface of the ground, and then filling it up with rich mould, a prodigious number of these flowers may be produced. A fine earth may likewise be made of tanner's bark, or the bottom of a wood pile, well mixed with about a third of natural soil, which will prove peculiarly serviceable.

As the wind and frost are very prejudicial to carnations and auriculas, they should this month be kept covered.

Anemones should be planted in beds of fine earth; no dung must be used in planting them. The roots of these flowers may be increased by breaking the knots, about the size of a small button, asunder, and letting them lie two or three days in the sun, before you plant them. It should be remembered, that the roots of the anemone are to be taken up about the end of June or the beginning of July; after being dried in the sun, they should be preserved in a dry cool place, or kept in sand for a month, and then put in papers till the season for planting them. When these roots are first transplanted, a thin layer of willow-earth, or rotten sally-wood, being put under them, forwards their growth.

**Fruit-Garden.**

The pruning of pears, vines, and plumbs, is the chief employment of this month. In pruning the pear, those buds which appear fuller than the rest should be carefully preserved; all branches that proceed from the knob, whereon the stalk of a pear grew, are to be taken away, but the knob must remain; and the extremity of the last year's pruning is to be taken off.

As the large branches of a pear-tree are useless in bearing, care should be taken to extend the branches sideways, and none but small branches suffered to grow in the middle, and not even those to grow directly perpendicular, as, by that means, they would soon become what is called great wood.

A pear-tree that is vigorous and luxuriant should not be pruned till after it has begun to shoot. A languishing pear-tree may be restored to its former state by pruning and removal into better ground. Another very good method of treating pear-trees not in a bearing state, is to bark the luxuriant branches all round about a quarter of an inch wide, more or less, according to their strength. Apple-trees will likewise bear this operation, which should be done in April. Trees that are too vigorous may be made to bear by cutting off the sap roots, or taking them up, and re-letting them, for they are often planted.
planted too deep. Plumbs and cherries may be pruned in the same manner as pears.

The winter pruning of the vine (which requires a first, second, third, and sometimes a fourth pruning) should be done either in October, November, December, or this month. The vigour of the vine is to be regarded; the small weak shoots that never bear any fruit must be cleared away, and the other branches are to be so proportioned as not to occasion any confusion; such as are thick and bell placed should be preferred, and the strong short branches left nine inches or more, according to the size of the vine. When they have shot twelve or fifteen inches long, which will be in the summer, you must begin to nail them up, and when they have shot two or three feet, flop or cut off the ends of the shoots; those on the side should not be broke off till the fruit is set: and a fruit bearing branch should be cut within three or four eyes of the fruit.

All suckers should be cut off as soon as they have shot seven or eight inches. The vine should be kept thinner of wood than any other tree, though it puts forth the largest shoots. All the old wood should be cut out, and its place supplied with vigorous young shoots.

All dead or cankered branches should this month be cut from the standard fruit-trees, as also such as cros each other; but in doing this you must be careful to make the wounded part as smooth as possible, and sloping, that the wet may not enter and be detained there, to the great prejudice of the trees.

**Kitchen-Garden.**

The management of hot-beds claims almost the sole attention of the kitchen-gardener this month. The place must exposed to the sun is best for making a hot-bed; when you have marked out the dimensions of the bed, drive stakes into the ground on every side, a yard above the ground, and a foot aunder; wind these round with bands made of hay or straw, and then fill them up with wet litter and new horse-dung, treading it down very hard as you fill; in doing which you must be careful to leave room for the earth and the shooting of your plants.

When you have thus laid the bed, fix your wooden frames fitted to the same, for the reception of the mould at top, and for the support of glass frames, which are to be fixed sloping.

The hot-bed should then be finished by putting in the earth; an old hot-bed, well rotted, affords excellent stuff for this purpose; but if that cannot be procured, some very rich mould well ftted will do.

Over the whole you must fix mats supported by short ficks, which must remain about a week; by which time the bed will abate of its extreme heat, and be of a proper temperature for use.

The bed should be warm, not hot; and when the heat lefens too much, by applying new dung to the sides, you may renew it.

When plants are come up in a hot-bed, they should have air and the sun by degrees; and when frong enough, should be removed to a second hot-bed, of less heat than the former, or into very rich earth, where they should be frequently watered gently, and kept from the meridian sun till well settled; and when the weather is cold, by covering the glaffes a little before sun-set with litter and mats, they may easily be defended from it.

Gardeners in general make their feed beds for cucumbers and melons in this month, for raising them before their natural season; but the better method is, to make hot-beds the latter end of October or beginning of November; about four feet square, and two feet high, is the proper size, wherein, after the heat is moderated, cucumbers and melons may be grown.

About a week after their coming up, plant them four inches apart in the same bed, after having well stirred up the earth. As the days in October are usually warm, the plants may be allowed to have air; but in January they must be kept covered up close. In this first raising of plants, a gardener may, with due care, make them as hardy as he pleases.

It is usual with some people to keep their melon seeds in milk four and twenty hours before they make use of them; others use them without that preparation: they should be set two or three in a hole, in the hot-bed, about an inch deep, and covered close up, to keep them warm. About the end of April is the time for planting melons, which should first be done in small baskets made of old willow-twigs, three inches deep, and eight or nine inches over.

Two or three plants should be planted in one basket, and when they will bear it, moved on another hot-bed, covered with a sandy loam five or six inches thick, sifted fine, wherein they are to grow all the summer.

Cucumbers are propagated after the same manner as melons; but as a bad season may prevent their being successfully raised, it is highly necessary to put some seeds into the bed at three or four different times this month, that if some should fail, the others may supply their loss. In order to raise asparagus for hot-beds, make choice of a piece of ground that has been well dug and mellowed, then strike out lines seven or eight inches from each other, and plant the asparagus roots in them at six or seven inches apart when they are a twelvemonth old: let them be kept free from weeds, and remain in the nursery two years, in which time they will be fit for the hot-bed. The hot-bed for the reception of these roots should be made pretty strong, and covered with earth six inches thick, encompassed round with bands of straw. The asparagus roots should be planted as close as they can be placed together without trimming; which being done, cover the buds of the plants two inches thick with earth; in which state let them remain five or six days before the frames and glaffes are put over them; and then lay on over the whole three inches thick of fresh earth.

As soon as the buds appear, give them what air the season will permit, which will make them green, and of a good taste. The bed will last good about a month, producing daily fresh buds. If the weather be not too severe: when it begins to cool, warm horse-litter laid upon the glaffes every night will contribute so much to facilitate the growth of the buds as if new dung were applied to the roots.
It should be observed, that the time for this work is not only in this month, but from November till April; (making fresh buds every month to follow one another for a constant supply) and in April comes the natural crop.

A very moderate hot-bed made after the manner first directed, will serve to propagate early strawberries.

You may make a bed in two or three hours, with the use of hot lime and powdered dung, the dung being in the middle, and the lime underneath and at top; over which you should lay a quantity of fine rich mould.

To raise radishes in the hot-bed with success, you should have sufficient thickness of rich light mould, that they may have proper depth to root in before they reach the dung.

Radishes may be sowed all the year, but in hot-beds in the winter.

Mustard, lettuce, cresses, and other fallaliing, are generally raised from the seeds sown in drills or lines, in such an exposure as is required by the season of the year; in the winter-season, on moderate hot-beds; in the spring, under glasses and frames; and in the summer, on natural beds of earth.

Cresses sown in the natural ground in August, refill the frosts of the winter, and help greatly to enrich the hot-bed fallals with the high talse they maintain by being exposed to the open air.

Small herbs should be drawn up by the roots from the hot beds; and, in sowing a second crop, seeds of another kind should be sown, and not the same kind in the same place.

The hotspur, charlton matter, and other peas, must be sown in drills three feet asunder, that you may have room to go between them; and the lines should run from north to south.

When they have shot about six inches high, earth them about four inches on both sides of the lines, raising a little bank on the east side of them, to defend them from the blasting winds.

In February you may sow a second crop, and in March a third.

You must, in the beginning of the winter, sow twice the quantity of peas you need to do, if you stay till February or March; because the cold weather and the mice will destroy great part of them.

FEBRUARY.

FLOWER-GARDEN.

For the better management of the auricula, which is to be sown this month, prepare a box of oak or deal, four feet long, two feet wide, and six inches deep, with holes in the bottom, six inches distance from each other; in which, after laying two inches thick of cinders or sea-coals; and spreading over them some earth taken out of hollow willow-trees, till you have filled the box, sow the seeds on the top, without any covering of earth, pressing them into the mould with a flat board, in order to settle them below the edges of the box that the light seeds may not float over the brim in watering.

From the time of sowing to the beginning of April, this box must be placed where it will receive the sun; but after that time, it must be removed into a shady place; and the seeds must be continually refreshed with gentle waterings.

If the seedlings do not come up the first year, they will the second; and in July or August, after they appear above ground, will be strong enough to transplant; when you must set them in beds of light earth well lifted, at about four inches distance from each other, and place them where they may receive only the morning sun.

The April afterwards they will begin to throw themselves, when they should be transplanted into pots filled with soil made of one load of melon earth, or dung well rotted, half a load of sea-fand, and half a load of sandy loam; or a load of melon earth, and the like of sandy loam; or one load of rotten wood, or the bottom of a wood pile, the same quantity of loam, and half a load of melon earth, prepared as above.

These flowers must be carefully sheltered from the rains, which greatly impair their colours.

Provided the weather is mild, you may, toward the end of this month, plant out your choice carnations into the pots where they are to remain to flower; in doing which, you should not take too much of the earth from their roots; and when they are planted, it will be proper to place the pots in a warm situation (but not too near walls, or pales, which will draw them up weak); and arch them over with hoops, that in bad weather they may be covered with mats; for unless they acquire strength in the spring before the heat comes on, they will not produce large flowers.

The polyanthus seed must be sown upon a place prepared with earth taken out of decayed willows, often watered and kept shaded from the sun all April and May, till the young plants are come up.

The seedlings will be fit to transplant the July or August following into beds: the soil of which should be somewhat binding, and their exposure only to the morning sun.

You may have an annual supply of larkspurs without the trouble of sowing, by suffering the seeds of the flowers to drop, which will come up the ensuing spring: they are sown in spots, and flourish in variety of ground.

The single sort of Sweet William is raised by seeds sown in February or March; the double sorts, propagated from slips taken near the root about March or April, and planted in a loamy soil: they may also be laid down in the earth like carnation layers.

Holyhocks are raised by seeds sown in this month, removed in August or September to their proper places of vegetation, in rich earth.

The most agreeable disposition of this flower is, under some coarse wall, which they will handsomely fill, or in any other place guarded from the winds.

Pinks, and candy-tufts, are generally used in edgings in gardens, and in edges of borders, where they are planted in spots, and have a very agreeable effect.

The seed is sown in lines in this month or March; or they may be propagated from slips planted very early in the spring, or in August.
Rose-trees, of which there are various sorts, succeed well in a strong holding ground, tolerably moist; they may either be raised from layers or suckers, laid down and taken from the old roots in February or March, and transplanted immediately before the roots grow dry; should there be a necessity for keeping them out of the ground for some time, lay their roots in water five or six hours before they are planted.

The rose-tree does well in borders, or in the quarters of wilderness works, among other flowering shrubs; and some or other of them will be in flower for ten months in the year.

The laburnum tree is commonly planted among the other flowering shrubs of the wilderness, and will grow in the moist open exposure, as well as under the shade of large trees: it may easily be raised from seeds sown in this month, and transplanted two years after it comes up.

The althaea may be raised from layers or seeds; there are several different colours of this flower, and they may be budded so as to have all the colours on one plant.

The pomegranate prospers moist in a light soil; and being propagated by laying down the young shoots in this month or March, may be transplanted either in the spring or autumn season, when they may be put in pots, or against a south wall, where the fruit will ripen.

The pomegranate may also be raised from seed.

The fyringa may be raised from seeds; but it is hardly thought worth the trouble, as it is very apt to put forth suckers; these, however, may with ease be taken off and transplanted at this time of the year, and in September.

It is a shady position which makes this shrub shoot, and the sun makes it flower; but it will grow almost anywhere.

The lilach is a plant which grows to a pretty large tree, bearing bunches of purple blossoms, like plumes of feathers, in May; and is raised by laying down the young branches in this month or March, or by taking off the suckers, and planting them in a light soil, about the same time, or in September.

These trees are highly ornamental in the quarters of wilderness works, and small walks of them are very pleasant.

The Spanish broom is planted in wilderness works, and may be raised from seeds sown in light earth; also by laying down the tender branches, and cutting them at the joints, after the manner of the carnation; but the latter method is not so certain as the other, though it is far more troublesome.

The laburnum is greatly admired for producing its flower in the winter; and may be raised from the berries, managed as the holly; or from layers, which is the most expeditious way.

This plant is greatly hurt by frost, and succeeds best in moist shady places; it will flourish in loamy soil, without the help of any rich manure, which forwards its growth too much.

The laburnum is, often trained up as a headed plant, though it be best planted against a wall, or in wildernesses; and it is observable, that this plant, like all other exotics, is naturally inclined to blossom about the spring in its own country, which is our autumn; for which reason, it should be pruned in our spring season after it has done blossoming.

The phillyrea, may in general be propagated from the berries, or raised from layers, which will presently take root.

This plant, which succeeds best in a natural light soil, grows very fast; and being well supported with rails or stakes, a number of them makes a very thick and handsome hedge.

The yew-tree delights in a light barren soil, and is more plentifully produced on the coldest mountains than in the richest soils.

The berries of the yew may be laid in sand, as those of the holly, before they are sown; and there is no difficulty in propagating this plant, or removing it, if the roots are pruned from time to time, by digging about it while it stands in the nursery.

The yew-tree will grow to a very large tree; but being a rooted plant, does not succeed well when transplanted, unless the roots have been often pruned in the nursery.

The berries of this plant, when ripe, are to be gathered; and after they have been laid to sweat some time, are to be put in sand or earth, till the autumn following, when, and like wise in this month, they may be sown in nursery beds.

They will lie in the ground for a long time before they begin to spring, and it will be four or five years before the young plants will be fit to graft or inoculate upon.

The grafting must be done in March, and the inoculating in July; but for standard trees or hedges, they must be planted at their proper distances while very young, that they may be accustomed to the soil.

The bay-tree, which is managed as the holly, is raised by berries sown in this month, on a bed of earth fresh dug, and covered with some fresh natural earth, well sifted, about two inches thick.

In about six weeks, the seeds thus sown will come up, should the weather prove moist; they should be covered with straw, or fern, for the three first winters, after which time they must be transplanted.

When these plants are discoloured by frost, cut off the top-branch in the spring, and they will shoot afresh.

The bay-tree may also be raised from layers laid down in the month of October, for cuttings, set in pots of fine earth, or two or three inches deep; and from suckers taken up with as much root as may be, and planted in the shade, in a gravelly soil, being well watered to settle the earth about their roots.

The laurel is propagated in the same manner as the bay-tree, loves shade, refits the weather, and will thrive in almost every soil.

Towards the end of this month, if the season proves favourable, drill the surface of the ground of your flower-beds, and clear them from weeds, moss, and whatever might appear thereon, which will not only make your garden look neat, but be of peculiar service to the flowers.

FRUIT-GARDEN.

The business of this month is chiefly pruning and grafting.
The multitude of branches in the first year, is not always
ing; and is more particularly the season for pruning fruit-
with some weak ones intermixed, they should be shortened
of the two branches be irregular, there must be
position of the two branches be irregular, there must be
the first year; when this happens, three or four
only of the best branches are to be preserved.
A multitude of branches in the first year, is not always
a sign of vigour; for they sometimes prove weak, occasion-
ly a vigorous tree cannot have too many branches, if
they are well disposed, nor a weak one too few.
The sap of all trees must be kept within due bounds,
and a greater liberty is to be allowed to strong trees
than to weak ones; for which reason strong and vigorous
branches are left of a greater length than feeble ones:
and it is best to prune weak sickly trees early, that the
sap may not be too much wasted.
In the pruning of wall-fruit-trees, all the branches
shooting directly forward are to be cut off close to the
branch they spring from; and the utmost care must be
taken to prevent their being too much crouded with wood,
it being often necessary to take off even bearing branches,
to preserve your trees in beauty and health; for it is im-
possible too great a number of branches should be supplied
with juices as they ought; and if they are not, either
the blossoms will drop off, or the fruit never ripen.
You should ever be careful to preserve a convenient
space between one branch and another in all prunings;
also that one branch does not cross another: a slender
bearing branch may, notwithstanding, sometimes be per-
mitted to steal behind the main body of the tree, and
be no offence to the eye.
That a tree may be the better disposed to bear fruit,
the branches should be carried horizontally as much as
possible; for the more perpendicular the branches of a tree
are led, the more they are inclined to run into great
wood and barrenness.
Small weak branches, shooting from the like, should
be cut away, as should all shoots put forth in autumn.
When an old tree shoots stronger branches towards the
bottom than the top, and the top is sickly, it must be cut
off, and a new figure formed from the lower branches;
but if the top be in good health, you must cut off the
lower ones, unless it be a few that are well placed.
Where old trees are in a weak condition, to preserve
them, they are to be disburthened totally, leaving a few
branches only shortened to five or six inches.
Having thus laid down the principal rules for pruning
in general, we now come to the management of the peach
and other fruit trees in particular.
When peach-trees are vigorous, it is best to defer the
first pruning till they are ready to blossom, when you may
be at a certainty in preserving those branches which are
most promising of fruit, and then to shorten them as they
require.
You may soon discover the fruit-bearing branches by
their swelling buds, and you should reduce them to the
length of five or six inches; the last year's shoots may be
left ten or twelve inches long.
In the space of about three years, all the wood must
at several prunings be taken away, but in the mean time
the wall is to be furnished with other wood.
When you have reduced your tree to beauty and order,
you have little to do but thinning your fruit till Midsummer,
when the shoots are to be shortened and fastened to
the wall, giving the fruit the advantage of the sun as much
as possible.
If the peach-tree makes over-haste in its bearing, it is
a sign of infirmity, and must be accordingly managed, by
pruning the branches shorter, and plucking off all or most
of the blossoms or fruit; which it is much less difficult
to do than when a peach is over vigorous; for then
nature is apt to make a confusion, which requires the greatest
to know which branches are fit to be chosen, and
what rejected.
The peach-tree requires a second, and sometimes a
third pruning; the last of which is to be performed ab-
bout the middle of May, or in June or July.
The apricot and nectarine may be pruned in the same
manner as the peach; but it should be observed, that the
apricot is more apt to run to wood than any other of these
kind of wall-fruit trees.
The usual ways of grafting are, in the cleft—in the
dark—by approach, and whip-grafting.
Grafting in the cleft, or flip-grafting, is performed on
the cherry, pear, and plum stocks, in the manner fol-
lowing.
When you have chosen a stock, in a smooth place cut
off the head of it, flopping: then, with your knife make
the top horizontally even; which being done, make a slit
of near two inches deep down the middle of the stock;
in which fix a cyon, floped on each side from a bud; and
closing the bark of both exactly, tie them round with
bafts.
When you have thus finished your grafting, put a
quantity of clay and horn-dung, tempered together,
round the stock and lower part of the cyon; in doing
which, be careful not to disturb the latter.
Grafting in the bark is generally performed only on ap-
les, by cutting the head of the stock as already directed;
but instead of fitting it, slit only the bark a little above
an inch on the south-west side, or as long as the floped part
of the cyon; then, loosening the top of the bark with
your knife, put in your cyon (being prepared with a flat
lope about an inch long, ending in a point, and begun
from the back-side of an eye) and closing it as above, co-
ver it also in the same manner with clay.
When either an apple, pear, plum, or cherry tree,
wants a branch to make the tree uniform, a graft may be
put into the side without cutting the head of it.
Grafting by approach, or inarching, is performed when
a stock grows fo near another tree, the fruit of which you
would propagate, that it may be joined with a branch of
that tree, by cutting the sides of the branch and stock ab-
out three inches long, and fitting them, that the passa-
ges of the sap may meet; in which posture let them be
bound and clayed.
When they are well cemented, cut off the head of the
flock
flock about four inches above the binding; and in March following, having cut off the stubb that was left of the flock, and the Cyan underneath, close the grafted place, that it may fasten by the flock only.

This manner of grafting agrees best with vines, pomegranates, oranges, and such like shrubs.

When the flock and cyan are of the same bigness, the operation of whip-grafting is performed, by tying the flock and cyan about an inch, so as to make them fit, and then tying them together, and claying the place.

**Kitchen Garden.**

Hot-beds for radishes and spring carrots should now be made, according to the directions given for a common hot-bed in the preceding month; which, by proper management, will do for all sorts of seeds that are annual.

To make a mulchum bed, dig a trench five or six inches deep, and lay in it either the dung of horses, mules, or ass'es, in ridges, which dung must be the last covering before the earth is laid on.

The bed, when it is complete, must be three or four feet high; and after covering the dung about two or three inches deep with such earth as is taken from under a turf, put some mushroom-earth all over the bed on the last covering of dung.

Should the weather be severe, you may defend the bed with straw or dry litter, eight or ten inches thick, or cover it with mats fastened on hoops.

The bed must be kept properly watered, twice or thrice a-week, and the mushrooms will come up in two months time at farthest; sometimes in a month, when they must be immediately cut.

By putting some mushroom earth on your cucumber-beds, you will greatly forward their growth.

In the natural ground potatoes love a sandy soil, and the smaller roots, or knots of them, are commonly saved to raise a crop from, being set about four or five inches deep in the ground, and five or six inches apart; and when their haulms begin to decay, which is generally about Michaelmas, you may take them out of the ground with forks as you have occasion to use them.

The Jerufalem artichoke succeeds best in a stiff soil, and affords a root as large as an ordinary turnip, being in taste somewhat like a potatoe, but rather more watery.

The several sorts of cabbages, as the red cabbage, the Dutch cabbage, the Savoy cabbage, the Ruffia cabbage, the Battersea cabbage, and the two sorts of the sugar-loaf cabbage, should be planted at proper distances, according to their several figures.

The Savoys cabbages are for winter use, and towards the spring put forth sprouts preferable to the cabbages themelves.

Almost any ground will serve for cabbages; but if the weather be dry, it must be well watered before planting.

The hardeft cabbages may be taken up before the great frosts come on; and after they have hung up by the roots about a fortnight, lay them in a cellar, where they will keep a long time; or plant them deep in the ground close to one another, and cover them with hulm or straw, till you have occasion to use them.

Carrots are most proper in a light ground, in which their roots will grow to a great bigness.

Spring-carrots are sown in July or August; these intendted for a winter-crop, in February or March, in dry weather.

When your carrots are come up, and have been above ground about a month, they must be hooughed, leaving the space of about five inches between the plants; and after the first hooughing they should be kept as clean as possible till they are full grown, when they may be taken up for present ufe, and kept in sand during the winter.

Parfnius thrive best in a rich soil, and, excepting that they should not stand too thick, are to be managed in the same manner as carrots.

The skirret requires a light, moist, yet a rich soil; and is propagated either by sowing seeds, or by transplanting the offsets from the roots.

As soon as the leaves begin to put forth, they should be taken out of the ground, and parted into as many slips as can be conveniently taken off with the roots, so as only the fresh springing fibres remain on them; drills about four or five inches deep must then be prepared to plant them five or six inches apart, and they must be kept well watered till their roots are fully grown.

The usual time for sowing turnips is in July or August, but some people sow them in this month, by way of providing them for the summer. They thrive best in a sandy, loamy soil, but will grow in any ground: when the plants have two or three leaves, they should be hooughed at the distance prescribed for parfnius and carrots.

Onions are sown in this month, and in March, in rich garden foil; and toward the latter end of April, when the plants are transplanted in July, in rich garden foil; and toward the latter end of April, being come up, they are hooughed, when about three inches should be left between the plants till they begin to grow at for fallads, and then they may be drawn, or thinned where they grow too clofe together.

In sowing onions you must not be sparing of seeds, as it often happens many of them, being bad, have no effect.

When the leaves begin to change their colour, they should be pulled up, (in dry weather;) and after being well dried without doors, they must be spread on some floor, to dry more thoroughly for winter ufe.

Such onions as spire in the houfe, may this month be planted in lines six inches apart, and two inches distance for feeds for another year.

The leek is sown in a well-wrought ground, and is to be kept free from weeds, and hooughed like the onion; the plants are transplanted in July, in rich light foil, in lines about five inches apart.

Strawberries proper most in ground inclining to clay; and the best way of managing them, is to provide a quantity of horse-dung and coal-ashes well mixed together, and lay it upon the land to be dug or trenched in this month; then make borders three feet wide, on which the slips are to be plantet from eight to eighteen inches apart, according to the sorts: the chila strawberries being largest, should be set two feet asunder.
Afterwards you may set beans for a summer crop, and plant roses, sweet brier, currants or gooseberries, at every five or six feet distance, as the plants will not begin to bear fruit to any purpose till the following year, and it will be the third year after planting before there will be a full crop; in the mean time the roses, gooseberries, &c. turn to a good account, besides being serviceable to the plants by shading them.

The strawberries should be kept clear of weeds, and, if their blooming season be dry, well watered; early in the spring you must cleanse them, and fling loose earth among them to strengthen their roots.

Of strawberries there are five sorts, the chila strawberry, the hautboy, the scarlet, the red, and the white wood strawberry.

There are two kinds of raspberries, the red and white; the latter is the greater rarity, and thrives in such ground as agrees best with strawberies, being propagated by slips taken from the roots the latter end of this month or in March.

Raspberries should be planted in single rows, about a foot or eighteen inches asunder, and three feet between every row, leaving the heads two feet high when planted.

The Mufcovy clustered raspberry, planted against a wall between the trees where there is a vacancy, will ripen very soon; and their chief culture is to keep them clean from weeds in the spring; to prune the tops of the strongest shoots of the last year, leaving them about three feet high; and to cut away all dead and weak branches.

The gooseberry is propagated either by seeds, suckers, or cuttings; the first may be sown as soon as ripe, and will ripen very soon; and their chief culture is to keep them clean from weeds in the spring; to prune the tops of the strongest shoots of the last year, leaving them about three feet high; and to cut away all dead and weak branches.

The strawberry is propagated either by seeds, suckers, slips or cuttings planted in May, June, or July. The several sorts of double wall-flowers may be raised from slips taken from the roots; it is also cultivated in pots, and requires a loamy soil, and open exposure.

The femel sorts of double wall-flowers may be raised from slips taken from the roots; it is also cultivated in pots, and requires a loamy soil, and open exposure.

The several sorts of double wall-flowers may be raised from slips taken from the roots; it is also cultivated in pots, and requires a loamy soil, and open exposure.

This tree requires a strong holding soil, and may be transplanted with more safety in October than at this time of the year.

Cultivars are to be raised in the same manner as the gooseberry, and thrive best in the same kind of soil.

Liquorice should be planted at this season of the year; and the ground made choice of for planting it should be trenched three feet deep, and the liquorice set at a foot distance every way.

F R O M   S A N D Y  F O I L.

The rose campion is propagated either from seeds sown this month, or from slips taken from the roots; the double-bloofom kind is raised from slips only, as it does not produce any seeds; the last-mentioned thrives best in a loamy soil, and open exposure.

In this month also off-sets of the white hellebore are planted in a rich light soil.

Seeds are now sown of the fox-glove, which succeed well in the shade and a loamy soil; this flower does not blow till two months from the time of sowing.

The poppy, which is an annual, is sown in spots; as is the Venus looking-glass; the latter is proper also for edgings.

The valerian is raised from seeds, and some kinds of it are increased by parting the roots.

The primrose tree will grow in any soil, and the seed of it is sown in the natural ground towards the end of this month: it is very proper for the middle of borders in large gardens; and the seedling plants, which will not bloom till the second year, are to be sown in the nursery, and the young plants removed to proper places in the August after they come up.

Slips of the gentianella are planted in a sandy soil in this month or August.

Cardinal flowers are raised by seeds sown in hot beds, in fine sifted earth; and the seeds being small, are to be lightly covered with mould: these flowers, which are commonly cultivated in pots, may be increased by parting their roots in April, and planting them in places well exposed to the sun.

You should sow the seeds of the flock-gillifowers, and transplant them in the August following, in a light natural dry soil.

The double kinds of this flower may be increased by slips or cuttings planted in May, June, or July.

You should sow the seeds of the acanthus, in a sandy soil, and in the shade.

A loamy soil is requisite for raising the double rocket flower, which is propagated from slips taken from about the root.

The scarlet lynchis is propagated either from seeds, or slips taken from the root; it is also cultivated in pots, and requires a loamy soil, and open exposure.

The several sorts of double wall-flowers may be raised from slips taken from the roots. It is also cultivated in pots, and requires a loamy soil, and open exposure.

The several sorts of double wall-flowers may be raised from slips taken from the roots. It is also cultivated in pots, and requires a loamy soil, and open exposure.

The monk's hood, a flower of a poisonous quality, is propagated by parting the roots, which should be done in this month, and will thrive well in a loamy soil, in the moft shady place in your garden.

The sun-flower, which will grow in any soil, is raised from seeds sown in this month: and a sandy soil is requisite to make them thrive.

The lilies, or starworts, will thrive in any soil, and are fit companions for the tallfeft flowers in your garden: they are propagated from slips taken from the roots; and the best method is to plant them in pots, otherwise they will grow so numerous as to become a nuisance rather than an ornament.

Seeds or layers of the passion-tree may be sown this month; and every cutting of it, being planted in fine earth, will take root about May or June.

This tree is a prodigious quick grower, and very hardy; loves moist and cool places; and, if constantly watered, and dugged about the roots, it will bear fruit resembling lemons.

The arbutus, thrives in a light, gravelly soil, and may be raised either from seeds or layers; and the fruit (which must be gathered about Christmas, and laid to dry for
as coverings or matts over your tulips, to prevent their being blighted; and transplant your carnation layers for blowing, if they were not planted out in autumn.

The seeds of the humble and sensitive plants may now be sown upon the hot-beds; and the noil nel tangere in the natural ground.

You may transplant your evergreens; graft the Spanish white jessamine upon the common English fortune, and dip or set box for edgings, or in figured works.

Such exotic plants as have suffered in the green-house, should be removed to the hot-houfe; where, to prevent the theft of the bed from being of bad consequence, the dung should be covered with a due thickness of earth.

**FRUIT-GARDEN.**

You may make layers of the vine either in this or the next month, and they will be fit to transplant at Michaelmas; this tree is also propagated by laying down the young branches as soon as the fruit is gathered, or by making plantations of cuttings at that time.

If the weather proves open in February, that is the best time for planting vines; and the soil in which they first succeed is rocky or gravelly.

A chalky hill, lying very open to the sun, will produce better grapes than any of the rich soils prepared with horse-dung; but a tolerable good compost, to mix with the earth about the roots, may be made with the rubbish of old buildings.

These vines are to be pruned the September before transplanted, according to their strength, leaving not more than four buds on the strongest; and to cleanse them from weeds is all the care they will require the first summer.

Shorten the summer-shoots about the end of September, and the strongest of them will begin to show a little fruit the following summer.

In May or June of this second year, the small shoots and superfluous branches are to be carefully broken off, and two or three shoots only preferred on each vine, which should be supported by flakes or poles, till the September following, (for the nearer the grapes grow to the ground, provided they do not touch it, the sweeter they will be) and then they may be shortened.

The vineyard, thus planted and managed, will, in five or six years time, produce a good crop of grapes.

The fig is raised either from layers, seeds, or suckers; the layers are ordered like those of the vine; the seeds are sown in rubbish, or such like soil; and the suckers are separated from the old roots the beginning of this month, and transplanted without cutting off their tops.

The fig tree thrives in the same sort of soil as the vine, and may be planted either against walls or in standards.

The pruning of this tree is very different from that
Direction have, in the month of January, been given how to sow peas in drills, or lines, and to earth them when they come out of the ground; when beans may be planted three feet afunder between the rows, and the large peas four feet, being set about five inches apart in a stiff soil, without any manure, kept clean and watered about the time of their blossoms.

Blossoms and tender fruit are more especially preferred by these horizontal shelters, than by matts, or coverings, of any kind whatsoever; and by their assistance a good quantity of the choicest fruit may be depended on in the most difficult and unseasonable year.

KITCHEN GARDEN.

Thyme is raised either by seeds sown in this month or April, or from slips planted at the same time.

Sage is also propagated from seeds or slips, but most commonly from the latter, taken from the roots at the end of this month, or the beginning of the next, and planted, in light earth, a foot apart.

Of marjoram there are two sorts; one of which is called winter sweet marjoram, and propagated by planting the slips about March or April in moist ground; and the other sort is sown annually on hot-beds.

Camomile and pennyroyal are propagated from slips planted in this or the next month, in fluff soil and in a shady part of the garden.

Fennel is sown from seeds sown in this month in the natural ground; as is parsley, dill, &c.

Mint and balm will grow anywhere, and are propagated by parting their roots in any time of the spring as well as by sowing.

Mint is more generally propagated than balm, and when it is about a foot high you may cut it in branches, and dry it in the shade for winter use.

Rue is a plant which is multiplied by slips sown in a light soil, and should have a place in the shade.

Tansy is a plant, which should always be kept dry in winter, and is increased by parting the roots in the spring.

Sellery is a hot herb, and raised from seed sown in this month, or April, in some well exposed place in the garden; it must be planted out about six weeks after it is come up in beds, allowing six inches distance between the plants, and they may remain to the middle of June, at which time some of the first sowing will be fit to plant in trenches for blanching, in a light rich soil.

Your trenches must be eight or ten inches wide, and of the same depth; in which the plants are to be put as soon as made, after having pruned off their tops and roots; place them at five inches distance; as they increase in growth, earth them up within four or five inches of their tops. Endive may be sown in this month, but April is the more proper time; a light soil agrees best with it, and when it has been come up about six weeks, plant it in beds as directed for sellery, and about the middle of July plant it in rows about six inches apart.

When it is well grown, tie up some of it to whiten; which work should be continued every ten or twelve days.

Parslane is sown in this month, and glassy are used to help it forward; and in April it is sown in warm places.

Sorrel is sown in rows or drills, like other fallalding.

Of spinach, in March, April, and May, you are to sow several parcels of ground at different times, about a fortnight from each other, as a constant supply for the table, till there is plenty of other greens.

There are two sorts of spinach, the prickly sort, and the round spinach, both of which thrive in a light rich soil; and such as is intended for winter use must be sown in August.

Chives are raised by off sets from the roots, planted at six inches distance, cutting off their branches at the time of planting; they succeed best in a light, rich ground; and the oftener they are cut, the smaller and finer they are.

Tarragon
The following is the method used by the best gardeners to produce a natural crop.

After measuring out the ground, allowing four feet for the breadth of each bed, and two feet for the alleys between the beds; open a trench at one end, and lay into the bottom of it horse-dung about six or eight inches thick; then go on and trench the same quantity of ground lying next to the first trench, throwing the earth of the second trench upon the dung at the bottom of the first, and thus continue working till the whole is done.

Having finished your beds, plant asparagus, taken fresh out of the nursery, in lines at eight or ten inches distance, spreading their roots, and covering their buds with earth about four inches thick; each bed takes up four rows; and when they are all planted, sow the whole with onions, and rake it level, for the alleys will not be of any use till after Michaelmas, when the onions will be off, and the shoots of the asparagus plants made that summer are to be cut down, the alleys dug up, part of the soil thrown upon the beds, to raise the earth about five or six inches above the buds of the plants, and the alleys supplied with dung, or some rich foil.

In March following the earth must be raked down; and the alleys are to be turned up every winter, and now and then enriched with dung.

When Michaelmas is past, you may cut down the haulm, and give them their winter-dressing; and you should not be later than the middle of March in raking and laying down the beds.

It is a general rule, not to cut any of the asparagus till the fourth year after planting; but where the plants are strong, a few may be taken here and there in very small quantities the third year.

The asparagus appears above ground the beginning of April, and may be cut till the beginning of June, when they have stood five years; but if they are younger, you must not cut them after the middle of May.

No buds that appear above ground should be suffered to grow in the cutting season, unless they proceed from fresh plants, to make good deficiencies; and those must be suffered to run up every year, till they have gathered strength: it is best to cut them downwards a little sloping with a knife made blunt at the point.

APRIL

FLOWER-GARDEN.

In this month, and the beginning of May, the seeds of the carnation are to be sown in a compost made of sandy loam, and well-confumed melon-earth, two loads of the former to one load of the latter; sift them well together, and let them lie in a heap for a time to mellow; then sift it a second time either to sow the carnation-seeds in, or to plant your layers or roots of them upon.

Having filled your pots with this earth, and smoothed them on the top, sprinkle on your seeds; and covering them with the same compost, press it gently with a board, and let them stand exposed to the weather.
The seed will come up in about three weeks; and in the July following the young plants will be big enough to transplant into beds, where they must be let about ten inches distant from one another, and shaded from the sun with mats for about three weeks.

You may find many varieties from the seedling plants in the second year; and whatever rarities appear, they must be laid down as soon as possible, by cutting half through a joint, and splitting the internode upwards, half way to the other joint above it; then the wounded part must be buried in the earth, and fastened down till it takes root, which, provided the earth is light, will be in about two months.

The most proper season for laying down the layers of the seedlings is in July; and when planted they must be carefully guarded, both from the intense heat in summer, and the chilling frosts in winter.

The flower items will begin to put forth about April, when each flower must be supported by its stem being tied to a stick about four feet long; and as soon as the flower-buds appear, leave only one or two of the largest upon each flower stem, to blossom; and about ten days before the flowers open, the round poded kinds will begin to crack their husks on one side, when you should split or open the hulk on the opposite side to the natural fraction with a fine needle; and three or four days before the complete opening of the flower, you must cut off the points on the top of the flower-pod, and supply the vacancies on each side of the hulk with two small pieces of vellum, which may be easily slipped between the flower-leaves and the inside of the hulk, by which means the flower will make an equal display of its parts, and the form of it, consequently, be entirely regular.

When the blossom begins to show its colour, you should fix a piece of flat board upon the sticks, to shelter it from the sun's extreme heat.

The seeds of the carnation must be gathered towards the end of September, in dry weather, and be exposed for a month or two, through a glass, without opening the hulks till the time of sowing the seeds comes round again.

The seeds of the columbine are sown in the nursery this month, from whence you may remove the choice plants to the garden, and next year they will yield flowers: the roots of this flower will hold good for three or four years, when you must have a supply of fresh ones.

The seed of the scarlet bean is annually sown in good ground, well exposed to the sun; and sticks should be fixed in the ground, round which they will twine, and make a very agreeable shew.

The amaranthus is an annual, sown on a hot-bed; and the seeds being sown in this or the preceding month, in the hottest part of your garden, are to be raised under glass.

The African marygold is also an annual, raised on a hot-bed.

**Fruit-Garden.**

You should now carefully weed your beds of strawberries, and take off their runners; and if the season is dry, it will be proper to water them, for they produce but little fruit when this is neglected.

Lay the branches of the peach-tree horizontally, and keep them free from great wood, and perpendicular shoots in the middle, that the sap may be carried in such due proportion as is necessary; and it should be ever observed, that too much vigour is as pernicious as too little, with respect to the tree bearing a sufficient quantity of fruit.

When a pear or apple-tree is un Governable, and will not bear fruit, strip off the bark of the strongest branches half an inch, or an inch, according to the size of the tree, and take it entirely away to the wood.

These branches will continue to bear fruit for several years; and when they die, there are always in a pear-tree a sufficient number of others to succeed them, especially in the middle of the tree; which, if unGovernable, ought to undergo the same kind of discipline.

This work, which should be practised only on low dwarfs, or wall-trees, is best done in March or April.

Cherry-trees, not in a thriving condition, should now be tied perpendicularly down with the point of a knife, just entering the bark of the stem of the tree, to prevent being hide-bound; after which operation they will thrive and flourish wonderfully, when, for want of it, they will continue almost barren for ten or fifteen years.

At this time you should look carefully to your young fruit-trees which were planted in the spring, observing to water them in dry weather; and if you observe the leaves beginning to curl up, you should water them gently all over their branches; which may also be practised to great advantage on old trees, but it must not be done in the heat of the day, left the sun should scorch their leaves, nor too late in the evening, especially if the nights are cold.

Where you observe the fruit-trees to be greatly infected with insects, you should wash the branches with water, in which a great quantity of tobacco-flakes have been steeped; which, if carefully done, will infallibly destroy the insects, and not do any any injury to the trees; or if the leaves which are curled are taken off, and some tobacco-dust thrown on the branches, it will destroy the insects, and may, in a day or two, be washed off again.

Towards the end of this month, you must look over your espaliers and walls of fruit-trees, training in the regular kindly shoots in their proper situation, and displacing all fore-right and luxuriant ones.

In the middle of this month uncover those fig-trees which were screened from the frost in the winter; but do it with caution, as the young fruit, which now begins to appear, may be greatly hurt by being exposed to the air too suddenly.

**Kitchen-Garden.**

The middle of this month is the proper time to plant out melons, which are to be raised under paper: in making these ridges, if the ground is dry, the dung should be but a half a foot higher than the surface of the ground, and the earth should be laid at least a foot and a half thick upon the dung, that the plants may have depth enough to root; they will require no watering, after they are well
well rooted, and hereby a choicer sort of melons may be
generally obtained; which, in the common method, fre-
quently miscarry, or produce but little fruit.

The alleys between these beds should be afterwards
raised with dung and earth to the level of the beds, that
the roots may have room to extend on each side, for the
roots of these plants spread as far in the ground as their
branches extend on the surface.

Of kidney-beans we have two sorts; the one, which
is called the Batterea-bean, bears early, and near the
root, without running high; and the other, grows near
six feet high.

We sow these beans, the first week in this month, about
four inches apart; in drills from north to south, in a light
fresh soil, covering them with earth, raised in a ridge, to
keep the wet from them: the lines of the Batterea-beans
should be too feet apart; and the other sort will be sown
in rows like rouncevaI-peas, having alleys between them
two feet and a half wide; the former kind need not be
flaked, but the others will not bear well unless they are
flaked.

From the first sowing, this month, you may, once
every three weeks till the middle of July, continue to
sow fresh ground with kidney-beans to succeed one an-
other; observing, that when the ground is very dry, as
in June and July, and the weather hot, you must water
the drills as soon as you have opened them, before you
put in the seed, which will contribute to their vegeta-
tion; but after they are sown, you must avoid watering
them.

Toward the end of this month, you may sow
the nonpareils, and the Spanish morotto-peas, about two or
three inches apart in lines; leaving a space of three or four
feet for alleys, till the whole is sown; and when they
grow up six inches high, earth them up, and set one row
of sticks or bouffs about six feet high, on each side, for
them to run up, and you will have a plentiful crop.

The charlton, or matter-hotspur, should be sown in
December, for the first crop, in drills about two or three
feet asunder, the lines running from north to south: a sec-
cord crop of the same kind of peas should be sown in Fe-
bruary; and in March we may put in a third crop of the
same sort.

Some ground may be prepared about the beginning of
April for the dwarf-peas, which seldom rise higher than half
a foot, and are to be set four or five inches apart, in lines
about eighteen inches distant from one another; and in
order to have a constant supply of young peas, there is a
fort of dwarf peas which may be sown in May or June,
in edgings upon a gentle hot-bed, the first week in Sep-
tember, and will produce peas in the winter.

Spanish chardons may now be sown in the natural ground;
you are to make holes for the seeds about five or six feet
distance, and put four or five seeds in each hole; and
when they are come up, leave growing only one strong
plant in a hole for blanching.

Lavender and rosemary are raised from slips planted in
this month, which take root almost immediately if they are
plants of the last year, but if they are older they will
not grow; these plants should be set in a light sandy
soil, in the warmest and driest part of the garden.

The seedlings, which is propagated by the cuttings,
being planted-abroad in a natural bed of earth in this
month, will be fit to put in pots in August, where it
can remain in open air till the latter end of September;
some kinds of this plant being annual, must be raised from
seeds every year; and one sort of it will stand the win-
ter, if we raise young plants of it about July or August,
that do not blossom in three or four months.

The shrub-kinds, which have their stalks woody, will
bear moderate waterings; but the others, which are more
succulent, must have very little water. These plants
must be exposed to the sun, which will open their blo-
foms, unless it be two kinds, which only flower in the
night. The cuttings of these plants should not be planted
before the wounded parts have been dried a day or two
in the sun.

The torch-thistle is a succulent plant, raised from cut-
tings planted between May and the end of July, upon a
little hill in the middle of the pot, for they can hardly
endure water: and before they are put into the hot bed,
their waterings must be seldom, and gentle: and the best
compoit for this plant is the rubbish of old walls, mixed
with about one third of sandy soil. The fidums, espe-
cially the tree-kind, are easily propagated from branches
set in the earth in a light sandy foil, either in this or any
of the summer-months, giving them a little water, and
as much air and shade as possible in the summer; and in
the winter no water at all.

There are several sorts of the geranium, which are
raised by planting the cuttings, this month, in natural
ground, where they will become proper for transplanting
the August following; and from seeds sown in March on
hot-beds. Those planted in the natural ground require a
medium foil without dung, must be frequently watered,
and housed with the orange-trees.

The amomum Plinii is raised from cuttings planted
this month in the natural ground: during the summer it
must stand in some place defended from the sun, and be
constantly supplied with water.

Cuttings of the Arabian j-f lamin may this month be
planted in a sandy foil, and is more injured by wet than
cold. At the time the cuttings are taken from this plant,
it should be pruned to within six inches of the last year's
shoot, and have fresh earth put to the roots; by which
means it will shoot near a foot in the ensuing summer.

Layers of the myrtle-tree should be made this month:
the youngest shoots must be bent into the earth, after it
is well firred; and being often refreshed with water, will
take root, and be fit to take off from the mother plants
in the spring following. In July, the cuttings of this
tree are planted, stripping off the leaves, two inches from
each cutting, and setting them that depth, about an inch
apart, in pots of fine light earth, watering them frequent-
ly till they have taken root, which will be about the latter
end of August: and this young plantation is to remain till
the second of March before they are to be transplanted
into pots. About the middle of April you may prune,
and put earth about the roots of such old myrtle-trees
as are in a bad state, and cut the branches off their
heads within three or four inches of the stem.

The melianthus is a plant propagated with ease from
clips taken about the roots any time between this month
and August, planted in a sandy soil, and frequently wa-
tered.

The pyracantha is raised from cuttings, planted in May
or June, in pots of fine earth, and watered frequently,
keeping them from the sun till the following summer,
when a warm exposure will be serviceable to them. This
tree may also be raised from layers and seeds, and thrives
best in a dry gravelly soil, unmixed with dung or any
other rich manure.

The oleander plant has many varieties; the most
common of which is the scarlet oleander, which being of
a hardy nature, may be kept abroad all the winter under
a south wall; but the sweet-scented oleander is more
tender, and should be housed with the orange-tree. These
shrubs are raised by layers in this month or the next, in
a medium soil, and with moderate watering, and will take
root to transplant the August following.

Orange and lemon trees may this month be removed and
transplanted without danger, as well as brought out of the
conservatory: upon bringing out your exotics, and other
plants, brush and cleanse them from the dust they have con-
traced in the house, give them fresh earth on the surface of
their pots, and water them well, when they are placed in the
order they are to stand. When you transplant or remove
orange-trees, you are to do it carefully, without injuring
their bodies; let the cafes for your trees be filled with a
composition of two parts in sandy loam, one part rotten
dung, and one part white sand; and when your orange-
trees are so removed, give them frequent waterings, but
without wetting either the stem or the leaves; let them
in the shade for a fortnight, and let them have the fun by
degrees; as, when it is too hot upon them, it turns their
leaves yellow.

FRUIT-GARDEN.

In the beginning of this month, look carefully over
your wall and espalier trees, and take off all fore-right
shoots, and such as are luxuriant and ill-placed; and train
such kindly branches as you would preserve regularly to
the wall or espalier, which will prevent your trees from
growing into confusion.

Fruit-trees may be transplanted in the summer months,
from May to August, even when the trees are in blossom:
the method of transplanting them is, by preparing holes
for them before you begin to take them up; and the earth
taken out of the holes you are to make very fine, and
mix with water in large tubs to the consistency of thin
batter, with which each hole is to be filled for the tree
to be planted in, before the earthy parts have time to
settle or fall to the bottom. A tree, thus planted in
batter, has its roots immediately closed, and guarded
from the air; and as the seafon now dispenses every part
of the tree for growth and shooting, it loses very little of
its vigour if you are careful of its roots, observing to
wound but few of them at the taking the tree out of
the ground, and not let them dry in the passage from one
place to another. Though this way is of use in summer-
plantations, yet in the usual winter-plantations it is per-
nicious, as it will then chill and rot the root of your
trees.

As the cutting and wounding some roots of a tree, and
among them of the capital ones, cannot be avoided, a
mixture of gum has been contrived to plaiifer over the
wounded parts of the great roots, and prevent the air
and wet penetrating too much into the vessels of the roots;
and if the root be very large, you may at the same time
mark its corresponding limb or branch in the head, to be
cut off about a fortnight afterwards in the same propor-
tion, and then to be plaiisered in the same manner as the
root was done before.

In the removal of trees, care must be taken that it be
fudden; for if the roots are permitted to grow the least
dry, we may presently discern a failure in the top-
branches, which will require time to redress; for which
reason, it has been thought impossible to remove a large
tree to any considerable distance.

There is one convenience in this last way of planting,
which is not in the common way; and that is, that the
tree may be taken up without any earth about the roots,
which makes the transportation more easy; and by this
method, and the assistance of prepared gums, peach trees,
nectarines, pear-trees, plum-trees, and cherry-trees,
with fruit upon them, either green or ripe, may be re-
moved, though the trees are fix or seven years old;
and trees of all sorts may be thus transplanted in the
summer.

KITCHEN-GARDEN.

You may now give your melons air in the middle of
the day, and look to your melon-ridges, weeding them,
and carefully pruning off the water-branches, which are
known by their flatness and extraordinary breadth; it is
also necesary to pinch off the tops of the runners that
have fruit upon them, having three or four joints above
the fruit, and taking care that the fruit be well sheltered
with leaves from the power of the sun, otherwise their
growth will be spoiled; but when the growth is perfected,
you cannot expose them too much to the sun for ripen-
ing. If the seafon be dry, rather float the alleys between
the melon-ridges, than pour water upon the plant, or
near the flems.

About the beginning of this month, sow cucumbers in
the natural ground, both for fallad and pickling: in fowing
those for fallads, put about twelve seeds in each hole;
but leave only four or five* when they come up; let the
earth be fresh, and well worked with a spade, rather
light than stiff; and a plantation of this kind will produce
twice as much fruit as one of the same quantity of ground
forced with dung.

To raise cucumbers for pickling, sow them in a drill,
as you do pease or French beans; and put a row of
bushy sticks on each side of them: the rows must be four
or five feet asunder; and if sowed in the south border,
where there is a vacancy, and nailed against the wall, they will grow firmer and finer flavoured than those on the ground.

Replant imperial and Silicia lettuce: sow some of the white and brown Dutch cos-lettuce, to be planted out for cabbaging in June: sow radishes and endive very thin, to be transplanted without transplanting; and you may also sow purslane and cabbage-feed; transplant cauliflower-plants; make your first drills for kohlrabi, if your plants are large enough. Plant out cabbages and beet-chard; and you may yet sow thyme, sweet marjoram, and gillyflowers.

You should now be very careful to destroy weeds before they shed their seeds; destroy also the nests of caterpillars and other insects which annoy your trees; prune off all crumpled leaves, for they harbour the worst of vermin; and if the weather be dry, water new-planted trees, asparagus, &c.

**JUNE.**

**FLOWER-GARDEN.**

The leaves of the saffron crocus appear as soon as the flower is past, and remain all winter, which in the spring should be tied together in knots to help the increase of the roots; and these will be fit to remove or transplant about Midsummer. This plant delights in chalky ground, should be tied together in knots to help the increase of flowers. To be branched without transplanting; and you may also transplant cauliflower-plants; make your first drills for kohlrabi, if your plants are large enough. Plant out cabbages and beet-chard; and you may yet sow thyme, sweet marjoram, and gillyflowers.

You should now be very careful to destroy weeds before they shed their seeds; destroy also the nests of caterpillars and other insects which annoy your trees; prune off all crumpled leaves, for they harbour the worst of vermin; and if the weather be dry, water new-planted trees, asparagus, &c.

**FRUIT-GARDEN.**

The inoculation of fruit-trees now demands the attention of the gardener, and the following is the most approved method of performing the operation. About Midsummer take off a vigorous shoot from any tree you would propagate; and after having made choice of a flock of about three or four years growth, in a smooth part of it make a down right slit in the bark, a little above an inch in length, and another crosswise at the top of that, to give way to the opening of the bark; then gently loosen the bark from the wood on both sides, beginning at the top; which being done, cut off your bud with a penknife, entering pretty deep into the wood, as much above as below the bud, to the length of the slit in the flock; after the bud is thus prepared, take out the woody part of it (carefully preserving the eye of the bud) then put it in between the bark and the wood of the flock at the cross slit, putting it downward by the stalk, where the leaf grew, till it exactly closes; then bind it about the leaf, and let them stand abroad till they take root, and then they may have the help of the hot-bed; you must give these plants a good deal of the sun, and the leaves should be planted during the summer months.

**KITCHEN-GARDEN.**

Kidney-beans, radishes, lettuces for cabbaging, and endive, may now be sown; as may also the large fort of peas, about five or six inches apart, allowing three or four feet distance between the lines, and they will in September afford a good crop.

Replant cabbage-lettuces; transplant leeks in light rich ground, and at six inches distance from each other; and if the weather be dry, you may gather herbs for drying a-
the branch (shorter than was intended, or is in the winter
ing that it is proper to spare the last of such shoots so far
other fruit; by placing phials of honey and ale near the
infestts, which now destroy the peaches, apricots, and o-
birds; and you should also guard against wasps and other
and leaves, the Autumn shoots will recover that fault.
consequence of which, there would be either a want of
bearing buds which lie at the bottom of the shoots; in
were all entirely removed, the vine would push at those
places next year, or a necessity of pruning

JULY.

FLOWER-GARDEN.

There is little to be done in the flower-garden this
month: the berries of the coffee-tree which are now
ripe, may be sown, first cleaning their seeds from the
pulp, in pots of fine earth, about an inch deep; and if
you give them the help of a hot-bed, in less than six
weeks time they will sprout.
The fruit of the annas being ripe in this month, if
you cut off the crown of the leaves which grows on the
top of it, and plant it in a light sandy earth, it will, with
the assistance of a hot-bed, prefently take root.
Anemony seeds, now sown, must be sprinkled with
water frequently and gently.

FRUIT-GARDEN.

The management of the vine should this month be
chiefly attended to: it is to be observed, that from a vi-
gorous shoot of a vine already once pruned, there will pull
again several Midsummer shoots weaker than the former,
from the first, second, and third bud towards the extremi-
ty; which shoots are to be taken off, only remembering
that it is proper to spare the last of such shoots so far
as to leave one bud upon it, from whence, in Autumn,
nature may a third time exert herself; for if those shoots
were all entirely removed, the vine would pull at those
bearing buds which lie at the bottom of the shoots; in
consequence of which, there would be either a want of
fruit at those places next year, or a necessuty of pruning
the branch shorter than was intended, or is in the winter
convenient.
There is no danger in exposing the grapes this month
to the sun; for though the vines appear thin of wood
and leaves, the Autumn shoots will recover that fault.
Put nets over your grapes to preserve them from the
birds; and you should also guard against wasps and other
insects, which now destroy the peaches, apricots, and o-
other fruit; by placing phials of honey and ale near the
trees, you may soon entrap a great number of them.

KITCHEN-GARDEN.

You may now sow kidney-beans, and some peas, to
bear in September and October; sow cucumbers upon a
bed made with dry horse-litter, and covered with light
earth ten inches thick; they must be covered at night in
September with a common frame and glass, to keep them
from frost and rain, and by this method you may have
some cucumbers till Christmas.

AUGUST.

FLOWER-GARDEN.

The tulip-tree being a plant of the wood, should be
among such trees as are designed for groves, where it will
rife to a great height: the seeds of this tree come from
Virginia, and are to be sown in pots this month, and
sheltered in the winter, and they will come up all in the
spring following.
At two years growth the young plants may be trans-
planted into single pots, and must have shelter in the win-
ter for the first nine years at least till they have gathered
strength enough to resist the severity of the frosts, when
they may be planted in the natural ground, rather a sandy
foil than any other.
The iris flower has many varieties, some with bulbous
and some with tuberous-roots: the roots of the bulbous iris
may be taken up as soon as the leaves begin to wither,
and planted in August; and they may be increased by off-
fets taken from their roots when their stalks are decayed :
the best of the tuberous kind is the Chalcedonian iris,
commonly called the toad flag, which requires a warm
and rich foil, and must be carefully ordered, or it will
not thrive well.
The narcissus, or daffodil, is a flower of a hardy na-
ture, and thrives greatly in any ground; these flowers
are propagated from off-sorts from their roots, planted in
this month, and may be raised by seeds sown in Septem-
ber, which will produce very varied kinds; the seedling
plants are to remain without removal two or three years,
when they are to be taken up in June, and replanted in
good ground at a proper distance.
The jonquil is of the same kind with the daffodil, and
flowers much about the same time; these flowers
are propagated from off-sorts from their roots, planted in
this month, and may be raised by seeds sown in Septem-
ber, which will produce very varied kinds; the seedling
plants are to remain without removal two or three years,
when they are to be taken up in June, and replanted in
good ground at a proper distance.

when they are to be taken up in June, and replanted in
good ground at a proper distance.
ped white lily is so great a rarity as to deserve a place in the nicest garden, and the orange-lily is a proper companion for it; the lily of the valley is easily raised from plants, and thrives best in shady ground.

The crown-imperial may be raised from seeds, but is commonly propagated from slips that spring yearly from old roots, which are to be taken up in June when the stalks are dry, and replanted in August.

The work to be done this month, in the fruit and kitchen-garden, is the same as directed in the preceding month.

SEPTEMBER.

Flower-Garden.

The tulip is propagated in the following manner: the stems of this flower being left remaining upon the root, will perfect their seeds about July, which will be fit to gather when the seed-vessels begin to burst; and then they are to be cut close to the ground in a dry day, and laid in some dry place till September, when they are to be sown, in a soil composed of natural black earth and sand; and after their second appearance above ground, they may be taken from the pots they were sown in, and put in a bed of natural sandy soil, well sifted, where the thickness of half an inch of the same earth should be spread over them; and thus they are to continue, without any other culture than every year adding half an inch for their covering, till they begin to blow, which will be in five or six years time: in this manner tulip seeds are every year to be sown for new varieties.

In planting tulips, all the forward blowers should be planted in a bed together; and of the late flowering tulips the tallest sorts should be placed in the middle line of the bed, with two rows of the shorter on each side.

Tulips planted in this month need no shelter till March, when, the flower buds appearing, they should be defended from blights with mats, or other covering; which covering will also serve to shelter them, when blown from the too powerful heat of the sun, and pernicious damp.

There are two classes of tulips; the precoce tulips or early blowers, and the ferotine or later blowers; and these are distinguished by their double and single flowers: they have also different denominations, from their colour and stature, as bagats, which are the tallest flowers, commonly purple and white marbled; agates, which grow shorter, and are veined with two colours; and bezarts, which have four colours, tending to yellow and red, of several sorts.

You may now take up the roots of the peony, part and plant them; they will prosper in any soil.

The seed of the mullein may now be sown, in a sandy soil, and a shady part of the garden; it is a beautiful plant, and blossoms four feet high.

Violets are increased by transplanting their runners either in this month or in February, which will of themselves take root at every joint; they thrive best in a binding soil, shady situation, and should be planted in the most rural parts of the garden.

You may now increase daisies by parting their roots; and they make very pretty edgings for flower beds.

Layers of the honeysuckle may now be put down; they thrive best in the shade, and are most easily trained up in pots.

There are seven sorts of the jeffamine: the common white, the yellow, and the Persian jeffamine, are propagated from layers or cuttings, and will grow in any soil; the layers are made in this month, and the cuttings may at the same time be planted, which should always be a foot long, and two joints be under ground. The jeffamine should be planted against walls or trees, or mixed in hedges. There are jeffamines of a more tender nature, which require to be sheltered in the conservatory in the winter, as the Spanish jeffamine, the Portuguese jeffamine, the Indian jeffamine, and the Arabian jeffamine: these are propagated by grafting on the common hitejeffamine in March, or by inarching in May, or cuttings planted at the same time; the inarched plants are to be cut off the middle of August following, and in February you are to cut off the branches within four or five inches of the stem; and, after they have fresh earth put to their roots, they may be set near the glass or windows of the greenhouse: they succeed best in a medium soil between sand and clay, without dung, and should not be watered too frequently.

The virgin’s bower is raised from layers in this month, and from cuttings also: it is of a twining nature, must be supported with flakes: it may either be planted against a wall, or set in the wilderness; and it thrives best in a light soil.

The Virginia dog-wood blossoms early in the spring; and the flowers are succeeded by red berries, which hang a long time upon the tree: the seeds are sown in pots of light earth in autumn, and they are to stand the winter in the greenhouse, giving them the assistance of the hot-bed the following spring.

The Virginian mistle, which bears berries, from which is drawn the green wax whereof candles are made, is propagated by sowing the berries in pots of black sandy earth, which should be kept continually moist.

The Jaffarans-tree is a plant of Virginia, which loses its leaves in winter, and in the spring puts forth its yellow flowers in clusters, which are succeeded by blue berries, like those of the laurus tinus; these berries are sown in autumn, in a sandy soil.

You may now make layers or slips of the box tree; and the seeds may be sown as soon as ripe, or laid in sand during the winter, to be sown in the spring following; this plant thrives best in a chalky soil.

The dwarf or Dutch box, is of great use for edging of flower-beds, or making scroll-works; it will remain good, without renewing, a long time; and so great is the increase of it, that being earthed up every year, in four or five years after the planting, it may be taken up, parted, or slipped, and be made to plant four times the ground it stood upon.

Fruit-Garden.

You may now gather the different sorts of fruit as they ripen; for those which are in eating this month, seldom continue long good.
G R A D E N E

Transplant strawberies, gooseberries, raspberries, and currants, towards the end of this month, if the weather proves moist, otherwise it will be better to defer it till the beginning of the next month; and this is the best season to plant cuttings of gooseberries and currants, which will take root, and make better plants than those which are propagated by suckers.

Your fruit trees against the wall of your forcing-frame, must now be pruned and trained close to the wall or espalier, that their buds may be preparing before the season for applying the heat; and you should also prepare for the ground where the fruit-trees are designed to be planted the next month, that it may lie to mellow and sweeten.

K I T C H E N - G A R D E N

Sow Spanish radishes for the winter, and spinach to be cut in February; make plantations of the Dutch brown lettuce to stand the winter; sow sorrell, chervil, and small herbs for sallets, in some well-exposed place, observing to provide such mixtures for this season as are hotter to the taste, than in the former months.

You may now replant endive, and all sorts of fibrous-rooted herbs; continue to earth up fellery; raise the banks of earth about charodies for blanching; transplant asparagus-roots; make plantations of cabbages and cole-worts; transplant young cauliflower plants in places where they are to flower; transplant strawberies; make beds for mushrooms; cover mushrooms fown in July every night; earth up your winter-plants; prepare composts; and, if the weather be dry, water your plants and herbs in the morning, and give your turmpis the first houghing.

Such cucumbers as are now ripe, must be cut open, and the seed or pulp taken out of them, which should lie three or four days together before they are washed, and ten days in the sun before it is laid up; and it should ever be observed, that if seeds are not thoroughly dry before they are laid up, they will rot, and be good for nothing.

O C T O B E R

F L O W E R - G A R D E N

You should now plant anemonies, and ranunculuses; and as soon as they appear, defend them from winds and frosts, with saw-duft, dry straw, or matts; and make an end of putting tulips into the ground: and likewise put hyacinths, tulips, narcissuluses, &c. in glasses made for that purpose, to blow early in the house.

Continue to transplant and lay roses, and such like flowering shrubs; and to plant the cuttings of jessamines and honeysuckles in shady borders. Sow the berries of yew, holly, and other evergreens, prepared in earth or sand; and prune those kinds of plants if the season be mild.

This is a proper time to remove your ananas or pineapples out of the bark-beds into the flove; and always keep a tub of water in the flove to water them when it is wanted, which should stand twenty-four hours before it is used.

Set your pots of carnations, which are now blowing, into your green-houfe near the door; and the beginning of this month you are to house your myrtles, amomum Plinii, melianthus, and such tender greens as remain yet abroad. Tie up those plants that grow disorderly, and place the aloes, torch-thistles, euphorbiiums, &c. nearest the fun; and the other plants, which are more hardy, towards the back of the house.

When you water your houfed greens, let it be in the morning, when the sun shines upon them; but you are to give no more waterings to your tender succulent plants after the middle of the month.

The windows of the green-houfe are to be kept open day and night till about the fifteenth of this month: after that, in the day-time only.

F R U I T - G A R D E N

You may now plant peaches, apricots, and other fruit-trees; and as nothing is more prejudicial to them than dung, this should be done in untried earth.

Should this month be a wet one, you must raise the borders, and the trees planted high; for it is certain death to peaches and apricots, to stand where the water flagrates in the winter.

Vines should now be planted against walls seven or eight feet asunder, in a foil composed of sea-coal ashes, drift sand, or the rubbiff of old buildings, with an equal quantity of natural earth mixed with rotten dung.

About the middle of this month sow cyder-prelings in beds of fresh earth, to raife flocks for grafting, or even making of orchards without grafting; and from a nursery of this kind we may have as many different sorts of apples as we raife plants, although the feeds come all from the fame tree.

You may now have plantations of apples, grafted upon paradise flocks, in pots; they will bear when the trees are very small, and very greatly set off an entertainment, being placed growing upon a table among dishes of fruit.

Transplant trees of all sorts, and lay up acorns and maif in sand; lay bare the roots of old unthriving for ward blowing trees; flir up new-planted ground; and lay in a good flock of untried earth to be ready upon all occasions, for fruit-trees, ever-greens, and flowers.

K I T C H E N - G A R D E N

T H I S is the proper season to lay up roots for winter-stooe, such as carrots and parfnips; take the roots of tur nips out of the ground, and lay them up in sand; make plantations of currants and gooseberries, from the suck ers or cuttings.

The firft week of this month sow cucumbers on the natural ground, to be afterwards transplanted into pots, for the convenience of sheltering from cold nights, till a pot bed is prepared for them. This is better than to begin after the usual method in December or January.

Make plantations of lettuce, for winter-ufe: transplant cabbages
cabbages and cauliflower plants. Take up those cauliflower plants which begin to flower, tie their leaves together, and bury their roots and stalks in sand, in a cellar, or some cool place. Cut artichokes with long stalks, and preserve them in the house by setting their stalks in sand. Earth up and dress such artichokes as have done blowing: and continue to earth up herring for blanching.

Sow kidney-beans in balks under a south wall, to be afterwards forwarded by hot-beds, for early beans; and hot-spur peas, and Spanish beans, in some well exposed border, under a wall or a hedge. Sow also radishes in some warm place, to draw early in the spring; and cress, lettuce, mustard, spinach, &c. upon a decayed hot-bed: Put likewise some roots of mint upon a gentle hot-bed for winter salads.

November

You may now cut down the stalks of such tall blowing flowers as have done blooming within three or four inches of the root. Tie up all trees and shrubs to stakes, otherwise by their being loose, and at liberty, the wind will destroy them. Lay up heaps of earth for your several roots of flowers, and make the proper mixtures for exotics; observing, that where the ground is too stiff, it may be brought to a state of loam, by adding to it a sufficient quantity of drift or sea-sand.

Peonies, and some floriferous roots, may now be planted. If the weather be open, you may yet transplant rockeries, fennilies, honey-fuckles, fyringa, and lilac. Unnail your pots from the wall, and lay them upon the ground, that in case of severe frosts they may be covered with straw.

Plant hyacinths, jonquils, narcissus's, and polyanthus's, in pots, and plunge them into hot-beds, to blossom about Christmas: lay down your auricula pots upon their sides, the plants towards the fun, to drain them from moisture, and preserve them from frosts; and shelter young seedling bulbs from the frost, but give them daily airings.

Fruit Garden.

The business of this month being principally planting, it may be necessary to give the reader directions for bringing fruits to perfection in the winter, so as to have, by a particular management in planting, ripe fruit throughout the year.

Apricots, cherries, early peaches, nectarines, currants, gooseberries, are to be planted in the following manner, against a paling of five feet high: the flakes to support this paling must be set about four feet distance from one another; to which you are to nail whole head-boards of twelve feet long, well-jointed to one another, and ploughed on the edge, so as to set in laths, that thereby the steam of the dung, which is to lie at the back, may not get among the plants; because wherever such steam comes, it will cause mildews.

The deals are to be an inch in thickness; for if they are not quite so thick, the trees will be apt to be scorched upon the first application of the hot dung; and if they are thicker, the artificial heat applied to their backs, upon the time it begins to decline, will not be powerful enough to warm thoroughly, and then the dung must be oftener refreshed.

When the paling is up, you are to mark out a border on the south side of it, about four feet wide; and on the outside of the border, fall ten to the ground, in a straight line, some scantlings of wood about four inches thick, to rest glafs lights upon, which are to slope back to the paling, to shelter the fruit as occasion requires: between these glafs-lights, there must be bars cut of whole deal, about four inches wide, for the glafs to rest upon; and the bars must always remain fixed, as in a frame for a hot-bed.

There must be a door, shaped to the profile of the frame, at each end, to be opened, either the one or the other, as the wind happens to blow, ever observing that the door be opened on that side only which is most free from the wind.

You may plant fruit-trees in a frame of this sort the same summer it is made, and the trees will take very good root before winter, and be so well flored with sap against the following forring, that they will shew no sign of their removal, but bear extremely. Besides, by this summer planting, the trees seldom or never throw away their strength in autumn shoots, or make any attempts towards it, till September and October, when the frosts prevent their design.

The trees planted must have time allowed for the juices to digest, before you begin to force them: therefore the hot dung is not to be applied to the back of the paling before November.

About the middle of this month, or towards the end of it, is the time to bring ripe cherries in February: and at the same time likewise the heat may be used for apricots, so as to make the masculine apricots as large as duke cherries by February, and ripen them the beginning of April. The Anne peach will ripen about the end of April, as will also several sorts of forward plums.

The early nectarine thus forced will ripen with the masculine apricot: we may have green gooseberries fit for tarts in January and February; and ripe gooseberries and currants in March and April; but cherries do not bear this alteration in nature so well.

The grapes that do best for this sort of work, are, the royal muscadine, marljmore, black sweet water, and black morillon: the best sorts of the forward peaches, nectarines, cherries, and plumbs, and the Dutch raspberry, should be ever fixed on for forcing in the above manner. A row or two of strawberries may also be planted in this frame, which would ripen at the end of February, or beginning of March; and amongst the fruit you may mix here and there a monthly rose-tree; and have a border planted with early tulips, hyacinths, jonquils, narcissus's, and other flowers, which by the forcing heats would make a kind of summer all the winter.

The trees planted in these frames must be close to the paling, contrary to the methods of planting against walls.
for the roots will run under the pales, and draw nourishment equally from the earth about them; but with walls it is otherwise.

The trees need not be planted at a greater distance than four or five feet; and those that have flood seven or eight years against walls, may be removed to these forcing-frames without any danger: as to pruning these trees, the same method is to be followed as recommended for other trees in February; but the scab for doing it is not the same; for in the forcing frames our spring begins in November; but in the other cafe it does not begin till the end of January, or beginning of February.

The trees are to be pruned and nailed to pales about a week before the forcing heat is applied, and all the glass-\_s put up as soon as they are pruned.

The hot-dung intended to be laid at the back of the pales, should be tossed up in an heap some days before it is used, that it may yield an heap every where alike; when it is fit to be applied to the pales, lay it four feet wide at the bafe; and let it slope to two feet at the top, the height in all being at first within four inches of the top of the pales, and in about six weeks time it will sink to four feet, when you are to apply fresh dung. The blossoming of the tree is very much helped by covering them with the glafs lights in frofty weather: but they should not be denied the rain, if the weather be tolerably mild, till the buds begin to fir; after that, the glass-\_s to remain over them contantly, till the sun begins to have some power.

When the sun shines warm, and the wind is not too sharp, give the air at the front of your frame; and if this does not happen during a fortnight's space, then give air at the end, and put up mats or canvas to correct the winds, and caufe the air to circulate in the frames.

About three changes of dung will be sufficient to bring your cherries to ripeness in February, allowing each parcel to remain a month at the back of the pales: but if April proves cold, the forcing heat is to be continued till May, for plumbs, peaches, nectarines, and apricots.

**Kitchen-Garden.**

**Hot beds for asparagus should now be made:** also gentle hot-beds for the cucumbers and kidney-beans sown in October: continue to sow radifhes, lettuce, cresses, spinach, &c. on a hot-bed; and if your nursery is without roots, provide them from some old plantations.

Sow peafe, and beans of the hotspur and Spanish kinds, in open ground; and if the weather be fair, earth up those sown in September. Earth up sellery, and tie up endive plants for blanching: and this is the best time to cut down asparagus hauim, when it is turned yellow; it must be cut within two or three inches of the ground, and the earth of the alleys flung up upon the beds; or if the asparagus be worn, you are to give it a covering of rich dung, not quite rotten: and cover well your artichokes with long dung, to defend them from frosts, otherwise they will be destroyed in a severe winter. Houfe, and cover with sand, carrots, parfnips, &c. and house-cabbages.

You must now trench your ground, and lay it up in ridges to mellow; and in a frofty season wheel on dung and other manures upon such places as want to be enriched.

Plants are to be guarded against frosts, and sheltered against cold rains; and trees must be flaked, to defend them against violent winds, common in this month.

**December.**

**Flower-Garden.**

You should now cover the beds of choice anemonies, hyacinths, and ranunculus's; pick off dead and rotten leaves from all exotic plants; lay mulch about the roots of new planted trees and shrubs; cover the pots of seedling flowers; turn over the earth prepared for the flower garden, that the frost may make it mellow; and mix up some new heaps, that there may be a sufficient quantity ready for use eight or ten months before it is wanted.

You must not be too hafly in warming your green-house with artificial heats, but let in as much fun as possible, which being a natural heat, is the most agreeable to your tender plants. The chief busines is to keep out frosts; to effect which, the doors and windows of your green-house must be well matted, and guarded from the piercing air.

But as no plant can live without air, therefore to recruit it in the house, and feed the plants therewith without pinching them, it is advisable, that at the end of your green-house there should be an antichamber, through which you are to pass to the house; which chamber will have fresh air from abroad every time you go into it; and upon opening the door of it into the green-house, the air will there mix with the other that has been pent up, and impregnate it with new parts, by which means, it will contribute to the vegetation of plants, without coming upon them too suddeinely.

**Fruit-Garden.**

Continue to prune vines; prune and nail wall-fruit trees, also fuch standards as are hardy; examine orchard trees, and take away such branches as make confusion; covering every considerable wound with a mixture of bees wax, rosin, and tar, in equal quantities, and of tallow about half the quantity of any of the others; which are to be melted together in an earthen vessel well glazed; and, with a painting brufh dipped into it, the wound is to be covered: destroy snails in every part of your garden; and you may, if the weather proves mild, remove or plant moft sorts of hardy trees that in the winter fled their leaves.

**Kitchen-Garden.**

If the season proves mild, you may earth up those artichokes which were in the former months neglected; in doing which, if the ground is not very good, bury some rotten dung in it, which will greatly promote the growth of your artichokes in the spring following.

Towards the middle of the month, make a hot-bed for asparagus,
asparagus, in like manner as that made in November. Sow upon hot-beds, lettuce, radish, cress, mustard, and other herbs which are hot, to cut for small salads.

In open weather you may sow early peas and beans of the same kinds, and in the same manner, as directed in November and the preceding months; and as vermin now very much destroy your roots and seeds, you are to set traps to catch them.

You should, when the weather is not too severe, uncover the cauliflower plants every day, that they may enjoy the benefit of the air, otherwise they will be very weakly; and in dry weather take up sellery, and endive to blanch.

Great care must now be taken of the mushroom-beds; they should be covered with fresh dry straw, so thick as to keep out the wet; for as, where proper care is taken, there will be a constant supply of them for the table in the most rigorous seasons, so, when they are neglected, the produce will be small in proportion.

**GARDENING.**

The tide flows up this river twenty miles above Bordeaux.

**GARTER.** a ligature for tying up the stocking; but particularly used for the badge of a noble order of knights, hence denominated the Order of the Garter, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by Edward III. This order consists of twenty-six knights-companions, generally princes and peers, whereof the king of England is the sovereign or chief. They are a college or corporation, having a great and little seal.

Their officers are a prelate chancellor, regent, king at arms, and usher of the black rod. They have also a dean with twelve canons, and petty canons, vergers, and twenty-six pensioners or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor; which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the regent, who, by his oath is to enter upon the regality, the scrutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two distinct offices united in one person. Garter carries the rod and sceptre at the seat of St George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See King at arms.

All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, with the chapel of St George, and the charter-house, erected by the founder for that purpose. The habit and ensign of the order are, a garter, mantle, cape, George, and collar. The four first were alligned the knights companions by the founder; and the garter and collar by Henry VIII. The garter (Plate LXXXVI. fig. 2. No. 1.) challenges pre-
ence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes, and absent knights, who, and all other knights-elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble chapez, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QUI MAL Y PENSE; i.e. Shame to him that thinks evil hereof: The meaning of which is, that King Edward having laid claim to the kingdom of France, retorted shame upon him that should dare to think amiss of the just enterprise he had undertaken, for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle (ibid. No 2.) is the chief of these vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights-companions. To the collar of the mantle is fixed a pair of long fringes, anciently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knots, or buttons, and tassels at the end. The left shoulder of the mantle has, from the institution, been adorned with a large garter, with the device, HONI SOIT, &c., within this is the cross of the order, which was ordained to be worn at all times by King Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver. (ibid. No 3.)

The collar (ibid. No 4.) is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold.

The manner of electing a knight companion into this most noble order, and the ceremonies of investiture are as follow. When the sovereign defigns to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which, passing under the sovereign’s sign-manual and signet of the order, are sent to the peron by garter principal king at arms; and are in this manner, or to the same effect: “We, with the companions of our noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shewn, and the honourable exploits you have done in our service, by virtue of the grants and maintaining our right, &c., have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon the — day of this present month, &c.”

The garter, which is of blue velvet bordered with fine gold-wire, having commonly the letters of the motto of the garter, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion, by garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: “To the honour of God omnipotent, and in memorials of the blessed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and, having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer.”

The princely garter being then buckled on, and the words of its signification pronounced, the garter is brought before the sovereign, who puts about his neck, a sky-coloured ribbon, (ibid. No 5.) whereunto is appendant, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: “Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St George, by whose imitation provoked, thou mayst overthrow all prosperous and adverse adventures, that having stoutly vanquished thy enemies, both of body and soul, thou mayst not only receive the praise of this transient combat, but be crowned with the palm of eternal victory.”

Then the knight elected kisses the sovereign’s hand, thanks his majesty for the great honour done him, rises up, and salutes all the companions severally, who return their congratulations. No 2. (ibid.) exhibits a view of a knight of the garter in the habit of this order.

Since the institution of this order, there have been eight emperors, and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related: the common account is, that it was erected in honour of a garter of the countess of Salisbury, which the dropper dancing with king Edward, and which that prince picked up: but our best antiquaries think it was instituted on account of the victory over the French at Crécy, where the king ordered his garter to be displayed as a signal of the battle.

GASCOIN, or GASTOIGN, denotes the hinder thigh of a horse, which begins at the ille: and reaches to the ploy or bending of the ham.

GASCONY, the most south-west province of France, bounded by Guienne, on the north; by Languedoc, on the east; by the Pyrenees, which separate it from Spain, on the south; and by the Bay of Biscay, on the west.

CASSENHOVEN, or GUTZHENHOVEN, a town of the Austrian Netherlands, fifteen miles east of Louvain: E: long. 50°, and N. lat. 5° 55’.

GASTEROSTEUS, in ichthyology, a genus of fishes belonging to the order of thoracidi. There are three
GASTRONEMIUS, in anatomy. See Anatomy, p. 209.

GASTRONEMIUS is also the name of one of the extensor-muscles of the foot.

GASTROMANCY, a method of divination by water, practised by the ancient Greeks.

GASTROMANCY was called gemara, or perfection, because it was considered as so perfect an explication of the law, that after it no further additions could be made, or any thing more defined.

GASTRONOMY, or Gens d'armes, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

The king's bodyguards, the light horse of the royal houfe, and the musquetcers, are at present reputed to belong to the gendarmerie.

The grand gendarmes are a troop composed of about 250 gentlemen, who guard the king's perfon. The king himself is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers. There are, besides these, gendarmes of the queen, the dauphin, &c.

GEM, in natural history, a common name for all precious stones; of which there are two classes, the pellicid and semi-pellucid.

The bodies composing the class of pellicid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, never found in small detached masses, extremely hard, pellicid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance, giving fire without steel, not fermenting with acid menstruums, and very difficultly calcimable in the fire.

The bodies composing the class of semi-pellucid gems are, stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crytalline matter, debated by earth, however, they are but lightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

GEMARA, in Jewish antiquity, a collection of decisions and determinations on the law, written after the Misna was completed.

It was called gemara, or perfection, because it was considered as so perfect an explication of the law, that after it no further additions could be made, or any thing more defined.

GEMBLOURS, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Orne, ten miles north-west of Namur: E. long. 4° 30', and N. lat. 50° 30'.

GEMELLUS, in anatomy. See Anatomy, p. 205.

GEMINI, the Twins, in astronomy, one of the twelve signs of the zodiac, the third in order, beginning with aries. See Astronomy.

GEMMA, in natural history. See Gem.

GENDER, or Gendarmes, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

The king's bodyguards, the light horse of the royal houfe, and the musquetcers, are at present reputed to belong to the gendarmerie.

The grand gendarmes are a troop composed of about 250 gentlemen, who guard the king's perfon. The king himself is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers. There are, besides these, gendarmes of the queen, the dauphin, &c.
GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

This was the original intention of gender; but, afterwards, other words which had no proper relation, either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus arbor, in Latin, is feminine; but arbre, in French, is masculine: and dens, in Latin, is masculine; but dent, in French, is feminine.

GENEALOGY, an enumeration of the ancestors of a person or family, both in the direct and collateral line.

GENEPI, a town in the duchy of Cleve, in Germany, situated on the Nierfe and Maefe, ten miles west of Cleve: E. long. S° 3° 5' and N. lat. 51° 40'.

GENERAL, an appellation given to whatever belongs to a whole genus. See Genus.

General charge, in law. See Charge to enter heir.

General terms, among logicians, those which are made the signs of general ideas.

General of an army, in the art of war, he who commands in chief.

The office of a general is, to regulate the march and encampment of the army; in the day of battle to choose out the most advantageous ground; to make the disposition of the army; to post the artillery; and where there is occasion, to send his orders by his aids de camp. At a siege, he is to cause the place to be invested; to order the approaches and attacks; to visit the works; and to send out detachments to secure his convoys.

GENERATING Line, or Figure, in geometry, is that which by its motion produces any other plane or solid figure.

GENERATION, in physiology, the act of procreating and producing a being similar to the parent.

According to Aristotle, the male animals contain the principle, and the female the matter of generation: for though both were furnished indeed with a female liquor, yet the femen of the males alone was prolific. The moderns, on the other hand, as well those who contend for the system of generation from eggs, as they who adopt that of the animalcules in the male seed, pretend that females have no such seminal liquor at all, and that what was commonly taken for it was some other animal fluid.

Harvey is of opinion, that all females are furnished with eggs, and that the embryos, or young animals, are formed in the same manner as a chick in the egg of any bird. Generation, according to this celebrated physician, is effected wholly by means of the uterus, or womb; which conceives the fetus by a kind of contagion communicated to it by the male-seed, much in the same way as the loadstone communicates magnetism to iron. This contagion, he thinks, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; tho' the uterus, he acknowledges, is the only part that is capable of conceiving the fetus, just as the brain is alone capable of forming ideas and notions. Agreeable to this doctrine of Harvey, Steno and other anthropologists have pretended to discover certain eggs in the ovaries or testicles of women; which Mr. Buffon denies to be the case, affirming, that there are no such eggs to be found in the ovaries or testicles of women.

We cannot enter into a detail of the reasonings for and against the system of generation from eggs; and shall therefore only observe, that its advocates pretend to have discovered eggs in all the females on which they made observations; that the largeness of those found in women did not exceed the bigness of a pea; that they are extremely small in young girls under fourteen, but that age and commerce with men makes them grow larger; that there are more than twenty such eggs in each ovary or testicle; that they are fecundated in the ovary by the spirituous and volatile part of the male-seed; that they afterwards are detached and fall into the uterus through the Fallopian tubes; that here the fetus is formed of the internal substance of the egg, and the placenta of the exterior part.

Leevenhoek is the author of another system of generation, from animalcules in the male seed. He tells us, he discovered many thousands of these in a drop less than a grain of sand. They are found in the semen of all males whatever, but not in that of females; and are so small, that 3,000,000,000 of them are not equal to a grain of sand, whose diameter is but the hundredth part of an inch. When any of these animalcules gets into an egg, fit to receive it, and this falls into the womb through the Fallopian tubes, the humours which distill through the vessels of the womb, penetrating the costs of the egg, swell and dilate it, as the sap of the earth does feed thrown into it. The placenta begins to appear like a little cloud, upon one side of the external coat of the egg; and, at the same time, the spine of the embryo-animalcule is grown so big, as to become visible; and a little afterwards, the cerebrum and cerebellum appear like two bladders; and the eyes stand next goggling out of the head; then the beating of the heart, or punctum faliens, is plainly to be seen; and the extremities discover themselves last of all.

These animalcules are of different figures, some like tadpoles, and others like cells. In the semen of a man, and in that of a dog, there have been discovered two different kinds of them, the one supposed to be males and the other females. Some even pretend to have seen animalcules disengage themselves from the membranes that surround them; and that they then appeared perfectly like men, with legs, arms, &c. like those of the human body.

All the advocates for the system of generation from animalcules strongly oppose that from eggs. They contend, that these animalcules cannot be looked upon as the inhabitants of the semen, since they were of greater extent than the liquor itself; not to mention, that no such animals are found in any other liquors of the body; and since females have nothing similar to these animals, they think it manifest that the prolific principle
principle resides in males. When they are asked, to what purpose serves such an immense profusion of human animalcules? they answer, that it is agreeable to the ordinary course of nature, both in the animal and vegetable part of the creation. They likewise strengthen their system, by adducing the many examples we have of similar transformations in the insect-clas of animals, which, from caterpillars and small worms, become winged animals of the butterfly or fly kinds.

By this system, says Mr Buffon, the first woman cannot be said to have contained the whole race of mankind, as being all, according to it, the true poerity of the first man, and in their animalcule state contained only in him. On this principle, he proceeds to invalidate the system of generation from animalcules: for supposing the size of a man to be 1, then will that of one of the spermatic animalcules be $\frac{1}{1000000000}$; and as a man is to an animalcule of the first generation in the same ratio that this animalcule is to an animalcule of the second generation, it follows, that this last will be expressed by the fraction $\frac{1}{1000000000}$. In this manner he computes the size of the animalcules of several generations, all supposed to be living animals, notwithstanding that their minuteness exceeds the power of imagination to conceive; and then tells us, that the system of generation from eggs is liable to the same objections, whereof the detail may be seen in his Hist. Natur. tom. II. p. 157, & seq.

As to Buffon's own system, he thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; that these molecules assume successively different forms, and are put into different motions, according to the circumstances they are in; but that they are much more numerous in the seminal liquors of both sexes, and the seeds of plants, than in other parts: that these organic molecules make the matter of nutrition; that this matter is always active, and tends to organization, forming itself into different shapes, according to the moulds it meets with. When the quantity of this organic matter is but small, as in man, and most large animals, generation only takes place at the age of maturity, and even then the number of animals produced is but small. The same is just the reverse in animals which abound with this matter, as in fishes, and most birds.

With respect to the generation of mankind, the same author thinks it a certain fact, that the male-feed is received into the womb of the woman; and that, for this purpose, it is highly probable the internal orifice opens during the act of coition. The female-feed also makes its way into the womb, where, being mixed with that of the male, they both together contribute to the formation of the fetus; which is either male or female, according as the seed of the man or woman abounds more with organic molecules; and the infant resembles either father or mother, according to the different combinations of these molecules. Both these seminal liquors he thinks equally active in the formation of the fetus, and that they fix and counterbalance each other; the molecules of each parent being thereby determined to form similar parts to those of the individual that furnished them, as the head, trunk, arms, legs, &c. He thinks the molecules proceeding from the genital parts fix themselves first; and that the other molecules arrange themselves successively round these, in the same order which they before occupied in the parent. When a great quantity of the seminal liquors of both sexes is received into the womb, there are formed different spheres of attraction, in different parts of these liquors; the conclusion of which is, that several foetuses are formed at the same time.

Nearly a kin to Mr Buffon's system is that of Mr Maupertuis, which he has explained in his Venus Physique. He observes, that all the variety observable among mankind, may have been accidental at first; but being once established in the constitution of the parents, they become natural to their posterity. To illustrate this, he gives an instance of a feuditory family at Berlin, who had five fingers, or five toes, and frequently both; and that this peculiarity was transmitted equally by the father and mother, but was lost by alliances with those who had but the usual number of fingers or toes.

He farther observes, that most animals, excepting mankind, have fixed seasons for procreation; and that the females go with young some a longer, others a shorter time. Mares go from eleven to twelve months; cows and hinds go nine months, as do also women; foxes and wolves, five months; and bitches go only seven weeks; cats nine weeks; and rabbits but thirty-one days. Most birds are hatched in twenty-one days; the canary birds, and some others, are hatched in thirteen or fourteen days. It appears, therefore, that there is an endless variety in the time and manner of the generation of animals.

Whoever reads this short sketch of the different theories of generation that have hitherto been invented, will probably require no other arguments to convince him, that physicians and philosophers are still as ignorant of the nature of this myriads operation as they were in the days of Noah.

*Parts of Generation*. See Anatomy, p. 270.

*Generation of Plants*. See Botany, p. 643.

*Genesis*, among mathematicians, signifies the formation or production of some figure or quantity.

*Genesis*, among divines, a canonical book of the Old Testament, and the first of the pentateuch or five books of Moses. The Hebrews call it Berechith, or, In the beginning, these being the first words in the book. The Greeks gave it the name of Genesis, from its beginning with the history of the creation of the world. See Bible.

**GENET, GENET, or JENNET**, in the menage, denotes a small-fixed well-proportioned Spanish horse.

To ride *a la genette*, is to ride after the Spanish fashion, so short, that the spurs bear upon the horse's flank.

**GENEVA**, a city near the confines of France and Switzerland, on the river Rhone, about sixty miles north-west of Lyons: E. long. 6°, N. lat. 46° 20'.

Geneva is a fortified town, about two miles in circumference, frastuted at the west end of a lake sixty miles long, and twelve broad, called the lake of Ge-
GENEVA, or GIN, among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper-berries.

Originally, the berries were added to the malt in the grinding; so that the spirit thus obtained was flavoured with the berries from first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

GENIAL, an epithet given by the Pagans to certain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

GENICULI, among botanists, the knots or joints in the stalks of plants; whence they are denominated geniculate plants.

GENIOGLOSSI, in anatomy. See Anatomy, p. 304.

GENIOHYOIDÆUS, in anatomy. See Anatomy, p. 304.

GENIS, a town of Savoy, situated on the river Guier, twelve miles west of Chambery.

GENISTA, Green-weed, or Dyer's weed, a genus of the diadelphia decandria class. The calix is bilabiated; the vexillum is oblong, and reflexed. There are 14 species, two of which are natives of Britain, viz. the tinctoria, or dyer's weed; and the anglica, or needle-furze.

GENITAL, an appellation given to whatever belongs to the parts of generation. See Generation.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of genites such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentle family.

GENITIVE, in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the genitive case: But in the vulgar tongues, they make use of a sign to express the relation of this case. In English they prefix the particle of, in French de or du, &c.

Though in strictness there are no cases in either of these languages; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit, or demon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and be his guard. See Demon.

The rank and office of the genii were inferior to those of the lares; for the latter were the tutelar gods of a family, whereas the genii had the care or government only of single persons, or places.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others cannot do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which only they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules, whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

GENOA, a city and archbishop's see of Italy, and capital of a republic of the same name, is built on a plain near the sea, and rises gradually to the top of a hill; the houses, which are lofty and well built, rising like the seats of a theatre, afford a fine prospect at sea. The harbour is large and deep, and the principal street, from one end to the other, resembles a double row of palaces: E. long. 5° 30', and N. lat. 44° 30'.

GENTIANA, in botany, a genus of the pentandria digynia class. The corolla consists of one petal; the capsule has two valves, and one cell. There are twenty-eight species, five of which are natives of Britain, viz. the pneumoanthe, or calathian violet; the amarella, or autumnal gentian; the centaurium, or lesser centaury; the campeliris, or vernal dwarf gentian; and the filiformis, or marsh century.

The root of this plant is large, remarkably tough, and of a firm texture. It is brought to us from Germany, where it is in many places cultivated as liquoricis is amongst us; and it is to be chosen fresh, tough, of a middle size, free from the small fibres, and well dried; tho' if it be scorched, it is to be rejected. This root is one of the best tonics.

GENTILE, in matters of religion, a pagan, or worshipper of false gods.

GENTILE, in the Roman law and history, a name which sometimes expresses what the Romans otherwise called barbarians, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire.

GENTLEMAN-usher of the black rod. See Rod.

Gentlemen of the chapel, officers whose duty and attendance is in the royal chapel, being in number thirty-two, whereof twelve are priests; the other twenty, commonly called clerks of the chapel, assist in the performance of divine service. One of the first twelve is chosen for confessor of the household, whose office it is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer the sacrament.

One of twenty clerks, well versed in music, is chosen first
GENUS, among metaphysicians and logicians, denotes a general name or term. It is plain, therefore, that by a genus we do not signify one particular thing, nor yet a plurality of things; but a sort or kind of things, all agreeing in certain general properties. Thus animal is said to be a genus in respect of man and brute, in regard man and brute agree in the common nature and character of animal: so a right-lined figure of four sides, is a genus in respect of a parallelogram, and a trapezium; and so likewise is substance, in respect of substance extended which is body, and thinking substance which is mind.

Genus is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences, as rhetoric, anatomy, and natural history.

Genus, in rhetoric. Authors distinguish the art of rhetoric, as also orations or discourses produced thereby, into three genera or kinds, demonstrative, deliberative, and judiciary.

To the demonstrative kind belong panegyrics, eulogia, orations, &c. To the deliberative kind belong persuasions, diffusions, commendations, &c. To the judiciary kind belong defences and accusatns.

Genus, in natural history, a sub-division of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See Natural History.

Geocentric, in astronomy, is applied to a planet or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

Geographical mile, the same with the sea-mile; being one minute, or the fiftieth part of a degree of a great circle on the earth’s surface.

GeoGRAPHY.

Geography, the doctrine or knowledge of the terrestrial globe; or the science that teaches and explains the properties of the earth, and the parts thereof which depend upon quantity.

The DESCRIPTION and USE of the GLOBES and ARMILLARY SPHERE.

If a map of the world be accurately delineated on a spherical ball, the surface thereof will represent the surface of the earth: for the highest hills are so inconsiderable with respect to the bulk of the earth, that they take off no more from its roundness than grains of sand do from the roundness of a common globe; for the diameter of the earth is 8000 miles, in round numbers, and no known hill upon it is three miles in perpendicular height.

For the proof of the earth’s being spherical, see Astronomy, p. 440.

With regard to what we call up and down, see Astronomy, p. 445.

To an observer placed any where in the indefinite space, where there is nothing to limit his view, all remote objects appear equally distant from him; and seem to be placed in a vast concave sphere, of which his eye is the centre. The moon is much nearer to us than the sun; some of the planets are sometimes nearer, and sometimes farther from us, than the sun; others of them never come so near as the sun always is; the remotest planet in our system, is beyond comparison nearer to us than any of the fixed stars are. And yet all these celestial objects appear equally distant from us. Therefore, if we imagine a large hollow sphere of glass to have as many bright studs fixed to its inside, as there are stars visible in the heaven, and these studs to be of different magnitudes, and placed at the same angular distances from each other as the stars are; the sphere will be a true representation of the starry heaven, to an eye supposed to be in its centre, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the centre of this starry sphere, and the sphere be made to turn round on this axis, it will represent the apparent motion of the heavens round the earth.

If a great circle be so drawn upon this sphere, as to divide it into two equal parts or hemispheres, and the plane of the circle be perpendicular to the axis of the sphere, this circle will represent the equinoctial, which divides the heaven into two equal parts, called the northern and the southern hemispheres: and every point of that circle will be equally distant from the poles, or ends of the axis in the sphere. That pole which is in the middle of the

Vol. II. No. 54.
northern hemisphere, will be called the north pole of the sphere; and that which is in the middle of the southern hemisphere, the south pole.

If another great circle be drawn upon the sphere, in such a manner as to cut the equinocial at an angle of 23½ degrees in two opposite points, it will represent the ecliptic, or circle of the sun's apparent annual motion: one half of which is on the north side of the equinoctial, and the other half on the south.

If a large fluid be made to move eastward in this ecliptic, in such a manner as to go quite round it, in the time that the sphere is turned round westward 366 times upon its axis; this fluid will represent the sun, changing his place and the other half on the south.

During one half of these revolutions, the fluid will be on the north side of the equinoctial; during the other half, on the south; and at the end of each half, in the equinoctial.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the flarry sphere to be about five or six feet, a small insect on the globe would see only a very little portion of its surface; but it would see one half of the flarry sphere; the convexity of the globe hiding the other half from its view. If the sphere be turned westward round the globe, and the insect could judge of the appearances which arise from that motion, it would see some stars rising to its view in the eastern side of the sphere, whilst others were setting on the western: but as all the stars are fixed to the sphere, the same stars would always rise in the same points of view on the east side, and set in the same points of view on the west side. With the fluid it would be otherwise, because the fluid is not fixed to any point of the sphere, but moves slowly along an oblique circle in it. And if the insect should look towards the south, and call that point of the globe, where the equinoctial in the sphere seems to cut it on the left side, the east point; and where it cuts the globe on the right side, the west point; the little animal would see the sun rise north of the east, and set north of the west, for 182½ revolutions; after which, for as many more, the sun would rise south of the east, and set south of the west. And in the whole 365 revolutions, the sun would rise only twice in the east point, and set twice in the west. All these appearances would be the same, if the flarry sphere should still (the sun only moving in the ecliptic) and the earthly globe were turned round the axis of the sphere eastward. For, as the insect would be carried round with the globe, he would be quite insensible of its motion; and the sun and stars would appear to move westward.

We may imagine as many circles described upon the earth as we please: and we may imagine the plane of any circle described upon the earth to be continued, until it marks a circle in the concave sphere of the heavens.

The horizon is either sensible or rational. The sensible horizon is that circle which a man standing upon a large plane obvers, to terminate his view all around, where the heaven and earth seem to meet. The plane of our sensible horizon continued to the heaven, divides it into two hemispheres; one visible to us, the other hid by the convexity of the earth.

The plane of the rational horizon, is supposed parallel to the plane of the sensible; to pass through the centre of the earth, and to be continued to the heavens. And although the plane of the sensible horizon touches the earth in the place of the observer, yet this plane, and that of the rational horizon, will seem to coincide in the heaven, because the whole earth is but a point compared to the sphere of the heaven.

The earth being a spherical body, the horizon, or limit of our view, must change as we change our place.

The poles of the earth, are those two points on its surface in which its axis terminates. The one is called the north pole, and the other the south pole.

The poles of the heaven, are those two points in which the earth's axis produced terminates in the heaven; so that the north pole of the heaven is directly over the north pole of the earth; and the south pole of the heaven is directly over the south pole of the earth.

The equator is a great circle upon the earth, every part of which is equally distant from either of the poles. It divides the earth into two equal parts, called the northern and southern hemispheres. If we suppose the plane of this circle to be extended to the heaven, it will mark the equinoctial therein, and will divide the heaven into two equal parts, called the northern and southern hemispheres of the heaven.

The meridian of any place is a great circle passing through that place and the poles of the earth. We may imagine as many such meridians as we please, because any place that is ever so little to the east or west of any other place, has a different meridian from that place; for no one circle can pass through any two such places and the poles of the earth.

The meridian of any place is divided by the poles into two semicircles: that which passes through the place is called the geographical, or upper meridian; and that which passes through the opposite place, is called the lower meridian.

When the rotation of the earth brings the plane of the geographical meridian to the sun, it is noon or mid-day to that place; and when the lower meridian comes to the sun, it is mid-night.

All places lying under the same geographical meridian, have their noon at the same time, and consequently all the other hours. All these places are said to have the same longitude, because no one of them lies either eastward or westward from any of the rest.

If we imagine 24 semicircles, one of which is the geographical meridian of a given place, to meet at the poles, and to divide the equator into 24 equal parts; each of these meridians will come round to the sun in 24 hours, by the earth's equable motion round its axis in that time. And, as the equator contains 360 degrees, there will be 15 degrees contained between any two of these meridians which are nearest to one another: for 24 times 15 is 360. And as the earth's motion is eastward, the sun's apparent motion will be westward, at the rate of 15 degrees each hour. Therefore,

They whole geographical meridian is 15 degrees eastward
The globe is hung in a brass ring, called the "brazen meridian"; and turns upon a wire in each pole sunk half its thickness into one side of the meridian ring; by which means, that side of the ring divides the globe into two equal parts, called the "eastern and western hemispheres"; as the equator divides it into two equal parts, called the "northern and southern hemispheres." The ring is divided into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to show the latitudes of places. The degrees on the other half of the meridian ring are numbered from the poles to the equator, where they end at 90: their use is to show how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is north or south of the equator.

The brazen meridian is let into two notches made in a broad flat ring, called the "wooden horizon"; the upper surface of which divides the globe into two equal parts, called the "upper and lower hemispheres." One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, and the 32 points of the compass. The graduated side of the brass meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globe.

There is a small horary circle, so fixed to the north part of the brazen meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an index, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brazen meridian.

There is a thin slip of brass, called the "quadrant of altitude," which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brazen meridian by a nut and screw. The divisions end at the nut, and the quadrant is turned round upon it.

The Description and Use of the Armillary Sphere.

[See Plate LXXXVII. Fig. 1.]

The exterior parts of this machine are, a compass of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial $AA$, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries) for shewing the sun's right ascension in degrees; and also into 24 hours, for shewing his right ascension in time. 2. The ecliptic $BB$, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year; in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The tropic of Cancer $CC$, touching the ecliptic at the beginning of Cancer in $e$, and the tropic of Capricorn $DD$, touching the ecliptic at the beginning of Capricorn in $f,$ each 23$\frac{1}{2}$ degrees from the equinoctial circle. 4. The arctic circle $E,$ and the antarctic circle $F,$ each 23$\frac{1}{2}$ degrees from its respective pole at $N$ and $S$. 5. The equinoctial colure $GG$, passing through the north and south poles of the heaven at $N$ and $S$, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure $HH$, passing through the poles of the heaven.
heaven, and through the solstitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for shewing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at $e$ and $f$, to its poles $b$ and $d$, for shewing the latitude of the stars.

In the north pole of the ecliptic is a nut $b$, to which is fixed one end of a quadrantial wire, and to the other end a small fun $T$, which is carried round the ecliptic $B$, by turning the nut $s$; and in the south pole of the ecliptic is a pin $d$, on which is another quadrantial wire, with a small moon $Z$ upon it, which may be moved round by hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of 57 degrees, in two opposite points called the moon's nodes; and also for shifting these points backward in the ecliptic, as the moon's nodes shift in the heavens.

Within these circular rings is a small terrestrial globe $J$, fixed on an axis $KK$, which extends from the north and south poles of the globe at $n$ and $s$, to those of the celestial sphere at $N$ and $S$. On this axis is fixed the flat celestial meridian $LL$, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon $MM$, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at the opposite points of its equator, which is a moveable brass ring left into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian $LL$. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass, for shewing the amplitude of the sun and moon, both in degrees and points. The celestial meridian $LL$ passes through two notches in the north and south points of the horizon, as in a common globe; but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixed to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal $N$, and may be elevated or depressed upon the joint $O$, to any number of degrees from 0 to 90, by means of the arc $P$, which is fixed in the strong brass arm $Q$, and slides in the upright piece $R$, in which is a screw at $r$, to fix it at any proper elevation.

In the box $T$ are two wheels (as in Dr Long's here) and two pinions, whose axes come out at $V$ and $U$; either of which may be turned by the small winch $W$. When the winch is put upon the axis $V$, and turn backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun $T$, and moon $Z$, round the same way, and causing them to rise above and set below the horizon. But when the winch is put upon the axis $U$, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by north, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest, and they were carried round it; showing that they rise and set in the same points of the horizon, and at the same times in the hour circle, whether the motion be in the earth or in the heaven.

If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to shew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw $r$ in the upright item $R$, and taking hold of the arm $Q$, move it up or down until the given degree of latitude for any place be at the side of the item $R$; and then the axis of the sphere will be properly elevated, so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian $LL$, down towards the north notch of the horizon, and set the horizon to that latitude; then, turn the nut $b$ until the fun $T$ comes to the given day of the year in the ecliptic, and the fun will be at its proper place for that day; find the place of the moon's ascending node, and also the place of the moon, by an Ephemeris, and set them right accordingly: lastly, turn the winch $W$, until either the fun comes to the meridian $LL$, or until the meridian comes to the fun (according as you want the sphere or earth to move) and set the hour-index to the XII, marked noon, and the whole machine will be rectified. Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour-index will shew the times thereof for the given day.

As those who understand the use of the globes will be at no loss to work many other problems by this sphere, it is needless to enlarge any farther upon it.

**Directions for using Globes.**

In using globes, keep the east side of the horizon towards you (unless your problem require the turning of it), which side you may know by the word East upon the horizon; for then you have the graduated side of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated side of the meridian.

In working some problems, it will be necessary to turn the whole globe and horizon about, that you may look on the west side thereof; which turning will be apt to jog the ball $s$, as to shift away that degree of the globe which was before set to the horizon or meridian: to avoid which inconvenience, you may thrust in the feather-end of a quill between the ball of the globe and the brazen meridian; which, without hurting the ball, will keep...
To find the latitude and longitude of any given place upon the globe. — Turn the globe on its axis, until the given place comes exactly under that graduated side of the brafen meridian, on which the degrees are numbered from the equator; and observe what degree of the meridian the place then lies under; which is its latitude, north or south, as the place is north or south of the equator.

The globe remaining in this position, the degree of the equator, which is under the brafen meridian, is the longitude of the place which is east or west, as the place lies on the east or west side of the first meridian of the globe. — All the Atlantic Ocean, and America, is on the west side of the meridian of London; and the greatest part of Europe, and of Africa, together with all Asia, is on the east side of the meridian of London, which is reckoned the first meridian of the globe by the British geographers and astronomers.

Prob. IV. Any place being given, to find all those places that have the same longitude or latitude with it. — Bring the given place to the brafen meridian, then all those places which lie under that side of the meridian, from pole to pole, have the same longitude with the given place. Turn the globe round its axis, and all those places which pass under the same degree of the meridian that the given place does, have the same latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the first meridian, it is evident, that the point of the equator which is cut by the first meridian, has neither latitude nor longitude. — The greatest latitude is 90 degrees, because no place is more than 90 degrees from the equator. And the greatest longitude is 180 degrees, because no place is more than 180 degrees from the first meridian.

Prob. V. To find the anteci, perioci, and antipodes, of any given place. — Bring the given place to the brafen meridian; and having found its latitude, keep the globe in that situation, and count the same number of degrees of latitude from the equator towards the contrary pole; and where the reckoning ends, you have the anteci of the given place upon the globe. Those who live at the equator have no anteci.

The globe remaining in the same position, set the hour-index to the upper XII on the horary circle, and turn the globe until the index comes to the lower XII; then, the place which lies under the meridian, in the same latitude with the given place, is the perioci required. Those who live at the poles have no perioci.

As the globe now stands (with the index at the lower XII) the antipodes of the given place will be under the same point of the brafen meridian where its anteci stood before. Every place upon the globe has its antipodes.

Prob. VIII. The hour of the day at any place being given, to find all those places where it is noon at that time.
time — Bring the given place to the braven meridian, and set the index to the given hour; this done, turn the globe until the index points to the upper XII, and then all the places that lie under the braven meridian have noon at that time.

N. B. The upper XII always stands for noon; and when the bringing of any place to the braven meridian is mentioned, the side of that meridian on which the degrees are reckoned from the equator is meant, unless the contrary side be mentioned.

Prob. IX. The hour of the day at any place being given, to find what o'clock it then is at any other place.—Bring the given place to the braven meridian, and set the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

Prob. X. To find the sun’s place in the ecliptic, and his declination, for any given day of the year.—Look on the horizon for the given day, and right against it you have the degree of the sign in which the sun is (or his place) on that day at noon. Find the same degree of that sign in the ecliptic line upon the globe, and having brought it to the braven meridian, observe what degree of the meridian stands over it; for that is the sun’s declination, reckoned from the equator.

Prob. XI. The day of the month being given, to find all those places of the earth over which the sun will pass vertically on that day.—Find the sun’s place in the ecliptic for the given day, and having brought it to the braven meridian, observe what point of the meridian is over it; then, turning the globe round its axis, all those places which pass under that point of the meridian, are the places required; for as their latitude is equal, in degrees and parts of a degree, to the sun’s declination, the sun must be directly over head to each of them at its respective noon.

Prob. XII. A place being given in the torrid zone, to find those two days of the year on which the sun shall be vertical to that place.—Bring the given place to the braven meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and observe the two degrees of the ecliptic which pass exactly under that degree of latitude: lastly, find on the wooden horizon, the two days of the year in which the sun is in those degrees of the ecliptic, and they are the days required: for on them, and none else, the sun’s declination is equal to the latitude of the given place; and consequently, he will then be vertical to it at noon.

Prob. XIII. To find all those places of the north frigid zone, where the sun begins to shine constantly without setting, on any given day, from the 21st of March to the 23d of September.—On these two days, the sun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and so make equal day and night to all places of the earth. But as the sun declines from the equator, towards either pole, he will shine just as many degrees round that pole, as are equal to his declination from the equator; so that no place within that distance of the pole will then go through any part of the dark, and consequently the sun will not set to it. Now, as the sun’s declination is northward, from the 21st of March to the 23d of September, he must constantly shine round the north pole all that time; and on the day that he is in the northern tropic, he shines upon the whole north frigid zone; so that no place within the north polar circle goes through any part of the dark on that day. Therefore, having brought the sun’s place for the given day to the braven meridian, and found his declination (by Prob. IX) count as many degrees on the meridian, from the north pole, as are equal to the sun’s declination from the equator, and mark that degree from the pole where the reckoning ends: then, turning the globe round its axis, observe what places in the north frigid zone pass directly under that mark; for they are the places required. The like may be done for the south frigid zone, from the 23d of September to the 21st of March, during which time the sun shines constantly on the south pole.

Prob. XIV. To find the place over which the sun is vertical at any hour of a given day.—Having found the sun’s declination for the given day (by Prob. IX), mark it with a chalk on the braven meridian: then bring the place where you are (suppose Edinburgh) to the braven meridian, and set the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point of the sun’s declination marked upon the meridian, has the sun that moment in the zenith, or directly over head.

Prob. XV. The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.—The moon is never eclipsed but when the sun is full, and so directly opposite to the sun, that the earth’s shadow falls upon her. Therefore, whatever place of the earth the sun is vertical to at that time, the moon must be vertical to the antipodes of that place: so that the sun will be then visible to one half of the earth, and the moon to the other.

Find the place to which the sun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the braven meridian, as in the former problem: then, as the sun will be visible to all those parts of the globe which are above the horizon, the moon will be visible to all those parts which are below it, at the time of her greatest obscurcation.

Prob. XVI. To rectify the globe for the latitude, the zenith, and the sun’s place.—Find the latitude of the place (by Prob. I) and if the place be in the northern hemisphere, raise the north pole above the north point of the horizon, as many degrees (counted from the pole upon the braven meridian) as are equal to the latitude of the place. If the place be in the southern hemisphere, raise the south pole above the south point of the horizon, as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the braven meridian, and fasten the quadrant of altitude so, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith, or
or point of latitude. This done, bring the sun’s place in
the ecliptic for the given day (found by Prob. X) to the
graduated side of the brass meridian, and set the hour-
index to XII at noon, which is the uppermost XII on the
hour-circle; and the globe will be rectified.

Prob. XVII. The latitude of any place, not exceeding
66° degrees, and the day of the month, being given;
to find the time of sun rising and setting, if con-
sequently the length of the day and night.—Having recti-
ed the globe for the latitude, and for the sun’s place on
the given day (as directed in the preceding problem)
bring the sun’s place in the ecliptic to the eastern side of
the horizon, and the hour-index will show the time of
sun rising; then turn the globe on its axis, until the sun’s
place comes to the western side of the horizon, and the
index will show the time of sun-setting.
The hour of sun-setting doubled, gives the length of
the day; and the hour of sun rising doubled, gives the
length of the night.

Prob. XVIII. The latitude of any place, and the day
of the month being given; to find when the morning
twilight begins, and the evening twilight ends, at that place.
—This problem is often limited: for, when the sun does
not go 18 degrees below the horizon, the twilight con-
tinues the whole night; and for several nights together in
summer, between 49° and 66° degrees of latitude; and
the nearer to 66°, the greater is the number of these
nights. But when it does begin and end, the following
method will show the time for any given day.

Rectify the globe, and bring the sun’s place in the eclip-
tic to the eastern side of the horizon; then mark that
point of the ecliptic with a chalk which is in the western
side of the horizon. It being the point opposite to
the sun’s place: this done, lay the quadrant of altitude over
the said point, and turn the globe eastward, keeping the
quadrant at the chalk mark, until it be just 18 degrees
high on the quadrant; and the index will point out the
time when the morning twilight begins: for the sun’s
place will then be 18 degrees below the eastern side of
the horizon. To find the time when the evening twilight
ends, bring the sun’s place to the western side of the ho-
lorizon, and the point opposite to it, which was marked
with the chalk, will be rising in the east: then, bring the
quadrant over that point, and keeping it thereon, turn
the globe westward, until the said point be 18 degrees
above the horizon on the quadrant, and the index will
show the time when the evening twilight ends; the sun’s
place being then 18 degrees below the western side of the
horizon.

Prob. XIX. To find on what day of the year the sun
begins to shine constantly without setting, on any given
place in the north frigid zone; and how long he continues
to do so.—Rectify the globe to the latitude of the place,
and turn it about until some point of the ecliptic, be-
tween aries and cancer, coincides with the north point of
the horizon where the brass meridian cuts it; then find,
on the wooden horizon, what day of the year the sun is
in that point of the ecliptic; for that is the day on which
the sun begins to shine constantly on the given place,
without setting. This done, turn the globe until some
point of the ecliptic, between cancer and libra, coincides
with the north point of horizon, where the brass meridian
cuts it; and find, on the wooden horizon, on
what day the sun is in that point of the ecliptic; which
is the day that the sun leaves off constantly shining on the
day place, and rises and sets to it as to other places on
the globe. The number of natural days, or complete
revolutions of the sun about the earth, between the two
days above found, is the time that the sun keeps con-
stantly above the horizon without setting; for all that portion
of the ecliptic, which lies between the two points which
intercept the horizon in the very north, never sets below
it; and there is just as much of the opposite part of the
ecliptic that never rises; therefore, the sun will keep as long
constantly below the horizon in winter, as above it in summer.

Prob. XX. To find in what latitude the sun shines
constantly without setting, for any length of time les
than 182° of our days and nights.—Find a point in the
 ecliptic half as many degrees from the beginning of can-
cer (either toward aries or libra) as there are natural
days in the time given; and bring that point to the north side
of the brass meridian, on which the degrees are num-
bered from the pole towards the equator: then, keep the
globe from turning on its axis, and slide the meridian up
or down, until the forefaid point of the ecliptic comes to
the north point of the horizon, and then the elevation
of the pole will be equal to the latitude required.

Prob. XXI. The latitude of a place, not exceeding
66° degrees, and the day of the month being given; to
find the sun’s amplitude, or point of the compass on which
he rises or sets.—Rectify the globe, and bring the sun’s
place to the eastern side of the horizon; then observe
what point of the compass on the horizon stands right
against the sun’s place, for that is his amplitude at ri-
fing. This done, turn the globe westward, until the sun’s
place comes to the western side of the horizon, and it will
cut the point of his amplitude at setting. Or, you may
count the rising amplitude in degrees, from the east point
of the horizon, to that point where the sun’s place cuts
it; and the setting amplitude, from the west point of
the horizon, to the sun’s place at setting.

Prob. XXII. The latitude, the sun’s place, and his
altitude, being given; to find the hour of the day, and
the sun’s azimuth, or number of degrees that he is dif-
fant from the meridian.—Rectify the globe, and bring
the sun’s place to the given height upon the quadrant of
latitude; on the eastern side of the horizon, if the time
be in the forenoon; or on the western side, if it be in the
afternoon; then the index will show the hour; and the
number of degrees in the horizon, intercepted between
the quadrant of altitude and the south point, will be the
sun’s true azimuth at that time.

Prob. XXIII. The latitude, hour of the day, and
the sun’s place, being given; to find the sun’s altitude and
azimuth.—Rectify the globe, and turn it until the index
points to the given hour; then lay the quadrant of al-
titude over the sun’s place in the ecliptic, and the degree
of the quadrant cut by the sun’s place is his altitude at
that time above the horizon; and the degree of the hori-
zon cut by the quadrant is the sun’s azimuth, reckoned
from the south.
his azimuth being given; to find his place in the ecliptic, the day of the month, and hour of the day, though they had all been lost.—Rectify the globe for the latitude and zenith, and set the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the sun's place; and the day of the month answering thereto, will be found over the like place of the sun on the wooden horizon. Keep the quadrant of altitude in that position; and, having brought the sun's place to the brazen meridian, and the hour-index to XII at noon, turn back the globe, until the sun's place cuts the quadrant of altitude again, and the index will shew the hour.

Any two points of the ecliptic, which are equidistant from the beginning of Cancer or of Capricorn, will have the same altitude and azimuth at the same hour, though the months be different; and therefore it requires some care in this problem, not to mistake both the month and the day of the month; to avoid which, observe, that from the 20th of March to the 21st of June, that part of the ecliptic which is between the beginning of Aries and beginning of Cancer is to be used: from the 21st of June to the 23d of September, between the beginning of Cancer and beginning of Libra; from the 23d of September to the 21st of December, between the beginning of Libra and the beginning of Capricorn; and from the 21st of December to the 20th of March, between the beginning of Capricorn and beginning of Aries. And as one can never be at a loss to know what quarter of the year he takes the sun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

Prob. XXV. To find the length of the longest day at any given place.—If the place be on the north side of the equator (find its latitude by Prob. I.) and elevate the north pole to that latitude; then, bring the beginning of Cancer to the brazen meridian, and set the hour-index to XII at noon. But if the given place be on the south side of the equator, elevate the south pole to its latitude, and bring the beginning of Capricorn to the brazen meridian, and the hour-index to XII. This done, turn the globe westward, until the beginning of Cancer or Capricorn (as the latitude is north or south) comes to the meridian; and the index will then point out the time from sun-rising to sun-setting. For, in all latitudes, the sun rises as long before midday, as he sets after it. Hence, the elevation of the pole will be equal to the latitude.

Prob. XXVI. To find in what latitude the longest day is, of any given length, less than 24 hours.—If the latitude be north, bring the beginning of Cancer to the brazen meridian, and elevate the north pole to about 66 degrees; but if the latitude be south, bring the beginning of Capricorn to the meridian, and elevate the south pole to about 66 degrees; because the longest day in north latitude is, when the sun is in the first point of Cancer; and in south latitude, when he is in the first point of Capricorn. Then set the hour-index to XII at noon, and turn the globe westward, until the index points at half the number of hours given; which done, keep the globe from turning on its axis, and slide the meridian down in the notches, until the aforesaid point of the ecliptic (viz. Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

Prob. XXVII. The latitude of any place, not exceeding 66 degrees, being given; to find in what climate the place is.—Find the length of the longest day at the given place, by Prob. XXV, and whatever be the number of hours whereby it exceedeth twelve, double that number, and the sun will give the climate in which the place is.

Prob. XXVIII. The latitude, and the day of the month, being given; to find the hour of the day when the sun shines.—Set the wooden horizon truly level, and the brazen meridian due north and south by a mariner's compass: then, having rectified the globe, flick a smallewing-needle into the sun's place in the ecliptic, perpendicular to that part of the surface of the globe: this done, turn the globe on its axis, until the needle comes to the brazen meridian, and set the hour-index to XII at noon; then, turn the globe on its axis, until the needle points exactly towards the sun (which it will do when it casts no shadow on the globe), and the index will shew the hour of the day.

The Use of the Celestial Globe.

Having done for the present with the terrestrial globe, we shall proceed to the use of the celestial; first premising, that as the equator, ecliptic, tropics, polar-circles, horizon, and brazen meridian, are exactly alike on both globes, all the former problems concerning the sun are solved the same way by both globes. The method also of rectifying the celestial globe is the same as rectifying the terrestrial.

N. B. The sun's place for any day of the year stands directly over that day on the horizon of the celestial globe, as it does on that of the terrestrial.

The latitude and longitude of the stars, or of all other celestial phenomena, are reckoned in a very different manner from the latitude and longitude of places on the earth: for all terrestrial latitudes are reckoned from the equator; and longitudes from the meridian of some remarkable place, as of London by the Briten, and of Paris by the French. But the astronomers of all nations agree in reckoning the latitudes of the moon, stars, planets, and comets, from the ecliptic; and their longitudes from the equinoctial colure, in that semi-circle of it which cuts the ecliptic at the beginning of Aries; and thence eastward, quite round, to the same semi-circle again. Consequenfly those stars which lie between the equinoctial and the northern half of the ecliptic, have north declination and south latitude; those which lie between the equinoctial and the southern half of the ecliptic, have south declination and north latitude; and all those which lie between the tropics and poles, have their declinations and longitudes of the same denomination.

There are six great circles on the celestial globe, which cut
cut the ecliptic perpendicularly, and meet in two opposite
points in the polar circles; which points are each ninety
degrees from the ecliptic, and are called its poles. These
polar points divide those circles into 12 semicircles;
which cut the ecliptic at the beginnings of the 12 signs.
They resemble so many meridians on the terrestrial globe
and as all places which lie under any particular meridian-
semicircle on that globe, have the same longitude, so all
those points of the heaven, through which any of the a-
bove semicircles are drawn, have the same longitude.
And as the greatest latitudes on the earth are at the north
and south poles of the earth, so the greatest latitudes in
the heaven are at the north and south poles of the ecliptic.

For the division of the stars into constellations, &c. see

Prob. I. To find the right ascension and declination
of the sun, or any fixed star.—Bring the sun's place in
the ecliptic to the brazen meridian; then that degree in
the equinoctial which is cut by the meridian, is the sun's right
ascension; and that degree of the meridian which is over
the sun's place, is his declination. Bring any fixed star
to the meridian, and its right ascension will be cut by the
meridian in the equinoctial; and the degree of the meri-
dian that stands over it, is its declination.

So that the right ascension and declination, on the cele-
frial globe, are found in the same manner as longitude
and latitude on the terrestrial.

Prob. II. To find the latitude and longitude of any
star.—If the given star be on the north side of the eclip-
tic, place the 90th degree of the quadrant of altitude on
the north pole of the ecliptic, where the twelve semicircles
meet, which divide the ecliptic into the 12 signs: but if
the star be on the south side of the ecliptic, place the 90th
degree of the quadrant on the south pole of the ecliptic:
keeping the 90th degree of the quadrant on the proper
pole, turn the quadrant about, until its graduated edge
cuts the star: then, the number of degrees in the qua-
drant, between the ecliptic and the star, is its altitude;
and the degree of the ecliptic, cut by the quadrant, is
the star's longitude, reckoned according to the sign in
which the quadrant then is.

Prob. III. To represent the face of the starry firm-
ament, as seen from any given place of the earth, at
any hour of the night.—Rectify the celestial globe for
the given latitude, the zenith, and sun's place, in every
respect, as taught by the XVIIth problem, for the ter-
restrial; and turn it about, until the index points to the
given hour: then, the upper hemisphere of the globe
will represent the visible half of the heaven for that
time: all the stars upon the globe being then in such
positions, as exactly correspond to those in the heaven.
And if the globe be placed duly north and south, by means
of a small sea-compas, every star in the globe will point
toward the like star in the heaven: by which means, the
constellations and remarkable stars may be easily known.
All those stars which are in the easterm side of the horizon,
are then rising in the easterm side of the heaven; all in the
western, are setting in the western side; and all those
under the upper part of the brazen meridian, between the
south point of the horizon and the north pole, are at their
greatest altitude, if the latitude of the place be north;
but if the latitude be south, those stars which lie under
the upper part of the meridian, between the north point
of the horizon and the south pole, are at their greatest
altitude.

Prob. IV. The latitude of the place, and day of
the month, being given; to find the time when any
known star will rise, or be upon the meridian, or set.—
Having rectified the globe, turn it about until the given
star comes to the eastern side of the horizon, and the in-
dex will shew the time of the star's rising; then turn the
globe westward, and when the star comes to the brazen
meridian, the index will shew the time of the star's com-
ing to the meridian of your place; lastly, turn on, un-
til the star comes to the western side of the horizon, and
the index will shew the time of the star's setting.

N. B. In northern latitudes, those stars which are
lefs distant from the north pole, than the quantity of its
elevation above the north point of the horizon, never
set; and those which are less distant from the south pole,
than the number of degrees by which it is depressed below
the horizon, never rise: and vice versa in southern
latitudes.

Prob. V. To find at what time of the year a given
star will be upon the meridian, at a given hour of the
night.—Bring the given star to the upper semicircle of
the brazen meridian, and set the index to the given hour;
then turn the globe, until the index points to XII at
noon, and the upper semicircle of the meridian will then
cut the sun's place, answering to the day of the year
fought; which day may be easily found against the like
place of the sun among the signs on the wooden horizon.

Prob. VI. The latitude, day of the month, and azimuth
of any known star, being given; to find the hour of the
night.—Having rectified the globe for the latitude, ze-
nith, and sun's place, lay the quadrant of altitude to the
given degree of azimuth in the horizon: then turn the
globe on its axis, until the star comes to the graduated
edge of the quadrant; and when it does, the index will
point out the hour of the night.

Prob. VII. The latitude of the place, the day of
the month, and altitude of any known star, being given;
to find the hour of the night.—Rectify the globe as in the
former problem, guess at the hour of the night, and turn
the globe until the index points at the supposed hour;
then lay the graduated edge of the quadrant of altitude
over the known star, and if the degree of the star's height
in the quadrant upon the globe, answers exactly to the
degree of the star's observed altitude in the heaven,
you have guessed exactly: but if the star on the globe is
higher or lower than it was observed to be in the heaven,
turn the globe backwards or forwards, keeping the edge
of the quadrant upon the star, until its centre comes to
the observed altitude in the quadrant; and then, the in-
dex will shew the true time of the night.

Prob. VIII. An easy method for finding the hour of
the night by any two known stars, without knowing ei-
ther their altitude or azimuth; and then, of finding
both their altitude and azimuth, and thereby the true
meridian.— Tie one end of a thread to a common musket
bullet; and, having rectified the globe as above, hold
the other end of the thread in your hand, and carry it
slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour-circle; which done, lay the graduated edge of the quadrant over any one of these two stars on the globe, which the thread cut in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then, the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitude in the quadrant. At which moment, if a common azimuth-compas be so set upon a floor or level pavement, that these stars in the heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compas will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

Prob. IX. To find the place of the moon, or of any planet; and thereby to shew the time of its rising, setting, and setting.—Seek in Parker's or Weaver's ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and, according to its longitude and latitude, as shewn by the ephemeris, mark the same with a chalk upon the globe. Then, having rectified the globe, turn it round its axis westward; and as the said mark comes to the eastern side of the horizon, to the braken meridian, and to the western side of the horizon, the index will shew at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.

For an explanation of the harvest moons by a globe, see Astronomy, p. 463.

For the description and use of a planetary globe, see Astronomy, p. 498.

For the equation of time, see Astronomy, p. 458.

Having thus explained the use of the globes, and general principles of geography, we must refer to the maps for the situation of each particular country, with regard to longitude, latitude, &c. The use of maps is obvious from their construction. The degrees of the meridian, and parallels, shew the longitudes and latitudes of places; and the scale of miles annexed, their distances. The situation of places, with regard to each other, as well as the cardinal points, appears by inspection; the top of the map being always the north, the bottom the south, the right-hand the east, and the left the west, unless the compass usually annexed shews the contrary.

The brevity, which we are necessarily obliged to observe, prevents us from taking any notice of many particulars, which are to be found in large treatises on this subject. A general account of countries, cities, rivers, mountains, &c. is given under their respective names, as they occur in the order of the alphabet. We shall therefore conclude this article with the following table, which will serve to give an idea of the general division of the habitable earth; and at the same time serve to explain the maps in Plates 87. 88. 89. 90. 91. and 92.

### The Division of the Habitable Earth, the square Miles of each Division and Subdivision, Capital Cities, with the Distance and Bearing of each from London; also the Time of each Country compared with that of England.

The terraqueous globe is divided into

* A degree of longitude being 4 minutes in time, therefore by having the longitude we have the time. A watch that is set to time at London would be 16 minutes too fast at Madrid, as it lies to the west of the meridian at London; and Vienna being 16 degrees and 20 minutes to the east of the meridian of London, consequently a watch set at London would be 1 hour and 3 minutes too slow at Vienna.

#### GEOMETRY

**GEOMETRY** originally signified no more than the art of measuring the earth, or any distances or dimensions within it; but at present, it denotes the science of magnitude in general; comprehending the doctrine and relations of whatever is susceptible of augmentation or diminution, considered in that light.

Hence to geometry may be referred the consideration not only of lines, surfaces, and solids; but also of time, velocity, number, weight, &c.

This science had its rise among the Egyptians, who were in a manner compelled to invent it, to remedy the confusion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their possessions. Thus this invention, which at first consisted only in measuring the lands, that every person might have what belonged to him, was called Geometry, or the art of measuring land; and it is probable that the draughts and schemes, which they were annually compelled to make, helped them to discover many excellent properties of these figures; which speculations continued to be gradually improved, and are so to this day.

From Egypt geometry passed into Greece; where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The Elements of Geometry, written by this last in fifteen books, are a most convincing proof to what perfection this science was carried among the ancients. However, it must be acknowledged, that it fell short of modern geometry; the bounds of which, what by the invention of fluxions, and the discovery of the almost infinite orders of curves, are greatly enlarged.

We may distinguish the progress of geometry into three ages; the first of which was in its meridian glory at the time when Euclid's Elements appeared; the second, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this science, which has been carried to its utmost perfection by Sir Isaac Newton and Mr Leibnitz.
GEOMETRY.

In treating this useful subject, we shall divide it into two parts; the first containing the general principles; and the second, the application of these principles to the measurement of surfaces, solids, &c.

PART I.

GENERAL PRINCIPLES OF GEOMETRY.

Art. 1. A point is that which is not made up of parts, or which is of itself indivisible.

2. A line is a length without breadth, as B—

3. The extremities of a line are points; as the extremities of the line AB, are the points A and B, fig. 1.

4. If the line AB be the nearest distance between its extremes A and B, then it is called a straight line, as A B; but if it be not the nearest distance, then it is called a curve line, as AB; fig. 1.

5. A surface is that which is considered as having only length and breadth, but no thickness, as B, fig. 2.

6. The terms or boundaries of a surface are lines.

7. A plain surface is that which lies equally between its extremes.

8. The inclination between two lines meeting one another (provided they do not make one continued line,) or the opening between them, is called an angle; thus the inclination of the line AB to the line CB (fig. 3,) meeting one another at B, or the opening between the two lines AB and CB, is called an angle.

9. When the lines forming the angle are right lines, then it is called a right-lined angle, as A, fig. 4. If one of them be right and the other curved, it is called a curve-lined angle, as AB; fig. 1.

10. A point is that which is not made up of parts, or which is of itself indivisible.

11. If a right line DC be fastened at one of its ends C, and the other end D be carried quite round, then the space comprehended is called a circle; the curve line described by the point D, is called the periphery or circumference of the circle; the fixed point C is called the centre of it, fig. 10.

12. The describing line CD is called the radius, viz., any line drawn from the centre to the circumference; whence all radii of the same or equal circles are equal.

13. Any line drawn through the centre, and terminated both ways by the circumference, is called a diameter, as BD is a diameter of the circle BADE. And the diameter divides the circle and circumference into two equal parts, and is double the radius.

14. The circumference of every circle is supposed to be divided into 360 equal parts, called degrees; and each degree is divided into 60 equal parts, called minutes; and each minute into 60 equal parts called, seconds; and these into thirds, fourths, &c., these parts being greater or less according as the radius is.

15. Any part of the circumference is called an arch, or arc; and is called an arc of as many degrees as it contains parts of the 360, into which the circumference was divided: Thus if AD be the 1/2 of the circumference, then the arc AD is an arc of 45 degrees.

16. A line drawn from one end of an arc to the other, is called a chord, and is the measure of the arc; thus the right line AB is the chord of the arc ADB, fig. 11.

17. Any part of a circle cut off by a chord, is called a segment; thus the space comprehended between the chord AB and circumference ADB (which is cut off by the chord AB) is called a segment. Whence it is plain, 16, That all chords divide the circle into two segments.

18. The lefs the chord is, the more unequal are the segments, and æ contra.

19. When the chord is greatest, viz. when it is a diameter, then the segments are equal, viz. each a semicircle.

20. Any part of a circle (lesss than a semicircle) contained between two radii and an arc, is called a sector; thus the space contained between the two radii, AC, BC, and the arc AB, is called the sector; fig. 12.

21. The right sine of any arc is a line drawn perpendicular from one end of the arc, to a diameter drawn through the other end of the same arc; thus (fig. 13.) AD is the right sine of the arc AB, it being a line drawn from A, the one end of the arc AB, perpendicular to CB, a diameter passing through B, the other end of the arc AB.

Now the sines standing on the same diameter, fill increase till they come to the centre, and then becoming the radius, it is plain that the radius EC is the greatest possible sine, and for that reason it is called the whole sine.

Since the whole-sine EC must be perpendicular to the a diameter FB (by def. 20.) therefore producing the diameter EG, the two diameters FB, EG, must cross one another at right angles, and so the circumference of the circle must be divided by them into four parts EB, BG, GF, and FE, and these four parts are equal to one another (by def. 10.) and fo EB a quadrant, or fourth part of the circumference; therefore the radius EC is always the sine of the quadrant, or fourth part of the circle EB.

Sines are said to be of so many degrees, as the arc contains parts of the 360, into which the circumference is supposed to be divided; so the radius being the sine of a quadrant, or fourth part of the circumference, which contains 90 degrees (the fourth part of 360), therefore the radius must be the sine of 90 degrees.
21. The part of the radius comprehended between the extremity of the right line and the lower end of the arc, viz. DB, is called the versed sine of the arc AB.

22. If to any point in the circumference, viz. B, there be drawn a diameter FCB, and from the point B, perpendicular to that diameter, there be drawn the line BH; that line is called a tangent to the circle in the point B; which tangent can touch the circle only in one point B, else if it touched it in more, it would go within it, and so not be a tangent but a chord, (by art. 17.)

23. The tangent of any arc AB, is a right line drawn perpendicular to a diameter through the one end of the arc B, and terminated by a line CAH, drawn from the centre through the other end A; thus BH is the tangent of the arch AB.

24. And the line which terminates the tangent, viz. CH, is called the secant of the arc AB.

25. What an arc wants of a quadrant is called the complement of that arc; thus AE, being what the arc AB wants of the quadrant EB, is called the complement of the arc AB.

26. And what an arc wants of a semicircle is called the supplement of that arc; thus since AF is what the arc AB wants of the semicircle BAF, it is the supplement of the arc AB.

27. The sine, tangent, &c. of the complement of any arc, is called the co-sine, co-tangent, &c. of that arc; thus the sine, tangent, &c. of the arc AE is called the co-sine, co-tangent, &c. of the arc AB.

28. The sine of the supplement of an arc is the same with the sine of the arc itself; for, drawing them according to the definitions, there results the self-same sine.

29. A right-lined angle is measured by an arc of a circle described upon the angular point as a centre, comprehended between the two legs that form the angle; thus (fig. 14.) the angle ABD is measured by the arc AD of the circle CADE that is described upon the point B as a centre; and the angle is said to be of as many degrees as the arc is; so if the arc AD be 45 degrees, then the angle ABD is said to be an angle of 45 degrees.

Hence the angles are greater or less, according as the arc described about the angular point and terminated by the two legs contain a greater or a less number of degrees.

30. When one line falls perpendicularly on another, as AB on CD, fig. 15, then the angles are right (by the 10th def.); and describing a circle on the centre B, since the angles ABC and ABD are equal, their measures must be 90 degrees, i.e. the arcs AC and AD must be equal; but the whole CAD is a semicircle, since CD, a line passing through the centre B, is a diameter; therefore each of the parts AC and AD is a quadrant, i.e. 90 degrees; so the measure of a right angle is always 90 degrees.

31. If one line AB fall any way upon another, CD, then the sum of the two angles ABC and ABD is always equal to the sum of two right angles; fig. 16. For on the point B, describing the circle CAD, it is plain, that CAD is a semicircle (by the 14th); but CAD is equal to CA and AD the measure of the two angles; therefore the sum of the two angles is equal to a semicircle, that is, to two right angles, (by the laft).

Cor. 1. From whence it is plain, that all the angles which can be made from a point in any line, towards one side of the line, are equal to two right angles.

2. And that all the angles which can be made about a point, are equal to four right ones.

32. If one line AC crosses another BD in the point E, then the opposite angles are equal, viz. BEA to CED, and EBC equal to AED; fig. 17. For upon the point E, as a centre, describing the circle ABCD, it is plain ABC is a semicircle, as also BCD (by the 14th); therefore the arc ABC is equal to the arc BCD; and from both taking the common arc BC, there will remain AB equal to CD, i.e. the Angle BEA equal to the angle CED (by art. 29.). After the same manner we may prove, that the angle BEC is equal to the angle AED.

33. Lines which are equally distant from one another, are called parallel lines; as AB, CD, fig. 18.

34. If a line GH crosses two parallels AB, CD, (fig. 19.) then the external opposite angles are equal, viz. GEB equal to CFH and AEG equal to HFD. For since AB and CD are parallel to one another, they may be considered as one broad line, and GH crossing it; then the vertical or opposite angles GEB and CFD are equal (by art. 32.), as also AEG and HFD by the same.

35. If a line GH crosses two parallels AB, CD, then the alternate angles, viz. AEF and EFD, or CFE and FEB, are equal; that is, the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the same); but GEB is equal to CFH (by the laft); therefore AEF, is equal to EFD. The same way we may prove FEB equal to EFC.

36. If a line GH crosses two parallel lines AB, CD, then the external angle GEB is equal to the internal opposite one EFD, or GEA equal to CFE. For the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the same); but GEB is equal to CFH (by the laft); therefore AEF, is equal to EFD. The same way we may prove AEF equal to CFE.

37. If a line GH crosses two parallel lines AB, CD, then the sum of the two internal angles, viz. BAE and EFD, or AEF and CFE, are equal to two right angles; for since the angle GEB is equal to the angle EFD (by the laft); but AEF is equal to GEB (by art. 32.), therefore GEB is equal to EFD. The same way we may prove AEF equal to CFE.

38. If a line GH crosses two parallel lines AB, CD, then the sum of the two angles ABC and CDB, known as a triangle, as A, fig. 24.

39. A figure is any part of space bounded by lines or a line. If the bounding lines be straight, it is called a rectilinear figure, as A, fig. 20. If they be curved, it is called a curvilinear figure, as B or C, fig. 21. and fig. 22. if they be partly curve lines and partly straight, it is called a mixt figure, as D, fig. 23.

35. The most simple rectilinear figure is that which is bounded by three right lines, and is called a triangle, as A, fig. 24.

40. Triangles are divided into different kinds, both with respect to their sides and angles: with respect to their sides they are commonly divided into three kinds, viz.
41. A triangle having all its three sides equal to one another, is called an equilateral triangle, as \(A\), fig. 25.

42. A triangle having two of its sides equal to one another, and the third side not equal to either of them, is called an isosceles triangle, as \(B\), fig. 26.

43. A triangle having none of its sides equal to one another, is called a scalene triangle, as \(C\), fig. 27.

44. Triangles, with respect to their angles, are divided into three different kinds, viz.

45. A triangle having one of its angles right, is called a right-angled triangle, as \(A\), fig. 28.

46. A triangle having one of its angles obtuse, or greater than a right angle, is called an obtuse-angled triangle, as \(A\), fig. 29.

47. Lastly, a triangle having all its angles acute, is called an acute-angled triangle, as \(C\), fig. 30.

48. In all right-angled triangles, the sides comprehending the right angle are called the legs, and the side opposite to the right angle is called the hypotenuse. Thus in the right-angled triangle \(ABC\), fig. 31. (the right angle being at \(B\)) the two sides \(AB\) and \(BC\), which comprehends the right angle \(ABC\), are the legs of the triangle; and the side \(AC\), which is opposite to the right angle \(ABC\), is the hypotenuse of the right-angled triangle \(ABC\).

49. Both obtuse and acute angled triangles are in general called oblique-angled triangles; in all which any side is called the base, and the other two the sides.

50. The perpendicular height of any triangle is a line drawn from the vertex to the base perpendicularly; thus if the triangle \(ABC\) (fig. 32.) be proposed, and \(BC\) be made its base, then \(A\) will be the vertex, viz. the angle opposite to the base; and if from \(A\) you draw the line \(AD\) perpendicular to \(BC\), then the line \(AD\) is the height of the triangle \(ABC\) standing on \(BC\) as its base.

Hence all triangles standing between the same parallels have the same height, since all the perpendiculars are equal by the nature of parallels.

51. A figure bounded by four sides is called a quadrilateral or quadrangular figure, as \(ABDC\), fig. 33.

52. Quadrilateral figures whose opposite sides are parallel, are called parallelograms. Thus in the quadrilateral figure \(ABCD\), if the side \(AC\) be parallel to the side \(BD\) which is opposite to it, and \(AB\) be parallel to \(CD\), then the figure \(ABDC\) is called a parallelogram.

53. A parallelogram having all its sides equal and angles right, is called a square, as \(A\), fig. 34.

54. That which hath only the opposite sides equal and angles right, is called a rectangle, as \(B\), fig. 35.

55. That which hath equal sides but oblique angles, is called a rhombus, as \(C\), fig. 36. and is just an inclined square.

56. That which hath only the opposite sides equal and the angles oblique, is called a rhomboid, as \(D\), fig. 37. and may be conceived as an inclined rectangle.

57. When none of the sides are parallel to another, then the quadrilateral figure is called a trapezium.

58. Every other right-angled figure, that has more sides than four, is in general called a polygon. And figures are called by particular names according to the number of their sides, viz. one of five sides is called a pentagon, of six a hexagon, of seven a heptagon; and so on. When the sides forming the polygon are equal to one another, the figure is called a regular figure or polygon.

59. In any triangle \(ABC\), fig. 28.) one of its legs, as \(BC\), being produced towards \(D\), the external angle \(ACD\) is equal to both the internal opposite ones taken together, viz. to \(ABC\) and \(BAC\).

In order to prove this, through \(C\) draw \(CE\) parallel to \(AB\); then since \(CE\) is parallel to \(AB\), and the lines \(AC\) and \(BD\) are cut by them, the angle \(ECD\) is equal to \(ABC\) (by art. 36.) and the angle \(ACE\) equal to \(BAC\) (by art. 35.); therefore the angles \(ECD\) and \(ECA\) are equal to the angles \(ABC\) and \(CAB\); but the angles \(ECD\) and \(ECA\) are together equal to the angle \(ACD\); therefore the angle \(ACD\) is equal to both the angles \(ABC\) and \(CAB\) taken together.

Cor. Hence it may be proved, that if two lines \(AB\) and \(CD\) (fig. 30.) be crooked by a third line \(EF\), and the alternate angles \(AEF\) and \(EFD\) be equal, the lines \(AB\) and \(CD\) will be parallel; for if they are not parallel, they

60. In any triangle \(ABC\), all the three angles taken together are equal to two right angles. To prove this, you must produce \(BC\), one of its legs, to any distance, supposing to \(D\); then by the last proposition, the external angle, \(ACD\), is equal to the sum of the two internal opposite ones \(CAB\) and \(ABC\); to both add the angle \(ACB\), then the sum of the angles \(ACD\) and \(ACB\) will be equal to the sum of the angles \(CAB\) and \(CBA\).

But the sum of the angles \(ACD\) and \(ACB\), is equal to two right ones (by art. 32.), therefore the sum of the three angles \(CAB\) and \(CBA\) and \(ACB\), is equal to two right angles; that is, the sum of the three angles of any triangle \(ACB\) is equal to two right angles.

Cor. 1. Hence in any triangle given, if one of its angles be known, the sum of the other two is also known: for since (by the last) the sum of all the three is equal to two right angles, or a semicircle, it is plain, that taking any one of them from a semicircle or 180 degrees, the remainder will be the sum of the other two. Thus (in the former triangle \(ABC\) if the angle \(ABC\) be 90 degrees, by taking 40 from 180 we have 140 degrees; which is the sum of the two angles \(BAC\) and \(ACB\): the converse of this is also plain, viz. the sum of any two angles of a triangle being given, the other angle is also known by taking that sum from 180 degrees.

2. In any right-angled triangle, the two acute angles must just make up a right one between them; consequently, any one of the oblique angles being given, we may find the other by subtracting the given one from 90 degrees, which is the sum of both.

61. If in any two triangles, \(ABC\) (fig. 40.) \(DEF\) (fig. 41.) two legs of the one, viz. \(AB\) and \(AC\), be equal to two
two legs in the other, viz. DE and DF, each to each respectively, i.e. AB to DE, and AC to DF; and if the angles included between the equal legs be equal, viz. the angle BAC equal to the angle EDF; then the remaining leg of the one shall be equal to the remaining leg of the other, viz. BC to EF; and the angles opposite to equal legs shall be equal, viz. ABC equal to DEF (being opposite to the equal legs AC and DF), also ACD equal to DEF (which are opposite to the equal legs AB and DE). For if the triangle ABC be supposed to be lifted up and put upon the triangle DEF, and the point A on the point D; it is plain, since BA and DE are of equal length, the point E will fall upon the point B; and since the angles BAC EDF are equal, the line AC will fall upon the line DF; and they being of equal length, the point C will fall upon the point F; and so the line BC will exactly agree with the line EF, and the triangle ABC will in all respects be exactly equal to the triangle DEF; and the angle ABC will be equal to the angle DEF, also the angle ACB will be equal to the angle DFE.

Cor. 1. After the same manner it may be proved, that if in any two triangles ABC, DEF, (see the preceding figure) two angles ABC and ACD of the one, be equal to two angles DEF and EDF of the other, each to each respectively, viz. the angle ABC to the angle DEF, and the angle ACD to the angle EDF, and the sides included between these angles be also equal, viz. BC to EF, and since the angles BAC EDF are equal, the line AC will fall upon the line DF; and they being of equal length, the point C will fall upon the point F; and so the line BC will exactly agree with the line EF, and the triangle ABC will in all respects be exactly equal to the triangle DEF; and the angle ABC will be equal to the angle DEF, also the angle ACB will be equal to the angle DFE.

Cor. 2. Hence all angles, ACD, ADB, AEB, &c. (fig. 44.) at the circumference of a circle, standing on the same arch AB, are equal to one another; for by the last corollary they are all measured by the same arc, viz. half the arc AB which each of them subtends.

Cor. 3. Hence an angle in a segment greater than a semicircle is less than a right angle; thus, if ABD be a segment greater than a semicircle, (see the last figure) the arc AB, on which it stands, must be less than a semicircle, and the half of it less than a quadrant or a right angle; but the angle ADB in the segment is measured by the half of AB, therefore it is less than a right angle.

Cor. 4. An angle in a semicircle is a right angle. For since ABD (fig. 45.) is a semicircle, the arc AED must also be a semicircle: but the angle ABD is measured by half the arc AED, that is, by half a semicircle or quadrant; therefore the angle ABD is a right one.

Cor. 5. Hence an angle in a segment less than a semicircle, as ABD, (fig. 46.) is greater than a right angle; for since the arc ABD is less than a semicircle, the arc AED must be greater than a semicircle, and so it is half greater than a quadrant, i.e. than the measure of a right angle; therefore the angle ABD, which is measured by half the arc AED, is greater than a right angle.

63. If from the centre C of the circle ABE (fig. 47.) there be let fall the perpendicular CD on the chord AB, then that perpendicular will bisect the chord AB in the point D. To demonstrate this, draw from the centre to the extremities of the chord the two lines CA, CB; then since the lines CA and CB are equal, the angles CBA, CB, which they subtend must be equal also, (by art. 62. cor. 2.) but the perpendicular CD divides the triangle ABE into two right-angled triangles ACD and CDR, in which the sum of the angles ACD and CAD in the one, is equal to the sum of the angles DCB and CBD in the other, each being equal to a right angle, (by cor. 2. of art. 61.) but CAD is equal to CBD, therefore ACD is equal to BCD. So in the two triangles ACD and BCD, the two legs AC and CD in the one, are equal to the two legs BC and CD in the other, each to each respectively, and the included angles ACD and BCD are equal; therefore the remaining legs AD and BD are equal (by art. 61.) and consequently AB bisected in D.
GEOMETRY.

66. If from the centre C of a circle ABE, there be drawn a perpendicular CD on the chord AB, and produced till it meet the circle in F, then the line CF bisects the chord AB in the point F; for (see the foregoing figure) joining the points A and F, F and B by the right lines AF, FB, then in the triangles ADF, BDF, AD is equal to DB (by art. 63.) and DF common to both; therefore AD and DF, two legs of the triangle ADF, are equal to BD and DF, two legs of the triangle BDF, and the included angles ADF, BDF are equal, being both right; therefore (by art. 61.) the remaining legs AF and FB are equal; but in the same circle equal lines are chords of equal arches, therefore the arches AF and FB are equal. So the whole arch AFB is bisected in the point F by the line CF.

Cor. 1. From art. 63, it follows, that any line bisecting a chord at right angles is a diameter; for since (by art. 63.) a line drawn from the centre perpendicular to a chord, bisects that chord at right angles; therefore, conversely, a line bisecting a chord at right angles, must pass thro' the centre, and consequently be a diameter.

Cor. 2. From the two last articles it follows, that the sine of any arc is the half of the chord of twice the arc; for (see the foregoing scheme) AD is the sine of the arc AF, by the definition of a sine, and HE is the arc AFB, and AD half the chord AB (by art. 63.); therefore the cor. is plain.

65. In any triangle, the half of each side is the sine of the opposite angle; for if a circle be supposed to be drawn through the three angular points A, B, and D of the triangle ABD, fig. 48, then the angle DAB is measured by half the arch BKD (by cor. 1. of art. 62.) but the half of BD, viz. BE, is the sine of the half the arch BKD, viz. the sine of BK (by cor. 2. of the last) which is the measure of the angle BAD; therefore, the half of BD is the sine of the angle BAD; the same way it may be proved, that the half of AD is the sine of the angle ABD, and the half of AB is the sine of the angle ADB.

66. The sine, tangent, &c. of any arc is called also the sine, tangent, &c. of the angle whose measure the arc is; thus because the arc GD (fig. 49.) is the measure of the angle GCD; and since GH is the sine, DE the tangent, HD the versed sine, CE the secant, also GK the co-sine, BF the co-tangent, and CF the co-secant, &c. of the arc GD; then GH is called the sine, DE the tangent, &c. of the angle GCD, whose measure is the arc GD.

67. If two equal and parallel lines, AB and CD (fig. 50.) be joined by two others, AC and BD; then these shall also be equal and parallel. To demonstrate this, join the two opposite angles A and D with the line AD; then it is plain this line AD divides the quadrilateral, ACDB, into two triangles, viz. ABDE, ACD, in which AB a leg of the one, is equal to DC a leg of the other, by supposition, and AD is common to both triangles; and since AB is parallel to CD, the angle BAD will be equal to the angle ADC, (by art. 36.) therefore in the two triangles BA and AD; and the angle BAD is equal to CD and DA; and the angle ADC, that is, two legs and the included angle in the one, is equal to two legs and the included angle in the other; therefore (by art. 61.) BD is equal to AC, and since the angle DAC is equal to the angle ADB, therefore the lines BD AC are parallel (by cor. 59.)

Cor. 1. Hence it is plain, that the quadrilateral ABDC is a parallelogram, since the opposite sides are parallel.

Cor. 2. In any parallelogram the line joining the opposite angles (called the diagonal) as AD, divides the figure into two equal parts; since it has been proved that the triangles ABD, ACD are equal to one another.

Cor. 3. It follows also, that a triangle ACD on the same base CD, and between the same parallels with a parallelogram ABDC, is the half of that parallelogram.

Cor. 4. Hence it is plain, that the opposite sides of a parallelogram are equal; for it has been proved, that ABDC being a parallelogram, AB will be equal to CD, and AC equal to BD.

68. All parallelograms on the same or equal bases, and between the same parallels, are equal to one another; that is, if BD and GH (fig. 51.) be equal, and the lines BH and AF be parallel, then the parallelograms ABD, BDFE, and EFHG, are equal to one another. For AC is equal to EF, each being equal to BD, (by cor. 4. of 67.) To both add CE, then AE will be equal to CF. So in the two triangles ABE, CDF, AB a leg of the one, is equal to CD a leg in the other; and AE is equal to CF, and the angle BAE is equal to the angle DCF (by art. 36.); therefore the two triangles ABE, CDF are equal (by art. 61.); and taking the triangle KCE from both, the figure ABECK will be equal to the figure KDFE; to both which add the little triangle KBD, then the parallelogram ABDK will be equal to the parallelogram BDFK. The same way it may be proved, that the parallelogram EFHG is equal to the parallelogram EFDB; so the three parallelograms ABD, BDFE, and EFHG will be equal to one another.

Cor. Hence it is plain, that triangles on the same base, and between the same parallels, are equal; since they are the half of the parallelograms on the same base and between the same parallels. (by cor. 3. of last art.)

69. In any right-angled triangle, ABC, (fig. 52.) the square of the hypotenuse BC, viz. BCMH, is equal to the sum of the squares made on the two sides AB and AC, viz. to ABDE and ACGF. To demonstrate this, through the point A draw AKL perpendicular to the hypotenuse BC, join AH, AM, DC, and BG; then it is plain that DB is equal to BA (by art. 53.), also BH is equal to BC (by the same); so in the two triangles DBC, AH, the two legs DB and BC in the one are equal to the two legs AB and BH in the other; and the included angles DBC and ABH are also equal; (for DBA is equal to CBH, being both right: to each add ABC, then it is plain that DBC is equal to ABH) therefore the triangles DBC and ABH are equal (by art. 61.) but the triangle DBC is half of the square ABDE (by cor. 3. of 67th) and the triangle ABH is half the parallelogram BKHL (by the same), therefore half the square ABDE, is equal to half the parallelogram BKHL. Consequently, the square ABDE is equal to the parallelogram BKHL. The same way it may be proved, that the square ACGF is equal to the parallelogram KCML. So the sum of the squares of the parallelograms BKHL and KCML, but the sum of the squares of the parallelograms is equal to the square BCMH, therefore the
Cor. 1. Hence in a right-angled triangle, the hypotenuse and one of the legs being given, we may easily find the other, by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder will be the leg required.

Cor. 2. Hence, the legs in a right-angled triangle being given, we may find the hypotenuse, by taking the sum of the squares of the given legs, and extracting the square root of that sum.

70. If upon the line AB (fig. 53.) there be drawn a semicircle ADB, whose centre is C, and on the point C there be raised a perpendicular to the line AB, viz. CD; then it is plain the arc DB is a quadrant, or contains 90 degrees; suppose the arc DB to be divided into 9 equal arcs, each of which will contain 10 degrees, then on the point B raising BE perpendicular to the line AB, it will be a tangent to the circle in the point B, and if to every one of the divisions of the quadrant, viz. B 10, B 20, B 30, B 40, &c. you draw the fine, tangent, &c. (as in the scheme) we shall have the fine, tangent, &c. to every 10 degrees in the quadrant: and the same way we may have the fine, tangent, &c. to every single degree in the quadrant, by dividing it into 90 equal parts beginning from B, and drawing the fine, tangent, &c. to all the arcs beginning at the fame point B. By this method they draw the lines of fines, tangents, &c. of a certain circle on the scale; for after drawing them on the circle, they take the length of them, and set them off in the lines drawn for that purpose. The fame way, by supposing the radius of any number of equal parts, (suppose 1000, or 10,000, &c.) it is plain the fine, tangent, &c. of every arc must consist of some number of these equal parts; and by computing them in parts of the radius, we have tables of fines, tangents, &c. to every arc in the quadrant, called natural fines, tangents, &c. and the logarithms of these give us tables of logarithmic fines, tangents, &c. See Logarithms.

71. In any triangle, ABC, (Plate XCIV. fig. 1.) if one of its sides, as AC, be bisected in E, (and consequently AC double of AE) and through E be drawn ED, parallel to BC, and meeting AB in D, then BC will be double of ED, and AB double of AD, through D draw DF, parallel to AC, meeting BC in F: for fines, by construction, DF is parallel to AC, and DF parallel to BC; therefore, (by art. 36.) the angle BFD will be equal to the angle BCA, (and by the same article) the angle BCA will be equal to the angle DEA, consequently the angle BFD will be equal to the angle DEA; also, (by art. 36.) the angle BDF will be equal to the angle DAE; and since DF is parallel to EC, and DB parallel to FC, the quadrilateral DFCE will be a parallelogram; and therefore, (by art. 59. cor. 4.) DF will be equal to EC, which, by construction, is equal to AE; so in the two triangles BDF DAE, the two angles BFD and BDF in the one, are equal to the two angles DBA and DAE in the other, each to each respectively; and the included side DF is equal to the included side AE; therefore, (by art. 61. cor. 1.) AD will be equal to DB, and consequently AB double of AD; also (by the same) DE will be equal to BF; but DE is also (by art. 67. cor. 4.) equal to FC; therefore BF and EC together, or BC, will be double of DE.

After the same manner it may be proved, that if in the triangle AKG, (fig. 2.) AE be taken equal to a third part of AK, and through E be drawn ED, parallel to KG, and meeting AG in D; then ED will be equal to a third part of GK, and AD equal to a third part of AG.

Likewise if in any triangle ABC, (fig. 3.) upon the side AB, be taken AE, equal to one fourth, one fifth, one sixth, &c. of AB, and through E be drawn ED parallel to BC and meeting AC in D; then DE will be one fourth, one fifth, one sixth, &c. of BC, and AD the like part of AC; and, in general, if in any triangle ABC, there be assumed a point E on one of its sides AB, and through that point be drawn a line ED, parallel to one of its sides BC, and meeting the other side AC in D; then whatever part AE is of AB, the same part will ED be of BC, and AD of AC.

Cor. Hence it follows, that if in any triangle ABC, there be drawn ED, parallel to one of its sides BC, and meeting the other two in the points E and D, then AE : AB :: ED : BC :: AD : AC; that is, AE is to AB, as ED is to BC, and that as AD to AC.

72. If any two triangles ABC, fig. 4. abc, fig. 5. are similar, or have all the angles of the one equal to all the angles of the other, each to each respectively; that is, the angle CAB equal to the angle abc, and the angle ABC equal to the angle ACB, and the angle ACB equal to the angle abc; then the legs opposite to the equal angles are proportioned, viz. AB : a b :: AC : a c :: and AB : a b :: BC : b c :: and AC : a c :: BC : b c.

On AB of the largest triangle set off AE equal to a, and through E draw ED parallel to BC, meeting AC in D; then since DE and BC are parallel, and AB crossing them, the angle AED will (by art. 36.) be equal to the angle ABC, which (by supposition) is equal to the angle a b c; also the angle DAE is (by supposition) equal to the angle a b c; so in the two triangles AED, a b c, the two angles DAE AED of the one, are equal to two angles a b c of the other, each to each respectively, and the included side AE is (by construction) equal to the included side a b; therefore, (by art. 61. cor. 1.) AD is equal to a c, and DE equal to c; but since, in the triangle ABC, there is drawn DE parallel to BC one of its sides, and meeting the two other sides in the points D and E, therefore (by cor. art. 71.) AB : AE :: AC : AD, and AB : AE :: BC : DE, and AC : AD :: BC : DE; and in the three last proportions, instead of the lines AE, DE, and AD, putting in their equal a b, c, and a c, we shall have AB : a b :: AC : a c, and AB : a b :: BC : b c, and finally, AC : a c :: BC : b c.

73. The chord, fine, tangent, &c. of any arc in one circle, is to the chord, fine, tangent, &c. of the same arc in another, as the radius of the one is to the radius of the other, fig. 6. 6. Let ABD abd be two circles, BD bd two arcs of these circles, equal to one another, or confisting of the fame number of degrees; FD fd the tangents, BD bd the chords, BE be the fines, &c.
of these two arcs BD bd, and CD cd the radii of the circles; then lay, CD : cd :: FD : fd, and CD : cd :: BD : bd, and CD : cd :: BE : be, &c. For since the arcs BD bd are equal, the angles BCD bcd will be equal; and FD fd, being tangents to the points D and d, the angles CDF cd will be equal, being each a right angle (art. 22.) so in the two triangles CDF cdf, the two angles CDF CDF of the one, being equal to the two angles fcd of the other, each to each, the remaining angle CFD, will be equal to the remaining angle CFD, (by art. 60.); therefore the triangles CDF cdf are similar, and consequently (by art. 73.) CD : cd :: FD : fd. In the same manner it may be demonstrated, that CD : cd :: BD : bd, and CD : cd :: BE : be, &c.

74. Let ABD (fig. 7.) be a quadrant of a circle described by the radius CD BD any arc of it, and BA its complement, BG or BF the sine, CG or BF the co- sine, DE the tangent, and CE the secant of that arc BD. Then since the triangles CDE CGB are similar or equal- angular, it will be (by art. 72.) DE : EC :: GB : BC, i.e. the tangent of any arc, is to the secant of the same, as the sine of it is to the radius. Also since DE : EC :: GB : BC, therefore, by inverting that proportion, we have EC : DE :: GB : BC, i.e. the secant is to the tangent, as the radius is to the sine of any arc.

Again, since the triangles CDE CGB are similar, therefore (by art. 72.) it will be CD : CE :: CG : CB, i.e. as the radius is to the secant of any arc, so is the co- sine of that arc to the radius. And by inverting the proportion we have this, viz. As the secant of any arc is to the radius, so is the radius to the co- sine of that arc.

75. In all circles the chord of 60 is always equal to length to the radius. Thus in the circle AEBD, (fig. 8.) if the arc AEB be an arc of 60 degrees, then drawing the chord AB, I lay AB shall be equal to the radius CB or AC; for in the triangle ACB, the angle ACB is 60 degrees, being measured by the arc AEB; therefore the sum of the other two angles is 120 degrees, (by cor. 1. of 60.) but since AC and CB are equal to the two angles CAB, CBA will also be equal; consequently each of them half their sum 120, viz. 60 degrees. Consequently all the three angles are equal to one another, consequently all the legs, therefore AB is equal to CB.

Cor. Hence the radius from which the lines on any scale are formed, is the chord of 60 on the line of chords.

Geometrical Problems.

Prob. 1. From a point C (fig. 9.) in a given line AB to raife a perpendicular to that line.

Rule. From the point C take the equal distances CB, CA on each fide of it. Then stretch the compaffes to any distance greater than CB or CA, and with one foot of them in B, sweep the arc EF with the other; again, with the fame opening, and one foot in A, sweep the arc GH with the other, and these two arcs will intersect one another in the point D; then join the given points C and D with the line CD, and that shall be the perpendicular required.

2. To divide a given right line AB (fig. 10.) into two equal parts; that is, to bifet it.

Rule. Take any distance with your compaffes that you are sure is greater than half the given line; then setting one foot of them in B, with the other sweep the arc DFC; and with the fame distance, and one foot in A, with the other sweep the arc CFD; these two arcs will intersect one another in the points C D, which joined by the right line DC will bifet AB in G.

3. From a given point D, (fig. 11.) to let fall a perpendicular on a given line AB.

Rule. Set one foot of the compaffes in the point D, and extend the other to any distance greater than the least distance between the given point and the line, and with that extent sweep the arc AEB, cutting the line in the two points A and B, then (by the last prob.) bifet the line AB in the point C, lastly join C and D, and that line CD is the perpendicular required.

4. (Fig. 12.) Upon the end B of a given right line BA, to raife a perpendicular.

Rule. Take any extent in your compassses, and with one foot in B fix the other in any point C without the given line; then with one point of the compassses in C, describe with the other the circle EBD, and thro' E and C draw the diameter ECD meeting the circle in D; join D and B, and the right line DB is that required; for EBD is a right angle (by cor. 4. of 63.).

5. (Fig. 13.) To draw one line parallel to another given line AB, that shall be diftant from one another by any given distance D.

Rule. Extend your compassses to the given distance D; then setting one foot of them in any point of the given line (suppose A), with the other sweep the arc FEC; again, at the fame extent, and one foot in any other point of the given line B, sweep the arc HDK; and draw the line CD touching them, and that will be parallel to the given line AB, and diftant from it by the line D as was required.

6. (Fig. 14.) To divide a given line AB into any number of equal parts, suppose 7.

Rule. From the point A draw any line AD, making an angle with the line AB, then through the point B, draw a line BC parallel to AD; and from A, with any small opening of the compassses, set off a number of equal parts (on the line AD) lefts by one than the proposed number (here 6); then from B set off the same number of the same parts (on the line BC); lastly, join 6 and 1, 2 and 5, 3 and 4, 4 and 2, 5 and 2, 6 and 1, and these lines will cut the given line as required.

7. (Fig. 15.) To quarter a given circle, or to divide it into four equal parts.

Rule. Thro' the centre C of the given circle, draw a diameter AB, then upon the point C raife a perpendicular DCE to the line AB; and these two diameters AB and DE shall quarter the circle.

8. (Fig. 16.) Thro' three given points A, B, and D, to draw a circle. (Note, The three points must not lie in the fame ftraight line.)

Rule. Join A and B, also B and D, with the frefight lines AB BD; then (by prob. 2.) bifet AB with the line.
GEOMETRY.

Line EC, also BD with the line FC, which two lines will cut one another in some point C; that is the centre of the circle required: then fixing one point of your compasses in D, and stretching the other to A, describe the circle ABDG, which will pass thro' the three points given. The reason of this is plain from cor. 1. of art. 64.

9. (Fig. 17.) From the point A of the given line AB, to draw another line (suppose AC) that shall make with AB an angle of any number of degrees, suppose 45.

Rule. Let the given line AB be produced, then take off your scale the length of the chord of 45 degrees, which is equal to the radius of the circle the scale was made for (by art. 75.); and setting one foot in A, with the other sweep of the arc BC; then with your compasses take from your scale the chord of 45 degrees, and set off that distance from B to C. Lastly, join A and C, and the line AC is that required. For the angle CAB, which is measured by the arc BC, is an angle of 45 degrees, as was required.

10. An angle BAC (fig. 18.) being given, to find how many degrees it contains.

Rule. With your compasses take the length of your chord of 60 from your scale. Then, setting one foot of them in A, with the other sweep the arc BC, which is the arc comprehended between the two legs AB, AC produced if needful. Lastly, take with your compasses the distance BC, and applying it to your line of chords on the scale, you will find how many degrees the arc BC contains, and consequently the degrees of the angle BAC which was required.

11. Three lines x, y, and z being given, (fig. 19. 19.) to form a triangle of them; but any two of these lines taken together must always be greater than the third.

Rule. Make any one of them, as x, the base; then with your compasses take another of them, as z, and setting one foot in one end of the line x, as B, with the other sweep the arc DE; and taking with your compasses the length of the other y, set one foot of them in A, the other end of the line x, and with the other sweep the arc FG, which will cut the other in C; lastly, join CA and CB, and the triangle CAB is that required.

12. To make a triangle, having one of its legs of any number of equal parts (suppose 160), and one of the angles at that leg 50 degrees, and the other 44 degrees.

Rule. Draw an indefinite line ED, (fig. 20.) then take off the line of equal parts with your compasses, 160 of them, and set them on the indefinite line, as BC; then (by prob. 9.) draw BA, making the angle ABC of 50 degrees, and (by the same) draw from C the line AC, making the angle ACB of 44 degrees; which two lines will meet one another in A, and the triangle ABC is that required. See Trigonometry.

13. Upon a given line AB (fig. 21.) to make a square.

Rule. Upon the extremity A of the given line AB, raise a perpendicular AC (by prob. 4.); then take AC equal to AB, and with that extent, setting one foot of the compasses in C, sweep with the other foot the arc CH; then with the same extent, and one foot in B, with the other sweep the arc EF, which will meet the former in some point D; lastly, join C and D, and B, and the figure ABDC will be the square required.

14. On a given line AB (fig. 22.) to draw a rhomb that shall have one of its angles equal to any number of degrees, suppose 60 degrees.

Rule. From the point A of the given line AB, draw the line AC, making the angle CAB of 60 degrees, (by the same) draw from C the line AC, making the angle ACB of 30 degrees; then with the other compasses take another of them, as z, and on the extremity A of that line, raise a perpendicular AC, on which take AC equal to AR, and with that extent, fixing one foot of the compasses in B, with the other describe the arc GH; and at the same extent, fixing one foot of the compasses in C, with the other describe the arc EF, which will meet the former in D; lastly, join CD and DB, and the figure ACDB is that required.

15. Given two lines x and z, of these two to make a rectangle.

Rule. Draw a line, as AB, (fig. 23. 23.) equal in length to one of the given lines x; and on the extremity A of that line, raise a perpendicular AC, on which take AC equal to the other z; then take with your compasses the length of the line AB, and at that extent, fixing one foot of them in C, with the other sweep the arc EF; and also taking with your compasses the extent of the line AC, fix one foot of them in B, and with the other sweep the arc GH, which will meet the former in D; lastly, join CD and DB, and the figure ACDB will be that required.

16. Two lines x and z being given, of these to form a rhomboides that shall have one of its angles any number of degrees, suppose 50.

Rule. Draw a line AB (fig. 24. 24.) equal in length to one of the lines, as x; then draw the line AC, making with the former the angle BAC equal to the proposed, suppose 50 degrees, and on that line take AC equal to the given line z, then with your compasses take the length of AB, and fixing one foot in C, sweep the arc EF; also, taking the length of AC, and setting one foot in B, with the other sweep the arc GH, which will cut the former in D; then join CD and DB, fo the figure ACDB will be that required.

PART II.

THE APPLICATION OF THE FOREGOING PRINCIPLES TO THE MENSURATION OF SURFACES, SOLIDS, &c.

Of the Mensuration of Lines and Angles.

A line, or length, to be measured, whether it be distance, height, or depth, is measured by a line less than it. With us the least measure of length is an inch; not that we measure no line less than it, but because we do not use the name of any measure below that of an inch; expressing lesser measures by the fractions of an inch: and in this treatise we use decimal fractions as the easiest. Twelve inches make a foot; three feet and an
inch make the Scots ell; six ells make a fall; forty falls make a furlong; eight furlongs make a mile: so that the Scots miles is 1184 paces, accounting every pace to be five feet. These things are according to the statutes of Scotland; notwithstanding which, the glaziers use a foot of only eight inches; and other artists for the most part use an English foot, on account of the several scales marked on the English foot-measure for their use. But the English foot is somewhat less than the Scots; so that 185 of these make 186 of thefe.

Lines, to the extremities and any intermediate point of which you have easy access, are measured by applying to them the common measure a number of times. But lines, to which you cannot have such access, are measured by methods taken from geometry; the chief whereof we shall here endeavour to explain. The first is by the help of the geometrical square.

As for the English measures, the yard is three feet, or thirty-six inches. A pole is sixteen feet and a half, or five yards and a half. The chain, commonly called Gunter's chain, is four poles, or twenty-two yards, or thirty-six inches. An English statute-mile is four-score chains, or 1760 yards, that is, 5280 feet. The chain (which is now much in use, because it is very convenient for surveying) is divided into a hundred links, each of which is 7 7/8 of an inch: whence it is easy to reduce any number of those links to feet, or any number of feet to links.

A chain that may have the same advantages in surveying in Scotland, as Gunter's chain has in England, ought to be in length seventy-four feet, or twenty-four Scots ells, if no regard is had to the difference of the Scots and English foot above mentioned. But, if regard is had to that difference, the Scots chain ought to consist of 74 3/4 English feet, or 74 feet 3 inches and 4 1/4 of an inch. This chain being divided into an hundred links, each of those links is 8 inches and 7 1/8 of an inch. In the following table, the most noted measures are expressed in English inches and decimals of an inch.

PROPOSITION I.

PROB. To describe the structure of the geometrical square.—The geometrical square is made of any solid matter, as brass or wood, or of any four plain rulers joined together at right angles, (as in Plate XCV. fig. 1.) where A is the centre, from which hangs a thread with a small weight at the end, so as to be directed always to the centre. Each of the sides BE and DE is divided into an hundred equal parts, or (if the sides be long enough to admit of it) into a thousand parts; C and F are two sights, fixed on the side AD. There is moreover an index GH, which, when there is occasion, is joined to the centre A, in such manner as that it can move round, and remain in any given situation. On this index are two sights perpendicular to the right line going from the centre of the instrument: these are K and L.

The side DE of the instrument is called the upright side; E the reclining side.

PROPOSITION II.

Fig. 2. To measure an accessible height, AB, by the help of a geometrical square, its distance being known. —Let BR be an horizontal plane, on which there stands perpendicularly any line AB; let BD, the given distance of the observer from the height, be 96 feet; let the height of the observer's eye be suppos'd 6 feet; and let the instrument, held by a steady hand, or rather leaning on a support, be directed towards the summit A, so that one eye (the other being shut) may see it clearly through the sights; the perpendicular or plumb line meanwhile hanging free, and touching the surface of the instrument.
ftament: let now the perpeoJicular be fappofei to cut
off on the right iideKN 80 equal parts. It is clear that
LKN, ACK, are limilar triangles ; for the angles LKN,
ACK are right angles, and therefore equal; moreover
the angles KLN, KAG, are equal; wherefore, (by arc.
the horizon ; c nfequently, (by art. 60. cor. i. part i.)
LN and AC are parallel, as being both perpendicular to
60 cor. 2. of part i.) the angles LNK, and AKC, are
Therefore, by the rule of three, CA will be found to
be 120 feet; and CB, which is 6 feet, being added, the
whole height is 126 feet. But if the distance of the observer from the height,
as BE, be fuch, that, when the instrument is directed as
formerly toward the summit A, the perpendicular falls on
the angle P, oppofite to H, the centre of the instrument,
and BE or CG be given of 120 feet; CA will also be
120 feet. For in the triangles HGP, ACG, equiangular,
as in the preceding cafe, as PG : GH :: GC : CA. But PG is equal to GH; therefore GC is like-
wise equal to CA: that is, CA will be 120 feet, and
the whole height 126 feet as before.

Let the distance BF be 300 feet, and the perpendicular
or plumb line cut off 40 equal parts from the reclining
fide: Now, in this cafe, the angles QAC, QZI,
are equal, and the angles QZI, ZIS, are equal; therefore
the angle ZIS is equal to the angle QAC. But
the angles ZSI QCA are equal, being right angles;
therefore, in the equiangular triangles ACQ, ZSI, it
will be, as ZS :: SI :: CO :: CA; that is, as 100 to 40,
so is 300 to CA. Therefore, by the rule of three,
CA will be found to be of 102 feet. And, by adding
the height of the observer, the whole BA will be 126
feet. Note, that the height is greater than the distance,
when the perpendicular cuts the right fide, and lefs if it
cut the reclined fide; and that the height and distance
are equal, if the perpendicular fall on the opposite angle.

SCHOLIUM.

If the height of a tower, to be measured as above, end
in a point, (as in fig. 2.) the distance of the obfervator
opposite to it, is not CD, but is to be accounted from
the perpendicular to the point A; that is, to CD must be
added the half of the thicknefs of the tower, viz.
BD: which muft likewife be underftood in the following
propositions, when the cafe is similar.

PROPOSITION III.

Fig. 4. From the height of a tower AB given, to
find a distance on the horizontal plane BC, by the geometrical square.—Let the instrument be so placed, as that
the mark C in the opposite plane may be seen through the
fights; and let it be observed how many parts are cut off
by the perpendicular. Now, by what hath been already
demonftrated, the triangles AEF, ABC, are similar;
therefore, it will be as EF to AE, so is AB to BC, it will be the dis-
fance sought.

PROPOSITION IV.

Fig. 5. To measure any distance at land or sea, by
the geometrical square.—In this operation, the index is
to be applied to the instrument, as was fhown in the de-
scription; and, by the help of a support, the instrument
is to be placed horizontally at the point A; then let it
be turned till the remote point F, whose distance is to be
measured, be seen through the fixed fights; and bringing
the index to be parallel with the other fide of the instru-
ment, obferve by the fights upon it any accessible mark B,
at a fensible distance: then carrying the instrument to the
point B, let the immovable fights be directed to the firft
flication A, and the fights of the index to the point F. If
the index cut the right fide of the square, as in K, in the
two triangles BRK, and BAF, which are equiangular,
it will be as BR to RK, fo BA (the distance of the ftaffs
to be measured with a chain) to AF; and the distance
AF fought will be found by the rule of three. But if
the index cut the reclined fide of the square in any point
L, where the distance of a more remote point is fought
in the triangles BLS, BAG, the fide LS shall be to SB,
as BA to AG, the distance fought; which accordingly
will be found by the rule of three.

PROPOSITION V.

Fig. 6. To measure an accessible height by means
of a plain mirror.—Let AB be the height to be
measured; let the mirror be placed at C, in the horizontal
plane BD, at a known distance BC; let the obfervfer
go back to D, till he fee the image of the summit in the
mirror, at a certain point of it, which he muft diligently
mark; and let DE be the height of the obfervator's eye.
The triangles ABC and EDC are equiangular; for the
angles at D and E are right angles; and ACB, ECD,
are equal, being the angles of incidence and reflexion of
the ray AC, as is demonstrated in optics; wherefore the
remaining angles at A and E are also equal: therefore
it will be, as CD to DE, fo CB to BA; that is, as the
distance of the obfervator from the point of the mirror
in the right line betwixt the obfervator and the height, is
to the height of the obfervator's eye, fo is the distance
of the tower from that point of the mirror, to the height of
the tower fought; which therefore will be found by the
rule of three.

Note 1. The obfervation will be more exact, if, at the
point D, a ftaff be placed in the ground perpendicularly,
over the top of which the obfervator may fee a point of
the glafs exactly in a line betwixt him and the tower.

Note 2. In place of a mirror may be used the sur-
face of water contained in a vefsid, which naturally
becomes parallel to the horizon.

PROPOSITION VI.

Fig. 7. To measure an accessible height AB by means
of two ftaffs.—Let there be placed perpendicularly in
the ground a longer ftaff DE, likewife a shorter one FG,
so as the obfervator may fee A, the top of the height to
be measured, over the ends D of the two ftaffs; let
FH and DC, parallel to the horizon, meet DE and AB
in H and C; then the triangles FHD, DCA, shall be
equiangular;
equiangular; for the angles at C and H are right ones; likewise the angle A is equal to the angle FDH; wherefore the remaining angles DFH, and A, C, are also equal: Wherefore, as FH, the distance of the staffs, to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff. And thence CA will be found by the rule of three.

To which if the length DE be added, you will have the whole height of the tower BA.

CHOLIUM.

Fig. 8. Many other methods may be occasionally contrived for measuring an accessible height. For example, from the given length of the shadow BD, to find out the height AB, thus: Let there be erected a staff CE perpendicularly, producing the shadow EF: The triangles ABD, CEF, are equiangular; for the angles at B and E are right; and the angles ADB and CFE are equal, each being equal to the angle of the sun's elevation above the horizon: Therefore, as EF, the shadow of the staff, to EC, the staff itself; so BD, the shadow of the tower, to BA, the height of the tower. Though the plane on which the shadow of the tower falls be not parallel to the horizon, if the staff be erected in the same plane, the rule will be the same.

PROPOSITION VII.

To measure an inaccessible height by means of two staffs.—Hitherto we have supposed the height to be accessible, or that we can come at the lower end of it; now if, because of some impediment, we cannot get to a tower, or if the point whose height is to be found out be the summit of a hill, so that the perpendicular be hid within the hill; if, for want of better instruments, such an inaccessible height is to be measured by means of two staffs, let the first observation be made with the staffs DE and FG, (as in prop. 6.); then the observer is to go off in a direct line from the height and first station, till he come to the second station; where (fig. 11.) he is to place the longer staff perpendicularly at KN, and the shorter staff at KO, so that the summit A may be seen along their tops; that is, so that the points KN, A may be in the same right line. Through the point N, let there be drawn the right line NP parallel to FA: Wherefore in the triangles KNP, KAF, the angles KNP, KAF are equal, also the angle AKF is common to both; consequently the remaining angle KPN is equal to the remaining angle KFA. And therefore, PN: FA:: KP:KF. But the triangles PNL, FAS are similar; therefore, PN: FA:: NL: SA. Therefore, (by the 11. 5. Eucl.) KP:KF:: NL:SA. Thence, alternately, it will be, as KP (the excess of the greater distance of the shorter staff from the long one above its lesser distance from it) to NL, the excess of the longer staff above the shorter; so KP, the distance of the two stations of the shorter staff to SA the excess of the height sought above the height of the shorter staff. Wherefore SA will be found by the rule of three. To which let the height of the shorter staff be added, and the sum will give the whole inaccessible height BA.

Note 1. In the same manner may an inaccessible height be found by a geometrical square, or by a plain speculum. But we shall leave the rules to be found out by the student, for his own exercise.

Note 2. That by the height of the staff we understand its height above the ground in which it is fixed.

Note 3. Hence depends the method of using other instruments invented by geometers; for example, of the geometrical crois; And if all things be justly weighed, a like rule will serve for it as here. But we incline to touch only upon what is most material.

PROPOSITION VIII.

Fig. 9. To measure the distance AB, to one of whose extremities we have access, by the help of four staffs.—Let there be a staff fixed at the point A; then going back at some sensible distance in the same right line, let another be fixed in C, so as that both the points A and B be covered and hid by the staff C: likewise going off in a perpendicular from the right line CH, at the point A, (the method of doing which shall be shewn in the following scholium), let there be placed another staff at H; and in the right line CKG (perpendicular to the same CH, at the point B), and at the point of it K, such that the points K, H, and B may be in the same right line, let there be fixed a fourth staff. Let there be drawn, or let there be suppos’d to be drawn, a right line GH parallel to CA. The triangles KGH, HAB, will be equiangular; for the angles HAB, KG are right angles. Also the angles ABH, KHG are equal; wherefore, as KG (the excess of CK above AH) to GH, or to CA, the distance between the first and second staff; so is AH, the distance between the first and third staff, to AB the distance sought.

CHOLIUM.

Fig. 10. To draw on a plane a right line AE perpendicular to CH, from a given point A; take the right lines AB, AD, on each side equal; and in the points B and D, let there be fixed stakes, to which let there be tied two equal ropes BE, DE, or one having a mark in the middle, and holding in your hand their extremities joined, (or the mark in the middle, if it be but one), draw out the ropes one the ground; and then, where the two ropes meet, or at the mark, when by it the rope is fully stretched, let there be placed a third stake at E; the right line AE will be perpendicular to CH in the point A (prob. 1. of part. i.). In a manner not unlike to this, may any problems that are resolved by the square and compasses, be done by ropes and a cord turned round as a radius.

PROPOSITION IX.

Fig. 11. To measure the distance AB, one of whose extremities is accessible.—From the point A, let the right line AC of a known length be made perpendicular to AB, (by the preceding scholium): likewise draw the right line CD perpendicular to CB, meeting the right line AB in D: then as DA:AC:: AC:AB. Wherefore, when DA and AC are given, AB will be found by the rule of three.

CHOLIUM.

All the preceding operations depend on the equality of some angles of triangles, and on the similarity of the triangles arising from that equality. And on the same principles.
principles depend innumerable other operations which a geometrician will find out of himself, as is very obvious. However, some of these operations require such exactness in the work, and without it are so liable to errors, that, ceteris paribus, the following operations, which are performed by a trigonometrical calculation, are to be preferred; yet could we not omit those above, being most easily in practice, and most clear and evident to those who have only the first elements of geometry. But if you are provided with instruments, the following operations are more to be relied upon. We do not insist on the easiest cases to those who are skilled in plain trigonometry, which is indeed necessary to any one who would apply himself to practice. See Trigonometry.

Proposition X.

Fig. 13. To describe the construction and use of the geometrical quadrant.—The geometrical quadrant is the fourth part of a circle divided into ninety degrees, to which two sights are adapted, with a perpendicular or plumb line hanging from the centre. The general use of it is for investigating angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. This instrument is made of any solid matter as wood, copper, &c.

Proposition XI.

Fig. 14. To describe and make use of the graphometer.—The graphometer is a semicircle made of any hard matter, of wood, for example, or brass, divided into 180 degrees; so fixed on a fuderum, by means of a brass ball and socket, that it easily turns about, and retains any situation; two sights are fixed on its diameter. At the centre there is commonly a magnetic needle in a box. There is likewise a moveable ruler, which turns round the centre, and retains any situation given it. The use of it is to observe any angle, whose vertex is at the centre of the instrument in any plane, (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

Proposition XII.

Fig. 15. and 16. To describe the manner in which angles are measured by a quadrant or graphometer.—Let there be an angle in a vertical plane, comprehended between a line parallel to the horizon HK, and the right line RA, coming from any remarkable point of a tower or hill, or from the sun, moon, or a star. Suppose that this angle RAH is to be measured by the quadrant: let the instrument be placed in the vertical plane, so that the centre A may be in the angular point: and let the sights be directed towards the object at R, (by the help of the ray coming from it, if it be the sun or moon, or by the help of the visual ray, if it is anything else), the degrees and minutes in the arc BC cut off by the perpendicular, will measure the angle RAH required. For, from the make of the quadrant, BAD is a right angle; therefore BAR is likewise right, being equal to it. But, because HK is horizontal, and AC perpendicular, HAC will be a right angle; and therefore equal also to BAR. From those angles subtract the part HAB that is common to both; and there will remain the angle BAC equal to the angle RAH. But the arc BC is the measure of the angle BAC; consequently, it is likewise the measure of the angle RAH.

Note, That the remaining arc on the quadrant DC is the measure of the angle RAZ, comprehended between the forefaid right line RA and AZ which points to the zenith.

Let it now be required to measure the angle ACB (fig. 16.) in any plane, comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its fulcrum (as was shown above); and let the immovable sights on the side of the instrument DE be directed towards the point A; and likewise (while the instrument remains immovable) let the sights of the ruler FG (which is moveable about the centre C) be directed to the point B. It is evident, that the moveable ruler cuts off an arc DH, which is the measure of the angle ACB sought. Moreover, by the same method, the inclination of CE, or of FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and is moveable about the centre of the instrument, and the measure of this inclination or angle found in degrees.

Proposition XIII.

Fig. 17. To measure an accessible height by the geometrical quadrant.—By the 12th prop. of this part, let the angle C be found by means of the quadrant. Then in the triangle ABC, right-angled at B, (BC being supposed the horizontal distance of the observer from the tower), having the angle at C, and the side BC, the required height BA will be found by the 3rd case of plain trigonometry. See Trigonometry.

Proposition XIV.

Fig. 18. To measure an inaccessible height by the geometrical quadrant.—Let the angle ACB be observed with the quadrant (by the 12th prop. of this part); then let the observer go from C to the second station D, in the right line BCD (provided BCD be a horizontal plane); and after measuring this distance CD, take the angle ADC likewise with the quadrant. Then, in the triangle ACD, there is given the angle ADC, with the angle ACD; because ACB was given before: therefore (by art. 59. of Part I.) the remaining angle CAD is given likewise. But the side CD is likewise given, being the distance of the station C and D; therefore (by the first case of oblique-angled triangles in trigonometry) the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypotenuse AC are given; consequently, by the fourth case of trigonometry, the height sought AB will be found; as also (if you please) the distance of the station C, from AB the perpendicular within the hill or inaccessible height.

Proposition XV.

Fig. 19. From the top of a given height, to measure the distance BC.—Let the angle BAC be observed by the 12th prop. of this; wherefore in the triangle ABC, right-angled at B, there is given by observation the angle at A; whence (by the 59th art. of Part I.) there will also be given the angle BCA: moreover the side AB (being the height of the tower) is supposed to be given. Wherefore,
Wherefore, by the 3d case of trigonometry, $BC$, the distance sought, will be found.

**Proposition XVI.**

*Fig. 20.* To measure the distance of two places $A$ and $B$, of which one is accessible, by the graphometer.—Let there be erected at two points $A$ and $C$, sufficiently distant, two visible signs; then (by the 12th prop. of this part) let the two angles $BAC$, $BCA$ be taken by the graphometer. Let the distance of the stations $A$ and $C$ be measured with a chain. Then the third angle $B$ being known, and the side $AC$ being likewise known; therefore, by the first case of trigonometry, the distance required, $AB$, will be found.

**Proposition XVII.**

*Fig. 21.* To measure by the graphometer, the distance of two places, neither of which is accessible.—Let two stations $C$ and $D$ be chosen, from each of which the places may be seen whose distance is sought: let the angles $ACD$, $ACB$, $BDC$, and likewise the angles $BDC$, $BDA$, $CDA$, be measured by the graphometer; let the distance of the stations $C$ and $D$ be measured by a chain, or (if it be necessary) by the preceding practice. Now, in the triangle $ACD$, there are given two angles $ACD$ and $ADC$; therefore, the third $CAD$ is likewise given; moreover the side $CD$ is given; therefore, by the first case of trigonometry, the side $AD$ will be found. After the same manner, in the triangle $BDC$, from all the angles and one side $DC$ given, the side $BD$ is found. Wherefore, in the triangle $ADB$, from the given sides $DA$ and $DB$, and the angle $ADB$ contained by them, the side $AB$ (the distance sought) is found by the 4th case of trigonometry of right-angled triangles.

**Proposition XVIII.**

*Fig. 22.* It is required by the graphometer and quadrant, to measure an accessible height $AB$, placed so on a steep, that one can neither go near it in an horizontal plane, nor recede from it, as we supposed in the solution of the 14th Prop.—Let there be chosen any situation as $C$, and another $D$; where let some mark be erected: let the angles $ACD$ and $ADC$ be found by the graphometer; then the third angle $DAC$ will be known. Let the side $CD$, the distance of the stations, be measured with a chain, and thence (by trigon.) the side $AC$ will be found. Again, in the triangle $ACB$, right-angled at $B$, having found by the quadrant the angle $ACB$, the other angle $CAB$ is known likewise: but the side $AC$ in the triangle $ADC$ is already known; therefore the height required $AB$ will be found by the 4th case of right-angled triangles. If the height of the tower is wanted, the angle $AFC$ will be found by the quadrant; which being taken from the angle $ACB$ already known, the angle $ACF$ will remain: but the angle $FAC$ was known before; therefore the remaining angle $AFC$ will be known. But the side $AC$ was also known before; therefore, in the triangle $AFC$, all the angles and one of the sides $AC$ being known, $AF$, the height of the tower above the hill, will be found by trigonometry.

**Scholium.**

It was easy to add many other methods of measuring heights and distances; but, if what is above be understood, it will be easy (especially for one that is versed in

*Vol.* II. *No.* 55.
In what follows, a figure is often to be laid down on paper, like to another figure given; and because this likeness consists in the equality of their angles, and in the sides having the same proportion to each other (by the definitions of the 6th of Eucl.) we are now to shew what methods practical geometricians use for making on paper an angle equal to a given angle, and how they confitute the sides in the same proportion. For this purpose they make use of a protractor, (or, when it is wanting, a line of chords), and of a line of equal parts.

**Proposition XX.**

*Fig. 2, 3, 4, 5, and 6.* To describe the construction and use of the protractor, of the line of chords, and of the line of equal parts. The protractor is a small semicircle of brass, or such solid matter. The semicircumference is divided into 180 degrees. The use of it is, to draw angles on any plane, as on paper, or to examine the extent of angles already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let the side AB coincide with one of the sides that contain the angle proposed; the number of degrees cut off by the other side, computing on the protractor from B, will shew the quantity of the angle that is to be measured.

But if an angle is to be made of a given quantity on a given line, and at a given point of that line, let AB coincide with the given line, and let the centre A of the instrument be applied to that point. Then let there be a mark made at the given number of degrees; and a right line drawn from that mark to the given point, will constitute an angle with the given right line of the quantity required; as is manifest.

This is the most natural and easy method, either for the extent of an angle on paper, or for describing on paper an angle of a given quantity.

But when there is scarcity of instruments, or because a line of chords is more easily carried about, (being described on a ruler on which there are many other lines besides), practical geometricians frequently make use of it. It is made thus: let the quadrant of a circle be divided into 90 degrees; (as in fig. 4.) The line AB is the chord of 90 degrees; the chord of every arc of the quadrant is transferred to this line AB, which is always marked with the number of degrees in the corresponding arc.

Note, that the chord of 60 degrees is equal to the radius, by corol. 15, 4th Eucl. If now a given angle EDF is to be measured by the line of chords from the centre D, with the distance DG, (the chord of 60 degrees,) describe the arch GF, and let the points G and F be marked where this arch intersects the sides of the angle. Then if the distance GF, applied on the line of chords from A to B, gives (for example) 25 degrees, this shall be the measure of the angle proposed.

When an obtuse angle is to be measured with this line, let its complement to a semicircle be measured, and thence it will be known. It were easy to transfer to the diameter of a circle the chords of all arcs to the extent of a semicircle; but such arc rarely found marked upon rules.

But now, if an angle of a given quantity, suppose of 50 degrees, is to be made at a given point M of the right line KL (fig. 6.) From the centre M, and the distance MN, equal to the chord of 60 degrees, describe the arc QN. Take off an arc NR, whose chord is equal to that of 50 degrees on the line of chords; join the points N and R; and it is plain that MR shall contain an angle of 50 degrees with the line KL proposed.

But sometimes we cannot produce the sides, till they be of the length of a chord of 60 degrees on our scale; in which case it is fit to work by a circle of proportions (that is a sector), by which an arc may be made of a given number of degrees to any radius.

The quantities of angles are likewise determined by other lines usually marked upon rules, as the lines of sines, tangents, and secants; but, as these methods are not so easy or so proper in this place, we omit them.

To delineate figures similar or like to others given, besides the equality of the angles, the same proportion is to be preferred among the sides of the figure that is to be delineated, as is among the sides of the figures given. For which purpose, on the rules used by artists, there is a line divided into equal parts, more or less in number, and greater or less in quantity, according to the pleasure of the maker.

A foot is divided into inches; and an inch, by means of transverse lines, into 100 equal parts: so that with this scale, any number of inches, below twelve, with any part of an inch, can be taken by the compasses, providing each part be greater than the one hundredth part of an inch. And this exactness is very necessary in delineating the plans of houses, and in other cases.

**Proposition XXI.**

*Fig. 7.* To lay down on paper, by the protractor or line of chords, and line of equal parts, a right-lined figure like to one given, providing the angles and sides of the figure given be known by observation or mensuration.

For example, suppose that it is known that in a quadrangular figure, one side is of 235 feet, that the angle contained by it and the second side is of 84°, the second side of 288 feet, the angle contained by it and the third side of 72°, and that the third side is of 294 feet. These things being given, a figure is to be drawn on paper like to this quadrangular figure. On your paper, at a proper point A, let a right line be drawn, upon which take 235 equal parts, as AB. The part representing a foot is taken greater or less, according as you would have your figure greater or less. In the adjoining figure, the 100th part of an inch is taken for a foot. And accordingly an inch divided into 100 parts, and annexed to the figure, is called a scale of 100 feet. Let there be made at the point B (by the preceding prop.) an angle ABC of 85°, and let BC be taken of 288 parts like to the former. Then let the angle BCD be made of 72°, and the side CD of 294 equal parts. Then let the side AD be drawn; and it will complete the figure like to the figure given. The measures of the angle A and D can be known by the protractor or line of chords, and the side AD by the line of equal parts; which will exactly answer to the corresponding angles and to the side of the primary figure.

After the very same manner, from the sides and angles given, which bound any right-lined figure, a figure like to it may be drawn, and the rest of its sides and angles be known.
GEOMETRY.

COROLLARY.

Hence any trigonometrical problem in right-lined triangles, may be resolved by delineating the triangle from what is given concerning it, as in this proposition. The unknown sides are examined by a line of equal parts, and the angles by a protractor or line of chords.

PROPOSITION XXII.

The diameter of a circle being given, to find its circumference nearly.—The periphery of any polygon inscribed in the circle is less than the circumference, and the periphery of any polygon described about a circle is greater than the circumference. Whence Archimedes first discovered that the diameter was in proportion to the circumference, as 7 to 22 nearly; which serves for common use. But the moderns have computed the proportion of the diameter to the circumference to greater exactness. Supposing the diameter 100, the periphery will be more than 314, but less than 315. The diameter is more nearly to the circumference, as 113 to 355. But Ludolphus van Cuelen exceeded the labours of all; for with all possible brevity, suggesting withal, that a surveyor or will improve himself more by one day's practice, than by a great deal of reading.

Fig. 8. To delineate a field by the help of a plain-table, from one station whence all its angles may be seen, and their distances measured by a chain.—Let the field that is to be laid down be ABCDE. At any convenient place F, let the plain-table be erected; cover it with clean paper, in which let some point near the middle represent the station. Then applying at this place the index with the sights, direct it so that through the sights some mark may be seen at one of the angles, suppose A; and from the point F, representing the station, draw a faint right line along the side of the index: then, by the help of the chain, let FA the distance of the station from the foresaid angle be measured. Then taking what part you think convenient for a foot or pace from the line of equal parts, let off on the faint line the parts corresponding to the line FA that was measured; and let there be a mark made representing the angle of the field A. Keeping the table immovable, the same is to be done with the rest of the angles; then right lines joining those marks shall include a figure like to the field, as is evident from 5. 6. Euc.

COROLLARY.

The same thing is done in like manner by the graphometer: for having observed in each of the triangles, AFB, BFC, CFD, &c. the angle at the station F, and having measured the lines from the station to the angles of the field, let similar triangles be protracted on paper (by the 21. prop. of this) having their common vertex in the point of station. All the lines, except those which represent the sides of the field, are to be drawn faint or obscure. Note 1. When a surveyor wants to lay down a field, let him place diligently in a register all the observations of the angles, and the measures of the sides, until at time and place convenient, he draw out the figure on paper.

Note 2. The observations made by the help of the graphometer are to be examined: for all the angles about the point F ought to be equal to four right ones. (by cor. 2. art. 30. of part I.)

PROPOSITION XXV.

Fig 9. To lay down a field by means of two stations, from each of which all the angles can be seen, by measuring only the distance of the stations.—Let the instrument be placed at the station F: and having chosen a point representing it upon the paper which is laid upon the plain table, let the index be applied at this point, so as to be moveable about it. Then let it be directed successively to the several angles of the field: and when any angle is seen through the sights, draw an obscure line along the side of the index. Let the index, with the sights, be directed after the same manner to the station A, on the obscure line drawn along its side, pointing to
A, set off from the scale of equal parts a line corresponding to the measured distance of the stations, and this will determine the point G. Then remove the instrument to the station G, and applying the index to the line representing the distance of the stations, place the instrument so that the first station may be seen through the sights. Then the instrument remaining immovable, let the index be applied at the point representing the second station G, and be successively directed by means of its sights, to all the angles of the field, drawing (as before) obscure lines: and the intersection of the two obscure lines that were drawn to the same angle from the two stations will always represent that angle on the plan. Care must be taken that those lines be not mistaken for one another. Lines joining those intersections will form a figure on the paper like to the field.

**Scholium.**

It will not be difficult to do the same by the graphometer, if you keep a distinct account of your observations of the angles made by the line joining the stations, and the lines drawn from the stations to the respective angles of the field. And this is the most common manner of laying down whole countries. The tops of two mountains are taken for two stations, and their distance is either measured by some of the methods mentioned above, or is taken according to common repute. The sights are successively directed towards cities, churches, villages, forts, lakes, turnings of rivers, woods, &c.

Note, The distance of the stations ought to be great enough, with respect to the field that is to be measured; such ought to be chosen as are not in a line with any angle of the field. And care ought to be taken likewise that the angles, for example, FAG, FDG, &c. be neither very acute, nor very obtuse. Such angles are to be avoided as much as possible; and this admonition is found very useful in practice.

**Proposition XXVI.**

Let ABCDHG be such a field. Let its angles (in going round it) be observed with a graphometer (by the 12. of this) and noted down; let its sides be measured with a chain; and (by what was said on the 21. of this) let a figure like to the given field be protruded on paper. If any mountain is in the circumference, the horizontal line hid under it is to be taken for a side, which may be found by two or three observations according to some of the methods described above; and its place on the map is to be distinguished by a shade, that it may be known a mountain is there.

If not only the circumference of the field is to be laid down on the plan, but also its contents, as villages, gardens, churches, public roads, we must proceed in this manner. Let there be (for example) a church F, to be laid down in the plan. Let the angles ABF, BAF be observed and protruded on paper in their proper places, the intersection of the two sides BF and AF will give the place of the church on the paper; Or, more exactly, the lines BF, AF being measured, let circles be described from the centres B and A, with parts from the scale corresponding to the distances BF and AF, and the place of the church will be at their intersection.

Note 1. While the angles observed by the graphometer are taken down, you must be careful to distinguish the external angles, as E and G, that they may be rightly protruded afterwards on paper.

Note 2. Our observations of the angles may be examined by computing if all the internal angles make twice as many right angles, four excepted, as there are sides of the figure: (for this is demonstrated by 32. 1. Eucl.) But in place of any external angle DEC, its complement to a circle is to be taken.

**Proposition XXVII.**

To lay down a plain field without instruments. If a small field is to be measured, and a map of it to be made, and you are not provided with instruments; let it be supposed to be divided into triangles, by right lines, as in the figure; and after measuring the three sides of any of the triangles, for example of ABC, let its sides be laid down from a convenient scale on paper, (by the 22. of this.) Again, let the other two sides BD, CD of the triangle CBD be measured and protruded on the paper by the same scale as before. In the same manner proceed with the rest of the triangles of which the field is composed, and the map of the field will be perfected; for the three sides of a triangle determine the triangle; whence each triangle on the paper is similar to its correspondent triangle in the field, and is similarly situated; consequently the whole figure is like to the whole field.

**Scholium.**

If the field be small, and all its angles may be seen from one station, it may be very well laid down by the plain-table, (by the 24. of this.) If the field be larger, and have the requisite conditions, and great exactness is not expected, it likewise may be plotted by means of the plain-table, or by the graphometer, (according to the 25. of this; but in fields that are irregular and mountainous, when an exact map is required, we are to make use of the graphometer, (as in the 26. of this,) but rarely of the plain-table.

Having protruded the bounding lines, the particular parts contained within them may be laid down by the proper operations for this purpose, (delivered in the 26th proposition; and the method described in the 27th proposition may be sometimes of service;) for we may trust more to the measuring of sides, than to the observing of angles. We are not to compute four-sided and many sided figures till they are resolved into triangles: for the sides do not determine those figures.

In the laying down of cities, or, the like, we may make use of any of the methods described above that may be most convenient.

The map being finished, it is transferred on clean paper, by putting the first sketch above it, and marking the angles by the point of a small needle. These points being joined by right lines, and the whole illuminated by colours proper to each part, and the figure of the mariners compass being added to distinguish the north and south, with a scale on the margin, the map or plan will be finished and neat.
We have thus briefly and plainly treated of surveying, and shown by what instruments it is performed; having avoided those methods which depend on the magnetic needle, not only because its direction may vary in different places of a field (the contrary of this at least doth not appear,) but because the quantity of an angle observed by it cannot be exactly known; for an error of two or three degrees can scarcely be avoided in taking angles by it.

As for the remaining part of surveying, whereby the area of a field already laid down on paper is found in acres, roods, or any other superficial measure; this we leave to the following section, which treats of the measurement of surfaces.

Besides the instruments described above, a surveyor ought to be provided with an off-set staff equal in length to ten links of the chain, and divided into ten equal parts. He ought likewise to have ten arrows or small straight sticks near two feet long, fixed with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have the ten arrows at first setting out. When the chain is stretched in the line, and the near end touches the place from which you measure, the leader flicks one of the ten arrows in the ground, at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being stretched in the line, so that the near end touches the first arrow, the leader flicks down another arrow at his end of the chain. The line is preferred straight, if the arrows be always set so as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain, the arrows are to be carried to him again, and he is to flick one of them into the ground, at the end of the chain. And the same is to be done at the 21, 31, 41, &c. chains, if there are so many in a right line to be measured. In this manner you can hardly commit an error in numbering the chains, unless of ten chains at once.

The off-set staff serves for measuring readily the distances of any things proper to be represented in your plan, from the station-line while you go along. These distances ought to be entered into your field-book, with the corresponding divisions from the last station, and proper remarks, that you may be enabled to plot them jufily, and be in no danger of making one for another when you extend your plan. The field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with distances from the stations. The distances taken by the off-set staff, on either side of the station-line, are to be entered into columns on either side of the middle column, according to their position with respect to that line. The names and characters of the objects, with proper remarks, may be entered in columns on either side of the left.

Because, in the place of the graphometer described by our author, surveyors now make use of the theodolite, we shall subjoin a description of Mr Sisson's latest improved theodolite from Mr Gardner's practical surveying improved. See a figure of it in Plate XCVI.

In this instrument, the three staffs, by brass ferrils at top, screw into bell-metal joints, that are moveable between brass pillars, fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press, that fix the limb horizontal: Next above is another such plate, through which the said screws pass, and on which, round the centre, is fixed a frustum of a cone of bell-metal, whose axis (being connected with the centre of the bell) is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass-box; and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes; in whose plate are fixed four brass pillars, that, joining at top, hold the centre pin of the bell-metal double sextant, whose double index is fixed on the centre of the same plate: Within the double sextant is fixed the spirit-level, and over it the telescope.

The compass box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

The limb has two fleurs de luce against the diamonds in the box, instead of 180 each; and is curiously divided into whole degrees, and numbered to the left hand at every ten to twice 180, having three indexes differing 120, (with Nonius's divisions on each for the decimals of a degree), that are moved by a pinion fixed below one of them, without moving the limb; and in another is a screw and spring under, to fix it to any part of the limb. It has also divisions numbered, for taking the quarter girt in inches of round timber at the middle height, when standing ten feet horizontally distant from its centre; which at 20 must be doubled, and at 30 tripled; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

The double sextant is divided on one side from under its centre (when the spirit-tube and telescope are level) to above 60 degrees each way, and numbered at 10, 20, &c. and the double index (through which it is moveable) shews on the same side the degree and decimal of any altitude or depression to that extent by Nonius's divisions: On the other side are divisions numbered, for taking the upright height of timber, &c. in feet, when distant 10 feet; which at 20 must be doubled, and at 30 tripled; and also the quantities for reducing hypothenus lines to horizontal. It is moveable by a pinion fixed in the double index.

The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distant object as perfect, as most of triple its length. In its focus are very fine cross wires, whose intersection is in the plane of the double sextant; and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that, whenever the limb is set horizontal, (which is readily done by making the spirit-tube level.
level over two screws, and the like over the other two),
the double sextant and telescope are moveable in a ver-
tical plane; and then every angle taken on the limb
(though the telescope be never so much elevated or
depressed) will be an angle in the plane of the horizon.
And this is absolutely necessary in plotting a horizontal
plane.
If the lands to be plotted are hilly, and not in any
one plane, the lines measured cannot be truly laid down
on paper, without being reduced to one plane, which
must be the horizontal, because angles are taken in that
plane.
In viewing your objects, if they have much altitude
or depression, either write down the degree and decimal
shown on the double sextant, or the links shown on the
back side; which last subtracted from every chain in
the station-line, leaves the length in the horizontal
plane. But if the degree is taken, the following table
will show the quantity.

A table of the links to be subtracted out of every chain
in hypothenusal lines of several degrees altitude, or
depression, for reducing them to horizontal.

Let the first station line really measure 1107 links,
and the angle of altitude or depression be 19°, 95;
looking in the table you will find against 19°, 95, is 6
links. Now 6 times 11 is 66; which subtracted from
1107, leaves 1041, the true length to be laid down
in the plan.
It is useful in surveying, to take the angles, which
the bounding lines form, with the magnetic needle,
in order to check the angles of the figure, and to plot
them conveniently afterwards.

Of the Surfaces of Bodies.
The smallest superficial measure with us is a square
inch; 144 of which make a square foot. Wrights make
use of these in the measuring of deals and planks; but
the square foot which the glaziers use in measuring of
glafs, consists only of 64 square inches. The other
measures are, first, the ell square; secondly, the fall,
containing 36 square ells; thirdly, the rood, containing
40 falls; fourthly, the acre, containing 4 roods. Slaters,
masons, and paviours, use the ell square and the fall; sur-
veyors of land use the square ell, the fall, the rood, and
the acre.
The superficial measures of the English are, first, the
square foot; secondly, the square yard, containing 9
square feet, for their yard contains only 3 feet; thirdly,
the pole, containing 304 square yards; fourthly, the
rood, containing 40 poles; fifthly, the acre, containing
4 roods. And hence it is easy to reduce our superficial
measures to the English, or theirs to ours.
In order to find the content of a field, it is most con-
venient to measure the lines by the chains described a-
bove, p. 693. that of 22 yards for computing the Eng-
lish acres, and that of 24 Scots ells for the acres of
Scotland. The chain is divided into 100 links, and the
square of the chain is 10,000 square links; ten squares
of the chain, or 100,000 square links, give an acre.
Therefore, if the area be expressed by square links,
divide by 100,000, or cut off five decimal places, and
the quotient shall give the area in acres and decimals
of an acre. Write the entire acres apart; but multi-
ply the decimals of an acre by 4, and the product shall
give the remainder of the area in roods and decimals
of a rood. Let the entire roods be noted apart after
the acres; then multiply the decimals of a rood by 40,
and the product shall give the remainder of the area in
falls or poles. Let the entire falls or poles be then
written after the roods, and multiply the decimals of a
fall by 36, if the area is required in the measures of
Scotland; but multiply the decimals of a pole by 30,4
if the area is required in the measures of England, and
the product shall give the remainder of the area in
square ells in the former case, but in square yards in
the latter. If, in the former case, you would reduce
the decimals of the square ells to square feet, multiply
them by 9,50994; but, in the latter case, the decimals
of the English square yard are reduced to square feet,
by multiplying them by 9.
Suppose, for example, that the area appears to con-
tain 12.65842 square links of the chain of 24 ells;
and that this area is to be expressed in acres, roods,
falls, &c. of the measures of Scotland. Divide the
square links by 100,000, and the quotient 12.65842
shows the area to contain 12 acres 10.33330 of an acre.
Multiply the decimal part by 4, and the product
29.3368 gives the remainder in roods and decimals of
a rood. Those decimals of a rood being multiplied
by 40, the product gives 25.3472 falls. Multiply the
decimals of the fall by 36, and the product gives
12.4992 square ells. The decimals of the square ell
multiplied by 9.50994 give 4.748 square feet;
Therefore the area proposed amounts to 12 acres, 2
roods, 25 falls, 12 square ells, and 4700 square
feet.
But if the area contains the same number of square
links of Gunter’s chain, and is to be expressed by
English measures, the acres and roods are computed in
the same manner as in the former case. The poles are
compared as the falls. But the decimals of the pole,
viz. , are to be multiplied by 30 4 (or 30.25),
and the product gives 10.5028 square yards. The
decimals of the square yard, multiplied by 9, give 4.525
square feet; therefore, in this case, the area is in
English measure 12 acres, 2 roods, 25 poles, 10 square
yards, and 4700 square feet.
The Scots acre is to the English acre, by statute,
as 100,000 to 78,694, if we have regard to the dif-
ference between the Scots and English foot above men-
tioned. But it is customary in some parts of England
GEOMETRICAL PROBLEMS AND THEOREMS.

PROPERTY XVIII.

Fig. 12. To find the area of a rectangular parallelogram ABCD.—Let the side AB, for example, be 5 feet long, and BC (which constitutes with BA a right angle at B) be 17 feet. Let 17 be multiplied by 5, and the product 85 will be the number of square feet in the area of the figure ABCD. But if the parallelogram proposed is not rectangular as BEFC, its base BC multiplied into its perpendicular height AB (not into its side BE) will give its area. This is evident from art. 68. of part 1.

PROPERTY XIX.

Fig. 13. To find the area of a given triangle.—Let the triangle BAC be given, whose base BC is supposed 9 feet long: let the perpendicular AD be drawn from the angle A opposite to the base, and let us suppose AD to be four feet. Let the half of the perpendicular be multiplied into the base, or the half of the base into the perpendicular, or take the half of the product of the whole base into the perpendicular, the product gives 18 square feet for the area of the given triangle.

But if only the sides are given, the perpendicular is found either by prolonging the triangle, or by 12th and 13th 2. Eucl. or by trigonometry. But how the area of a triangle may be found from the given sides only, shall be shown in the 31st prop.

PROPERTY XX.

Fig. 14. To find the area of any rectilineal figure.—If the figure be irregular, let it be resolved into triangles; and drawing perpendiculars to the bases in each of them, let the area of each triangle be found by the preceding prop. and the sum of these areas will give the area of the figure.

SCHOLIUM 1.

In measuring boards, planks, and glass, their sides are to be measured by a foot-rule divided into 100 equal parts; and after multiplying the sides, the decimal fractions are easily reduced to lesser denominations. The mensuration of these is easy, when they are rectangular parallelograms.

SCHOLIUM 2.

If a field is to be measured, let it first be plotted on paper, by some of the methods above described, and let the figure so laid down be divided into triangles, as was shown in the preceding proposition.

The base of any triangle, or the perpendicular upon the base, or the distance of any two points of the field, is measured by applying it to the scale according to which the map is drawn.

SCHOLIUM 3.

But if the field given be not in a horizontal plane, but uneven and mountainous, the scale gives the horizontal line between any two points, but not their distance measured on the uneven surface of the field. And indeed it would appear, that the horizontal plane is to be accounted the area of an uneven and hilly country. For if such ground is laid out for building on, or for planting with trees, or bearing corn, since these stand and perpendicular to the horizon, it is plain, that a mountainous country cannot be considered as of greater extent for those uses than the horizontal plane; nay, perhaps, for nourishing of plants, the horizontal plane may be preferable.

If, however, the area of a figure, as it lies regularly on the surface of the earth, is to be measured, this may be easily done by resolving it into triangles as it lies. The sum of their areas will be the area sought; which exceeds the area of the horizontal figure more or less, according as the field is more or less uneven.

PROPERTY XXXI.

Fig. 15. The area of the ordinate figure ABFEGH is equal to the product of the half circumference of the polygon, multiplied into the perpendicular drawn from the centre of the circumferiused circle to the side of the polygon.—For the ordinate figure can be resolved into as many equal triangles, as there are sides of the figure;
figure; and since each triangle is equal to the product of half the base into the perpendicular, it is evident that the sum of all the triangles together, that is the polygon, is equal to the product of half the sum of the bases (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the sides; for example, to AB.

**Proposition XXXIII.**

Fig. 16. The area of a circle is found by multiplying the half of the periphery into the radius; or the half of the radius into the periphery.—For a circle is not different from an ordinate or regular polygon of an infinite number of sides, and the common height of the triangles into which the polygon or circle may be supposed to be divided is the radius of the circle.

Were it worth while, it were easy to demonstrate accurately this proposition, by means of the inscribed and circumscribed figures, as is done in the 5th prop. of the treatise of Archimedes concerning the dimensions of the circle.

**Corollary.**

Hence it appears, that the area of the sector ABCD is produced by multiplying the half of the arc into the radius, and likewise that the area of the segment of the figure; and since each triangle is equal to the product of half the base into the perpendicular, it is evident that the sum of all the triangles together, that is the polygon, is equal to the product of half the sum of the bases (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the sides; for example, to AB.

**Proposition XXXIV.**

Fig. 17. The circle is to the square of the diameter, as 11 to 14 nearly.—For if the diameter AB be supposed to be 7, the circumference AHBK will be almost 22 (by the 22d prop. of this part), and the area of the square DC will be 49; and, by the preceding prop. the area of the circle will be 38½: therefore the square DC will be 49 to 38½, or as 98 to 77, that is, as 14 to 11. 

If greater exactness is required, you may proceed to any degree of accuracy: for the square DC is to the inscribed circle, as 1 to 1 – 1/3 + 1/4 – 1/5 + 1/6 + 1/7 + 1/8, &c. in infinitum.

"This series will be of no service for computing the area of the circle accurately, without some further artifice, because it converges at too slow a rate. The area of the circle will be found exactly enough for most purposes, by multiplying the square of the diameter by 7854, and dividing by 10,000, or cutting off four decimal places from the product; for the area of the circle is to the circumscribed square nearly as 7854 to 10,000."

**Proposition XXXV.**

Fig. 18. To find the area of a given ellipse.—Let ABCD be an ellipse, whose greater diameter is BD, and the lesser AC, bisecting the greater perpendicularly in E. Let a mean proportional HF be found (by 13th 6. Eucl.) between AC and BD, and (by the 32d of this) find the area of the circle described on the diameter HF. This area is equal to the area of the ellipse ABCD. For because, as BD to AC, so the square of BD to the square of HF, (by 2. cor. 20th 6. Eucl.) as the square of BD to the square of HF, so is the circle of the diameter BD to the circle of the diameter HF: therefore as BD to AC, so is the circle of the diameter BD to the circle of the diameter HF. And (by the 5th prop. of Archimedes of spheroids) as the greater diameter BD to the lesser AC, so is the circle of the diameter BD to the ellipse ABCD. Consequentially, (by the 11th 5. Eucl.) the circle of the diameter BD will have the same proportion to the circle of the diameter HF, and to the ellipse ABCD. Therefore, (by 9th 5. Eucl.) the area of the circle of the diameter HF will be equal to the area of the ellipse ABCD. 

**Scho-}

From this and the two preceding propositions, a method is derived of finding the area of an ellipse. There are two ways: 1st, Say, as one is to the lesser diameter, so is the greater diameter to a fourth number, (which is found by the rule of three.) Then again say, as 14 to 11, so is the 4th number found to the area sought. But the second way is shorter. Multiply the lesser diameter into the greater, and the product by 11; then divide the whole product by 14, and the quotient will be the area sought of the ellipse. For example, Let the greater diameter be 10, and the lesser 7; by multiplying 10 by 7, the product is 70; and multiplying that by 11, it is 770; and dividing 770 by 14, the quotient will be 55, which is the area of the ellipse sought. 

"The area of the ellipse will be found more accurately, by multiplying the product of the two diameters by 7854."

We shall add no more about other plain surfaces, whether rectilinear or curvilinear, which seldom occur in practice; but shall subjoin some propositions about measuring the surfaces of solids.

**Proposition XXXVI.**

To measure the surface of any prism.—By the 14th definition of the 11th Eucl. a prism is contained by planes, of which two opposite sides (commonly called the bases) are plain rectilinear figures; which are either regular and ordinat, and measured by prop. 32. of this; or however irregular, and then they are measured by the 38th prop. The other sides are parallelograms, which are measured by prop. 28th; and the whole superficies of the prism consists of the sum of those taken altogether.

**Proposition XXXVII.**

To measure the superficies of any pyramid.—Since its base is a rectilinear figure, and the rest of the planes terminating in the top of the pyramid are triangles; these measured separately, and added together, give the surface of the pyramid required.

**Proposition XXXVIII.**

To measure the superficies of any regular body.—These bodies are called regular, which are bounded by equilateral and equiangular figures. The superficies of the tetraedron consists of four equal and equilateral triangles; the superficies of the hexaedron, or cube, of six equal squares; an octaedron, of eight equal equilateral triangles; a dodecaedron, of twelve equal and ordinate pentagons; and the superficies of an icoshedron, of twenty equal and equiangular triangles. Therefore it will be easy to measure these surfaces from what has been already shown.

In the same manner we may measure the superficies of a solid contained by any planes. 

**Propo-**
PROPOSITION XXXIX.

Fig. 10. To measure the superflcies of a sphere.—Because a sphere differs very little from a prism, whose opposite planes (or bases) are ordinate figures of an infinite number of sides, it appears that the superflcies of a sphere, without the bases, is equal to an infinite number of parallelograms; the common altitude of all which is the same with the height of the cylinder, and the bases of them all differ very little from the periphery of the circle which is the base of the cylinder. Therefore this periphery multiplied into the common height, gives the superflcies of the cylinder, excluding the bases; which are to be measured separately by the help of the 33d prop.

This proposition concerning the measure of the surface of the cylinder (excluding its bases) is evident from this, that when it is conceived to be spread out, it becomes a parallelogram, whose base is the periphery of the circle of the base of the cylinder stretched into a right line, and whose height is the same with the height of the cylinder.

PROPOSITION XL.

Fig. 20. To measure the surface of a right cone.—The surface of a right cone is very little different from the surface of a right pyramid, having an ordinate polygon for its base of an infinite number of sides; the surface of which (excluding the base) is equal to the sum of the triangles. The sum of the bases of these triangles is equal to the periphery of the circle of the base, and the common height of the triangles is the side of the cone AB; wherefore the sum of these triangles is equal to the product of the sum of the bases (i.e. the periphery of the base of the cone) multiplied into the half of the common height, or it is equal to the product of the periphery of the base.

If the area of the base is likewise wanted, it is to be found separately by the 33d prop. If the surface of a cone is supposed to be spread out on a plane, it will become a sector of a circle, whose radius is the side of the cone; and the arc terminating the sector is made from the periphery of the base. Whence, by corol. 33d prop. of this, its dimension may be found.

COROLLARY.

Hence it will be easy to measure the surface of a frustum of a cone cut by a plane parallel to the base.

PROPOSITION XLI.

Fig. 21. To measure the surface of a given sphere.—Let there be a sphere, whose centre is A, and let the area of its convex surface be required. Archimedes demonstrates (17 prop. 1. book of the sphere and cylinder) that its surface is equal to the area of four great circles of the sphere; that is, let the area of the great circle be multiplied by 4, and the product will give the area of the sphere; or, (by the 20th 6. and 2d 12 of Eucl.) the area of the sphere given is equal to the area of a circle whose radius is the right line BC, the diameter of the sphere. Therefore having measured (by 33d prop.) the circle described with the radius BC, this will give the surface of the sphere.

PROPOSITION XLII.

Fig. 22. To measure the surface of a segment of a sphere.—Let there be a segment cut off by the plane...
gallon, nine gallons a firkin, four firkins a barrel. In ale, eight gallons make a firkin, and 32 gallons make a barrel. By an act of the first of William and Mary, 24 gallons is the barrel, both for beer and ale, in all places, except within the weekly bills of mortality.

In Scotland it is known that four gills make a mucktin, two mucktins make a chopin; a pint is two chopins; a quart is two pints; and a gallon is four quarts, or eight pints. The accounts of the cubical inches contained in the Scots pint vary considerably from each other. According to our author, it contains 103.75 cubic inches. But the standard-jugs kept by the dean of guild of Edinburgh (one of which has the year 1555, with the arms of Scotland, and the town of Edinburgh, marked upon it) have been carefully measured several times, and by different persons, the Scots pint, according to those standards, was found to contain about 105.75 cubic inches. The pewterers jugs (by which the vessels in common use are made) are said to contain sometimes between 105 and 106 cubic inches. A cask that was measured by the brewers of Edinburgh, before the commissioners of Excise in 1707, was found to contain 46.7 Scots pints; the same vessel contained 18.75 English ale gallons. Supposing this measuring to be just, the Scots pint will be to the English ale-gallon as 280 to 750; and if the English ale-gallon be supposed to contain 282 cubic inches, the Scots pint will contain 108.664 cubic inches. But it is suspected, on several grounds, that the experiment was not made with sufficient care and exactness.

The commissioners appointed by authority of parliament to settle the measures and weights, in their act of February 19. 1618, relate, That having caused fill the Linlithgow firlot with water, they found that it contained 21.5 pints of the just Stirling jug and measure. They likewise ordain that this shall be the just and on-
tained about 2118.94, cubic inches; which agrees nearly with the flatute of 1618 the barley firlot was to contain 31 pints of the just Stirling jug. The French contains 644.680.99 Paris cubic inches, or 780.36 English cubic inches.

The Roman amphora was a cubical Roman foot, the congius was the eighth part of the amphora, the sextarius was one fixth of the congius. They divided the sextarius like the as or libra. Of dry measures, the medimnus was equal to two amphorae, that is, about 13 English bushels; and the modius was the third part of the amphora. The two amphorae, or 120 cubic inches, make a measure. The pewterers jugs, of the size mentioned above, were contained in the firlot. Then 19^ Scots pints will amount to 2118.94 cubic inches; which agrees nearly with the sextarius, the measure of the firlot by statute above mentioned. But it is probable, that in this he followed the act 1587, where it is ordained, That the wheat-firlot shall contain 19 pints and two joucattes. A wheat-firlot marked with the Linlithgow flamps being measured, was found to contain about 2211 cubic inches. By the statute of 1618 the barley-firlot was to contain 31 pints of the just Stirling-jug. A Paris pint is 48 cubic Paris inches, and is nearly equal to an English wine-quart. The Beisican contains 644.680.99 Paris cubic inches, or 780.36 English cubic inches.

The Roman amphora was a cubical Roman foot, the congius was the eighth part of the amphora, the sextarius was one fixth of the congius. They divided the sextarius like the as or libra. Of dry measures, the medimnus was equal to two amphorae, that is, about 13 English bushels; and the modius was the third part of the amphora.

To find the solid content of a given prism.—By the 29th prop. let the area of the base of the prism be measured, and be multiplied by the height of the prism, the product will give the solid content of the prism.

To find the solid content of a given pyramid.—The area of the base being found, (by the 30th prop.) let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, the product will give the solid content, by 7th 12. Eucl.

Fig. 23. And in this manner may be measured the solid content of vessels and casks not much different from a cylinder, as ABCD. If towards the middle EF it be somewhat groffer, the area of the circle of the base being found (by 33d prop.) and added to the area of the middle circle EF, and the half of their sum (that is, an arithmetical mean between the area of the base and the area of the middle circle) taken for the base of the vessel, and multiplied into its height, the solid content of the given vessel will be produced.

Note, That the length of the vessel, as well as the diameters of the base, and of the circle EF, ought to be taken within the flaves; for it is the solid content within the flaves that is sought.

To find the solid content of a given cone.—Let the area made in the 1707 before the commissioners of excise, described above; then 19^ such pints will amount to 2118.94 cubic inches; which agrees nearly with 2115.85, the measure of the firlot by statute above mentioned. But it is probable, that in this he followed the act 1587, where it is ordained, That the wheat-firlot shall contain 19 pints and two joucattes. A wheat-firlot marked with the Linlithgow flamps being measured, was found to contain about 2211 cubic inches. By the statute of 1618 the barley-firlot was to contain 31 pints of the just Stirling-jug. A Paris pint is 48 cubic Paris inches, and is nearly equal to an English wine-quart. The Beisican contains 644.680.99 Paris cubic inches, or 780.36 English cubic inches.

The Roman amphora was a cubical Roman foot, the congius was the eighth part of the amphora, the sextarius was one fixth of the congius. They divided the sextarius like the as or libra. Of dry measures, the medimnus was equal to two amphorae, that is, about 13 English bushels; and the modius was the third part of the amphora.
of a cone cut by a plane parallel to the plane of the base, there will remain the solid content of the frustum of and thence (by the preceding prop.) its solid content; from which subtract the solid content of the cone cut off at the top, there will remain the solid content of the frustum of the cone.

How the content of the entire cone may be found, appears thus: Let ABCD be the frustum of the cone (either right or scalenous, as in the figures 2. and 3.) let the cone ECD be supposed to be completed; let AG be drawn parallel to DE, and let AH and EF be perpendicular on CD; it will be (by 2d 6. Eucl.) as CG:CA::CD:CE; but (by art. 72. of part. 1.) as CA:AH::CE:EF; consequently (by 22d 5. Eucl.) as CG:CA::CE:CD; that is, as the excess of the diameter of the lesser base is to the height of the frustum, so is the diameter of the greater base to the height of the entire cone.

**COROLLARY.**

Fig. 24. 25. To find the solid content of a frustum of a cone cut by a plane parallel to the plane of the base.—First, let the height of the entire cone be found, that is, having its base equal to a great circle of the sphere, and its height equal to the diameter of the sphere, having their bases in the surface of the sphere, and their common vertex in the centre of the sphere, so that the superintendencies of the sphere, (of whose dimension see prop. 41. of this) multiplied into the third part of the semidiameter, gives the solid content of the sphere.

**PROPOSITION XLVII.**

**PROPOSITION XLVIII.**

**COROLLARY.**

Hence it follows, that the sphere is equal to a cone whose whole height is equal to the semidiameter of the sphere, having for its base a circle equal to the superintendencies of the sphere, or to four great circles of the sphere, or to a circle whose radius is equal to the diameter of the sphere, (by prop. 41. of this.) And indeed a sphere differs very little from the sum of an infinite number of cones that have their bases in the surface of the sphere, and their common vertex in the centre of the sphere; so that the superintendencies of the sphere, (of whose dimension see prop. 41. of this) multiplied into the third part of the semidiameter, gives the solid content of the sphere.

**PROPOSITION XLIX.**

**COROLLARY 1.**

Hence it appears, that the half of the spheroid, formed by the rotation of the space AHFC around the axis AC, is double of the cone generated by the triangle AFC about the same axis; which is the 32d prop. of Archimedes of conoids and spheroids.

**COROLLARY 2.**

Hence, likewise, is evident the measure of segments of the
the spheroid cut by planes perpendicular to the axis. For the segment of the spheroid made by the rotation of the space ANHE, round the axis AE, is to the segment of the sphere having the same axis AC, and made by the rotation of the segment of the circle AMGE, as CD to CD.

But if the measure of this solid be wanted with less labour, by the 24th prop. of Archimedes of conoids and spheroids, it will be as BE to AC+EB; so is the cone generated by the rotation of the triangle AHE round the axis AE, to the segment of the sphere made by the rotation of the space ANHE round the same axis AE; which could easily be demonstrated by the method of indivisibles.

**COROLLARY 3.**

Hence it is easy to find the solid content of the segment of a sphere or spheroid intercepted between two parallel planes, perpendicular to the axis. This agrees as well to the oblate as to the oblong spheroid; as is obvious.

**COROLLARY 4.**

**Fig. 30.** If a calk is to be valued as the middle piece of an oblong spheroid, cut by the two planes DC and FG, at right angles to the axis: first, let the solid content of the half spheroid ABCED be measured by the preceding prop. from which let the solidity of the segment DEC be be subtracted, and there will remain the segment ABCD; and this doubled will give the capacity of the calk required.

The following method is generally made use of for finding the solid content of such vessels. The double area of the greatest circle, that is, of that which is described by the diameter AB at the middle of the calk, is added to the area of the circle at the end, that is, of the circle DC or FG (for they are usually equal), and the third part of this sum is taken for a mean base of the calk, OP, gives the content of the vessel required.

Sometimes vessels have other figures, different from those we have mentioned; the easy methods of measuring which may be learned from those who practice this art. What hath already been delivered, is sufficient for our purpose.

**PROPOSITION LI.**

**Fig. 31.** and 32. To find how much is contained in a vessel that is in part empty, whose axis is parallel to the horizon.—Let AGBH be the great circle in the middle of the calk, whose segment GBH is filled with liquor, the segment GAH being empty; the segment GBH is known, if the depth EB be known, and EH a mean proportional between the segments of the diameter AB and EB; which are found by a rod or ruler put into the vessel at the orifice. Let the basis of the calk, at a medium, be found, which suppose to be the circle CKDL; and let the segment KCL be similar to the segment GAH (which is either found by the rule of three, because as the circle AGBH is to the circle CKDL, so is the segment GAH to the segment KCL; or is found from the tables of segments made by authors); and the product of this segment multiplied by the length of the calk will give the liquid content remaining in the calk.

**PROPOSITION LII.**

To find the solid content of a regular and ordinate body.—A tetraedron being a pyramid, the solid content is found by the 44th prop. The hexaedron, or cube, being a kind of prism, it is measured by the 43d prop. An octaedron consists of two pyramids of the same square base and of equal heights; consequently its measure is found by the 44th prop. A dodecaedron consists of twelve pyramids having equal equilateral and equiangular pentagonal bases; and to one of these being measured (by the 44th prop. of this) and multiplied by 12, the product will be equal to the solid content of the dodecaedron. The icosahedron consists of 20 equal pyramids having triangular bases; the solid content of one of which being found (by the 44th prop.) and multiplied by 20, gives the whole solid. The bases and heights of these pyramids, if you want to proceed more exactly, may be found by trigonometry. See **Trigonometry**.

**PROPOSITION LIII.**

To find the solid content of a body however irregular.—Let the given body be immerged into a vessel of water, having the figure of a parallelopipedon or prism, and let it be noted how much the water is raised upon the immersion of the body. For it is plain, that the space which the water fills, after the immersion of the body, exceeds the space filled before its immersion, by a space equal to the solid content of the body, however irregular. But when this excess is of the figure of a parallelopipedon or prism, it is easily measured by the 43d prop. of this, viz. by multiplying the area of the base, or mouth of the vessel, into the difference of the elevations of the water before and after immersion. Whence is found the solid content of the body given.

In the same way the solid content of a part of a body may be found, by immersing that part only in water.

There is no necessity to infilt here on diminishing or enlarging solid bodies in a given proportion. It will be easy to deduce these things from the 11th and 12th books of Euclid.

"The following rules are subjoined for the ready computation of the contents of vessels, and of any solids in the measures in use in Great Britain.

"I. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and altitude of the vessel being given in inches and decimals of an inch.

"Square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height: then multiply the product by the decimal fraction .0034; and this last product shall give the content in wine gallons and decimals of such a gallon. To express the rule arithmetically; let D represent the number of inches and decimals of an inch in the diameter of the vessel, and H the inches and decimals of an inch in the height of the vessel; then the content in wine-gallons shall be DDH x .0034, or DDHX.0034. Ex. Let the diameter D = 51.2 inches, the height H = 62.3 inches, then the content shall be 51.2 x 51.2 x 62.3 x .0034 = 555.27.342 wine-gallons. This rule follows from prop. 33. and 45: for, by the former, the area of the base of the vessel is in square inches DDX.7854; and by the latter, the content of the vessel in solid inches
VI. Supposing the bear-firlot to contain 31 Scots
leth exceptionable *, and therefore we suppose the fir-
several respects; yet this part of the act that relates
lot to contain 21 pints of the Edinburgh standard, or

V. Supposing the Scots wheat firlot to contain 21½
pints of the Edinburgh standard, according to experiments
mentioned above) are allowed to be a wine-gallon.

II. Supposing the English ale-gallon to contain 282
cubical inches, the content of a cylindric vessel is com-
puted in such gallons, by multiplying the square of the
diameter of a vessel by its height, and the product by the
decimal fraction .027851: that is,

A, the product of A multiplied by B, and the square
of B, and collect them into a sum. Then find the
third part of this sum, and substitute it in the preceding
rules in the place of the square of the diameter; and
proceed in all other respects as before. Thus, for ex-
ample, the content in wine-gallons is AA X AB X BB

X ½ X HH X .0034.

Or, to the square of half the sum of the diameters
A and B, add one third part of the square of half their
difference, and substitute this sum in the preceding rules
for the square of the diameter of the vessel; for the
square of \( \frac{1}{2} A \times \frac{1}{2} B \) added to \( \frac{3}{4} \) of the square of \( A - \frac{1}{2} B \), gives \( \frac{1}{2} AA \times \frac{1}{2} AB \times BB \).

VII. To compute the content of a vessel that may
be considered as a frustum of a cone in any of those
measures.

Let A represent the number of inches in the diame-
ter of the greater base, B the number of inches in the
diameter of the lesser base. Compute the square of
A, the product of A multiplied by B, and the square
of B, and collect these into a sum. Then find the
third part of this sum, and substitute it in the preceding
rules in the place of the square of the diameter; and
proceed in all other respects as before. Thus, for ex-
ample, the content in wine-gallons is AA X AB X BB

X ½ X HH X .0034.

VIII. When a vessel is a frustum of a parabolic
coneid, measure the diameter of the section at the mid-
dle of the height of the frustum; and the content will be
precisely the same as of a cylinder of this diameter, of
the same height with the vessel.

IX. When a vessel is a frustum of a sphere, if you mea-
ure the diameter of the section at the middle of the
height of the frustum, then compute the content of a
cylinder of this diameter of the same height with the
vessel, and from this subtract \( \frac{1}{4} \) of the content of a
cylinder of the same height, on a base whose diameter
is equal to its height; the remainder will give the con-
tent of the vessel. That is, if D represent the diam-
ter of the middle section, and H the height of the
frustum, you are to substitute DD - \( \frac{1}{4} \) HH for the
square of the diameter of the cylindrical vessel in the
first fix rules.

X. When the vessel is a frustum of a spheroid, if the
diameters are equal, the content is readily found by the
rule in p 708. In other cases, let the axis of the solid
be to the conjugate axis as \( n \) to 1; let D be the dia-
ometer of the middle section of the frustum, H the
height or length of the frustum; and substitute in the
first six rules DD - HH for the square of the square
of the diameter of the vessel.

XI. When the vessel is an hyperbolic coneid, let
the axis of the solid be to the conjugate axis as \( n \) to
1, D the diameter of the section at the middle of the
frustum, H the height or length; compute DD - \( \frac{2n}{3} \)
X HH, and substitute this sum for the square of the
square of the diameter of the cylindrical vessel in the first six rules.

XII. In general, it is usual to measure any round
vessel, by distinguishing it into several frusta, and

--- taking

---
taking the diameter of the section at the middle of each frustum; thence to compute the content of each, as if it was a cylinder of that mean diameter; and to give their sum as the content of the vessel. From the total content, computed in this manner, they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the frustum to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry or wet inches; having regard to the inclination or drip of the vessel, when it has any.

This method of computing the content of a frustum from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use, the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same, in the content computed in this manner exceeds the truth. When the vessel is a portion of a parabolic conoid, the content computed in this manner exceeds the truth. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same, in the different parts of the same or of similar vessels, when the altitude of the frustum is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactness be required, the error in measuring the frustum of a conical vessel, in this manner, is \( \frac{1}{3} \) of the content of a cone similar to the vessel, of an altitude equal to the height of the frustum. In a sphere, it is \( \frac{1}{3} \) of a cylinder of a diameter and height equal to the frustum. In the spheroid and hyperbolic conoid, it is the same as in a cone generated by the right-angled triangle, contained by the two semi-axes of the figure, revolving about that side which is the semi-axis of the frustum.

In the usual method of computing a table for a vessel, by subtracting from the whole content the number that expresses the uppermost area, as often as there are inches in the uppermost frustum, and afterwards the numbers for the other areas successively; it is obvious that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high, if the vessel stands on its lesser base, but too low when it stands on its greater base; because, when one inch is dry, for example, it is not the area at the middle of the uppermost frustum, but rather the area at the middle of the uppermost inch, that ought to be subtracted from the total content, in order to find the content in this case.

XIII. To measure round timber: Let the mean circumference be found in feet and decimals of a foot; square it; multiply this square by the decimal 0.795,777, and the product by the length. Ex. Let the mean circumference of a tree be 10 feet, and the length 24 feet. Then \( 10.3 \times 10.3 \times 0.795,777 \times 24 = 202.615 \), is the number of cubic feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is 0.795,774,715, and that the areas of circles are as the squares of their circumferences.

But the common way used by artificers for measuring round timber, differs much from this rule. They call one fourth part of the circumference the girt, which is by them reckoned the side of a square, whose area is equal to the area of the section of the tree; therefore they square the girt, and then multiply by the length of the tree. According to their method, the tree of the last example would be computed at 159.13 cubic feet only.

How square timber is measured, will be easily understood from the preceding propositions. Fifty solid feet of hewn timber, and forty of rough timber, make a load.

XIV. To find the burden of a ship, or the number of tons it will carry, the following rule is commonly given. Multiply the length of the keel taken within board, by the breadth of the ship within board, taken from the midship beam from plank to plank, and the product by the depth of the hold, taken from the plank below the keelson to the under part of the upper deck, and divide the product by 94, the quotient is the content of the tonnage required. This rule however cannot be accurate; nor can one rule be supposed to serve for the measuring exactly the burden of ships of all sorts. Of this the reader will find more in the Memoirs of the Royal Academy of Sciences at Paris, for the year 1721.

Our author having said nothing of weights, it may be of use to add briefly, that the English Troy-pound contains 12 ounces, the ounce 20 penny-weight, and the penny-weight 24 grains; that the Averdupois pound contains 16 ounces, the ounce 16 drams, and that 112 pounds is usually called the hundred weight. It is commonly supposed, that 14 pounds Averdupois are equal to 17 pounds Troy. According to Mr Everard's experiments, 1 pound Averdupois is equal to 14 ounces 12 penny-weight and 16 grains Troy, that is, to 7000 grains; and an Averdupois ounce is 437\(\frac{1}{2} \) grains. The Scots Troy-pound (which, by the statute of 1718, was to be the same with the French) is commonly supposed equal to 15\(\frac{1}{2} \) ounces English Troy, or 7560 grains. By a mean of standards kept by the Dean of Guild at Edinburgh, it is 7599\(\frac{1}{2} \) or 7600 grains. They who have measured the weights which were sent from London, after the union of the kingdoms, to be the standards by which the weights in Scotland should be made, have found the English Averdupois pound (from a medium of the several weights) to weigh 7000 grains, the same as Mr Everard; according to which, the Scots, Paris, or Amsterdampound, will be to the pound Averdupois as 38 to 35. The Scots Troy-stone contains 16 pounds, the pound 2 marks or 16 ounces, an ounce 16 drops, a drop 36 grains. Twenty Scots ounces make a Tron pound; but because it is usual to allow one to the score, the Tron pound is commonly 21 ounces. Sir John Skene, however, makes the Tron stone to contain only 19\(\frac{1}{2} \) pounds.

GEORGE,
GERMAN, or Knights of St George, has been the
denomination of several military orders, whereof that
of the garter is one of the most illustrious. See Gar-
ter.

St George del Mina, the capital of the Dutch settle-
ments, on the gold-coasts of Guinea, situated seven
or eight miles west of Cape-coast castle, the capital of
the British settlements there: W. long. 5°, and N. lat.
5°.

Fort St George, a town and fort on the coast of Cor-
mandel, in the Hither India: E. long. 80°, and N. lat.
13°.

The town is divided into the White and Black town.
The fort, and White-town, which adjoins to it, are
inhabited only by British; the whole circumference,
which is not above half a mile, being surrounded by a
stone wall. The outward, or Black-town, called Ma-
draf, has been lately encompassed by a stone-wall
and bastions and is about a mile and a half in circum-
ference; the whole being almost environed by a river
and the sea.

St George's, the largest of the Bermuda, or Summer-
ilands.

Croft of St George, a red one in a field argent, which
makes part of the British standand.

GEORGIA, in Asia, a province bounded by Circassia
and Dagelian on the north, by the Caspian sea on the
east, by Armenia or Turcomania on the south, and by
Mingrelia on the west.

Georgia, in America, one of the British plantations,
taken out of South-Carolina, from which it is sepa-
rated by the river Savannah on the north, and bound-
ed by the Atlantic ocean on the east, by the river of
St John, which divides it from Spanish Florida, on
the south and west.

GEORGIC, a poetical composition upon the subject of
husbandry, containing rules therein, put into a pleas-
ing drefs, and set off with all the beauties and embell-
ishments of poetry.

Hesiod and Virgil are the two greatest masters in this
kind of poetry.

The moderns have produced nothing in this kind, ex-
cept Rapin's book of Gardening, and the celebra-
ted poem entitled Cyder by Mr Philips, who, if he
had enjoyed the advantage of Virgil's language, would
have been second to Virgil in a much nearer degree.

GERANITES, in natural history, an appellation given
like the bill of a crane. There are fifty-seven fpe-
cies, sixteen of which are natives of Britain, viz. the
cicutarium, or hemlock-leaved crane's bill; the maf-
seum, or jagged-leaved dove's-foot crane's bill; and
the tundifolium, or round-leaved crane's bill; the per-
vellum, or perennial dove's-foot crane's bill; the molle,
or mountain crane's bill; the robertianum, or herb Robert; the
fanguineum, or bloody crane's bill. The leaves of the
robertianum and pratense were formerly used as a-
stringents, but are now left out both of the London
and Edinburgh dispensatories.

GERARDIA, in botany, a genus of the didynamia an-
gioperma clafs. The calix consists of five segments;
the corolla is bilabiated, the inferior lip being divided
into three parts; the lobes are emarginated, the mid-
dle one being divided into two segments; and the cap-

eule is bilocular, and opens at the base. There are five
species, none of them natives of Britain.

GERFALCON, or GyrFALCON. See Falco.

GERGENTUM, a town of Sicily, the Agrigentum of
the ancients, about fifty miles south-east of Palermo:
E. long. 13° 30', N. lat. 35° 20'.

GERMAINS, or St Germain's, a town and royal pa-
lace of France, fourteen miles north-west of Paris.

St. Germain's is also a borough of Cornwall, eight miles
west of Plymouth. It sends two members to parlia-
ment.

Germ, among gardeners. See Bud.

German, in genealogy, denotes entire or whole:
thus, a brother german is one both by the father's and
mother's side; and cousins german are the children of
brothers or sisters.

German, or Germanic, also denotes any thing belong-
ning to Germany; as the German empire, German
flute, &c.

GEMANDER, in botany. See Teucrium.

GERMANY, an extensive empire of Europe, situated
between 5° and 19° E. long. and between 45° and
and 55° N. lat.; bounded by Denmark and the Bal-
tic sea on the north, by Poland and Hungary on the
east, by Switzerland and the Alps on the south, and
by France, Holland, &c. on the west.

It is divided into ten circles, three of which lie on
the north, viz. Upper and Lower Saxony, and Welf-
phia; three on the south, viz. Austria, Bavaria, and
Swabia; three about the middle, viz. Franconia, and
the Upper and Lower Rhine; the tenth, which con-
formed of the duchy of Burgundy and the seventeen pro-
vinces of the Netherlands, have long been detached
from the empire.

There are in Germany upwards of three hundred
sovereign princes and dukes, most of them arbitrary in
their respective territories.

GERMEN, or Germ. See Bud.

GERMERSHEIM, a town of Germany, subject to
France, about ten miles east of Landau: E. long. 8°
15', and N. lat. 49° 12'.

GERMINATION, the first sprouting of the seeds of
plants. See Agriculture, Part I.

GERONTES, in Grecian antiquity, a fort of magi-
strates of ancient Sparta, anwering to the areopagites
at Athens.
GERTRUDENBURG, a fortified town of the united Netherlands, in the province of Holland, nine miles north of Breda; subject to the prince of Orange.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as, nom. amandum, gen. amandi, dat. amando, accus. amandum, abl. amando.

GESNERIA, in botany, a genus of plants, of the dicotyledonous class. The calyx consists of five segments; the corolla is bent inwards and backwards; the capsule is below the flower, and bilocular. There are three species, none of them natives of Britain.

GESTATION, among physicians. See Pregnancy.

GESTRICIA, a province of Sweden, bounded by Helsingfors on the north, by the Bothnian gulf on the east, by Upland on the south, and by Dalecarlia on the west.

GESTURE, in rhetoric, consists chiefly in the proper action of the hands and face.

CETHYLLIS, in botany, a genus of the decandria-monogynia class. The calyx is a spathula; the corolla consists of six segments; and the capsule has three cells. There is but one species, a native of Africa.

GEVAUDAN, a territory of Languedoc, adjoining to the Cevennes.

GEUM, in botany, a genus of the icofandria-pentagynia class. The calyx has eight segments; the petals are eight; and the seeds are hairy and caudated. There are five species, two of which are natives of Britain, viz. the urbanum, or common avens; and the rivale, or water avens. The root of the avens is sometimes used as a stomachic.

GEVAUT, or GAUNT, a city and capital of Flanders, thirty miles north-west of Brussels: E. long. 3° 36', N. lat. 51°.

It is a large fortified town, twelve miles in circumference, and defended by a citadel; and yet is a place of no great strength, by reason of the vast extent of ground it takes in.

GIACH, in chronology, a cycle of twelve years; in use among the Turks and Cathayans.

Each year of the giach bears a name of some animal: the first, that of a mouse; the second, that of a bullock; the third, of a lynx or leopard; the fourth, of a horse; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They also divide the day into twelve parts, which they call giachs, and distinguish them by the name of some animals. Each giach consists of two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIALLOLINO, in natural history, a heavy, friable, fine, yellow ochre, called Naples yellow, and much used among painters, who esteem it a very fine colour.

GIANT'S CAUSEWAY, a vast collection of a black kind of marble, called basaltes, in the county of Antrim, in Ireland. See Basaltes.

GIBBOUS, a term in medicine, denoting any protuberance or convexity of the body, as a person hounded, or hump-backed.

Gibbous, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned, or calved; and the light one hunched out, convex, or gibbous.

GIBELINS, Gibelins, a famous faction in Italy, opposite to another called the Guelphs.

These two factions ravaged and laid waste Italy for a long series of years, so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violations and slaughters. The Gibelins fought for the emperor against the pope: but concerning their origin and the reason of their names, we have but a very obscure account. According to the generality of authors, they date from the year 1240, upon the emperor Frederick II.'s being excommunicated by the pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor.

But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibling, and that of the Guelphs of Adorf.

GIBRALTAR, a port-town of Andalusia, in Spain, subject to Great Britain: W. long. 6°, and N. lat. 36°.

It stands at the foot of mount Calpe, one of Hercules's pillars, about sixteen miles north of Ceuta, in Africa, from which it is divided by the Straights, to which it gives name. It is built on a rock, in a peninsula, and can only be approached on the land-side by a very narrow passage between the mountain and the sea: crofs this passage the Spaniards have drawn a line, and fortified it, to prevent the garrisons having any communication with the country.

The Straits of Gibraltar are about twenty-four miles long, and fifteen broad.

GIFT, in Scots law. See Donation.

GIGG, or Jigg, in music, denotes a brisk and lively air; or an airy kind of dance to a sprightly measure.

GILAN, a province of Persia, bounded by the Caspian Sea on the north. Its capital is a city of the same name: E. long. 48°, and N. lat. 37°.

GILBERTINES, a religious order founded in England by St Gilbert, in the reign of Henry I. The nuns followed the rule of St Benedict, and the monks that of Augustin. There were many monastries of this order in different parts of England.

GILDING, the art of spreading or covering a thing with gold, either in leaf or liquid.

We have this advantage over the ancients, in the manner of using and applying gold, that the secret of painting in oil, lately discovered, furnishes us with means of gilding works, capable of enduring all the violence of time and weather, which theirs could not.
There are several methods of gilding in use among us, as gilding in water, gilding in oil, gilding by fire, &c.

The method of water-gilding. Water-gilding requires more preparation than oil gilding, and is chiefly on wooden works, and those made of stucco; and these must be sheltered from the weather. A size is used for this way of gilding made of flthers, &c. of parchment or gloves boiled in water to the consistence of a jelly. If the thing to be gilt be of wood, it is first washed with this size, boiling hot, and then set to dry; and afterwards with white paint mixed up with the same size. Some use Spanish white for this purpose, and others plaster of Paris, well beaten and sifted. This sized paint must be laid on with a soft brush; which is to be repeated seldom or oftener according to the nature of the work, as ten or twelve times in flat or smooth works; but seven or eight times will be sufficient in pieces of sculpture. In the former case they are applied by drawing the brush over the work, in the latter by daubing it. When the whole is dry, they moisten it with fair water, and rub it over with several pieces of coarse linen, if it be on the flat; if not, they beat or switch it with several slips of the same linen, tied to a little stick, to make it follow and enter all the cavities and depressures thereof.

Having thus finished the white, the next thing to be done, is to colour it with yellow ochre: but if it be a piece of sculpture in relief, they first touch it up, and prepare the several parts, which may have happened to have been disfigured, by the small iron instruments, as gouges, chisels, &c. The ochre used for this purpose must be well ground and sifted, and mixed up with the size before-mentioned. This colour is to be laid on hot; and in works of sculpture, supplies the place of gold, which sometimes cannot be carried into all the depressions and cavities of the foliages and ornaments. A lay is also applied over this yellow, which serves for the ground on which the gold is to be laid: this lay is usually composed of Armenian bole, blood-flone, black-lead, and a little fat; to which some add soap, and oil of olives; others, burnt bread, bifre, antimony, glafs of tin, butter, and sugar-candy. These ingredients being all ground down together with hot size, three layers of this composition is applied upon the yellow, the one after the other has been dried; being cautious not to put any into the cavity of the work to hide the yellow.

The brush used for this purpose, must be a soft one; and when the matter is become very dry, they go over it again with a stronger brush, to rub it down, and take off the small grains that stick out, in order to facilitate the burnishing of the gold.

To be prepared for gilding, you must have three sorts of pencils; one to wet, another to touch up and amend, and a third to flatten; also a gilding cushion, for spreading the leaves of gold on when taken out of the book; a knife to cut them; and a squirrel's tail fitted with a handle; or else a piece of fine soft stuff on a stick, to take them up directly and apply them. You are first to begin with wetting your pencils; by which the last lay laid on with water is moistened, that it may the better receive and retain the gold. Then you are to lay the leaves of gold on the cushion; and if whole, you must take up with the squirrel's tail, but, if in pieces, with the other instrument, or the knife wherewith they are cut, and lay and spread them gently on the parts of the work you had moistened before. If the leaves, as they frequently do, happen to crack or break in laying on, these breaches must be made up with small bits of leaf, taken upon the repairing pencil, and the whole work is to be smoothed either with the same pencil, or another something larger; the gold being pressed into the dents, into which it could not be so easily carried by the squirrel's tail.

The work having been thus far gilded, must be set to dry, in order to be burnished and flattened. See Burnishing.

The last operation is the applying the vermeil in all the little lines and cavities; and to stop and amend any little faults with shell-gold. The composition called of vermeil is made of gum guttae, vermilion, and a little of some ruddy-brown, ground together with venetian varnish and oil of turpentine. Some gilders, instead of this, make shift with fine lacca, or dragon's blood, with gum-water.

Sometimes, instead of burnishing the gold, they burnish the ground or composition laid on the last before it, and only afterwards wash the part over with the size. This method is chiefly practised for the hands, face, and other mutilities in relief: which, by this means, do not appear so very brilliant as the parts burnished, though much more so than the parts perfectly flat.

To gild a piece of work, and yet preserve white grounds, they apply a lay of Spanish white, mixed with a weak fust-glue, on all the parts of the ground, whereon the yellow or the last lay might run. See Burnishing.

The method of gilding in oil. This operation requires much less apparatus than that before-mentioned. The base or matter whereon the gold is laid, in this method, is the remains of colours found settled to the bottom of the pots in which painters wash their pencils. This matter, which is very viscous or sticky, is first ground, and then passed through a linen-cloth, and thus laid on the matter to be gilt, after it is washed once or twice over with size; and if it be wood, with some white paint.

When this is almost dry, but yet is still unctuous enough to catch and retain the gold, the leaf-gold is laid on, either whole, if the work be large, or cut to pieces, if smaller: the leaves of gold are taken up and laid on with a piece of fine, soft, well carded cotton; or sometimes by a pallet for the purpose, or sometimes with the knife with which the leaves were cut, according to the parts of the work that are to be gilded, or the breadth of the gold that is to be laid on. As the gold is laid on, they pass over it a coarse fluff pencil brush, to make it stick and as it were incorporate with the ground; and after this they mend any cracks that may
may have happened in it, either with the same pencil or one that is smaller, as has been shewn before in water-gilding.

This kind of gilding is chiefly used for domes and roofs of churches, courts, banqueting-houses, &c. and for figures of platter of Paris, lead, &c.

The method of Gilding with liquid gold. This is performed by gold reduced to a calx and amalgamated with mercury, in the proportion of about an ounce of mercury to a dram of gold. To perform this, they heat a crucible red hot, and then put the gold and mercury into it, fifting them gently about till the gold be found melted, and incorporated into a mass with the mercury. When this is done, they call them into water, to wash and purify them; and out of that into other waters, where the amalgama, which is almost as liquid as if there were nothing but quicksilver in it, may be preferred a long time for use.

Before they proceed to lay this amalgamated gold on the metal, they fift render the metal rough, by washing it over with aqua fortis, or aqua fecunda; and afterwards rinse the metal in fair water, and scour it a little with fine sand, and then it is ready for the gold.

They next cover over the metal with the mixture of gold and mercury, taking it up with a fil of copper, or a brush made of brass-wire, spreading it as even as possible, to do which they wet the brush from time to time in fair water. Then they fift the metal to the fire, upon a grate, or in a sort of cage, under which stands a pan of coals; and in proportion as the mercury, evaporating and flying off, discovers the places where gold is wanting, they take care to supply them by adding new parcels of amalgama.

Then the work is rubbed over with the wire-brush, dipt in beer or vinegar, which leaves it in a condition to be brought to a colour which is the last part of the process, and which the gilders keep to themselves as a mighty secret.

The method of Gilding by fire on metal. To prepare the metal, they fcratch it well, or rake it; then polifh it with a polifer; and afterwards fift it to the fire to blue, i.e. to heat, till it appear of a blue colour. When this has been done, they clap on the firft lay of leaf-gold, rubbing it lightly down with a polifer, and expose it thus to a gentle fire. They usually give it but three such lays, or four at the most, each lay consisting of a fingle leaf for common works, and of two for extraordinary ones: after each lay, it is fet a-fresh to the fire; and after the laft lay, the gold is in condition to be burnifhed.

To gild paper. Grind bole-armoniac with rain-water, and give one laying of it; when it is dry, take glair of eggs, and add to it a little fugar-candy and gum-water, which lay over the former; and upon this, when it is dry enough, lay leaf-silver, or leaf-gold.

To gild the leaves of books. Take bole-armoniac, eight penny-weight; fugar-candy, two penny-weight; mix and grind them with glair of eggs: then on a bound book (while it is in the press, after it hath been fmear-
ed with glair of eggs, and is dried) fift the laid composition; let it dry, then rub it well and polifh it; then with fair water wet the edges of the book, and suddenfly lay on the gold, prefs it down gently with cotton, let it dry, and then polifh it with a tooth.

GILL, a measure of capacity, containing a quarter of an English pint.

GILLS, in ichthyology. See Branchie.

GILOLO, a large island of the pacific ocean, lying between 1° S. lat. and 2° N. lat. and between 125° and 128° E. long.

GILOLO is also the name of the capital of the above island, situated in 40° N. lat.

GIN, in mechanics, a machine for driving piles, fitted with a windlafs and winches at each end, where eight or nine men heave, and round which a rope is receved that goes over the wheel at the top: one end of this rope is feized to an iron-monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a crofs-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the fame into ground: then the monkey’s own weight over-hauls the windlafs, in order for its being hooked again to the beetle.

GINGEN, an imperial city of Germany, twenty miles E. of Ulm: E. long. 10°, and north lat. 48° 36’.

GINGER, the root of a species of amomum, too well known to need any description: It is a very useful spice in cold flatulent colics, and in laxity and debility of the intestines.

GLINGYMS, in anatomy. See Anatomy, p. 149.

GINSENG, a small root brought from North America, and sometimes from China. It has a sweet taste, accompanied with a slight bitterness and warmth. The Chinese look upon it as an universal restorative in all decays.

GFONNE, a large city and bishop’s see of Spain, in the province of Catalonia, forty five miles north-east of Barcelona: E. long. 3° 35’, and N. lat. 32°.

GIRONNE, or GIRONNY, in heraldry, a coat of arms divided into girons, or triangular figures, meeting in the centre of the shield, and alternately colour and metal. See Plate XCVII. fig. 5.

GISBON, a market-town of Yorkshire, fifty miles west of York.

GISBOROUGH, another market-town of Yorkshire, thirty seven miles north of York.

GISORS, a city of Normandy in France, twenty-eight miles south-east of Rouen: E. long. 1° 25’, N. lat. 50° 10’.

GLACIS, in building, an easy insensible slope or declivity.

The declent of the glacias is less steep than that of the talus. In gardening, a declent sometime begins in talus, and ends in glacias.

The glacias of the cornice, is an easy imperceptible slope in the cymatium, to promote the declent and draining off the rain water.

GLACIS, in fortification, that mass of earth which serves
GLADIATORS, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like our prize fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asia-tics; and we find that the very high-priests had their ludi pontificales, and ludi factodotales. As from the earliest ages of antiquity we read that it was customary to sacrifice prisoners of war to the maen of the great men that fell in the engagement; in process of time they came to sacrifice slaves at the funerals of all persons of condition; but as it would have appeared barbarous to cut their throats like beasts, they were appointed to fight with each other, and do their best to save their own lives by killing their adversary.

Hence arose the matters of arms called lanista, and men learned to fight. These lanistas bought slaves to train up to this cruel trade, whom they afterwards sold to such as had occasion to exhibit shows. Junius Brutus, who expelled the kings, was the first that honoured the funeral of his father with these human diversions at the sepulchre of the deceased; but afterwards they were removed to the circus and amphitheatres; and other persons, besides slaves, would hire themselves to this infamous office.

They were all first sworn that they would fight till death; and if they failed, they were put to death, either by fire, swords, clubs, whips, &c. It was usual with the people, or emperor, to grant them life when they shewed no signs of fear. Augustus decreed that it should always be granted them.

From slaves and freed men, the wanton sport spread to persons of rank, as we find in Nero’s time. And Domitian exhibited combats of women in the night-time: we also read, that dwarfs encountered with one another. Conflation the Great first prohibited these combats in the East; but the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths, in the year 500.

When any person designed to entertain the people with a show of gladiators, he set up bills in the public places, giving an account of the time, the number and names of the combatants, and the circumstances whereby they were to be distinguished; each having his several badge, which generally was a peacock’s feather: they also gave notice what time the show would last; and sometimes gave representations of these things in painting, as is practiced among us, by those who have any thing to show at fairs, &c.

Upon the day appointed for the show, in the first place the gladiators were brought out all together, and obliged to take a circuit round the arena in a very fo-lemn and pompous manner. After this they proceeded to the show, parauta compressae, to match them by pairs, in which great care was taken to make the matches equal. The first sort of weapons they made use of were lances, or wooden staves, called rude: and the second were effective weapons, as swords, poniards, &c.

The first were called arma futoria, or exercitioria; the second, decretoria, as being given by decree or sentence of the pretor, or of him at whose expense the spectacle was exhibited.

They began to fence or skirmish with the first, which was to be the prelude to the battle; and from thence, when well warmed, they advanced to the second, with which they fought naked. The first part of the engagement was called ventilar, praeludere; and the second dimicar ad certum, or verifer armis pugnare.

When any received a remarkable wound, either his adversary or the people used to cry out, Habet, or Hoc habet. If the vanquished surrendered his arms, it was not in the victor’s power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant this boon. The two signs of favour and dislike given by the people were, premere pollicem, and vertere pollicem; the former of which M. Dacier takes to be a clenching of the fingers of both hands between one another, and to holding the two thumbs upright close together, was a sign of the peoples admiration of the courage shewn by both combatants; and at the same time for the conqueror to spare his antagonist’s life: but the contrary motion, or bending back of the thumbs, signified the dissatisfaction of the spectators, and authorised the victor to kill the other combatant downright for a coward. The emperor saved whom he liked, if he was present at the solemnity, in the same manner.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and oftentimes a sum of money, perhaps gathered up among the spectators: but the most common rewards were the pileus and the rudis; the former being given only to such gladiators as were slaves, for a token of obtaining their freedom; but the rudis seems to have been bestowed both on slaves and free men, with this difference, that it procured the former no more than a discharge from any further performance in public, upon which they commonly turned lanista: but the rudis, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty. See pileus, rudis, and lanista.

GLADIOLUS, in botany, a genus of the triandria monogynia class. The corolla is ringent, and divided into six parts. There are ten species, none of them natives of Britain.

GLAMA. See Camelus.

GLAMORGANSHIRE, a county of South Wales, bounded by Brecknockshire on the north, and by the Bristol channel on the south. Its capital is Cardiff.

GLANDERS,
GLASGOW, a large city of Scotland, in the shire of Claris, the capital of one of the cantons of Switzerland, of the same name, the inhabitants of which are both protestant and papish: it is situated thirty-five miles south-east of Zurich, in E. long. 9°, and N. lat. 47°.

GLASS, a transparent, brittle, fatalicious body, produced by the action of fire upon a fixt salt and sand, or flone, that readily melts.

The chemists hold, that there is no body but may be vitrified, or converted into glass; being the last effect of fire, as all its force is not able to carry the change of any natural body beyond its vitrification.

When or by whom the art of making glass was first found out is uncertain: some will have it invented before the flood; but without any proof. Neri traces the antiquity of this art as far back as the time of Job: but Dr Merret will have it as ancient as either pottery, or the making of bricks: because that a kiln of bricks can scarce be burnt, or a batch of pottery be made, but some of the bricks and the ware will be at least superficially turned to glass; so that it must have been known at the building of Babel, and as long before as the making of bricks was used. It must have been known, consequently, among the Egyptians, when the Israelites were employed by them in making bricks. Of this kind, no doubt, was that fossil glass mentioned by Ferrant. Imperat. to be found under-ground in places where great fires had been. The Egyptians indeed boat, that this art was taught them by the great Hermes. Aristophanes, Arilitote, Alexander Aphrodiseus, Lucretius, and John the divine, put us out of all doubt that glass was in use in their days.

Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea, who, being obliged to continue there, and drest their vials, by making a fire on the ground, where there was great plenty of the herb kalm; that plant burning to ashes, its salts mixed and incorporated with sand, or stones fit to vitrify, and produced glasses: that this accident being known, the people of Sidon, in that neighbourhood, assayed the work, improved the hint, and brought it into use; and that this art has been improving ever since.

Venice, for many years, excelled all Europe in the fineness of its glasses; but of late the French and English have excelled in the Venetians, so that we are no longer supplied with this commodity from abroad.

Nature and characters of Glass. Naturalists are divided in what classes of bodies to rank glasses: some making it a concrete juice; others a flone; others again rank it among semi-metals; but Dr Merret observes, that these are all natural productions, whereas glasses are a fatalicious compound, produced by fire, and never found in the earth, but only the sand and stome that form it: that metals are formed by nature into certain species; and that fire only produces them, by its faculty of separating heterogeneous, and uniting homogeneous bodies: whereas it produces glasses, by uniting heterogeneous matter, viz. salt and sand, of both which it evidently confists; 100 lb weight of sand yielding above 150 lb of glasses.

The same learned doctor gives us a precise and accurate enumeration of the several characters, or properties of glasses, whereby it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by strong fire. 3. When fused, tenacious and coherent. 4. It does not waste nor confume in the fire. 5. When melted, it cleaves to iron. 6. When it is red hot, it is dulcile, and may be fashioned into any form; but not malleable; and capable of being blown into a hollowness, which no mineral is. 7. Frangible when thin, without annealing. 8. Friable, when cold. 9. Diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Difsoluble by cold and moisture. 12. Only capable of being graven or cut with a diamond, or other hard flone and emery. 13. Receives any dye or colour both externally and internally. 14. Not dissoluble by aqua fortis, aqua regia, or mercury. 15. Neither acid juices nor any other matter extract either colour, taste, or any other quality from it. 16. Adorns of polishing. 17. Neither lofes weight nor subfance by the longel and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open glass being filled with water in the summer-time, will gather drops of water on the outside, just so far as the water on the inside reaches; and a person's breath blown on it will manifestly moisten it. 22. Little glasses balls filled with water, mercury, and other liquor, and thrown into the fire, as also drops of green glasses being broken, will fly asunder with a great noise. 23. Neither wine, beer, nor any other liquor, will make it mufty, or change its colour, or ruft it. 24. It may be cemented, as stones and metals. 25. A drinking glasses, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glasses is more or less full, and will make the liquor frisk and leap.

Materials for making of Glass. The materials whereof glasses is made, we have already mentioned to be salt and sand, or stones. The salt here used, is procured from a fort of ashes, brought from the Levant, called polverine, or rochetta; which ashes are thofe of a fort of water-plant, called kali, cut down in the summer-time, dried in the sun, and burnt in heaps, either on the ground, or on iron grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use.

To extract the salt, these ashes, or polverine, are powdered and sifted, then put into boiling water, and there kept till one third of the water be consumed; then
This experiment duly varied, says Dr Shaw, may lead to some considerable improvements in the art of glass-making, enamels, and artificial gems. It threw us an expeditious method of making glass without the use of fixed salts, which has generally been thought an essential ingredient in glass, and which is the ingredient that gives common glass its softness; and it is not yet known, whether calcined crystal, or other substances being added to this salt, instead of sand, it might not make a glass approaching to the nature of a diamond.

Kinds of Glass. Of these materials we have many sorts of glass made, which may principally be distinguished according to their beauty: as the crystal salt glass, the crystall white glass, the green glass, and the bottle glass. Again these several sorts are distinguished by their several uses: as plate or coach glasses, looking glasses, optic-glasses, &c. which are made of the salt glass. The second sort includes crown-glasses, toys, phials, drinking-glasses, &c. The third sort is well known by its colour, and the second by its form.

Balas Coloured Glass is made thus: Put into a pot of crystal frit, thrice washed in water; tinge this with manganese prepared into a clear purple: to this add alumnum tritflfined in small quantities, and at several times: this will make the glass grow yellowish, and a little redder, but not blackish, and always dilutes the manganese. The last time you add manganese, give no more of the alumnum carvium, unlefs the colour be too dull. Thus will the glass be exactly of the colour of the balas-ruby.

Red Glass. A blood-red glass may be made in the following manner: Put six pounds of glass of lead, and ten pounds of common glass, into a pot glazed with white glass: when the whole is boiled and refined, add, by small quantities, and at small distances of time, copper calcined to a redness, as much as, on repeated proofs, is found sufficient: then add tartar in powder by small quantities at a time, till the glass is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

Yellow Glass. It is a necessary remark in glass-making, that the crystal glass made with salt has an admixture of tartar will never receive the true gold yellow, though it will all other colours: for yellow glass, therefore, a salt must be prepared from polverine, or pot ashes alone, to make the glass.

Furnaces for the making Glass. In this manufacture, there are three sorts of furnaces; one, called calcar, is for the frit; the second is for working the glass; the third serves to anneal the glass, and is called the hearer. See Furnace.

The calcar A (Plate XCVII. fig. 1.) resembles an oven ten feet long, seven broad, and two deep: the fuel, which in England is sea-coal, is put into a trench on one side of the furnace; and the flame reverberating from the roof upon the frit, calcines it. The glases furnace, or working furnace B, is round, of three yards diameter, and two high; or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part C is properly called the crown,
and is made in that form. Its use is to keep a brisk fire of coal and wood, which is never put out. The mouth of it is called the bocca. There are several holes in the arch of this crown, through which the flame passes into the second vault, or partition, and reverberates into the pots filled with the ingredients above mentioned. Round the insides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccales D, or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in, while he works out of the other. Through the working holes the metal is taken out of the pots, and the pots are put into the furnace; and these holes are flopped with movable covers made of lute and brick, to screen the workmen eyes from the scorching flames. On each side of the bocca, or mouth, is a bocharella, or little hole, out of which coloured glases, or finer metal, is taken from the piling pot. Above this oven, there is the third oven or leer, about five or six yards long, where the vessels, or glases, is annealed, or cooled: this part consists of a tower, besides the leer F, into which the flame ascends from the furnace. The tower has two mouths, through which the glases are put in with a fork, and set on the floor or bottom; but they are drawn out on iron pans, called fraches, through the leer, to cool by degrees; so that they are quite cold by the time they reach the mouth of the leer, which enters the faroefel, or room where the glases are to be flowed.

But the green glases furnace is square; and at each angle it has an arch for annealling, or cooling glases. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnen holes, for the fire to come from the furnace to bake the frit, and to discharge the smoke. Pires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick, and the inner part to bear the fire is made of a sort of fuller's earth, or tobacco-pipe clay, of which earth they also make their melting-pots.

Mr Blancourt observes, that the worst and roughest work in this art, is the changing the pots, when they are worn out, or cracked. In this case the great workmen picks, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in, while he works out of the other. Through the working holes the metal is taken out of the pots, and the pots are put into the furnace; and these holes are flopped with movable covers made of lute and brick, to screen the workmen eyes from the scorching flames. On each side of the bocca, or mouth, is a bocharella, or little hole, out of which coloured glases, or finer metal, is taken from the piling pot. Above this oven, there is the third oven or leer, about five or six yards long, where the vessels, or glases, is annealed, or cooled: this part consists of a tower, besides the leer F, into which the flame ascends from the furnace. The tower has two mouths, through which the glases are put in with a fork, and set on the floor or bottom; but they are drawn out on iron pans, called fraches, through the leer, to cool by degrees; so that they are quite cold by the time they reach the mouth of the leer, which enters the faroefel, or room where the glases are to be flowed.

But the green glases furnace is square; and at each angle it has an arch for annealling, or cooling glases. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnen holes, for the fire to come from the furnace to bake the frit, and to discharge the smoke. Pires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick, and the inner part to bear the fire is made of a sort of fuller's earth, or tobacco-pipe clay, of which earth they also make their melting-pots.

Mr Blancourt observes, that the worst and roughest work in this art, is the changing the pots, when they are worn out, or cracked. In this case the great working hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, through the flames, by the hands only. For this work, the man guards himself with a garment made of flints, in the shape of a pantaloons, that covers him all but his eyes, and is made as wet as possible: the eyes are defended with a proper fort of glases.

Instruments for making of Glass. The instruments made use of in this work, may be reduced to these that follow. A blowing pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glases, after it is blown, and to cut off the former. Scissors to cut the glases when it comes off from the first hollow iron. Shears to cut and shape great glases, &c. an iron ladle, with the end of the handle cased with wood, to take the metal out of the refining pot, to put it into the workmen pots. A small iron ladle, cased in the same manner, to skim the alkaline falt that swims at top. Shovels, one like a peel, to take up the great glases; another, like a fire-shovel, to feed the furnace with coals. A hooked iron fork, to flir the matter in the pots. An iron rake for the fame purpofe, and to flir the frit. An iron fork, to change or pull the pots out of the furnace, &c.
GLASS (719) GLASS

If there remains any superfluities, they are cut off with the shears L; for till the glass is cool, it remains in a soft, flexible state. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguished, keeping it turning; because that motion prevents any settling, and preserves an evenness in the face of the glass, where, as it cools, it comes to its consistence; being first cleared from the iron rod by a light stroke by the hand of the workman.

If the vessel conceived in the workman’s mind, and whose body is already made, requires a foot, or a handle, or any other member or decoration, he makes them separate; and now affrays to join them with the help of hot metal, which he takes out of the pots with his iron rod: but the glass is not brought to its true hardness, till it has passed the leers, or annealing oven, described before.

Working, or blowing, of window or table glass. The method of working round glasses, or vessels of any sort, imperfects have been remedied by an invention of wanted substance to bear the necessary grinding. These were larger were always found to warp, which prevented them from reflecting the objects regularly, and wanted substance to bear the necessary grinding. These imperfections have been remedied by an invention of the Sieur Abraham Thevart, in France, about the year 1688, of casting or running large plates of glass in the following manner.

Casting, or running of large locking glass plates. The furnace G, fig. 2, is of a very large dimension, enroined with several ovens, or annealing furnaces, called carquasles, besides others for making of frit, and calcining old pieces of glass. This furnace, before it is fit to run glasses, costs 3500L. It seldom lasts above three years, and even in that time it must be refitted every six months. It takes six months to rebuild it, and three months to refit it. The melting-pots are as big as large hogheads, and contain about 2000 weight of metal. If one of them bursts in the furnace, the losfs of the matter and time amounts to 250L. The heat of this furnace is so intense, that a bar of iron laid at the mouth thereof becomes red hot in less than half a minute. The materials in these pots are the same as described before; and A is the man breaking the frit for that purpose. When the furnace is red-hot, these materials are put in at three different times, because that helps the fusion; and in twenty-four hours they are vitrified, refined, setted, and fit for casting. H is the bocca, or mouth of the furnace; K is the ciftern that conveys the liquid glass it receives out of the melting-pots in the furnace to the casting table. These cifterns are filled in the furnace, and remain therein six hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pulley marked I, and placed upon a carriage with four wheels marked L, by two men P P. This carriage has no middle piece; so that when it has brought the ciftern to the casting-table M, they slip off the bottom of the cifern, and cut rushes a torrent of flaming matter O, upon the table: this matter is confined to certain dimensions by the iron rulers N, N, which are moveable, retain the fluid matter, and determine the width of the glass; while a man R, with the roller Q, relying on the edge of the iron rulers, reduceth it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trusses for the convenience of moving to the annealing furnace; into which, frewed with sand, the new plate is shoved, where it will harden in about ten days. After this, the glass needs only be ground, polished, and foliated for use.

Grinding and polishing of plate-glass. Glace is made transparent by fire, but it receives its luster by the skill and labour of the grinder and polisher, the former of whom takes it rough out of the hands of the maker.

In order to grind plate glasses, they lay it horizontally upon a flat fioote-table, (fig. 3,) made of a very fine-grained free-stone; and for its greater security they plaster it down with lime, or sluzco: for otherwise the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This stone-table is supported by a strong frame A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glasses. Upon this glasses to be ground, is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented
Painting in Glass. The ancient manner of painting in glass, to guard it from the injury it must otherwise receive from the scraping of the wheel, to which this plank is fastened; and from the weights laid upon it, to promote the grinding, or friture, of the glasses. The whole is covered with a wheel, B, made of hard light wood, about six inches in diameter; by pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the word advances, till at last they must pour in the powder of smalt. As the upper or incumbent glasses polish, and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a mill by the artists, and is used only in the largest size glasses; for in the grinding of the lesser glasses, they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glasses to an exact plainness, it is turned over to the care of the polisher, who with the fine powder of tripoli-stone, or emery, brings it to a perfect evenness and lusitre. The instrument made use of in this branch, is a board, c, c, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artift in working this roller, is affisted with a wooden hoop or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

Painting in Glass. The ancient manner of painting in glasses was very simple; it consisted in the mere arrangement of pieces of glasses of different colours in some sort of simmetry, and constituted what is now called Mosaic. See Mosaic.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glasses of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, basilicas, &c. they found out means of incorporating the colours in the glasses itself, by heating them in the fire to a proper degree; having first laid on the colours. The colours used in painting or staining of glasses are very different from those used in painting either in water or oil colours.

For black, Take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce; reduce them to powder, and mix them. For blue, Take powder of blue, one pound; sal nitre, half a pound; mix them and grind them well together. For carnation, Take red chalk, eight ounces; iron scales and latharh of silver, of each two ounces; gum arabic, half an ounce; dissolve in water; grind altogether for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, Take red lead, one pound; scales of copper, one pound; and flint, five pounds; divide them into three parts; and add to them as much sal nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, Take silver an ounce; antimony, half an ounce; melt them in a crucible; then pound the mass to powder; and grind it on a copper plate; add to it yellow oker, or brick-dust calcined again, fifteen ounces; and grind them well together with water. For purple, Take minium, one pound; brown stone, one pound; white flint, five pounds; divide them into three parts, and add to them as much sal nitre as one of the parts; calcine, melt, and grind it as you did the green. For red, Take jet, four ounces; latharh of silver, two ounces; red chalk, one ounce; powder them fine, and mix them. For white, Take jet, two parts; white flint, ground on a glass very fine, one part; mix them. For yellow, take Spanish brown, ten parts; leaf silver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c., there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one third of a line; though this was more or less according to the nature of the colour; the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glasses, though already coloured, they could give other kind of colours where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till such time as they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By these means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bored of its colour with emery, without tingling the place with any colour at all; and this
diftribute the design itself, or papers it is drawn on, this was the manner by which they wrought their lights, glaffes as well as papers, that they may be known by this precaution, never to apply a new wash till the former is sufficiently dried.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black; and repeat it several times, according as the shades are desired to be heightened, which is very pernicious to the other colours, by blending them therewith. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay, till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glases, and incorporates therewith by the fire; the red, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace, or oven, to anneal, or bake the colours.

The furnace here used is small, built of brick, from eighteen to thirty inches square. At fix inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition, is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, fix or seven inches deep; and five or six inches less every way than the perimeter of the furnace. On the one side hereof is a little aperture, through which to make trials, placed directly opposite that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed, in the following manner. First, the bottom of the pan is covered with three strata, or layers, of quick lime powdered; those strata being separated by two others of old broken glass, the design whereof is to secure the painted glass from the too intense heat of the fire.

This done, the glass is laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder, an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthen ware, closely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even suffices out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace, and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon bum the colours, and break the glasses.

Glass porcelain, the name given by many to a modern invention of imitating the china-ware with glass.

The method of making it, as given by Mr Reaumur, who was the first that carried the attempt to any degree of perfection, is as follows.

The glass vessels to be converted into porcelain, are to be put into large vessels, such as the common fine earthen dishes are baked in; or into sufficiently large crucibles: the vessels are to be filled with a mixture of fine white sand, and of fine gypsum; or plaster stone, burnt into what is called plaster of Paris; and all the interfaces are to be filled up with the same powder, so that the glass vessels may no where touch either one another, or the sides of the vessels they are baked in.

The vessel is to be then covered down, and luted, and the fire does the rest of the work: for this is only to be put into a common potter’s furnace, and when it has stood there the usual time of taking the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted into a white opaque sub stance, which is a very elegant porcelain, and has almost the properties of that of china.

GLASS OF ANTIMONY. See Chemistry, p. 87.

GLASTONBURY, a market town of Somersetshire, five miles south of Wells.

GLATZ, the capital of a county of the same name in Bohemia, 100 miles east of Prague. E. long. 16° 8', N. lat. 50° 25'.

GLAUBER'S SALT. See Chemistry, p. 127.

GLAUCION, in ornithology. See Anas.

GLAZING, the polishing or coating over earthen ware.

GLAZIER, an artificer who works in glass. See Glass.

GLAUCOMA, in medicine, the change of the crystalline humour of the eye into an azure-colour. See Medicine.

GLAUCIUM, in botany. See Chelidonium.

GLAZIER'S liquid. See Glass.

GLAZING, the polishing or coating over earthen ware, by running melted lead or litharge over it.

The common ware is glazed with a composition of 50 lb. clean sand, 70 lb. lead ashes, 30 lb. wood ashes, and 12 lb. salt, all melted into a cake. With this mixture they glaze it over, and then set it in an earthen glazing pan; taking care that the vessels do not touch one another. As several colours are used for this purpose, we shall give the following receipts, from Smith's laboratory.

1. For a black, take lead ashes, 18 parts; iron filings, 3; copper ashes, 3; and zaffre, 2. This, when melted, will make a brown black; and if you would have it blacker, put some more zaffre to it. 2. For blue, take lead ashes, 1 lb. clear sand or pebble, 2 lb. salt, 2 lb. white calcined tartar, and 1 lb. Venice or other glass, 16 lb. and zaffre, half a pound; mix them well together; and after melting, quench them in water, and then melt them again; which operation is to be repeated several times; and if you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two. 3. A brown glazing may be given with a mixture of lead glases, 12 parts, and common glass and manganese, of each one part. 4. A citron yellow may be made of 6 parts of red-lead, 7 parts of fine red brick dust, and 2 parts of antimony, all melted together. 5. A flesh-colour, with 12 parts of lead-ashes, and one of white glases. 6. For a green-colour, take 8 parts of litharge, 8 parts of Venice glases, 4 parts of brafs dust, and melt them together for use; or melt together two parts yellow glases, with as much copper dust. 7. For a gold-yellow, take of antimony, red lead, and sand, an equal quantity, and melt them into a cake. 8. For a fine purple brown, take lead ashes, 15 parts; clear sand, 18; manganese, 1; white glases, 15 meafeures; and 1 of zaffre. 9. For a fine red, take antimony, 2 lb. litharge, 3 lb. dust of iron calcined, 1 lb. and grind them to a fine powder. 10. For a fine white glazing, take 2 lb. of lead, 1 lb. of tin, and calcine them to ashes; of which take 2 parts; of calcined flint or pebble, 1 part; of salt, 1 part; and mixing them well together, melt them into a cake. At Rotterdam, they make a fine shining white glazing, by melting together 2 lb. clean tin-ashes, 10 lb. lead ashes, 2 lb. fine Venice glases, and 1 lb. tartar. 11. A yellow glazing is made of 4 ounces of red lead, and 2 ounces of antimony, melted together. 12. For a fine yellow, take red lead, 3 parts; antimony and tin, of each 2 lb. then melting them into a cake, grind it fine; and repeating this several times, you will have a good yellow.

GLOBE, among miners, signifies a piece of earth, wherein is contained some mineral ore.

GLOBE, in law, the land belonging to a parish-church, besides the tithes.

GEOCHOMA, in botany, a genus belonging to the di-dynamia gymnospermae class. The calyx consists of five segments; and each pair of anthers are disposed in the form of a cross. These are three species, two of which are natives of Britain, viz. the hederacea, or ground-ivy; and the arvensis, or upright ground-ivy. The leaves of the hederacea are coriaceous, aperient, and detergent.

GLEDITSIA, in botany, a genus of the polygamia dioecia class. The calyx of the hermaphrodite has four segments; the corolla four petals; there are five stamens, and one pistillum. The calyx of the male consists of three leaves, and the corolla of three petals; and it has five stamens. The calyx of the female consists of five leaves, and the corolla of five petals; it has but one pistillum; and the capsule is a legumen. There are two species, none of them natives of Britain.

GLOBET, in medicine, the flux of a thin limpid humour from the urethra. See Medicine.

GLORES, the name of Linneus's fourth order of mammalia. See Natural History.

GLENOIDES, the name of two cavities, or small depressions, in the inferior part of the first vertebra of the neck.

GLIS, in zoology. See Sciurus.

GLISCHROMICTHES, in natural history, the name by which Dr Hill calls the tougher and more viscid loams.

GLISTER, in surgery. Clyster.

GLOBULARIA, in botany, a genus of the tetrandria monogynia class. The calyx consists of one leaf; it has no corolla; the capsule has one cell, 5 valves, and 5 seeds. There is but one species, viz. the maritima, which is a native of Britain.

The principal part of a glazier's business consists in fitting panes and plates of glass to the frames and window-frames of houses, pictures, &c. and in cleaning the same.

GLOUCESTER.*
GLUCERN, the capital of Gloucester-shire, ninety
miles west of London: W. long. 2° 16', and N. lat.
51° 50'.

It is a bishop's see, and sends two members to par-
liament.

GLOGAW, a city of Silefia, situated on the river Oder,
fifty miles south of Breslaw: E. long. 16° 8', and N. lat. 51° 40'.

GLORIOSA, a genus of the axeandra monogyphus clas.
The corolla consists of six undulated and reflected petals; and the stigmas are ob-
lique. There is but one species, native of Malabar.

GLOSSARY, a fort of dictionary, explaining the ob-
ferve and anticipated terms in some old author.

GLOSSOPETRA, in natural history, a genus of extra-
naneous fossils, so called from their having been supposed
the tongues of serpents turned into stone, though they
are really the teeth of sharks, and are daily found in
the mouths of those fishes, where ever taken.

GLOTTIS, in anatomy. See Anatomy, p. 204.

GLUE, among artificers, a tenacious viscid matter,
made of the skins of animals, as oxen, cows, calves,
and N. lat. 54° 20'.

GLUE, among artificers, a tenacious viscid matter,
which serves as a cement to bind or connect things to-
gether.

Glues are of different kinds, according to the vari-
ous uses they are designed for, as the common glue,
plove-glue, and parchment glue; whereof the two lat-
ter are properly called size.

The common or strong glue is chiefly used by car-
penters, joiners, cabinet-makers, &c., and the best kind
is that made in England, in square pieces of a ruddy
brown colour; and, next to this, the Flanders glue. It
is made of the skins of animals, as oxen, cows, calves,
and the older the creature is, the better is the
glue made of its hide. Indeed, whole skins are but
rarely used for this purpose, but only the shavings, pa-
rings, or scraps of them; or the feet-fines, &c. That
made of whole skins, however, is undoubtedly the best;
as that made of fines is the very worst.

The method of making Glue. In making glue of pa-
rings, they first steep them two or three days in water;
then washing them well out, they boil them to the
consistence of a thick jelly; which they pass, while hot,
through ozier-baskets, to separate the impurities from
it, and then let it stand some time, to purify it fur-
ther: when all the filth and ordures are settled to the
bottom of the vessel, they melt and boil it a second
time. They next pour it into flat frames or moulds,
and after which, with a brush dipped in it, smear the fa-
me, and N. lat. 51° 40'.

The best glue is that which is oldest; and the surest
way to try its goodness, is to lay a piece to steep three
or four days, and if it swell considerably without melt-
ing, and when taken out refumes its former driness, it
is excellent.

A glue that will hold against fire or water, may be
made thus: mix a handful of quicklime with four
ounces of linseed oil; boil them to a good thicknes,
then spread it on tin-plates in the shade, and it will be-
come exceeding hard, but may be easily dissolved over
a fire, as glue, and will effect the business to admir-
ation.

Method of preparing and using Glue. Set a quart of
water on the fire, then put in about half a pound of
good glue, and boil them gently together till the glue
be entirely dissolved and of a due consistence. When
the glue is to be used, it must be made thoroughly hot;
with which, after a bruAh dipped in it, befme the faces
of the joints as quick as possible; then clapping them
together, glide or rub them lengthwise one upon
another, two or three times, to settle them close; and
so let them stand till they are dry and firm.

GLUME, among botanists. See Botany, p. 637.

GLUTENS, in anatomy. See Anatomy, p. 204.

GLYCINE, in botany, a genus of the diadelphia dec-
candria clas. The calix is bilabiated; and the pod
consists of two cells. There are nine species, none of
them natives of Britain.

GLYCyrRHiza, liquorice, in botany, a genus of the
diadelphia decidua clas. The calix is bilabiated;
and the pod consists of two cells. There are
three species, none of them natives of Britain.

The common liquorice is cultivated in most coun-
tries of Europe for the sake of its root. That which
is cultivated in Britain is preferable to such as comes
from abroad; this last being generally mouldy, which
this root is very apt to become, unless kept in a dry
place. The powder of liquorice usuallyfold is often
mingleed with flour, and probably too often with substan-
ces not quite so wholesome: the best form is of a brown-
lilh yellow colour (the fine-pale yellow being generally
sophisticated) and of a very rich sweet taffe, much
more agreeable than that of the fresh root. Liquorice
is almost the only sweet that quenches thirst; whence
it was called by the Greeks atipon. Galen takes no-
tice, that it was employed in this intention in hydro-
pic cafes, to prevent the necessity of drinking. Mr
Fuller, in his Medicina gymnasica, recommends this
root as a very useful pectoral, and says it excellently
softens acrimonious humours, at the fame time that it
proves gently detergent; and this account is warrant-
ed by experience.

GLYPH, in sculpture and architecture, denotes any ca-
nal or cavity used as an ornament.

GMELINA, in botany, a genus of the didynamia angio-
permia clas. The calix has four teeth; the corolla
is bell-shaped, and divided into four segments; the an-
thera are divided into two parts; and the fruit is a bi-
locular drupa. There is but one species, a native of the
Indies.

GNaphALiUM, cudweed, in botany, a genus of the
syngnesia.
fyniasia polygama superflua clauis. The receptacle is naked; the pappus is plumose; and the calyx is imbricated. There are 41 species, five of them natives of Britain, viz. the dioicum, mountain cudweed, or cat's foot; the margaritaceum, or American cudweed; the luteo-album, or Jersey cuweed; the sylvaticum, or upright cuweed; and the uliginolium, or black-headed cuweed.

GNAT, in zoology. See Musca.

GNESNA, the capital city of great Poland, situated one hundred and ten miles well of Warsaw: E. long. 18°, and N. lat. 54°. It is the see of an archbishop, who is always pri-

GOLD. See Chemistry, p. 78, and 129.

Gold-wire, a cylindrical ingot of silver, superficially

Gold-wire, a cylindrical ingot of silver, superficially girt, or covered with gold at the fire, and afterwards drawn successively through a great number of little, round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of

It may be observed, that before the wire be reduced to this excelle fineness, it is drawn through above an hundred and forty different holes; and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

Gold-wire flatted, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a

Gold thread, or Spun-gold, is a fitted gold, wrap-

Manner of forming Gold-wire, and Gold-thread, both round and flat. First, an ingot of silver, of twenty-four pounds, is forged into a cylinder, of about an inch in diameter: then it is drawn through eight or ten holes, of a large, coarse, wire-drawing iron, both to finish the roundness, and to reduce it to about three fourths of its former diameter. This done, they file it very carefully all over, to take off any filth remaining on the forge; then they cut it in the middle; and thus make two equal ingots thereof, each about twenty six inches long, which they draw through several new holes, to take off any inequalities the file may have left, and to render it as smooth and equable as possible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking some gold leaves, each about four inches square, and weighing twelve grains, they join four, eight, twelve, or sixteen of these, as the wire is intended to be more or less girt; and when they are so joined, as only to form a single leaf, they rub the ingots recking hot with a burnisher. These leaves being thus prepared, they apply over the whole surface of the ingot, to the number of six, over each other, burnishing or rubbing them well down with the blood-

The ingot was the peculiar privilege of the goddesses to be represented naked on medals; for it was supposed that the imagination must be awed and restrained by the consideration of the divine character.

Goat, in zoology. See Capra.
Gold-leaf, or Beaten Gold, is gold beaten with a hammer into exceedingly thin leaves, so that it is computed, that an ounce may be beaten into fifteen hundred leaves, each three inches square, in which state it takes up more than 15,552 times its former surface.

This gold they beat on a block of black marble, about a foot square, and usually raised three feet high: they make use of three sorts of hammers, formed like mallets, of polished iron: the first, which weighs three or four pounds, serves to chase, or drive; the second, of eleven or twelve pounds, to close; and the third, which weighs fourteen or fifteen pounds, to stretch and finish. They also make use of four moulds of different sizes, viz. two of vellum, the smallest whereof consists of forty or fifty leaves, and the larger of two hundred; the other two, consisting each of five hundred leaves, are made of bullocks guts well scour'd, and prepared. See Mould.

Method of preparing and beating Gold. They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them: after they have been hammered here a while with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould; out of which they are taken, divided into four, as before, and laid in the last, or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper-books, prepared with a little red bole, for the gold to stick to; each book ordinarily contains twenty-five gold leaves. There are two sizes of these books; twenty-five leaves of the smallest only weigh five or six grains, and the same number of the largest nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire drawers to gild their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. withal. See Gilding.

Gold-finch, in ornithology. See Fringilla.

Goldsmith, or, as some choose to express it, silversmith, an artificer who makes vessels, utensils; and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures, are cast in a mould, and afterwards polished and finished: plates, or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates folded together, and their mouldings are beat, not cast. The business of the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted: but there are now invented flattening-mills, which reduce metals to the thinness that is required, at a very small expense. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy, to be able to assay mixed metals, and to mix the alloy.

Golden, something that has a relation to gold, or consists of gold.

Golden number. See Astronomy, p. 492.

Golden rule. See Arithmetic, p. 381.

Goldingen, a city of Poland, in the duchy of Courland, fifty miles west of Mittau: E. long. 22°, N. lat. 57°.

Gombron, the greatest sea-port town in Persia, situated on the strait at the entrance of the gulf of Persia, opposite to the island of Ormus: E. long. 55° 30', N. lat. 27° 30'.

Gomera, one of the Canary islands, subject to Spain, and situated west of Teneriff: W. long. 18°, N. lat. 28°.

Gomorbo islands, situated between 10° and 13° S. lat., on the eastern coast of Africa.

Gomphophysis, in anatomy. See Anatomy, p. 143.

Gomphrena, the purple everlasting flower, in botany, a genus of the pentandria digynia class. The calyx consists of three coloured leaves; the nectarium is cylindrical, with ten teeth; and the capsule contains one seed. There are seven species, none of them natives of Britain.

Gondola, in naval architecture, a flat kind of boat, very long and narrow, chiefly used on the canals at Venice.

Gonorrhoea, in medicine, an involuntary efflux of the seminal juices, and some other excrementitious matters. See Medicine.

Good, in general, whatever is apt to cause or increase pleasure, or diminish pain in us; or, which amounts to the same, whatever is able to procure or preferve to us that possession of agreeable sensations, and remove those of an opposite nature.

Moral-good, denotes the right conduct of the several fenses and passions, or their just proportion and accommodation to their respective objects and relations. See Morals.

Good-hope, or Cape of Good-hope, the most southern promontory of Africa, where the Dutch have built a good town and fort: E. long. 16° and N. lat. 34° 15'.

Goose, in ornithology. See Anas.

Gooseberry, in botany. See Ribes.

Goose-neck.
Goose-neck, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whipstaff or the wheel-rope conies, for steering the ship.

Goose-wing, in the sea-language. When a ship fails before, or with a quarter wind on a fresh gale, to make the more haste, they launch out a boom, and fail on the lee side; and a fail so fitted, is called a goose-wing.

GOR, the capital of a province of the same name, in the East Indies, subject to the Mogul: E. long. 85°, N. lat. 37° 15'.

GORCUM, a city of the United Provinces, situated in that of Holland, on the river Waal, twenty two miles east of Rotterdam: E. long. 4° 50', N. lat. 51° 50'.

GORLITZ, a city of Upper Saxony, in Germany, fifty miles east of Dresden: E. long. 15° 6', N. lat. 51° 12'.

GOSLAR, an imperial city of Lower Saxony, in Germany, thirty miles south of Brunswick: E. long. 10° 30', N. lat. 52°.

GOSPEL, the history of the life, actions, death, resurrection, ascension and doctrine of Jesus Christ. The word is saxon, and of the same import with the Latin term evangelium, which signifies glad tidings, or good news.

This history is contained in the writings of St Matthew, St Mark, St Luke, and St John; who from thence are called evangelists. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSYPHIUM, in botany, a genus of the monadelphia polyandria class. The calix is double, the exterior one consisting of three leaves; the capsule has four cells; and the seeds are covered with down. There are four species, none of them natives of Britain.

Gotha, the capital of the duchy of Saxe Gotha, in Lower Saxony; E. long. 10° 36', N. lat. 51°.

It is subject to the duke of Saxe Gotha, brother of her royal highness the princes dowager of Wales.

GOTHIC, in general, whatever has any relation to the Goths: thus, we say, Gothic customs, Gothic architecture, &c.

Gothland, the most southern province of Sweden, being a peninsula surrounded on three sides by the Baltic Sea. It is subdivided into East and West Gothland, Smaland, Halland, Bleken, and Schoen.

Gothland, is also an island of the Baltic, situated without the province of Gothland and Livonia.

GOTTENBURG, a port-town of Sweden, situated between the Sound, on the coast of the Schaggerack Sea, near the entrance of the Baltic.

GOTTINGEN, a city of Germany, in the circle of Lower Saxony and dukedom of Brunswick: E. long. 6° 45', N. lat. 51° 32'.

GOTTORP, a city of the dukedom of Slefwic, in Denmark, and capital of the territories of the duke of Holstein Gottorp: E. long. 10°, N. lat. 54° 40'.

GOUDE, a city of the United Netherlands, in the province of Holland, ten miles north-east of Rotterdam.

GOVERNMENT, in general, is the polity of a date, either the civil authority is delegated to one or more, in power; whence arises the known distinction of government into monarchy, aristocracy, and democracy.

Mr Hooker thinks, that the first government was arbitrary, and administered by a single person; till it was found by experience, that to live by one man's will, was the cause of all mens misery: and this, he concludes, was the original of inventing laws. The Roman and most of the Grecian states were built up-
on the republican plan; but when the Goths, and other northern nations, destroyed the Roman empire, and extended their conquests into far distant countries, they established, where ever they came, a mixed form of government. The preservation of this constitution depending upon the balance between the king, nobility, and people, the legislative power was lodged in these three states, called by different names in different countries; in the north, diets; in Spain, cortes; in France, estates; and in Britain, parliaments. The excellency of this mixed government, consists in that due place or balance between rule and subject, so justly observed in it, that by the necessary concurrence of the nobility and commons, in making and repealing all laws, it has the main advantage of an aristocracy, and a democracy, and yet is free from the disadvantages and evils of either of them. This mixed form of government is, however, now driven almost out of Europe, in some parts of which we can hardly find the shadow of liberty left, and in many there is no more than the name of it remaining. France, Spain, Portugal, Denmark, and part of Germany, were all, an age or two ago, limited monarchies, governed by princes, well advised by parliaments or courts, and not by the absolute will of one man. But now all their valuable rights and liberties are swallowed up by the arbitrary power of their princes: whilst we in great Britain have still happily preserved this noble and ancient Gothic constitution, which all our neighbours once enjoyed. There is such a due balance of property, power, and dominion in our constitution, that, like the ancient government of Sparta, it may be called an empire of laws, and not of men; being the most excellent plan of limited monarchy in the world.

Governments are commonly divided into two classes, arbitrary and free governments; but there are many different forms of each. Thus the governments of France and Spain are generally called arbitrary; tho' they differ as much from the governments of Turkey and other eastern empires, where absolute despotism prevails, as they do from the government of England, and other European nations, where liberty is said to flourish in its fullest perfection.

Government is also a post or office which gives a person the power or right to govern or rule over a place, a city, or province, either supremely or by delegation.

Government is also used for the city, country, or place to which the power of governing is extended.

GOURD, in botany. See Cucurbita.

GOURD, in medicine. See Medicine.

GRABOW, or Grubow, a town of Lower Saxony and duchy of Mecklenburg: E. long. 16° 30', N. lat. 47° 22'.

GRACE, among divines, is taken, 1st, For the free love and favour of God, which is the spring and source of all the benefits which we receive from him. 2dly, For the work of the spirit, renewing the soul after the image of God, and continually guiding and strengthening the believer to obey his will, to resist and mortify sin, and to overcome it.

GRACE, in geography, a city of Provence, in France, fifteen miles south-west of Nice: E. long. 6° 50', N. lat. 45° 40'.

All of Grace, the appellation given to the act of parliament 1696, c. 32. which allows prisoners for civil debts to be set at liberty, upon making oath, that they have not wherewithal to support themselves in prison, unless they are admonished by the creditors upon whose diligence they were imprisoned, within ten days after intimation made for that purpose. See SCOTS LAW, tit. 32.

Days of Grace, three days immediately following the term of payment of a bill, within which the creditor must protest it, if payment is not obtained, in order to intitle him to recourse against the drawer. See SCOTS LAW, tit. 32.

Grace is also a title of dignity given to dukes, archbishops, and in Germany to barons and other inferior princes.

Graces, in heathen mythology, three goddesses, whose names were Agla, Thalia, and Euphrosyne; that is, shining, flourishing, and gay; or, according to some authors, Paphia, Euphrosyne, and Eupheme. Some make them the daughters of Jupiter, and Eurynome, or Euonoma, the daughter of Oceanus; but the most common opinion is, that they were the daughters of Bacchus and Venus.

They are sometimes represented dressed, but more frequently naked; to show, perhaps, that whatever is truly graceful, is so in itself, without the aid of exterior ornaments. They presided over mutual kindness and acknowledgment; bestowed liberality, eloquence, and wisdom, together with a good grace, gaiety of expression, and easiness of manners.

GRACULA, in ornithology, a genus belonging to the order of picce. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is flexible and sharpish; it has three toes before, and one behind. There are eight species, principally distinguished by their colour.

GRACULUS, in ornithology. See Corvus.

GRADATION, in general, the ascending step by step, or in a regular and uniform manner.

GRADISKA, a city of Slavonia, situated on the river Save, twenty five miles west of Pofega: E. long. 18°, N. lat. 45° 33'.'

GRADUATE, a person who has taken a degree in the university. See Degree.

GRAFT, or Graff, in gardening, a cion or shoot of a tree inserted into another, so as to make it yield fruit of the same nature with that of the tree from whence the graft was taken. See Gardening.

GRAIL, a market-town of Essex, situated on the river Thames, seventeen miles east of London.

GRAIN, all sorts of corn, as wheat, barley, oats, rye, &c. See Corn, Wheat, &c.
Grammar is the art of speaking or of writing any language with propriety.

Grammar considered as an art, necessarily supposes the previous existence of language; and as its design is to teach any language to those who are ignorant of it, it must be adapted to the genius of that particular language of which it treats.—A just method of grammar, therefore, supposing a language introduced by custom, without attempting any alterations in it, furnishes certain observations called rules, to which the methods of speaking and writing in this language may be reduced; this collection of rules is what is called a grammar of any particular language. For the greater distinctness with regard to these rules, grammarians have usually divided this subject into four distinct heads, viz. Orthography, or the art of combining letters into syllables, and syllables into words; Etymology, or the art of deducing one word from another, and the various modifications by which the sense of any one word can be diversified; Syntax, or what relates to the construction or due disposition of the words of a language into sentences or phrases; and Prosody, or that which treats of the quantities and accents of syllables, and the art of making verses.

But grammar considered as a Science, views language in itself: neglecting particular modifications, or the analogy which words may bear to each other, it examines the analogy and relation between words and things; distinguishes between those particulars which are essential to language, and those which are only accidental; and thus furnishes a certain standard by which different languages may be compared, and their several excellencies or defects pointed out. This is what is called Philo-

**OF UNIVERSAL GRAMMAR.**

It is not necessary here to inquire how language was originally invented, to trace the various changes it may have undergone, or to examine whether any one language may be considered as the original from which all others have been derived; it is sufficient for our purpose to observe, that all mankind, however diversified in other respects, agree in the common use of language; from which it appears, that language is not merely accidental and arbitrary, but founded in the nature of things, and within the reach of all mankind. It is therefore an object worthy of a philosophic inquiry to discover the foundations upon which this universal fabric has been raised.

The design of speech is to publish to others the thoughts and perceptions of our mind. The most acute feelings of man, as well as of every other animal, are expressed by simple inarticulate sounds, which, as they tend to the preservation of the individual, are universally understood. These inarticulate but significant sounds, therefore, constitute a natural and universal language, which man, as a mere sensitive being, partakes in common with the other animals. But as man is not only endowed with sensation, but with the faculty of reasoning, simple inarticulate sounds are insufficient for expressing all the various modifications of thought, or for communicating to others a chain of argumentation: it was therefore necessary to call in the aid of articulation; which by modifying these simple sounds, and by fixing a particular meaning to these modifications, forms the language peculiar to man, and which distinguishes him from all other animals, and enables him to communicate with facility all that diversity of ideas with which his mind is flored. These sounds, thus modified and having a determinate meaning, are called Words; and as all language is composed of significant words variously combined, a knowledge of them is necessary previous to our acquiring an adequate idea of language.

But, as it is by words that we express the various ideas which occur to the mind, it is necessary to examine how ideas themselves are suggested, before we can ascertain the various classes into which words may be distributed. With this view, therefore, let us suppose a reasonable being, devoid of every prepossession whatever, placed upon this globe. His attention would, in the first place, be directed to the various objects which he saw existing about him: these he would naturally endeavour to distinguish from one another, and give them names, by means of which the idea of them might be recalled when the objects themselves were absent. This is one copious source of words, and forms a natural class which must be common to every language; and which is distinguished by the name of Nouns. And as these nouns are the names of the several substances which exist, they have likewise been called Substantives.

It would likewise be early discovered, that every one of these substances were endowed with certain qualities or attributes, to express which another class of words would be requisite. Thus, to be weighty, is a quality of matter; to think, is an attribute of man. Therefore, in every language, words have been invented to express the various qualities of the several objects which exist. These may all be comprehended under the general denomination of Attributes.

These two classes of words must comprehend all things that exist; for whatever exists, must of necessity be either a substance, or the attribute of some substance; and hence these two classes must comprehend all those words which are significant of themselves, and may be called Words Significant of Themselves. If any other words occur, they can only be significant in so far as they tend to explain or connect the words of the two former classes.

But, although these words form the basis or matter of a language, in the same manner as stones form the matter

of a building; yet, as stones cannot be arranged into a regular structure without a cement to bind and connect them, so these original words stand in need of others to connect them, before they can be made to express all the variety of our ideas. Another order of words, therefore, were necessary, which, although not of themselves significant, yet, when joined with others, might acquire a meaning. These form a second general class of words that may be called words not significant of themselves, and which cannot acquire any meaning but so far as they serve either to explain or connect the others.

Hence, therefore, all words which can possibly be invented, may be divided into two general classes; those that are significant of themselves, and those that are not. Words which are significant of themselves, are either expressive of the names of substances, and therefore called substantives; or, of qualities, which we call attributes. Words which are not significant of themselves, must acquire a meaning either as defining or connecting others, which we shall arrange under the two classes of definitives and connectives, each of which shall be examined in their order.

**Chapter I.**

**Of Substantives.**

Substantives may be divided into two classes, viz. those which are primary, commonly called nouns; and those of a secondary order, which are often substituted for nouns, and are hence called pronouns: each of which we shall consider separately.

**Section I. Of Substantives of the First Order, called Nouns.**

Nouns are all those words by which objects or substances are denominated, and which distinguish them from one another, by names applicable to each, without marking either quantity, quality, action, or relation. And as all the objects which exist must be either in the same state that they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, this naturally suggests a division of nouns into natural, as man, vegetable, tree, &c.; artificial, as house, tower, church, &c.; or abstract, as whiteness, temperance, &c. But the diversity of objects being so great as to render it impossible for any person to know the distinct names of every individual, therefore it has been found expedient to arrange them under certain general classes, the names of which may be more easily acquired, so that by referring any unknown object to the class to which it belongs, we in some measure supply the want of proper names. Hence, therefore, each of the above species of nouns are divided into thofe which denote genera, species, and individuals. Thus, in natural substances, animal, vegetable, and fossil, denote genera; man, dog, tree, metal, are species; and Alexander, Caesar, oak, gold, are individuals. In artificial substances, edifice is a genus; house, tower, church, are species; and the Vatican, Troy, church, and Herriot’s hospital, are individuals. In abstract substances, motion is a genus; flight and course, are species; the flight of a hawk, the course of a greyhound, are individuals. Each of these general classes might be subdivided into many smaller; but as these latter divisions can only relate to the particular genus of different languages, it does not fall within our plan to consider them. We therefore proceed to take notice of the accidents which accompany nouns. Of which kind may be reckoned number and gender.

As nouns are the names of substances, and as there may be many substances of the same kind, therefore nouns must be adapted to express whether there is one or more of those objects of which we speak. Nouns, therefore, in every language, admit of a certain variation to denote this circumstance, which is called number. Thus, in the English language, when we speak of a single place of habitation, we call it a house; but if of more, we call them houses. In the first of these cases the noun is said to be in the singular, and in the last case, the plural number: nor does the English, or any other language except the Greek, admit of any other variation but these two: and although the Greek language admits of a particular variation of the noun called the dual number, which is a plural limited to two objects; yet this cannot be considered as a language; and it is perhaps doubtful whether this variation ought to be considered as an elegance or a defect in that language. But although number be a natural accident of nouns, it can only be considered as essential to those which denote genera or species, as it does not depend on individuals. Thus we say, animal, or animals, vegetable, or vegetables, and fossil; as also, man, or men, dogs, trees, &c. But we only say, Xenophon, Cesar, Bucephalus, &c. in the singular. Nor do these admit of a plural, excepting when we consider any proper name, as a general appellative under which many others are arranged,—when it is no longer the name of an individual, but that of a species, and as such admits of a plural; as the Alexanders, the Ptolemies, the Howards, the Pelhams, the Montagues, &c. The reason of all which will be obvious, if we consider, that every genus may be found whole and entire in each of its species; for man, horse, and dog, are each of them an entire and complete animal: and every species may be found whole and entire in each of its individuals; for Socrates, Plato, and Xenophon, are each of them completely and entirely a man. Hence it is, that every genus, though one, is multiplied into many; and every species, though one, is also multiplied into many, by reference to those beings which are their subordinates. But as no individual has any such subordinates, it can never in strictness be considered as many, and so is truly an individual as well in nature as in name, and therefore cannot admit of number.

Besides number, another accident of nouns is gender, the nature of which may be thus explained: As nouns are the names of the various objects in nature; and as the distinctions of sex is perceptible among all those objects which are animated; and as those which are inanimate...
cannot admit of any sex at all; therefore all the beings which can become the objects of our speculation, may be considered as either *males*, or *females*, or such as admit of no sex, and therefore may be said to be neuter, or of neither sex. Hence, therefore, grammarians have made a threefold distinction of nouns, into *masculine genders*, or those which denote *males*; *feminine*, or those which denote *females*; and *neuter*, which denote those substances that admit of no sex. But, although the origin of genders is thus so clear and obvious; yet every language that we know of, except the English, deviates from the order of nature, and often attributes sex to those substances which are totally incapable of any; nay, some languages are so particularly defective in this respect, as to class every object inanimate as well as animate under either the *masculine* or *feminine genders*, as they admit of no gender for those that are of neither sex. This is the case with the French, Italian, and Spanish. But the English, strictly following the order of nature, puts every noun which denotes a male animal, and no others, in the *masculine gender*; every name of a female animal, in the *feminine*; and every animal whose sex is not obvious, or known, as well as every inanimate object whatever, in the *neuter gender*. Nor does this rule admit of any exceptions; although poets take the liberty of personifying any objects they think proper, and endow them with whatever sex suits their purpose best; which serves admirably to distinguish between the cool language of philosophy, and the enthusiasm of poetry.

Although *Cæsar* are not necessary accidents of nouns; yet as they have been often considered as such, it will perhaps be deemed proper to take some notice of them. —As natural objects remain the same, although viewed from many different points of view, they are not in their own nature altered, although they may be connected with others in many different ways: their names therefore ought to remain unchanged, although their relations to other words may be varied. However, there are certain circumstances in which nouns may be considered with respect to their relation to, and connection with other words, which occur more frequently than others. Some languages, particularly the Greek and Latin, express some of these circumstances, by a variation of the original noun, which variations are called *cases*. But the English, and almost all the modern languages of Europe, have followed the order of nature, and allow the noun to remain the same, expressing its relation and connection with other words by the help of distinct words called prepositions. —Of these methods is best, it is not our present purpose to inquire. See Language.

It has been supposed the English nouns admit of one variation which answers to the genitive case of the Latin.—Thus the word *Alexander* is an English noun in its proper form, and in that case which in Latin would be called the *Nominative*. The variation which they called the *Genitive Case*, is expressed in English by adding the preposition or before the noun; thus, *of Alexander* or *Alexander's houfe*. This, therefore, has been called a true inflection of the original noun. However, although this opinion has been adopted by all grammarians, it appears to have been adopted without sufficient examination, as will be evident from the following considerations.

There are certain circumstances in which this supposed genitive cannot be substituted instead of the other: for I may say, *I speak of Cæsar*, I *think of Pompey*; but I cannot say, *I speak Cæsar's*, or *I think Pompey's*. Hence these two are not in all cases synonymous terms; and therefore one of them must be considered as only accidentally coinciding with the other in particular circumstances.

Again, every one of these supposed genitives can with propriety assume all the various signs of the different cases in the English language: for we may say simply, as in the nominative case, *Alexander's houfe*; but we can also say, *of Alexander's houfe*, *to, with, from, in, by, or for Alexander's houfe*, &c. If this then be a real genitive, it requires the sign of the genitive, as well as of the other cases, to explain it; which would be an absurdity too great to be admitted. —But it may be asked, if these are not genitives, to what class of words can they be referred?

In answer to this, it has been already observed, that the variety of substantives is so great, that it is impossible for any person to know the names of every one of them; and therefore they have been arranged under the several orders of genera and species. We now further observe, that the individuals are so exceedingly numerous, it would be impossible even to invent proper names for each, and far less would it be possible to make these names be known to every person who might accidentally see them: therefore when we want to ascertain any individual object, and distinguish it from all the other individuals of the same species, we are obliged to have recourse to particular epithets, or definitive, to ascertain that individual. —Thus, I see a particular house which I want to distinguish from other houses; this has no particular name of its own; I must therefore ascertain it in the best manner I can; and as the shortest is always the best, we most naturally denominate it from its owner or possessor if we know him, and therefore call it Alexander's, James's, or John's house. —Here then we see, that the words *Alexander's*, *James's*, and *John's*, do not stand as nouns, but as *articles or definitives* serving to ascertain and point out the individuality of the noun with which they are joined, and are much nearer allied to adjectives than to substantives. These, therefore, like other articles, do not alter the case of the noun; to that the term *Alexander's houfe*, is as much the proper name of a particular house, as *Alexander* or *James* are the proper names of particular men, and of consequence may be varied thro' the different cases as well as the other. —It is surprising, that this idea never occurred to grammarians; for St Peter's at Rome, and St Paul's at London, are as truly the proper names of these two noble edifices, as the *Rotundo* or the *Circus* are the proper names of two other structures. —We may therefore safely conclude, that the English language admits of no cases at all, and that the only essential accidents of nouns are gender and number.

---

**Sec.**
Section II. Of Substantives of the Second Order, called Pronouns.

All conversation passes between individuals. When these individuals are unknown to each other, how shall the one speaker address the other, when he knows not his name; or how explain by his own name, of which the other is wholly ignorant? This might perhaps have been at first effected by pointing; but as this method behaved to be extremely inconvenient and defective, it was necessary that a particular class of words should be invented for this purpose; and as these words always supply the noun, they have been called pronouns; — the nature of which may be explained as follows.

Suppose the parties converging to be wholly unacquainted, and the subject of the conversation to be the speaker himself: here, to supply the place of pointing, the inventors of language have furnished the speaker with the pronoun I; write, I desire; and as the speaker is always principal with respect to his own discourse, they have therefore called this the pronoun of the first person.

Again, suppose the subject of the conversation to be the party addressed: here, for similar reasons, they invented the pronoun thou, thou writestl, thou walkest; and as the party addressed is next in dignity to the speaker, or at least comes next with reference to the discourse, they therefore called this the pronoun of the second person.

But as the subject of the conversation may be some third object different from either the speaker or the party addressed, another pronoun was necessary; and as this object might be either a male or a female, or a neuter, it was necessary to have one pronoun for each of the genders, he for the masculine, she for the feminine, and it for the neuter: and this, in distinction to the former, was called the pronoun of the third person.—Hence the distribution of pronouns into persons.

We have already seen that nouns admit of number; pronouns, which are their substitutés, likewise admit of number. There may be many speakers of the same sentiment, as well as one, who including himself speaks the same sentiment with many; speech may likewise be addressed to many at a time as well as to one; and the subject of the discourse may likewise be many; therefore the pronoun of every one of the persons must admit of number, to express this singularity or plurality. Hence, therefore, the pronoun of the first person I, has the plural we; that of the second person thou, has the plural you; and that of the third person he, she, or it, has the plural they, which is equally applied to all the three genders.

With regard to gender, we do not find in any language that the pronouns of the first or second persons admit of any distinction in this respect: nor was it necessary that they should; as the speaker and party addressed are usually present with one another, this distinction is generally obvious from dress and external appearance. But this is not the case with regard to the pronoun of the third person; of whose gender and distinctions we often know no more than what we learn from the discourse itself; and hence it is, that in almost all languages the pronoun of the third person admits of genders, as we have already seen the English admits of the triple distinction of masculine, feminine, and neuter.—The utility of which threefold distinction will be best shown by an example. Supposing there was no such distinction, and that we should read in any history he caused him to destroy him, and were told that the pronoun which is here thrice repeated flood each time for something different; that is to say, for a man, for a woman, and for a city, whose names were Alexander, Thais, and Persepolis. Taking the pronoun thus diversified of its genders, it does not appear which of the three was destroyed, which the destroyer, or which the causer that moved to the destruction. But there is no ambiguity when we hear the genders distinguished; and when, instead of the ambiguous sentence, he caused him to destroy him, we are told with the proper distinctions that she caused him to destroy it. Then we know with certainty, that the promoter was the woman, that her instrument was the here, and that the subject of her cruelty was the unfortunate city.—From this example we would be surprised how the Italian, French, and Spanish could express themselves with precision or elegance, with no more than two variations of this person.

From the same causes as a distinction of gender is unnecessary in the pronouns of the first and second persons, we see the reason why a single pronoun to each person, an I for the first, and a thou for the second, are sufficient for all the purposes of language, as these are always supplied present and obvious. But it is not so with respect to the third person, as the various relations of different objects made it necessary to have not one, but many; such as he, she, it, this, that, other, some, all, any, &c.

Although we have said that there is only one pronoun for each of the first and second persons, yet the English reader may perhaps be puzzled with finding two distinct words applied to each; I and me, for the first person; thou and thee, for the second. The learned reader will at once see that these two words me and thee are equivalent to the accusative case of the Latin pronoun: but, in order to make the meaning of this as plain as possible without embarrassing ourselves about unnecessary terms, we shall only observe, no effect can be produced without a cause, and no action can be performed without producing some effect. The same person may in different circumstances be either the active and efficient cause of, or the passive subject who suffers by an action: some languages have therefore formed different words to express the same object in these different circumstances.

Thus in the Latin sentences, Brutus amavit Cassium, Brutus loved Cassius; and Cassius amavit Brutum, Cassius loved Brutus; the word Brutus in the first, and Cassius in the second, is the form which the noun assumes when it is used as the efficient cause; and Brutum and Cassium the forms which the same nouns assume when they are represented as the passive subjects. This last was what was called the accusative case of the noun, and the first was called the nominative. We have already seen that the English noun admits of no cases, the active subject always preceding the verb, and the passive following it, as is plain from the above sentences, where Brutus and Cassius remain changed in both situations; and the same might be observed of all other modern languages.
Yet the English and all modern languages admit of a
different word to express the different state of the pro-
nouns. Thus, we say, I esteem thee, I admire him.
I love her: in all of which sentences I, the pronoun of
the first person, is the active, and thee of the second
person, and he and her of the third, are the passive sub-
jects, and are therefore expressed by the words thee,
him, and her. But if the case be reversed, and the pro-
noun of the first person becomes the passive subject, and
the others the active, they assume a different form; thus,
thou esteemst, he admires, she loves me. Hence,
therefore, it appears that we have two distinct words for
each of these pronouns to express the different states in
which they may be represented, exactly analogous to the
nominative and accusative cases of the Romans—Whether
these are to be admitted as cases of our pronouns, or
whether they may not rather be considered as distinct
words formed for that particular purpose, is of little con-
sequence for us to enquire; as, in whatever light they
may be considered, this variation cannot be looked upon
as an essential part of language, but only as a particular
refinement, invented to prevent the disagreeable repetition
of the pronoun, which behaved frequently to have hap-
pened without this contrivance. This seems to be the
only reason why pronouns have been endowed with this
variety, and not nouns. For as nouns are in themselves
greatly diversified, the sameness of sounds does not here
so often occur as it would have done in the pronouns,
where the same I, thou, he, she, or it, answers for
the name of every object which occurs in nature; but, by
this diversity in the form of the words, this circumstance
is in some measure obviated. And it is probably for
the same reason, that the plural of each of these pronouns
is so very different from the singular. Thus, from I of
the first person is formed we in the plural, and from me
the plural us; from thou and thee the plurals you and
you; from he, she,—him, her, and it, the plurals they,
and them. In all of which there is not the slightest resemblance between the singular and plural of any
one word; and, except in he and him, they and them,
there is not any similarity between what may by
some be thought to be the different cases of the same
word.

We have seen that the same object may sometimes be
the cause of an action, and sometimes the object which suf-
fers by it. We now observe, that the same object may
sometimes be, with regard to the same action, both the
active cause and passive subject; as when we say, Brutus
killed himself. In which case it is evident, that Brutus
was both the cause that produced, and the object that
suffered by the action; the pronoun himself being put for
his name; for, were it not for the sameness of the sound,
and the ambiguity which would be occasioned by it,
we might surely say, Brutus killed Brutus. It was there-
fore necessary to have a particular pronoun for the pas-
sive subject, in all these cases where the same object was
the agent; and on this account the word self has been in-
vvented, having the plural selves. This pronoun there-
fore, which serves on all occasions to represent the action
as returning upon the agent that produced it, may be call-
ed the reciprocal pronoun; which has this peculiarity,
that it can never stand by itself, but must always have the
affiliation of the pronoun in whose place it is substituted;
as, myself, thyself, himself, herself, itself, with their plurals. But although this seems to have been
the original use of this pronoun; yet, in the English lan-
guage, its use has been extended further; and, from its
always having a reference to the agent of any action, it
has been employed to denote that agent by way of em-
phasis, as performing the action without the aid or af-
filiation of any other; as, he himself went. And from this
circumstance it has been further extended to denote any
object as performing or suffering any thing which we would
not naturally have expected from its known character or
nature; as in this sentence: “The most daring of man-
kind are sometimes startled before they venture upon the
commission of any extraordinary crime; even Caesar him-
self felt the utmost perturbation of mind before he de-
red to pass the Rubicon.”

These are all that can be properly called personal pro-
nouns; but there are others which are derived from them,
called possessive pronouns, as, my, thy, mine, his,
her, its, &c., the nature of which it will be neces-
fary here to explain. We have already shown how nouns,
when they came to denote possession, were no longer to
be considered as nouns, but rather as definitional articles;
so the pronouns which we here consider, being the real
substitutes of nominal articles, ought also to be consider-
ed as a distinct class of pronominal articles; for these
never, in any case, can be substituted for a noun, they
cannot be considered as nouns. Grammarians have
been led into the mistake of placing them under this head,
because they are the substitutes of these words, which, altho’
they assume the appearance of nouns, only perform the
different of definitives. Thus we have seen, that when we
say, Alexander’s house; the word Alexander’s can only be
considered as a defective: and, in the same manner,
if Alexander was the speaker, he might say, my house;
if the party addressed, it would be thy house; or, if any
third person, his, and in the same manner hers or its
house. In all which cases this possessive pronoun is sub-
stituted for that word which only serves to define and af-
certain the identity of the noun, and not for the noun it-
self, which must always be either expressed or underlie.
Hence the reason why one pronoun becomes the substitutive
of this noun and its proper definite, whether that definit-
ive appears in the form of a noun or pronoun: for I can
say, “Alexander’s house is more elegant than Mary’s, or
his house is more elegant than hers, although it neither
is so commodious nor agreeable to live in.” In which ex-
ample it is plain, that the words his and hers are strictly
the substitutes only of Alexander’s and Mary’s, and
nothing more; whereas the pronoun it is the substitu-
tive of the whole noun with its definite Alexander’s
house. The other classes of pronouns possessive, mine,
thine, &c., as they do not so much serve to distinguish
individuals, as to ascertain the property of the thing spoken
of, which may, in a certain sense, be considered as an at-
tribute thereof, are more nearly allied to attributives, and
have therefore by some been called adjectives. And
it must be acknowledged, that these two classes of words are so nearly allied to one another, that it is difficult to ascertain in all cases, the precise boundary between them.

Besides these, there are other words which sometimes assume the province of pronouns, and are generally considered as belonging to this class, although in many cases improperly; such as, this, that, any, some, these, those, all, and some others; which may be called impersonal pronouns. To distinguish when they may be considered as pronouns, we may observe, that when they stand by themselves, and supply the place of a noun, as when we say, this is virtue, give me that, then are they pronouns. But when they are associated to some noun, as when we say, this habit is virtue, or that man dejected me; then, as they do not supply the place of a noun, but only serve to ascertain one, they fall rather under the species of definitive, or articles. And indeed it must be confessed, that these, as well as the possessive pronouns, are more properly adapted to define and ascertain individuals among nouns, than to supply their place; and therefore are oftener to be considered as articles than as pronouns. The best rule to distinguish when they are to be considered as the one or the other, is this. The genuine pronoun always stands by itself, allowing the power of a noun, and supplying its place. The genuine article never stands by itself, but appears at all times associated to something else, requiring a noun for its support, as much as attributives or adjectives.

The three orders of pronouns already mentioned, may be called prepositive; because they are capable of introducing or leading a sentence, without having reference to any thing previous. But there is another order of pronouns which can never be employed but to connect sentences, and must therefore always have a reference to some sentence that precedes them; as who, which, what. The nature of which may be explained as follows.

Suppose I say, light is a body; light moves with great celerity; these would apparently be two distinct sentences. But if, instead of the second light, I were to place the prepositive pronoun it, and say, light is a body, it moves with great celerity; the sentences would still be distinct, and two. But if I add a connective (as for example, and) saying, light is a body, and it moves with great celerity; I then, by connection, make the two into one. Now it is in the united powers of a connective and another pronoun, that we may see the force and character of the pronoun here treated of. For if, instead of the words and it, we substitute that or which; saying, light is a body which moves with great celerity; the sentence still retains its unity, and becomes, if possible, more compact than before. We may therefore call this pronoun the subjunctive; because it cannot introduce an original sentence, but only serves to subjoin one to some other which is previous.

The application of this subjunctive, like the other pronouns, is universal. It may be the subjunctive of all kinds of substantives, natural, artificial, or abstract; general, special, or particular: for we may say, the man who, the ship which; Alexander who, virtue which, &c. Nay, it may even be the subjunctive of all the other pronouns, and is therefore of course expressive of all the persons. Thus we say, I who now write; thou who now readest; he who now heareth, &c. And thus the subjunctive is truly a pronoun from its substitution; there being no substantive existing in whose place it may not stand. At the same time it is essentially distinguished from the other pronouns by this particular, that it is not only a substitute, but likewise a connective.

As to the accidents of this pronoun: From its performing the part of a connective, it of course follows, that neither gender nor number can be considered as essential to it; because these are always expressed in the preceding parts of the sentence to which it refers; nor do we in fact find, that this pronoun, at least in modern languages, admits of any distinction to denote number, although the English language admits of one variation for the gender; as we employ who for the masculine and feminine, and which for the neuter gender: thus: The man, or the woman who went to Rome; the tree which stands on yonder plain, &c. It likewise admits of a variation similar to that of the acciative case; at least when applied to males or females. For when the object which it represents is the efficient cause of action, it is who; as, the man who fell, &c; but when it is the passive subject, it then, in certain circumstances, takes the form of whom; as, the man of whom I speak; although this is not universal; as we likewise say, the man who was beaten. But the neuter admits of no such distinctions, as we equally say, the tree which fell, or the tree of which I spoke. But both of these admit of a variation to denote possession or qualities, which is the word whose for all genders. Thus, we say, Socrates whose only study was virtue; Elizabeth whose reign was glorious.

To conclude: We have seen that substantives are either primary or secondary; or, in other words, nouns or pronouns. The nouns denote subiances, either natural, artificial, or abstract; and these either general, special, or particular. The pronouns, their sublitudes, are either prepositive or subjunctive: the prepositive is distinguished into three orders, called the first, the second, and the third persons: the subjunctive includes the powers of all the three, having superadded, as of its own, the peculiar force of a connective.

Chapter II.

Of ATTRIBUTIVES.

As all attributives must either be expressive of the attributes of substances, or of other attributes, we divide this class into two kinds; calling those of the first kind, ATTRIBUTIVES OF THE FIRST ORDER; and those of the second kind, ATTRIBUTIVES OF THE SECOND ORDER.

Section I. ATTRIBUTIVES OF THE FIRST ORDER.

Attributives are all those principal words that denote attributes considered as attributes. Such, for example,
are the words, black, white, great, little, wise, eloquent, to write, to walk, to speak, &c. all of which are the attributes of substances. Thus black is an attribute of substance; white of substance; wise and eloquent, as also, to write and to speak, are attributes of men.

In examining the different attributes of substances, we readily perceive that some of them have their essence in motion; such as, to walk, to fly, to strike, to live, &c. Others have it in the privation of motion; as, to flop, to rest, to cease, to die, &c. And others have it in subjects that have nothing to do with either motion or its privation; such as the attributes of great and little, wise and foolish, white and black, and, in a word, the several quantities and qualities of all things. This therefore furnishes a natural division of attributes of this order; and grammarians have called all those, whose essence consists in motion, or energies, verbal attributives; whose essence consists in motion or its privation, verbs; and all the others have been called adjectives; each of which we shall consider separately.

I. Of Verbs.

Verbs are all those principal words which denote attributes, whose essence consists in motion, or energies, (for we chuse to make use of this last term, as it implies the exertions of the mind as well as those of the body), or their privation. This order of attributives differs from the other called adjectives; not only in the particular above-mentioned, but also because adjectives denote only qualities or quantities, which do not admit of any change or state; whereas the verbal attributives may be considered as in several different states, and therefore admit of several variations in the term employed to express them. It may, in the first place, be considered as a simple attribute or energy, without particularizing any circumstance relating to the state it may be in; as in the word write. Or, in the second place, as these are all attributes which denote motions or energies, they may be represented as in the state of actual motion or exertion; as in the word writing. Or, lastly, the motion or energy may be finished, and its effect completed; as in the word written. Hence, therefore, every verb admits of a threefold variation in every language, in each of which languages they are distinguished by some particular names. Our grammarians have given the name of the infinitive mode to the original verb itself, and the other two variations of it are both distinguished by the name of participles; that variation which exhibits the verb in its state of energy being called the participle present or active, and the other variation is called the participle perfect or past.

These variations of the verb are founded in the nature of things, and therefore must be found in every language under some form or other. As to the other supposed variations of verbs relating to person, number, time, &c. the slightest reflection on this subject will show, that a verb, considered as a simple attributive, can admit of none of these affections, but must for ever remain the same at all times and in all situations whatever; for who does not see, that the attribute to write is the same whether it is possessed by you, by me, or by any number of different persons? Nor does this attribute suffer any change, whether it is represented as having been exerted a thousand years ago, or at this present moment, or at any other assignable period of duration; but, like every other attribute, it must remain for ever the same. For however substances may vary with time, and be incessantly changing; yet attributes of every sort are altogether beyond its power. And we must easily perceive, that the attribute which is expressed by the word oon, is the same now as it was at creation, or will be while the world exists. And in the same manner, to walk, to write, to fly, denote attributes, which must each of them preserve their own particular nature during all the successive ages of time. Hence therefore we see, that the verbal attribute must for ever remain in that state, or modification, in which it is at first represented. Nor can it suffer any change, however different the circumstances may be in which it can be applied in language. All, therefore, that can be said of these several variations with which grammarians have usually endowed verbs, is this, That, as an attributive, it hath such an intimate connection with a substantive, as necessarily to be united with one, before it can make a principal figure in language: And as that union may be represented as taking place at different times, and under different circumstances, the inventors of some languages have contrived to express these different connections by a single word, instead of doing it by different words, as the thing in itself would naturally require; in the same manner as those who use the short-hand method of writing, make a single character express a whole word, or sentence: And as it was most natural for the contrivers of these words to derive them from the verb itself of which they are compounded, they have each of them become a real variation of the original word which expresses the verbal attribute; and, from this being a variation of the verbal word, they have at last come to be considered as an essential variation of the verb itself, which has occasioned those contradictory definitions, and that confusion of ideas which we meet with among all writers on this subject. But as we here consider language as in itself, without regarding the particular forms under which it may appear, we must reject all these variations of persons, numbers, modes, and tenses, which the verb itself has usually been supposed to undergo; and consider them, not as essential variations of the verb itself, but as variations produced in language by the combination of the verb with other parts of speech; and therefore relating to syntax, and of course belonging to those grammatical difficulties alone which treat of the peculiarities of any particular language. But as these variations have been so universally considered as essential parts of the verb itself, and as the terms which this division of the verb have introduced into grammar are so frequently to be met with, it will be necessary to explain in some measure the meaning of these several terms.

In the natural world, no attribute can possibly exist without a substance to which it belongs, nor any substance without possessing certain attributes. So necessary and intimate is the connection between these, that it is as impossible...
impossible to separate them, as to create or annihilate the several substances that possess these attributes. But although we are thus circumscribed as to our bodily powers, the mind admits not of such limitation; but can with the utmost facility separate every quality from every object whatever, and consider them apart; as, colour without superficies, superficies without solidity, or weight without matter, &c. and, when thus separated, apply them to what objects, and in what manner, it pleases. In this manner the mind abstracts those attributes which denote motions or energies from their agents or energizers, in the same way as it abstracts qualities from their substances. And it is these energies thus abstracted, which form that species of words called verbs; in the same manner as those attributes which denote quantities and qualities abstracted from their necessary substances, form adjectives. Thus, the term to walk, denotes a particular energy as considered perfectly apart from every energizer, in the same manner as the word good denotes a certain quality without regard to any particular substance.

Here then we discover a most essential difference between the order of nature, and that representation of it which man makes by means of words. For in nature, every quality must at all times be united with some substance, nor can ever be exhibited separate from it; but in language, every attributive, if it be considered at all, must be separated from the object to which it naturally belongs. Hence we see the reason why, in language, every energy and energizer, not only may be considered separately, but must for ever remain separate, unless they be united by some other power than what is necessarily their own. For the attribute to write, can no more be united to mean its proper energizer, than a motion could commence without a cause; and till this attribute is united to its proper energizer, it must remain in a great measure dead and inefficacious in language.—To communicate life and energy, therefore, to this inert attribute, it must be united to its proper energizer; which can only be effected by the help of an assertion of the speaker himself; which may be considered as the same with regard to language, as life is in the natural world.

It is evident that, by the abstinence of an assertion, the speaker is enabled to write any energy to any particular energizer, and thus, without making any change upon the attribute itself, represent a variety of changes produced upon other bodies by its means.—Thus, if I say, I write, what do I more than assert that I myself am possessed of that particular attribute denoted by the verb to write? If I say, You write, or He writes, what do I more than assert that another person is possessed of that particular attribute?—If I say, He did write, I only assert that the same attribute was possessed at another time, by the same person, as before. Hence therefore, by the help of this assertion of the speaker, we are enabled to join this particular attribute to many different energizers, as well as to re-present these different combinations as occurring at many different times; so that the same attribute may thus be made to appear under a great many different circumstances, and exhibit a great variety of changes upon other objects, although itself remains unchanged; the several variations which we perceive, only relating to the objects with which it is combined, or the means by which that union is effected.—In the same manner it often happens, that any object in nature, a house for example, may appear extremely different when viewed from different situations.

From the intimate connection that takes place between the energy, the energizer, the assertion, and time, these several accessories have been considered as essential parts of the verb; and therefore some grammarians have defined a verb to be a word denoting an energy, with time, and an assertion. But if we were thus to confound things with those which may necessarily accompany them, we could never arrive at a clear perception of any subject whatever. But not to enter into the arguments that might be produced to shew the impropriety of this definition, we shall only observe, that by the universal acknowledgment of all grammarians this cannot be just. For they unanimously agree, that the infinitive mode is not only a part of every verb, but the most essential part; as it forms the root from which all the other parts are derived. But as this mode neither denotes either time or an assertion, it is evident that these, even by their own acknowledgment, can be at best but accessories, and not essential parts of the verb.

From these arguments, therefore, we must conclude, that the verb itself admits of no other variations but those already taken notice of; that before it can produce any active effect in language, like every other attribute, it must be united to some proper energizer;—that this union in language can never be effected but by means of an exertion of the vital powers of the speaker, whereby he either publishes his perception thereof, or his will that it should be;—and that this union may be re-presented as taking place at all the different times that can be assigned. These, therefore, are each of them necessary accompaniments of a verb, but each of them separate and distinct in their own nature, not only from this verb, but from one another; and it becomes an essential part of the syntax of every language, to consider the various ways in which these can be combined and affect one another.—Nay, so intimate has this connection been thought to be by some, that the contrivers of certain languages have arranged them under particular classes, for the sake of definiteness and precision.—The form which a verb assumed, when thus varied in all the ways that their particular language would admit of, was called the conjugation of the verb; the several parts of which may be under-foot from the following sketch.

When the verb is considered under the compound form of which we now speak, it can admit of variations chiefly in three respects. For, first, supposing the attribute, the energizer, and the time when that attribute was exerted by the energizer, to be the same; a variation may be occasioned by a change being produced in the perception or volition of the speaker, (which, for brevity, we will call the assertion) as in these examples: I write, scribo; I may write, scribam; do you write, scribs. The variations produced by this means have been called modes. Secondly, supposing the attribute, the energizer, and the assertion, to be the same; a change may be produced in the time, as in these examples: I do write,
The variations produced from this cause have been called **tenses**. And, thirdly, Supposing the attribute, the time, and the assertion, to remain unchanged, there may be a difference in the energizer; and this likewise admits of a division: for as the energizer may be only one or more persons, it must have a variation into singular and plural, on these accounts; as in these examples: *I write, scribo; thou writest, scribis; he writes, scribat*, and in the plural, *we write, scribamus; ye write, scribatis; they write, scribant*.

The variations produced from this cause have been called **person and number**. These are all the variations which have been made in the Latin or Greek languages; and therefore our grammarians, who have adopted every idea they have of grammar from these languages, mention no more; but it was not necessary that they should have flopt here, for an attribute is surely as susceptible of the distinction of sex as of person, so that they might have had a variation for gender also; and instead of having one word *scribatur* to answer for all the three persons, he, he, or it wrote, they might have had three different words —The compofer of the Hebrew language have adopted this plan, and admit of two variations on this account; and the Russian language admits of a like variation in their verb for these genders; as in this example: *on zohela, he has done; ona zohela, she has done, &c.*

But as the two languages above mentioned do not admit of this distinction, therefore all the variations that our verbs are said to admit of are **modes**, which include within them tenses, which include under them persons, under which head is included number; and these are all the parts into which a conjugation has been divided. —As to what concerns the nature and different divisions of each of these, the following general remarks may be sufficient.

With regard to **modes**; as this relates solely to the perception or volition of the speaker, it necessarily follows, that there ought to be a distinct and particular mode for each diversity that there can be in his manner of perceiving or willing any thing whatever, the principal of which are the following.

If we simply declare that we perceive any object, or that such a thing is or will be, without any limitation or contingency, it forms what has been called the **declarative or indicative mode**; as, *I write*. —Again, if we simply represent it to be within our power, or to depend on our choice, it forms two other modes, which may be called the **potential**, as, *I can write*; or the **elective**, as, *I may write* —In the same manner, if the speaker represents himself, or any other object, as determined to perform any action, or as compell'd to it, or as it is his duty to perform it; these form so many distinct modes, which may be called the **determinative**, as, *I will write*; the **compulsive**, as, *I must write*; and the **obligative**, as, *I should write*. But although each of these represents the speaker as perceiving the agent under a different light with respect to the action; yet as all of them, except the indicative, agree in this, that however much they may represent it as the duty or inclination, &c. of the agent to perform any action with which they are associated, yet as they are full of the nature of contingents which may never take effect, they are frequently subjoined to any other verb; therefore the Latines have comprehended all of these under one mode which they have called the **subjunctive**. We only take notice of this circumstance here, to shew, that however naturally **sentences** may be distinguished into modes, according to the different situation of the speaker; yet as the whole order of the variation of words in the conjugation of a verb is merely arbitrary, those who invent them may arrange them into whatever order they please, and call them by whatever names they may think most proper. But however they may vary the names or external arrangement, this does not affect the things themselves. For by whatever name the **mode** may be known which comprehends the words expressive of these several meanings, the sentences formed by these will be either particular, **obligative**, **compulsive**, &c. as above explained.

All these modes above mentioned only relate to the different **perceptions** of the speaker. But as man is not only endowed with the powers of perception, but those of volition also, he must have words to express these, which forms another order of modes. As he is not only dependent himself, but has others depending upon him, he may command, interreat, bid, pray, wish, inquire. —Hence, therefore, so many different orders of modes, the **imperative**, **requisitive**, **prescriptive**, **optative**, **interrogative**, &c. to which may be added the **vocative**. But although each of these display a distinct affection of the speaker, yet grammarians have allotted only one variation of their verb for all of these purposes, called the **imperative mode**; all the other volitions being expressed by this, or some other modes, by the help of particular conFrugacies, which are different in different languages.

With regard to that variation of the verb which relates to time, called **tenses**: As an action or event may be represented as happening at any assignable period of time, it is necessary to divide that duration into certain parts, that we may be able to represent the different relations which events bear to one another with respect to this particular. The first and most obvious division of time is into **present, past, and future**. But we may go farther still in our divisions of time. For as time past and future may be infinitely extended, we may in universal time past assume many particular times past, and in universal time future many particular times future; some more, some less remote, and corresponding to each other under different relations. Even present time, however, in strict physical truth, it may be incapable of it, is by the power of the imagination brought to admit of these differences, and as necessarily implies some degree of extension, as every given line however minute: And hence it is not sufficient for language to denote **indefinitely** mere past, present, or future times; but on many occasions to **define** with more precision what kind of past, present, or future is meant.

Tenses, therefore, or those variations of a verb which denote a difference of time only, may be all divided into **present, past, and future**; each of which may be subdivided into **definite** and **indefinite**.
definite tenses are those where the particular instant of time, whether present, past, or future, is pointed out. The indefinite tenses are those where past, present, or future time is indicated in general, without confining it to a particular instant in either of these cases. These have been distinguished among grammarians by the name of aorists.—Thus when Milton makes Adam say,

_Millions of spiritual creatures walk the earth,
Unseen, both when we wake and when we sleep._

the verb walk means not that they were walking at that instant only when Adam spoke, but indefinitely in any instant whatever. So likewise, when the same author calls hypocritry,

—_the only evil which walks_

_Invisible except to God alone._

the verb walks has the like aoristical signification. _He went, he fell_, are aorists of the past, as they do not specify any particular instant, but refer to past time in general. So likewise in the legislative sentences, _thou shalt not kill, thou shalt not steal_, &c. the same aoristical meaning is perceived, as the prohibition does not relate to any particular time future, but is extended indefinitely to every time future.

But it is not sufficient for a language to denote time in this indefinite manner: it is necessary likewise that it should be capable of specifying any particular instant of time in an exact and definite manner. Thus, if, instead of the word walk in the first sentence above quoted, we were to put are walking, it brings down the verb to denote a particular time, and specifies that these spiritual creatures are, at that very instant in which Adam speaks, walking upon the earth unseen. In like manner, in the second sentence, if the word walks were changed to is walking, it denotes, that hypocrisy, at that particular instant in which the sentence was pronounced, was walking invisible upon the earth. And in the same manner, in walking, or will be walking, each of them denote, that these energies were or will be exerted at a particular specified time. These, therefore, form so many distinct definite tenses, under whatever technical name these may be known.

Here then we see the use of that distinction of the different states of the verb, into the verb properly so called, and participles. For as the verb itself exhibits the word as altogether indefinite; when this is joined to its proper energizer, it forms all these indefinite tenses which our language requires. Thus, _I write, I did write, I will write, I may write, I can write_, &c. each of them, although they represent the attribute as united to the energizer in some past, present, or future time, do not specify any particular instant, and are therefore so many aorists or indefinite tenses. Whereas in the participle the attribute is represented as in a state of exertion, it necessarily follows, that if it be ever united to its energizer, it must point out the particular instant when that union took effect, and of consequence form as great a variety of definite tenses as the verb forms of indefinite.

Thus, _I am writing_, necessarily implies that I am actually exerting this particular energy at the very instant that I declare it. So likewise if I say _I was writing_, it indicates, that at one particular instant of past duration, to which this has a reference, I was actually employed in that particular occupation. This instant is generally fixed by some collateral circumstance; as, "_upon the twentieth day of August last, at ten o'clock, I was writing_," or, "_when the thunder broke upon the tower in my neighbourhood, I was writing_," &c. And the same may be said of future time; as, "_to morrow at ten o'clock I shall be writing_," &c. In all of which cases it is obvious, that a particular new or instant is pointed out, in which the attribute is represented as united to its proper energizer. We might here proceed to the various times that each of these different states of the verb might be made to indicate; the number of tenses that each mode admitted of; the several changes that might be produced by joining the participle perfect with any object; which cannot be here called the energizer, but the subject; for as the energy is by this participle represented as completed, if it has any connection with any person, the attribute cannot be affected by any energizer after it is completed, it must of necessity affect the person, instead of being affected by it; and hence it is that the several variations produced by this participle perfect have been called the passive voice of the verb. But as all these particulars only relate to the construction of one particular language, it would lead us a great deal too far from the particular subject of which this article treats. We shall therefore only observe, that besides the above variations of the verb, which the Greeks and Romans have thought proper to make, the terms of which we have adopted; there are many others that they might with equal propriety have made, but which they rather chose to express by the help of other words called adverbs. But some other languages have gone farther in this respect, and endowed their verbal word with several variations to express several other circumstances than they do. This is particularly the case with the Hebrew language, which, besides the variation for gender above mentioned, has allotted certain other variations of its verb to express several other circumstances. Thus, _pakad in that language signifies he vifited_; _pakedah_, _he visited diligently_; _hephked, he made him visit_; and _hemhek_, _he visited himself_; in this manner is every verb in that language varied; and each of these different conjugations of their verb admits of a particular variation for the passive of each.

Hence, therefore, the conjugation of a verb in that language admits of a great many variations which neither the Greeks nor Romans were acquainted with: for besides the distinctions of modes, tenses, persons, and numbers, they have divided their verb into so many distinct divisions to answer for these distinctions above mentioned, which they have denominated _kal, pihel, HipniL_ and _hithpahel_, with their passives _niphal, pualah_, and _hophal_; each of which admits of variations through all the modes, tenses, persons, numbers, and genders which any of their verbs admit of.

The only use which we meant to make of these observations on the Hebrew verbs, is this: That as the authors, who have formed their idea of grammar from the forms which the several parts of speech admit of in the Greek and Latin languages, have supposed that every variation which these languages admitted of was a natural and necessary part of language; and that therefore every language which did not admit of the same number of variations,
tions with theirs in every part of speech, was in so far defective and incomplete. So, for the same reason, an author who had formed his idea of grammar upon the model of the Hebrew tongue, would as naturally suppose, that the several variations which the verb admitted of in his own favourite language, were essential and necessary; and that, of consequence, every language which did not admit of as many variations was imperfect and incomplete. But to any one who considers this matter with attention, it will appear, that there could be no end to these unnecessary discusions and groundfalls claims of fancied superiority: for if compound words have such an advantage over simple, the Chinese language, in which we are told almost every sentence has a particular compound character to express it, must be by far the most perfect in the world; but so far is this from being the case, that every one allows it to be the most imperfect and incomplete. The only method, therefore, which remains for us to consider this subject, is to regard every particular form of language, and consider the words in themselves, as divided of every extraneous circumstance, and observe what variations they necessarily require, allowing every particular language to compose theses with one another in the manner they shall think most proper. It is in this manner we have considered the verbal attributes, and endeavoured to disentangle them from these unnecessary fetters with which they have been loaded, and restore them to their own original freedom.

Besides the variations above-mentioned, verbs have been distinguished from one another in a different manner; the names and nature of which may be thus explained.

We have already seen, that all verbs, as they denote energies, necessarily have reference to certain energizing substances. For, how could there be such energies as to love, to fly, to wound, &c. were there not such beings as men, birds, swords, &c. Further, every energy not only requires an energizer, but is necessarily conversant about some subject. For example, if we say, Brutus loves, we must needs supply—loves Cato, Cæfærus, or some one. And thus it is, that every energy is necessary; and that, of consequence, every language which serves what variations they necessarily require, allowing every particular language to compose theses with one another in the manner they shall think most proper. It is in this manner we have considered the verbal attributes, and endeavoured to disentangle them from these unnecessary fetters with which they have been loaded, and restore them to their own original freedom.

Some languages, as the Greek and French, have another class of verbs, which are called by the first verbs middle, and by the last reciprocal verbs; which are employed to denote that state of any transitive verb, when the energizer himself becomes the subject; as thus, Brutus killed himself, &c. But as these only express a slight variation of an accompaniment of a verb, they have no claim to be considered as a distinct species.

II. Of Adjectives.

Adjectives are all those words which denote attributes whose essence does not consist in motion or its privation: or, in other words, they are those words which denote the attributes of quantity, quality, and relation; such as, many, few, great and little, black and white, good and bad, double, treble, quadruple, &c.

As these attributes admit of no change of nature, nor can be effected by the variations of time, or any other accident, but are in their own nature perfectly fixed and invariable, the words which express them ought to be in all situations and on all occasions the same. For as the qualities good or bad, black or white, admit of no change in their own nature, whether they be applied to a man, to a woman, to many, or to few; neither ought the word which expresses any one of these attributes in strictness to admit of any alteration, whether it be joined to one or other of these substantives. So that although in some languages, from the particular construction of the other parts of speech, it has been found necessary to endow their adjectives with the threefold distinction of gender, number, and case; yet this must only be considered as an accidental variation occasioned by particular circumstances, and not in the least essential to language, but rather a deviation from the order of nature, which would require them to be kept invariably the same in all cases. This order, the English language (which in this and almost every other case is most strictly conformable to the nature of things than any other language we are acquainted with) most strictly observes; as we say equally, a good man, or a good woman, a good house, or good men, good houses, &c.

It has probably been from observing, that the adjectives in some particular languages are endowed with variations conformable to the gender, number, and case of their substantives, that grammarians have been led into the strange absurdity of ranging them with nouns, and separating them from verbs; though with respect to verbs they are perfectly homogeneous, and with respect to nouns they are quite the contrary. Adjectives are homogeneous with respect to verbs, as both sorts denote...
attributes; they are heterogeneous with respect to nouns, as never properly denoting substances.

Besides original adjectives, there is another class which are formed from substantives. Thus when we say, the party of Pompey, the style of Cicero, the philosophy of Socrates; in these cases, the party, the style, and philosophy spoken of, receive a name and character from the persons they respect, and actually pass into attributives, and as such assume the form of adjectives. And hence we say the Pompeian party, the Ciceronian style, and the Socratic philosophy. In like manner, for a trumpet of brass, we say, a brazen trumpet; for a crown of gold, a golden crown, &c. Even pronounal substantives admit the like mutation; as, instead of saying the book of me, of thee, or of him, we say, my book, thy book, his book, &c. Yet it must be acknowledged, that these, as they often serve rather to define a noun than to denote any quality appertaining it, they partake more of the nature of appendages than adjectives; so that it is in many cases difficult to ascertain exactly to which class they are to be referred. But of this we have already taken particular notice, p. 713. col. 2. & 716. col. 2.

The nature of these variations of adjectives which have been called degrees of comparison, will be more properly explained under the following section.

Section II. Of Attributives of the Second Order, called Adverbs.

As the attributives hitherto mentioned denote the attributives of substances, so there is an inferior class of them which denote the attributes only of attributes. To explain these by examples of either kind: when we say, Cicero and Pliny were both of them eloquent; Statius and Virgil both of them wrote; in these infances, the attributives eloquent and wrote, are immediately referable to the substantives Cicero, Virgil, &c.: As, therefore, denoting the attributes of substances, we call them attributives of the first order. But when we say, Pliny was more eloquent than Cicero; Cicero exceedingly eloquent; Statius wrote indifferently, but Virgil wrote admirably: in these infances, the attributives moderately, exceedingly, indifferently, and admirably, are not referable to substantives, but to other attributes; that is, to the words eloquent and wrote: As, therefore, denoting attributes of attributes, we call them attributives of the second order. These have been, by grammarians, called adverbs. And indeed, if we take the word verb in its most comprehensive signification, as including all the words which denote the attributives of substances, (which was the sense in which Aristotle and many of the most ancient grammarians employed it) we shall find the name adverb to be a very just appellation, as denoting a part of speech the natural appendage of verbs. So great is this dependence in grammatical syntax, that an adverb can no more subsist without its verb, than a verb can subsist without its substantive.

Among the attributes of substances are reckoned quantities and qualities. Thus we say, a white garment, a

high mountain, &c. Now some of these quantities and qualities are capable of intenfion and remsfion. Thus we say, a garment exceedingly white, a mountain tolerably of moderately high. Hence, then, one copious source of secondary attributives, or adverbs, to denote these two, that is, intenfion and remifion; such as, greatly, vastly, extremely, sufficiently, moderately, tolerably, indifferently, &c.

But where there are different intenfions of the same attribute, they may be compared together; thus, if the garment A be exceedingly white, and the garment B be moderately white, we may say, the garment A is more white than the garment B. In these infances, the adverb more not only denotes intenfion, but relative intenfion. Nay, we stop not here, as we not only denote intenfion merely relative, but relative intenfion than which there is none greater. Thus we not only say, the mountain A is more high than the mountain B, but that it is the most high of all mountains. Even verbs, properly so called, as they admit of simple intenfions, so they admit also of these comparative ones. Thus, in the following example, Fame be loveth more than riches, but virtue of all things be loveth most; the words more and most denote the different comparative intenfions of the verbal attribute loveth.

Hence the rise of comparison of adjectives, and of its different degrees, which cannot well be more than the two species above-mentioned; one to denote simple excess, and one to denote superlative. Were we indeed to introduce more degrees than these, we ought perhaps to introduce infinite, which is absurd. For why flop at a limited number, when in all subjects susceptible of intenfion the intermediate excesses are in a manner infinite? There are infinite degrees of more white, between the first simple white, and the superlative whitest; and the same may be said of more great, more strong, more minute, &c. The doctrine of grammarians about three such degrees of comparison, which they call the positive, the comparative, and the superlative, must be absurd; both because in the positive there is no comparison at all, and because their superlative is a comparative as much as their comparative itself. Examples to evince this may be met with every where; Socrates was the most wise of all the Athenians; Homer was the most sublime of all poets, &c.

The authors of language have in some infances contrived a way to retrench these comparative adverbs, by expressing their force by an inflexion of the primary attributive. Thus, instead of more fair, they say, fairer; instead of most fair, fairest: and the same method of composition takes place both in the Greek and Latin languages; with this difference however between the genius of these languages and ours, that we are at liberty to form the comparison, either in the one method or the other; but in these languages, the comparison is almost never formed by the affilance of the adverb, but always by the inflexion of the adjective; and hence this inflexion is always considered by them as a necessary accident of the adjective. But this method of expressing the power of the adverb has reached no farther than to adjectives.
adjectives, or to their participles, which were so nearly allied to adjectives. Verbs were perhaps thought to be too much diversified, to admit of more variations without perplexity.

Some qualities admit of comparison, others admit of none: such, for example, are those which denote that quality of bodies arising from their figure; as, when we say, a circular table, a quadrangular court, a conical piece of metal, &c. The reason is, that a million of things participating the same figure, participate it equally if they do it at all. To say, therefore, that while A and B are both quadrangular, that A is more or less quadrangular than B, is absurd. The same holds in all attributives denoting definite quantities of whatever nature. For, as there can be no comparison without intention or remission, and as there can be no intention and remission in things always definite, therefore these attributives can admit of no comparison. By the same method of reasoning, we discover the cause why no substantive is susceptible of these degrees of comparison. A mountain cannot be said more or to exist than a mole-hill; nor the lion A cannot be more a lion than the lion B; but the more or less must be sought for in their quantities or qualities; a mountain is more bulky than a mole-hill, and the lion A is more fierce than the lion B; the excess being always derived from their attributes.

Of the adverbs or secondary qualities already mentioned, those denoting intention and remission may be called adverbs of QUANTITY CONTINUOUS; once, twice, trice, &c. are adverbs of QUANTITY DISCRETE; more and most, left and least, to which may be added equally, proportionally, &c. are adverbs of RELATION.

There are others of QUALITY; as when we say, honestly industrious, prudently brave, they fought bravely, he painted finely, &c.

The adverbs hitherto mentioned, are common to verbs of every species; but there are some which are confined to verbs properly so called, that is to say, to such as denote motions or energies with their privations. All motion and rest imply time and place as a kind of necessity coincidence. Hence, if we express the place or time of either, we must needs have recourse to adverbs formed for this purpose; of place, as when we say, he stood there, he went hence, he travelled far, &c.; or of time, as when we say, he stood then, he went afterward, he travelled formerly, &c. Should it be asked, Why adverbs of time, when verbs have tenses? The answer is, though tenses may be sufficient to denote the greater distinctions of time, yet to denote them all by tenses would be a perplexity without end. What a variety of forms would be necessary to denote yesterday, to day, to-morrow, formerly, just now, now, immediately, presently, soon, hereafter? &c.

To these adverbs just mentioned may be added those which denote the intentions and remissions peculiar to motion, such as speedily, hastily, swiftly, slowly, &c.; as also adverbs of place made out of prepositions, such as upward and downward, from up and down. In some instances the preposition suffers no change, but becomes an adverb by nothing more than its application; as when we say, he rides about, he was near falling, &c.

There are likewise adverbs of INTERROGATION; such as, where, whence, whither, how, &c. of which there is this remarkable, that when they lose their interrogative power, they assume that of a relative, so as to represent the relative or subjunctive pronoun; as in this doggerel translation of a line from Virgil,

And corn doth grow where Troy town stood;
that is to say, corn groweth in that place in which Troy stood, the power of the relative being implied in the adverb. It is in like manner, that the relative pronoun becomes an interrogative; as in this line from Milton,

Who first seduced them to that foul revolt?

The reason of this is as follows: the pronoun and adverbs here mentioned are all, in their original character, RELATIVES. Even when they become interrogatives, they lose not this character, but are still relatives as much as ever: the difference is, that without an interrogation they have reference to a subject which is antecedent, definite, and known; with an interrogation, to a subject which is subsequent, indefinite, and unknown, and which it is expected the answer should express and ascertain.

Who first seduced them? The question itself supposes a seducer, to which, though unknown, the pronoun who has a reference—Th' infernal serpent. Here, in the answer, we have the subject, which was indefinite, ascertained; so that we see who, in the interrogation, is as much a relative as if it had been said originally, without any interrogation at all, It was the infernal serpent who first seduced them: and thus interrogatives and relatives mutually pass into one another.

Having thus considered all those parts of speech which are significant of themselves, we proceed to those AUXILIARY PARTS, which are only significant when associated with others, which we have already said are either DEFINITIVES or CONNECTIVES. Of which in their order.

CHAPTER III.

Concerning DEFINITIVES commonly called ARTICLES.

The knowledge of man is at best but limited and confined. Although we have invented words to denominate almost all the substances which exist, yet as it is impossible for any person to be acquainted with all of these, it was necessary to fall upon some contrivance in language to obviate the difficulties which would arise from this cause. With this view, we have already seen, that substances have been divided into general classes, each of which includes under it several lesser subdivisions; the names of which general classes, being but few, may be more easily retained, as animal, edifice, motion, &c. for by referring the several objects that we may accidentally see, and with which we are unacquainted, to the several classes to which they may belong, we are in some measure enabled to communicate our ideas without the knowledge
judge of the particular names. But as this particular object must in some manner be distinguished from others of the same class to which it belongs, a particular class of words was found necessary to define and ascertain these individuals, which has given rise to this order of words of which we now treat, and which we have called definitives, because they serve to define and ascertain any particular objects, so as to separate it from the general class to which it does belong, and, of course, denote its individuality. The principal of these definitives have been usually called ARTICLES, the nature of which may be explained as follows.

Supporting I see an object with which I am totally unacquainted, having a head and limbs, and appearing to possess the powers of self motion and sensation. If I know it not as an individual, I refer it to its proper species, and call it a dog, a horse, a lion, or the like; and if none of the names of any species with which I am acquainted fit it, I refer it to the genus, and call it an animal.

But this is not enough. The object at which we are looking, and want to distinguish, is perhaps an individual.—Of what kind? Known or unknown? Seen now for the first time, or seen before and now remembered? It is here we shall discover the use of the two articles A and THE; for the article THE respects our primary perception, and denotes individuals as unknown; whereas the respects our secondary perception, and denotes individuals as known; whereas the respects our secondary perception, and denotes individuals as known. To explain this by an example, I see an object pale by which I never saw till now: What do I say? There goes a beggar with a long beard. The man departs, and returns a week after: What do I then say? There goes the beggar with the long beard. Here the article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual once vague is now recognized as some-
cause they are by nature as definite as may be; so there are others which admit it not. because they are not be
defined at all. Of this sort are all interrogatives. If we
question about substances, we cannot say the who
is this; but who is this? And the same as to qua-
lities, and both kinds of quantities: for we say, with-
out an article, what sort of, how many, how
great? The reason is, the article the respects beings
already known, and interrogatives respect beings about
which we are ignorant; for as to what we know, interroga-
tion is superfluous. In a word, the natural associators with
articles are all those common appellatives which
denote the several genera and species of be-
ings. It is these, which, by assuming a different artic-
le, serve either to explain an individual upon its first be-
ing perceived, or else to indicate, upon its return, a recog-
nition or repeated knowledge.

But although proper names do not admit of the artic-
le, being in their own nature definite; yet as these often
fall into homonymic, that is, different persons often go
by the same name, it is necessary to distinguish them from
one another, to prevent the ambiguity that this would
occur. For this purpose we are obliged to have recur-
coufe to adjectives or epithets. For example, there
were two Grecian chiefs who bore the name of Ajax;
and was it not without reason that Menelaus uses ep-
ithets, when his intention was to distinguish the one from
the other: \( \text{"If both Ajaxes cannot be spared, (says he) \"at least let mighty Telamonic Ajax come." But as e-} \)

Thus, among the Greeks, the poet meant Hosner,
which we are ignorant-, for we know, interrogatives refpe-
ts about which we are ignorant; for as to what we know, interroga-
tion is superfluous. It is evident in such sentences as these: \( \text{"some substances have sensation, others want it;} \)
choose any way of acting, and some men will find fault, &c." For here, \( \text{some, other, and any, serve all of them to define} \)
different parts of a given whole; \( \text{some, to denote a de-
f} \)
inite part; \( \text{any, to denote an indefinite; and other,} \)
to denote the remaining part, when a part has been al-
ready assumed. Even the attributive pronouns, my, thy,
his, her's, &c. are, in strictness, more properly articles
than any thing else, seeing each of them serve only to
define and ascertain the individual object to which they
are applied. As when we say, \( \text{"my house is less com-
modious than yours; her form is more elegant than his, &c." For in these examples what do the words} \)

Thus, when we say, \( \text{"this picture I approve, but that I dislike;\" what do we perform by the} \)
help of these definitives, but bring down the common ap-
pellatives to denote individuals? So when we say,
\( \text{"some men are virtuous, but all men are mortal;\" what is} \)
the natural effect of this all and some, but to
define that universality and particularity which would
remain indefinite were we to take them away? The fame
truth, if the essence of an article be to define and ascer-
tain, they are much more strictly articles than any thing
else, and ought to be considered as such in universal
grammar. Thus, when we say, \( \text{"this picture I approve, but that I dislike;\" what do we perform by the} \)
help of these definitives, but bring down the common ap-
pellatives to denote individuals? So when we say,
\( \text{"some men are virtuous, but all men are mortal;\" what is} \)
the natural effect of this all and some, but to
define that universality and particularity which would
remain indefinite were we to take them away? The same
truth, if the essence of an article be to define and ascer-
tain, they are much more strictly articles than any thing
else, and ought to be considered as such in universal
grammar. Thus, when we say, \( \text{"this picture I approve, but that I dislike;\" what do we perform by the} \)
help of these definitives, but bring down the common ap-
pellatives to denote individuals? So when we say,
\( \text{"some men are virtuous, but all men are mortal;\" what is} \)
the natural effect of this all and some, but to
define that universality and particularity which would
remain indefinite were we to take them away? The same
truth, if the essence of an article be to define and ascer-
tain, they are much more strictly articles than any thing
else, and ought to be considered as such in universal
grammar. Thus, when we say, \( \text{"this picture I approve, but that I dislike;\" what do we perform by the} \)
help of these definitives, but bring down the common ap-
pellatives to denote individuals? So when we say,
Chapter IV.

Of Connectives.

Connectives, according as they connect either sentences or words, are called by the different names of conjunctions, or prepositions. Of these names, that of the proposition is taken from a mere accident, as it commonly stands in connection before the part which it connects. The conjunction, as is evident, has reference to its essential character. We shall treat of these two separately.

Section I. Of Conjunctions.

A conjunction is a part of speech void of signification itself, but so formed as to help signification, by making two or more significant sentences to be one significant sentence. As, therefore, it is the essence of a conjunction to connect sentences; at the same time that they do this, they must either connect their meaning or not. For example, let us take these two sentences, Rome was enslaved,—Caesar was ambitious, and connect them together by the conjunction because; Rome was enslaved, because Caesar was ambitious. Here the meanings, as well as the sentences, appear to be connected. But if I say, manners must be reformed, or liberty will be lost; here the conjunction or, though it join the sentences, yet, as to their respective meanings, is a perfect disjunctive. And thus it appears, that though all conjunctions connect sentences, yet, with respect to the sense, some are conjunctive, and others are disjunctive.

Those conjunctions which connect both sentences and their meanings are either copulative or continuative. The principal copulative in English is and. The continuatives are much more numerous; if, because, therefore, wherefore, hence, and so. The difference between these is this: The copulative does no more than barely couple sentences, and is therefore applicable to all subjects whose natures are not incompatible: Continuatives, on the contrary, by a more intimate connection, confound sentences into one continuous whole; and are therefore applicable only to subjects which have an essential coincidence. For example, it is no way improper to say, Lyseppus was a flautary, and Prisician a grammarian; the sun shineth, and the sky is clear; because these are things that may co-exist, and yet imply no absurdity. But it would be absurd to say, Lyseppus was a flautary, because Prisician was a grammarian; though not today, the sun shineth because the sky is clear. The reason is, with respect to the first, the co-incidence is merely accidental; with respect to the last, it is essential, and founded in nature.

As to the continuatives, they are suppositive, such as if; or positive, such as because, therefore, as, &c. Take examples of each:—You will live happily if you live honestly:—You live happily because you live honestly:—You live honestly, therefore you live happily. The difference between these continuatives is this: The suppositives denote connection, but do not affect actual existence; the positives imply both the one and the other.

Those positives above-mentioned are either casual, such as because, since, as, &c. or collective, such as therefore, wherefore, &c. The difference between which is this: The casuals subjoin causes to effects; "the sun is in eclipse because the moon intervenes." The collectives subjoin effects to causes; "the moon intervenes, therefore the sun is in eclipse." We therefore use casuals in those instances where the effect being conspicuous we seek for its cause; and collectives, in demonstrations and science, properly so called, where the cause being first known, by its help we discern effects.

All these continuatives are resolvable into copulatives: For, instead of saying, Because it is day, it is light; we may say, It is day, and it is light. Instead of If it is day, it is light; we may say, It is at the same time necessary-to be day, and to be light. The reason is, That the power of the copulative extends to all connections, as well to the essential as to the casual. Hence the continuative may be resolved into a copulative and something more; that is to say, into a copulative implying an essential coincidence in the subjects conjoined.

As to casual conjunctions, we may further observe, that there is no one of the four species of causes which they are not capable of denoting. For example, the material cause; The trumpet sounds, because it is made of metal. The formal; The trumpet sounds, because it is long and hollow. The efficient; The trumpet sounds, because an artist blows it. The final; The trumpet sounds, that it may rouse our courage. It is worth observing, that the three first causes are expressed by the strongest affirmation; because, if the effect actually be, that must be also. But this is not the case with respect to the last, which is only affirmed as a thing that may happen. The reason is, that however this may be the end which set the artist first to work, it may still be beyond his power to obtain, and which, like all other contingents, may either happen or not. Hence also it is connected by a particular conjunction, that; absolutely confined to this cause.

We now come to the disjunctive conjunctions; a species of words which bear this contradictory name, because, while they disjoin the sense, they conjoin the sentences.

With respect to these, we may observe, that as there is a principle of union diffused through all things by which this whole is kept together and preferred from dissipation; so there is, in like manner, a principle of di-
versity diffused through all, the source of distinction, of number, and of order. Now, it is to express in some degree the modifications of this diversity, that disjunctive conjunctions seem at first to have been invented.

Of these conjunctions, some are simple, some adverbial. Simple; as when we say, either it is day, or it is night:—Adverbial; as when we say, It is not day, but it is night. The difference between these is, that the simple do no more than merely disjoin; the adverbial disjoin with a concomitant opposition. Add to this, that the adverbial are definite; the simple indefinite. Thus, when we say, the number three is not an even number, but an odd; we not only disjoin two opposite attributes, but we definitely affirm one, and deny the other. But when we say, the number of the stars is either even or odd; though we assert one attribute to be, and the other not to be, yet the alternative is notwithstanding left indefinite.

As to adverbial disjunctives, it has been already said, that they imply opposition. Now, there can be no opposition of the same attribute in the same subject; as when we say, Nereus was beautiful: but the opposition must be either of the same attribute in different subjects, as when we say, "Brutus was a patriot, but Caesar was not;" or of different attributes in the same subject, as when we say, "Gorgias was a sophist, but not a philosopher;" or of different attributes in different subjects, as when we say, "Plato was a philosopher, but Hippas was a sophist." The conjunctions used for all these purposes may be called absolute adverbials.

But there are other adverbials besides these; as when we say, "Nereus was more beautiful than Achilles;—Virgil was as great a poet as Cicero was an orator." The character of the latter is, that they go farther than the former, by marking not only opposition, but that equality or excess which arises from the comparison of subjects; and therefore they may be called adverbials of comparison.

Besides the adverbials here mentioned, there are two other species, of which the most eminent are unless and although. For example, "Troy will be taken, unless the Palladium be preferred; Troy will be taken, although Hector defend it." The nature of these adverbials may be thus explained. As every event is naturally allied to its cause, fo, by parity of reason, it is opposed to its preventive; and as every cause is either adequate or inadequate (inadequate, when it endeavours, without being effectual), so in like manner is every preventive. Now, adequate preventives are expressed by such adverbials—as unless: "Troy will be taken, unless the Palladium be preferred;" that is, that this alone is sufficient to prevent it. The inadequate are expressed by such adverbials as although: "Troy will be taken, although Hector defend it;" that is, Hector’s defence will prove ineffectual. These may be called adverbials adequate and inadequate.

Before we leave this subject, we may observe, that the words when and where, and all others of the same nature, such as whence, whether, whenever, wherever, &c. may be called adverbial conjunctions; because they participate the nature both of adverbs and conjunctions; of conjunctions, as they conjoin sentences; of adverbs, as they denote the attributes either of time or place. And these adverbial conjunctions (contrary to the character of accessory words, which have strictly no signification but when associated with other words) have a kind of obscure signification when taken alone, by denoting these attributes of time and place. And hence it is, that they appear in grammar like zoophytes in nature, a kind of middle beings, of amphibious character, which, by sharing the attributes of the higher and the lower, conduct to link the whole together.

Section II. Of those Connectives, called Prepositions.

A preposition is a part of speech devoid itself of signification, but so formed as to unite two words that are significant and that refuse to coalesce of themselves. This connective power (which relates to words only, and not to sentences) will be better understood by the following observations.

Some things naturally coalesce and unite of themselves, while others refuse to do so without help, and as it were by compulsion. For example, all quantities and qualities coalesce immediately with their substantives: thus it is we say, a fierce lion, a vast mountain, &c. In like manner actions coalesce with their agents, and passions with their patients: thus it is we say, Alexander conquers, Darius is conquered. Nay, as every energy is a kind of medium between its agent and patient, the whole three, agent, energy, and patient, coalesce with the same facility; as when we say, Alexander conquers Darius. Farther than this, as the greatest part of substantives themselves may be characterized, as when we say of such attributes as ran, beautiful, learned, &c. "he ran hastily, he was very beautiful, he was moderately learned." &c. these must readily coalesce with the attributes which they thus characterize. From all which it appears, that these parts of speech unite of themselves in grammar whose original archetypes unite of themselves in nature. Hence, therefore, it is, that although substantives naturally coincide with their attributes, yet they absolutely refuse doing so one with another: and hence those known maxims in physics, that body is impenetrable, that two bodies cannot pass the same place, &c.

From these principles it follows, that when we form a sentence, the substantive without difficulty coincides with the verb, from the natural coincidence of substantive with energy; the sun warmeth: so likewise the energy with the subject on which it operates; warmeth the earth: so likewise both substantive and energy with their proper attributes; the splendid sun genially warmeth the fertile earth. But suppose we are to add other substantives, as, for instance, air, or beams; how could these coincide, or under what character be introduced? not either as the energizer of the verb, nor as the subject on which it operates; for both of these places are already filled up, the first by the word sun, and the last by the substantive earth: not as attributes to these last, or to any other thing; for attributes by nature
true they neither are nor can be made. Here, then, we
perceive the rise and use of prepositions; by these we con-
nect these substantives to sentences, which, at the time,
are unable to coalesce of themselves. Let us assume, for
instance, a pair of these connectives, through and with,
and mark their effect upon the substantives here mention-
ed; the splendid sun with his beams genially warm-
eth through the air the fertile earth: the sentence,
as before, remains entire and one; the substantives re-
quired are both introduced, and not a word which was
there before is displaced from its proper station.
It must be here observed, that most if not all prepositions
seem originally formed to denote the relations of place;
because this is that grand relation which bodies or natu-
ral substances maintain at all times to one another, whe-
ther they are contiguous or remote, whether in motion
or at rest: thus we have prepositions to denote the con-
tiguous relation of body; as when we say, Caius
walked with a staff; the statue stood upon a pedestal;
the river ran over a precipice: others for the detached
relation; as when we say, he is going to Italy; the sun
is risen above the hills; these figs came from Turkey:
So as to motion and rest; only with this difference, that
here the preposition varies its character with the verb:
thus if we say, that lamp hangs from the ceiling, the
preposition from assumes the character of quiescence:
but if we say, that lamp is falling from the ceiling, the
preposition assists a character of motion. So in Milton

To support uneasy feet:
Over the burning marle—
Again,

He with looks of cordial love
Hung over her enamour'd.—

In the first of these examples, over denotes motion, and
in the last it denotes rest.

But though the original use of prepositions was to de-
note the relations of place, they could not be confined to
this office only; but by degrees extended themselves to
subjects incorporeal, and came to denote relations as
well intellectual as local. Thus because, in place, he
who is above has commonly the advantage of him who is
below, we transfer over and under to dominion and
obedience: of a king we say, he ruled over his people;
of a common soldier, he served under such a general:
so too we say, with thought; without attention;
thinking over a subject; under anxiety; from fear;
out of love; through jealousy, &c. All which in-
fiances, with many of the like kind, shew, that the first
words of men, like their first ideas, had an immediate
reference to sensible objects; and that, in after days,
when they began to d ink with their intellect, they
took these words which they found already made, and
transferred them, by metaphor, to intellectual conceptions.
There is indeed no method to express new ideas, but
either by metaphor, or by coining new words; both
which have been practised by philosophers, according to
the nature and exigence of the occasion.

In the foregoing use of prepositions, we have seen how
they are employed by way of juxta-position; that is tosay, where they are prefixed to a word without becoming
a part of it: but they may be also used by way of com-
position; that is, they may be prefixed to a word so as
to become a part of it: thus, to understand, to fore-
tell, to overlook, to undervalue, to outgo, &c. are
so many distinct words formed by prepositions joined in-
timately with some other word: in all which cases, the
prepositions commonly transuse something of their own
meaning into the word with which they are compounded;
and this imparted meaning, in most instances, will be found
resolvable into some of the relations of place, as used ei-
ther in its proper or metaphorical acceptance.

Besides the above parts of speech, there is another,
which cannot be comprehended under any of the fore-
going classes, called interjections: of this kind are
the words, ah! alas! fie! &c. This species of
words coincide with no part of speech, but are either ut-
tered alone, or else thrown into a sentence, without alter-
ing its form either in syntax or signification. It may
be therefore objected, that as we say, that all language
is divided into the several parts above enumerated, and
this class cannot be comprehended in any of these divi-
sions; of course, the analysis that we have made cannot be
just, because it does not comprehend the whole. To this
objection it may be answered, that the language of which
we have been treating, is that which has been formed by
mutual compact, for the purposes of reasoning and specu-
lation; besides this artificial language, man, like e-
evry other sensitive animal, is endowed with a natural
language, by which he can express any strong sensation.
This language does not owe its characteristic expression
with the arbitrary form of articulation; but derives its
whole force from the tone of voice, and modification
of countenance and gesture; and from consequence these
tones and gestures express the same meaning without any
relation to the articulation which they may assume,
and are therefore universally understood by all mankind. Now,
interjection is the name by which we distinguish these
natural expressions: these cannot be properly called
words, or parts of speech; but certain adventitious sounds,
or voices of nature, expressing those passions and natural
emotions which spontaneously arise in the mind upon
the view or narrative of interesting events. We must
therefore, still conclude, that all language properly so
called is composed of words, all of which may be ar-
ranged into the several classes above mentioned; and as a
recapitulation of the whole that we have said, we subjoin
the following table, which presents at one view the se-
veral classes and subdivisions of words.
GRAMMONT, a town of the Austrian Netherlands, in the province of Flanders, situated on the river Dender: E. long. 3° 50', and N. lat. 50° 55'.

GRAMPUS, in ichthyology. See Delphinus.

GRANADO, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter; which, being filled with fine powder, is set on fire by means of a small fusee, fastened to the touch-hole, made of the same composition as that of a bomb: as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time.

Sir Henry Wotton advises, to make it look towards the north, because that quarter is the coolest and most temperate. Mr Worlidge observes, that the best granaries are built of brick, with quarters of timber wrought in theinside, to which the boards may be nailed; with which the inside of the granary must be lined so close to the bricks, that there may not be any room left for vermin to shelter themselves. There may be many flories one above another, which should be near the one to the other; because the shallower the corn lies, it is the better, and more easily turned.

GRANADE, a branch of the river Niger in Africa, which discharges itself into the Atlantic ocean, in 15° W. long. and 11° N. lat.

GRANDE, a branch of the river Nicaragua, which discharges itself into the Atlantic ocean, in 51° W. long. and 32° S. lat.

GRANDE, a branch of the river Niger in Africa, which discharges itself into the Atlantic ocean, in 15° W. long. and 11° N. lat.

GRANDE, is also a river of Brazil, in the province of Del Rey, in South America, which discharges itself into the Atlantic ocean, in 51° W. long. and 32° S. lat.

GRANDEE, a designation given to a nobleman of Spain or Portugal.

The grandees are suffered to be covered before the king, who treats them like princes, styling them Illustrious, in his letters; and in speaking to them, or of them, they are styled Eminences.

GRANDENTZ, or Grandentz, a city of Poland, forty-two miles south of Danzig: E. long. 19°, and N. lat. 53° 30'.

GRANDPRE, a town of Champaign, in France, thirty miles east of Rheims: E. long. 4° 56', and N. lat. 49° 18'.

GRANICUS, a little river near the Hellepont, in the Lesser Asia, where Alexander fought the first battle with the forces of Darius.

GRANITE, in natural history, a distinct genus of stones, of different composition, and affixed to each other; each pure and distinct, but often mixed together; of great hardness, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire.

Of this genus there are three species: 1. The hard white granite, with black spots, commonly called morr-black: this is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running in one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass; it is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required. 2. The hard red granite, variegated with black and white, and common in Egypt and Arabia. 3. The pale whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

GRANIVOROUS, an appellation given to animals which feed on corn or seeds. These are principally of the bird-kind.

GRANT; in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversion, services, &c.

GRANTHAM, a borough-town of Lincolnshire, twenty-two miles south of Lincoln. It sends two members to parliament:

GRANVILLE, a port-town of Normandy, from whence the noble family of Carteret take the title of earl.

GRANVILLE, a port-town of Normandy, from whence the noble family of Carteret take the title of earl.

GRANULATED, something that has undergone granulation. See the next article.

GRANULATION, according to Cramer, is the reducing.
GRAPNELS, a sort of anchors with four flooks, serving for boats to ride by.

There is also a kind called fire and chain grapnels, made with four barbed claws instead of flooks, and used to catch hold of the enemy's rigging, or any other part, in order for boarding them.

GRASS, in botany, a genus of the diandria monogynia class. The corolla is irregular; the capsule has two cells; and the calix consists of seven leaves. There are four species, none of them natives of Britain.

GRAY, in geography, a city of Franche Comte in France, twenty-two miles northwest of Besancon; E. long. 5° 32', N. lat. 49° 30'.

GREEN, one of the original colours, exhibited by the rays of light. See Optics.

GREEN, among painters. See Botany, p. 634.

Gamboge will give five or six sorts of green with verdigrase. But the yellow, which some prefer before all others, is made of French berries; which is either deeper or fainter, according as the liquor is more or less stained by them. In like manner, a yellow, drawn from the roots of the barberry or mulberry, will answer the same purpose, being mixed with transparent verdigrase. As to verdigrase itself, it produces a fine bluish green, flows readily in the pencil, and may even serve as an ink to write with; but is subject to decay. Mountain-green is used for a grafs colour. Verditer is a light green, seldom used but to colour landflips that seem afar off. Sap-green is dark and dirty, and therefore never used but to shadow over greens in the darkest places. Copper-green is an excellent transparent and shining grafs-green, if thickened in the fun shine, or over a gentle fire. It is the most used of any green in washing of prints or maps.

GREEN-CLOTH, a board, or court of justice, held in the compting house of the king's houfhold, composed of the lord steward, and officers under him, who sit daily. To this court is committed the charge and overfight of the king's houfhold matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court royal, which is every way about two hundred yards from the last gate of the palace where his majesty resides.

It takes its name, board of green cloth, from a green cloth spread over the board where they sit.

Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

Clerks of the Green Cloth, are two officers of the board of green cloth, who appoint the diet of the king and his houfhold; and keep all records, ledgers and papers relating thereto; make up bills, parcels and debentures for salaries, and provisions and necessaries for the officers of the pantry, buttery, cellar, &c.
They also wait upon foreign princes when entertained by his majesty.

Grey finch, in ornithology, the English name of the greynith fringilla, with the wings and tail variegated with yellow. See fringilla.

Green house, or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

Greenland, or W. Greenland, extends from the meridian of London to 50° W. long., and from 60° to 80° N. lat.

The Danes have some colonies here, and pretend to the property of the whole. However, the Dutch make very free with the fisheries on this coast, notwithstanding the representations and even menaces of the Danes on that head.

Greenwich, a town of Kent, situated on the southern shore of the Thames, five miles east of London; remarkable for its royal and magnificent hospital, erected for decaying or disabled seamen who have served their country, and for its palace and most delightful park.

On the top of a steep hill in the park, stands the royal observatory, built by Charles II. and furnished with all manner of instruments for astronomical observations, and a deep dry well for observing the stars by day.

Gregarious, among zoologists, a term applied to such animals as do not live solitary, but in flocks, herds, or coveys.

Gregorian calendar, that which began the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epacts, disposed through the several months of the Gregorian year. See Astronomy, p. 490.

Gregorian year. See Astronomy, p. 490.

Greanoble, a city of France, capital of Dauphiny, forty-five miles south-east of Lyons, and thirty-six miles south-west of Chambery: E. long. 5° 28', and N. lat. 45° 12'.

Greenock, or Greenock, a port-town of Scotland, near the mouth of the river Clyde; being the principal station for the herring-fishery.

Grewia, in botany, a genus of the gynandria polyandria class. The calix consists of five leaves; the petals are five; at the base of each petal there is a nectariferous scale; and the berry has four cells. There are two species, none of them natives of Britain.

Grey, or Gray, a mixed colour partaking of the two extremes, black and white.

Griffon, in heraldry, an imaginary animal, feigned by the ancients to be half eagle and half lion; by this form they intended to give an idea of strength and swiftness joined together, with an extraordinary vigilance in guarding the things intrusted to its care. Thus the heathen naturalists perfused the ignorant, that gold mines were guarded by these creatures with incredible watchfulness and resolution.

Grümpen, a city of Germany, in the circle of the Lower Rhine, and earldom of Trier: E. long. 60° 33', N. lat. 49° 80'.

Grimsby, a borough and port-town of Lincolnshire, situated at the mouth of the Humber: E. long. 47° 12', N. lat. 53° 34'. It sends two members to parliament.

Grinding, the reducing hard substances to fine powders.

Method of Grinding optic glofses. Mr Huygens directs, in general, to make the breadth of the concave tool, plate, dish, or form, in which an object-glass must be ground, almost three times the breadth of the glass. Though in another place he speaks of grinding a glass whose focal distance was 200 feet, and breadth 83 inches, in a plate only fifteen inches broad. But for eye-glasses, and others of lesser spheres, the tools must be broader in proportion to the breadth of these glasses, to afford room enough for the motion of the hand in polishing. Mr Huygens made his tools of copper, or of cast brass, which, for fear they should change their figure by bending, can hardly be cast too thick: however, he found by experience, that a tool fourteen inches broad, and half an inch thick, was strong enough for the forming glasses to a sphere of thirty-six feet diameter; when the tool was strongly cemented upon a cylindrical stone an inch thick, with hard cement made of pitch and ashes.

In order to make moulds for cutting such tools as are pretty much concave, he directs, that wooden patterns should be turned in a lathe, a little thicker and broader than the tools themselves; but for tools that belong to spheres above twenty or thirty feet diameter, he says it is sufficient to make use of flat boards turned circular to the breadth and thickness required. When the plates are cast, they must be turned in a lathe exactly to the concavity required; and for this purpose it is requisite to make a couple of brass gages in the manner following, according to the directions of Mr Molynex.

Take a wooden pole, a little longer than the radius of the spherical surface of the glasses to be formed; and through the ends of it strike two small steel points, at a distance from each other equal to the radius of the sphere intended; and by one of the points hang up the pole against a wall, so that this upper point may have a circular motion in a hole or socket made of brass or iron, fixed firmly to the wall. Then take two equal plates of brass or copper, well hammered and smoothed, whose length is somewhat more than the breadth of the tool of cast brass; whose thickness may be about a tenth or a twelfth of an inch, and whose breadth may be two or three inches. Then having fastened these plates flat against the wall in a horizontal position, with the moveable point in the pole, strike a true arch upon each of them. Then file away the brass on one side exactly to the arch struck, so as to make one of the brasses edges convex, and the other concave; and to make the arches correspond more exactly, fix one of the plates flat upon a table, and grind the other against it with emery. These are the gages to be made use of in turning the brass tools exactly to the sphere required.
GRINDSTEAD, or East Grindstead, a borough-town of Sussex, twenty-four miles directly south of London, which sends two members to parliament.

GRIPSWALD, a town of Germany, in the circle of Upper Saxony, and province of Swedish Pomerania, situated on a bay of the Baltic sea: E. long. 13° 40', N lat. 54° 15'.

GRISON, allies of Switzerland; their country is almost of a circular form, about sixty miles over every way, and is bounded on the north by Tyrol and part of Switzerland; on the east, by Tyrol and Trent; on the south, by Italy; and by the Swiss cantons on the west.

GRIST, in country-affairs, denotes corn-ground, or ready for grinding.

GROATS, in country-affairs, oats after the hulls are off, or great oat meal.

GROCERS, anciently were such persons as engaged all merchandise that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

GROENLAND, or Spitzbergen, a cold miserable country without inhabitants, and with very few animals or vegetables, situated between 10° and 30° E. long. and between 77° and 82° N. lat.

GROGRAM, a kind of stuff, made of silk and mohair.

GRONINGEN, the capital of a province of the same name, which makes one of the seven united provinces: E. long. 6° 40', N. lat. 53° 20'.

GRONOVA, in botany, a genus of the pentandria monogynia class. The petals are five, inserted along the axis of the flower. There is but one species.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stable. See Stole, and Wardrobe.

Groom is more particularly used for a servant appointed to attend on horses in the stables.

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding, stile, or rail, to put their panels in, in wainscotting.

GROSS-beak, in ornithology. See Loxia.

GROSSULARIA. See Ribles.

GROTESQUE, or Grotesk, in sculpture and painting, something whimsical, extravagant, and monstrous; confisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprize and ridicule.

GROTSKA, a city of Silesia, and capital of a duchy of the same name, thirty miles south of Breslaw: E. long. 17°, N. lat. 50° 40'.

GROTTO, a large deep cavern or den in a mountain or rock.

Of these we find several remarkable ones in different parts of the world. The most celebrated one of our own country, is that called Oakley-hole, on the fourth side of Mendip hills. Its length is about two hundred yards, and its height various; being in some places very low, and in others eight fathoms. There is another at Puzzoli, about four leagues from Naples, called the Dog's Grotto; because a dog thrown into it is immediately killed, by a destructive vapour equally fatal to all animals within its reach. The milky grotto, cripta lactea, about a mile from the ancient village of Bethlehem, is said to have been thus called from the holy virgin's letting fall some drops of her milk in it; on which account the earth of this cavern has been supposed to possess the virtue of restoring women's milk.

Grotto is also used for a small artificial edifice made in a garden, in imitation of a natural grotto.

The outsides of these grottos are usually adorned with rustic architecture, and their inside with shellwork, coral, &c. and also furnished with various fountains, and other ornaments.

The following is recommended as a good cement for grotto work. Take two parts of white rosin, melt it clear, add to it four parts of bees' wax; when melted together, add some flower of the stone you design to cement, two or three parts, or so much as will give the cement the colour of the stone; to this add one part of the flower of sulphur: first incorporate all together over a gentle fire, and afterwards knead it with your hands in warm water. With this stuff the stones, shells, &c. after they are well dried, and warmed before the fire.

GROVE, in gardening, a small wood impervious to the rays of the sun.

GROVES are not only great ornaments to gardens, but are also the greatest relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the garden are useles.

GROUND, in agriculture, is much the same with earth or soil. See Agriculture, p. 50.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other.

GROUP, or Growse. See Tetrao.

GRUBS, in medicine, certain unctuous pimpls arising in different parts of the face, but chiefly in the ale of the nose.

GRUBE, in medicine, denotes a concreted clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscidity, and stagnating in the capillary vessels, produces several disorders.

GRUMOSE roots, such as are knotty, and fastened to the head, like those of celandine and anemones.
GRUS, in ichthyology. See Ardea.

Gryllus, in zoology, the name of the cricket and locust kind, which, together with the grasshoppers, make only one genus of insects, belonging to the order of hemiptera: the characters of which are these: the antennae are facetuous and stiltiform; the exterior wings are membranaceous, narrow, and have much of the appearance of the wings of some of the fly kind; the thorax is compressed and angulated; and the legs are formed for leaping. There are no less than 64 species. See Plate LXXVI. fig. 3: 4: 5.

Gryphites, in natural history, an English crown's stones, an oblong fossile shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward.

Guadalajar a, a city of Mexico, in North America, and the capital of Guadalajara; or New Galicia: W. long. 108°, and N. lat. 20° 45'.

Guadalquivir, a river of Spain, which rises in the province of Arago, and runs south-east through the province of Valencia, falling into the Mediterranean a little below the city of Valencia.

Guadalaxara, a city of Spain, in the province of New Castile, twenty-eight miles north-west of Madrid: W. long. 3° 50', and N. lat. 40° 40'.

Guadalupe, one of the largest of the Caribbean islands, eighty miles north of Martinico, subject to France: W. long. 61°, and N. lat. 16° 30'.

Guadiana, a river of Spain, which rises in the middle of New Castile, and running through Estremadura, enters Portugal; where, passing through the provinces of Alentejo and Algarva, it discharges itself into the Atlantic ocean.

Guadilbarbar, a river of Africa, which rises in the mountains of Atlas, runs through the kingdom of Tunis, and falls into the Mediterranean sea near Bona.

Guadilquivir, a river of Spain, which rises in the mountains of Segura in New Castile, runs the whole length of Andalusia, and passing by Cordova and Seville falls into the Atlantic ocean at St. Lucar.

Guadix, a city of Spain, in the province of Granada: W. long. 3° 3', and N. lat. 37° 15'.

GuaCum, in botany, a genus of the decandria monogynia class. The calix consists of five unequal segments; the petals are five, and inserted into the calyx; and the capsule is angular, and has from three to five cells. There are three species, all natives of the Indies.

The wood is very ponderous, of a clove compact texture; the outer part is of a yellow colour, the heart of a deep blackish green, or variegated with black, green, pale, and brown colours: the bark is thin, smooth, externally of a dark greyish hue: both have a slightly aromatic, bitterish, pungent taste; the bark is somewhat the weakest. The resin (which exudes from incisions made in the trunk of the tree) is brought to us in irregular masses, usually visible, of a dirty greenish, and sometimes of a reddish cast, with pieces of the wood among them: its taste is more acrid and pungent than that of the wood or bark.

Their general virtues are those of a warm, purgating medicine: they strengthen the stomach and other viscera; and remarkably promote the urinary and cutaneous discharges: hence in cutaneous defecations, and other disorders proceeding from obstructions of the excretory glands, and where flagnant feros humourous abound, they are eminently useful: rhumatic and other pains have often been relieved by them. The resin is the most active of these drugs; and the efficacy of the others depends upon the quantity of this part contained in them: the resin is extracted from the wood in part by watery liquors, but much more perfectly by spirituous ones; the watery extract of this wood, kept in the shops, proves not only less in quantity, but considerably weaker than one made with spirit. This last extract is of the same quality with the native resin, and differs from that brought to us only in being purer. The gum, or extracts, are given from a few grains to a scruple or half a dram; which last dose proves for the most part considerably purgative.

Guam, the chief of the Ladrone islands, in the Pacific ocean: E. long. 140°, and N. lat. 14°.

Guanihani, or St. Salvador, now called Cat unin, one of the Bahamas islands in the Atlantic ocean, in North America: W. long. 76°, N. lat. 24°.

Guanuco, a town of Peru, in South America, one hundred and eighty miles north-east of Lima: W. lon. 75° 15', and S. lat. 15°.

Guaranty, in matters of policy, the engagement of mediatorial or neutral states, whereby they plighted their faith, that certain treaties shall be inviolably observed, or that they will make war against the aggressor.

Guard, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprize; or the care, precaution, and attention, we make use of, to prevent anything happening contrary to our intention or inclination.

Guard, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy.

Advanced Guard, is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger.

Artillery Guard, is a detachment from the army, to secure the artillery: their corps de garde is in the front, and their centries round the park. This is a forty eight hours guard: and upon a march, they go in the front and rear of the artillery, and must be sure to leave nothing behind; if a gun or waggon breaks down, the captain is to leave a part of his guard to assist the gunners and matrofes in getting it up again.

Corps de Garde, are soldiers entrusted with the guard of a post, under the command of one or more officers.

Forrage Guard, a detachment sent out to secure the forragers, which are posted at all places, where either the enemy's party may come to disturb the forragers, or where they may be spread too near the enemy, fo
GUERNSEY, or GARNSEY, an island in the English channel, on the coast of Normandy, fifty-eight miles south of Portland, in Dorsetshire, and twenty-two miles west of Cape la Hogue, in Normandy; about ten miles long and as many broad, containing ten parishes. The natives, who speak French, are still governed by the Norman laws, but are subject to England.

GUIAQUIL, a city and port-town of Peru, situated near the Pacific ocean: W. long. 80°, and N. lat. 3°.

GUIDON, also denotes the officer who bears the guidon. He is the same in the horse-guards that the ensign is in the foot. The guidon of a troop of horse takes place next below a cornet.

GUIDON, a sort of flag or standard, borne by the king's life guards; being broad at one extreme, and almost pointed at the other, and slit or divided into two.

GUIDON, a fraternity or company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed; upon which the neighbours enter into an association, and become bound for each other, either to produce him who committed any offence, or to make satisfaction to the injured party; in order to which they raised a sum among themselves, which they put into a common stock; out of which they, upon occasion, made a pecuniary compensation according to the quality of the offence committed. These guilds are now companies joined together with laws and orders made by themselves, by the licence of the prince.

Dean of Guild, in Scots law, a magistrate of a royal borough, who is head of the merchant-company. See Scots Law, title 4.

GUILDFORD, or Gulesford, a borough-town of Surrey, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.

GUILLESTRE, a city of France, in the province of Lionois: E. long. 6° 20', and N. lat. 44° 45'.

GUILLESTRE, a city of France, in the province of Lionois: E. long. 6° 20', and N. lat. 44° 45'.

GUILFORD, or Guelforst, a borough-town of Surrey, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.

GUILLESTRE, a city of France, in the province of Lionois: E. long. 6° 20', and N. lat. 44° 45'.

GUILD, a fraternity or company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed; upon which the neighbours enter into an association, and become bound for each other, either to produce him who committed any offence, or to make satisfaction to the injured party; in order to which they raised a sum among themselves, which they put into a common stock; out of which they, upon occasion, made a pecuniary compensation according to the quality of the offence committed. These guilds are now companies joined together with laws and orders made by themselves, by the licence of the prince.

Dean of Guild, in Scots law, a magistrate of a royal borough, who is head of the merchant-company. See Scots Law, title 4.

GUILFORD, or Gulesford, a borough-town of Surrey, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.

GUILLESTRE, a city of France, in the province of Lionois: E. long. 6° 20', and N. lat. 44° 45'.

GUILFORD, or Gulesford, a borough-town of Surrey, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.

GUILLESTRE, a city of France, in the province of Lionois: E. long. 6° 20', and N. lat. 44° 45'.

GUILFORD, or Gulesford, a borough-town of Surrey, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.
GUM, in pharmacy, a concreted vegetable juice, which Gum Seneca, is a gum extremely resembling gum arabic. See Mus.

Gum Arabic. See Czw Arabic.

GULPH, or Gulf, in geography, a part of the sea, nor, the river Senega runs, in loose or single drops, which the negroes dissolve in milk, and in that state make it a principal ingredient in many of their dishes; and often feed on it thus alone.

GUM TRAGACANTH. See Tragacanth.

GUM MANNA. See Manna.

GUM ALOEs, a preparation of aloes, as set down in the London Dispensatory.

It is made thus: Take of succotrine aloes, four ounces; of water, a quart: boil the aloes till it is dissolved as much as may be; and let all by for a night: the resin will be precipitated to the bottom of the vessel; the liquor poured off and strained, being evaporated, will have the gum. The intention of this separation of the resin, is to procure in the gum, a medicine less purgative, but more agreeable to the stomach, than the crude aloes.

GUM AMMONIAC. See Ammoniac.

GUM ELEMI. See Elemi.

GUM GLIACUM. See Guaiaicum.

GUM LACCA. See Lacca.

GUMS, in anatomy. See Anatomy, p. 305.

GUN, a fire arm, or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, thro' a cylindrical barrel, by means of gun-powder. See Gun-Powder.

Gun is a general name, under which are included divers or even most species of fire-arms. They may be divided into great and small.

Great guns, called also by the general name cannons, make what we also call ordinance, or artillery; under which come the several sorts of cannons, as cannon-royal, demi-cannon, &c. Culverins, demi-culverins, fakers, minions, falcons, &c. See Cannon.

Small guns include musquets, musqueteoons, carbines, blunderbusses, fowling pieces, &c. See Musquet, &c.

Pistols and mortars are almost the only sort of regular weapons, charged with gun-powder, that are excepted from the denomination of guns. See Pistol and Mortar.

The advantage of large guns, or cannons, over those of a smaller bore, is generally acknowledged. Robins observes, that this advantages arises from several circumstances, particularly in distant cannonading. The distance to which larger bullets fly with the same proportion of powder, exceeds the flight of the smaller ones, almost in proportion to their diameters; so that a thirty-two pound shot, for instance: being somewhat more than six inches in diameter, and a nine pound shot but four inches; the thirty-two pound will fly near half as far again as that of nine pound, if both pieces are so elevated as to range to the farthest distance possible. Another and more important advantage of heavy bullets is, that with the same velocity they break holes in all solid bodies, in a greater proportion than their...
A cannon is a military engine, or fire-arm, for throwing iron, lead, or stone bullets, by force of gun-powder, to a place exactly opposite to the axis of the cylinder whereof it consists.

Cannons are made cylindrical, that the motion of the ball might not be retarded in its passage; and that the powder, when on fire, might not flip between the ball and the surface of the cannon, which would hinder its effect. With regard to the names, dimensions, weight, &c. of cannons, see Cannon.

Each fort of ordnance is more or less fortified; which fortification is reckoned by the thickness of the metal at the touch hole, at the trunnions, and at the muzzle, in proportion to the diameter of the bore.

There are three degrees used in fortifying each fort of ordnance, both cannons and culverines: First, such as are ordinarily fortified, which are called legitimate pieces; secondly, such whose fortifications are lessened, which are called bastard pieces; thirdly, double fortified pieces, or extraordinary pieces.

The cannons double fortified have full one diameter of their bore in thickness of metal at their touch-hole, and \( \frac{2}{3} \) at their trunnions, and \( \frac{1}{3} \) at their muzzle. The lessened cannons have, at their touch hole, but \( \frac{1}{3} \) or \( \frac{2}{3} \) of the diameter of their bore in thickness of metal, and \( \frac{1}{3} \) at their trunnions, and \( \frac{1}{3} \) at their muzzle. The ordinary fortified cannons, have \( \frac{3}{4} \) at the touch hole, \( \frac{3}{4} \) at the trunnions, and \( \frac{3}{4} \) at the muzzle. All the double fortified culverines, and all lesser pieces of that kind, have one diameter and \( \frac{1}{3} \) at the touch-hole, \( \frac{1}{3} \) at the trunnions, and \( \frac{1}{3} \) at the muzzle. All the ordinary fortified culverines, are fortified every way as the double fortified cannons; and the lessened culverines, as the ordinary cannons in all points.

With regard to bullets, or balls, whereinof bullets are loaded, they are of various kinds, viz. 1. Red-hot bullets, intended to set fire to places, where combustible matters are found. The bullet is made red-hot, by digging a place in the earth, and lighting in it a great quantity of charcoal, or sea coal, and placing over it a strong iron grate. When the fire is well lighted, the bullets are placed on the grate, where, in a very short time, they grow red-hot; they are taken out with tongs, or iron ladles for the purpose, and carried into the piece; having before put some clay over the powder the cannon is loaded with, left it should be set on fire by the red-hot bullet: then the piece is fired. Where-ever the bullet passes, and meets with combustible matters, it sets them on fire. But when a trench is before the battery of red-hot bullets, hay is rammed over the powder; because, if it was clay, the pieces of it would wound and kill the workmen.

Red-hot bullets are never fired but with eight or four pounders. For if they were of a stronger caliber, the bullets could not be served easily.

2. Hollow bullets are shells made cylindrical, with an aperture and fusee at one end, which giving fire to the inside, when in the ground, it burns, and has the same effect with a mine.
3. Chain-bullets consist of two balls joined by a chain, three or four foot a-piece.

4. Branch bullets are two balls joined by a bar of iron, five or six inches a-part.

5. Two-headed bullets, called also angels, being two halves of a bullet, joined by a bar or chain: these are chiefly used at sea, for cutting of cords, cables, sails, &c.

As bullets, as well as the pieces of ordnance, are of different caliber, which caliber, in a piece of ordnance, is the diameter of the mouth thereof; and in a bullet, its circumference; there are means found to proportion these two calibers to one another, viz. with an instrument called a caliber rule, wherein a right line is so divided, as that the first part being equal to the diameter of an iron or leaden ball of one pound weight, the other parts are to the first, as the diameters of balls of two, three, four, &c. pounds, are to the diameter of one ball of one pound.

The caliber consists of two thin pieces of brass, six inches long, joined by a rivet, so as to move quite round each other: the head, or one end of the piece, is cut circular, and one half of its circumference divided into every second degree. On the other half are divisions from one to ten; each again subdivided into four: the use of which divisions and subdivisions, is when the diameter of a bullet, &c. not exceeding ten inches, is taken, the diameter of the semicircle will, among the divisions, give length of the diameter, taken between the points of the calibers, in inches and fourth parts.

The degrees on the head serve to take the quantity of an angle, the method of which is obvious. If the angle be inward, apply the outward edges to the planes that form the angle; the degree cut by the diameter of the semicircle, shews the quantity of the angle sought.

For an outward angle, open the branches till the points be outward, and applying the straight edges to the planes that form the angle, the degrees cut by the diameter of the semicircle shew the angle required; reckoning from 180° towards the right hand.

On one branch of the calibers, on the same side, are, first, six inches; and each of these subdivided into ten parts. Secondly, a scale of unequal divisions, beginning at two, and ending at ten, each subdivided into four parts. Thirdly, two other scales of lines, shewing, when the diameter of the bore of a piece is taken with the points of the calibers, the name of the piece, whether of the iron or brass, i.e. the weight of the bullet it carries, or that it is such or such a pounder, from one to forty-two pounds.

On the other branch of the calibers, on the same side, is a line of cords to about three inches radius; and a line of lines on both branches, as on the sector; with a table of the names of the several pieces of ordnance. On the same face is a hand engraved, and a right line drawn from the finger towards the centre of the rivet, shewing, by its cutting certain divisions made on the circle, the weight of an iron shot, when the diameter is taken by the points of the calibers. Lastly, on the circle or head, on the same side, are engraved several geometrical figures, inscribed in each other, with numbers; as a cube, whose side is sup-
pored one foot; a pyramid on the same base or altitude, and the proportions of their weight, &c. a sphere inscribed in a cube; a cylinder, cone, circle, figure, &c.

The outside of the caliber serves to take the diameter of the mouth of the piece; and the inside, called the heel, that of the bullet.

There is another method of taking the caliber of the pieces, which is to have a rule very well divided, on which are graved the calibers both of the pieces and bullets. That rule must be applied on the mouth of the piece, and the caliber is presently found.

Sometimes, in lieu of bullets, the pieces are charged with cartouches, which are cafes loaded with musket-balls, nails, chains, and pieces of old iron; sometimes, also, with small cannon-balls. See Plate XCVIII.

There are cartouches made in form of grapes, which are musket-balls joined together with pitch, and disposed on a small board, in a pyramidal form round a wooden fickle, which arises from the middle of the board. (ibid.)

The cartouches made of tin are the best, because they carry further.

There are also cartouches made in form of pine apples, whose figure is pyramidal. Their base is equal to the caliber of a bullet, propos'd for the piece they are to be fired with; their height is of a caliber and a half; they are dipped in tar, and afterwards rolled on musket-balls, and when well covered with those balls, dipped again in the same tar, after which they may be used, thrusting the biggest foremost into the piece. These pine-apples are very good at sea, because, besides that the musket-balls flying about wound a great number of people, the bullet which is at the bottom of the cartouch does also much execution.

There are several sorts of carriages for ordnance, viz. ball-ard carriages, with low wheels, and high wheels. Sea-carriages, made in imitation of those for ship-guns, and carriages for field-pieces, of which there are two kinds.

The carriages must be proportioned to the pieces mounted on them. — The ordinary proportion is, for the carriage to have 1/4 of the length of the gun; the wheels to be half the length of the piece in height; four times the diameter or caliber, gives the depth of the planks the fore end, in the middle 3/4.

The piece thus mounted on its carriage, several instruments are employed, some to prepare the piece to be load'd, some to load it, others to point it, and others to clean it, &c. Those instruments have each their proper name, which are as follows: The lantern or ladle, (ibid.) which serves to carry the powder into the piece, and which consists of two parts, viz. of a wooden box, appropriated to the caliber of the piece for which it is intended, and of a caliber and a half in length with its vent; and of a piece of copper nailed to the box, at the height of a half caliber.

This lantern must have three calibers and a half in length, and two calibers in breadth, being rounded at the end to load the ordinary pieces.

The rammer, (ibid.) which is a round piece of wood, commonly called a box, furnished to a fickle twelve foot long,
long; for the pieces from twelve to thirty three pounders; and ten for the eight and four pounders; which serve to drive home the powder and ball to the breech.

The sponge, (ibid.) which is a long stuff or rammer, with a piece of sheep or lamb skin wound about its end, to serve for fouling the cannon when discharged, before it be charged with fresh powder; to prevent any spark of fire from remaining in her, which would endanger the life of him who should load her again.

Wad-fcrew, (ibid.) which are two points of iron turned screw-fenire, to extract the wad out of the pieces, when one wants to unload them, or the dirt which had chanced to enter into it.

The botefeux, (ibid.) which are sticks two or three feet long, and an inch thick, split at one end, to hold an end of the match twisted round it, to fire the cannon.

The priming iron, (ibid.) which is a pointed iron rod, to clear the touch-hole of the pieces of powder or dirt; and also to pierce the cartridge, that it may sooner take fire.

The primer, (ibid.) which must contain a pound of powder at least, to prime the pieces.

The quoin of mire, which are pieces of wood with a notch on the side to put the fingers on, to draw them back or push them forward, when the gunner points his piece. They are placed on the sole of the carriage.

Leaden plates, which are used to cover the touch-hole, when the piece is charged, lest some dirt should enter it and stop it.

Before you charge the piece, spunge it well, to clean it of all filth and dirt within it; then the proper weight of gunpowder, which powder drive in and ram down; taking care that the powder be not bruised in ramming, which weakens its effect; run over it a little quantity of paper, hay, or the like; and then throw in the ball.

To point, level, or direct the piece, so as to play against any certain point, is done by the help of a quadrant with a plummet; which quadrant consists of two branches made of brass or wood; one about a foot long, eight lines broad, and one line in thickness; the other four inches long, and the same thickness and breadth as the former. Between these branches is a quadrant, divided into 90 degrees, beginning from the shorter branch, and furnished with thread and plummet.

Place the longest branch of this instrument in the cannon's mouth, and elevate or lower it till the thread cuts the degree necessary to hit the proposed object. Which done, prime the cannon, and then let fire to it.

To point a cannon well, so as to do the execution proposed, we must know the path of a bullet, or the line it describes, from the mouth of the piece to the point where it lodges, which path is commonly called range.

If the piece be laid in a line parallel to the horizon, it is called the right or level range; and if it be mounted to 45 degrees, the ball is said to have the utmost range, and fo proportionally; all others between 00 degrees and 45, being called intermediate ranges.

A shot made when the muzzle of a cannon is raised above the horizontal line, and is not designed to shoot directly or point blank, is called random-shot.

The utmost random of any piece is about ten times as far as the bullet will go point blank; and the bullet will go farthest when the piece is mounted to about 45 degrees above the level range.

Mr Norton observes, that

A 24 pounder may very well fire 90 or 100 shots, every day in summer; at 60 or 75 in winter. In case of necessity, it may fire more. And some French officers of artillery assure, that they have caused such a piece to fire every day 150 shots in a siege.

A 16 and a 12 pounder fire a little more, because they are easier served. There have even been some occasions, where 200 shots have been fired from these pieces, in the space of nine hours, and 138 in the space of five.

To range pieces in a battery, take care to reconnoitre well the ground where it is to be placed, and the road to convey it, in the night time, the cannon and the munitions.

The pieces must be armed, each with two lanterns, or ladders, a rammer, a sponge, and two priming irons. The battery must also be provided with carriages, and other implements, necessary to remount the pieces which the enemy should chance to dismount.

To serve expeditiously and safely a piece in battery, it is necessary to have to each a sack of leather, large enough to contain about twenty pounds of powder to charge the lanterns or ladders, without carrying them to the magazine; and to avoid thereby making those trains of powder in bringing back the lantern from the magazine, and the accidents which frequently happen thereby.

A battery of 3 pieces must have 30 gabions, because they are employed on each of the two sides or epaulments, which make twelve, and nine for each of the two merlons.

There ought to be two gunners and six soldiers to each piece, and four officers of artillery.

The gunner, posted on the right of the piece, must take care to have always a pouch full of powder, and two priming-irons; his office is to prime the piece, and load
GUN (757)

GUN

where the tampon is placed, 8 inches. The touillons have 5 inches of diameter.

The chamber must enter an inch into the touillons; the thickness of the metal about the chamber, 3 inches; the thickness of the belly, 2 inches; and the length of the chafe, 1 inch and 1/2; about each ring, 1 inch and 4/3.

Mortars, for throwing bombs, are of several kinds.

There are some in the ancient manner, of 6, 7, 8, 9, 10, 11, 12, and 18 inches diameter at their mouth, and which contain in their chambers 3, 4, 5, 6, and 12 pounds of powder.

The chamber where the powder is put is cylindrical, and a little rounded at bottom.

Those of new invention have a concave chamber, and of these there are some which have 12 inches in diameter, and contain in their chambers 18 pounds of powder; others 12, and others 8.

The proportions of mortars are as follow: The mortar which throws a bomb of 17 inches 10 lines of diameter, has the bore 27 inches long, and 18 inches 4 lines of diameter: it has in thickness between the bourelet, and its small reinforced ring, 3 inches; its small reinforced ring, is 3 1/2 inches thick; its great one, 4 inches; the entrance of its chamber has 5 inches of diameter; its chamber, in form of a pear, is 13 inches long, and 7 inches of diameter at its greatest breadth; and also 7 1/2 inches thick, and contains 12 pounds of powder.

The touillons of the mortar have 32 inches in length from one end to the other, and 9 of diameter. The mortar has in height 4 foot 4 inches.

The bomb has 17 inches 10 lines of diameter, is 2 inches thick everywhere, except the bottom, which has 2 inches 10 lines. The aperture of the touch-hole is of 20 lines within and without.

The bomb contains 48 lb. of powder, and weighs 490 lb., and a little more.

The bore of the concave mortar, whose chamber contains 18 pounds of powder, has 12 inches of diameter, and is 18 1/2 inches long. It has in thickness between the bourelet, and its reinforced ring, 3 inches; and its reinforced ring is 4 1/2 inches thick. Its chamber has 9 inches 7 lines of diameter at its greatest width: the higher part thereof has 6 inches of diameter, and 4 inches in height; and its lower part 2 1/2 inches. The thickness of the metal round the chamber is of 26 inches 9 lines. The touillons have, from one end to the other, 8 inches of diameter. The mortar has in height 3 feet 5 inches.

It throws a bomb of 11 inches 8 lines diameter, which is 1 inch 4 lines thick every where, except at its cullot, which has 1 inch 8 lines. The aperture of its touch-hole is 16 lines inside and outside. The bomb contains 15 pounds of powder, and weighs 130 pounds, or thereabout.

The bore or chafe of the concave mortar, whose chamber contains 12 pounds of powder, has 12 inches 6 lines of diameter, and 17 inches 6 lines in length. Its thicknesses between the bourelet and its reinforced ring, is of 2 1/4 inches. Its reinforced ring is 3 inches thick. Its chamber has of diameter, at its greatest width, 9 inches 6 lines. The portion of that chamber a-top has 5 inches 4 lines of diameter, and 2 inches at bottom. The thick-
nefs of the metal round the chamber is 6 inches. The tourillons are, from one end to the other, 30 inches long, and 7 inches of diameter; and the mortar is in all 3 foot 2 inches high.

It throws a bomb 11 inches 8 lines of diameter, which is 1 inch 4 lines thick every where, except at its cullot, which has 1 inch 8 lines.

The aperture of its touch-hole outside and inside, is 16 lines.

The bomb contains 15 pounds of powder, and weighs 130.

The mortar, which has a concave chamber containing 8 pounds of powder, must throw a bomb of 11 inches 8 lines. Its diameter is of 12 ½ inches; its bore 18 inches long; its thickness at the chase 2¼ inches; its reinforced ring 6 inches long, and 3 inches thick; its concave chamber 8 inches 8 lines long, and 7 inches in diameter; the thickness of the metal round it 5 inches; its tourillons 3 inches long from one end to the other, and 7 inches in diameter. The concave chamber contains 8 pounds of powder, and throws a bomb as above.

The ordinary mortar, which throws a bomb of 11 inches 8 lines, has a bore of 12 inches diameter, and 18 long; its thickness at the neck 2 inches; at its reinforced ring 2½ inches; its chamber 9½ inches in length, its diameter of 5½ inches, the thickness of the metal round the chamber 7 inches, which chamber contains 6 pounds of powder; the tourillons have in length, from one end to the other, 28 inches, and 8 inches of diameter.

The mortar, which throws a bomb of 8 inches, has the bore 12 inches long, and 8 inches 4 lines in diameter; its thickness 1 inch 4 lines at the chase; its reinforced rings 4 inches 8 lines long, and 1 inch 8 lines thick; its chamber 6 inches long, and 2 inches 8 lines of diameter; its tourillons 18 inches 8 lines in length, and 4 inches 8 lines of diameter. The bomb of 8 inches of diameter is 10 lines thick every where, except at the cullot, which is 13, and its touch-hole 1 inch of diameter inside and outside. The chamber contains 4 pounds of powder, and the bomb weighs 40 pounds.

The bore of the mortar, which is to throw a bomb of 6 inches, is of 6½ inches of diameter, and 9 inches long; its thickness at the chase 1 inch; its reinforced ring 1½ inch thick, and 3½ inches long; its chamber 4½ inches long, and 2 inches of diameter; the thickness of the metal 2 inches, and from the bottom of the chamber to behind the recoil of the mortar 4 inches thick.

Common mortars are very good for the bombardment of a place, when they can be carried near the place; throwing the bomb to 45 degrees of elevation, and to 700 fathoms distance: the chamber is charged with 5 or 6 pounds of powder, which is the greatest charge, and carries farther: the nearer a place a mortar is mounted, the less powder is wanted for its charge. The mortars, with a concave chamber of the same diameter, 1 e. of 12 and 12½ inches, pointed at 45 degrees, are proper to bombard places afar off; they carry their bombs from 1200 to 1800 fathoms. Those whole chamber contains 8 pounds of powder, throw the bomb to 1200 fathoms, and weigh 2000 lb. Those of 12 pounds of powder will carry their bombs to 1400 fathoms, and weigh 2500 lb.

The carriage for a mortar of 12 inches of diameter must be 6 foot long, the flanks 12 inches long and 10 thick. The trunnions are placed in the middle of the carriage.

The carriage of 18 must be 4 foot long; and the flanks 11 inches high, and 6 thick.

To mount the mortars of new invention, they use carriages of cast iron.

In Germany, to mount mortars from 8 to 9 inches, and carry them into the field, and execute them horizontally as a piece of cannon, they make use of a piece of wood 8 feet 2 inches long, with a hole in the middle to lodge the body of the mortar and its trunnions as far as their half diameter, and mounted on two wheels four feet high, to which they join a vantrain proportioned to it, and made like those which serve to the carriages of cannon.

Having mounted the mortar on its carriage, the next thing is to calibcr the bomb, by means of a great calibcr, the two branches whereof embrace the whole circumference of the bomb: these two branches are brought on a rule where the different calibers are marked, among which that of the bomb is found.

A bomb is a hollow iron ball, or shell, filled with gunpowder, and furnished with a vent for a fusee or wooden tube filled with combustible matter to be thrown out from a mortar. The method of preparing a bomb is as follows: A hollow iron globe is call pretty thick, having a round aperture by which it may be filled and lighted; and circular anae for the commodiously putting it into the mortar. To prove whether it be staunch, after heating it red hot on the coals, it is exposed to the air so as it may cool gently; for, since fire dilates iron, if there be any hidden chinks or perforations, they will thus be opened and enlarged, and the rather because of the spring of the included air continually acting from within. This done, the cavity of the globe is filled with hot water, and the aperture well stopped, and the outer surface washed with cold water and soap; so that if there be the smallest leak, the air, rarified by the heat, will now perpare and form bubbles on the surface.

If no defect be found in the bomb, its cavity is filled, by means of a funnel, with whole gun-powder; a little space or liberty is left, that when a fusee or wooden tube, of the figure of a truncated cone, is driven through the aperture, (with a wooden mallet, not an iron one, for fear of accident), and fastened with a cement made of quick lime, ashes, brick-dust, and steel filings worked together in a glutinous water, or of four parts of pitch, two of colophony, one of turpentine, and one of wax; the powder may not be bruised. This tube is filled with combustible matter, made of two ounces of niter, one of sulphur, and three of gun-powder-dust well rammed.

This fusee set on fire, burns slowly till it reaches the gun powder, which goes off at once, bursting the shell to pieces with incredible violence. Special care, however, must be taken, that the fusee be so proportioned, as that
that the gun-powder do not take fire ere the shell arrives at the defined place; to prevent which, the fusee is frequently wound round with a wet clammy thread.

The mortar mounted on its carriage, and the bomb ready, let us place our piece in battery, which battery must conform—1. Of an epaulment to shelter the mortars from the fire of the enemy. 2. Of platforms on which the mortars are placed. 3. Of small magazines of powder. 4. Of a boyau which leads to the great magazine. 5. Of ways which lead from the battery to the magazine of bombs. 6. Of a great ditch before the epaulment. 7. Of a berm or retraite.

The platforms for mortars of 12 inches must have 9 feet in length, and 6 in breadth.—The lambourds for common mortars must be four inches thick; those of a concave chamber of 8 lb. of powder, 5 inches; those of 12 lb. 6 inches; those of 18 lb. 7 inches, or thereabouts. Their length is at discretion, provided there be enough to make the platforms 9 feet long.—The fore-part of the platform will be situated at two foot distance from the epaulment of the battery.—The bombadiers, to shelter themselves in their battery, and not be seen from the town beleaguered, raised an epaulment of 7 foot or more high, which epaulment has no embrasures.

To serve expeditiously a mortar in battery are required,—five strong handspikes; a dame or rammer, of the caliber of the conic chamber, to ram the wad and the earth; a wooden knife a foot long, to place the earth round the bomb; an iron scraper two foot long, one end whereof must be 4 inches broad and roundwise, to clean the bore and chamber of the mortar, and the other end made in form of a spoon to clean the little chamber; a kind of brancard to carry the bomb, a shove, and pick-ax.

The officer who is to mind the service of the mortar must have a quadrant to give the degrees of elevation.

Five bombadiers, or others, are employed in that service; the first must take care to fetch the powder to charge the chamber of the mortar, putting his priming-iron in the touch-hole before he charges the chamber; and never going to fetch the powder before he has asked his officer at what quantity of powder he designs to charge, because more or less powder is wanted, according to the distance where it is fired; the same will take care to ram the wad and earth, which another soldier shall put in the chamber.

That on the right will put again two shovels full of earth in the bottom of the bore, which should be likewise very well rammed down.

This done, the rammer or dame is returned into its place, against the epaulment on the right of the mortar; he takes an handspike in the same place to pull himself behind the carriage of the mortar, in order to help to pull it into battery: having laid down his handspike, he takes out his priming-iron, and primes the touch-hole with fine powder.

The second soldier on the right and left, will have by that time brought the bomb ready loaded, to be placed.
Granadoes are charged like the bombs, and are very much like them, except that they have no ansa.

A granado is a hollow ball, or shell of iron, brass, or even glass, or potters earth, filled with gun powder, and fitted with a fusee to give it fire. (ibid.)

Of these there are two kinds; the one large for ditches, or fosses, called sometimes bombs, whose caliber is the same with that of the bullets of 33 lb. and which weigh 16 lb. of 24, and which weigh 12 lb. of 16, which weigh 8 lb.

These granadoes are rolled from the ramparts, or other works, into the ditch, or on a breach, and do much execution.

</table>

The other are hand-granadoes, of the bigness or caliber of a bullet of 4 lb., and weigh only 2 lb., containing 4 or 5 ounces of powder, or thereabout.

These serve to throw with the hand into the trenches, or retrenchments, in the middle of a troop or company, and they infallibly lame or kill.

Care is taken, as much as possible, that they be well emptied, shaved, and of brittle iron. Their aperture or orifice must have fix lines, or thereabout.

Small lanterns or ladles of copper, and small rammers, are used to charge the granadoes.

As to the proportions of granadoes, those of the caliber
The third, which is the best, is of 3 lb. of powder, 2 lb. of saltpetre, and 1 lb. of sulphur.

The fourth is of 3 lb. of powder, 2 lb. of saltpetre, and 4 lb. of sulphur.

The fusées must be charged even, i.e., they must burn without spitting.

The fusee of the hand-granado, which is of the caliber of 4, must be 2 inches 2 lines long, 9 lines of diameter, and 6 lines at the small end: the orifice of the fusee 2 1/2 lines.

As soon as the fusee is placed to the granado, the head thereof must be sauced in melted pitch, and afterwards dipped in water, which hinders the composition from spoiling, and the wood from rotting.

The petard (ibid.) is the next piece of artillery which deserves our attention, and is a kind of engine of metal, somewhat in shape of a high-crowned hat, serving to break down gates, barricades, draw-bridges, or the like works; which are intended to be surprised. It is very short, narrow at the breach, and wide at the muzzle, made of copper mixed with a little brass, or of lead with tin.

The petards are not always of the same height and signes: they are commonly 10 inches high, 7 inches of diameter a-top, and 10 inches at bottom. They weigh commonly 40, 45, and 50 pounds.

The madrier, on which the petard is placed, and where it is tied with iron circles, is of two feet for its greatest width, and of 18 inches on the sides, and no thicker than a common madrier. Under the madrier are two iron bars passed cros-ways, with a hook, which serves to fix the petard.

To charge a petard 15 inches high, and 6 or 7 inches of caliber or diameter at the bore, the inside must be filled very well cleaned and heated, so that the hand may bear the heat; then take the best powder that may be found, throw over it some spirit of wine, and expost it to the sun, or put it in a frying-pan; and when it is well dried, 5 or 6 lb. of this powder is put into the petard, which reaches within three fingers of the mouth: the vacancies are filled with tow, and stopped with a wooden tampon; the mouth being strongly bound up with cloth tied very tight with ropes; then it is fixed on the madrier, that has a cavity cut in it to receive the mouth of the petard, and fastened down with ropes.

Some, instead of gun powder for the charge, use one of the following compositions, viz. gun-powder seven pounds, mercury sublimate one ounce, camphor eight ounces; or gun-powder six pounds, mercury sublimate three ounces, and sulphur three; or gun-powder six, beaten glass half an ounce, and camphor half an ounce.

Before any of these pieces are appropriated for service, it is necessary to have each undergo a particular trial of its foundness, which is called a proof, to be made by or before one authorized for the purpose, called the proof-muder.

To make a proof of the piece, a proper place is chosen, which is to be terminated by a mound of earth very thick to receive the bullets fired against it, that none of them may run through it. The piece is laid on the ground, supported
The carabine is a kind of medium between the pistol and the musket; and bears a near affinity to the archer-buts, only that its bore is smaller. It was formerly made with a match-lock, but of late only with a flint-lock.

The musquetoon is of the same length of the carabine, the barrel polished, and clean within.

The musquetoon carries five ounces of iron, or seven and a half of lead, with an equal quantity of powder.

The barrel of a pistol is generally 14 inches long.

As to the invention of cannon and gun powder, we are certain that they are discoveries of a modern date; but there is no depending upon the various accounts given of them by authors. All that can be said with certainty is, that there is mention made of gun-powder in the register of the chamber of accounts in France, in the year of Chrifi 1338; that Alphonfus XI. king of Castile, besieged the Moors with iron mortars, in the year of Chrifi 1443; and that our King Edward, in 1346, first carried those thundering machines of war and death into France, where he availed himself of five or six pieces of cannon at the battle of Crefly.

Before the invention of these instruments of war, the ancients made use of the aries, or battering-ram, the catapultæ, the ballista, the scorpion, and telludo. See Ram, &c.

For the mathematical principles of Gunnery, see Projectiles.

**GUN-POWDER,** a composition of saltpetre, sulphur, and charcoal, mixed together, and usually granulated; which easily takes fire, and, when fired, rarifies, or expands, with great vehemence, by means of its elastic force.

It is to this powder we owe all the action and effect of guns, ordnance, &c. so that the modern military art, fortification, &c. in a great measure depend thereon.

**Method of making Gun Powder.** Dr Shaw's recipe for this purpose is as follows. Take four ounces of refined saltpetre, an ounce of brimstone, and six drams of small coal: reduce these to a fine powder, and continue beating them for some time in a stone mortar, with a wooden pestle, wetting the mixture between whiles with water, so as to form the whole into an uniform paste, which is reduced to grains, by passing it through a wire sieve for the purpose; and in this form being carefully dried, it becomes the common gun-powder.

For greater quantities, mills are usually provided, by means of which more work may be performed in one day, than a man can do in a hundred.

The nitre or saltpetre is refined thus: dissolve four pounds of rough nitre as it comes to us from the Indies, by boiling it in as much water as will commodiously suffice for that purpose: then let it float for two or three days in a covered vessel of earth, with sticks laid across for the crystals to adhere to. These crystals being taken out, are drained and dried in the open air.

In order to reduce this salt to powder, they dissolve
a large quantity of it in as small a proportion of water as possible; then keep it constantly stirring over the fire, till the water exhalates, and a white powder is left behind.

In order to purify the brimstone employed, they dissolve it with a very gentle heat; then scum and pass it through a double strainer. If the brimstone should happen to take fire in the melting, they have an iron cover that sits on close to the melting vessel, and damps the flame. The brimstone is judged to be sufficiently refined if it melts, without yielding any fibrous odour, between two hot iron plates, into a kind of red substance.

The coal for the making of gun-powder is either of willow, or hazel, well charred in the usual manner, and reduced to powder. And thus the ingredients are prepared for making this commodity: but as these ingredients require to be intimately mixed, and as there would be danger of their firing if beat in a dry form, the method is to keep them continually moist, either with water, urine, or a solution of salt-petre: they continue thus flaping them together for twenty-four hours, after which the mass is fit for corning and drying in the sun, or otherwise, so as sedulously to prevent its firing.

Rationale of Gun-powder. The explosive force of gun-powder is now a thing commonly known, but the physical reason thereof may not perhaps be hitherto sufficiently understood. In order to explain it, Dr Shaw propofes the following observations: 1. That brimstone of itself is not inflammable; and though it melts in the fire, and grows red hot, yet does not explode, unless it comes in contact with the coals. 2. That brimstone easily melts at the fire, and easily catches flame. 3 That powdered charcoal readily takes fire, even from the sparks yielded by a flint and steel. 4. That if nitre be mixed with powdered charcoal, and brought in contact with the fire, it burns and flames. 5. That if sulphur be mixed with powdered charcoal, and applied to the fire, part of the sulphur burns slowly away, but not much of the charcoal; and, 6. That if a lighted coal be applied to a mixture of nitre and sulphur, the sulphur presently takes fire with some degree of explosion; leaving part of the nitre behind, as we see in making the fulprinelle, and ful polychrestum.

These experiments duly considered, adds the doctor, may give us the chemical cause of the strange explosive force of gun-powder. For each grain of this powder consisting of a certain proportion of sulphur, nitre, and coal, the coal presently takes fire, upon contact of the smallest spark: at which time both the sulphur and the nitre immediately melt, and by means of the coal interposed between them, burst into flame; which, spreading from grain to grain, propagates the same effect almost instantaneously: whence the whole mass of powder comes to be fired: and as nitre contains both a large proportion of air and water, which are now violently rarified by the heat, a kind of fiery explosive blast is thus produced, wherein the nitre seems, by its aqueous and aerial parts, to act as bellows to the other inflammable bodies, sulphur and coal, to blow them into a flame, and carry off their whole substance in smoke and vapour.

Different kinds of Gun-powder. The three ingredients of gun powder are mixed in various proportions according as the powder is intended for muskets, great guns, or mortars; though these proportions seem not to be perfectly adjusted or settled by competent experience.

Semienowitz, for mortars, directs an hundred pounds of salt-petre, twenty-five of sulphur, and as many of charcoal; for great guns, an hundred pounds of salt-petre, fifteen pound of sulphur, and eighteen pound of charcoal; for muskets and pistols, an hundred pound of salt-petre, eight pound of sulphur, and ten pound of charcoal. Mithius extols the proportion of one pound of salt-petre to three ounces of charcoal, and two, or two and a quarter of sulphur; than which, he affirms, no gun-powder can possibly be stronger. He adds, that the usual practice of making the gun-powder weaker for mortars than guns, is without any foundation, and renders the expense needlessly much greater; for whereas to load a large mortar, twenty-four pound of common powder is required, and consequently, to load it ten times, two hundred and forty pound, he shews, by calculation, that the same effect would be had by one hundred and fifty pound of the strong powder.

To increase the strength of powder, Dr Shaw thinks it proper to make the grains considerably large, and to have it well sifted from the small dust. We see that gun-powder, reduced to dust, has little explosive force; but when the grains are large, the flame of one grain has a ready passage to another, so that the whole parcel may thus take fire nearly at the same time, otherwise much force may be lost, or many of the grains go away as shot unfired.

It should also seem that there are other ways of increasing the strength of powder, particularly by the mixture of salt of tartar; but perhaps, adds the last-mentioned author, it were improper to divulge any thing of this kind, as gun powder seems already sufficiently destructive.

Method of trying and examining Gun-powder. There are two general methods of examining gun-powder; one with regard to its purity, the other with regard to its strength. Its purity is known by laying two or three little heaps near each other upon white paper, and firing one of them: for if this takes fire readily, and the smoke rises upright, without leaving any droppings or feculent matter behind, and without burning the paper, or firing the other heaps, it is esteemed a sign that the sulphur and nitre were well purified, that the coal was good, and that the three ingredients were thoroughly incorporated together: but if the other heaps also take fire at the same time, it is presumed, that either common salt was mixed with the nitre, or that the coal was not well ground, or the whole mass not well beat, and mixed together; and if either the nitre or sulphur be not well purified, the paper will be black or spotted.

In order to try the strength of gun-powder, there are two kinds of instruments in use; but neither of them:
them appear more exact than the common method of
trying to what distance a certain weight of powder will
throw a ball from a musket.

There has been much talk of a white powder, which,
if it answered the character given it, might be a dan-
gorous composition; for they pretend that this white
powder will throw a ball just as far as the black, yet with-
out making a report; but none of the white powder
we have seen, says Dr Shaw, answers to this charac-
ter; being, as we apprehend, commonly made either
with touchwood or camphor, instead of coal.

Observations on the force of Gun-powder. Gun pow-
der, fired either in vacuum, or in air, produces, by
its explosion, a permanent elastic fluid. For if a red-
hot iron be included in a receiver, after being exhaus-
ted, and gun powder be let fall on the iron, the pow-
der will take fire, and the mercurial gage will sud-
denly descend upon the explosion; and though it im-
mEDIATELY ascends again, yet it will never rise to the
height it first did at, but will continue depressed by
a space proportioned to the quantity of gun powder
which was let fall on the iron.

The same production likewise takes place, when
gun powder is fired in the air: for if a small quantity
of powder be placed in the upper part of a glass tube,
and the lower part of the tube beimmerged in wa-
ter, and the water be made to rise so near the top,
that only a small portion of air is left in that part
where the gun-powder is placed; if in this situation
the communication of the upper part of the tube with
the external air be closed, and the powder be fired,
which will safely be done by a burning-glass, the wa-
ter will in this experiment descend upon the explo-
zion as the quicksilver did in the last; and will always con-
tinue depressed below the place at which it stood be-
fore the explosion; and the quantity of this depres-
sion will be greater, if the quantity of powder be in-
creased, or the diameter of the tube be diminished.
From whence it is proved, that as well in air as in a
vacuum, the explosion of fired powder produces a
permanent elastic fluid. It also appears from experi-
ment, that the elasticity or pressure of the fluid pro-
duced by the firing of gun powder, is 
\( \text{cateris paribus,} \)
directly as its density. This follows from hence,
that if in the same receiver a double quantity of
powder be let fall, the mercury will subside twice as
much as in the firing of a single quantity.

To determine the elasticity and quantity of this ela-
tic fluid, produced from the explosion of a given quan-
tity of gun powder, Mr Robins premised, that the
elasticity of this fluid increases by heat, and diminishes
by cold, in the same manner as that of the air; and
that the density of this fluid, and consequently its
weight, is the same with the weight of an equal bulk
of air having the same elasticity, and the same tempera-
ture.

From these principles, and from his experiments,
(for a detail of which we must refer the reader to his
New Principles of Gunnery, in Scholium to prop. II.)
he concludes, that the fluid produced by the firing of
gun powder will be \( \frac{1}{10} \) of the weight of the gun pow-
der, and the ratio of the respective bulks of the pow-
der, and the fluid produced from it, will be in round
numbers 1 to 244.

Hence we are certain, that any quantity of powder
fired in any confined space, which it adequately fills,
exerts, at the instant of its explosion, against the
sides of the vessels containing it, and the bodies it im-
pels before it, a force at least 244 times greater than
the elasticity of common air; or, which is the same
thing, than the pressure of the atmosphere; and this
without considering the great addition which this
force will receive from the violent degree of heat
with which it is ended at that time, the quantity
of which augmentation is the next head of Mr Ro-
bin's enquiry. He determines that the elasticity of the
air is augmented when heated to the extremest heat of
red hot iron, in the proportion of 796 to 194.4; and
supposing that the flame of fired gun powder is not
less hot than red hot iron, and the elasticity of the
air, and consequently of the fluid, generated by the
explosion, being augmented by the extremity of this
heat in the ratio of 796 to 194.4, it follows, that if 244
be augmented in this ratio, the resulting number, which
is 964.5, will determine how many times the elasticity
of the flame of fired powder exceeds the elasticity of
common air, supposing it to be confined in the fame
space which the powder filled before it was fired.

Hence then, the absolute quantity of the pressure
exerted by gun powder at the moment of its explo-
SION may be assigned: for since the fluid then gener-
ated has an elasticity of 999.4, or, in round numbers,
1000 times greater than common air; and since com-
mon air, by its elasticity, exerts a pressure on any gi-
ven surface equal to the weight of the incumbent at-
mosphere with which it is in equilibrium, the pressure
exerted by fired powder, before it has dilated itself,
is 1000 times greater than the pressure of the at-
mosphere; and consequently the quantity of this force
on a surface of an inch square amounts to above six
ton weight, which force however diminishes as the
fluid dilates itself. The variations of the density of
the atmosphere does not any way alter the action of
powder by any experiment that can be made. But
the moisture of the air has a very great influence on
the force of it: for that quantity which in a dry sea-
son would communicate to a bullet a velocity of 1700
feet in one second, will not in damp weather commu-
nicate a velocity of more than 12 or 1300 feet in a se-
cond, or even less, if the powder be bad and negli-
gently kept.

The velocity of expansion of the flame of gun-
powder, when fired in a piece of artillery, without
either bullet, or any other body before it, is prodigi-
ous. By the experiments of Mr Robins, it seems
this velocity cannot be much less than 7000 feet in a se-
cond. This, however, must be understood of the
most active part of the flame. For, as was observed
before, the elastic fluid, in which the activity of gun-
powder confists, is only \( \frac{1}{7} \) of the fulstance of the
powder, the remaining \( \frac{6}{7} \) will in the explosion be
mixed with the elastic part, and will by its weight re-
tard
To recover damaged Gun powder. The method of the powder-merchants is, to put part of the powder on a sail-cloth, to which they add an equal weight of melted salt petre. Afterwards, these ingredients are to be moistened and mixed well, so that nothing can be discerned in the composition, which may be known by cutting the mass; and then they granulate it as aforesaid. In case the powder be in a manner quite spoiled, the only way is to extract the salt-petre with water, according to the usual manner, by boiling, filtering, evaporating, and crystallizing; and then with fresh sulphur and charcoal to make it up anew again.

In regard to the medical virtues of gun-powder, it is afterward asserted that the flame of it affords a very healthy fume in the height of the plague: because the explosive acid vapour of nitre and sulphur corrects the air; and that the same fume, if received in a small closet in place, kills insects.

It is enacted by 5 and 11 of Geo. I. and 5 Geo. II. c. 20. that gun-powder be carried to any place in a covered carriage; the barrels being close jointed; or in cafes and bags of leather, &c. And persons keeping more than 200 pounds weight of gun-powder at one time, within the cities of London and Westminster, or the suburbs, &c. are liable to forfeitures if it be not removed; and justices of peace may issue warrants to search for, seize, and remove the same.

The invention of gun powder is ascribed by Polidore Virgil to a chemist, who having accidentally put some of the ingredients in this composition in a mortar, and covered it over with a flone, it happened to take fire, and blew up the flone. Thevet says, the person here spoken of was a monk of Friburg, named Constantin Anzelin; but Belleforet and others hold it to be Bartholdus Schwartz, or the black; at least it is affirmed, that he first taught the use of it to the Venetians, in the year 1380, during the war with the Genoese. But what contradicts this account, and shows gun-powder to be of an older date, is, that Peter Mexia, in his Variae Lectiones, relates, that Alphonfus XI. king of Castile, used mortars against the Moors in a siege in 1343. Ducange adds; that there is mention made of this powder in the registers of the chambers of accounts in France, as early as the year 1338; and frier Bacon, our countryman, mentions the composition in express terms, in his treatise De nulitate magiae, published at Oxford, in the year 1216.

GUN-shot-wounds. See Surgery.

GUNTSBERG, a town of Germany in the circle of Swabia, situated on the eft tide of the Danube: E. long. 10° 15', N. lat. 48° 35'.

GUNTER's line, a logarithmic line, usually graduated upon scales, sectors, &c.

It is also called the line of lines, and line of numbers; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into an hundred parts, every tenth whereof is numbered, beginning with 1, and ending with 10; so that, if the first great division, marked 1, stand for one tenth of any integer, the next division, marked 2, will stand for two tenths; 3, three tenths, and so on; and the intermediate divisions will, in like manner, represent 1000th parts of the same integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the greater divisions be suppos'd each 100, the subdivisions will be each 10.

Use of Gunter's line. 1. To find the product of two numbers. From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the dividend, will reach to the product. Thus if the product of 4 and 8 be required, extend the compasses from 4 to 32, and that extent laid from 8 the same way, will reach to 32, their product.

2. To divide one number by another. The extent from the divisor to unity, will reach from the dividend to the quotient: thus, to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought.

3. To three given numbers, to find a fourth proportional. Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required.

4. To find a mean proportional between any two given numbers. Suppose 8 and 32; extend the compasses from 8, in the left hand part of the line, to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought.

5. To extract the square root of any number. Suppose 25; bisect the distance between 1 on the scale and the point representing 25; then half of this distance, let off from 1, will give the point representing the root.

Gunter's quadrant, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being suppos'd placed in one of the poles.
GUTTIE, in architecture, are ornaments in the form of
guts. See Anatomy, p. 257.

GUTSKROW, a city of Germany in the circle of Up-
guts. See Anatomy, p. 257.

GUTSROW, a city of Saxony, and province of Swedifh Pomerania: E. long. 1 2

GUTTARE, in architecture, are ornaments in the form of
little cones, used in the plafond of the Doric corniche,
or on the architrave underneath the triglyphs, repre-
senting a sort of drops or bells. See Architecture.

GUTTÆ, in architecture, are ornaments in the form of
little cones, used in the plafond of the Doric corniche,
or on the architrave underneath the triglyphs, repre-
senting a sort of drops or bells. See Architecture.

GUTTA SERENA, a disease in which the patient, without
any apparent fault in the eye, is entirely deprived of
sight. See Medicine.

GUTTIES, in heraldry, is formed by a line drawn from
the dexter or sinister chief points, and falling down
perpendicularly to the extreme base. See Plate XCVII.

GUY, in a ship, is any rope used for keeping off things
from bearing or falling against the ship's side when
they are hoisting in.

That rope which at one end is made fast to the fore-
mast, and frizzed to a single block at the pendant of the
garnet, is called the guy of the garnet.

GUZES, in heraldry, roundles of a fanguine or murry
colour. These, from their bloody hue, are by some
supposed to represent wounds.

GYMNASIARCH, in antiquity, the director of the
gymnæum. He had two deputies under him; the one
called xylyarch, who presided over the athletes, and
had the oversight of the wrestling; the other gymna-
siarchs, who had the direction of all the other exercices.

GYMNASIUM, in Grecian antiquity, a place fitted for
performing exercices.
HABAT, the north-west province of the empire of Morocco, situated on the straits of Gibraltar.

HABAKKUK, or the prophecy of Habakkuk, a canonical book of the Old Testament. There is no mention made in scripture, either of the time when this prophet lived, or of the parents from whom he was descended; but according to the authors of the lives of the prophets, he was of the tribe of Simeon, and a native of Bethzaczar.

HABEAS CORPUS, in law, is a writ of two kinds; the one being the great writ of the English liberty, which lies where a person is indicted for any crime or trespasses before justices of the peace, or in a court of any franchise, and on being imprisoned has offered sufficient bail, which has been refused, though the cause be bailable; in which case he may have this writ out of the king's bench, in order to remove himself thither, to answer the cause at the bar of that court.

The practice in this case is, first to procure a certiorari out of the court of chancery, directed to all the justices for removing the indictment into the king's bench; and upon that to obtain this writ, directed to the sheriff, for causing the body of the party to be brought at a certain day.

The other kind of habeas corpus is used for bringing the body of a person into court, who is committed to any goal or prison, either in civil or criminal causes; which writ will remove the person and cause from one court and prison to another.

No habeas corpus, or other writ, to remove a cause from...
from out of an inferior court, can be allowed, if the
same be not delivered to the judge of the court, before
the jury who are to try the cause have appeared, and
before any of them are sworn, 43 Eliz. c. 5.

The habeas corpus act, 31 Car. II. c. 2, has or-
dained, that a person may have a habeas corpus from
any judge, on complaint made and view of the warrant
of commitment, (except such person is committed for
treason or felony expressed in the warrant, or some oth-
er offence that is not bailable) which habeas corpus
must be made returnable immediately; and on produc-
ing a certificate of the cause of commitment, the pri-
foner is to be discharged on bail given to appear in
the court of king's bench the next term, or next aizees, &c.
Perfons committed, for either treason or felony, ex-
pressly mentioned in the warrant, upon a motion made
in open court, in the first week of the term, or day of
fellions, &c. after commitment, are to be brought to
trial; and if they are not indicted the next term or
fellions after commitment, on a motion made the last
day of that term, they shall be let out upon bail, ex-
cept it appear on oath, that the king's witnesses are
not ready; and in case they are not indicted or tried
the second term after commitment, they shall be dis-
charged.

Judges denying a habeas corpus, shall forfeit 500 l.
and if an officer refuse to obey it, or to deliver a true
copy of the commitment-warrant, he forfeits 100 l.
for the first offence.

HABIT, in philosophy, an aptitude or dispozition either
of mind or body, acquired by a frequent repetition of
the same act.

Habit, in medicine, denotes the settled constitution
of the body, or the habitude of any thing else, as the
structure or composition of a body, or the parts there-
of.

Habit is also used for a dress or garb, or the composi-
tion of garments, wherewith a person is covered; in
which we say, the habit of an ecclesiastic, of a
religious, &c. a military habit, &c.

HABITE AND REPUTE, in S ots law, the common
opinion of the people, among whom a person lives,
with respect to any circumstance relating to him.

HABITUAL, something grown to a habit by long use.

See Habit.

HABITUDE, among schoolmen, the respect or relation
one thing bears to another. See Relation.

HACHA, a town of terra firma, in South America, fi-
suated on the north sea, at the mouth of the river
Hacha, in W. long. 72°, N lat. 11° 0'.

HACKNEY, a village on the north-east side of London,
with a handsome church, three meeting-houses, and
seventeen almshouses.

HADDINGTON, a parliament-town in Scotland, a-
about one hundred miles east of Edinburgh.

HADDOCK, the English name of a well known fish of
the gadus kind. See Gadus.

HADRUMUT, a city of Arabia Felix, the capital of
the province of Hadrumut, situated in E. long. 50°
30', N. lat. 18°, three hundred and sixty miles north-
east of Muscat.

HAGAI, a canonical book of the Old Testament, so
called
HAL (769)

called from the prophet of that name, who, in all probability was born at Babylon, from whence he returned with Zerubbabel.

HAEGENAU, a fortified town of Germany, in the Landgraviate of Alsace: E. long. 7° 40', N. lat. 48° 45'.

HAGUE, a town of the United Provinces, in the province of Holland, situated two miles east of the sea, and fourteen north-west of Rotterdam. This is one of the finest towns in Europe; but though it enjoys all the privileges of a city of Holland, except that of sending representatives to the state, yet, as it has no walls, it is only esteemed a village. Here every city of the United provinces has a house for their respective deputies, and here the states of the province of Holland assemble, and all public affairs are transacted.

HAIL, in physiology, an aqueous concretion, in form of white or pellucid spherules, descending out of the atmosphere.

Hail is evidently no other than drops of rain concealed into ice. This happens when in their passage through the inferior air, they meet with nitrous particles, which are known to contribute greatly to freezing. Their magnitude is owing to a fresh accession of matter as they pass along. Hence we see the reason why hail is so frequent in summer, because at that time greater quantities of nitre are exhaled from the earth, and float up and down the air. See Rain and Frost.

HAINSUCKEN, in Scots law, the assaulted or beating of a man in his own house. See Scots Law, title 33.

HAIRED, slender, oblong, and flexible filaments, growing out of the pores of animals, and serving most of them as a covering. See Anatomy, p. 256.

HAKE, in ichthyology. See Gadus.

HALBERSTAT, a city of Germany, in the circle of Upper Saxony, the capital of the duchy of the same name; subject to the king of Prussia: E. long. 14° 6', N. lat. 51° 55'.

HALCRIPTUM, a name given by Dr Hill to the salt suspended in a fluid form, and in very small quantities in mineral waters, scarce discernible by the taste, and with much difficulty separable from them.

HALCYON, in ornithology, a name given by the ancients to the alcedo, or kings-fisher. See Alcedo.

HALCYON DAYS, in antiquity, a name given to seven days before and as many after the winter solstice; by reason the Halcyon, invited by the calmness of the weather, laid its eggs in nests build in the rocks, close by the brink of the sea, at this feast.

HALE, in the sea-language, signifies pull; as, to haul up, is to pull up; to haul in or out, is to pull in or out. To over-hale a rope, is to haul it too stiff, or to haul it the contrary way.

Kee Hale. See Ducking.

HALEM, a town of the Austrian Netherlands, in the province of Brabant, twenty-five miles west of Maastricht: E. long. 5° 5', N. lat. 51° 5'.

HALESWORTH, a market town of Suffolk, thirty-five miles east of Bury: E. long. 1° 40', N. lat. 52° 30'.

HALF-BLOOD, in law, is where a man marries a free woman, the first being dead, and by the second venter has a son, and by his second venter has likewise a son, the two brothers, in this case, are but of half blood.

HALF-MERK, a noble, or 6s. 8d.

HALF-MOON, in fortification, an outwork composed of two faces, forming a salient angle, whose gorge is in form of a crescent, or half moon; whence the name. See Fortification.

HALIÆTUS, in ornithology. See Falco.

HALIOTIS, the ear-shell, a genus of insects belonging to the order of Vermes reflected. This is an animal of the snail-kind, with an open shell resembling an ear. There are seven species, distinguished by the figure of their shells.

HALLE, in geography, a town of Germany, in the circle of Austria, and county of Tyrol, situated six miles north-east of Innsbruck: E. long. 11° 28', N. lat. 47° 15'.

HALLE is also a town in the Austrian Netherlands in the province of Brabant, seven miles south of Brussel: E. long. 4° 10', N. lat. 50° 50'.

HALLE is also a city of Germany, in the circle of Upper Saxony, in the capity of a duchy situated on the river Sala, subject to the king of Prussia: E. long. 12° 5', N. lat. 51° 35'.

HALLE is also a town of Germany, in the circle of Swabia, twenty miles east of Hailbron; being an imperial city, or sovereign state: E. long. 9° 45', N. lat. 49° 20'.
HAM, in geography, a city in Germany, in the circle of HAM, in anatomy, the part behind the knee.

HALTWESEL, a market-town of Northumberland, thirty-two miles west of Newcastle; W. long. 2°, N. lat. 55°.

HAM, in anatomy, the part behind the knee.

HAMAD AN, a city of Persia, in the province of Eyrac HAMA, or Apamea. See Apamea.

HAMLE, the name of the eleventh month of the Ethiopian year, beginning on the 25th of June, old style.

HAMADRYADS, in heathen theology, certain rural deities; being nymphs of the woods, whose fate depended upon certain trees, together with which they were suppoted both to be born and to die.

HAM AMELIS, in botany, a genus of the tetrandra digynia class. The involucrum consists of three leaves, and the proper calyx of four; the petals are four; and the nut has two cells. There is but one species, a native of Virginia.

HAMAXOBIANS, hamaxobii, an ancient people of Europian Sarmatia, so called from their living together in chariots or wagons, for the convenience of shifting the place of their abode at pleasure.

HAMBURGH, a large city and well fortified port town of Germany, in the circle of Lower Saxony, and duchy of Holstein, situated on the north side of the river Elb, partly on islands, and partly on the continent. It is an imperial city, or sovereign state, governed by its own magistrates, and subject only to the general laws of the empire. Merchants from all parts of Europe resort to it, from whence their goods are sent into the heart of the empire.

HANSE, or Hans, a company of merchants united for mutual defence, and the protection of their trade.

HANSE-towns, port-towns of Germany of which Lubeck and Hamburg were the chief. They were formerly all of them imperial cities, confederated for their mutual defence, and the protection of their trade.

HAPPINESS, among philosophers, consists in the prosecution or enjoyment of some good.

HARBINGER, an officer of the king's household, having charge of the stables.

HARBOUR, a place where ships may ride safe at anchor, chiefly used in speaking of those secured by a boom and chain, and furnished with a mole.

HARBOROUGH, a town of Leicestershire, thirteen miles south-east of Leicesters.

HARBOUR, a place where ships may ride safe at anchor, chiefly used in speaking of those secured by a boom and chain, and furnished with a mole.

HARCOURT, a town of France, in the province of Normandy, twenty-three miles south-west of Rouen.

HARDENING, the giving a greater degree of hardness to bodies than they had before.

There are several ways of hardening iron and steel, as by hammering them, quenching them when hot in cold water, &c. Chemistry, p. 124.
The relations of sounds had only been considered in the series of numbers, $1:2, 2:3, 3:4, 4:5, \&c.$ which produced the intervals called octave, fifth, fourth, third, \&c. Mr Sauveur first considered them in the natural series, $1, 2, 3, 4, 5, \&c.$ and examined the relations of sounds arising therefrom. The result is, that the first interval, $1:2,$ is an octave; the second, $1:3,$ a twelfth; the third, $1:4,$ a fifteenth, or double octave; the fourth, $1:5,$ a seventeenth; the fifth, $1:6,$ a nineteenth, \&c.

This new consideration of the relations of sounds is more natural than the old one; and is, in effect, all the music that nature makes without the affliction of art.

HARMONICS, that part of music which considered the differences and proportions of sounds, with respect to acute and grave; in contradistinction to rhythmica and metrika.

HARMONY, in music, the agreeable result or union of several musical sounds heard at one and the same time; or the mixture of divers sounds, which together have an effect agreeable to the ear.

HARMONY of the spheres, or Celestial Harmony, a sort of music much talked of by many of the ancient philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals. It is impossible, according to them, that such prodigious large bodies, moving with so much rapidity, should be silent; on the contrary, the atmosphere continually impelled by them, must yield a set of sounds proportionate to the impression it receives; consequently, as they do not all run the same circuit, nor with one and the same velocity, the different tones arising from the diversity of motions, directed by the hand of the Almighty, must form an admirable symphony, or concert.

They therefore supposed, that the moon, as being the lowest of the planets, corresponded to $mi$; mercury, to $fa$; venus, to $fe$; the sun, to $la$; mars, to $fa$; jupiter, to $ut$; saturn, to $re$; and the orb of the fixed stars, as being the highest of all, to $mi$, or the octave.

HARP, a musical instrument of the fising-kind, of a triangular figure, held upright between the legs of the person who plays upon it.

HARPIES, among the ancient poets, fabulous impure monsters, said to be the daughters of Neptune and Earth. Virgil mentions three of them, Aello, Ocy- pete, and Celeneo; they are described to be fowls, with the face of a virgin, bears ears, their bodies like vultures, and hands like their crooked talons.

HARPINEER, or Harponeer, the person who manages the harping-iron.

HARPSICHORD, the most harmonious of all the musical instruments of the fising-kind. It is played on after the manner of the organ, and is furnished with a set, and sometimes with two sets of keys; the touching or striking of these keys moves a kind of little jacks, which...
which also move a double row of chords or strings, of brass or iron, stretched over four bridges on the table of the instrument.

HARQUEBUS, a piece of fire-arms, of the length of a musket, usually cocked with a wheel. It carried a ball that weighed one ounce seven eighths.

There was also a larger fort, called the great harquebus, used for the defence of strong places, which carried a ball of about three ounces and a half; but they are now but little used, except in some old castles, and by the French in some of their garrisons.

HARRIER, a kind of hound, endowed with an admirable gift of smell, and very bold in the pursuit of his game.

HARROW, in agriculture. See Agriculture, p. 58.

HART, a flag, or male deer, in the fifth year. See Cervus.

HARTWORT, in botany. See Tordyllum.

HARVEST, the time or season that the corn is ripe, and fit to be reaped and taken into barns.

HARVICH, a borough and port-town of Essex, sixty-two miles north-east of London: E. long. 1° 25', N. lat. 52° 5'. It sends two members to parliament.

HASLEM, an island of Denmark, in the Catedge-lea, north of the island of Zealand.

HASLEMERE, a borough-town of Surry, thirty-eight miles south-west of London, and ten miles south-west of Guildford. It sends two members to parliament.

HASSELT, a town of Westphalia, in Germany, fifteen miles north-west of Maestricht.

HASSIDEANS, or ASSIDEANS, an appellation given to those Jews who returned to Mattathias, to fight for the law of God, and the liberties of their country.

HASSOCK, a hat made of rushes, to kneel or rest the feet upon in churches.

HASP and STAPE, in Scots law, the symbol commonly used in burgage tenements for entering and infesting an heir, by delivering into his hands the hapl and staple of the door. See Scots Law, title 27.

HASTA, among medallists, a kind of javelin, not shod or headed with iron; or rather an ancient sort of spear, longer than ordinary, occasionally given to all the gods.

HASTATED LEAF. See Botany, p. 639.

HASTINGS, a borough town of Sussex, situated on the coast of the English channel, fifty miles south-east of London: E. long. 56', and N. lat. 50° 50'.

HAT, a covering for the head, worn by the men in most parts of Europe. Those most in esteem are made of the pure hair of the cauffer or beaver; for they are also made of the hair or wool of divers other animals, and that by much the same process.

Method of making Hats. To make the beaver-hats, they tear off the long and short hair from the skin, with knives suitable to the occasion: after which they proportion the quantity of the several sorts of beaver-hair, by mixing one third of the dry cauffer to two thirds of old-coat, which is a term for a skin that has been worn some time by the Indians of America, who catch and sell them to the Europeans. The hair, so mixed, is carded and weighed out into parcels, according to the size and thickness of the hat intended. The stuff is now laid on the hurdle, with an instrument called a bow, resembling that of a violin, but larger; whose string being worked with a small bow-stick, and made to play on the furs, they fly, and mix themselves together, the dull and sift at the same time passing through the chinks. Instead of a bow, some hat-makers use a searce of hair, through which they pass the stuff. Thus hats are formed of an oval figure, ending with an acute angle at the top: with what stuff remains, they strengthen them where stiffer, yet defignify make them thicker in the brim near the crown, than towards the circumference, or in the crown itself. They next harden the stuff, so managed, into more compact flakes, by pressing down a hardened leather upon it. This done, they are carried to the bafon, upon which laying one of the hardened hats, they sprinkle it over with water, and mould it: and the heat of the fire, with the water and pressing, imbibe the stuff into a slight hairy sort of felt; after which, turning up the edges all round over the mould, they lay it by, and proceed with another; which being in like manner reduced to the same consistence and form, they are both joined together, so as to make them meet in an angle at top, making only one conical cap. The next process is to remove the hat to a trough, refumbling a mill-hopper, which is a copper kettle filled with water and grounds, kept hot for the purpose; and, after being dipped in the kettle, the hat is laid on the sloping side, called the plank. Here they proceed to work it, by rolling and unrolling it again.
HATCHING, the maturating fecundated eggs, whether
by the incubation and warmth of the parent-bird, or
by artificial heat, so as to produce young chickens
alive.

The art of hatching chickens by means of ovens has
long been practised in Egypt; but it is there only
known to the inhabitants of a single village named
Berme, and to those that live at a small distance from
it. Towards the beginning of autumn they scatter
themselves all over the country, where each person
among them is ready to undertake the management
of an oven, each of which is of a different size, but
in general they are capable of containing from forty to
fourscore thousand eggs. The number of these ovens
placed up and down the country is about three hundred
and eighty-six, and they usually keep them working
for about six months; as therefore each brood takes
up in an oven, as under a hen, only twenty-one days,
it is easy in every one of them to hatch eight different
broods of chickens. Every Bermean is under the
obligation of delivering to the person who instructs
him with an oven, only two thirds of as many chickens as
there have been eggs put under his care; and he is a
gainer by this bargain, as more than two thirds of the
eggs usually produce chickens. In order to make
a calculation of the number of chickens yearly so hatched
in Egypt, it has been supposed, that only two thirds
of the eggs are hatched, and that each brood consists
of at least thirty thousand chickens; and thus it would
appear, that the ovens of Egypt give life yearly to at
least ninety-two millions six hundred and forty thou-
fand of these animals.

This useful and advantageous method of hatching
eggs has been lately discovered in France, by the in-
genious Mr Reaumur, who, by a number of experi-
ments, has reduced the art to certain principles. He
found by experience that the heat necessary for this
purpose is nearly the same with that marked 32 on his
thermometer, or that marked 96 on Farenheit’s. This
degree of heat is nearly that of the skin of the hen,
and, what is remarkable, of the skin of all other do-
mestic fowls, and probably of all other kinds of birds.
The degree of heat which brings about the develop-
ment of the cygnet, the goosling, and the turkey-pout,
is the same as that which suits for hatching the canary-
fozgler, and, in all probability, the smallest humming
bird: the difference is only in the time during which
this heat ought to be communicated to the eggs of dif-
f erent birds: it will bring the canary bird to perfection
in eleven or twelve days, while the turkey-pout will
require twenty seven or twenty-eight.

After many experiments, Mr Reaumur found that
floses heated by means of a baker’s oven, succeeded
better than those made hot by layers of dung: and the
furnaces of glafs houses, and those of the melters
of metals, by means of pipes, to convey heat into a room,
might, no doubt, be made to answer the same purpose.
As to the form of the flozes, no great nicety is re-
quired; a chamber over an oven will do very well;
nothing more will be necessary but to ascertain the de-
gree of heat, which may be done by melting a lump of
butter, of the size of a walnut, with half as much tal-
low,
low, and putting it into a phial; this will serve to indicate the heat with sufficient exactness, for when it is too great, this mixture will become as liquid as oil, and when the heat is too small, it will remain fixed in a lump; but it will flow like a thick syrup, upon inclining the bottle, if the fmove be of a right temper: great attention therefore should be given to keep the heat always at this degree, by letting in fresh air, if it be too great, or shutting the fmove more close, if it be too small; and that all the eggs in the fmove may equally share the irregularities of the heat, it will be necessary to shift them from the fides to the centre; thereby imitating the hens, who are frequently seen to make use of their bills, to push to the outer parts those eggs that were nearest to the middle of their nets, and to bring into the middle such as lay nearest the fides.

Mr Reaumur has invented a fort of low boxes, without bottoms, and lined with furs. These, which he calls artificial parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, and put them under the wings of a hen. After hatching, it will be necessary to keep the chickens, for some time, in a room artfully heated and furnished with these boxes; but afterwards they may be safely exposed to the air in the court yard, in which it may not be amiss to place one of these artificial parents to shelter them if there should be occasion for it.

As to the manner of feeding the young brood, they are generally a whole day after being hatched, before they take any food at all; and then a few crumbs of bread may be given them for a day or two, after which they will begin to pick up insects and grubs for themselves.

But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr Reaumur assures us, that he has seen above two hundred chickens at once, all led about and defended only by three or four such capons. Nay, cocks may be taught to perform the same office, which, if not timely removed, will put it quite out.

HAY, any kind of grass, cut and dried, for the food of cattle.

receives the river Spree, near Berlin, and discharges itself into the Elbe, a little below Havelburg

HAVELBURG, a town of Germany, in the circle of Upper Saxony, and marchent of Brandenburg, subject to the king of Prussia: E. long. 42° 44', and N. lat. 53°.

and Liège, on the east; by the Cambresis, Picardy, and Champaign, on the south; and by Artois, and another part of Flanders, on the west: the north part is subject to the house of Austria, and the south part to France. Its capital is Mons.

HAYWARD, the person who keeps the common herd or cattle of a town.

HAZARD, a game on dice, without tables, is very properly so called; since it speedily makes a man, or undone him.

It is played with only two dice; and as many may play at it as can fland round the largest round table.

Two things are chiefly to be observed, viz. main and chance; the latter belonging to the caller, and the former, or main, to the other gamesters. There can be no main thrown above nine, nor under five; so that five, fix, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, fix to seven, seven to fix, eight to five; and mine and ten a chance to five, fix, seven, and eight: in short, four, five, six, seven, eight, nine, and ten, are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and ten. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five: and ames-ace and duce-ace, are out to all mains whatever.

HAZLE, in botany. See Corylus.

HAZLE earth, or Hazley earth, a kind of red loam, which is said to be an excellent mixture with other sorts of earth; uniting what is too loose, cooling what is too hot, and gently entertaining the moisture.

HEAD, in anatomy. See Anatomy, Part I. II &c.

HEADACH, a most troublesome sensation in the head, produced by various causes, and attended with different symptoms, according to its different degrees, and the place where it is seated. See Medicine.

Dragon’s Head, in astronomy, &c. is the ascending node of the moon, or other planet.

HEADFORD, a town of Galway, in Ireland, twelve miles north of the city of Galway.

HEALTH is a right disposition of the body, and of all its parts; consisting in a due temperature, a right conformation, just connection, and ready and free exercise of the several vital functions.

HEAM, in beasts, is the same with the secundines, or after-birth in women.

HEARING the sense whereby we perceive sounds.

The organ of hearing is the ear, and particularly the auditory nerve and membrane. See Anatomy, p. 295.

This membrane, in the various degrees of tension and relaxation, adapts itself to the several natures and states of sonorous bodies; becoming tense for the reception of acute sounds, and relaxed for the admission of grave sounds. In short, it is rendered tense and relaxed in a thousand different degrees, according to the various degrees of acuteness or gravity in sounds.

Sound, then, is in effect nothing but a certain modulation of the air, which being collected by the external ear, passes through the meatus auditorius, and beats upon the membrane of the tympanum, which moves the bones in the tympanum; these move the internal air, which finally communicates the motion to the auditory nerve, in the labyrinth and cochlea; and according as the vibrations are quick or slow, the sound is either acute or grave.

It deserves observation, that though the air be the usual matter of sounds; so that if a bell be hung in vacuo, it will not be heard at all; yet most other bodies, properly disposed, will do its office, only some more faintly than others. Thus a sound may be heard through water, or even through earth, of which there are various instances.

As the sight is assisted by spectacles, or other glasses; so the hearing is enlivened and rendered quick, by means of acoustical instruments; which are of various figures, but for the most part bear some resemblance to a trumpet, diverging and growing wider towards the external mouth.

HEARSE, among sportsmen, a kind of the second year of her age.

HEART, in anatomy. See Anatomy, p. 278.

Force of the Heart. Several ingenious persons have, from time to time, attempted to make estimates of the force of the blood in the heart and arteries; who have as widely differed from each other, as they have from the truth, for want of a sufficient number of data to argue upon. This set the truly ingenious Dr Hales upon making proper experiments, in order to ascertain the force of the blood in the veins and arteries of several animals.

If, according to Dr Keil’s estimate, the left ventricle of a man’s heart throw out in each systole an ounce of 1.638 cubic inches of blood, and the area of the orifice of the aorta be 0.4187, then dividing the former by this, the quotient 3.9 is the length of the cylinder of blood, which is formed in passing through the aorta in each systole of the ventricle; and in the seventy-five pulsations of a minute, a cylinder of 292.5 inches in length will pass: this is at the rate of 1462 feet in an hour. But the systole of the heart being performed in one third of this time, the velocity of the blood in that instant will be thrice as much, viz. at the rate of 4386 feet in an hour, or 73 feet in a minute. And if the ventricle throws out one ounce in a pulse, then in the seventy-five pulsations of a minute, the quantity of blood will be equal to 4.4 lb 11 oz. and, in thirty-four minutes, a quantity equal to a middle-sized man, viz. 158 lb, will pass through the heart. But if, with Dr Harvey and Dr Lower, we suppose two ounces of blood, that is, 3.276 cubic inches, to be thrown out at each systole of the ventricle, then the velocity of the blood in entering the orifice of the aorta, will be double the former, viz. at the rate of 146 feet in a minute, and a quantity of blood equal to the weight of a man’s body will pass in half the time, viz. 17 minutes.

If we suppose, what is probable, that the blood will rise 7.5 feet high in a tube fixed to the carotid artery
HEAT, in physiology, one of the secondary qualities of bodies, produced by fire, and opposed to cold.

Under the article fire, we considered the sun as the principal source of heat upon the earth's surface, and the confines of the earth and atmosphere: without this, all the bodies upon our globe would doubtless grow rigid, lifeless, and fixed. It is this that flirs within them, as the main spring of their actions. Hence vegetation and animalization are evidently promoted; and hence the ocean and the atmosphere continue in a fluid state.

Heat in us is properly a sensation, excited by the action of fire; or it is the effect of fire on our organs of feeling. Hence it follows, that what we call heat is a particular idea or modification of our own mind, and not any thing existing in that form in the body that occasions it. Heat, says Mr Locke, is no more in the fire that burns the finger, than pain is in the needle that pricks it. In effect, heat in the body that gives it, is only motion; and in the mind, only a particular idea.

Heat in the hot body, according to 'S Graveefande, is an agitation of the parts of the body, made by means of the fire contained in it: by such an agitation a motion is produced in our bodies, which excites the idea of heat in our mind; so that heat in respect of us is nothing but that idea, and in the hot body nothing but motion. If such motion expel the fire in right lines, it gives us the idea of light; if in a various and irregular motion, only heat.

Heat, with respect to our sensations, or the effect produced on us by a hot body, is estimated by its relation to the organ of feeling; no object appearing to be hot, unless its heat exceed that of our body. Whence the same thing to different persons, or at different times to the same person, shall appear both hot and cold. The degree of heat is measured by the expansion of the air, or spirit in the thermometer.
It has been justly observed, by some of our modern philosophers, that actual or absolute heat, is to sensible or relative heat, the same as motion is to velocity: for absolute heat is nothing but the whole motion of all the parts of the ignited body; and sensible or relative heat, respects only the comparative velocity of the parts. Thus, equal bulk of mercury and water set in a sand heat, where the heat of the fire may be uniformly communicated to both, will acquire in equal times equal degrees of absolute heat: but the relative heat of the water, or that which is sensible to the finger, will be near 14 times as great as that of the mercury, because the water, having 14 times a less quantity of matter, will admit of velocity so much in proportion greater.

Again, if mercury and water have the same relative or sensible heat, that is, if both are heated in such a manner as to cause an equal accent in the thermometer, then a quantity of mercury will heat 14 times as much water as the same quantity of water will do; or it will make the same quantity of cold water 14 times hotter than the same quantity of hot water can. All which is easy to be shown by experiment, and abundantly proves, that heat and fire are wholly owing to the velocity of the parts of the heated or ardent body; on which theory the various phenomena of heat, cold, fire, burning, &c. are rationally accounted for. For, first, we are to consider, that cold and heat are only comparative terms, or that the same thing may either be too hot, or too cold, according to the relative idea or standard-degreet. Thus, ice or snow is said to be cold with respect to the finger but ice or snow is warm if compared to a freezing mixture; so that (as we commonly do) we make the hand or any part of the body the standard of heat or cold, or the term of comparison; then it is evident, 1. If the parts of any body, applied to the hand, have the same velocity as the parts of the hand, such a body we naturally pronounce is neither hot nor cold. 2. If the particles of the body have a greater velocity than those of the hand, we pronounce it warm, if the excess be small; but hot, if it be great. 3. If the velocity of the parts of the body applied be less than that in the hand, the sensation then is what we call cold, which also may be in various degrees. 4. Hence it is plain, there can be no such thing as absolute cold, but where the particles of matter are absolutely quiescent or at rest. 5. Hence also, there can be no such thing as absolute heat, because no degree of velocity can be assigned but a greater is still attainable, till we come to infinity, where we are quite lost, as having no idea of infinite velocity or heat.

From this theory of heat and cold we may conclude, that there is no body in nature whose parts are not in motion, in some degree. Since we have yet been able to discover no ultimate degree or limit of cold; and if any such thing were to be found in nature, it is likely that it would be as impossible to bear or endure the teft, as any extreme degree of heat; both heat and cold naturally tending to destroy the animated part, or teft, in the extreme degrees: cold, by destroying the vital motion, and fixing the part rigid and inflexible; but heat, by putting the parts into too great an agitation, causing a greater velocity of the fluids, and diffipation and a force of tension in the foldis beyond what the natural state of the body can bear; and therefore it will inevitably destroy it.

Heat, in the animal economy, known by the several names of natural heat, vital heat, innate heat, and animal heat, is commonly supposed to be that generated by the attrition of the parts of the blood, occasioned by its circulatory motion, especially in the arteries.

To what organs or operations, the heat of the human body, and other animal bodies, is owing, is hitherto extremely doubtful. The opinions that at present prevail are, 1. That the heat of animal-bodies is owing to the attrition between the arteries and the blood. 2. That the lungs are the fountain of this heat. 3. That the attrition of the parts of the solids on one another produce it. 4. That it is owing to the mechanical attrition of the particles of our fluids. To which opinions Dr. Stevenfon of Edinburgh added a 5th, viz. That whole procès by which our aliment and juices are constantly undergoing some alteration.

The reasonings in favour of these several opinions may be seen at large, as laid down by the above-mentioned author in an essay on the cause of animal heat, in the Medical Essays, vol. vi. The chief arguments in favour of the first opinion, are, that if an artery is tied, or cut, the part to which it goes turns cold; and on the ceasing of the pulsation of the arteries, cold and death follow. An increase of heat attends a brisk circulation, and a languid circulation is accompanied with a small heat. One who burns in a fever, or is hot with exercise, has a full and frequent pulse. In cold faintings, chlorosis, &c. the pulse is small and flow. To these they add, that the thermometer shews the arterial blood to be a little hotter than that of the veins.

This is accounted for from the conical figure of the arteries, from their fluxes and branches into exquisitely small capillaries; whence the resistance, and consequently the attrition, must be great, from the number, strength, and elasticity of their coats, from the propelling power of the heart, and their strong resistance. From all these it is inferred, that the particles of blood perpetually getting new motions, directions, and rotations, are attenuated, condensed, have their angles grinded off, and are made homogeneous: hence, it is said, follows the fluidity, red colour, and heat of the maws, which is here perfected.

The second opinion is, that the lungs are the fountain of heat in the human body. All that has been said for the blood's being heated in the arteries is advanced to prove this hypothesis, with considerable additions, viz. that in the lungs the blood-veiss every where attend, divide, and subdivide, along with the ramifications of the wind-pipe; and as these are perpetually changing their situation and form, becoming longer or shorter, making more acute or more obtuse angles,
angles, so must the concomitant blood-vessels every moment make new angles, and give the blood new directions; that at last it enters into an exquisitely fine net-work, spreads everywhere on the vastly thin air-vessels, where these air-bladders are perpetually changing their angles, points of contact, their form, volume, interludes, and so forth. From these and the elasticity of the air, and weight of the atmosphere, the blood is said to be churned, pressed backward and forward, broken and kneaded together, diffolved and condened, made red and hot in respiration.

The third opinion is, that the cause of the animal heat is owing to the action of the solid parts upon one another. The reason in support of this opinion, is, that the heart and arteries move most; thence that it is natural to think, that the heat should be owing to this motion.

The fourth opinion is, the mechanical attrition of the particles of the fluids upon one another. Dr Stevenfon observes, that those who support this hypothesis, must not only suppose that mechanical attrition begets heat, but begets itself without diminution; that they must not only shew what sets this attrition agoing, but what maintains it, because all mechanical force perpetually decreases in a resisting medium; in short, that they must shew the possibility of a perpetuum mobile, the impossibility of which they themselves demonstrate.

The fifth opinion is, what Dr Stevenfon calls the animal process, or that process by which our aliment and fluids are perpetually undergoing some alteration. This process, according to that writer, may be one sui generis, somewhat of a middle nature between fermentation and putrefaction; and he thinks it comes so near to the latter, that he choos to call it by that name. In putrefaction, which is a most powerful dissolvent of bodies, the intelline action of their minute particles creates, collects, or some way or other is the cause of means of heat. The doctor thinks it probable that this process is constantly carried on in all our juices, especially where there is blood; and this is chiefly in the veins, so that the blood is both the fountain of heat and the first spring and motion. The late Dr Mortimer, in the Philof. Trans. no. 446. gives it as his opinion, that the heat of animals is explicable from the phosphorus and air they contain. Phosphorus exsifts, at least in a dormant state, in all our juices, especially where there is blood; and this is chiefly in the veins, so that the blood is both the fountain of heat and the first spring and motion.

The late Dr Mortimer, in the Philof. Trans. no. 446. gives it as his opinion, that the heat of animals is explicable from the phosphorus and air they contain. Phosphorus exsifts, at least in a dormant state, in all our juices, especially where there is blood; and this is chiefly in the veins, so that the blood is both the fountain of heat and the first spring and motion. The late Dr Mortimer, in the Philof. Trans. no. 446. gives it as his opinion, that the heat of animals is explicable from the phosphorus and air they contain. Phosphorus exsifts, at least in a dormant state, in all our juices, especially where there is blood; and this is chiefly in the veins, so that the blood is both the fountain of heat and the first spring and motion.

The Hebrews acknowledged three heavens: the first, the aerial heaven, in which the birds fly, the winds blow, and the showers are formed; the second, the firmament in which the stars are placed; the third, the heaven of heavens, the residence of the Almighty, and the abode of saints and angels.

Heaven is considered by Christian divines and philosophers, as a place in some remote part of infinite space, in which the omnipresent Deity is said to afford a nearer and more immediate view of himself, and a more sensible manifestation of his glory, than in the other parts of the universe. This is often called the empyrean, from that splendor with which it is supposed to be invested; and of this place the inspired writers give us the most noble and magnificent descriptions.

The pagans considered heaven as the residence only of the celestial gods, into which no mortals were admitted after death, unless they were deified. As for the souls of good men, they were consigned to the ely- sian fields. See Elysian fields.

HEBDOMARY, a solemnity of the ancient Greeks, in honour of Apollo, in which the Athenians sung hymns in honour of that god, and carried in their hands branches of laurel. The word signifies the seventh day, this solemnity being observed on the seventh day of every lunar month.

HEBENSTREIA, in botany, a genus of the didynamia angiofpermia class. The corolla is bilabiated; the capsule contains two seeds. There are two species, both natives of Ethiopia.

HEBRAISM, an idiom or manner of speaking peculiar to the Hebrew language. See the next article.

HEBREW, or Hebrew Language, that spoken by the ancient Jews, and wherein the Old Testament is wrote.

This appears to be the most ancient of all the languages in the world; at least we know of none older; and some learned men are of opinion, that this is the language in which God spoke to Adam in Paradise. The books of the Old Testament are the only pieces to be found, in all antiquity, written in pure Hebrew; and the language of many of these is extremely sublime; it appears perfectly regular, and particularly in its conjugations; indeed, properly speaking it has but one conjugation, but this is varied in each seven or eight different ways, which has the effect of so many different conjugations, and affords a great variety of expressions to represent by a single word the different modifications of a verb, and many ideas which in the modern and in many of the ancient and learned languages cannot be expressed without a peripherals.

The primitive words, which are called roots, have seldom more than three letters or two syllables.

In this language there are twenty two letters, only five of which are usually reckoned vowels, which are the same with ours, viz. a, e, i, o, u; but then each vowel is divided into two, a long and a short, the sound of the former being somewhat grave and long, and that of the latter short and acute: it must however be remarked, that the two last vowels have sounds that differ in other respects besides quantity, and a greater or less elevation. To these ten or twelve vowels may be added others called semi-vowels, which serve to connect the consonants, and to make the easier transitions from
HEDYSARUM, in botany, a genus of the diadelphia decandria class. The corolla is transversely carinated; and the pod is jointed, each joint containing one seed. There are 46 species, only one of which is a native of Britain. *viz.* the St Foin, or cocks-head.

HEEL, in anatomy. See Anatomy, *p. 185.*

HEELER, or *Bloody heel-cock,* a fighting cock that strikes or wounds much with his spurs.

The masters know such a cock, even while a chicken, by the striking of his two heels together in his going.

HEGIRA, in chronology, a celebrated epocha among the Mahometans.

The event which gave rise to this epocha was the flight of Mahomet from Mecca, with his new pro- lytes, to avoid the persecution of the Coraifchites; who, being then most powerful in the city, could not bear that Mahomet should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mahomet had commenced prophet: he retired to Medina, which he made the place of his residence.

HEIDELBURG, a city of Germany, in the circle of the lower Rhine, the capital of the Palatinate, situated on the river Neckar: *E.* long. 8° 40', and *N.* lat. 54° 30'.

HEILUSE, among hunters, a roe-buck of the fourth year.

HEINUSE, a female heir to one who has an estate in her own right. 

HEIR, in Scots law, a generic term applicable to those who are intitled by law to take the possessiion of any subjeft which belonged to a person deceased. — For the different kinds of heirs, *viz.* see Law, tit. 27 & 28.

HEIRESHIP moveables, in Scots law, the best of certain kinds of moveables, which the heir of line is intitled to take, besides the heritable estate. See Law, *tit. 27.*

HEIR-apparent, is a person so called in the lifetime of his ancestor, at whose death he is heir at law.

HEIRESS, a female heir to one who has an estate in land, *et.* Stealing an heiress, and marrying her against her will, was declared felony by 3 Hen. VII.

HELENA, or St Helena, an island in the Atlantic ocean, situated 1200 miles west of the coast of Africa, and 1800 east of the coast of South America: *W.* long. 6° 30', *S.* lat. 16°.

HELENIUM, in botany, a genus of the syngenefia class. The receptacle is naked; the calix is simple, and consists of many leaves; and the corollula of the radius is semitrifid. There is but one species, a native of Auffria.
HELIEA, in Grecian antiquity, was the greatest and most frequented court in Athens for the trial of civil affairs. The judges who sat in it were at least fifty, but the more usual number was either two or five hundred. When causes of great moment were to be tried, it was customary to call the judges of the other courts sometimes a thousand were called in, and then two courts are said to have been joined; sometimes fifteen hundred or two thousand were called in, and then three or four courts met together.

They had cognizance of civil affairs of the greatest weight and importance, and were not permitted to give judgment till they had taken a solemn oath to do it with impartiality, and to give sentence according to the laws.

HELACAL, in astronomy, a term applied to the rising or setting of the stars; or, more strictly speaking, to their emersion out of, and immersion into, the rays and superior splendor of the sun.

A star is said to rise heliacally, when after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him, as to be seen in the morning before sun-rising; the sun, by his apparent motion, receding from the star towards the east; on the contrary, the heliacal setting is when the sun approaches so near a star, as to hide it with his beams, which prevent the fainter light of the star from being perceived; so that the terms apparition and occultation would be more proper than rising and setting.

HELIANTHEMUM, in botany, see the article Cistus.

HELIANTHUS, the Great Sun-flower, in botany, a genus of the Syngenesia Polygonia fruticans class. The receptacle is paleaceous and plane; the pappus consists of two leaves; and the calyx is imbricated and squarrous. There are twelve species, none of them natives of Britain.

HELIASTES, in antiquity, one of the judges of the court heliaea. See Heliæa.

HELICTERES, the Serev-Tree, in botany, a genus of the gymnandra digynia class. It has five styli; the calyx consists of one oblique leaf; the petals are five; the nectarium consists of five small leaves; and it has five twisted capsules. There are four species, none of them natives of Britain.

HELIANTHA, in botany, a genus of the dodecanthus class. The receptacle is paleaceous and plane; the pappus consists of two leaves; and the calyx is imbricated and squarrous. There are twelve species, none of them natives of America.

HELIARUM, in botany, a genus of the dodecanthus digynia class. The calyx consists of four leaves; the petals are four; the styli are simple; and the capsule consists of two compressed cells, radiated on each side. There is but one species, a native of America.

HELIACENTRIC latitude of a planet, the inclination of a line drawn between the centre of the sun and the center of a planet, to the plane of the ecliptic.

HELIACENTRIC place of a planet, in astronomy, the place of the ecliptic wherein the planet would appear to a spectator placed at the centre of the sun.

HELIOMETES, a phenomenon sometimes observed about sun setting; being a large luminous tail or column of light, proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

HELIOSCOPE, in optics, a sort of telescope, peculiarly fitted for viewing the sun without hurting the eyes.

HELIOSTATA, in optics, an instrument invented by the late learned Dr S. Gravefande; who gave it this name, from its fixing, as it were, the rays of the sun in an horizontal direction across the dark chamber all the while it is in use.

HELIUM, in anatomy. See Anatomy, p. 298.

HELIX, in zoology, a genus belonging to the order of vermes Tectaceae. It is an animal of the snail-kind; the shell consists of one spiral, brittle, and almost diaphanous valve; and the aperture is narrow. There are 60 species, principally distinguished by the figure of their shells.

HELL, the place of diving punishment after death.

As all religions have suppos'd a future state of existence after this life; so all have their hell or place of torment, in which the wicked are supposed to be punished. The hell of the ancient heathens was divided into two mansions; the one called elysium, on the right hand, pleasant and delightful, appointed for the souls of good men; the other called tartara, on the left, a region of misery and torment, appointed for the wicked. The latter only was hell in the present reigned sense of the word. See Elysium.

The philosophers were of opinion, that the infernal regions were at an equal distance from all the parts of the earth; nevertheless it was the opinion of some, that there were certain passages which led thither, as the river Lethe near the Syrtis, and the Acherusian cave in Epirus. At Hermione it was thought, that there was a very short way to hell; for which reason the people of that country never put the fare into the mouths of the dead to pay their passage.

The Jews placed hell in the centre of the earth, and believed it to be situated under waters and mountains. According to them, there are three passages leading to it: the first is in the wilderness, and by that Korah, Dathan and Abiram descended into hell; the second is in the sea, because Jonah, who was thrown into the sea, cried to God out of the belly of hell; the third is in Jerusalem, because it is said the fire of the Lord is in Zion, and his furnace is in Jerusalem. They likewise acknowledged seven degrees of pain in hell, because they find this place called by seven different names in Scripture. Though they believed that infidels, and perfons eminently wicked, will continue for ever in hell; yet they maintained, that every Jew who is not infected with some hereASY, and has not acted contrary to the points mentioned by the rabbins, will not be punished therein for any other crimes above a year at most.

The Mahometans believe the eternity of rewards and punishments in another life. In the Koran it is said, that hell has seven gates, the first for the Mufullmans, the second for the Chriftians, the third for the Jews, the fourth for the Sabians, the fifth for the Magians, the
the sixth for the pagans, and the seventh for the hypocrites of all religions.

Among Christians, there are two controverted questions in regard to hell; the one concerns locality, the other the duration of its torments. The locality of hell, and the reality of its fire, began first to be controverted by Origen. That father, interpreting the scripture account metaphorically, makes hell to consist not in external punishments, but in a conscientious or sense of guilt, and a remembrance of past pleasures. Among the moderns, Mr Whiston advanced a new hypothesis. According to him, the comets are so many hells appointed in their orbits alternately to carry the damned into the confines of the sun, there to be scorched by its violent heat, and then to return with them beyond the orbit of Saturn, there to starve them in these cold and dismal regions. Another modern author, not satisfied with any hypothesis hitherto advanced, assigns the sun to be the local hell. As to the second question, viz. the duration of hell torments, we have Origen again at the head of those who deny that they are eternal; it being that father's opinion, that not only men, but devils, after a due course of punishment suitable to their respective crimes, shall be pardoned and reformed to heaven. The chief principle upon which Origen built his opinion, was the nature of punishment, which he took to be emendatory, applied only as phylic for the recovery of the patient's health. The chief objection to the eternity of hell torments among modern writers, is the disproportion between temporary crimes and eternal punishments. Those who maintain the affirmative, ground their opinions on scripture accounts, which represent the pains of hell under the figure of a worm which never dies, and a fire which is not quenched; as also upon the words, "These shall go away into everlasting punishment, but "the righteous into life eternal.

HELLEBORUS, hellebore, in botany, a genus of the polyandria polygyna class. It has no calix; the petals are five or more; the nectarium is tubular and bilabiated; and the capsule contains many seeds. There are five species, two of them natives of Britain, viz. the satidus, or great bastard black hellebore; and the viridis, or wild black hellebore. The hellebore, when taken in large quantities, is poisonous; but the root, in small doses, is supposed to attenuate the humours, and to promote urinary and uterine discharges.

HELENISM, in matters of language, a phrase in the idiom, genius, or construction of the Greek tongue. This word is only used when speaking of the authors who, writing in a different language, express themselves in a phraseology peculiar to the Greek.

HELENISTIC, or Hellenistic language, that used by the Grecian Jews who lived in Egypt and other parts where the Greek tongue prevailed. In this language it is said the Septuagint was written, and also the books of the New Testament; and that it was thus denominated to shew that it was Greek filled with Hebrews and Syriacisms.

HELLESPONT, the entrance of the straits which divides Asia from Europe, and passes from the Archipelago to Constantinople. It is now called the Dardanelles, and is about two miles wide.

HELM of a ship, is a piece of timber fastened into the rudder, which comes forward into the steerage, or place where the person at the helm steers the ship, by holding the whipstaff in his hand, which is joined to the helm. They begin however to be left off, steering-helm and rudder, being used in their room.

There are several terms in the sea-language relating to the helm; as, bear up the helm; that is, let the ship go more large before the wind. Helm a mid-ship, or right the helm; that is, keep it even with the middle of the ship. Port the helm, put it over the left side of the ship. Starboard the helm, put it on the right side of the ship.

HELMET, an ancient defensive armour worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor.

HELMINTHOLITHUS, in natural history, a name given by Linnaeus to petrified bodies resembling worms. Of these he reckons four genera. 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes. 4. Petrified reptiles.

HELMONT, a town of the Netherlands, in the province of Dutch Brabant, situated on the river Aa: E. long. 5° 40', N. lat. 51° 30'.

HELMSTAT, a town of Germany, in the circle of Lower Saxony, and dukedom of Brunswick: E. long. 11° 15', N. lat. 52° 20'.

HELOTS, in Grecian antiquity, the inhabitants of Helos, a town of Laconia, conquered by the Spartans; who made them all prisoners of war, and reduced them into the condition of slaves.

The freemen of Sparta were forbidden the exercise of any mean or mechanical employment, and therefore the whole care of supplying the city with necessaries devolved upon the Helots.

HELSINGFORD, a port-town of Sweden, situated on the gulph of Finland, in 24° 6' E. long. and 60° 8' N. lat.

HELSINGIA, a province of Sweden, bounded by the Bothnic gulph on the east, and by Dalecarlia on the west.

HELSINGIC character, a peculiar kind of character, found inscribed on stones in the province of Helsingia: the Runic and Helsingic characters may be easily transformed into each other.

HELSTON, a borough of Cornwall, nine miles south-west of Falmouth; it sends two members to parliament.

HELVOETSLUYS, a port-town of the united Netherlands, situated in the island of Voorn, in the province of Holland, five miles south of the Briel: it is one of the best harbours in Holland, and that to which the English packet always goes.

HEMEROBIUS, in zoology, a genus of insects of the neuroptera order, the characters of which are these: The mouth is furnished with two teeth; the palpi are four; the wings are deflected, but not plaited; and the
the antennae are briskly and longer than the breast. There are 15 species, principally distinguished by their colours.

Hemerocallis, Day-lily, in botany, a genus of the hexandria-monogynia class. The corolla is bell-shaped, with a cylindrical tube; and the stamens are dehiscent. There are two species, none of them natives of Britain.

Hemi, a word used in the composition of divers terms, signifying the same with semi, or demi, *viz.* one half.

Hemina, in Roman antiquity, a liquid measure which, according to Arbuthnot, was equal to half a wine-pint English measure; its contents being 2.818 solid inches.

Hemionitis, in botany, a genus of the cryptogamia class. The parts of fructification lie in decussating lines. There are three species, none of them natives of Britain.

Hemiplegia, or Hemiplexia, among physicians, a palsy of one half of the body.

Hemisphere, in geometry, the half of a globe or sphere, when it is supposed to be cut through its centre in the plane of one of its great circles.

Hemisphere is also used to denote a projection of half the terrestrial globe, or half the celestial sphere, on a plane, and frequently called planisphere.

Hemistiche in poetry, denotes half a verse, or a verse not completed.

Hemitritaeus, among physicians, a kind of intermittant fever, being a semiterian. See Medicine.

Hemlock, in botany. See Cicuta.

Hemp, in botany. See Cannabis.

The raising and dressing of hemp scarcely differs from the raising and dressing of flax, but in the following particulars.

Hemp requires a light, free, dry, dusty, and even a sandy warm soil; which if not naturally rich, must be made so by manure. New broke up ground does not answer for hemp, producing it thin and poor upon the stalk. Hemp does well to follow beans. The ground should be ploughed and harrowed three or four times, a fortnight or three weeks intervening between each time. In some parts of Lincoln and Holland the soil is naturally so free and rich, that it will produce hemp confantly year after year without manure. The leaves which fall off the stalk help to manure the ground. It is frequently sown with a view to clear the ground of weeds; which it does most effectually, growing tall, and soon checking every weed but mugwort, which is picked out with a fork.

It is sown about the first of May; so thin, that about four pecks are sufficient for an English acre; and the ground must then be covered as much as possible to preserve the seed from the birds, who are very fond of it.

The taper-topped stalk which does not bear the pods, is called the female, though in fact it is the male, flowering from its bloom a small duff, which impregnates the pods of the bushy-topped; which last is commonly, though improperly, called the male or carle hemp.

When hemp is the object of the farmer more than a crop of seed, the whole should be pulled when the stalk begins to grow yellow, and the earth remaining about the roots should be beat off to prevent more growth; but if the seed is wanted in its greatest perfection, the stalks bearing the pods must be pulled before the uppermost pod begins to open; the earth should not be beat off from the roots; it should be fooked in the leaves upon the field, to dry and win as corn; and the top of these stalks should be covered with undergrowth, or the like, to preserve the seed from the birds.

Hemp is sooner watered than flax, and the canals must be deeper.

In keeping the seed, care must be taken to preserve it from rats, mice, and such like vermin, who are all fond of it.

It's dressed as coarse flax, but is sooner dressed; and its greater length requires more care, and renders it more troublesome in the handling, especially in the skutching of it by the water lint-mills with horizontal skutchers, when it must be folded double. What is too coarse and strong in the stalk for the hand or foot machines, may be broke and peeled by the hand.

See Flax:

Hempstead, a market-town of Hartfordshire, twenty-four miles north-west of London.

Hen, in ornithology. See Phasianus.

Hen-bane. See Hyoscyamus.

Hendecagon, in geometry, a figure that hath eleven sides and as many angles.

Henley, a market-town of Oxfordshire, situated on the river Thames, twenty miles south-east of Oxford, and thirty-two miles west of London.

Henneburg, a town of Germany, in the circle of Franconia, and the capital of the county of Henneburg: E. long 10° 27', and N. lat. 50° 40'.

Henoticon, in church-history, a decree or edict of the emperor Zeno, made at Constantinople, in the year 482, by which he pretended to reconcile all parties under one faith. It is generally agreed that Peter, patriarch of Alexandria, and Acacius, patriarch of Constantinople, were the authors of this decree, and that their design was to compliment the emperor with a right of prescribing regulations in matters of faith. The emperor, by this decree, arrogated to himself the right of being head of the church. Pope Simplicius, however, in the year 483, condemned the henoticon, and cited Acacius, the chief promoter of it, to appear before him at Rome; but it was not entirely suppressed till the year 518.

Henrico, a county of the colony of Virginia, in North America.

Henry, or Cape-henry, the south cape of Virginia, at the entrance of Chesapeake-bay: W. long. 74° 50', N. lat. 37°.

Heptasulphuris, or Liver of Sulphur. See Chemistry.

Hepatic, in medicine and anatomy, any thing belonging to the liver.

Hepatica, in botany. See Anemone.

Hepatitis, in medicine. See Medicine.
HERALD, an officer at arms, whose business it is to declare war, to proclaim peace, to marshal all the solemnities at the coronation, christening, marriage, and funeral of princes, to blazon and examine coats of arms, &c.

HERCINIAN,
HERCINIAN FOREST, a forest which anciently extended the whole length of Germany and Bohemia, some remains of which are still in being, viz. the Black Forest, Odenwald near Heidelberg, Stigewald in Wurtzburg, and Hartswald in Brunswick.

HERCOLE, a port-town of Tuscany, on the coast called Stato del Presidii: E. lon. 24°, N. lat. 46° 32'.

HERCULES, in astronomy. See Astronomy, p. 486.

HERCULES-PILLARS, in antiquity, a name given to mount Calpe in Spain, near Gibraltar, on the European side of the straits, and mount Avila on the African side.

HEREDITAMENTS, whatever immovable things a person may have to himself and his heirs by way of inheritance; and which, if not otherwise bequeathed, descend to him who is next heir, and not to the executor, as chattels do.

HEREDITARY, an appellation given to whatever belongs to a family by right of succession, from heir to heir.

HEREDITAS JACENS, in Scots law. An estate is said to be in hereditate jacente, after the proprietor's death, till the heir's entry.

HEREFORD, the principal city of Herefordshire, situated on the river Wye, twenty-four miles north-west of Glocefter, and one hundred and twenty west of London: W. lon. 2° 42', and N. lat. 52° 6'.

It sends two members to parliament.

HEREFY, the crime of obstinately persisting in opinions that are contrary to the fundamentals of religion.

HEREITABLE RIGHTS, in Scots law, all rights affecting land, houses, &c. or any immovable subject. See Law, tit. 9.

HEREITAGE, in Scots law, lands, houses, &c. or any immovable subject, in contradistinction to moveables or moveable subjects. See Law, tit. 9. It also sometimes signifies such immovable property as a person succeeds to as heir to another, in contradistinction to that which he himself purchases or acquires in any other manner, called conquet. See Law, tit. 27.

HEREITIC, a general name for all such persons, under any religion, but especially the Christian, as professors or teach religious opinions contrary to the established faith, or to what is made the standard of orthodoxy.

HERLING, a market-town of Norfolk, twenty miles south-west of Norwich.

HERMÆ, among antiquarians, statues of the god Mercury, made of marble, and sometimes of brass, without arms or feet, and set up by the Greeks and Romans in the crofs ways.

HERMÆA, in antiquity, ancient Greek festivals, in honour of the god Hermes or Mercury.

HERMANIA, in botany, a genus of the monadelphian pentaandria class. It has but one stylum; the capsule has five cells; and the petals are semitubular at the base. There are nine species, none of them natives of Britain.

HERMANSTAT, the capital city of Transylvania, subject to the house of Austria: E. lon. 24°, N. lat. 46° 32'.

HERMAPHRODITE, a person of both sexes, or who has the parts of generation both of male and female.

It is now generally allowed, that there is no such thing as a true hermaphrodite; nofif, if not all those who pass for such, being mere women, whose cliitoris is grown to an enormous size, and the labia pudendi become unusually tumid.

Among the insect-clas of animals, indeed, hermaphrodites are very frequent: such as worms, snails, leeches, &c.

HERMAPHRODITE FLOWERS, among botanists. See Botany.

HERMATHENA, among antiquarians, a statue representing Mercury and Minerva both in one.

HERMES. See HERMA.

HERMETIC, or HERMETICAL, an appellation given to whatever belongs to chemistry, from Hermes Trismegistus, who is supposed to have been its inventor.

HERMATIC PHILosophY, that which undertakes to solve the various phenomena of nature, from the chemical principles salt, sulphur, and mercury.

HERMETICAL SEAL, among chemists, a method of stopping glafs-vessels, used in chemical operations, so closely, that the most subtil spirit cannot escape through them.

It is commonly done by heating the neck of the vessel in a flame, till ready to melt, and then twirling it closely together with a pair of pincers. Or, vessels may be hermetically sealed, by stopping them with a glass plug, well luted; or, by covering the vessel with another ovum philosophicum.

HERMIT, a devout person retired into solitude to be more at leisure for contemplation, and to disencumber himself from the affairs of the world.

HERMON, a mountain on the east of Syria and Palestine, in Asia.

HERNANDIA, in botany, a genus of the monoecá triandria class. The calix of the male has three segments, and the corolla three petals. The calix of the female is entire and truncated; the corolla consists of six petals; and the drupa is hollow, with an open mouth, and a loose kernel. There are two species, both natives of the Indies.

HERNGRUNT, a town of Upper Hungary, situated north of Buda, near the Carpathian mountains: E. lon. 10° 20' lat. 48° 47'.

HERNIA, in medicine. See Medicine and Surgery.

HERNIARIA, rupture-wort, in botany, a genus of the pentandria digynia class. The calix of the male has five segments; it has no corolla; and the capsule contains one seed. There are four species, three of them natives of Britain, viz. the glabra, or smooth rupture-wort; the hirfuta, or rough rupture-wort; and the lenticulata, or sea rupture-wort. The leaves may be used as a mild refrigerent; but have no title to their former reputation of curing ruptures.

HERO, in the ancient mythology, a great and illustrious person, of mortal nature, though supposed by the populace
lace to partake of immortality; and, after his death, placed among the number of the gods.

HEROIC POEM, that which describes some extraordinary enterprise; being the fame with epic poem. See Composition.

HEROIC VERSE, that wherein heroic poems are usually composed; or it is that proper for such poems. In the Greek and Latin, hexameter verses are usually denominated heroic verses, as being alone used by Homer, Virgil, etc.

HERON, in ornithology. See Ardea.

HERPES, in medicine, a bilious putule, which breaking out in different manners upon the skin, accordingly receives different denominations. See Medicine.

HERRING, in ichthyology. See Clupea.

HERON, in ornithology. See Ardea.

HETEROCLITE, among grammarians, one of the three dimensions in irregular nouns, and defined by Mr Rudiman, a noun that varies in declension; as, hoc est, ade ; hae est, adesturum.

HETERODOX, in polemical theology, any thing contrary to the faith and doctrines of a church.

HETEROCLITE, among grammarians, one of the three dimensions in irregular nouns, and defined by Mr Rudiman, a noun that varies in declension; as, hoc est, ade ; hae est, adesturum.

HETEROCLES, or HETEROGENEOUS, something that consists of parts of dissimilar kinds, in opposition to homogeneous.

HETEROSCHI, in geography, a term of relation, denoting such inhabitants of the earth as have their shadows falling but one way, as those who live between the tropics and polar circles, whose shadows at noon in north latitude are always to the northward, and in south latitude to the southward.

HEUCHERA, in botany, a genus of the pentandria di-gynia class. The petals are five; and the capsule has a double beak, and two cells. There is but one species, a native of Virginia.

HEXACHORD, in ancient music, a concord called by the moderns a sixth.

HEXAGON, in geometry, a figure of six sides and angles; and if these sides and angles be equal, it is called a regular hexagon. See Geometry.

HEXAHEDRON, in geometry, one of the five Platonic bodies, or regular solids; being the same with a cube.

HEXAMETER, carmen hexametrium, in ancient poetry, a kind of verse consisting of six feet; the first four of which may be indifferently either spondees or dactyls, the fifth is generally a dactyl, and the sixth always a spondee. Such is the following verse of Homer:

```
1 2 3 4 5 6
```

AUT prodeles volunt, aut delebras poetae.

HEXANDRIA, in botany. See Botany, p. 635.

HEXASTYLE, in architecture, a building with six columns in front.

HEXHAM, a market-town of Northumberland, sixteen miles west of Newcastle.

HEYDON, a borough town in Yorkshire, thirty-seven miles east of York, and six miles west of Hull.

HEYTSBURY, a borough town of Wiltshire, fourteen miles north of Salisbury, sends two members to parliament.

HIATICULA, in ornithology. See Charadrius.

HIATUS, properly signifies an opening, chasm, or gap; but it is particularly applied to those verses, where one word ends with a vowel, and the following word begins but it is particularly applied to thofe verfes, where one word ends with a vowel, and the following word begins with one, and thereby occasions the mouth to be more open, and the foun to be very harsh.

The term hiatus is alfo used in speaking of manuscripts, to denote their defects, of the parts that have been lost or effaced.

HIBISCUS, in botany, a genus of the monadelphia class. The calix is double; the exterior one consists of many leaves; the capule has five cells, and contains many seeds. There are twenty-five species, none of them natives of Britain.

HICCUP, or Hiccough, in medicine, a spasmodic affection of the stomach and diaphragm, arising from anything that irritates and vellicates their nervous coats. See Medicine.

HIDE, the skin of beasts, but particularly applied to those of large cattle, as bullocks, cows, horses. See Tanning.

HIDES are either raw or green, just as taken off the carcass; salted or seafoned with salt, alum, and tallow, to prevent their spoiling; or cured and tanned. See Tanning.

HIDE of land, was such a quantity of land as might be plowed with one plough within the compass of a year, or so much as would maintain a family; some...
call it sixty, some eighty, and some an hundred acres.

Hide-bound. See Farriery, p. 563.

Hierachium, hawkweed, in botany, genus of the fyngefnnea polygamy æquills clas. The receptacle is naked; the calix is oval and imbricated; and the pappus is simple and feffile. There are 28 species, 8 of them natives of Britain. The leaves of the pilofella, or common creeping mouse-ear, are recommend-
ed as astringents.

Hieracites, in church-hiftory, Chriftian heretics in the third century, so called from their leader Hierax, a philosopher of Egypt; who taught that Melchifedek was the Holy Ghofi, denied the refurreftion, and con-
demned marriage.

Hierarchy, among divines, denotes the subordina-
tion of angels.

Some of the rabbins reckon four, others ten, orders or ranks of angels; and give them different names, according to their different degrees of power and know-
ledge.

Hierarchy likewise denotes the subordination of the clergy, ecclefiafical polity, or the conftitution and go-

dernment of the Chriftian church confidered as a fo-
ciety.

Hieroglyphics, in antiquity, myftical characters, or symbols, in ufe among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and me-

canical instruments.

But besides the hieroglyphics in common ufe among

the people, the priests had certain myftical characters, in which they wrapped up and concealed their doc-

trines from the vulgar. It is faid, that these some-
things resembled the Chinefe characters, and that

they were the invention of Hermes. Sir John Mar-

fham conjectures, that the ufe of these hieroglyphi-
fical figures of animals introduced the strange wor-

ship paid them by that nation: for as these figures were made choice of, according to the refpective qualities of each animal, to exprefs the qualities and dignity of the perons reprefted by them, who were generally

their gods, princes and great men, and being placed in their temples, as the images of their deities; hence

they came to pay a superflitious veneration to the ani-

mals themselves.

The meaning of a few of these hieroglyphics, has

been refurred by ancient writers. Thus we are told

they reprefted the supreme Deity by a ferpent with

the head of a hawk. The hawk itself was the hiero-

glyphic of Obris; the river-horfe, of Typhon; the
dog, of Mercury; the cat, of the moon, or Diana; the

beetle, of a Courageous warrior; a new-born child, of

the rifing fun; and the like.

Hierogrammatists, i.e. holy registers, were an

order of priests among the ancient Egyptians, who

professed over learning and religion.

They had the care of the hieroglyphics, and were

the expofitors of religious doctrines and opinions. They were looked upon as a kind of prophets, and it is pre-
tended that one of them predicted to an Egyptian king, that an Israelite, (meaning Mofes) eminent for his qualifications and achievements, would leffen and de-
prefs the Egyptian monarchy.

Hieromancy, in antiquity, that part of divination which predicted future events from observing the various things offered in sacrilice. See Divination and Sacrifice.

Hieronymon, the name of an officer in the Greek church, whose principal function it was to stand behind the patriarch at the facraments and other ceremonies of the church, and to shew him the prayers, psalms, &c. in the order in which they were to be reheard.

Hierophantes, in Grecian antiquity, the name by which the Athenians called those priests and priestefles who were appointed by the flate to have the supervifal things sacred, and to take care of the sacrilices.

Hierophylax, an officer in the Greek church, who

was guardian or keeper of the holy utenfils, veftments, &c. answering to our sacrifia or veftry-keeper.

High way, a free paflage for the king's fubjeets, on

which account it is called the king's high-way, tho'

the freehold of the foil belong to the owner of the land. Thofe ways that lead from one town to an-
other, and fuch as are drift or cart-ways, and are for all travellers in great roads, or that communicate with them, are high-ways only; and as to their reparation, are under the care of surveyors.

Higham Ferrers, a borough town of Northam-
ptonshire, twelve miles north-east of Northampton : it fends two members to parliament.

Highness, a title given to princes. Before king

James I. the kings of England had no other title but that of highnefs; which was also the cafe of the kings of Spain before Charles V.

At prefent all the sons of crowned heads are styled

royal highnefses, as the electors of Germany are elec-
toral highnefses.

Highworth, or Higworth, a market-town of Wilts-
fhire, fiated thirty miles north of Salisbury.

Hilaria, an ancient Roman festival, obferved on the eighth of the calends of April, or the twenty-fifth day of March, in honour of the goddess Cybele. It was fo called from the various exprefions of joy and mirth on this ocation.

Hilarodi, in the ancient music and poetry, a fort of

poets among the Greeks, who went about finging little gay poems or fongs, somewhat graver than the Ionic pieces, accompanied with fome instrument. From the streets they were at length introduced into tragedy, as the magodi were into comedy. They appeared
dressed in white, and were crowned with gold. At first they wore shoes, but afterwards they aumned the crepita, being only a fole tied over with a ftrap.

Hilary-termin. See Term.

Hildesheim, the capital of a bifhopric, surrounded

by the territories of Brunfwic, and subjeft to its own bifhop: E. long. 10°, N. lat. 52° 17'.

Hilum, among botanifis, denotes the eye of a bean.

Hin, a hebrew meafure of capacity for things liquid, con-
taining the fixth part of an ephah, or one gallon two

pints, or 2.533 solid inches, English meafure.

Hind,
Hind, a female flag in the third year of its age. See Cervus.

Hindon, a borough town of Wilshire, situated fourteen miles west of Salisbury; it sends two members to parliament.

Hindon, the capital of the country of the Hindouns, in the hither India: E. long 76° 30', N. lat 27°.

Hine, or HInD, a husbandman's servant. Thus the best description hitherto given of him is that of a male.

Hindstone, is far from being sufficiently delineated. The sthree figures. Their teeth are of such a hard substance, firmly set, of an equal length and breadth, and are somewhat more than two inches; each toe is furnished with a claw, and each foot with four toes. The tail is about one foot long, more than a foot in circumference near the origin, and about 3 inches near the point. The tail is not round, but flatish. The head, from the extremity of the lips to the neck, is about 2 feet 4 inches, and the circumference 5 feet 8 inches. The ears are about 3 inches long, and nearly as broad; they are a little pointed, and covered in the interior side with short white hair. The mouth, when open, is about 1 foot wide, and furnished with 44 teeth of different figures. Their teeth are of such a hard substance, that they give fire with steel. These dimensions are taken from a female hippopotamus; but the male is generally about one third larger.

With such powerful arms, and such a prodigious strength of body, the hippopotamus might render himself formidable to every other animal. But he is naturally a mild disposition; and besides, his body is so heavy, and his motions so slow, that he cannot overtake any other quadruped. He swims swifter than he runs, and preys upon fishes. He dives in the water, and can stay very long under. He has no membrane between his toes, as the caffer or the otter; and he only swims easily in consequence of the great bulk of his belly, which makes him nearly of an equal specific gravity with the water. Moreover, he often keeps himself at the bottom, and walks upon the channel with the same freedom as upon dry land. Besides preying upon fishes, crocodiles, &c., he frequently goes out of the water and feeds upon sugar-canies, rufts, millet, rice, roots, &c. Thence he devours in large quantities, and often does great damage in the cultivated field. But as he is more timid on land than in the water, he is easily driven away. His legs are so short, that he cannot escape by flight when at a distance from the river. He generally flies when approached by people in boats; but, if they wound him, he returns with fury, attacks the boats with his teeth, and frequently over-turns them.

This animal seems to be confined principally to the rivers.
HIPPURIS, in botany, a genus of the monandria mono
gynia class. It has neither calix nor corolla; the
stigma is simple; and there is but one seed. There
is only one species, viz. the vulgaris, a native of Brit-
tain.

HIPPURIS, in ichthyology. See Coryphena.

HISTORY, a description or recital of things as they are,
or have been, in a continued orderly narration of the
principal facts and circumstances thereof.

HISTORIOGRAPHER, a professed historian, or writer
of history.

HISTORICAL, of history, with regard to its subject, is
divided into the history of Nature. (See Nat. Hist.) and the hi-
story of Actions. The history of Actions is a conti-
nued relation of a series of memorable events.

HISTRIUM, in the ancient drama, signified an actor or
comedian, but more especially a pantomime, who ex-
hibited his part by gestures and dancing.

HOG, in zoology. See Sus.

HOGSHEAD, in commerce, a measure of capacity, con-
taining sixty-three gallons.

HOGSKIN, a kind of leather made from the skin of a
hog.

HOGSKIN, a term used in the furniture trade for
embracing all kinds of leather, especially for
upholstery purposes.

HOLCUIT, in botany, a genus of the polygamia moncecia
class. The calix is divided into five parts; the
petals are five, and equal; the filaments are spiral,
and the stigmas lateral. There is but one species, a
native of Brazil.

HOLCUS, in botany, a genus of the tr'andria mon-
gynia class. The calix is divided into five parts; the
petals are five, and equal; the stigmas are spiral,
and the stigmas lateral. There is but one species, a
native of Brazil.

HOLCUS, in botany, a genus of the polygamia moncecia
class. The calix is divided into five parts; the
petals are five, and equal; the filaments are spiral,
and the stigmas lateral. There is but one species, a
native of Brazil.

HOLLAND, a city of Germany, in the circle of
Holland, in commerce, a fine and close kind of
linen.

HOLLAND, one of the United Provinces. It is about
one hundred miles long from north to south, and
scarce thirty miles broad: but enjoys the greatest trade of
any province in the world, and in point of strength and
riches is equal to the other six United Provinces. It
is situated one hundred miles east of England, and is
bounded on the north and west by the German sea, on
the east by the Zuider sea, and on the south by the pro-
vinces of Zealand and Utrecht.

HOLLAND, in commerce, a fine and close kind of
linen,

HITCHING, a market-town in Hartfordshire, fourteen
miles north-west of Hartford, and thirty-two north-
west of London.

HITHE, one of the Cinque Ports in the county of Kent,
situated on the English channel, six miles west of Do-
ver.

HIV, (783) HOL

HIVING of Bees. See Apis.

HOAR-HOUND, in botany. See Marubium.

HOARSENESS, in medicine, a diminution of the voice,
commonly attended with a preternatural asperity or
roughness thereof.

HOBBY, in ornithology. See Falco.

HOE, in country-affairs, a tool made like a cooper's adz,
to cut upwards in gardens, field, &c. This tool is com-
monly called the hand-hoe. See Agriculture.

HOGG, in zoology. See Sus.

HOGSHEAD, in commerce, a measure of capacity, con-
taining sixty-three gallons.

HOGUE, a town and cape on the north-west point of
Normandy in France, near which admiral Rook burnt
the French admiral's ship called the Rising Sun with
twelve more large men of war: W. lon. 2°, and N. lat.
46° 30'.

HOMICIO, a river of North America; which rising in the
Apalachian mountains, near the confines of Carolina
and Virginia, runs south-west, and falls into the river
Mississippi.

HOKE-DAY, the Tuesday after Easter-week; which was
the day on which the English conquered and expelled
the Danes: this was therefore kept as a day of rejoic-
ing; and a duty, called hoke-tuesday money, was paid
to the landlord, for giving his tenants and bondmen
leave to celebrate it.

HOLDING, in Scots law, the tenor or terms upon which
a proprietor of lands holds or enjoys them of his
superior.—See Blench, Burgage, Feu, Ward.

HOLDY, one of the Cinque Ports in the county of Kent,
situated on the English channel, six miles west of Do-
ver.

HIVE, in country affairs, a convenient receptacle for
bees. See Apis.
HOLMEN, man, is ranked by Linnaeus under the order of
HOMILY, in ecclesiastical writers, a sermon, or dis-
HOMICIDE, signifies in general the taking away of any
HOMER. See Omer.
Homberg is also a town of Germany, in the circle of
Holy-well, a town of north Wales, in Flintshire, ten
Holy-island, an island in the German sea, six miles
south of Berwick upon Tweed: W. long. 10° 42', and
N. lat. 55° 45'..
Holy-well, a town of north Wales, in Flintshire, ten
miles east of St. Asaph.
HOMAGE, in law, is the submision, loyalty, and ser-
vice which a tenant promised to his lord when he was
first admitted to the land which he held of the lord in
fee: also that owing to a king, or to any superior.
HOMBERG, a town of Germany, in the circle of the
upper Rhine, and landgraviate of Hesse, situated ten
miles north of Francfort: E. long. 8° 24', N. lat.
53° 26'.
HOMBERG is also a town of Germany, in the palatinate
of the Rhine, and dukedom of Deuxponts: E. long. 7°
6', and N. lat. 49° 20'.
HOMER. See Omer.
HOMILY, in ecclesiastical writers, a sermon, or dis-
course, upon some point of religion, delivered in a
plain manner, so as to be easily understood by the com-
mon people.
HOMO, MAN, is ranked by Linnaeus under the order of
primates, and characterized by having four parallel
forefeeth both in the upper and lower jaw, and two
mammæ on the breast. The species, according to this
author, are two, viz. the homo sapiens, and the homo
trogloidytes. He subdivides the homo sapiens into five
varieties, viz. the American, the European, the As-
Biotic, the African, and what he calls the monstrous.
The troglodytes, or orang outang, is a native of A-
Ethiopia, Java, and Amboina. His body is white; he
HOMILE, man, is ranked by Linnaeus under the order of
HOMILY, in ecclesiastical writers, a sermon, or dis-
feminated by fire: of this kind was the daily sacrifice
in the Jewish church. This was done by way of ac-
novation, that the perfom offering and all that
belonged to him, were the effects of the divine bounty.
HOLOGRAPH, among civilians, a will wholly written
by the hand of the testator.
HOLSTEIN, a duchy of Germany, in the circle of
HOLSTEIN and the south Jutland on the north,
by the Baltic sea and the duchy of Sax-Lauenburg on
the east, by the riven Elbe on the south, and by the
German sea on the west.
HOLY-MAID, in heraldry, is that next above the
HONOUR-POINT, in heraldry, is that next above the
centre of the escutcheon, dividing the upper part into
two equal portions.
HOOF, the horny substance that covers the feet of divers
animals, as oxen, horses, sheep, &c.
HOOKS are a necessary sort of utensils, and used for va-
rious purposes.
HOOKER, in naval architecture, a vessel much used by
the Dutch, built like a pink, but rigged and manned like
a hoy. Hookers will lie nearer a wind than vessels with
cros sails can do. They are from fifty to two hun-
dred tons burden, and with a few hands will sail to the
East Indies.
HOP, in botany. See Humulus.

New land is found to succeed better with hops than old; and on this principle they are very cautious in their plantations in Kent, and look forward for the after-produce. When they make a new hop-ground, they plant it with apple-trees at a large distance aurther, and with cherry trees between; by this means, when the hops have grown ten years, which they judge as much as they will do well, they place their account in the cherry-trees, which bear large crops; these they gather for about thirty years, and then they cut them up, and depend upon their apple-trees only, which they find very large and strong by that time.

The dry stalks of hops should be burnt on the ground in winter, covering them with a little fresh earth as they burn. This makes together an excellent compost, to make the hills of. The land must be dug or plowed well, and laid very even, and then the places for the hills marked out by a line, and a stick put in every place where one is to be. A thousand hills may be made in an acre of ground, and fix or seven plants set on every hill. From fix to nine feet should be allow-
ed between every hill, and the grounds in the hills should be better and richer than the common earth. Some plant hops in March and April, but the most experienced people prefer the month of October, because they will then strike firm roots, and be strong and vigorous against spring. The largest plants are to be chosen; and it is best to procure them from some rich ground, where the hills have been laid high; they should be about eight or ten inches long, and have three or four joints or buds a-piece; the holes for planting them are to be dug eight or ten inches deep, and about a foot over; and in each of these holes four plants are to be set, one in each corner; they may be covered an inch deep over the top, if planted in Octo-
ber; but in spring, when they have shot from the joints, then they must not be buried: after this, the ground must be carefully kept clear of weeds.

Dressing of Hops. This is preparing the ground in winter and spring for the making a good summer-crop. In doing this, the hills upon which the plants stand must be all pulled down, and undermined on every side, till the spade comes near the principal root; then shake off or remove with the hand the loose mould from the upper or loofe roots, that you may see where the new roots grow out of the old fets. The old fets are to be carefully preferred, but the other roots may be cut away. Whatever time the hills are pulled down, the roots must not be cut till March. When the young hops are dressed for the first time, all the roots are to be cut away that grew the year before, and the fets are to be cut off within one inch of the fame; and every year after, they must be cut as close as may be to the old roots; but to a weak hop, some of the fhoots are to be left at the dressing. Those roots of the plant which grow downwards, are never to be injured, but only those which run horizontally are to be cut. The old roots and the young ones may be easily distinguished, in that the old ones are always red, and the young white. If there are by accident any wild hops got among the rest, the places where they grow are to be marked with sticks, or otherwise, at the time of their being gathered; and after this, at the time of dressing the ground, that whole hill is to be destroyed, and a new one made with new plants in the room of it. When the roots are cut and dressed, the rich compost is to be put to them; and the hills must not be made too high at first, left they hinder the young fhoots.

Gathering and drying of Hops. Hops blow in the latter end of July, in the beginning of August they bell; and they are sometimes ripe at the beginning of September, sometimes later. When they begin to change colour, they are easily pulled to pieces, and their seeds look brown within them, they are ripe; and they are then to be gathered as quick as possible, for the least blast of wind will hurt them at this time.

The manner of gathering hops, is to take down four hills standing together in the midst of the garden, and to cut the roots even with the ground, then lay the ground level; and when it is swept clean, it makes a floor, on which the hops may be laid and picked. The hop-plants are first unwound from the poles, and then the people sit round and pick off the hops into baskets.

Care should be taken to dry the hops as fast as they are picked, for in lying undried they are apt to heat and change colour very quickly. If the quantity picked be too large, that the kiln in which they are to be dried is over-stocked, they must be spread thin upon a floor, and they will keep two or three days in that manner without any harm. Indeed, where the quantity is small, there is no need to have recourse to the kiln at all, for they will dry much better than any other way, by being laid thin upon a floor, and often turned. The drying of hops is the most material part of their manufacture; for if they be ill dried, they lose all their agreeable flavour; and great caution should be used, that they be all equally dried.

Bagging of Hops. A term used by the farmers, who cultivate hops, for the last thing they have to do with them, in order to bring them to market; that is, the putting them up in large bags of coarse cloth, for carriage. When the hops have been picked and dried in the oofi, or tin-floor, they are so brittle that they would break to pieces and be spoiled if they were immediately to be put up; they are therefore to lie together three weeks, or thereabouts, that they may become tough: if they are covered from the air by blankets in the heap, they may be bagged much sooner than if left open.

The manner of bagging them is this: a hole is made in an upper-floor, so large that a man may easily go up and down it; then a hoop is fitted to the mouth of the bag, and fixed firmly sewed on, that it cannot be torn off; the bag is then let down through the hole, and the hoop remaining above, stops it from being pulled quite through, being larger than the hole: a few hops are to be first thrown into the bag, and a person below is to take up a parcel of these in each corner of the bag, tying it with a packthread; this makes a fort of tassel, by which the bags are afterwards the easier managed and
and turned about. When this is done, one man must go down into the bag, and, while another calls in the hops, he must tread them down equally every way with his feet; when the bag is in this manner filled, it is to be ripped from the hoop, and fewed up, leaving two taffels at the corners, as at the bottom. A bag of hops thus prepared, may be kept for several years in a dry place.

The tops of this plant, being of a cooling quality, are eaten, when boiled, as an emollient. A decoction of hop-flowers is also accounted an antidote against poison, and cures the itch, as well as the syrup thereof, and is esteemed excellent in choleric and pestilential fevers. The heads and tendrils are good in the scurvy and most cutaneous diseases. Juleps and apoemps are also prepared with hops for hypochondriacal and hysterical affections, and to promote the menses: but the chief use of this plant consists in preserving beer and other malt-liquors (in which the flower of this plant is a principal ingredient) from turning sour, and rendering it wholesome and grateful to the taste.

H O R S E M A N S H I P;
Or, The Art of Riding, and of Training and Managing Horses.

The method of preparing horses to be mounted.

THOUGH all horses are generally bought at an age when they have already been backed, they should be begun and prepared for the rider with the same care, gentlenefs and caution, as if they had never been handled or backed, in order to prevent accidents, which might else arise from skittifhness or other causes: and as it is proper that they should be taught the figure of the ground they are to go upon, when they are at first mounted, they should be previously trotted in a longe on circles, without any one upon them.

The manner of doing this is as follows: Put an easy cavellon upon the horse's nose, and make him go forwards round you, standing quiet and holding the longe; and let another man, if you find it necessary, follow him with a whip. All this must be done very gently, and but a little at a time: for more horses are spoilt by over-much work, than by any other treatment whatever; and that
The method of placing the rider and rendering him firm on horseback, with some occasional instructions for riders and horses.

It is necessary that the greatest attention, and the same gentleness, that is used in teaching the horses, be observed likewise in teaching the rider, especially at the beginning. Every method and art must be practised to create and preserve, both in man and horse, all possible feeling and sensibility, contrary to the ufe of mott riding masters, who deem indifferently to labour at aboli-thing these principles both in one and the other. As fo many essential points depend upon the manner in which a man is at firft placed on horseback, it ought to be considered and attended to with the stricteft care and exactness.

The absurdity of putting a man, who perhaps has never before been upon a horse, on a rough trottng horse, on which he is obliged to flick with all the force of his arms and legs, is too obvious to need mentioning. This rough work, all at once, is plainly as detrimental at firft, as it is excellent afterwards in proper time. No man can be either well, or firmly seated on horseback, unless he be master of the balance of his body, quite unconstrained, with a full possession of himzelf, and at his ease; none of which requisites can be enjoyd, if his attention be otherwise engaged; as it must wholly be in a raw, unsup-pled, and unprepared lad, who is put at once upon a rough horse: in such a distressful state he is forced to keep himself on at any rate, by holding to the bridle, (at the expense of the sensibility both of his own hand, and the horse's mouth,) and by clinging with his legs, in danger of his life, and to the certain deprivation of a right feeling in the horse.

The firft time a man is put on horseback, it ought to be upon a very gentle one. He never should be made to trot, till he is quite easy in the walk; nor gallop, till he is able to trot properly. The same must be observed in regard to horses: they should never be made to trot, till they are obedient, and their mouths are well formed on a walk; nor be made to gallop, till the same be effect-ed on a trot. When he is arrived at such a degree of firmness in his feet, the more he trots, and the more he rides rough horses, the better. This is not only the best method, but also the easiest and the shortest: by it, a man is soon made sufficiently an horfeman for a soldier; but by the other detestable methods, that are commonly used, a man, instead of improving, contracts all sorts of bad habits, and rides worse and worse every day; the horse too becomes daily more and more unfit for use. In proceeding according to the manner proposed, a man is rendered firm and easy upon the horse, both his own and the horse's sensibility is preferred, and each in a situation fit to receive and practice all lessons effectually.

Among the various methods that are used of placing people on horseback, few are directed by reason. Before you let the man mount, teach him to know, and al-ways to examine, if the curb be well placed, (that is, when the horse has a bit in his mouth, which at firft he should not; but only a snaffle, till the rider is firm in his feat, and the horse alfo somewhat taught;) and likewise if the nose-band be properly tight; the throat-band loose, and the mouth-piece neither too high nor too low in the horse's mouth, but rightly put so as not to wrinkle the skin, nor to hang lax; the girths drawn moderately, but not too tight; and the crupper and the breast-plate properly adjusted. A very good and careful hand may venture on a bit at firft, and succeed with it full as well, as by beginning with a snaffle alone: on colts, indeed, it is better, in all schools whatsoever, to avoid any preffure on the bars just at firft, which a curb, though ever so delicately used, muft in some degree occasion. When the bridle, &c. have been well looked to, let the man approach the horse gently near the shoulder; then taking the reins and an handful of the mane in his left hand, let him put his foot softly in the left stirrup, by pulling it towards him, lefl he touch the horse with his toe, then raising himself up, let him reft a moment on it with his body upright, but not stiff; and after that passing his right leg clear over the saddle without rubbing against any thing, let him seat himself gently down. He must be
be cautious not to take the reins too short, for fear of making the horse rear, run, or fall back, or throw up his head; but let him hold them of an equal length, neither tight nor slack, and with the little finger between them. It is fit that horses should be accustomed to stand still to be mounted, and not to stir till the rider pleasure. All soldiers should be instructed to mount and dismount equally well on both sides, which may be of very great use in times of hurry and confusion. Then place the man in his saddle, with his body rather back, and his head held up with ease; without stiffness; seated neither forwards, nor very backwards, with the breast pulled out a little, and the lower part of the body likewise a little forwards; the thighs and legs turned in without constraint, and the feet in a straight line, neither turned in nor out: By this position, the natural weight of the thighs has a proper and sufficient pressure of itself, and the legs are in readiness to act, when called upon: they must hang down easy and naturally, and be so placed, as not to be wriggling about, touching and tickling the horse's sides, but always near them in case they should be wanted, as well as the heels.

The body must be carefully kept easy and firm, and without any rocking, when in motion; which is a bad habit very easily contracted, especially in galloping. The left elbow must be gently leant against the body, a little forwards; unless it be so refited, the hand cannot be steady, but will be always checking, and consequently have pernicious effects on the horse's mouth: and the hand ought to be of equal height with the elbow; if it were lower, it would confine and confine the motion of the horse's shoulders; but, as the mouths of horses are different, the place of the hand also must occasionally differ: a leaning, low, heavy fore-hand requires a high hand; and a horse that pokes out his nose, a low one. The right hand arm must be placed in symmetry with the left; only let the right hand be a little forwards; the thighs and legs turned in without constrain, and the feet in a straight line, neither turned in nor out; the dressage, which is a sufficient business for it. A soldier's right hand should be kept unemployed in riding; it carries the sword, which is a sufficient business for it.

There remains one farther observation, that ought not to be omitted, about the hand, that it must be kept clear of the body; i.e. about two inches and half forwards from it, with the nails turned opposite to the belly, and the wrist a little rounded with ease; a position not less graceful than ready for slackening, tightening, and moving the reins from on side to the other, as may be found necessary.

When the men are well placed, the more rough trotting they have without stirrups, the better; but with a strict care always, that their position be preferred very exactly. In all cafes, great care must be taken to hinder their clapping with their legs: In short, no flicking by hands or legs is ever to be allowed of at any time. If the motion of the horse be too rough, flacken it, till the rider grows by degrees more firm: and when he is quite firm and easy on his horse in every kind of motion, flir-

rups may be given him; but he must never leave off trotting often without any.

The stirrups must be neither short nor long; but of such a length, that when the rider, being well placed, puts his feet into them, (about one third of the length of each foot from the point of it,) the points may be between two and three inches higher than the heels. The rider must not bear upon his stirrups, but only let the natural weight of his legs rest on them: For if he bear upon them, he would be raised above and out of his saddle; which should never be, except in charging sword in hand, with the body inclined forwards at the very instant of attacking. Spurs may be given, as soon as the rider is grown familiar with stirrups, or even long before, if his legs are well placed.

A hand should always be firm, but delicate: a horse's mouth should never be surprized by any sudden transition of it, either from slack to tight, or from tight to slack. Everything in horsemanship must be effected by degrees, but at the same time with spirit and resolution. That hand which, by giving and taking properly, gains its point with the least force, is the best; and the horse's mouth, under this same hand's directions, will also consequently be the best, supposing equal advantages in both from nature. This principle of gentleness should be observed upon all occasions in every branch of horsemanship. Sometimes the right hand may be necessary, upon some troublesome horses, to assist the left; but the feldomer this is done, the better; especially in a soldier, who has a sword to carry, and to make use of.

The snaffle on all occasions be uppermost; that is to say, the reins of it must be above those of the bridle, whether the snaffle or the bit be used seperately, or whether they be both used together. When the rider knows enough, and the horse is sufficiently prepared and settled to begin any work towards suppling, one rein must be shortened according to the side worked to; but it must never be so much shortened, as to make the whole strength rest on that rein alone; for, not to mention that the work would be false and bad, one side of the horse's mouth would by that means be always deadened; whereas on the contrary, it should always be kept fresh by its own play, and by the help of the opposite rein's acting delicately in a somewhat smaller degree of tension; the joint effect of which produces in a horse's mouth the proper, gentle and easy degree of appui or bearing.

A coward and a madman make alike bad riders, and are both alike discovered and confounded by the superior sense of the creature they are mounted upon, who is equally spoilt by both, though in very different ways. The coward, by suffering the animal to have his own way, not only confirms him in his bad habits, but creates new ones in him: and the madman, by false and violent motions and corrections, drives the horse, through despair, into every bad and vicious trick that rage can suggest.

It is very requisite in horsemanship, that the hand and legs should act in correspondence with each other in every thing; the latter always subservient and affillant to the former. Upon circles, in walking, trotting, or galloping, the outward leg is the only one to be used, and that only for a moment at a time, in order to set off the horse
true, or put him right, if he be false; and as soon as that is done, it must be taken away again immediately: but if the horse be lazy, or otherwise retains himself, both legs must be used, and pressed to his sides at the same time together. The lefts the legs are used in general, the quicker becomes more familiar, the quickness of motion must be taken away again immediately: if the horse offers to rear, the legs must be instantly removed away. The inward rein must be the tighter on circles, so that the horse may bend and look inwards; and the outward one crossed over a little towards it; and both held in the left hand.

Let the man and horse begin on very slow motions, that they may have time to understand, and reflect on what is taught them; and in proportion as the effects of the reins are better comprehended, and the manner of working becomes more familiar, the quickness of motion must be increased. Every rider must learn to feel, without the help of the eye, when a horse goes false, and remedy the fault accordingly: this is an intelligence, which nothing but practice, application and attention can give, in the beginning on slow motions. A horse may not only gallop false, but also trot and walk false. If a horse gallops false, that is to say, if going to the right, he leads with the left leg; or if going to the left, he leads with the right; or in case he is disinclined, i.e. if he leads with the opposite leg behind to that which he leads with before; stop him immediately, and put him off again properly: the method of effecting this, is by approaching your outward leg and putting your hand outward, still keeping the inward rein the shorter, and the horse's head inwards, if possible; and if he should still resist, then bend and pull his head outwards also, but replace it again, bent properly inwards, the moment he goes off true. A horse is said to be disinclined to the right, when going to the right, and consequently leading with the right leg before, he leads with the left behind; and is said to be disinclined to the left, when going to the left, and consequently leading with the left leg before, he leads with the right behind. A horse may at the same time be both false and disinclined; in correcting both which faults, the same method must be used. He is both false and disinclined to the right, when in going to the right he leads with the left leg before, and the right behind; notwithstanding that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the right: and he is false and disinclined to the left, when in going to the left he leads with the right leg before, and the left behind; notwithstanding, as above, that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the left.

In teaching men a right seat on horseback, the greatest attention must be given to prevent stiffness, and flicking by force in any manner upon any occasion: stiffness disgraces every right work; and flicking serves only to throw a man (when displaced) a great distance from his horse by the spring he must go off with: whereas by a proper equilibrating position of the body, and by the natural weight only of the thighs, he cannot but be firm, and secure in his seat.

As the men become more firm, and the horses more supple, it is proper to make the circles less, but not too much so, for fear of throwing the horses forwards upon their shoulders.

Some horses, when first the bit is put into their mouths, if great care be not taken, will put their heads very low. With such horses, raise your right hand with the bridoon in it, and play at the same time with the bit in the left hand, giving and taking.

On circles, the rider must lean his body inwards; unless great attention be given to make him do it, he will be perpetually loosing his seat outwards. It is scarcely possible for him to be displaced if he leans his body properly inwards.

The method of suppling horses with men upon them, by the Epauler end dedans, &c. with and without a longe, on circles and on straight lines.

When a horse is well prepared and settled in all his motions, and the rider firm, it will be proper then to proceed on towards a farther suppling and teaching of both.

In setting out upon this new work, begin by bringing the horse's head a little more inwards than before, pulling the inward rein gently to you by degrees. When this is done, try to gain a little on the shoulders, by keeping the inward rein the shorter, as before, and the outward one crossed over towards the inward one. The intention of these operations is this; the inward rein serves to bring in the head, and procures the bend; whilst the outward one, that is a little crossed, tends to make that bend perpendicular, and as it should be, that is to say, to reduce the nose and the forehead to be in a perpendicular line with each other: it also serves, if put forwards, as well as also crossed, to put the horse forwards, if found necessary, which is often requisite, many horses being apt in this and other works rather to lode their ground backwards than otherwise, when they should rather advance: if the nose were drawn in towards the breast beyond the perpendicular, it would confine the motion of the shoulders, and have other bad effects. All other bends, besides what are above specified, are false.

The outward rein, being crossed, not in a forward sense, but rather a little backwards, serves also to prevent the outward shoulder from getting too forwards, and makes it approach the inward one; which facilitates the inward leg's crossing over the outward one; which is the motion that so admirably supplies the shoulders. Care must be taken, that the inward leg pafs over the outward
one, without touching it; this inward leg’s crossing over must be helped also by the inward rein, which you must cross towards and over the outward rein every time the outward leg comes to the ground, in order to lift and help the inward leg over it: at any other time, but just when the outward leg comes to the ground, it would be wrong to cross the inward rein, or to attempt to lift up the inward leg by it; nay, it would be demanding an absolute impossibility, and /agging about the reins and horse to no purpose: because in this case, a very great part of the horse’s weight resting then upon that leg, would render such an attempt, not only fruitless, but also prejudicial to the sensibility of the mouth, and probably oblige him to defend himself: and moreover, it would put the horse under a necessity of straddling before, and also of leading with the wrong leg, without being productive of any impelling motion whatsoever.

When the horse is thus far familiarly accustomed to what you have required of him, then proceed to effect by degrees the same crossing in his hinder legs. By bringing in the fore-legs more, you will of course engage the hinder ones in the same work: if they refit, the rider must bring both reins more inwards; and, if necessary, put back also, and approach his inward leg to the horse; and if the horse throws out his croup too far, the rider must bring both reins outwards, and if absolutely necessary, he must also make use of his outward leg, in order to replace the horse properly; observing that the croup should always be considerably behind the shoulders, which in all actions must go first; and the moment that the horse obeys, the rider must put his hand and leg again into their usual position.

Nothing is more ungraceful in itself, more detrimental to a man’s seat, or more destructive of the sensibility of a horse’s sides, than a continual wriggling unsettledness in a horseman’s legs, which prevents the horse from ever going a moment together true, steady, or determined.

A horse should never be turned, without first moving a step forwards; and when it is doing, the rider must not lift up his elbow, and displace himself; a motion only of the hand from the one side to the other being sufficient for that purpose. It must also be a constant rule never to suffer a horse to be stopped, mounted, or dismounted, but when he is well placed. The flower the motions are, when a man or horse is taught any thing, the better.

At first, the figures worked upon must be great, and afterwards made less by degrees, according to the improvement which the man and horse make; and the cadenced pace also, which they work in, must be accordingly augmented. The changes from one side to the other, must be in a bold determined trot, and at first quite straight forwards, without demanding any side motion on two pisters, which is very necessary to regulate afterwards, when the horse is sufficiently tugged. By two pisters is meant, when the fore-parts and hinder-parts do not follow, but describe two different lines.

In the beginning, a longe is useful on circles, and also on straight lines, to help both the rider and the horse; but afterwards, when they are grown more intelligent, they should go alone. At the end of the lefson, rein back; and then put the horse, by a little at a time, forwards, by approaching both legs gently to his sides, and playing with the bridle: if he rears, push him out immediately into a full trot. Shaking the cavesson on the horse’s nose, and also putting one’s self before him and rather near to him, will generally make him back, though he otherwise refuse to do it: and moreover a slight use and approaching of the rider’s legs, will sometimes be necessary in backing, in order to prevent the horse from doing it too much upon his shoulders; but the pressure of the legs ought to be very small, and taken quite away the moment that he puts himself enough upon his haunches. If the horse does not back upon a straight line properly, the rider must not be permitted to have recourse immediately to his leg, and to distort himself by it, but first try, if crossing over his hand and reins to which ever side may be necessary, will not be alone sufficient; which most frequently it will; if not, then employ the leg.

After a horse is well prepared and settled, and goes freely on in all his several paces, he ought to be in all his works kept, to a proper degree, upon his haunches, with his hinder legs well placed under him; whereby he will be always pleasant to himself, and his rider, will be light in hand, and ready to execute whatever may be demanded of him, with facility, vigour, and quickness.

The common method that is used, of forcing a horse sideway, is a most glaring absurdity, and very hurtful to the animal in its consequences; for instead of suddling him, it obliges him to stiffen and defend himself, and often makes a creature, that is naturally benevolent, revengeful, frightened and vicious.

For horses, who have very long and high fore-hands, and who poke out their noses, a running snaffle is of excellent use; but for such as bore and keep their heads low, a common one is preferable; though any horse’s head indeed may be kept up also with a running one, by the rider’s keeping his hands very high and forwards: but whenever either is used alone without a bridle upon horses that carry their heads low and that bore, it must be fawed about from one side to the other.

This lefson of the epaul en dedans, should be taught to such people as are likely to become useful in helping to teach men and to break horses; and the more of such, that can be found, the better: none others should ever be suffered upon any occasion to let their horses look any way besides the way they are going. But all horses whatever, as likewise all men, who are designed for the teaching others, must go thoroughly and perfectly through this excellent lefson, under the directions of intelligent instructors, and often practice it too afterwards, and when that is done, proceed to, and be finished by the lefson of the head and tail to the wall.

Of the head to the wall, and of the croup to the wall.

This lefson should be practic’d immediately after that of the epaul en dedans, in order to place the horse properly the way he goes, &c. The difference between the head to the wall, and the croup to the wall, consists in this: in the former, the fore parts are more remote from the centre, and go over more ground; in the latter, the hinder parts are more remote from the centre, and consequently.
It is the rider's business to find out from whence the obstacles arise; and if he finds it to be from the first mentioned cause, the previous lessons must be resumed again for some time; if from the second, proper remedies must be applied; and if from the last cause, when all means that can be tried have failed, proper corrections with coolness and judgment must be used.

In practicing this lesson to the right, bend the horse to the right with the right rein; helping the left leg over the right (at the time when the right leg is just come to the ground,) with the left rein crooked towards the right, and keeping the right shoulder back with the right rein towards your body, in order to facilitate the left legs crossing over the right; and fo likewise to the left, each rein helping the other by their proper mixed effects. In working to the right, the rider's left leg helps the horse's hind parts on to the right, and his right leg flops them, if they get too forwards; and so likewise to the left; but neither ought to be used, till the hand being employed in a proper manner has failed, or finds that a greater force is necessary to bring what is required about than it can effect alone; for the legs should not only be corresponding with, but also subservient to the hand; and all unnecessary aids, as well as all force, ought always to be avoided, as much as possible.

In the execution of all lessons, the equilibre of the rider's body is of great use to the horse: it ought always to go with and accompany every motion of the animal; when to the right, to the right; and when to the left, to the left.

Upon all horses, in every lesson and action, it must be observed, that there is no horse but has his own peculiar appui or degree of bearing, and also a sensibility of mouth, as likewise a rate of his own, which it is absolutely necessary for the rider to discover and make himself acquainted with. A bad rider always takes off at least the delicacy of both, if not absolutely destroys it. The horse will inform his rider when he has got his proper bearing in the mouth, by playing pleasantly and steadily with his bit, and by the sprays about his chaps. A delicate and good hand will not only always preferve a light appui, or bearing, in its sensibility; but also of a heavy one, whether naturally so or acquired, make a light one. The lighter this appui can be made, the better; provided that the rider's hand corresponds with it; if it does not, the more the horse is properly prepared, so much the worse. Instances of this inconvenience of the best of appuis, when the rider is not equally taught with the horse, may be seen every day in some gentlemen, who try to get their horses bitted as they call it, without being suitably prepared themselves for riding them: the consequence of which is, that they ride in danger of breaking their necks; till at length after much hauling about, and by the joint insensibility and ignorance of themselves and their grooms, the poor animals gradually become mere senseless, unfeeling poits; and thereby grow, what they call, settled. When the proper appui is found, and made of course as light as possible, it must not be kept duly fixed without any variation, but be played with; otherwise one equally continued tension of reins would render both the rider's hand and the horse's mouth very dull. The lightest, and frequent giving and taking, is therefore necessary to keep both perfect.

Whatever pace or degree of quickness you work in, (be it ever so fast, or ever so slow,) it must be cahnded; time is as necessary for a horseman as for a musician.

This lesson of the head and of the tail to the wall, must be taught every soldier: scarce any manoeuvre can be well performed without it. In closing and opening of files, it is almost every moment wanted.

The method of teaching horses to stand fire, noises, alarms, &c.

In order to make horses stand fire, the sound of drums, and all sorts of different noises, you must use them to it by degrees in the flable at feeding-time; and instead of being frightened at it, they will soon come to like it as a signal for eating.

With regard to such horses as are afraid of burning objects, begin by keeping them still at a certain distance from some lighted straw: caress the horse; and in proportion as his fright diminishes, approach gradually the burning straw very gently, and increase the size of it. By this means he will very quickly be brought to be so familiar with it, as to walk undaunted even through it.

As to horses that are apt to lie down in the water, if animating them, and attacking them vigorously, should fail of the desired effect, then break a straw bottle full of water upon their heads, and let the water run into their ears, which is a thing they apprehend very much.

All trooper-horses must be taught to stand quiet and still when they are shot off from, to stop the moment you present, and not to move after firing, till they are required to do it; this lesson ought especially to be observed in light-troops; in short, the horses must be taught to be so cool and undisturbed, as to suffer the rider to act upon him with the same freedom as if he was on foot. Patience, coolness, and temper, are the only means requisite for accomplishing this end. Begin by walking the horse gently, then stop and keep him from striding for some time, so as to accustom him by degrees not to have the least idea of moving without orders; if he does, then back him; and
and when you flop him, and he is quite still, leave the reins quite loose.

To use a horse to fire arms, first put a pistol or carbine in the manger with his feed; then use him to the sound of the lock and the pan; after which, when you are upon him, flew the piece to him, presenting it forwards, sometimes on one side, sometimes on the other when he is thus far reconciled, proceed to flash in the pan; after which, put a small charge into the piece, and continue augmenting it by degrees to the quantity which is commonly used; if he seems uneasy, walk him forwards a few steps slowly, and then, flop, back and carefs him.

Horses are often also disquieted and unstable at the clash, and drawing, and returning of swords, all which they must be familiarized to by little and little, by frequency and gentleness.

It is very expedient for all cavalry in general, but particularly for light cavalry, that their horses should be very ready and expert in leaping over ditches, hedges, gates, &c. The leaps, of whatever form they are, which the horses are brought to in the beginning, ought to be very small ones; the riders must keep their bodies back, raise their hands a little in order to help the foreparts of the horse up, and be very attentive to their equilibrium. It is best to begin at a low bar covered with furze, which prickings the horse's legs, if he does not raise himself sufficiently, prevents his contracting a sluggish and dangerous habit of touching, as he goes over, which anything yilding and not prickings would give him a custom of doing. Let the ditches you first bring horses to, be narrow; and in this, as in everything else, let the increase be made by degrees. Accustom them to come up to every thing which they are to leap over, and to stand coolly at it for some time; and then to raise themselves gently up in order to form to themselves an idea of the distance. When they leap well standing, then use them to walk gently up to the leap, and to go over it without first halting at it; and after that practice is familiar to them, repeat the like in a gentle trot, and so by degrees faster and faster, till at length it is as familiar to them to leap flying on a full gallop, as any other way, as all which is to be acquired with great facility by calm and soft means without any hurry.

As horses are naturally apt to be frightened at the sight and smell of dead horses, it is advisable to habituate them to walk over, and leap over carcasses of dead horses: and as they are particularly terrified at this sight, the greater gentleness ought consequently to be used.

Horses should also be accustomed to swim, which often may be necessary upon service; and if the men and horses both are not used to it, both may be frequently liable to perish in the water. A very small portion of strength is sufficient to guide a horse, any where indeed, but particularly in the water, where they must be permitted to have their heads, and be no ways confined in any shape.

The unreasonable rage in Britain of cutting off all extremities from horses, is in all cafes a very pernicious custom. It is particularly fo in regard to a troop horse's tail. It is almost incredible, how much they suffer at the picket for want of it: continually fretting, and sweating, kicking about and laming one another, tormented, and flung off their meat, miserable, and helpless; whilst other horses, with their tails on, brush off all flies, are cool and at their ease, and mend daily, whilst the docked ones grow every hour more and more out of condition.

The method of reining back.—and of moving forwards immediately after.—of piafing.—of pillars, &c.

Never finish your work by reining back with horses that have any disposition towards retaining themselves; but always move them forwards and a little upon the haunches also after it, before you dismount, (unless they retain themselves very much indeed, in which case nothing at all must be demanded from the haunches.) This lesson of reining back, and piafing, is excellent to conclude with, and puts an horse well and properly on the haunches: it may be done, according as horses are more or less supplied, either going forwards, backing, or in the same place: if it is done well advancing, or at most on the same spot, it is full sufficient for a soldier's horse: for to piafe in backing, is rather too much to be expected in the hurry, which cannot but attend such numbers both of men and horses as must be taught together in regiments. This lesson must never be attempted at all, till horses are very well supplied, and somewhat accustomed to be put together; otherwise it will have very bad consequences, and create relapse.

If they refuse to back, and stand motionless, the rider's legs must be approached with the greatest gentleness to the horse's sides; at the same time as the hand is acting on the reins to solicit the horse's backing. This febold fails of procuring the desired effect, by raising one of the horse's fore-legs, which being in the air, has no weight upon it, and is consequently very easily brought backwards by a small degree of tension in the reins. When this lesson is well performed, it is very noble, and useful, and has a pleasing air; it is an excellent one to begin teaching scholars with.

The lesson is particularly serviceable in the pillars, for placing scholars well at first. Very few regimental riding-houses have pillars, and it is fortunate they have not; for though, when properly made use of with skill, they are one of the greatest and best discoveries in horsemanship; they must be allowed to be very dangerous and pernicious, when they are not under the direction of a very knowing person.

The method of curing restiveness, vices, defences, starting, &c.

Whenever a horse makes resistance, one ought, before a remedy or correction is thought of, to examine very minutely all the tackle about him, if any thing hurts or tickles him, whether he has any natural or accidental weaknesses, or in short any the least impediment in any part. For want of this precaution, many fatal disasters happen: the poor dumb animal is frequently accused falsely of being relvive and vicious; is used ill without reason, and, being forced into despair, is in a manner obliged to act accordingly, be his temper and inclination ever so well
HORSEMANSHIP.

well disposed. It is very seldom the case, that a horse is really and by nature vicious; but if such be found, he will despise all careness, and then chastisements become necessary.

Correction, according as you use it, throws a horse into more or less violent action, which, if he be weak, he cannot support; but a vicious strong horse is to be considered in a very different light, being able both to undergo and consequently to profit by all lessons; and is far preferable to the best natured weak one upon earth. Patience and science are never-failing means to reclaim such a horse: in whatsoever manner he defends himself, bring him back frequently with gentleness (not however without having given him proper chastisement, if necessary,) to the lesson which he seems most averse to. Horses are by degrees made obedient, through the hope of recompence and the fear of punishment: how to mix these two motives judiciously together, is a very difficult matter; it requires much thought and practice; and not only a good head, but a good heart likewise. The coolest, and best natured rider, will always succeed best. By a dextrous use of the incitements above mentioned, you will gradually bring the horse to temper and obedience; mere force and want of skill and coolness, would only tend to confirm him in bad tricks. If he be impatient or choleric, never strike him, unless he absolutely refuses to go forwards; which you must resolutely oblige him to do, and which will be of itself a correction, by preventing his having time to meditate, and put in execution any defence by retaining himself. Restfulness in horses, you must consider, is sometimes a mark of strength and vigour, and proceeds from spirits, as well as sometimes from vice and weakness. Weakness frequently drives horses into viciousness, when anything wherein strength is necessary is demanded from them; nay, it inevitably must: great care therefore should always be taken to distinguish from which of these two causes any remedy or punishment is thought of. It may sometimes be a bad sign, when horses do not at all defend themselves, and proceed from a sluggish disposition, a want of spirit, and of a proper sensibility. Whenever one is so fortunate as to meet with a horse of just the right spirit, activity, delicacy of feeling, with strength and good-nature, he cannot be cherished too much; for such a one is a rare and inestimable jewel, and, if properly treated, will in a manner do every thing of himself. Horses are oftener spoilt by having too much done to them, and by attempts to dress them in too great an hurry, than by any other treatment.

If after a horse has been well suppled, and there are no impediments, either natural or accidental, if he still persifls to defend himself, chastisements then become necessary: but whenever this is the case, they must not be frequent, but always firm, though always as little violent as possible: for they are both dangerous and very prejudicial, when frequently or slightly played with; and still more so, when used too violently.

It is impossible, in general, to be too circumspect in lessons of all kinds, in aids, chastisements, or careness. Some have quicker parts, and more cunning, than others. Many will imperceptibly gain a little every day on their rider. Various, in short, are their dispositions and capacities. It is the rider’s business to find out their different qualities, and to make them sensible how much he loves them, and desires to be loved by them; but at the same time that he does not fear them, and will be master.

Plunging is a very common defence among refrive and vicious horses: if they do it in the same place, or backing, they must, by the rider’s legs and spurs firmly applied, be obliged to go forwards, and their heads kept up high. But if they do it flying forwards, keep them back, and ride them gently and very slow for a good while together. Of all bad tempers and qualities in horses, those which are occasioned by harsh treatment and ignorant riders, are the worst.

Rearing is a bad vice, and, in weak horses especially, a very dangerous one. Whilst the horse is up, the rider must yield his hand, and when the horse is descending, he must vigorously determine him forwards: if this be done at any other time but whilst the horse is coming down, it may add a spring to his rearing, and make him fall backwards. With a good hand on them, horses seldom perish in this vice; for they are themselves naturally much afraid of falling backwards. If this method fails, you must make the horse kick up behind, by getting somebody on foot to strike him behind with a whip; or, if that will not effect it, by pricking him with a goad.

Starting often proceeds from a defect in the flight; which therefore must be carefully looked into. Whatever the horse is afraid of; bring him up to it gently; if you carefs him every step he advances, he will go quite up to it by degrees, and soon grow familiar with all sorts of objects. Nothing but great gentleness can correct this fault: for if you inflict punishment, the apprehension of chastisement becomes prevalent, and cau zes more startling than the fear of the object. If you let him go by the object, without bringing him up to it, you increase the fault, and confirm him in his fear: the consequence of which is, he takes his rider perhaps a quite contrary way from what he was going, becomes his master, and puts himself and the person upon him every moment in great danger.

With such horses as are to a very great degree fearful of any objects, make a quiet horse, by going before them, gradually entice them to approach nearer and nearer to the thing they are afraid of. If the horfe, thus alarmed, be undisciplined and headstrong, he will probably run away with his rider; and if so, his head must be kept up high, and the snaffle sawed backwards and forwards from right to left, taking up and yielding the reins of it, as also the reins of the bit: but this latter must not be sawed backwards and forwards, like the snaffle, but only taken up, and yielded properly. No man ever yet did, or ever will flop a horse, or gain any one point over him, by main force, or by pulling a dead weight against him.

Remarks and hints on Shoeing.

As feet differ, so should shoes accordingly. The only system of farriers, is to shoe in general with excessive heavy and
and clumsy ill-shaped shoes, and very many nails, to the
total destruction of the foot. The cramps they annex,
tend to destroy the bullet; and the shoes made in the shape
of a walnut-shell prevent the horse's walking upon the
firm basis which God has given him for that end, and
thereby oblige him to stumble and fall. They totally
pare away also, and lay bare the inside of the animal's
foot with their destructive buttines, and afterwards put on
very long shoes, whereby the foot is hindered from having
any pressure at all upon the heels, which pressure otherwise
might still perchance, notwithstanding their dreadful
cutting, keep the heels properly open, and the foot in
good order. The frog should never be cut out; but as it
will sometimes become ragged, it must be cleaned every
now and then, and the ragged pieces cut off with a knife.
In one kind of foot indeed a considerable cutting away
must be allowed off, but not of the frog; we mean that
very high feet must be cut down to a proper height;
because if they were not, the frog, though not cut, would
still be so far above the ground, as not to have any bearing
on it, whereby the great tendon must inevitably be
damaged, and consequently the horse would go lame.

The weight of shoes must greatly depend on the quality
and hardnes of the iron. If the iron be very good, it
will not bend; and in this case, the shoes cannot possibly
be made too light: care however must be taken, that
they be of a thickness so as not to bend; for bending
would force out the nails, and ruin the hoof. That part
of the shoe which is next the horse's heel, must be nar-
rower than any other, (as is seen in the draught, plate
101. fig. 4,) that flones may be thereby prevented from
getting under it, and flicking there; which otherwise
would be the case; because the iron, when it advances
inwardly beyond the bearing of the foot, forms a cavity,
wherein flones being lodged would remain, and, by
preying against it, lame the horse. The part of
the shoe, which the horse walks upon, should be quite flat,
and the inside of it likewise; only just space enough be-
ing left next the foot, to put in a picker, (which ought
to be used every time the horse comes into the stable,) and
also to prevent the shoe's pressing upon the edge. Four
nails on each side hold better than a greater number, and
keep the hoof in a far better state. The toe of the hoof
must be cut short, and nearly square. (the angles only
just rounded off,) nor must any nails be driven there;
this method prevents much stumbling, especially in de-
scents, and serves, by throwing northriment to the
heels, to strengthen them; on them the horse should
depend for measure walk, and the shoe be made of a proper
length accordingly; by this means, narrow heels are pre-
vented, and many other good effects produced. Many
people drive a nail at the toe, but it is an absurd practice.
Leaving room to drive one there caues the foot to be of
an improper length; and moreover that part of the hoof
is naturally so brittle, that even when it is kept well grea-
fed, the the nail there seldom stays in, but tears out and
damages the hoof. That the directions for shoeing a pro-
per length may be the more clear and intelligible, we have
annexed (plate 101.) a draught of a foot fixed a proper
length standing on a plain surface, and with it a draught
of the right kind of shoe.

In wet, spungey, and soft ground, where the foot sinks
in, the pressure upon the heels is of course greater, than
on hard ground; and so indeed it should be upon all ac-
counts. The hinder feet must be treated in the same
manner as the fore-ones; and the shoes the same: except in
hilly and slippery countries, they may not improperly be
turned up a little behind; but turning up the fore-shoes
is of no service, and is certain ruin to the fore legs, es-
specially to the bullets. In descending hills, cramps are
apt to throw horses down, by stepping the fore-legs, out
of their proper basis and natural bearing. when the hinder
ones are rapidly pressed; which unavoidably must be the
case, and consequently cannot but push the horse upon
his nose. With them on a plain surface, a horse's foot
is always thrown forwards on the toe, out of its proper
bearing, which is very liable to make the horse stumble.

The notion of their utility in going up hills is a false one.
In ascending, the toe is the first part of the foot, which
bears on, takes hold of the ground, and whether the
horse draws or carries, and consequently the business
is done before the part where the cramps are coming
to the ground. Ice nails are preferable to anything to
prevent slipping, as also to help horses up hill, the molt
forward ones taking hold of the ground early, consider-
ably before the heels touch the ground: they must be so made,
as to be, when driven in, scarce half inch above the
shoe, and also have four sides ending at the top in a point.
They are of great service to prevent slipping on all kinds
of places, and by means of them a horse is not thrown out
of his proper basis. They must be made of very
good iron. If they are not, the heads of them will be
perpetually breaking off. From the race-horse to the
cart-horse, the same system of shoeing should be observed.
The size, thickness, and weight of them only should differ.
A shoe of a race-horse must of course be lighter than
that of a saddle horse; that of a saddle horse lighter than
that of a coach or bit horse; and these last more so than
a cart, waggon, or artillery horse. At present all shoes
in general are too heavy; if the iron is good, shoes need
not be so thick as they are now generally made.

The utmost severity ought to be inflicted upon all those who
clap shoes on hot: This unpardonable laziness of farriers
in making feet thus fit shoes, instead of shoes fitting
feet, dries up the hoof; and utterly destroys them. Fre-
quently removals of shoes are detrimental and tear the
foot, but sometimes they are very necessary: this is an in-
convenience which half-shoes are liable to; for the end of
the shoe, being very short, is apt to work into the
foot, and consequently must then be moved.

For the Natural History and Treatment of the Dis-
etias of Horses, see Equus, and Farriery.

HORSEMANSHIP.

HORRAGILERS.

HORSHAM, a market town and borough of Sussex,
situated twenty miles north west of Lewis, in W. long,
HORTAGILERS, in the grand feignior's court, upholderers, or tapestry-hangers. The grand feignior has constantly four hundred in his retinue when he is in the camp: these go always a day's journey before him, to fix upon a proper place for his tent, which they prepare first; and afterwards those of the officers, according to their rank.

HORTUS SICCUS, a dry garden, an appellation. In the camp: these go always a day's journey before

HOSEANNA, a Hebrew word, signifying or

HOSEA, a canonical book of the Old Testament, so call-

HOST, denotes either a person who entertains another, to fix upon a proper place for his tent, which

they prepare first; and afterwards those of the officers, according to their rank.

HOSTAGE, a person given up to an enemy as a security for the performance of the articles of a treaty.

HOTBEDS, in gardening, beds made with fresh horde-

HUTTONIA, water-violet, in botany, a genus of the pentadactyly monogynia class. The corolla is shaped like a jug; the stamens are fixed to the tube of the corolla; and the capsule has but one cell. There are two species, none of them natives of Britain.

HOVINGHAM, a market-town of the east riding of Yorkshire, seventeen miles north-east of York.

HOUND. See Canis.

HOUR, in chronology, an aliquot part of a natural day, usuall y a 24th, sometimes a 12th. See Astronomy, Dialing. Geography.

HOUSE, a habitation, or place built with conveniences for dwelling in. See Architecture.

HOUSE, in astrology, denotes the twelfth part of the heavens.

HOY, in naval architecture, a small vessel, fitted only with one mast.

HOYE, a town of Westphalia, capital of a county of the

HOUDSON'S BAY, a large Mediterranean sea of north America, situated between 51° and 63° of N. lat. and of unequal breadth from 130 to 35 leagues.

HOUDSON'S JUSTRIGHTS, giving entrance into Hudson's bay, lie between 60° and 75° of W. lon.

Hudson's river, rises near the lake Champlain, in Canada, and falls into the Atlantic, a little below the city of New-York.

HUE AND CRY, in law, the pursuit of a person who has committed felony on the highway.

HUEGLY, a large town in the East Indies, situated on an island in the most westerly branch of the river Ganges, in the province of Bengal: E. long. 87° N., lat. 23°.

HUETTE, a city of Spain, in the province of New Castile, sixty seven miles east of Madrid: W. lon. 4° 45', N. lat. 40° 35'.

HUGENOTS, a name given by way of contempt to the Calvinists of France.

The name had its rise in the year 1560; but authors are not agreed as to its origin. The most plausible opinion, however, is that of Pasquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion, that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time; from whence as those of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots, that is, the disciples of king Hugon.
HUNDRED, hundredth, or centuria, a part or division of a county, which was anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king’s wars. After King Alfred’s dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were at first made by the king to particular persons, but they are now held by grant or prescription; their jurisdiction being devolved to the county court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

HUNTINGDON, the capital of Huntingdonshire, situated on the river Nene, thirty-four miles north-east of York. It sends two members to parliament.

HUNTINGDONSHIRE, a county, bounded by Northamptonshire, and by the counties of Lincolnshire and Rutland on the west, and by the county of Norfolk on the north; it contains an hundred families, and is divided into thousands, hundreds, and parishes, with its statute being devolved to the county court; but they are not now held by grant or prescription; a few of them only excepted, that have been by privilege annexed to the crown.

HUNGRY, an uneasy sensation, which creates an appetite or desire of food. Hunger is by some attributed to a sharp acrimonious humour, which vivifies the coats of the stomach; others, who deny the existence of any such liquor, attribute it to the attrition or rubbing of the coats of the stomach; and others, again, account for it from the acidity of the blood.

HUNGRY WATER, a distilled water, so denominated from a queen of Hungary, for whole use it was first prepared.

HUNGRYWATER, a river formed by the Trent, the Ouse, and several other streams united. It divides Yorkshire from Lincolnshire, and falls into the German Sea at Holderness.

HUMBLE BEE. See Apis.

HUMBLE, in general, is an appellation given to whatever relates to mankind: thus we say, the human soul, human body, human laws, &c.

HUMANITY, the peculiar nature of man, whereby he is distinguished from all other beings.

HUMANITIES, in the plural, signify grammar, rhetoric, and poetry, known by the name of litterae humaniores; for teaching of which, there are professors in the universities of Scotland, called humanists.

HUMERUS, in anatomy. See Anatom. p. 176.

HUMERUS, in anatomy. See Anatom. p. 176.

HUMIDITY, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity, and seems to be merely a relative thing, depending upon the congruity of the component particles of the liquor to the pores of such particular bodies, as it is capable of adhering to, penetrating a little into, or wetting. Thus, for instance, quicksilver is not a moist thing with regard to our hands or clothes, but may be called so in reference to gold, tin, or lead, to whose surfaces it will perfectly adhere, and render them soft and moist.

HUMING-BIRD. See Trochilus.

HUMOUR, in general, denotes much the same with liquid or fluid. See Fluid.

HUMOUR, in general, denotes much the same with liquid or fluid. See Fluid.

HUMOUR. See Wit.

HUMULUS, in botany, a genus of the dioecia penta-andria class. The calyx of the male is divided into five parts, and it has no corolla. The calyx of the female consists of one entire leaf opening at one side; the corolla is wanting; it has two stamens; and the nut has two valves, and is included within the calyx. There is but one species, viz. the lupulus, or hop, a native of Britain. See Hop.

HUNDRED, hundredth, or centuria, a part or division of a county, which was anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king’s wars. After King Alfred’s dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were at first made by the king to particular persons, but they are not now held by grant or prescription; their jurisdiction being devolved to the county court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

HUNGERFORD, a market-town of Berkshire, situated on the river Kennet, twenty-four miles west of Reading.

HUNNINGHEN, a town of Germany, in the province of Brabant, situated nine miles south-east of Bruges: E. long. 4° 22’. N. lat. 50° 42’.

HUMAN, in general, is an appellation given to whatever relates to mankind: thus we say, the human soul, human body, human laws, &c.

HUMANITY, the peculiar nature of man, whereby he is distinguished from all other beings.

HUMANITIES, in the plural, signify grammar, rhetoric, and poetry, known by the name of litterae humaniores; for teaching of which, there are professors in the universities of Scotland, called humanists.

HUMERUS, in anatomy. See Anatom. p. 176.
on the north, and by Quamni and Canton on the south; lying between 25° and 30° of north latitude.

HUSA, the sand box tree, in botany, a genus of the monoeica monadelphia class. The male has no calix; the corolla consists of four petals; it has eight stamens, and four glumular bearded nectaria; the calix and corolla of the female are the same as in the male; the stigmas is filiform; the stigmatic are parted; the capsule has four valves, and but one seed. There is only one species, a native of Mexico.

HURDLES, in fortification, twigs of willows or of hazel-rods, laid together, to serve for gates in inclosures, or to make sheep-folds, &c.

HURDS, or HORDS, of flax, or hemp, the coarser parts separated in the dressings from the tear or fine stuff. See Flax.

HURLE BONE, in horse, a bone near the middle of the buttoc, very apt to go out of its sockets with a hurt or strain.

HURON, a vast lake of North America, situated between 84° and 89° W. long and between 43° and 46° N lat from whence the country contiguous to it is called the country of the Hurons, whose language is spoken over a great extent in the southern parts of North America.

HURRICANE, a furious storm of wind, owing to a contrariety of winds. See Wind and Whirlwind.

HURST, a strong town in the bishopric of Liege, situated on the German sea: subject to the duke of Holstein Gottorp: E long. 8° 30', N. lat. 54° 40'.

HUTORFIELD, a market town in the Lindsey riding of Yorkshire: W. long. 1° 34', N. lat. 53° 37'.

HUY, a strong town in the bishopric of Liege, situated on the Maes, sixteen miles north-east of Namur: E long. 5° 15', N. lat. 50° 35'.

HYACINTH, in botany. See Hyacinthus.

Hyacinths in natural history a genus of pellucid gems, whose colour is red with an admixture of yellow.

The hyacinth, though less striking to the eye than any other red gems, is not without its beauty in the finest specimens. It is found of various sizes, from that of a pin's head to the third of an inch in diameter. Like common crystal, it is sometimes found columnar, and sometimes in a pebble-form; and is always hardest and brightest in the larger masses.

Its colour is a dull or deadish red, with an admixture of yellow in it; and this mixed colour is found in all the variety of tints that a prevalence of the red or of the yellow in different degrees is capable of giving it.

Our jewelers allow all those gems to be hyacinths or jacinths, that are of a due hardness with this mixed colour; and as they are of very different beauty and value in their several degrees and mixture of colours, they divide them into four kinds; three of which they call hyacinths, but the fourth, very improperly, a ruby. 1. When the stone is in its most perfect state, and of a pure and bright flame-colour, neither the red nor the yellow prevailing, in this state they call it hyacintha la belle 2. When it has an over proportion of the red, and that of a ducker colour than the fine high red in the former, and the yellow that appears in a faint degree in it is not a fine, bright, and clear, but a dusky brownish-yellow, then they call it the faffron hyacinth 3 Such stones as are of a dead whitish-yellow, with a very small proportion of red in them, they call amber-hyacinths. And, 4. When the
the stone is of a fine deep red, blended with a dusky
and very deep yellow, they call it a rubacelle. But
though the over-proportion of a strong red in this gem
has made people refer to the class of rubies, its evi-
dent mixture of yellow shows that it truly belongs to
the hyacinths.

The hyacinth la belle is found both in the East and
West Indies. The oriental are the harder, but the
American are often equal to them in colour. The rub-
acelle is found only in the East Indies, and is gener-
bly brought over among the rubies, but it is of little
value: the other varieties are found in Silecia and Bo-
hemia.

HYACINTHUS, in botany, a genus of the hexanda-
ria clafs. The capule has two cells, and a double
nella, m. elcan, jalop, fyc.

Their appendages, they squeeze out water enough to
make the fruits appear little else.

There are four fpecies, only one of which, viz. the vul-
garis, march penny wort, or white rot, is a native of
Britain.

HYADES, in astronomy, seven stars in the bull's head,
famous among the poets for the bringing of rain. See
Astronomy, p. 487.

HYATIDES, in medicine, little transparent veficles or
bladders, full of water, fometimes found solitary, and
sometimes in clufters, upon the liver, and various oth-
er parts, efpzialy in hydropical confituptions.

HYDATOSCOPIA, called also hydromancy, a kind of
divination or method of foretelling future events by
means of water.

HYDNUM, in botany, a genus of the cryptogamia
class: it is an horizontal fungus, echinated or
befet with fharp-pointed fibres on its under part There
are five fpecies, only one of them, viz. the vulgaris,
commonly beft known by the name of thread tied to
their finger, hefd it over the water,

And repeated a certain form of words, defiring to be
satisfied with regard to their inquiry; and if the
question was anfwered in the affirmative, the ring would
strike the fides of the bowl of its own accord.

Another kind of hydromancy was to look upon the
water in which the figure of feveral demons was reflected.

This expedient Numa is faid to have made use of, to fettle the ceremonies of religion.

This way of divination is faid to have been refifted by the Pancraes, and afterwards approved by Pytha-
goras.

HYDROMEL, among phyficians, water impregnated
with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is faid to
be good for the gravel. See the article Mead.

HYDROMETER, an instrument to measure the gra-
vity, density, velocity, force, &c. of water and other
fluids. See Hydrometers.

HYDRENGEA, in botany. See Hydrangea.

HYDROMEL, in botany, a genus of the diccia decan-
dria clafs. The spathas of the male confifts of two leaves, the calyx
of three fhapes, and the corolla of three petals. The
caffix of the female confifts of three fhapes, and the
orolla of three petals; it has fix fylph: and the cap-
Hulates have fix cells and many seeds. There is but one
fpecies, viz. the morbus range, or frog bit, a native of
Britain.

HYDROCORAX, in ornithology. See Bucerus.

HYDROCOTYLE, in botany, a genus of the pentan-
dria clafs. The corolla is bell-shaped; and
there are three melliferous pores in the germen. There
are 13 fpecies, only one of which, viz. the non-scriptus,
English hyacinth, or hare bells, is a native of
Britain.

HYDROCEPHALUS, in surgery. See Buceros.

HYDROCEPHALUS, in surgery, a preternatural dif-
tention of the head, to an uncommon size, by a flag-
nation and extravafation of the lymph, which, when
collected within fide of the bones of the cranium, the
hydrocephalus is then termed internal; as it is exter-
nal when retained betwixt the common integuments
and the cranium. See Surgery.

HYDROCHLORIC, the little water-lily, in
botany, a genus of the diccia decandria clafs. The
spathas of the male confifts of two leaves, the calix
of three fhapes, and the corolla of three petals. The
calyx of the female confifts of three fhapes, and the
corolla of three petals; it has fix fylph: and the cap-
Hulates have fix cells and many seeds. There is but one
fpecies, viz. the morbus range, or frog bit, a native of
Britain.

HYDROCROCELE, in surgery, a fpecies of her-
tia, wherein the intestines defend into the ferotum, to-
gether with a quantity of water.

HYDROCELE, in surgery, denotes any hernia arifing
from water; but is particularly used for fuch a one of
the ferotum which fometimes grows to the fize of one's
head, without pain, but exceeding troublesome to the
patient. See Surgery.

HYDROCEPHALUS, in surgery, a preternatural dif-
tention of the head, to an uncommon size, by a flag-
nation and extravafation of the lymph, which, when
collected within fide of the bones of the cranium, the
hydrocephalus is then termed internal; as it is exter-
nal when retained betwixt the common integuments
and the cranium. See Surgery.

HYDROGRAPHY, the art of measuring and describing
the sea, rivers, lakes, and canals.

With regard to the sea, it gives an account of its
tides, counter tides, foundings bays, gulphs, creeks,
&c. as also of the rocks, shelves, fands, flawflops,
promontories, harbours, the distance and bearing of
one port from another, with every thing that is re-
markable, whether out at sea, or on the coast.

HYDROMANCY, a method of divination by water,
practifd by the ancients in this manner. They filled
a cup or bowl of water: then fuffing a ring to a piece
of thread tied to their finger, held it over the water,
and repeated a certain form of words, defiring to be
fatisfied with regard to their inquiry; and if the
question was anfwered in the affirmative, the ring would
strike the fides of the bowl of its own accord.

Another kind of hydromancy was to look upon the
water in which the figure of feveral demons was reflected.

This expedient Numa is faid to have made use of, to fettle the ceremonies of religion.

This way of divination is faid to have been refifted by the Pancraes, and afterwards approved by Pytha-
goras.

HYDROMEL, among phyficians, water impregnated
with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is faid to
be good for the gravel. See the article Mead.

HYDROMETER, an instrument to measure the gra-
vity, density, velocity, force, &c. of water and other
fluids. See Hydrometers.

HYDROTUS, among phyficians, water im-
pregnated with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is faid to
be good for the gravel. See the article Mead.

HYDROMETRY, an instrument to measure the gra-
vity, density, velocity, force, &c. of water and other
fluids. See Hydrometers.

HYDROPATHY, in botany. See Lemna.

HYDROMEL, in botany, a genus of the pentan-
dria clafs. The corolla is bell-shaped; and
there are three melliferous pores in the germen. There
are 12 fpecies, only one of which, viz. the non-scriptus,
English hyacinth, or hare bells, is a native of
Britain.

HYDROPHACE, in botany. See Lemna.

HYDROMETER, an instrument to measure the gra-
vity, density, velocity, force, &c. of water and other
fluids. See Hydrometers.

HYDROMEL, among phyficians, water impregnated
with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is faid to
be good for the gravel. See the article Mead.

HYDROMETER, an instrument to measure the gra-
vity, density, velocity, force, &c. of water and other
fluids. See Hydrometers.

HYDROTUS, among phyficians, water impregnated
with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is faid to
be good for the gravel. See the article Mead.
imperfectly, as in the chalcedony; and giving a general cloudiness or mistiness to the stone, but of so imperfect and irregular an admixture, as not to be capable of so good a polish as the chalcedony; and appearing of a dulky and foul surface, till thrown into water, in which they become lucid, and in some degree transparent, either in part or totally; also changing their colour, which returns to them on being taken out of the water.

To this genus belong the oculus beli of authors, or whitish-grey hydrophanes, variegated with yellow, and with a black central nucleus; and the oculus mundi, or lapis mutabilis, which is likewise a whitish-grey kind without veins.

HYDROPHOBIA, an aversion or dread of water; a terrible symptom of the rabies canina. See Medicine.

HYDROPHILUM, in botany, a genus of the penandria monogynia class. The corolla is bell-shaped; the stamens is six; and the capsule is roundish with two valves. There are two species, none of them natives of Britain.

HYDROPS, in medicine. See Medicine.

HYDROSCOPES, an instrument anciently used for the measuring of time.

The hydroscope was a kind of water-clock, consisting of a cylindrical tub, conical at bottom: the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successestively contiguous, as it trickled out at the vertex of the cone, pointed out the hour.

HYDROSTATICS.

The science of Hydrostatics treats of the nature of gravity, pressure, and motion of fluids in general; and of weighing solids in them.

A fluid is a body that yields to the least pressure or difference of pressures. Its particles are so exceedingly small, that they cannot be discerned by the bell of microscopes; they are hard, since no fluid, except air or steam, can be pressed into a leaf of paper than it naturally presses; and they are round and smooth, since they are so easily moved among one another.

All bodies, both fluid and solid, press downwards by the force of gravity: but fluids have this wonderful property, that their pressure upwards and sidewise is equal to their pressure downwards; and this is always in proportion to their perpendicular height, without any regard to their quantity: for, as each particle is quite free to move, it will move towards that part or side on which the pressure is least. And hence, no particle or quantity of a fluid can be at rest, till it is every way equally pressed.

(Plate XCIX. fig. 2.) To show by experiment that fluids press upward as well as downward, let AB be a long upright tube filled with water near its top; and CD a small tube open at both ends, andimmered into the water in the large one: if the immersion be quick, you will see the water rise in the small tube to the same height that it stands in the great one, or until the surfaces of the water in both are on the same level: which shows that the water is pressed upward into the small tube by the weight of what is in the great one; otherwise it could never rise therein contrary to its natural gravity; unless the diameter of the bore were so small, that the attraction of the tube would raise the water; which will never happen, if the tube be as wide as that in a common barometer. And as the water rises no higher in the small tube than till its surface be-on a level with the surface of the water in the great one, this shows that the pressure is not in proportion to the quantity of water in the great tube, but in proportion to its perpendicular height therein: for there is much more water in the great tube all around the small one, than what is raised to the same height in the small one, as it stands in the great.

Take out the small tube, and let the water run out of it; then it will be filled with air. Stop its upper end with the cork C, and it will be full of air all below the cork: this done, plunge it again to the bottom of the water in the great tube, and you will see the water rise up in it to the height E; which shows that the air is a body, otherwise it could not hinder the water from rising up to the same height as it did before, namely, to A; and in so doing it drove the air out at the top; but now the air is confined by the cork C: and it also shows that the air is a compressible body; for if it were not so, a drop of water could not enter into the tube.

The preffure of fluids being equal in all directions, it follows, that the sides of a vessel are as much preffed by a fluid in it, all around in any given ring of points, as the fluid below that ring is preffed by the weight of all that stands above it. Hence the preffure upon every point in the fides, immediately above the bottom, is equal to the preffure upon every point of the bottom. To show this by experiment, let a hole be made at E (fig. 2.) in the side of the tube AB close by the bottom; and another hole of the same fize in the bottom, at C; then pour water into the tube, keeping it full as long as you chufed the holes should run, and have two two fasons ready to receive the water that runs through the two holes, until you think there is enough in each fason; and you will find, by meafuring the quantities, that they are equal; which shows that the water run with equal speed through both holes; which it could not have done, if it had not been equally preffed through them both: for if a hole of the fame fize be made in the fide of the tube, as about $f$, and if all three are permitted to run together, you will find that the quantity run through the hole at $f$ is much less than what has run in the fame time through either of the holes C or $e$. In
In the same figure, let the tube be re-curved from the bottom at O into the shape DE, and the hole at C be stopped with a cork. Then pour water into the tube to any height, as Ag, and it will spout up in a jet EFG, nearly as high as it is kept in the tube AB, by continuing to pour in as much there as runs through the hole E; which will be the case when the surface Ag keeps at the same height. And if a little ball of cork G be laid upon the top of the jet, it will be supported thereby, and dance upon it. The reason why the jet rises not quite as high as the surface of the water Ag, is owing to the resistance it meets with in the open air: for if a tube, either great or small, were fixed upon the pipe at E, the water would rise in it until the surfaces of the water in both tubes were on the same level; as will be shown by the next experiment.

The hydrostatic paradox.

Any quantity of a fluid, however small or great, may be made to balance and support any quantity, however great or small. This is defined as the hydrostatic paradox, which we shall first shew by an experiment, and then account for it upon the principle above-mentioned, namely, that the pressure of fluids is directly as their perpendicular height, without any regard to their quantity.

Let a small glass tube DCG, (fig. 4.) open at both ends, and bended at B, be joined to the end of a great one AE at cd, where the great one is also open; so that these tubes in their openings may freely communicate with each other. Then pour water through a small-necked funnel into the small tube at H; this water will run through the joining of the tubes at cd, and rise up into the great tube: and if you continue pouring until the surface of the water comes to any part, as A, in the great tube, and then leave off, you will see that the surface of the water in the small tube will be just as high at D; so that the perpendicular altitude of the water will be the same in both tubes, however small the one be in proportion to the other. This shews, that the small column DCG balances and supports the great column Acd; which it could not do if its presfures were not equal against one another in the recurred bottom at B.—If the small tube be made longer, and inclined in the situation GEF, the surface of the water in it will stand at F, on the same level with the surface A in the great tube; that is, the water will have the same perpendicular height in both tubes, although the column in the small tube is longer than that in the great one; the former being oblique, and the latter perpendicular.

Since then the presfure of fluids is directly as their perpendicular heights, without any regard to their quantities, it appears that whatever the figure or size of vessels be, if they are of equal heights, and if the areas of their bottoms are equal, the presfures of equal heights of water are equal upon the bottoms of these vessels; even though the one should hold a thousand or ten thousand times as much water as would fill the other. To confirm this part of the hydrostatic paradox by an experiment, let two vessels be prepared of equal heights, but very unequal contents, such as AB in fig. 5. and AB in fig. 6. Let each vessel be open at both ends, and their bottoms Dd Dd be of equal widths. Let a brass bottom CC be exactly fitted to each vessel, not to go into it, but for it to stand upon; and let a piece of wet leather be put between each vessel and its brass bottom, for the sake of clefteness. Join each bottom to its vessel by a hinge D, so that it may open like the lid of a box; and let each bottom be kept up to its vessel by equal weights E and E, hung to lines which go over the pulleys F and F (whose blocks are fixed to the sides of the vessels at f) and the lines tied to hooks at d and d, fixed in the brass bottoms opposite to the hinges D and D. Things being thus prepared and fitted, hold the vessel AB (fig. 5.) upright in your hands over a basin on a table, and cause water to be poured into the vessel slowly, till the presfure of the water bears down its bottom at the side d, and raises the weight E; and then part of the water will run out at d. Mark the height at which the surface H of the water stood in the vessel, when the bottom began to give way at d; and then, holding up the other vessel AB (fig. 4.) in the same manner, cause water to be poured into it at H; and you will see that when the water rises to A in this vessel, just as high as it did in the former, its bottom will also give way at d, and it will lose part of the water.

The natural reason of this surprising phenomenon is, that since all parts of a fluid at equal depths below the surface are equally presfured in all manner of directions, the water immediately below the fixed part Bf (fig. 4.) will be presfured as much upward against its lower surface within the vessel, by the action of the column Ag, as it would be by a column of the same height, and of any diameter whatever; (as was evident by the experiment with the tube, fig. 3.) and therefore, since action and reaction are equal and contrary to each other, the water immediately below the surface Bf will be presfured as much downward by it, as if it was immediately touched and presfured by a column of the height ga, and of the diameter Bf: and therefore, the water in the cavity Bddf will be presfured as much downward upon its bottom CC, as the bottom of the other vessel (fig. 5.) is presfured by all the water above it.

To illustrate this a little farther, let a hole be made at f(fig. 5.) in the fixed top Bf, and let a tube G be put into it; then, if water be poured into the tube A, it will (after filling the cavity Bd) rise up into the tube G, until it comes to a level with that in the tube A; which is manifestly owing to the presfure of the water in the tube A, upon that in the cavity of the vessel below it. Consequently, that part of the tube Bf, in which the hole is now made, would, if corked up, be presfured upward with a force equal to the weight of all the water which is supported in the tube G; and the same thing would hold at g, if a hole were made there. And so if the whole cover or top Bf were full of holes, and had tubes as high as the middle one Ag put into them, the water in each tube would rise to the same height as it is kept into the tube A, by pouring more into it, to make up the deficiency that it suffers by supplying the others, until they were all full: and then the water in the tube A would support equal heights of water in all the rest of the
HYDROSTATICS.

Hence, if a man stands upon the upper board, and blows into the bellows through the pipe B, he will raise himself upward upon the board; and the smaller the bore of the pipe is, the easier he will be able to raise himself. And then, by clapping his finger upon the top of the pipe, he can support himself as long as he pleases; provided the bellows be air-tight, so as not to let what is blown into it.

Upon this principle of the upward pressure of fluids, a piece of lead may be made to swim in water, by immersing it to a proper depth, and keeping the water from getting above it. Let CD (fig. 8.) be a glass tube, open at both ends, and EFG a flat piece of lead, exactly fitted to the lower end of the tube, not to go within it, but for it to stand upon; with a wet leather between the lead and tube to make close work. Let this leaden bottom be half an inch thick, and held close to the tube by pulling the packthread IHL upward at L with one hand, whilst the tube is held in the other by the upper end C. In this situation, let the tube be immersed in water in the glass vessel AB, to the depth of six inches below the surface of the water at K; and then, the leaden bottom EFG will be plunged to the depth of somewhat more than eleven times its own thickness; holding the tube at that depth, you may let go the thread at L; and the lead will not fall from the tube, but will be kept to it by the upward pressure of the water below it, occasioned by the height of the water at K above the level of the lead. For as lead is 11.33 times as heavy as its bulk of water, and is in this experiment immersed to a depth of somewhat more than 11.33 times its thickness, and no water getting into the tube between it and the lead, the column of water EabcG below the lead is pressed upward against it by the water KDEGL all around the tube; which water being a little more than 11.33 times as high as the lead is thick, is sufficient to balance and support the lead at the depth KE. If a little water be poured into the tube upon the lead, it will increase the weight upon the column of water under the lead, and cause the lead to sink from the tube to the bottom of the glass vessel, where it will lie in the situation bd. Or, if the tube be raised a little in the water, the lead will fall by its own weight, which will then be too great for the pressure of the water around the tube upon the column of water below it.

Let two pieces of wood be plained quite flat, so as no water may get in between them when they are put together: let one of the pieces, as bd, be cemented to the bottom of the vessel AB (fig. 8.), and the other piece be laid flat and close upon it, and held down to it by a flick, whilst water is poured into the vessel; then remove the flick, and the upper piece of wood will not rise from the lower one: for, as the upper one is pressed down both by its own weight and the weight of all the water over it, whilst the contrary pressure of the water is kept off by the wood under it, it will lie as still as a stone would do in its place. But if it be raised ever so little at any edge, some water will then get under it; which being acted upon by the water above, will immediately press it upward; and as it is lighter than its bulk of water, it will rise, and float upon the surface of the water.

All fluids weigh just as much in their own element as they.
they do in open air. To prove this by experiment, let as much hot be put into a phial, as, when corked, will make it sink in water: and being thus charged, let it be weighed, first in air, and then in water, and the weights in both cases wrote down. Then, as the phial hangs suspended in water, and counterpoised, pull out the cork, that water may run into it, and it will defend, and pull down that end of the beam. This done, put as much weight into the opposite scale as will restore the e-boy: which weight will be found to answer exactly to the additional weight of the phial when it is again weighted in air, with the water in it.

The velocity with which water spouts out at a hole in the side or bottom of a vessel, is as the square root of the depth or distance of the hole below the surface of the water. For, in order to make double the quantity of a fluid run through one hole as through another of the same size, it will require four times the preflure of the other, and therefore must be four times the depth of the other below the surface of the water: and for the same reason, three times the quantity running in an equal time through the same port of hole, must run with three times the velocity, which will require nine times the preflure; and consequently must be nine times as deep below the surface of the fluid: and so on. To prove this by an experiment, let two pipes, as C and E (fig. 9), be fixed into the side of the vessel AB; the pipe C being four times as deep below the surface of the water at b in the vessel as the pipe C is: and whilst these pipes run, let water be constantly poured into the vessel, to keep the surface still at the same height. Then, if a cup that holds a pint be so placed as to receive the water that spouts from the pipe C, and at the same moment a cup that holds a quart be so placed as to receive the water that spouts from the pipe C, both cups will be filled at the same time by their respective pipes.

The horizontal distance, to which a fluid will spout from a horizontal pipe, in any part of the side of an upright vessel below the surface of the fluid, is equal to twice the length of a perpendicular to the side of the vessel, drawn from the mouth of the pipe to a semicircle described upon the altitude of the fluid: and therefore, the fluid will spout to the greatest distance possible from a pipe whose mouth is at the centre of the semicircle; because a perpendicular to its diameter (supposed parallel to the side of the vessel) drawn from that point, is the longest that can possibly be drawn from any part of the diameter to the circumference of the semicircle. Thus, if the vessel AB (fig. 9) be full of water, the horizontal pipe D be in the middle of its side, and the semicircle Neeb be described upon D as a centre, with the radius or semidiameter DgN, or DfB, the perpendicular Dd to the diameter NDd is the longest that can be drawn from any part of the diameter to the circumference Neeb. And if the vessel be kept full, the jet G will spout from the pipe D, to the horizontal distance NM, which is double the length of the perpendicular Dd. If two other pipes as C and E, be fixed into the side of the vessel at equal distances above and below the pipe D, the perpendiculars Ce and Ee, from these pipes to the semicircle, will be equal; and the jets F and H spouting from them will each go to the horizontal distance NK; which is double the length of the equal perpendiculars Ce or Dd.

Fluids by their preflure may be conveyed over hills and valleys in bended pipes, to any height not greater than the level of the springs from whence they flow. But when they are designed to be raised higher than the springs, forcing engines must be used; which shall be described when we come to treat of pumps.

A syphon, generally used for decanting liquors, is a bended pipe, whose legs are of unequal lengths; and the shorter leg must always be put into the liquor intended to be decanted, that the perpendicular altitude of the column of liquor in the other leg may be longer than the column in the immersed leg, especially above the surface of the water. For, if both columns were equally high in that respect, the atmosphere, which press as much upward as downward, and therefore acts as much upward against the column in the leg that hangs without the vessel, as it acts downward upon the surface of the liquor in the vessel, would hinder the running of the liquor through the syphon, even though it were brought over the bended part by suction. So that there is nothing left to cause the motion of the liquor, but the superior weight of the column in the longer leg, on account of its having the greater perpendicular height.

Let D (fig. 10.) be a cup filled with water to C, and ABC a syphon, whose shorter leg BCF is immersed in the water from C to F. If the end of the other leg were no lower than the line AC, which is level with the surface of the water, the syphon would not run, even though the air should be drawn out of it at the mouth A. For although the suction would draw some water at first, yet the water would stop at the moment the suction ceased; because the air would act as much upward against the water at A, as it acted downward for it by pressing on the surface at C. But if the leg AB comes down to G, and the air be drawn out at G by suction, the water will immediately follow, and continue to run, until the surface of the water in the cup comes down to F; because, till then, the perpendicular height of the column BAG will be greater than that of the column CB; and consequently, its weight will be greater, until the surface comes down to F; and then the syphon will stop, though the leg CF should reach to the bottom of the cup. For which reason, the leg that hangs without the cup is always made long enough to reach below the level of its bottom; as from d to E: and then, when the syphon is emptied of air by suction at E, the water immediately follows, and by its continuity brings away the whole from the cup; just as pulling one end of a thread will make the whole line follow.

If the perpendicular height of a syphon, from the surface of the water to its bended top at B, be more than 33 feet, it will draw no water, even though the other leg were much longer, and the syphon quite emptied of air, because the weight of a column of water 33 feet high is equal to the weight of as thick a column of air, reaching from the surface of the earth to the top of the atmosphere; so that there will then be an equilibrium; and consequently, though there would be weight enough of air upon the surface C to make the water ascend in the leg,
leg CB almost to the height B, if the syphon were emptied of air, yet the weight would not be sufficient to force the water over the bend; and therefore, it could never be brought into the leg BAC.

**Tantalus's cup.**

Let a hole be made quite through the bottom of the cup A (fig. 11.) and the longer leg of the bended syphon BCED he cemented into the hole, so that the end D of the shorter leg DE may almost touch the bottom of the cup within. Then, if water be poured into this cup, it will rise in the shorter leg by its upward pressure, extruding the air all the way before it through the longer leg: and when the cup is filled above the bend of the syphon at F, the preface of the water in the cup will force it over the bend of the syphon: and it will descend in the longer leg CBG, and run through the bottom, until the cup be emptied.

This is generally called Tantalus’s cup, and the legs of the syphon in it are almost close together; and a little hollow statue, or figure of a man, is sometimes put over the syphon to conceal it; the bend E being with the neck of the figure as high as the chin. So that poor thirsty Tantalus stands up to the chin in water, imagining it will rise a little higher, and he may drink; but instead of that, when the water comes up to his chin, it immediately begins to descend; and so, as he cannot stop to follow it, he is left as much pained with thirst as ever.

**The fountain at command.**

The device called the fountain at command acts upon the same principle with the syphon in the cup. Let two vessels A and B (Plate C, fig. 1.) be joined together by the pipe C which opens into them both. Let A be open at top, B close both at top and bottom (save only a small hole at b to let the air get out of the vessel B) and A be of such a size as to hold about six times as much water as B. Let a syphon DEF be soldered to the vessel B, so that the part DEe may be within the vessel, and F without it: the end D almost touching the bottom of the vessel, and the end F below the level of D: the vessel B hanging at A by the pipe C (folded into both) and the whole supported by the pillars G and H upon the stand I. The bore of the pipe must be considerably less than the bore of the syphon.

The whole being thus constructed, let the vessel A be filled with water, which will run through the pipe C, and fill the vessel B. When B is filled above the top of the syphon at E, the water will run through the syphon, and be discharged at F. But since the bore of the syphon is larger than the bore of the pipe, the syphon will run faster than the pipe, and will soon empty the vessel B: upon which the water will cease from running through the syphon at F, until the pipe C re-fills the vessel B, and then it will begin to run as before. And thus the syphon will continue to run and stop alternately, until all the water in the vessel A has run through the pipe C.—So that after a few trials, one may easily guess about what time the syphon will stop, and when it will begin to run: and then to amuse others, he may call out either, or run, accordingly.

Upon this principle, we may easily account for intermittent or reciprocating springs. Let AA (fig. 2.) be part of a hill, within which there is a cavity BB; and from this cavity a vein or channel running in the direction BCDE. The rain that falls upon the side of the hill will sink and drain through the small pores and crannies G, G, G, G; and fill the cavity H with water. When the water rises to the level HHC, the vein BCDE will be filled to C, and the water will run through CDF as through a syphon; which running will continue until the cavity be emptied, and then it will stop until the cavity be filled again.

**The common pump.**

The common sucking pump, with which we draw water out of wells, is an engine both pneumatic and hydraulic. It consists of a pipe open at both ends, in which is a moveable piston, bucket, or sucker, as big as the bore of the pipe in that part wherein it works; and is leathered round, so as to fit the bore exactly, and may be moved up and down, without allowing any air to come between it and the pipe or pump-barrel.

We shall explain the construction both of this and the forcing pump by pictures of glass models, in which both the action of the pilions and motion of the valves are seen.

Hold the model DCBL (fig. 3.) upright in the vessel of water K, the water being deep enough to rise at least as high as from A to L. The valve a on the moveable bucket G, and the valve b on the fixed box H, (which box quite fills the bore of the pipe or barrel at H) will each lie close, by its own weight, upon the hole in the bucket and box, until the engine begins to work. The valves are made of brass, and covered underneath with leather for closing the holes the more exactly; and the bucket G is raised and depressed alternately by the handle E and rod D d, the bucket being suspended at B before the working begins.

Take hold of the handle E, and thereby draw up the bucket from B to C, which will make room for the air in the pump all the way below the bucket to dilate itself, by which its spring is weakened, and then its force is not equivalent to the weight or pressure of the outward air upon the water in the vessel K: and therefore, at the first stroke, the outward air will press up the water through the notched foot A, into the lower pipe, about as far as e: this will condense the rarefied air in the pipe between e and C to the same rate it was in before; and then, as its spring within the pipe is equal to the force or pressure of the outward air, the water will rise no higher by the first stroke; and the valve b, which was raised a little by the dilation of the air in the pipe, will fall, and stop the hole in the box H; and the surface of the water will stand at e. Then, depress the piston or bucket from C to B, and as the air in the part B cannot get back again through the valve b, it will (as the bucket descends) raise the valve a, and so make its way through the upper part of the barrel d into the open air. But upon raising the bucket...
bucket  \( G \) a second time, the air between it and the water in the lower pipe at \( e \) will be again left at liberty to fill a larger space; and so its spring being again weakened, the pressure of the outward air on the water in the vessel \( K \) will force more water up into the lower pipe from \( e \) to \( f \); and when the bucket is at its greatest height \( C \), the lower valve \( b \) will fall, and stop the hole in the box \( H \) as before.

At the next stroke of the bucket or piston, the water will rise through the box \( H \) towards \( B \), and then the valve \( a \), which was raised by it, will fall when the bucket \( G \) is at its greatest height. Upon depressing the bucket again, the water cannot be pushed back through the valve \( a \), which keeps close upon the hole whilist the piston descends. And upon raising the piston again, the outward pressure of the air will force the water up thro' \( H \), where it will raise the valve, and follow the bucket to \( C \). Upon the next depression of the bucket \( G \), it will go down into the water in the barrel \( B \); and as the water cannot be driven back through the now close valve \( b \), it will raise the valve \( a \) as the bucket descends, and will be lifted up by the bucket when it is next raised. And now, the whole space below the bucket being full, the water above it cannot sink when it is next depressed; but upon its depression, the valve \( a \) will rise to let the bucket go down; and when it is quite down, the valve \( a \) will fall by its weight, and stop the hole in the bucket. When the bucket is next raised, all the water above it will be lifted up, and begin to run off by the pipe \( F \). And thus, by raising and depressing the bucket alternately, there is still more water raised by it; which getting above the pipe \( F \), into the wide top \( I \), will supply the pipe, and make it run with a continued stream.

So, at every time the bucket is raised, the valve \( b \) rises, and the valve \( a \) falls; and at every time the bucket is depressed, the valve \( b \) falls, and \( a \) rises.

As it is the pressure of the air or atmosphere which causes the water to rise and follow the piston or bucket \( G \) as it is drawn up; and since a column of water 33 feet high is of equal weight with as thick a column of the atmosphere from the earth to the very top of the air; therefore, the perpendicular height of the piston or bucket from the surface of the water in the well must always be less than 33 feet; otherwise the water will never get above the bucket. But, when the height is less, the pressure of the atmosphere will be greater than the weight of the water in the pump, and will therefore raise it above the bucket; and when the water has once got above the bucket, it may be lifted thereby to any height, if the rod \( D \) be made long enough, and a sufficient degree of strength be employed, to raise it with the weight of the water above the bucket; without ever lengthening the stroke.

The force required to work a pump, will be as the height to which the water is raised, and as the square of the diameter of the pump-bore, in that part where the piston works. So that, if two pumps be of equal heights, and one of them be twice as wide in the bore as the other, the widest will raise four times as much water as the narrowest; and will therefore require four times as much strength to work it.

The wideness or narrowness of the pump, in any other part besides that in which the piston works, does not make the pump either more or less difficult to work; except what difference may arise from the friction of the bore, which is always greater in a narrow bore than in a wide one, because of the greater velocity of the water.

The pump-rod is never raised directly by such a handle as \( E \) at the top, but by means of a lever, whose longer arm (at the end of which the power is applied) generally exceeds the length of the shorter arm five or six times; and, by that means, gives five or six times as much advantage to the power. Upon these principles, it will be easy to find the dimensions of a pump that shall work with a given force, and draw water from any given depth. But, as these calculations have been generally neglected by pump-makers (either for want of skill or industry) the following table was calculated by the late ingenious Mr Booth for their benefit. In this calculation, he supposed the handle of the pump to be a lever increasing the power five times; and had often found that a man can work a pump four inches diameter, and 30 feet high above the bucket, and discharge 272 gallons of water (English wine measure) in a minute. Now, if it be required to find the diameter of a pump, that shall raise water with the same ease from any other height above the bucket; look for that height in the first column, and over against it in the second you have the diameter or width of the pump; and in the third, you find the quantity of water which a man of ordinary strength can discharge in a minute.

_The forcing-pump._

The forcing-pump raises water through the box \( H \) (fig. 4) in the same manner as the sucking-pump does, when the plunger or piston \( g \) is lifted up by the rod \( D D \). But this plunger has no hole through it, to let the water in the barrel.
barrel BC get above it when it is deprefled to B, and the valve a (which rofe by the afcent of the water through the box H when the plunger g was drawn up) falls down and flops the hole in H, the moment that the plunger is raiffed to its greatest height. Therefore, as the water between the plunger g and box H can neither get through the plunger upon its defcent, nor back again into the lower part of the pump Le, but has a free paffage by the cavity around H into the pipe MM, which opens into the air-veffel KK at P; the water is forced through the pipe MM by the defcent of the plunger, and driven into the air-veffel; and in running up through the pipe at P, it opens the valve a; which fhuts at the moment the plunger begins to be raised, because the action of the water against the under fide of the valve then ceafes.

The water, being thus forced into the air-veffel KK by repeated ftrokes of the plunger, gets above the lower end of the pipe GHI, and then begins to condence the air in the veffel KK. For, as the pipe GH is fixed air-tight into the veffel below F, and the air has no way to get out of the veffel but through the mouth of the pipe at I, and cannot get out when the mouth I is covered with water, and is more and more condenced as the water rifes upon the pipe, the air then begins to act forcibly by its fpur against the fpur of the water, at H: and this action drives the water up through the pipe IH GF, from whence it fpouts in a jet S to a great height; and is supplied by alternately raiffing and depreffing of the plunger g, which conftantly forces the water that it raiffes through the valve H, along the pipe MM, into the air-veffel KK.

The higher that the fpur of the water H is raiffed in the air-veffel, the lefs space will the air be condenced in, to which before filled that veffel; and therefore the force of its fpur will be fo much the stronger upon the water, and will drive it with the greater force through the pipe at F: and as the fpur of the air continues whilst the plunger g is raiffing, the fpur or jet S will be uniform, as long as the action of the plunger continues: and when the valve d opens, to let the water follow the plunger upward, the valve a fhuts, to hinder the water, which is forced into the air-veffel, from running back by the pipe MM into the barrel of the pump.

If there was no air-veffel to this engine, the pipe GHI would be joined to the pipe MMN at P; and then the jet S would flop every time the plunger is raiffed, and run only when the plunger is depreffed.

Mr Newhams water-engine, for extinguifhing fire, conffits of two forcing pumps, which alternately drive water into a clofe veffel of air; and by forcing the water into that veffel, the air in it is thereby condenced, and comprefles the water fo strongly, that it rufhes out with great impetuofity and force through a pipe that comes down into it; and makes a continued uniform fpur by the condensation of the air upon its fpur in the veffel.

By means of forcing pumps, water may be raiffed to any height above the level of a river or fpur; and maftines may be contrived to work these pumps, either by a running fpur, a fall of water, or by horfes. An instance in each fort will be fufficient to fhew the method.

First, by a running fpur, or a fall of water. Let AA (fig. 5.) be a wheel turned by the fall of water BB; and have any number of cranks (fpurpoften fix) as C, D, E, F, G, H, on its axis, according to the strength of the ftroke of the pumps, and the height to which the water is intended to be raiffed by the engine. As the wheel turns round, these cranks move the levers c, d, e, f, g, h, up and down, by the iron rods i, k, l, m, n, o; which alternately raiff and depreff the pistons by the other iron rods p, q, r, s, t, u, w, x, y, in twelve pumps; nine whereof, as L, M, N, O, P, Q, R, S, T, appear in the plate; the other three being laid behind the work at V. And as pipes may go from all thefe pumps, to convey the water (drawn up by them to a small height) into a clofe ciftern, from which the main pipe proceeds, the water will be forced into this ciftern by the defcent of the pistons. And as each pipe, going from its refpective pump into the ciftern, has a valve at its end in the ciftern, these valves will hinder the return of the water by the pipes; and therefore, when the ciftern is once full, each piston upon its defcent will force the water (conveyed into the ciftern by a former fpur) up the main pipe, to the height the engine was intended to raife it: which height depends upon the quantity raiffed, and the power that turns the wheel. When the power upon the wheel is lejjened by any defect of the quantity of water turning it, a proportionable number of the pumps may be laid afide, by difengaging their rods from the vibrating levers.

This figure is a representation of the engine eredted at Blenheim for the Duke of Marlborough, by the late ingenious Mr Alderfe. The water-wheel is 7½ feet in diameter, according to Mr Switzer’s account in his Hydraulics.

When fuch a machine is placed in a fpur that runs upon a small declivity, the motion of the levers and action of the pumps will be but flow; since the wheel muft go once round for each fpur of the pumps. But, when there is a large body of flow running water, a cog or spur-wheel may be placed upon each fide of the water-wheel AA, upon its axis, to turn a trundle upon each fide; the cranks being upon the axis of the trundle. And by proportioning the cog-wheels to the trundles, the motion of the pumps may be made quicker, according to the quantity and fpur of the water upon the firft wheel; which may be as great as the workman pleafes, according to the length and breadth of the float-boards or wings of the wheel. In this manner, the engine for raifing water at London-Bridge is conftructed; in which the wheel-wheel is 20 feet diameter, and the floats 14 feet long.

A quadruple pump-mill for raifing water.

The engine is reprefented in Plate 99. fig 1. In which ABCD is a wheel, turned by water according to the order of the letters. On the horizontal axis are four small wheels, toothed almost half round; and the parts of their edges on which there are no teeth are cut down so as to be even with the bottoms of the teeth where they stand.

The teeth of these four wheels take alternately into the
HYDROSTATICS.

811

3 is come down to the position of b, a will be in the position of c.

The more perpendicularly the piston rods move up and down in the pumps, the freer and better will their strokes be; but a little deviation from the perpendicular will not be material. Therefore, when the pump-rods D, E, and F go down into a deep well, they may be moved directly by the cranks, as is done in a very good horse-engine of this sort at the late Sir James Creed's at Greenwich, which forces up water about 64 feet from a well under ground, to a reservoir on the top of his house. But when the cranks are only at a small height above the pumps, the pistons must be moved by vibrating levers, as in the above engine at Blenheim: and the longer the levers are, the nearer will the strokes be to a perpendicular.

Let us suppose, that in such an engine as Sir James Creed's, the great wheel is twelve feet diameter, the trundle four feet, and the radius or length of each crank nine inches, working a piston in its pump. Let there be three pumps in all, and the bore of each pump be four inches diameter. Then, if the great wheel has three times as many cogs as the trundle has staves, the trundle and cranks will go three times round for each revolution of the horsetreadle and wheel, and the three cranks will make nine strokes of the pumps in that time, each stroke being 18 inches (or double the length of the crank) in a four-inch bore. Let the diameter of the horse-walk be 18 feet, and the perpendicular height to which the water is raised above the surface of the well be 64 feet.

If the horses go at the rate of two miles an hour (which is very moderate walking) they will turn the great wheel 187 times round in an hour.

In each turn of the wheel the pistons make nine strokes in the pumps, which amount to 1683 in an hour.

Each stroke raises a column of water 18 inches long, and four inches thick, in the pump barrels; which column, upon the descent of the piston, is forced into the main pipe, whose perpendicular altitude above the surface of the well is 64 feet.

Now, since a column of water 18 inches long, and four inches thick, contains 226.18 cubic inches, this number multiplied by 1683 (the strokes in an hour) gives 380661 for the number of cubic inches of water raised in an hour.

A gallon, in wine-measure, contains 231 cubic inches, by which divide 380661, and it quotes 1468 in round numbers, for the number of gallons raised in an hour; which, divided by 63, gives 26½ horseheads. If the horses go faster, the quantity raised will be so much the greater.

In this calculation it is supposed that no water is wasteful by the engine. But as no forcing engine can be supposed to lose less than a fifth part of the calculated quantity of water, between the pistons and barrels, and by the opening and shutting of the valves, the horses ought to walk almost 2½ miles per hour to fetch up this loss.

A column of water four inches thick, and 64 feet high, weighs 349½ pounds avoirdupois, or 424½ pounds troy; and this weight, together with the friction of the engine, is the resistance that must be overcome by the strength of the horses.

The
The horse tackle should be so contrived, that the horses may rather pull on than drag the levers after them. For if they draw, in going round the walk, the outside leather-strap will rub against their sides and hams; which will hinder them from drawing at right angles to the levers, and so make them pull at a disadvantage. But if they pull the levers before their breasts, instead of dragging them, they can always walk at right angles to these levers.

It is no ways material what the diameter of the main or conduct pipe be: for the whole refitance of the water therein, against the horses, will be according to the height to which it is raised, and the diameter of that part of the pump in which the piston works; as we have already observed. So that by the same pump, an equal quantity of water may be raised in (and consequently made to run from) a pipe of a foot diameter, with the same ease, because its velocity in a large pipe will be less than as in a pipe of five or six inches; or rather with more ease, because its friction against the sides of the pipe will be less than in a small one, and therefore its friction against the sides of the pipe will be less also.

And the force required to raise water depends not upon the length of the pipe, but upon the perpendicular height to which it is raised therein above the level of the spring. So that the same force, which would raise water to the height AB (fig. 7.) in the upright pipe AEFGH, will raise it to the same height or level BIH in the oblique pipe AEFH. For the pressure of the water at the lower end of a pipe is always as the sine of the angle to which the pipe is raised; and therefore, in all positions, yet its pressure at the lower end decreases, as the sine of the angle of elevation decreases; as will appear plainly by a farther consideration of the figure.

Let two pipes, AB and BC, of equal lengths and bores, join each other at A; and let the pipe AB be divided into 100 equal parts, as the scale S is; whose length is equal to the length of the pipe. Upon this length, as a radius, describe the quadrant BCD, and divide it into 90 equal parts or degrees.

Let the pipe AC be elevated to 10 degrees upon the quadrant, and then filled with water; then, part of the water that is in it will rise in the pipe AB, and if it be kept full of water, it will raise the water in the pipe AB from A to B; that is, to a level with the mouth of the pipe at 10; and the upright line a 10, equal to AB, will be the sine of 10 degrees elevation; which being measured upon the scale S, will be about 17.3 of such parts as the pipe contains 100 in length: and therefore, the force or pressure of the water at A, in the pipe A 10, will be to the force or pressure at A in the pipe AB as 17.3 to 100.

Let the same pipe be elevated to 20 degrees in the quadrant, and if it be kept full of water, part of that water will run into the pipe AB, and rise therein to the height AB, which is equal to the length of the upright line b 20, or to the sine of 20 degrees elevation; which, being measured upon the scale S, will be 34.2 of such parts as the pipe contains 100 in length; and therefore the pressure of the water at A, in the full pipe A 20, will be to its pressure, if that pipe were raised to the perpendicular situation AB, as 34.2 to 100.

Elevate
Elevate the pipe to the position A 30 on the quadrant; and if it be supplied with water, the water will rise from it into the pipe AB, to the height A4, or to the same level with the mouth of the pipe at 30. The fine of this elevation, or of the angle of 30 degrees, is e 30; which is just equal to half the length of the pipe, or to 50 of such parts of the scale as the length of the pipe contains 100. Therefore, the pressure of the water at A, in a pipe elevated 30 degrees above the horizontal level, will be equal to one half of what it would be, if the same pipe stood upright in the situation AB.

And thus, by elevating the pipe to 40, 50, 60, 70, and 80 degrees on the quadrant, the title of these elevations will be d 40, e 50, f 60, g 70, and h 80; which will be equal to the heights Aw, An, Ao, Ap, and Ag; and these heights measured upon the scale 8 will be 64.3, 76.6, 86.6, 94.0, and 98.5; which express the pressures at A in all these elevations, considering the pressure in the upright pipe AB as 100.

Because it may be of use to have the lengths of all the sides of a quadrant from 0 degrees to 90, we have given the foregoing table, shewing the length of the sine of every degree in such parts as the whole pipe (equal to the radius of the quadrant) contains 1000. Then the sines will be integral or whole parts in length. But if you suppose the length of the pipe to be divided only into 100 equal parts, the last figure of each part or fine must be cut off as a decimal; and then those which remain at the left hand of this separation will be integral or whole parts.

Thus, if the radius of the quadrant (supposed to be equal to the length of the pipe AC) be divided into 1000 equal parts, and the elevation be 45 degrees, the fine of that elevation will be equal to 707 of these parts; but if the radius be divided into 100 equal parts, the same sine will only be 70.7 or 70.7 of these parts. For, as 1000 is to 707, so is 100 to 70.7.

As it is of great importance to all engine makers, to know what quantity and weight of water will be contained in an upright round pipe of a given diameter and height, so as, by knowing what weight is to be raised, they may proportion their engines to the force which they can afford to work them; we shall subjoin tables shewing the number of cubic inches of water contained in an upright pipe of a round bore, of any diameter from one inch to six and a half; and of any height from one foot to two hundred; together with the weight of the said number of cubic inches, both in Troy and Avoirdupoise ounces. The number of cubic inches divided by 231, will reduce the water to gallons in wine measure; and divided by 322, will reduce it to the measure of ale-gallons. Also, the Troy ounces divided by 12, will reduce the weight to Troy pounds; and the Avoirdupoise ounces divided by 16, will reduce the weight to Avoirdupoise pounds.

And here we must repeat it again, that the weight or pressure of the water acting against the power that works the engine, must always be computed according to the perpendicular height to which it is to be raised, without any regard to the length of the conduct pipe, when it has an oblique position; and as if the diameter of that pipe were just equal to the diameter of that part of the pump in which the piston works. Thus by the tables on the two following pages, the pressure of the water against an engine whole pump is of a 4/6 inch bore, and the perpendicular height of the water in the conduct pipe is 80 feet, will be equal to 8057.5 Troy ounces, and to 8846.2 Avoirdupoise ounces; which makes 671.4 Troy pounds, and 553 Avoirdupoise.

Example. Required the number of cubic inches, and the weight of the water, in an upright pipe 278 feet high, and 1/8 inch diameter?

Answ. 278 5895.1 3111.0 3416.3

Here the nearest single decimal figure is only taken into the account; and the whole, being reduced by division, amounts to 259.2 wine-gallons in measure, to 259.2 pounds Troy, and 2123 pounds Avoirdupoise.

These tables were at first calculated to fix decimal places for the sake of exactness; but in transcribing them there are no more than two decimal figures taken into the account, and sometimes but one; because there is no necessity for computing to hundredth parts of an inch or of an ounce in practice.

The fire engine.

The fire-engine comes next in order to be explained; but as it would be difficult, even by the best plates, to give a particular description of its several parts, so as to make the whole intelligible, we shall only explain the principles upon which it is constructed.

1. Whatever weight of water is to be raised, the pump rod must be loaded with weights sufficient for that purpose, if it be done by a forcing pump, as is generally the case; and the power of the engine must be sufficient for the weight of the rod, in order to bring it up.

2. It is known, that the atmosphere presses upon the surface of the earth with a force equal to 15 pounds upon every square inch.

3. When water is heated to a certain degree, the particles thereof repel one another, and constitute an elastic fluid, which is generally called steam or vapour.

4. Hot steam is very elastic; and when it is cooled by any means, particularly by its being mixed with cold water, its elasticity is destroyed immediately, and it is reduced to water again.

5. If a vessel be filled with hot steam, and then closed so as to keep out the external air and all other fluids; when that steam is by any means condensed, cooled, or reduced to water, that water will fall to the bottom of the vessel; and the cavity of the vessel will be almost a perfect vacuum.

6. Whenever a vacuum is made in any vessel, the air by its weight will endeavour to rush into the vessel, or...
to drive in any other body that will give way to its pressure; as may be easily seen by a common syringe. For, if you stop the bottom of a syringe, and then draw up the piston, if it be so tight as to drive out all the air before it, and leave a vacuum within the syringe, the piston being let go will be driven down with a great force.

7. The force with which the piston is drove down, when there is a vacuum under it, will be as the square of the diameter of the bore in the syringe. That is to say, it will be driven down with four times as much force in a syringe of a two-inch bore, as in a syringe of one inch: for the areas of circles are always as the squares of their diameters.

8. The pressure of the atmosphere being to 15 pounds upon every square inch, it will be equal to about 12 pounds upon every circular inch. So that if the bore of the syringe be round, and one inch in diameter, the piston will be press'd down into it by a force nearly equal to 12 pounds; but if the bore be two inches diameter, the piston will be press'd down with four times that force.

And hence it is easy to find with what force the atmosphere presses upon any given number either of square or circular inches.

The data are based on the weight of the piston and the atmospheric pressure at sea level.

The cylinder is about 40 inches diameter, bored so smooth, and its leathered piston fitting so close, that little or no water can get between the piston and sides of the cylinder.

Things being thus prepared, the cylinder is placed upright, and the shank of the piston is fixed to one end of the beam, which turns on a centre like a common balance.

The cylinder is placed under the cylinder, with a communication between them, which can be opened and shut occasionally.

The cylinder is filled about half full of water, and a strong fire is made under it: then, if the communication between the boiler and the cylinder be opened, the cylinder will be filled with hot steam, which would drive the piston quite out at the top of it. But there is a contrivance by which the piston, when it nears the top of the cylinder, stops the communication at the top of the boiler.

This is no sooner shut, than another is opened, by which a little cold water is thrown upwards in a jet into the cylinder, which mixing with the hot steam, condenses it immediately; by which means a vacuum is made in the cylinder, and the piston is press'd down by the weight of the atmosphere; and so lifts up the loaded pump-rod at the other end of the beam.

HYDROSTATICAL TABLES.
HYDROSTATICS.

If the cylinder be 42 inches in diameter, the piston will be pressed down with a force greater than 30,000 pounds, and will consequently lift up that weight at the opposite end of the beam, and as the pump-rod with its plunger is fixed to that end, if the bore where the plunger works were 10 inches diameter, the water would be forced up through a pipe of 180 yards perpendicular height.

But, as the parts of this engine have a good deal of friction, and must work with a considerable velocity, and there is no such thing as making a perfect vacuum in the cylinder, it is found that no more than 8 pounds of pressure must be allowed for, on every circular inch of the piston in the cylinder, that it may make about 16 strokes in a minute, about 6 feet each.

Where the boiler is very large, the piston will make between 20 and 25 strokes in a minute, and each stroke 7 or 8 feet; which, in a pump of 9 inches bore, will raise upwards of 300 hogsheads of water in an hour.

It is found by experience, that a cylinder 40 inches diameter will work a pump 10 inches diameter and 100 yards long; and hence we can find the diameter and length of a pump that can be worked by any other cylinder.

For the convenience of those who would make use of this engine for raising water, we shall subjoin part of a table calculated by Mr. Beighton, shewing how any given quantity of water may be raised in an hour, from 48 to 440 hogsheads; at any given depth, from 15 to 100 yards; the machine working at the rate of 16 strokes per minute, and each stroke being 6 feet long.

One example of the use of this table, will make the whole clear. Suppose it were required to draw 150 hogsheads per hour, at 90 yards depth; in the second column from the right hand, I find the nearest number, viz. 149 hogsheads 40 gallons; against which, on the right hand, I find the diameter of the bore of the pump must be 7 inches; and in the same collateral line, under the given depth 90, I find 27 inches, the diameter of the cylinder fit for that purpose. And so for any other.

A Table shewing the Power of the Engine for raising Water by Fire; Calculated to the Measure of Ale-gallons, at 282 cubic Inches per Gallon.

The Persian wheel.

WATER may be raised by means of a stream AB (Plate 100, fig. 8.), turning a wheel CDE, according to the order of the letters, with buckets a,a,a,a, &c. hung upon the wheel by strong pins b,b,b, &c. fixed in the side of the rim: but the wheel must be made as high as the water is intended to be raised above the level of that part of the stream in which the wheel is placed. As the wheel turns, the buckets on the right hand go down into the water, and are thereby filled; and go up full on the left hand, until they come to the top at K; where they strike against the end n of the fixed trough M, and are thereby over set, and empty the water into the trough; from which it may be conveyed in pipes to the place which it is designed for: and as each bucket gets over the trough, it falls into a perpendicular position again, and goes down empty, until it comes to the water at A, where it is filled as before. On each bucket is a spring r, which, going over the top or crown of the bar m (fixed to the trough M) raises the bottom of the bucket above above the level of
of its mouth, and so causes it to empty all its water into
the trough.

Sometimes this wheel is made to raise water no higher
than its axis; and then, instead of buckets hung upon it,
its spokes C, d, e, f, g, h are made of a bent form, and
hollow within; these hollows opening into the holes C,
D, E, F, in the outside of the wheel, and also into those
at O in the box N upon the axis. So that, as the holes
C, D, &c. dip into the water, it runs into them; and as
the wheel turns, the water rises in the hollow spokes,
e, d, &c. and runs out in a stream P from the holes at O,
and falls into the trough Q, from whence it is conveyed
by pipes. And this is a very easy way of raising water,
because the engine requires neither men nor horses to
turn it.

Of the specific gravities of bodies.

The art of weighing different bodies in water, and
thereby finding their specific gravities, or weights, bulk
for bulk, was invented by Archimedes.

The specific gravities of bodies are as their weights,
bulk for bulk; thus a body is said to have two or three
times the specific gravity of another, when it contains
two or three times as much matter in the same space.

A body immersed in a fluid will sink to the bottom, if
it be heavier than its bulk of the fluid. If it be suspend-
ed therein, it will lose as much of what it weighed in air,
as its bulk of the fluid weighs. Hence, all bodies of equal
bulk, which would sink in fluids, lose equal weights when
suspended therein. And unequal bodies lose in proportion
to their bulks.

The hydrostatic balance.

The hydrostatic balance differs very little from a com-
mon balance that is nicely made; only it has a hook at
the bottom of each scale, on which small weights may be
hung by horse-hairs, or by silk threads. So that a body,
suspended by the hair or thread, may be immer-
sed in water without wetting the scale from which it hangs.

If the body thus suspended under the scale, at one end
of the balance, be first counterpoised by air in weights
in the opposite scale, and then immersed in water, the equi-
librium will be immediately destroyed. Then, if as much
weight be put into the scale from which the body hangs
as will restore the equilibrium (without altering the
weights in the opposite scale), that weight which restores
the equilibrium will be equal to the weight of a quantity
of water as big as the immersed body. And if the weight
of the body in air be divided by what it loses in water,
the quotient will shew how much that body is heavier
than its bulk of water.

If a piece of brass, glass, lead, or silver, be immersed
and suspended in different sorts of fluids, its different
looses of weight therein will shew how much it is heavier
than its bulk of the fluid; the fluid being lightest, in which
the immersed body looses half of its weight. A solid
bubble of glass is generally used for finding the specific
gravities of fluids.

Hence we have an easy method of finding the specific
gravities both of solids and fluids, with regard to the re-
spective
specific bulks of common pump water, which is generally made a standard for comparing all the others by.

In constructing tables of specific gravities with accuracy, the gravity of water must be represented by unity or 1.000, where three cyphers are added, to give room for expressing the ratios of other gravities in decimal parts, as in the following table.

Take away the decimal point from the numbers in the right hand column, or (which is the same) multiply them by 1000, and they will shew how many ounces avoirdupois are contained in a cubic foot of each body.

How to find out the quantity of adulteration in metals.

The use of the table of specific gravities will best appear by an example. Suppose a body to be compounded of gold and silver, and it is required to find the quantity of each metal in the compound.

First find the specific gravity of the compound, by weighing it in air and in water, and dividing its aerial weight by what it loses thereof in water, the quotient will shew its specific gravity, or how many times it is heavier than its bulk of water. Then, subtract the specific gravity of silver (found in the table) from that of the compound, and the specific gravity of the compound from that of gold; the first remainder shews the bulk of gold, and the latter the bulk of silver, in the whole compound: and if these remainders be multiplied by the respective specific gravities, the products will shew the proportion of weights of each metal in the body. Example,

Suppose the specific gravity of the compounded body to be 13; that of standard silver (by the table) is 10.5, and that of gold 19.63: therefore 10.5 from 13, remains 2.5, the proportional bulk of the gold; and 13 from 19.63, remains 6.63, the proportional bulk of silver in the compound. Then, the first remainder 2.5, multiplied by 19.63, the specific gravity of gold, produces 49.075 for the proportional weight of gold; and the last remainder 6.63 multiplied by 10.5, the specific gravity of silver, produces 69.615 for the proportional weight of silver in the whole body. So that, for every 49.07 ounces or pounds of gold, there are 69.6 pounds or ounces of silver in the body.

Hence it is easy to know whether any suspected metal be genuine, or allayed, or counterfeit; by finding how much it is heavier than its bulk of water, and comparing the same with the table: if they agree, the metal is good; if they differ, it is allayed or counterfeited.

How to try spirituous liquors.

A cubic inch of good brandy, rum, or other proof spirits, weighs 235.7 grains; therefore, if a true inch cube of any metal weighs 235.7 grains less in spirits than in air, it shews the spirits are proof. If it loses less of its aerial weight in spirits, they are above proof: if it loses more, they are under. For, the better the spirits are, they are the lighter; and the worse, the heavier.

The hydrometer is one of the most useful instruments of the philosophic kind; for though the hydrostatic balance be the most general instrument for finding the

</tbody>
</table>
specific gravities of all sorts of bodies, yet the hydrometer is best suited to find those of fluids in particular, both as to ease and expedition.

This instrument should be made of copper, since ivory imbibes spirituous liquors, and thereby alters its gravity; and glass is apt to break. The most simple kind, used for finding the strength of spirits, consists of a copper-ball B & Plate 101. (fig. 1. n° 1.) with a brass wire, AB, \( \frac{1}{2} \) of an inch thick, folded into it. The upper part of this wire being filed flat on one side, is marked proof at w, because it sinks exactly to this mark in proof-spirits. There are other two marks at A and B, to show whether the liquor be \( \frac{1}{2} \) above or \( \frac{1}{2} \) low proof, according as the hydrometer sinks to A or emerges to B, when a brass weight as C or K has been screwed on at the bottom c. There are also weights to be screwed on, for showing the specific gravities of fluids quite to common water. The round part of the wire above the ball, may be marked to represent river water when it sinks to R W, (ibid. n° 2.) the weight which fits the instrument for river water being screwed on at e: also when put into spring-water, mineral water, tea-water, and water of salt springs, it will emerge or rise gradually to the marks SP, MI, SE, SA; and, on the contrary, when put into Bristol-water, rain-water, port-wine, and mountain wine, it will successively sink to the marks, hr, ra, po, no.

Another kind, which serves to distinguish the specific differences of fluids to great nicety, consists of a large hollow ball B, (ibid. n° 3.) with a smaller ball h under it, partly filled with quicksilver or small shot, and screwed on to the lower part of the former, in order to render it but little specifically lighter than water: it has also a small short neck at C, into which is screwed the graduated brass wire AC, which by its weight causes the body of the instrument to descend in the fluid, with part of the film.

When this instrument is swimming in the liquor, contained in the jar LLMK, the part of the fluid displaced...
placed by it will be equal in bulk to the part of the instrument under water, and equal in weight to that of the whole instrument. Suppose the weight of the whole were 4000 grains, then it is evident we can by this means compare together the different bulbs of 4000 grains of various sorts of fluids. For if the weight A be such as shall cause the aræometer to sink in rain-water, till its surface comes to the middle point of the stem 20; and if, after this, it be immersed in common spring water, and the surface is observed to stand \( \frac{1}{10} \) of an inch below the middle point 20; it is evident that the same weight of each water differs in bulk only by the magnitude of \( \frac{1}{10} \) of an inch in the stem.

Now suppose the stem were ten inches long, and weighed 100 grains, then every tenth of an inch would be one grain weight; and since the stem is of brass, and brass is about eight times heavier than water, the same bulk of water will be equal to \( \frac{1}{8} \) of a grain; and consequently to the \( \frac{1}{8} \) of 4000 part, that is, a 333 1/3 th part of the whole bulk, which is a degree of exactness as great as can be defined. Yet the instrument is capable of still greater exactness, by making the stem or neck consist of a flat thin slab of brass, instead of one that is round or cylindrical: by this means we increase the surface, which is the most requisite thing; and diminish the solidity, by which the instrument is rendered more exact.

In order to adapt this instrument to all sorts of uses, there ought to be two different stems to screw on and off in a small hole at a. One stem should be such a nice thin slab of brass, or rather of steel, like a watch-spring fett straight, as we have just mentioned, on one side of which ought to be the several marks or divisions to which it will sink in various sorts of waters, as rain-water, river-water, spring-water, sea-water, salt spring-water, &c. And on the other side you may make the division to which it sinks in various lighter fluids, as hot bath-water, Brilifol water, Lincomb water, Chelten water, portwine, mountain, madeira, and various other sorts of wine. But in this case the weight A on the top must be a little less than before, when it was used for the heavier waters.

But, in case of trying the strength of spirituous liquors, a common cindric stem will do best, because of its strength and fleadiness; and this ought to be so contrived, that, when immersed in what is called proof-spirit, the surface of the spirit may be upon the middle point 20; which is easily done by duly adjusting the small weight A on the top, and making the stem of such a length, that, when immersed in water, it may just cover the ball, and ride to a; but, when immersed in pure spirit, it may arise to the top at A; then by dividing the upper and lower parts a 20, A 29, into ten equal parts each, when the instrument is immersed in any sort of spirituous liquor, it will immediately shew how much it is above or below proof.

This proof-spirit consists of half water and half alcohol or pure spirit; that is, such as when poured upon gunpowder, and set on fire, will burn all away, and permit the powder to take fire, which it will, and flith as in the open air. But if the spirit be not so highly rectified, there will remain some phlegm or water, which will make the powder wet, and unfit to take fire. This proof-spirit of any kind weighs seven pounds twelve ounces per gallon.

The common method of shaking the spirits in a vial, and, by raising a crown of bubbles, to judge by the manner of their rising or breaking away whether the spirit be proof or near it, is very precarious, and capable of great fallacy. There is no way so easy, quick, certain, and philosophical, as this by the aræometer, which will demonstrate infallibly the difference of bulks, and consequently specific gravities, in equal weights of spirits, to the 30, 40, or 50 thousandth part of the whole, which is a degree of accuracy beyond which nothing can be defined.

All bodies expand with heat, and contract with cold; but some more and some less than others: and therefore the specific gravities of bodies are not precisely the same in summer as in winter. It has been found, that a cubic inch of good brandy is 10 grains heavier in winter than in summer; as much spirit of nitre, 20 grains; vinegar 6 grains, and spring water 3. Hence it is most profitable to buy spirits in winter, and sell them in summer, since they are always bought and sold by measure. It has been found, that 32 gallons of spirits in winter will make 33 in summer.

The expansion of all fluids is proportionable to the degree of heat; that is, with a double or triple heat a fluid will expand two or three times as much.

Upon these principles depends the construction of the thermometer, in which the globe or bulb, and part of the tube, are filled with a fluid, which, when joined to the barometer, is spirits of wine tinged, that it may be the more easily seen in the tube. But when thermometers are made by themselves, quicksilver is generally used.

In the thermometer, a scale is fitted to the tube, to shew the expansion of the quicksilver, and consequently the degree of heat. And, as Farenheit’s scale is most in esteem at present, we shall explain the construction and graduation of thermometers according to that scale.

First, let the globe or bulb, and part of the tube, be filled with a fluid; then immerse the bulb in water just freezing, or snow just thawing; and even with that part in the scale where the fluid then stands in the tube, place the number 32, to denote the freezing point: then put the bulb under your armpit, when your body is of a moderate degree of heat, so that it may acquire the same degree of heat with your skin; and when the fluid has risen as far as it can by that heat, there place the number 97: then divide the space between these numbers into 65 equal parts, and continue those divisions both above 97 and below 32, and number them accordingly.

This may be done in any part of the world; for it is found that the freezing point is always the same in all places, and the heat of the human body differs but very little: so that the thermometers made in this manner

will
will agree with one another; and the heat of several bodies will be shewn by them, and expressed by the number upon the scale, thus.

Air, in severer cold weather, in our climate, from 15 to 25. Air in winter, from 26 to 42. Air in spring and autumn, from 43 to 53. Air at midsummer, from 65 to 68. Extreme heat of the summer sun, from 86 to 100. Butter just melting, 95. Alcohol boils with 540. Milk freezes about 30, vinegar 28, and blood 27.

A body specifically lighter than a fluid will swim upon its surface, in such a manner, that a quantity of the fluid equal in bulk with the immersed part of the body, will be as heavy as the whole body. Hence, the lighter a fluid is, the deeper a body will sink in it; upon its surface, in such a manner, that a quantity of the fluid equal in bulk with the immersed part of the body, will be as heavy as the whole body. Hence, the lighter a fluid is, the deeper a body will sink in it; upon which depends the construction of the hydrometer or water-poie.

From this we can easily find the weight of a ship, or any other body that swims in water. For, if we multiply the number of cubic feet which are under the surface, by 62.5, the number of pounds in one foot of fresh water; or by 63, the number of pounds in a foot of salt water; the product will be the weight of the ship, and all that is in it. For, since it is the weight of the ship that displaces the water, it must continue to sink until it has removed as much water as is equal to it in weight; and therefore the part immersed must be equal in bulk to such a portion of the water as is equal to the weight of the whole ship.

To prove this by experiment, let a ball of some light wood, such as fir or pear-tree, be put into water contained in a glass vessel; and let the vessel be put into a scale at one end of a balance, and counterpoised by weights in the opposite scale: then, marking the height of the water in the vessel, take out the ball; and fill up the vessel with water to the same height that it stood at when the ball was in it; and the same weight will counterpoise it as before.

From the vessel's being filled up to the same height at which the water stood when the ball was in it, it is evident that the quantity poured in is equal in magnitude to the immersed part of the ball; and from the same weight counterpoising, it is plain that the water poured in is equal in weight to the whole ball.

In troy weight, 24 grains make a pennyweight, 20 pennyweight make an ounce, and 12 ounces a pound. In avoirdupoise weight, 16 drams make an ounce, and 16 ounces a pound. The troy pound contains 5760 grains, and the avoirdupoise pound 7000: and hence, the avoirdupoise dram weighs 27.34875 grains, and the avoirdupoise ounce 437.5.

HYDROMETER, a machine, or instrument whereby to measure the degrees of dryness, or moisture of the air, or rather of the atmosphere.

There are divers sorts of hygrometers; for whatever body either swells or shrinks, by dryness or moisture, is capable of being formed into a hygrometer. Such are woods of most kinds, particularly ash, deal, poplar, &c. Such also is catgut, the beard of a wild oat, &c.

HYMEN, in anatomy. See Anatomy, p. 277.

HYMENÆA, in botany, a genus of the decandria monogyia class. The calix consists of five segments, and the corolla of five petals; and the pod is filled with a farinaceous pulp. There is but one species, a native of America.

HYMENÆAL, something belonging to marriage, so called from hymen.

HYMN, a religious song. The hymns sung in the christian church, as distinguished from the psalms, are pieces of poetry composed by pius but not inspired authors.

HYOIDES, in anatomy. See Anatomy, p. 166.

HYOSCYAMUS, hen-bane, in botany, a genus of the tetrandria digynia class. The calyx consists of two leaves, and the corolla of four petals, the two outermost of which are broader, and divided into three segments. There are four species, none of them natives of Britain.

HYPERBATON, in grammar, a figurative construction inventing the natural and proper order of words and sentences.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged or diminished.

An object uncommon with respect to size, either very great of its kind or very little, strikes us with surprise; and this emotion forces upon the mind a momentary conviction that the object is greater or less than it is in reality: the same effect, precisely, attends figurative grandeur or littleness; and hence the hyperbole, which expresses this momentary conviction. A writer, taking advantage of this natural delusion, enriches his description greatly by the hyperbole: and the reader, even in his coolest moments, relishes this figure, being sensible that it is the operation of nature upon a warm fancy.
It cannot have escaped observation, that a writer is generally more successful in magnifying by a hyperbole than in diminishing. The reason is, that a minute object contracts the mind, and fetters its powers of imagination; but that the mind, dilated and inflamed with a grand object, moulds objects for its gratification with great facility. Longinus, with respect to a diminishing hyperbole, cites the following ludicrous thought from a comic poet: "He was owner of a bit of ground not larger than a La- cesian letter." But, for the reason now given, the hyperbole has by far the greater force in magnifying objects; of which take the following examples:

For all the land which thou feest, to thee will I give it, and to thy seed for ever. And I will make thy seed as the dust of the earth, so that if a man can number the dust of the earth, then shall thy seed also be numbered.

Ipsa vel intrae fegetis per summa volaret
Gramina: nec teneras curtis laesisset aristas,

Atque imo barathri ter gurgite vaftos
Sorbet in abruptum fluctus, rurfufque sub auras
Erigit alternos, et fidera verberat unda.

Horrificis juxta tonat Etna ruinis,
Interdumque atram prorumpit ad aethera nubem,
Turbine fumantem piceo et candente favilla:
Attollitque globos flammarum, et fidera lambit.

Speaking of Polyphemus,

Ipse arduus, altaque pulsat
Sidera.

When he speaks,
The air, a charter'd libertine, is still.

Now shield with shield, with helmet helmet clos'd,
To armour armour, lance to lance oppos'd,
Himself with his good arms, in lufty strokes
To th' shore, that o'er his wave-borne baifs bow'd,
As swooping to relieve him.

I saw him beat the furges under him,
And ride upon their backs; he trod the water;
Whose emity he flung aside, and breathed
'bove the contentious waves he kept, and oar'd
Himself with his good arms, in lusty strokes
To th' shore, that o'er his wave-borne baifs bow'd,
As swooping to relieve him.

In the next place, it may be gathered from what is said, that an hyperbole can never suit the tone of any diparating passion; forrow in particular will never prompt such a figure; and for that reason the following hyperboles must be condemned as unnatural:

K. Rich. Aumerle, thou weep'st, my tender-hearted cousin!
We'll make foul weather with despifed tears;
Our sighs, and they, shall lodge the summer-com.
And make a dearth in this revolting land.

Draw them to Tyber's bank, and weep your tears
Into the channel, till the lowest stream
Do kifs the most exalted shores of all.

Thirdly, a writer, if he wish to succeed, ought always to have the reader in his eye: he ought in particular never to venture a bold thought or expression, till the reader be warmed and prepared. For this reason, an hyperbole in the beginning of a work can never be in its place. Example:

Jam pauc a aratro jugera repig
Moles relinquent.

In the fourth place, the nicest point of all, is to ascertain the natural limits of an hyperbole, beyond which being overstrained it has a bad effect. Longinus, (chap. iii.) with great propriety of thought, enters a caveat against an hyperbole of this kind: he compares it to a bowstring, which relaxes by overstraining, and produceth an effect directly opposite to what is intended. To ascertain any precise boundary, would be difficult, if...
not impracticable. We shall therefore only give a specimen of what may be reckoned overstrained hyperboles. No fault is more common among writers of inferior rank; and instances are found even among those of the finest taste; witness the following hyperbole, too bold even for an Hotspur.

Speaking of Henry V.

England ne'er had a King until his time:
Virtue he had, deferring to command:
His brandish'd sword did blind men with its beams:
His arms spread wider than a dragon's wings:
His sparkling eyes, replete with awful fire,
More dazzled, and drove back his enemies,
Than mid-day sun fierce bent against their faces.
What should I say? his deeds exceed all speech:
He never lifted up his hand, but conquer'd.

Lastly, An hyperbole, after it is introduced with all advantages, ought to be comprehended within the fewest words possible; as it cannot be relished but in the hurry and swelling of the mind, a leisurely view dissolves the charm, and discovers the description to be extravagant at least, and perhaps also ridiculous. This fault is palpable in a sonnet which passes for one of the most com

HYPERCATALECTIC, in the Greek and Latin poetry, is applied to a verse, which has one or two syllables too much, or beyond the regular and just measure: as,

Muse forores sunt Minerve.
Alfo,
Muse forores Palladis lugent.

HYPERICUM, St John's wort, a genus of the polyadephia polyandria class. The calix consists of five segments, and the corolla of five petals: and the filaments are numerous, and bound in five bundles. There are twenty-nine species, eight of them natives of Britain.

HYPERSARCOSES, in medicine and surgery, an excess of flesh, or rather a fleshy excrescence, such as those generally arising upon the lips of wounds, &c.

HYPHEN, an accent or character, in grammar, implying that two words are to be joined, or connected into one compound word, and marked thus: as, pre-established, five-leaved, &c.

Hyphens also serve to connect the syllables of such words as are divided by the end of the line.

HYPOCAUSTUM, among the Greeks and Romans, a subterraneous place, wherein was a furnace to heat the baths.

Another sort of hypocaust was a kind of kiln, to heat their winter parlours.

Among the moderns, it is that place where the fire is kept that warms a stove or hot-house.

HYPOCHÆRIS, in botany a genus of the syngenia aquilas class. The receptacle is plicate: the calix is imbricated; and the pappus is plumose. There are four species, two of them natives of Britain, viz. the radicata, or long-rooted hawkweed; the macrodonta, or spotted hawkweed; and the maculata, or spotted hawkweed.

HYPOCHAERIS, in botany, a genus of the cryptogamia musci class. There are forty-two species, all natives of Britain.

HYPOCHONDRIA, in anatomy. See Anatomy, p. 256.

HYPOCHONDRIAC Passion. See Medicine.

HYPOCYSTIS, in pharmacy, an infipitated juice, obtained from the seifile afalam, much resembling the true Egyptian acacia.

They gather the fruit, while unripe, and express the juice, which they evaporate over a very gentle fire, to the confidence of an extract, and then form into cakes, and expose them to the sun to dry.

Hypocyst is an astringent, and that of considerable power; it is good against diarrhœas and hemorrhages of all kinds, and may be used in repellant gargarisms in the manner of the acacia; but it is very rarely met with genuine in our shops, the german acacia being usually sold under its name.
HYPOGASTRIC, an appellation given to the internal branch of the iliac artery.

HYPOGASTRIUM, in anatomy. See Anatomy, p. 256.

HYOPHYLLOCARPODENDRON, in botany. See Leucodendron.

HYPOPYON, in medicine, a collection of purulent matter under the cornea of the eye.

HYPOSTASIS, among divines, signifies a person or substance; chiefly used in speaking of the persons of the Trinity.

HYPOTHESIS, in general, denotes something supposed to be true, or taken for granted, in order to prove or illustrate a point in question.

Hypotheses, however elegant and artful, ought to be first proved by repeated observations and constant experience, before they are received as truths.

HYSSOPUS, in botany, a genus of the didynamia gymnospermae clafs. The inferior lip of the corolla has a small crenated segment; and the stamens are erect and distant. There are three species, none of them natives of Britain. The leaves are said to be good in asthma, coughs, and other disorders of the lungs.

HYSTERICS, or Hysteric passion. See Medicine.

HYSTERON PROTERON, in grammar and rhetoric, a species of the hyperbaton, wherein the proper order of construction is so inverted, as that the part of any sentence which should naturally come first is placed last; as in this of Terence, 

HYS (324)

HYSTRIX, in zoology, a genus of quadrupeds belonging to the order of glires, the characters of which are these: They have two fore-teeth, obliquely divided, both in the upper and under jaw, besides eight grinders; and the body is covered with quills or prickles. (See Plate CI. fig. 5.) There are four species, viz.

1. The crisifata, or crested porcupine, has four toes on the fore-feet, five on the hind-feet, a crested head, a short tail, and the upper lip is divided like that of a hare. The length of the body is about two feet, and the height about two feet and a half. The porcupine is covered with prickles, some of them nine or ten inches long, and about \( \frac{1}{2} \) of an inch thick. Like the hedge-hog, he rolls himself up in a globular form, in which position he is proof against the attacks of the most rapacious animals. The prickles are exceedingly sharp, and each of them has five large black and as many white rings, which succeed one another alter-nately from the root to the point. These quills the animal can erect or let down at pleasure; when irritated, he beats the ground with his hind-feet, erects his quills, shakes his tail, and makes a considerable rattling noise with his quills.

Most authors have asserted that the porcupine, when irritated, darts his quills to a considerable distance against the enemy, and that he will kill very large animals by this means. But Mr Buffon, and some other late historians, affirm that the animal possesses no such power. Mr Buffon frequently irritated the porcupine, but never saw any thing like this darting of his quills. He says indeed, that when the creature was much agitated with passion, some of the quills which adhered but slightly to the skin, would fall off, particularly from the tail; and this circumstance, he imagines, has given rise to the milllake.

The porcupine, though originally a native of Africa and the Indies, can live and multiply in the more temperate climates of Spain and Italy. Pliny, and every other natural historian since the days of Aristotle, tells us that the porcupine, like the bear, conceals itself during the winter, and that they bring forth their young in 50 days. But these circumstances remain to this day uncertain. It is remarkable, that although this animal be very common in Italy, no person has ever given us a tolerable history of it. We only know in general, that the porcupine, in a domesticate state, is not a fierce or ill-natured animal; that with his fore-teeth, which are strong and sharp, he can cut through a strong board; that he eats bread, fruits, roots, &c. that he does considerable damage when he gets into a garden; that he grows fat, like most animals, about the end of summer; and that his flesh is not bad food.

2. The prehensilis, or cuandu, has four toes on the fore-feet, five on the hind feet, and a long tail. It is considerably less than the former species, being only 17 inches long from the point of the muzzle to the origin of the tail, which is nine inches long; the legs and feet are covered with long brownish hair; the rest of the body is covered with quills interpersed with long hairs; the quills are about five inches long and about \( \frac{1}{2} \) of an inch in diameter. He feeds upon birds and small animal. He sleeps in the day like the hedge-hog, and searche for his food in the night. He climbs trees, and supports himself by twisting his tail round the branches. He is generally found in the high grounds of America from Brazil to Louisiana and the southern parts of Canada. His flesh is esteemed very good eating.

3. The dorfata, has four toes on the fore-feet, five on the hind-feet, and has quills only on the back, which are short, and almost hid among the long hair. He is about two feet long. He is a native of Hudson's bay. The favages eat his flesh, and make use of his skin as a fur after taking off the prickles.

4. The macroura, has five toes both on the hind and fore feet; his tail is very long, and the prickles are elevated. He is a native of Asia the East Indies.
JACCA, a city and bishop's see of Arragon, in Spain, sixty miles north of Saragossa; W. lon. 50°, and N. lat. 42° 50'.

JACEA. See CENTAURIA.

JACK, in mechanics, a well-known instrument of common use for raising very great weights of any kind.

The common kitchen-jack is a compound engine where the weight is the power applied to overcome the friction of the parts, and the weight with which the spit is charged; and a steady and uniform motion is obtained by means of the fly.

JACK FLAG, in a ship, that hoisted up at the spirit fail top-mast head. See FLAG.

JACK-DAW, in ornithology. See CORVUS.

JACKALL, in zoology. See Canis.

Jacob's Ladder, a term of reproach bestowed on the persons, who, vindicating the doctrines of passive obedience and non-resistance with respect to the arbitrary proceedings of princes, defiary of the late revolution, and affirmt the supposed rights and adhere to the interests of the late abdicated king James and his family.

JACOBITES, in church history, a sect of Christians in Syria and Mesopotamia; so called either from Jacob, a Syrian, who lived in the empire of the emperor Maurice; or from one Jacob, a monk, who flourished in the year 550.

The Jacobites are of two sects, some following the rites of the Latin church, and others continuing separated from the church of Rome. There is also at present a division among the latter, who have two rival patriarchs, one of whom resides at Caramit, and the other at Derzapharan. As to their belief, they hold but one nature in Jesus Christ; with respect to purgatory and prayers for the dead, they are of the opinion of the Greeks and other eastern Christians: they consecrate unleavened bread at the eucharist, and are against confession, believing that it is not of divine institution.

JACOBUS, an ancient gold coin worth twenty-five shillings.

JAFFA, anciently called JOPPA, is a port-town of Palestine in Asiatic Turkey, situated thirty miles north-west of Jerusalem; E. lon. 36°, N. lat. 32° 20'.

JAFNAPATAN, a port-town at the north end of the island of Ceylon, in the East Indies; subject to the Dutch: E. lon. 79°, N. lat. 10°.

JAGENDORF, a city of Silesia, twelve miles north-west of Tropawl: E. lon. 17° 6', N. lat. 50° 8'.

St. JAGO, the chief of the Cape Verde islands, in Africa, 500 miles west of Cape Verde; subject to Portugal: W. lon. 24°, N. lat. 15°.

St. Jago, the capital of the island of Cuba, 100 miles north-west of Jamaica: W. lon. 76°, 30', N. lat. 20°.

St. JAGO, the capital of the province of Chili, in south America, situated six miles west of the mountains of Andes, and eighteen east of the Pacific ocean: W. lon. 77°, S. lat. 34°.

JAGO DE LA VEGA, or Spanish town, the capital of Jamaica, situated at the south-east part of the island, about seven miles north-west of Port Royal and the bay of Port Royal: E. lon. 76° 30', N. lat. 18° 20'.

JALAP, in botany. See Mirabilis.

JAMAICA, an island of America, situated in the Atlantic ocean, between 76° and 79° of west longitude, and between 17° and 18° odd minutes north latitude, near 5000 miles south-west of England, 100 miles south of the island of Cuba, and 300 miles north of Terra Firma. The island lies east and west, and is about 140 miles long, and 60 broad. The wind sets on the shore almost all the day in every part of the island, and off the shore in the night; it sometimes hails, but the people there never see frost or snow. The produce of the island is chiefly sugar; but there are plantations of coffee, of the cocoa or chocolate tree, of indigo, tobacco, pepper, cotton, woods for dyeing, and the mahogany and mahogany wood, ginger, medicinal drugs and gums. The common diseases of the country are fevers, fluxes, and the dry gripes.

JAMANA, the chief town of a province of Arabia, also of the same name: E. lon. 47° 15', N. lat. 25°.

JAMBA, a city of the hither India, and the capital of the province of the same name, situated 220 miles north-east of Delli: E. lon. 82°, N. lat. 31°.

JAMBOLIFERA, in botany, a genus of the ooliandra monogyia glads. The calix has four teeth, and the corolla four funnel-shaped petals; and the stigma is simple. There is but one species, a native of India.

JAMBUS, in ancient poetry, a most ample foot consisting of a short and a long syllable, as pis.

JAMBY, a town on the east side of the island of Sumatra, in the East Indies, situated in 101° E. lon. and 1° 30' S. lat.

JAMES, or knights of St. James, a military order in Spain, first instituted about the year 1170, by Ferdinand II, king of Leon and Galicia. The greatest dignity belonging to this order is grand master, which has been united to the crown of Spain. The knights are obliged to make proof of their descent from families that have been noble for four generations, on both sides; they must also make it appear that their said ancestors have neither been Jews, Saracens, nor Heretics; nor have ever been called into question by the inquisition. The novices are obliged to serve six months in the galleys, and to live a month in a monastery; they observe the rules of St. Austin, making no vows but of poverty, obedience, and conjugal fidelity.

St. James's Day, a festival of the Christian church, observed ...
JANERO, a province of Brazil, in south America, site of St James, a canonical book of the New Testament, being the first of the catholic or general epistles, which are so called, as not being written to one, but to several Christian churches.

JAMES-TOWN, once the capital of Virginia in America, and of James-country, situated in a peninsula on the north side of James, or Pauhatan river, in W. lon. 76° 30', N. lat. 37° 30'.

JANEIRO, a province of Brazil, in south America, situated between 44° and 49° of W. lon., and between the tropic of capricorn and 22° of S. lat.

JANICAW, or Janowitz, a town of Bohemia, situated forty-five miles south-east of Prague.

JANIZARIES, an order of the Turkish infantry, reputed the grand signior's guards, and the main strength of the Ottoman army.

JANSENISTS, in church-history, a sect of the Roman catholics in France, who followed the opinions of Janfenius, bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, in relation to grace and predestination.

In the year 1642, the two universities just mentioned, and particularly father Molina and father Leonard Celsius, thought fit to condemn the opinions of the Jesuits on grace and free-will. This having set the controversy on foot, Janfenius opposed to the doctrine of the Jesuits the sentiments of St Augustine, and wrote a treatise on grace, which he entitled Augustinus. This treatise was attacked by the Jesuits, who accused Janfenius of maintaining dangerous and heretical opinions; and afterwards in 1642, obtained of pope Urban VIII. a formal condemnation of the treatise wrote by Janfenius; when the partisans of Janfenius gave out that this bull was spurious, and composed by a person entirely devoted to the Jesuits. After the death of Urban VIII. the affair of Janfenism began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace; and what occasioned some mirth, was the titles which each party gave to their writings: one writer thought fit to commend the five following propositions, extracted from Janfenius's Augustinus: I. Some of God's commandments are impossible to be observed by the righteous, even though they endeavour with all their power to accomplish them. II. In the state of corrupted nature, we are incapable of refiting inward grace. III. Merit and demerit in a state of corrupted nature, does not depend on a liberty which excludes necessity, but on a liberty which excludes constraint. IV. The semipelagians admitted the necessity of an inward preventing grace for the performance of each particular act, even for the beginning of faith; but they were heretics in maintaining that this grace was of such a nature, that the will of man was able either to refilt or obey it. It is semipelagianism to say, that Jesus Christ died, or shed his blood, for all mankind in general.

In the year 1652, the pope appointed a congregation for examining into the dispute in relation to grace. In this congregation Janfenius was condemned, and the bull of condemnation, published in May 1653, filled all the pulpits in Paris with violent outcries and alarms against the heresy of the Janfenists. In the year 1656, pope Alexander VII. issued out another bull, in which he condemned the five propositions of Janfenius: However, the Janfenists affirm, that these propositions are not to be found in this book; but that some of his enemies having caused them to be printed on a sheet, inferted them in the book, and thereby deceived the pope. At last Clement the XI. put an end to the dispute by his constitution of July the 17, 1705; in which, after having recited the constitutions of his predecessors in relation to this affair, he declares, "That in order to pay a proper obedience to the past pal constitutions concerning the present question, it is "necessary to receive them with a respectful silence," the clergy of Paris, the same year, approved and accepted this bull, and none dared to oppose it.

This is the famous bull Unigenitus, so called from its beginning with the words Unigenitus Dei Filius, &c. which has occasioned so much confusion in France.

JANUARY, in chronology, the first month of the year, the death of Urban VIII. the affair of Janfenism began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace; and what occasioned some mirth, was the titles which each party gave to their writings: one writer thought fit to commend the five following propositions, extracted from Janfenius's Augustinus: I. Some of God's commandments are impossible to be observed by the righteous, even though they endeavour with all their power to accomplish them. II. In the state of corrupted nature, we are incapable of refiting inward grace. III. JAPANNING, the art of varnishing and drawing figures on wood, &c. in the manner as is done by the natives of Japan.

The method of preparing woods for japanning is as follows. 1. Take plasterer's size, dissolve it over the fire, and mix it with whitening powdered till it is of a good body, but not too thick. 2. By means of a strong ax, lay your work over with the former mixture; and letting it dry very well, repeat this till the wood is perfectly plain, or the pores and crevices painted with two faces; one whereof was supposed to look towards the new year, and the other towards the old.

JAPAN, or islands of Japan, are situated between 120° and 144° of E. lon. and between 30° and 40° N. lat.

JAPANING, the art of varnishing and drawing figures on wood, &c. in the manner as is done by the natives of Japan.

JAP (827)

water till it is fine and thin, into which put the finest sawdust, till it is indifferently thick: then with a brush lay your wooden-work over with it, and when it is dry, repeat it so often till all the roughness and grain of the wood is sufficiently hidden; and two or three days after let it be scraped with a scraper, as pear tree and olive-wood are done, to make it as smooth as possible: then varnish it as before directed. This, if well done, might not come behind any other work either for beauty or durability; but, however, those woods that are firm and clofe grained are chiefly to be chafen.

Method of taking off japan patterns. 1. Having laid your ground, whether black, or of any other colour, and rendered it fit for drawing; and having your draught or design before you on paper, either drawn or printed, do as follows. 2. Rub this draught or print all over the back side with whiting or fine chalk, wiping off all that whiting which lies loose upon the paper; then laying this paper upon the table, or piece of varnished-work, with the white side next upon the very place where you would have that figure made, with a needle not sharp-pointed, fixed in a wooden handle, and called a tracing-pencil, go over and trace as much of the drawing as you think proper: thus by means of the whiting, you will have the gross form of the draught, and such other lines as will be a direction to you how to perform what you would have done. 3. Having done this, if you draw in gold-lice, use fine cinnabar mixed with gum-water; and with a small pencil dip it into it, go over all the lines made by the chalk: this will hold it so as not to come off. 4. If you work your metals or colours in gum-water, then trace over your design with gum-water mixed with gold or brass dust; by either of these ways when it is dry and finished, viz. either in gum-water or gold size, you may compleat and finish your work.

Method of japanning wood. The wood being prepared as before directed, it is japanned with black, as follows. 1. Take of the thickest lac-varnish, fix ounces; and lamp-black, enough to colour it: with this wash over your piece three times, letting it dry thoroughly between each time: again, with the same varnish, wash it over three other several times, letting it dry as before, and rub it smooth between each washing. 2. Then take the following: Of thickell feed-lac varnish, fix ounces; and venice turquoise, one ounce, wash over your work with it fix times, letting it stand twelve hours between the three first and the three last varnishings. 3. Your work being thus far done, take the following japann-lac varnish: Of the finest feed-lac varnish, six ounces; of lamp black, a sufficient quantity; mix them, and with that let your work be washed twelve times, standing twelve hours between the first six and the last six washings. 4. Then letting it stand to dry for fix or seven days, polish it with tripoli and a rag, as before directed: but in polishing you must work at it only till it is almost smooth; and then let it stand by for two days: afterwards polish it again, almoft enough; then let it stand for six days, after which polish the polishing of it; finally, clear it up with oil and lampblack, by which means you will have a good black japan scarce at all interior to the true japan.

For a white japan. 1. Lay the ground with ifing-

Common red japan. 1. Take of the finest gold-lice size, mixed with as much whiting scraped into it as will make it of a proper thickenefs; with this whiten your work once over, and being thoroughly dry, do it over again; and in like manner repeat it the third time; after which let it stand for twelve hours, covering it from dust; rub it with Dutch rubbing as near the grain of the wood as is proper. 2. Then taking first thin-glafs size, and flake white, so much as will make the size of a fair body, mix them well together, and with this go over your work three several times, letting it dry between each time, and rub it as before. 3. Then take white flarch boiled in fair water, till it is somewhat thick, wash over the whole work twice with it, blood-warm; letting it dry as before. 4. Letting it stand for a day or two, it being first washed with rectified spirit of wine, to clear it from the dust, dip a pure clean pencil into the finest white varnish, and do over the work fix or seven times; and if this be well done, it will give a finer gloss than if it were polished: if it be not well done, polishing will be necessary, for which reason you must give it five or fix varnishings more. In polishing you must make use of the finest tripoli; and instead of lamp-black and oil, use fluff putty and oil, and conclude with white flarch mixed with oil.

A deeper red japan may be made by mixing fine fanguis draconis, in powder, with the varnish; and a pale red japan may be had by mixing so much white lead with it, as to make it of whatever degree of paleness you please.

Blue japan. 1. Take gum-water what quantity you please, and a sufficient quantity of white lead; grind them well upon a marble: take ifing-glafs size what quantity you please, and the finest and finest black a sufficient quantity; mix them well together; then add to them of the white lead, ground as before, so much as will give it a sufficient body; mix all together to the consistence of a paint. 2. Do your work over with this mixture three or four times, till you perceive the blue to lie with a good and fair body, letting it dry thoroughly between each time: if your blue is too pale, put more flane among your size, without any white lead, and fo vice versa. 3. Then rub it smooth, and go over it again with a stronger blue; and when it is dry, wash it three times with the clearest ifing glafs size alone, and let it stand for two days to dry, covering it. 4. Warm your work gently at the fire, and with a pencil varnish it over with the finest white varnish, repeating it seven or eight times, letting it stand to dry two days as before. After which repeat again the washes seven or eight times in like manner. 5. Let it now stand for a week, and then polish it as before, and clear it up with lamp-black and oil.
Chesnut-coloured japan. Take indian red, grind it with window-glass size upon a porphyry-flone, till they are as soft and as fine as butter; then mix a little white lead, which grind strongly; and, lastly, lamp-black, in due proportion.

A tortoise-shell japan. First lay a white ground, as before directed; then with proper colours, as vermilion, auripigment, &c. duly mixed with turpentine- varnish, streak and cloud or shadow the white ground with any irregular fancy at pleasure, in imitation of tortoise-shell; then let it harden to dry, and striking it here and there with reddish yellow varnish, mixed with a little cinnabar, cloud the work up and down, touching it up also with varnish mixed with lamp or ivory black. Having done this, varnish it five or six times over with the finest white varnish, letting it dry between every washing.

Japanning with gold size. The size being laid over that part only which you intend to gild, as already directed, let it remain there till it is dry, that when you put your finger on it, it be glutinous and clammy, but not fo moist that the particles should come off with your fingers. It is in this temper that the gold is to be applied: then take a piece of washing leather, or the like, and wrapping it round your fore finger, dip it in the gold dust, and rub it where your gold size is laid; for it will stick no where but on the size; and if any gold-dust lies about your work, brush it away with a fine clean varnishing brush. Then, with your pencil, draw that part with gold size also which is designed for your copper, and letting it dry as in the former case, cover it over with copper dust in the same manner. Having done this, lay your silver-size; and when it is dry, as before, lay on your silver-dust, as in the two former. But it is to be observed, that the metallic colours are to be laid successively one after another, letting each be covered and thoroughly dry before you enter upon a distinct colour. After all these, the other colours which are not metallic are to be laid on with gum-water, referring the rock, &c. for the last part of the work. Let your size be of a due consistence, neither too thick nor too thin, that it may run smooth and clean. See Size.

Japanning metals with gum-water. Take gum water, put it into a mussel-shell; with which mix so much of your metal or colour as may give it a proper consistence, so that it may run fine and smooth: having prepared and well mixed your metals and colours, lay on your design; your gum-water being thoroughly dried, you are to run it over with fine feed-lac varnish, and afterwards polish and clear it.

Laying speckles or firenings on japan-work. To do this, either on outside or inside boxes, drawers, &c. mix your speckles with ordinary lac-varnish, so much as may make it fit to work, but not so thick as for colour, and mix them well with a proper brush. Warm the work to be done gently by the fire, and with a pencil wash it over with the former mixture; and when it is dry, repeat it again, and so often till your speckles lie as thick and even as you desire. When it is thoroughly dry, go over and beautify the work three or four times with feed-lac varnish mixt with turpentine, and so let it dry, and the work is finished, except you have a mind to polish it.

But if you polish it, you must wash it eight or ten times over with the best feed-lac varnish, letting it stand to dry every time; and afterwards polish it, as before directed. All sorts of coloured speckles may be thus used, except those of silver; the laying on of which requires the best and finest of the lac-varnish, or the best white varnish, which must make it fit for polishing; but if you have not a mind to polish it, fewer washes of the varnish will be sufficient.

Japanned and laquered ware of the East indies, pay duty for every 100 l. gros value at the sale 38 l. on importation, and the drawback is 35 l. 12s. 6d. on exportation.

JASMINUM, in botany, a genus of the diandria monogyenia class. The corolla consists of five segments; the berry is tricoccous; and the seed is arilatated. There are six species, none of them natives of Britain.

JASPER, in natural history, a genus of the moncecia monadelphia class. The male has three, and bisid; the capule has three cells, and contains but one seed. There are seven species, none of them natives of Britain.

JAV, an island of the East Indies, situated between 102° and 113° of E. longitude, and between 5° and 8° of Ormus: E. long. 58°, N. lat. 21°.
ICE-house, a building contrived to preserve ice for the quantity to be kept; for it is proper to have it sealed, which should be of a size and depth proportionable most proper for the well in which the ice is to be preserved to the fancy of the owner; but a circular form is visible. The place should also be selected, and as much exposed to the sun and air as possible. The external wall may be built in what form the proprietor pleases; and as these ice-houses are placed in gardens, they are sometimes so contrived as to have an handsome alcove-seat in front, with a small door behind it, through which a person might enter to take out the ice; and a large door on the other side, fronting the north, with a porch wide enough for a small cart to back, in order to shoot down the ice near the mouth of the well, which need not be more than two feet diameter, and a stone so contrived as to shut it up in the exactest manner: all the vacant space above and between this and the large door should be filled up with barley-straw. The building thus finished, should have time to dry before the ice is put into it.

It is to be observed, that upon the wooden grate, at the bottom of the well, there should be laid some small faggots; and if upon these a layer of reeds is placed smooth for the ice to lie upon, it will be better than straw, which is commonly used. As to the choice of the ice, the thinner it is, the easier it may be broken to powder; for the smaller it is broken, the better it will unite when put into the well. In putting it in, care must be taken to ram it as close as possible; and also to allow a vacancy of two inches, all round, next the side of the well, to give passage to any moisture occasioned by the melting of some of the ice. When the ice is put into the well, if a little salt-petre be mixed with it at every ten inches or a foot in thickness, it will cause it to unite more closely into a solid mass.

ICHNEUMON, in zoology. See Viverra. Ichneumon is also the name of a genus of flies, of the hymenoptera order. It has no tongue; the antennae have above thirty joints; the abdomen, in most of the species, is petiolated; and it has a ring in the tail inclosed in a double-valved cylindrical sheath. There
are seventy-seven species, principally distinguished by their colour.

ICHNOGRAPHY, in perspective, the view of anything cut off by a plain parallel to the horizon, just at the base of it.

Among painters, it signifies a description of images, or of ancient statues of marble and copper, of bulls and semi-bulls, of paintings in fresco, mosaic works, and ancient pieces of miniature.

ICHNOGLANS, the grand signior's pages serving in the seraglio.

They are the children of Christian parents, either taken in war, purchased, or presents from the viceroys and governors of distant provinces: they are the most sprightly, beautiful and well-made that can be met with; and are always reviewed and approved of by the grand signior himself, before they are admitted into the seraglios of Pera, Constantinople, or Adrianople, being the three colleges where they are educated, or fitted for employments, according to the opinion of the court entertainers of them.

ICHOR, properly signifies a thin watery humour, like serum: but is sometimes also used for a thicker kind, flowing from ulcers, called also fainies.

ICHTHYOCOLLA, isinglass, a preparation from the fish known by the name of hufo. See Accipenser.

This is a tough and firm substance, of a whitish colour, and in some degree transparent; it is light, moderately hard, very flexible, and of scarce any smell, and very little taste. We usually receive it in twisted pieces of an oblong and rounded figure, and bent in the shape of a horse-hoe: this our druggists usually beat and pull to pieces, and sell it in thin shreds like skins, which easily dissolve: besides this kind of round isinglass, we meet with some in small thin square cakes, white and very transparent; these are the finest of all. But isinglass, of whatever shape, is to be chosen clean, whitish, and pellucid.

The method of preparing the ichthyocolla is this: they cut off all the fins of the hufo, close to the flesh, and take out the bladder, stomack, and intestines; they wall thefe very clean, and then cut them in pieces, and throwing them into a large quantity of water, they let them steep four and twenty hours, and after this they kindle a fire under the vessel, and keep the liquor just boiling till the greater part of the matters are dissolved; they then stir the whole briskly about; then strain it through flannels, and let the liquor by to cool. When there is a large quantity of fat usually formed upon it, which is carefully skimmed off, and the clear liquor is poured off from the groffer parts which subside, it is put over the fire again, and gently evaporated and skimmed afresh all the time, till by trials they find, that on taking a spoonful of it cool it will harden into the consistence of glue. Great care is taken to keep the fire very gentle, to prevent burning towards the end of this evaporation. They then pour it out upon a large, smooth, wooden table; and as it cools, form it into the mallees we meet with it in, by cutting and rolling it up.

The greatest quantity of isinglass is made in Russia. We have it principally from Holland, the Dutch contrading for the most of it before it is made.

It is an excellent agglutinant and strengthener; and is often prescribed in jellies and broth, but rarely enters any compositions of the regular medicinal form. It is the most efficacious as well as the most safe and innocent of all the ingredients used for cleaning wines, upon which account the wine-coopers use a much greater quantity of it than the apothecaries.

A very valuable glue is also made of this drug, which is a proper form to keep it for the wine-coopers use.

ICHTHYOLOGY, the science of fishes, or that branch of zoology which treats of fishes. See Natural History.

ICHTHYPERIA, in natural history, a name given by Dr Hill to the bony plates and mouths of fishes, usually met with either foliole, in single pieces, or in fragments. They are of the same substance with the buforomite; and are of very various figures, some broad and short, others longer and slender; some very gibbous, and others plainly arched. They are likewise of various sizes, from the tenth of an inch to two inches in length, and an inch in breadth.

ICOSAHEDRON, in geometry, a regular solid, consisting of twenty triangular pyramids, whose vertexes meet in the centre of a sphere, supposed to circumscribe it; and therefore, have their height and bases equal: wherefore the solidity of one of those pyramids multiplied by 20, the number of bases, gives the solid content of the icosahedron.

ICOSANDRIA, in the Linnean system of botany, See Botany, p. 625.

IDA, a mountain in the island of Candia or Crete; also another in Natolia, or leffer Asia, celebrated by the poets for the judgment of Paris on the beauty of the three goddesses, Minerva, Juno, and Venus, to the last of whom he gave the preference.

IDEA, the reflex perception of objects, after the original perception or impression has been felt by the mind. See Metaphysics.

IDENTITY, denotes that by which a thing is itself, and not any thing else; in which sense, identity differs from similitude as well as diversity. See Metaphysics.

IDES, in the ancient Roman calendar, were eight days in each month; the first of which fell on the 15th of March, May, July, and October; and on the 13th day of the other months.

They were reckoned backwards, in the manner already explained under the article Calendar.

Thus they called the 14th day of March, May, July, and October; and the 12th of the other months, the pridie idus, or the day before the ides; the next preceding day, they called the tertio idus; and so on, reckoning always backwards, till they come to the nones. See Nones. This method of reckoning time is still retained in the chancery of Rome, and in the calendar of the breviary.

IDIOM, among grammarians, properly signifies the pecu-
IDIOT, a person that is born a natural fool.

IDIOPATHY, in physic, a disorder peculiar to a certain part of the body, and not arising from any preceding disease; in which sense, it is opposed to sympathetic.

Thus, an epilepsy is idiopathic, when it happens merely through some fault in the brain; and sympathetic, when it is the consequence of some other disorder.

IDIOSYNCRASY, among physicians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain disorders than persons of a different constitution usually are.

IDIOT, a person that is born a natural fool.

IDOLATRY, or the worship of idols, may be distinguished into two sorts. By the first, men adore the works of God, the sun, the moon, the stars, angels, demons, men and animals: by the second, men worship the work of their own hands, as statues, pictures, and the like: and to these may be added a third, that by which men have worshipped the true God under sensible figures and representations. This indeed may have been the case with respect to each of the above kinds of idolatry; and thus the Israelites adored God under the figure of a calf.

The stars were the first objects of idolatrous worship; and on account of their beauty, their influence on the productions of the earth, and the regularity of their motions, particularly the sun and moon, which are considered as the most glorious and repulsive images of the Deity: afterwards, as their sentiments became more corrupted, they began to form images, and to entertain the opinion, that by virtue of consecration, the gods were called down to inhabit or dwell in their statues. Hence Arnobius takes occasion to rally the pagans for guarding so carefully the statues of their gods, it is certain, that the wiser Jews, extended this precept to the making the figure of any man: by the law of Moses, they were obliged to destroy all the images they found, and were forbidden to apply any of the gold or silver to their own use, that no one might receive the least profit from any thing belonging to an idol. Of this the Jews, after they had smarred for their idolatry, were so sensible, that they thought it unlawful to use any vessel that had been employed in sacrificing to a false god, to warm themselves with the wood of a grove, after it was cut down, or to shelter themselves under its shade.

But the preaching of the Christian religion, wherever it prevailed, entirely rooted out idolatry; as did also that of Mahomet, which is built on the worship of one God. It must not, however, be forgotten, that the profest Christians charge those of the church of Rome with paying an idolatrous kind of worship to the pictures or images of saints and martyrs: before these, they burn lamps and wax-candles; before these, they burn incense, and kneeling offer up their vows and petitions: they, like the pagans, believe that the saint to whom the image is dedicated, presides in a particular manner about its shrine, and works miracles by the intervention of its image; and that if the image was destroyed or taken away, the saint would no longer perform any miracle in that place.

IDyllion, in ancient poetry, is only a diminutive of the word [idios] and properly signifies any poem of moderate extent, without considering the subject. But as the collection of Theocritus's poems were called idyllia, and the pastoral pieces being by far the best in that collection, the term idyllion seems to be now appropriated to pastoral pieces.

JEALOUSY, in general, denotes the fear of a rival; but is more especially understood of the suspicion which married people entertain of each other's fidelity and affection.

JEDBURGH, the capital of Tiviotdale or Roxburgh, in Scotland, thirty-six miles south-east of Edinburgh: W. long 2° 15', N. lat. 55° 25'.

JEDDO, the capital city of Japan Proper, situated on the east side of the island: E. long. 143° N. lat. 36°.

The splendor of the royal palace and public buildings of this city, in the opinion of those Europeans who have seen it, is no where to be equalled. The emperor's palace and gardens, which are in the middle of the city, are five miles in circumference. All the houses are built upon one floor, and the rooms are only divided by folding screens.

JEER, or Jeer-rose, in a ship, is a large rope secured through double or treble blocks, lashed at the mainhead and on the yard, in order to hoist or lower the yards.

Jehovah, one of the scripture-names of God, signifying the Being who is self-existent and gives existence to others.

So great a veneration had the Jews for this name, that they left off the custom of pronouncing it, whereby its true pronunciation was forgotten. They call it tetragrammaton, or the name with four letters; and believe, that whoever knows the true pronunciation of it cannot fail to be heard by God.
JEJUNUM, in anatomy. See Anatomy, p. 260.

JEMPTERLAND, a province of Sweden, bounded by Angermania on the north, by Medelpada on the east, by Helsingia on the south, and by Norway on the west.

JENA, a city of Germany, in the circle of Upper Saxony, and the landgraviate of Thuringia: E. lon. 11° 44', N. lat. 51°.

JUNKOPING, a city of Sweden, in the province of Gotland, situated ninety miles south-east of Gotenburg: E. long. 14° 30', N. lat. 57° 30'.

JEREMIAH, The prophecy of, a canonical book of the Old Testament. This divine writer was of the race of the priests, the son of Hilkah of Anathoth, in the tribe of Benjamin. He was called to the prophetic office when very young, about the thirteenth of Josiah, and continued in the discharge of it about forty years. He was not carried captive to Babylon with the other Jews, but remained in Judea to lament the desolation of his country. He was afterwards a prisoner in Egypt with his disciple Barach, where it is supposed he died in a very advanced age. Some of the Chritian fathers tell us, he was slain by death to the Jews, for preaching against their idolatry; and some say, he was put to death by Pharaoh Hophra, because of his prophecy against him. Part of the prophecy of Jeremiah relates to the time after the captivity of Israel, and before that of Judah, from the first chapter to the forty-fourth; and part of it was in the time of the latter captivity, from the forty-fourth chapter to the end. The prophet lays open the sins of Judah with great freedom and boldness, and reminds them of the severe judgments, which had befallen the ten tribes for the same offences. He passionately laments their misfortune, and recommends a speedy reformation to them. Afterwards he predicts the grievous calamities that were approaching, particularly the seventy years captivity in Chaldeas. He likewise foretells their deliverance and happy return, and the remiscence which Babylon, Moab, and other enemies of the Jews should meet with in due time. There are likewise several intimations in this prophecy concerning the kingdom of the Messiah; also several remarkable visions, and types, and historical passages relating to those times. The fifty-second chapter does not belong to the prophecy of Jeremiah, which probably was added by Ezra, and contains a narrative of the taking of Jerusalem, and of what happened during the captivity of the Jews, to the death of Jechonias. St. Jerom has observed upon this prophet, that his style is more easy than that of Isaiah and Hosea; that he retains something of the rusticity of the village where he was born; but that he is very learned and majestic, and equal to those two prophets in the depth of his prophecy.

JERSEY, an island in the English channel, fifteen miles west of the coast of Normandy, and eighty miles south of Portland in Dorsetshire: W. long. 2° 20', N. lat. 49° 20'.

New JERSEY, a province in North America, which may be bounded on the north by a line drawn from the river Delaware to Hudson's river, which divides it from New York; by the Atlantic Ocean, on the east; by the same ocean on the south; and by Delaware bay and river, which separates it from Pennsylvania, on the west. It lies between 74° and 76° of W. long., and between 39° and 41° of N. lat., and is about 140 miles in length, and 60 in breadth. It is subject to Britain.

JERUSALEM, the capital city of Judea, or Palestine, in Asia. Situated thirty miles east of the Levant, or Mediterranean sea, and ninety miles south of Damascus: E. long. 36°, N. lat. 32°.

The city is at present a high rock, with steep ascents on every side, except on the north; and is surrounded with a deep valley, which is again encompassed with hills. The city is at present three miles in circumference, and has a little altered its situation: for mount Calvary, which was formerly without the walls, stands now in the middle of the city; and mount Zion, which stood near the centre, is now without the walls.

JESI, a city of Italy, in the province of Ancona, and territory of the pope: E. long. 14° 45', N. lat. 43° 45'.

JESSELMERE, the capital of the province of the same name in the East Indies, subject to the Mogul: E. long. 73° 20', N. lat. 27°.

JESSO, or YEDDO, a country of Asia, which lies north of Japan, and is said to extend north-east to the continent of America: E. long. 140°, N. lat. 40°.

JESUAT, a province of India, bounded by Patan on the north, and by Bengal on the south; subject to the Mogul.

JESUITES, or the society of Jefus, a famous religious order in the Romish church, founded by Ignatius Loyola, a native of Guipuzcoa in Spain, who in the year 1538 assembled ten of his companions at Rome, principally chosen out of the university of Paris, and made a proposal to them to form a new order: when, after many deliberations, it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth; which was, to go into all countries whither the pope should please to send them, in order to make converts to the Romish church. Two years after, pope Paul III. gave them a bull, by which he approved this new order, giving them a power to make such statues as they should judge convenient: on which, Ignatius was created general of the order; which in a short time spread over all the countries of the world, to which Ignatius sent his companions, while he staid at Rome, from whence he governed the whole society.

The entire society is composed of four sorts of members: novices, scholars, spiritual and temporal coadjutors, and professed members. The novices continue two years; after which they are admitted to make the three simple vows, of chastity, poverty, and obedience, in the presence of their superiors: the scholars add some spiritual exercises to their studies. The spiritual coadjutors assist the professed members, and also make the three simple vows: the temporal coadjutors, or...
or lay-brothers, take care of the temporal affairs of the society; and the professed members, which compose the body of the society, besides the three simple vows, add a special vow of obedience to the head of the church in every thing relating to millions among idolaters and heretics. They have professed houses for their professed members and their coadjutors; colleges, in which the sciences are taught to strangers; and seminaries, in which the young Jefuits go through a course of philosophy and theology. They are governed by a general, who has four assistants, and who appoints rectors, superiors of houses, provincials, visitors, and commissaries. The discipline of these houses, and especially of the colleges, was regulated by Ignatius himself. On account of the grous doctrines and bad practices of the Jefuits, the order, within these few years, has been suppressed in most Roman-catholic countries, the members banished, and their goods confiscated.

JET, in natural history, a solid, dry, opaque, inflammable substance, found in large detached mafses, of a fine and regular structure, having a grain like that of wood, splitting more easily horizontally than in any other direction, very light, moderately hard, not fusible, but readily inflammable, and burning a long time with a fine greenish flame.

It is of a fine deep black colour, very glossy and shining, except upon its surface, where it has been fouled by accident. When examined by the microscope, it is found to be composed of a number of parallel plates, very thin, and laid closely upon one another. It is not soluble in, nor makes any effervescence with acids. It should be chosen of the deepest black, of a moderate hardness, very light, and such as will split most evenly in a horizontal direction; this being its great characteristic, by which it is distinguished from the cannel coal, which breaks equally easy any way.

JET is of great use to perfumers, and is sometimes prescribed in medicine. Dioscorides tells us, that it is an excellent emollient and diffusant, and recommends a fumigation of it for diseases of the womb; and among the eastern nations, it is still in high repute as a cordial, a strengthener, and prolonger of life.

Every pound of jet pays on importation a duty of 7½ d. and draws back 6½ d. on exportation.

JET D'EAU, a French term, frequently also used with us, for a fountain that casts up water to a considerable height in the air.

JEWEL, any precious stone, or ornament befit with them. See the articles DIAMOND, RUBY, &c.

JEWS, those who profess obedience to the laws and religion of Moses. When a modern Jew builds an house, he must leave part of it unfurnished, in remembrance that the temple and Jerufalem now lie desolate. They lay great stress upon frequent washings. They abstain from meats prohibited by the Levitical law; for which reason, whatever they eat must be dressed by Jews, and after a manner peculiar to themselves. Every Jew is obliged to marry, and a man who lives to twenty unmarried, is accounted as actually living in sin.

The Jews, it is said, were formerly at the disposal of the chief lord where they lived, and likewise all their goods. A Jew may be a witness by our law, being sworn on the Old Testament, and taking the oaths to the government.

For a farther account of the Jew, see the articles CARAITES, CIRCUMCISION, LEVITES, PASSOVER, PHARISEE, RABBINS, SADDUCEES, SANHEDRIM, SYNOGOGUE, TALMUD, &c.

JEW'S EARS, in botany. See Tremella.

IGLAW, a town of Germany, in the province of Moravia, situated on the river Igla, on the frontiers of Bohemia; subject to the house of Austria: E. long. 15° 7', N. lat. 49° 16'.

IGNAVUS, in zoology. See Bradypterus.

IGNIS. See Fire.

IGNIS-FATUUS. See Will-with-a-wisp.

IGNITION, in chemistry, the heating metals red-hot, without melting them.

IGNORANCE, the privation or absence of knowledge. The causes of ignorance, according to Locke, are chiefly these three. 1. Want of ideas. 2. Want of a discoverable connection between the ideas we have. 3. Want of tracing and examining our ideas. See Metaphysics.

IGUANA, in zoology. See Lacerta.

IHOR, the capital of the province of Ibor, in Malacca, near the south cape of the further peninsula of India, subject to the Dutch: E. long. 103°, N. lat. 3°.

ICHESTER, a borough-town of Somerfetshire, fourteen miles south of Wells. It sends two members to parliament.

ILEX, the holm-oak, or ever-green oak, in botany, a genus of the tetrandria tetragynia class. The cahn has four teeth; the corolla is rotated; it has no stigmas; and the berry contains four seeds. There are five species, none of them natives of Britain. The kermes of the shops adheres and is gathered off the branches of the ilex aquifolium. The kermes is a round grain about the bulk of a pea. These grains appear full of small reddish ovule, or animalules, of which they are the nidi. The kermes is a grateful mild reftringent and corrobosint.

ILHEOS; or RIO DE ILHEOS, a province of Brazil in south America, subject to Portugal. It is bounded by the bay of All-faints on the north, and by the Atlantic ocean on the eaf.

ILIAC PASSION, in medicine. See Medicine.

ILIACUS MUSCULUS, in anatomy. See Anatomy, p. 204.

ILIAD, the name of an ancient epic poem, the first and finest of those composed by Homer. The poet's design in the iliad was to show the Greeks, who were divided into several little states, how much it was their interef to preserve a harmony and good understanding among themselves; for which end, he sets before them the calamities that befel their ancestors from the wrath of Achilles, and his misuder-
standing with Agamemnon; and the advantages that afterwards accrued to them from their union. The Iliad is divided into twenty-four books, or rhapsodies, which are marked with the letters of the alphabet.

ILLENOIS, the inhabitants of a country contiguous to the illinois-lake, in Canada, in north America, which is situated between 88° and 93° of W. lon. and between 41° and 46° of N. lat.

ILMEN, a lake in the province of Great Novogrod, in Russia, in 34° E. lon. and 58° N. lat.

ILMENSTAT, a town of Germany, in the circle of Tyrol, runs north through Swabia, and falls into the Danube at Ulm.

IMAGE, in a religious sense, is an artificial representation or similitude of some person or thing, used either by way of decoration and ornament, or as an object of religious worship and veneration; in which last sense, it is used indiscriminately with the word idol.

IMAGINATION, a power or faculty of the mind, exercising and performing actions in the mind, either as fancy, opinion, judgment, or reasoning.

IMMAN, a name applied by the Mahometans to him who is head of the congregations in their mosques; and, by way of eminence, to him who has the supreme authority both in respect to spirituals and temporals.

IMBECILLITY, a languid, infirm state of body, which, being greatly impaired, is not able to perform its usual exertions and functions.

IMBIDING, the action of a dry porous body, that absorbs or takes up a moist or fluid one: thus, sugar imbibes water; a sponge, the moisture of the air, &c.

IMBRICATED, among botanists. See Botany, p. 641.

IMMENSTAT, a town of Germany, in the circle of Swabia; situated in E. lon. 10° 8'; N. lat. 47° 26'.

IMITATION, the acts of doing or having to copy another person or thing. Du Bos observes, that the principal merit of poems and pictures consists in the imitation of such objects as would have excited real passions; and that the passions which these imitations give rise to, are only superficial, and not so strong as that of the object imitated, and are therefore soon effaced. He also maintains, that the imitation of tragic objects in poems and pictures, affords most pleasure: we listen, therefore, with pleasure to those unhappy men who make a recital of their misfortunes by means of a painter's pencil, or of a poet's verses; but, as Diogenes Laertius observes, it would affllict us extremely, were we to hear them bewailing their sad disasters in person.

IMMACULATE, something without stain, chiefly applied to the conception of the holy virgin.

IMMATERIAL, something devoid of matter, or that is pure spirit: thus God, angels, and the human soul, are immaterial beings.

IMMEDIATE, whatever is capable of producing an effect without the intervention of external means; thus we say, an immediate cause, in opposition to a mediate or remote one.

IMMENSITY, an unlimited extension, or which no finite and determinate space, repeated ever so often, can equal.

IMMERSION, that act by which any thing is plunged into water or other fluid. It is used in chemistry for a species of calcination, when any body is immered in a fluid to be corroded; or it is a species of solution, as when a substance is plunged into any fluid in order to deprive it of a bad quality, or communicate to it a good one.

IMMERSION, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being, as it were, enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth.

IMMORTAL, that which will last to all eternity, as having in it no principle of alteration or corruption; thus God and the human soul are immortal.

IMMUNITY, a privilege or exemption from some office, duty, or imposition, as an exemption from tolls, &c.

Immunity is more particularly understood of the liberties granted to cities and communities.

IMPALLED, in heraldry; when the coats of a man and his wife who is not an heiress are borne in the same quarter, or entered in the shield without the intervention of external means; thus the court.

IMPALPABLE, that whose parts are so extremely minute that they cannot be distinguished by the senses, particularly by that of feeling.

IMPATNATION, a term used by divines, to signify the opinion of the Lutherans with regard to the eucharist, who believe that the species of bread and wine remain together with the body of our Saviour after consecration.

IMPAPELING, in law, signifies the writing down of the names of a jury summoned by the sheriff to appear for such public services as juries are employed in.

IMPARABLE, that whose parts are so exactly minute that they cannot be distinguished by the senses, particularly by that of feeling.

IMPASSIBILITY, in law, a petition in court for a day or time to consider or advise what answer the defendant shall make to the plaintiff's action; and is the continuance of the cause till another day, or a longer time given by the court.

IMPASSICATION, the mixture of various materials of different colours and consistencies, baked or bound together with some cement, and hardened either by the air or by fire.

IMPATIENTS, in botany, a genus of the syngenesia monogynia class. The calix consists of two leaves, and the
the corolla of five irregular petals; and the capsule has five valves. There are seven species, only one of which, *V. the noli-me-tangere*, or touch-me-not, is a native of Britain.

**IMPEACHMENT**, an accusation and prosecution for treason and other crimes and misdemeanors.

**IMPERIAL**, something belonging to an emperor or empire, as imperial crown, imperial chamber, imperial cities, imperial diet, &c.

**IMPERATOR**, in Roman antiquity, a title of honour conferred on victorious generals, by their armies, and afterwards confirmed by the senate.

**IMPERATORIA, MASTER-WORT**, in botany, a genus of the pentandria digynia class. The fruit is roundish, has five valves. There are seven species, only one of which, viz. the noli-me-tangere, or touch-me-not, is a native of Britain.

**IMPERFBCT**, something that is defective, or that wants some of the properties found in other beings of the same kind.

**IMPERIAL**, something belonging to an emperor or empire, as imperial crown, imperial chamber, imperial cities, imperial diet, &c.

**IMPERSONAL VERB**, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb defective of the two first and primary persons, as *deceit, defpote*, &c.

**IMPERVIOUS**, a thing not to be pervaded nor passed through, either by reason of the closeness of its pores, or the particular configuration of its parts.

**IMPETUS**, in mechanics, the force with which one body impels or strikes another. See Mechanics.

**IMPLICATION**, in law, is where something is implied, that is not expressed by the parties themselves in their deeds, contracts, and agreements.

**IMPORTATION**, in commerce, the bringing merchandise into a kingdom from foreign countries; in contradistinction to exportation. See Exportation.

We shall here give some of the principal laws relating to the importation of goods into this kingdom. Goods imported without entry, or paying customs, are forfeited; and the lord-treasurer, the barons of the exchequer, or chief magistrates of the place where the offence was committed, or next adjoining to it, may grant a warrant to any person, who, with the assistance of a constable, may break open doors, cellars, &c. and take thence any prohibited or unacquainted goods; but this is to be done within one month after the offence was committed. But if false information is given, the person wrongfully accused, may recover costs and damages.

No ship or vessel arriving from beyond sea is to be above three days in failing from Gravesend to the place of discharge on the river Thames, unless hindered by contrary winds or other impediment. And no ship bound for the port of London is to touch or stay at any place adjoining to any shore, between Gravesend and Chertsey quay. True entries are to be made of all such ships lading, upon oath of the master or purser for that voyage; also where she took in her lading, where she was built, how manned, who were the owners, and who the master during the voyage. In all out-ports, ships are to come directly to the place of unlading, and make true entries as aforesaid, upon penalty of the forfeiture of 100 l.

After any ship is cleared, and the watchmen and tedmen discharged from their attendance, if there be found on board any concealed goods that have not paid the duty inwards, the master, or other person taking charge of the ship, shall forfeit 100 l.

Porters, carmen, watermen, &c. assisting in landing unacquainted goods, shall, on conviction, for the first offence, be committed to the next jail till they find security for their good behaviour; and for their second offence, they are to be committed to prison for two months, without bail or mainprize, or till they are discharged by the court of exchequer, or each of them pay 5 l. to the sheriff of the county.

No merchant-denizen shall cover a stranger's goods, but shall, by himself or agent, sign one of his bills of every entry, with the mark, number, and contents of every parcel of goods, without which no entry shall pass. And no children of aliens under the age of twenty one years, shall have entry made in their names, nor be permitted to trade.

Merchants, trading into the port of London, shall have free liberty to lade and unlade their goods at any of the lawful quays between the Tower and London-bridge, from sunrising to sunsetting, from September 10, to March 10; and between six o'clock in the morning and six in the evening, from March 10, to September 10; giving notice thereof to the respective officers, appointed to attend the lading and unlading of goods. And such officers as shall refuse to be present shall forfeit 5 l. for every default.

To prevent combination between importers, and feizers of goods unlawfully imported or exported, none shall seize them but the officers of the customs, or such as shall be authorized to do by the lord treasurer, under-treasurer, or a special commission from his majesty, under the great privy seal.

If any feizer of prohibited or unacquainted goods does not make due prosecution thereof, it is lawful for the customs-house officers, or others deputed thereto, to make seizure of such goods, and they shall be, in law, adjudged the first true informers and feizers, and have the benefit thereof, notwithstanding any law and statute to the contrary.

All foreign goods permitted to be landed by bills at sight, bills at view or suffrance, shall he landed at the most convenient quays and wharfs, as the officers of the customs shall direct; and there, or at the king's storehouse of the respective ports, shall be measured, weighed, numbered, &c. by the officers appointed, who shall perfect the entry, and subscribe their names to it, and the next day make their report to the collector.
or comptroller; or in default thereof, shall forfeit 100l.

Any merchant who shall import goods, shall have liberty to break bulk in any lawful port or quay, the master or purser first making oath of the true contents of the ship's lading. No English merchant shall put on shore in Scotland or Ireland, any merchandise of the growth or produce of any of his majesty's plantations, unless the same have been first landed in England, Wales, or Berwick, and paid the duties with which they are chargeable, under the penalty of forfeiting their goods may be put on shore, under the hands of the principal officers of the customs there refiding, till the goods can be put on board some other vessel, to be transported to some part of England or Wales.

Natives of England or Ireland may import into England, directly from Ireland, any hemp, flax, thread, yarn and linen, of the growth and manufacture of Ireland, custom-free; the chief officer so importing bringing a certificate from the chief officer in Ireland, expressing the particulars of the goods, with the names and places of abode of the exporters thence, and of such as have sworn that the said goods are, bona fide, of the growth and manufacture of that kingdom, and who they are consigned to in England; and the chief officer shall make oath, that the said goods are the same that are on board, by virtue of that certificate.

IMPOST, in law, signifies in general a tribute or custom, but is more particularly applied to signify that tax which the crown receives for merchandizes imported into any port or haven.

IMPOSTHUME, in surgery, See Abscess.

IMPOTENCE, or Impotency, in general, denotes want of strength, power, or means to perform any thing.

Divines and philosophers distinguish two sorts of impotency; natural, and moral. Impotency is the first, is a want of some physical principle, necessary to an action; or where a being is absolutely defective, or not free and at liberty to act: the second only imports a great difficulty, as a strong habit to the contrary, a violent passion, or the like.

Impotency is, more particularly, used for a natural inability to coition. Impotence with respect to men, is the same as sterility in women; that is, an inability of propagating the species. There are many causes of impotency; as, a natural defect in the organs of generation, which seldom admits of a cure: accidents, or diseases; and in such cases the impotence may, or may not be remedied, according as these are curable or otherwise.

IMPRESSION, the getting a female with-child, See Pregnancy.

The term impregnation is also used, in pharmacy, for communicating the virtues of one medicine to another, whether by mixture, coction, digestion, &c.

IMPRESSION is applied to the species of objects, which are supposed to make some mark or impression on the fenesthes, the mind, and the memory.

The peripatetics assert, that bodies emit species resembling them, which are conveyed to the common seneforium, and they are rendered intelligible by the active intellect; and when thus spiritualized, are called expressions, or express species, as being expreffed from the others.

IMPRESSION also denotes the edition of a book, regarding the mechanical part only; whereas edition, besides this, takes in the care of the editor, who corrected or augmented the copy, adding notes, &c. to render the work more useful.

IMPROBATION, in Scots law, the name of that action brought for setting any deed or writing aside upon the head of forgery. See Law, tit. 33.

IMPROPRIATION, a parsonage or ecclesiatical living, the profits of which are in the hands of a layman; in which sense, it stands distinguished from appropriation, which is where the profits of a benefice are in the hands of a bishop, college, &c. though these terms are now often used promiscuously.

IMPULSE, in mechanics. See Mechanics.

IMPUORITY, in the law of Moses, is any legal defilement. Of these there were several sorts; some were voluntary, as the touching a dead body, or any animal that died of itself, or any creature that was esteemed unclean; or the touching things holy, by one who was not clean, or was not a priest; the touching one who had a leprosy, one who had a gonorrhoea, or who was polluted by a dead carcasse, &c. Sometimes these impurities were involuntary, as when any one inadvertently touched bones, or a sepulchre, or any thing polluted; or fell into such diseases as pollute, as the leprosy, &c.

IMPUTATION, in general, the charging something to the account of one, which belonged to another: thus, the affirrors of original sin maintain, that Adam's sin is imputed to all his posterity.

In the same sense, the righteousness and merits of Christ are imputed to true believers.

INACCESSIBLE, something that cannot be come at, or approached, by reason of intervening obstacles, as a river, rock, &c. It is chiefly used in speaking of heights and distances. See Geometry.

INALIENABLE, that which cannot be legally alienated or made over to another: thus the dominions of the king, the revenues of the church, the effates of a minor, &c. are inalienable, otherwise than with a reserve of the right of redemption.

INANIMATE, a body that has either lost its soul, or that is not of a nature capable of having any.

INANITION, among physicians, denotes the state of the stomach when empty, in opposition to repletion.

INARCHING, in gardening, is a method of grafting, commonly called grafting by approach, and is used when the stock intended to graft on, and the tree from which the graft is to be taken, stand so near, or can
can be brought so near, that they may be joined together.

INAUGURATION, the coronation of an emperor or king, or the consecration of a prelate: so called from the ceremonies used by the Romans, when they were received into the college of augurs.

INCA, or Ynca, a name given by the natives of Peru to their kings and the princes of the blood. Pedro de Cieça, in his Chronicle of Peru, gives the origin of the inacas, and says, that that country was, for a long time, the theatre of all manner of crimes, of war, diffention, and the most dreadful disorders, till at last two brothers appeared, one of whom was called Mangocapa; of this perfon, the Peruvians relate many wonderful stories. He built the city of Cufco, made laws, establifhcd order and harmony by his wife regulations; and he and his defcendents took the name of inca, which signifies king or great lord. These inacas became so powerful, that they rendered themselves masters of all the country from Paflto Chilli, and from the river Maule on the south, to the river Augamago on the north; these two rivers forming the bounds of their empire, which extended above thirteen hundred leagues in length. This they enjoyed till the divisions between inca Guafcar and Atabalipa; which the Spaniards laying hold of, made themselves masters of the country, and defroyed the empire of the incas.

INCAMERATION, a term used in the chancery of Rome, for the uniting of lands, revenues, or other rights, to the pope's domain.

INCANTATION, denotes certain ceremonies, accompanied with a formula of words, and supposed to be capable of raising devils, spirits, &c. See CHARM, &c.

INCAPACITY, in the canon-law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimation in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

INCARNACTION, in theology, the act whereby the second person of the holy Trinity assumed the human nature, viz. a true body and reasonable soul, in order to accomplish the redemption of fallen mankind.

INCARNATIVES, in surgery, medicines which affift nature in filling up wounds or ulcers with flesh; or rather remove the obstructions thereto.

INCENSE, of Frank-incense, in the materia medica, &c. a dry resinous substance, known among authors by the names thus and olibanum.

Incense is a rich perfume, with which the ancient pagans, and the Roman Catholics still, perfume their temples, altars, &c.

The burning of incense made part of the daily service of the ancient Jewifh church. The priests drew lots to know who should offer it; the defined perfon took a large silver dish, in which was a cenfer full of incense; and being accompanied by another priest, carrying some live coals from the altar, went into the temple. There, in order to give notice to the people, they struck upon an instrument of brass placed between

...
incompatible in the same subject, the strongest over-
coming and expelling the weakest.
INCORPORATION, in pharmacy, is much the same
as immobilization, being a reduction of dry substan-
ces to the consistence of a paste, by the admixture of some
fluid; thus pills, boles, troches, and plasters are made
by incorporation. Another incorporation is, when
things of different consistencies, are by digestion redu-
ced to one common consistence.
INCORPORATION, a thing, or substance, which has no
body; as God, angels, and the soul of man.
INCOORPUTIBLE, that which cannot be corrupted.
INCRASSATING, in pharmacy, &c. the rendering
fluids thicker by the mixture of other substances less
fluid, or by the evaporation of the thinner parts.
INCUBATION, the action of a hen, or other fowl
brooding on her eggs.
INCUBUS, or NIGHT-MARE, in medicine. See ME-
DICINE.
INCUMBENT, a clerk, or minister who is resident on
his benefice: he is called incumbent, because he does,
or at least ought, to bend his whole study to discharge
the cure of his church.
INCURVATION of the rays of light, their bending out
of a rectilinear straight course, occasioned by refraction.
See Optics.
INCUS, in anatomy. See Anatomy, p. 296.
INDEFINITE, that which has no certain bounds, or
to which the human mind cannot affix any.
INDEFINITE, in grammar, is underflow of nouns, pro-
nouns, verbs, participles, articles, &c. which are left
in an uncertain indeterminate feme, and not fixed to
any particular time, thing, or other circumstance.
INDELIBLE, something that cannot be cancelled, or
effaced.
INDEMNITY, in law, the saving harmless; or, a
writing to secure one from all damage and danger that
in incompatible is the same subject, the stronget over-
coming and expelling the weakest.
INDEPENDENTS, a sect of Protestants in Britain and
Holland, so called from their independency on other
churches, and their maintaining that each church or
congregation has sufficient power to act and perform
every thing relating to religious government within it-
self, and is no way subject or accountable to other
churches or their deputies.
They therefore disallow parochial and provincial
subordination, and form all their congregations upon a
scheme of co-ordinancy. But though they do not think
it necessary to assemble synods; yet if any be held,
they look on their resolutions as prudential councils,
but not as decisions to which they are obliged to con-
form.
INDETERMINATE, in general, an appellation given
to whatever is not certain, fixed, and limited; in
which sense, it is the same with indefinite.
INDEX, in arithmetic and algebra, shews to what power
any quantity is involved, and is otherwise called ex-
ponent.
INDEX, in botany. See INDICOFERA.
INDIGO, in botany. See INDIGOPOERA.
INDIGOSTONE, a name which the ancients gave to fome
of their gods.
INDIGO, in botany. See INDIGOPOERA.
INDIGESTION, in medicine, a crudity, or want of
INDEPENDENTS, a sect of Protestants in Britain and

ponent.
INDEX, in botany. See INDICOFERA.
INDIGO, in botany. See INDIGOPOERA.
INDIGESTION, in medicine, a crudity, or want of

gins of the alæ are connivent, and of the same shape with the vexillum; and the pod is flat. There are six species, all of them natives of the Indies. The tinctoria, anil, or indigo, grows about two feet high, with roundish leaves.

As to the indigo blue, it is a peculiar, or settling, made by means of water and oil olive out of the leaves of the anil, or indigo plant; there is a difference between that made by the leaves only, and that which is made of the leaves and small branches. The choicest of the former sort is that which bears the foreign name of Serquiffe, from a village of that name some leagues from Surat in the East Indies. It is made also about Biana and Coffa near Agra; and also in the kingdom of Golconda. In making the fecula of anil, in order to make indigo of it, they cut the herb with a fickle, when the leaves begin to fall upon touching them; and after they have stripped them from the branches, they put them into a sufficient quantity of water in a vessel called the steeping vat; and let them infuse there thirty or thirty-five hours; after which they turn the cock, in order to let the water run off, which is become of a green colour inclining towards blue, into a vessel of the nature of a churn, where it is worked by means of a roller or turner of wood, the ends of which are pointed and faced with iron: this they work till the water abounds with a lather; then they cast into it a little oil of olive, that is, one pound into such a quantity of the liquor as will yield seventy pounds of indigo, such as is saleable; and as soon as the said oil is thrown in, the latter separates into two parts, so that you may observe a quantity curdled as milk is when ready to break; then they cease working, and let it stand to settle; which when it has done some time, they open the pipe or cock of the vessel, in order to let the water clear off, that the fecula which is subfided may remain behind at the bottom of the vessel like the lees of wine. Then taking it out, they put it into straining bags of cloth, to separate what water was left; after which they convey it into chests or boxes that are shallow, to dry it; and being dried, it is what we call indigo.

Chufe the indigo of Serquiffe in flat cakes, of a moderate thickness, neither too soft nor too hard, of a deep violet colour, light, and such as swims on water, and when broken has no white spots in it; and lastly, such as is copperish or reddish on being rubbed with one's nail, and has the leafy duff and broken pieces in it.

The other sort of indigo is also the fecula made from the anil; and differs nothing from the former, but as it is made of the whole plant, stalk and leaf; the best of which kind is that which bears the name Guatimala, that comes from the West Indies. In choosing this indigo, it should be as near the other kind as can be; but the surest proof of its goodness is its burning upon the fire like wax, and leaving only a little ashes behind. The second sort of indigo is that of St Domingo, differing nothing from the Guatimala, only that it is not of so lively a colour; the third is the Jamaica indigo; the fourth is that of the Leeward islands; all which are better or worse, according as they are more or less near and pure.

The use of the indigo is for the the dyer and landrefles, serving the leaf to put among their linen. The painters use it to grind with white for painting in blue; for if it is used alone and neat, it turns black; ground with yellow, it makes a green: some confectioners and apothecaries profequently use this to colour sugars with which to make conferves and syrup of violets, by adding some orice.

INDIVIDUAL, in logic, a particular being of any species, or that which cannot be divided into two or more beings equal or alike.

The usual division in logic is made unto genera, or genus's, those genera into species, and those species into individuals.

INDIVISIBLE, among metaphysicians. A thing is said to be absolutely indivisible, that is a simple being, and consits of no parts into which it may be divided. Thus God is indivisible in all respects, as is also the human mind, not having extension or other properties of body.

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be utterly resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similal surfaces.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received.

There is likewise an indorsement, by way of assignment, on bills of exchange and notes of hand; which is done by writing a person's name on the back thereof. See Bill.

INDUCTION, in law, is putting a clerk or clergyman in possession of a benefice or living to which he is collated, or presented.

INDULGENCES, in the Roman church, are a remission of the punishment due to sins, granted by the church, and supposed to save the sinner from Purgatory. Clement VI. in his decreal, which is generally received by the church of Rome, declares, that our Saviour has left an infinite treasure of merits, arising from his own sufferings, besides those of the blessed virgin and the saints; and that the pastor and guides of the church, and more especially the popes, who are the sovereign dispensers of this treasure, have authority to apply it to the living by virtue of the keys, and to the dead by way of suffrage, to discharge them from their respective proportions of punishment, by taking just so much merit out of this general treasure as they conceive the debt requires, and offering it to God.

The power of granting indulgences has been greatly abused in the church of Rome. It was one of the chief things which the council of Constance laid to the charge of John XXIII. in 1415, that he impowered his legates to absolve penitents from all sorts of crimes, upon the payment of sums proportionable to their guilt. Pope Leo X. in order to carry on the magnificent structure of St. Peter's at Rome, published indulgences, and a plenary remission to all such as should contribute money.
money towards it. Finding the project take, he gave his father, the princes of Cibo, the benefit of the indulgences of Saxony and the neighbouring parts, and farmed out those of other countries to the highest bidders, who, to make the best of their bargains, procured the ablest preachers to cry up the value of the ware.

"Happy times for sinners! says a modern writer, "their crimes were rated, and the remission of them set up by auction. The apostolic chancery taxed sins at a pretty reasonable rate. It cost but ninety livres and a few ducats, for crimes which people on this side the Alps punished with death."

It was this great abuse of indulgences that contributed not a little to the first reformation of religion in Germany, where Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two rials a-piece, and sometimes more.

The pope likewise grants indulgences to persons at the point of death; that is, he grants them, by a brief, power to chuse what confessors they please, who is authorized thereby to absolve them from all their sins in general.

**INDULT**, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indulgences of Saxony and the neighbouring parts, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two rials a-piece, and sometimes more.

**INDULGENCE**, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indulgences of Saxony and the neighbouring parts, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two rials a-piece, and sometimes more.

**INDULGENTIA**, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indulgences of Saxony and the neighbouring parts, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two rials a-piece, and sometimes more.

**INDUSTRIOSO**, a duty, tax, or custom, paid to the king.
In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would have been produced in that time, if the generating motion had continued uniform: therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method by fluxions. See Fluxions.

INFIRMARY, a kind of hospital, where the weak and sickly are properly taken care of.

INFLAMMABILITY, that property of bodies which disposed them to kindle, or catch fire. See Fire.

INFLAMMATION. See Medicine and Surgery.

INLECTION, or Point of Indecision, in the higher geometry, is a point where an arc begins to bend a contrary way.

INJECTION, the forcibly throwing certain liquid medicines into the body, by means of a syringe, tube, or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method by fluxions. See Fluxions.

INFUSION, in pharmacy, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

Hot infusions are made by pouring boiling water, or

any other menstruum, on the drugs whose virtues we would extract: thus, in order to obtain the common infusion of senna, take the leaves of senna, an ounce and a half; of crystals of tartar, three drams; of the lesser cardamom seeds husked, two drams; boil the crystals of tartar in a pint of water, till they are dissolved; then pour the water, while boiling hot, upon the senna and the rest; and when the liquor is cold, strain it off.

INGELSHHEIM, a town of Germany, in the palatinate of the Rhine, eight miles south-west of Mentz, E. long. 7° 40', N. lat. 50°.

INЛИУVIES, the crop or claw of granivorous birds, serving for the immediate reception of the food, where it is macerated for some time, before it is transmitted to the true stomach.

INGOLSTAT, a town of Germany, in the circle of Bavaria, situated on the river Danube, thirty miles west of Ratibon: E. long. 11° 30', and N. lat. 48° 45'.

INGOT, a mass of gold or silver, melted down and cast in a mould, but not coined or wrought.

INGRAFTING, in gardening. See Gardening.

INGRESS, in astronomy, signifies the sun's entering into the first scrupt of one of the four cardinal signs, especially Aries.

INGRIA, a province of Russia, bounded by the lake Ladoga, the river Nieva, and the gulf of Finland on the north, by Novgorod on the east and south, and by Livonia on the west.

INGROSSER, one who buys up great quantities of any commodity, before it comes to market, in order to raise the price.

INGUEN, in anatomy, the same with what is otherwise called groin, or pulces.

INHERITANCE, a perpetual right or interest in lands, invested in a person and his heirs.

INHIBITION, in Scots law, a diligence obtained at the suit of a creditor against his debtor, prohibiting him from selling or contracting debts upon his estate, to the creditor's prejudice. See Law, tit. 18.

INHUMATION, in chemistry, a method of digesting substances by burying the vessel in which they are contained in horse-dung or earth.

INJECTION, the forcibly throwing certain liquid medicines into the body, by means of a syringe, tube, or clyster-pipe, or the like.

Anatomical Injection, the filling the vessels with some coloured sub stance, in order to make their figures and ramifications visible.

For this purpose, a fine red injection is prepared thus: pour a pint of oil of turpentine on three ounces of vermilion, stir them well together, and then strain all through a fine linen cloth. If a green injection is wanted, distilled verdigree may be used instead of the vermilion.

A coarse injection may be made of one pound of tallow, five ounces of white wax, three ounces of oil of olives, melted together, and adding two ounces of venice-turpentine; and when this is dissolved, three ounces of vermilion or verdigree are to be thoroughly mixed with the other ingredients, and the whole strained through a linen cloth.

INJURY,
INK (842) INN

INK, a black liquor generally made of an infusion of galls, copperas, and a little gum arabic.

To make a very good ink for writing: take three ounces of good galls, reduced to powder; which infuse in three pints of river or rain water, letting it in the sun or a gentle heat, for two days; then take common copperas, or green vitriol, three ounces; powder it, put it into the infusion, and let it in the sun for two days more; lastly, shake it well, and add an ounce of good gum arabic.

To make the London powder-ink: take ten ounces of the clearest nut-galls, which reduce to a fine powder; then add two ounces of white copperas, four ounces of Roman vitriol, and of gum arabic or sandarach an ounce; pound and sift them very fine. This powder, though whitish; will, when put into water, turn it to a good black ink: an ounce of the powder serves to make a pint of ink.

To make a shining ink: take gum arabic and Roman vitriol, of each an ounce; galls well bruised, a pound; put them into rape-vinegar, or vinegar made of clear small beer; let them in a warm place, stir them often till the liquor becomes black, and then add to a gallon of this preparation an ounce of ivory-black, and a quarter of a pint of feed-lac varnish.

To make a shining Japan or China ink: take an ounce of lamp-black, and clarify it in an earthen pipkin to take out the dross; two drams of indigo; half a dram of peach black; one dram of black endive, burnt; reduce them to a very fine powder, and then take a moiety of fig-leaf water, another part of milk, and a very little gum arabic; and mixing all the ingredients well together, make them up for use.

Printing Ink is made by boiling or burning linseed-oil till it is pretty thick, adding a little rosin to it while hot, and then mixing this varnish with lamp-black.

INK is also an appellation given to any coloured liquor, used in the same manner as the stramineum or black ink; as red, green, blue, yellow, &c. inks.

Red ink is made thus: take wine-vinegar a pint; rapsings of Brazil, one ounce; alum, half an ounce; boil them gently, and add five drams of gum arabic: dissolve the gum, strain the ingredients, and keep the liquid for use.

Green ink is made by boiling verdigrease with argol in fair water, and adding a little gum arabic.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infusion of saffron in water, with a little alum and gum arabic.

Sympathetic Ink, a liquor with which a person may write, without the letters appearing, till some means betaken to render them legible:

Of this kind are the glutinous juices of plants, or any other thick and viscous fluids, provided they have no remarkable colours themselves; for being written on white paper, nothing will appear, till some fine powder of any coloured earth is thrown over the paper, whereby the letters become legible: the reason of this is evident, as the powder sticks only to the letters formed by the invisible but viscous liquor.

Another sort of sympathetical inks are made of infusions, the matter of which easily burns to a charcoal: thus if a scruple of sal ammoniac be dissolved in two ounces of fair water, letters written therewith will be invisible till held before the fire; for the sal ammoniac being burnt to a charcoal, by a heat not strong enough to scorched the paper, the letters are thereby rendered visible.

Another sort of sympathetical ink is made of a solution of leaden vinegar, and a lixivium of lime and opomint; for if a letter be written with the former, nothing will appear: but to conceal the affair still more, some different subject may be written above it, with a black ink made of burnt cork and gum-water; then, if a piece of cotton, wetted with the said lixivium, be rubbed over the paper, the sentence that was visible will disappear, and the invisible one before written with the solution of lead will be seen in its place very black and strong.

INN, a place appointed for the entertainment and relief of travellers.

INNS of Court, are colleges in London, for the study of the laws of England, with all conveniences for the lodging and entertainment of the professors and students.

The four principal inns of court are the Inner temple, Middle-temple, Lincoln's inn, and Gray's inn; the other inns are the two serjeant's inns; and the others, which are less considerable, are Clifford's inn, Symond's inn, Clement's inn, Lion's inn, Furnival's inn, Staple's inn, Thavie's inn, Barnard's inn, and New-inn. These are mostly taken up by attorneys, solicitors, &c. but they belong to the inns of court, who send yearly some of their barristers to read to them.

INN, in geography, a large river which rises in a mountain of the Alps, in the country of the Grisons, runs north-east through Tyrol and Bavaria, and discharges itself into the Danube.

INNATE ideas, those supposed to be stamped on the mind from the first moment of its existence, and which it constantly brings into the world with it: a doctrine, which Mr. Locke has abundantly refuted.

INNERKEITHING, a port town of Scotland, in the county of Forth, ten miles north-west of Edinburgh.

INNISKILLING, a strong town of Ireland, in the province of Ulster, and county of Fermanagh: W. long. 7° 50', and N. lat. 54° 20'.

INNOCENTS day, a festival of the Chriftian church, observed on December 28, in memory of the massacre of the innocent children by the command of Herod king of Judea; who being alarmed at hearing that an infant was born king of the Jews, and imagining that his own kingdom was in danger, sent orders to have all the children slain that were in Bethlehem and the adjacent country.

The Greek church in their calendar, and the Abyssinians of Ethiopia in their offices, commemorate fourteen thousand infants on this occasion.
INQUISITION, in the church of Rome, a tribunal in several Roman Catholic countries, erected by the popes for the examination and punishment of heretics.

This court was founded in the twelfth century by father Dominic and his followers, who were sent by pope Innocent III. with orders to excite the Catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called inquisitors; and this gave birth to the formidable tribunal of the inquisition, which was received in all Italy, and the dominions of Spain, except the kingdoms of Naples and the Low Countries.

This diabolical tribunal takes cognizance of heresy, Judaism, Mahometanism, Sodomy, and polygamy; and the people stand in so much fear of it, that parents deliver up their children, husbands their wives, and masters their servants, to its officers, without daring in the least to murmur. The prisoners are kept for a long time, till they themselves turn their own accusers, and declare the cause of their imprisonment; for they are neither told their crime, nor confronted with witnesses. As soon as they are imprisoned, their friends go into mourning, and speak of them as dead, not daring to solicit their pardon, lest they should be brought in as accomplices. When there is no shadow of proof against the pretended criminal, he is discharged, after suffering the most cruel tortures, a tedious and dreadful imprisonment, and the loss of the greatest part of his effects. The sentence against the prisoners is pronounced publicly, and with extraordinary solemnity. In Portugal they erect a theatre capable of holding three thousand persons, in which they place a rich altar, and raise seats on each side in the form of an amphitheatre. There the prisoners are placed, and over against them is a high chair, whither they are called, one by one, to hear their doom, from one of the inquisitors.

These unhappy people know what they are to suffer, by the clothes they wear that day. Those who appear in their own cloaths, are discharged upon payment of a fine: those who have a fanto benito, or strict yellow coat without sleeves, charged with St. Andrew's cross, have their lives, but forfeit all their effects: those who have the semblance of flames, made of red serge, sewed upon their fanto benito, without any crosses, are pardoned, but threatened to be burnt if ever they relapse: but those who, besides these flames, have upon their fanto benito their own picture, surrounded with figures of devils, are condemned to expire in the flames. The inquisitors, who are ecclesiastics, do not pronounce the sentence of death; but form and read an act, in which they say, that the criminal being convicted of such a crime, by his own confession, is with much reluctance delivered to the secular power to be punished according to his demerits; and this writing they give to the seven judges, who attend at the right side of the altar, who immediately passes sentence. For the conclusion of this horrid scene, see Act of Faith.

INSCRIBED, in geometry. A figure is said to be inscribed in another, when all its angles touch the side or planes of the other figure.

INSCRIPTION, a title or writing carved, engraved, or affixed to any thing, to give a more distinct knowledge of it, or to transmit some important truth to posterity.

The inscriptions mentioned by Herodotus and Dio-dorus Siculus, sufficiently shew that this was the first method of conveying instructions to mankind, and transmitting the knowledge of history and sciences to posterity: thus the ancients engraved upon pillars both the principles of sciences, and the history of the world. Filifratius carved precepts of husbandry on pillars of stone; and the treaties of confederacy between the Romans and Jews, were engraved on plates of brass. Hence, antiquarians have been very curious in examining the inscriptions on ancient ruins, coins, medals, &c.

INSECTS, in zoology, a numerous class of animals. See Natural History.

INSERTION, in anatomy, the close conjunction of the vessels, tendons, fibres, and membranes of the body, with some other parts.

INSIPID, an appellation given to things without taste.

INSOLATION, in chemistry, the suffering matters to stand and digest in the heat of the sun, instead of that of a furnace.

INSOLVENT, a term applied to persons unable to pay their debts.

INSPIRATION, among divines, implies the conveying of certain extraordinary and supernatural notices or notions into the soul.

INSPISSATING, in pharmacy, an operation whereby a liquor is brought to a thicker consistence, by evaporating the thicker parts.

INSPRUCK, a city of Germany, in the circle of Austria, capital of the county of Tyrol, situated on the river Inn, in E. long. 11° 26', N. lat. 47° 12'.

INSTALLMENT, the initiating or establishing a person in some dignity.

INSTANT, such a part of duration wherein we perceive no succession; or it is that which takes up the time only of one idea in our minds.

INSTAURATION, the re-establishment or reformation of a religion, a church, or the like, to its former state.

INSTEP, in the manage, is that part of a horse's hind leg which reaches from the ham to the pattern joint.

INSTINCT, an appellation given to the sagacity and natural inclinations of brutes, which supplies the place of reason in mankind.
INSTITUTES, in literary history, a book containing the elements of the Roman law, and constitutes the last part of the civil-law.

The Institutes are divided into four books, and contain an abridgment of the whole body of the civil law; being designed for the use of students.

INSTITUTE, in Scots law. When by disposition, or deed of entail, a number of persons are called to the succeffion of an estate one after another, the person first named is called the institute, and the others sub-institutes. See Law, tit. 27.

INSTITUTION, in general, signifies the establishing or founding something.

In the canon and common law, it signifies the repairing a clerk with the spiritualities of a rectory, &c. which is done by the bishop, who uses the formula, "I institute you rector of such a church, with cure of souls, and receive your care and mine."

INSURANCE, in law and commerce, a contract or agreement whereby one or more persons, called insurers, &c. oblige themselves to answer for the loss of a ship, house, goods, &c. in consideration of a premium paid by the proprietors of the things insured.

Insurances are of various kinds, as on ships or parts of ships, on merchandise singly, and on ships and goods jointly: and these are again branched out to run either for a time stipulated, or to one single port, or out and home, with liberty to touch at the different places mentioned in the policy. Insurances may likewise be made on goods sent by land, or by horse, &c. on rivers; and this is frequently done, more especially on jewels, and other things of great value.

The principal offices for the insurance of ships and merchandise in London, are the Royal-exchange assurance, and the London assurance, both of which are established by act of parliament. These offices also insure houses and other buildings, goods, wares, and merchandise, from loss or damage by fire; and the former of them also affurn lives.

The Royal-exchange insurance, on a brick or stone building, insures any sum not exceeding 200l. at 5s. per annum, and any larger sum not exceeding 1000l. after the rate of 2s. 6d. per cent. per annum. Above 1000l. and not exceeding 2000l. at 3s. per cent. Above 2000l. and not exceeding 3000l. at 4s. per cent. On goods and merchandise, the property of the assured, within any brick or stone building, or on the goods and building together, this office insures any sum not exceeding 300l. for 7s 6d. per annum and larger sums after the rates above mentioned; but timber or plaster buildings, or goods or merchandise therein, pay 8s. per annum, for 200l. and after the rate of 4s. per cent. for any greater sum not exceeding 1000l., and 5s. per cent. for all insurances above 1000l. and not exceeding 2000l. On a timber or plaster-building with goods and merchandise together, any sum, not exceeding 300l. may be insured for 12s. per annum. and larger sums at the above rates. The goods belonging to hazardous trades, as distillers, chemists, apothecaries, colour-men, tallow-chandlers, oilmen, innholders, &c. deposited in brick houses, pay 8s. per annum, for insuring 200l. and after the rate of 4s. per cent. for any greater sum not exceeding 1000l.; and above 1000l. and not exceeding 2000l. 5s. per cent. but when the houses and goods are put together, the price of insurance is 4s. per cent. per annum, without any other charge except the policies.

The Friendly Society insurance, has some very extraordinary regulations; the principal of which is, that every one of the assured becomes a member of the society; and when any loss happens, contributes in proportion to the sum he has insured, to make good the damage; on which account he pays only 1s. 4d. per cent. per annum, premium, and 6s. 8d. per cent, as a caution; but what is unexpended of the 6s. 8d. is returned to the party insured at the end of seven years.

We have also insurances for lives, in virtue of which, when the person insured dies, a sum of money becomes payable to the person on whose behalf the policy of insurance was granted. The principal insurance-office of this kind, is that of the Amicable Society for a perpetual assurance, kept in Serjeant's inn, Fleet-street, London.

In this office, after paying the charges of the policy, and 10s. entrance-money, each perfon pays 51. per annum, by quarterly payments; and from these payments the dividends, which usually amount to 100l. and upwards, are to arise. All persons admitted are to be between the ages of twelve and forty five, and in a good state of health. Any person is allowed to have two or three insurances or numbers on the same life, whereby such person will be intitled to a claim on each number for a part of the sum insured; and every claimant is empowered to put in a new life, in the room of one deceased, within twelve calendar months next after the end of the current year. By becoming members of this society, clergymen, physicians, lawyers, tradesmen, and all whose income ceases at the time of their death, may, in all probability, leave to their families a claim of not less than 100l. for every 51. actually paid in.

INTAGLIOUS, precious stones on which are engraved the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetick, a whole number.

INTERTCALARY, an appellation given to the odd day inserted in leap year; which was so called from calix, calare, to proclaim, it being proclaimed by the priests with a loud voice.
INTERCOLUMNNIATION, in architecture, denotes the space between two columns, which is always to be proportioned to the height and bulk of the columns.

INTERCOSTAL, in anatomy, an appellation given to such muscles, nerves, arteries and veins as lie between the ribs. See Anatomy, Part II.

INTERDICT, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c.

INTERDICTION, in Scots law, a legal restraint laid upon weak or profuse persons from signing any deed to their own prejudice, without the consent of curators or interdictors. See Scots Law, tit. 7.

INTEREST, is the premium or money paid for the loan or use of money; and is distinguished into two kinds, simple and compound.

Simple interest is that which is paid for the principal, or sum lent, at a certain rate or allowance made by law, or agreement of parties, whereby so much as 5l. or 6l. or any other sum, is paid for 100l. lent out for one year; and more or less proportionally for greater or lesser sums, and for more or less time. For example, if it is 5l. to 100l. for one year, it is 2l. 10s. for half a year, and 10l. for two years; also 10l. for one year of 200l. and 5l. for half a year; and so on, for other sums and times. Thus, as the law, or agreement of parties, fixes a certain ratio, or, as we call it, rate of interest, which is so much on the 100l. for one year, being plainly the part of the interest of 100l. so if this is 5l. that is .05l. if this is 6l. that is .06l. and if this is 5l. 10s. or 5.5l. that is .055l. Wherefore, if we understand the rate of interest to be the interest of 1l. for one year, the more common questions about simple interest will relate to these four things, viz. any principal sum, its interest, the time in which it gives that interest, and the rate, or interest of 1l. for one year; according to which, that principal, interest, and time, are adjusted to one another.

From which we have four problems; in the rules whereof we suppose the principal and interest expressed in the denomination of pounds, by reducing what is less than 1l. to a decimal of 1l. and the time to be expressed in years, and decimal parts of one year.

Prob. I. Having any principal, sum, and time, with the rates of interest given, to find the interest of that sum for that time and rate.

Rule: Multiply the principal rate, and time, continually into one another; the product is the interest sought.

Example: The rate .05l. principal 85l. interest 20l. 3s. 9d. or 20.1875l. the time is 4.75 years, or 4 3 quarters. Thus, 4.75 = 20.1875, or 403.75/4.25

Demonstration: This rule is deduced from the former; thus, since $n = trp$, then dividing both sides by $tp$, it is $\frac{n}{tp} = r$.

Prob. II. Having the rate, principal and interest, to find the time.

Rule: Divide the interest by the product of the rate and principal, the quote is the time: thus, $t = \frac{n}{rp}$.

Example: The rate .05l. principal 85l. interest 20l. 3s. 9d. or 20.1875l. the time is 4.75 years, or 4 3 quarters. Thus, $4.75 = 20.1875$, or $20.1875/403.75 = 4.25$

Demonstration: This rule is deduced from the former; thus, since $n = trp$, then dividing both sides by $tp$, it is $\frac{n}{tp} = r$.

Prob. III. Having the principal, interest, and time, to find the rate.

Rule: Divide the interest by the product of principal and time, the quote is the rate: thus, $r = \frac{n}{tp}$.

Example: $n = 20.1875l$, $t = 4.75$ years, $p = 85l$. then is $r = \frac{20.1875}{403.75} = 4.75 \times 0.05 = 0.2375$

Demonstration: Since $n = trp$, divide both by $tp$; it is $\frac{n}{tp} = r$.

Prob. IV. Having the rate, time and interest, to find the principal.

Rule: Divide the interest by the product of rate and time, the quote is the principal; thus, $p = \frac{n}{rt}$.

Example: $n = 20.1875l$, $t = 4.75$ years, $r = .05$. then is $p = 85l = \frac{20.1875}{4.75 \times 0.05} = 403.75$

Demonstration: Since $n = trp$, divide both sides by $tr$, the quote is $\frac{n}{tr} = p$.

Scholium: If the interest of any sum for any time is added to the principal, this total sum is called the amount, (viz. of the principal and its interest for that time.) And then from these four things, viz. the amount, which we call $a$, the principal, the time, and
and rate, arise four problems; for having any three of these, the fourth may always be found. Thus,

Prob. V. Having the principal, time, and rate, to find the amount.

Rule: Find the interest by prob. I. and add it to the principal; the sum is the amount.

Thus, by prob. I. the interest is ptr; therefore the amount is a = rtr + p. The reason is evident.

Note: Because ptr = rtXp, and p = rXp; therefore r^2 + p = r + 1Xp. And so the rule may be expressed thus: To the product of the rate and time add unity, and multiply the sum by the principal, the product is the amount.

Example: What is the amount of 2461. principal in 2 years and 2.5 years, the rate of interest being 0.05? Answer 2461 + 30.751 = 2761.152. For the interest is 246X.05X2.5 = 30.751. Or thus; 0.05X2.5 = 1251, to which add 1, it is 1+1.251 which multiplied by 276, produces 276.751.

Prob. VI. Given the principal, amount, and time, to find the rate.

Rule: Take the difference betwixt the principal and amount, and divide by the product of the time and principal, the quote is the rate: thus, r = \frac{a-p}{tp}.

Example: Suppose \(a = 276.751\), \(p = 246\), \(t = 2.5\) years; then is \(r = 0.051 = 276.751 - 246 = 30.751\). 2.5X246 = 615

Demonstration: Since by prob. V. \(a = rtr + p\), take \(p\) from both sides, it is \(a - p = rtr\); then divide both by \(tp\), it is \(\frac{a-p}{tp} = r\).

Prob. VII. Given the amount, principal, and rate, to find the time.

Rule: Take the difference of the amount and principal, and divide by the product of the principal and rate, the quote is the time: thus \(t = \frac{a-p}{rp}\).

Example: Suppose \(a = 276.751\), \(p = 246\), \(r = 0.05\); then \(t = 2.5\) years = \(276.751 - \frac{246}{30.751} = 246\). 246X.05 = 12.3

Demonstration: In the last problem, \(a - p\) was equal to \(trp\); and dividing both by \(rp\), it is \(\frac{a-p}{rp} = t\).

Prob. VIII. Given the amount, rate, and time, to find the principal.

Rule: Add 1 to the product of the rate and time, and by that sum divide the amount, the quote is the principal: thus, \(p = \frac{a}{rt+1}\).

Example: \(a = 276.751\), \(r = 0.05\), \(t = 2.5\) years; then \(p = 246 = \frac{276.751}{25X0.05 + 1} = 276.751\)

Demonstration: By prob. V. it is \(a = rt+1 \times p\); therefore dividing both sides by \(rt+1\), it is \(\frac{a}{rt+1} = p\).

Compound Interest, is that which is paid for any principal sum, and the simple interest due upon it for any time, accumulated into one principal sum. Example: if 1001. is lent out for one year at 61. and if at the end of that year the 61. due of interest be added to the principal, and the sum 1061. be considered as a new principal bearing interest for the next year (or whatever less time it remains unpaid) this is called compound interest, because there is interest upon interest, which may go on by adding this second year's interest of 61. to the principal 1061. and making the whole a principal for the next year.

Now, although it be not lawful to let out money at compound interest, yet in purchasing of annuities or pensions, &c. and taking leaves in reversion, it is very usual to allow compound interest to the purchaser for his ready money; and therefore, it is very necessary to understand it.

Let therefore, as before, \(p\) = the principal put to interest; \(t\) = the time of its continuance; \(a\) = the amount of the principal and interest; \(R\) = the amount of 11. and its interest for one year, at any given rate, which may be thus found.

Thus, \(R\) = amount of 11. for 1 year, at any rate. \(R^2\) = amount of 11. for 2 years. \(R^3\) = amount of 11. for 3 years. \(R^4\) = amount of 11. for 4 years. \(R^5\) = amount of 11. for 5 years.

Here \(t = 5\). For \(R = 11\) : \(R = 11\) :: 1 : 1.06 = the amount of 11. at 6 per cent.

Example: Suppose \(a = 276.751\), \(r = 0.05\), \(t = 2.5\) years; then is \(a = 276.751\) as above.

Theorem I. \(R^t/a = a\), as above.

From hence the two following theorems are easily deduced.

Theorem II. \(\frac{a}{R^t} = \frac{1}{R}\).

Theorem III. \(\frac{a}{p} = R^t\).

By these three theorems, all questions about compound interest may be truly resolved by the pen only, \(viz\). without tables: though not so readily as by the help of tables calculated on purpose.

Example
Example I. What will 2561. 10s. amount to in 7 years, at 5 per cent. per annum, compound interest? Here is given \( p = 256.5 \), \( t = 7 \), and \( R = 1.05 \), which being involved until its index = 7 (viz. 7) will become \( R^7 = 1.40710 \). Then \( 1.40710 \times 256.5 \times 360.92115 = a = 360.18 \) s. 5 d. which is the answer required.

Example II. What principal or sum of money must be put out to raise a flock of 3601. 18s. 5d. in seven years, at 5 per cent. per annum, compound interest?

Here is given \( a = 360.92115 \), \( R = 5.07 \) and \( t = 7 \) to find \( p \) by theorem II. Thus \( R^7 = 1.40710 \times 360.92115 = a \). That is, \( p = 2561.108 \), which is the sum or principal required.

Example III. In what time will 2561. 10s. raise a flock of (or amount to) 3601. 18s. 5d. allowing 5 per cent. per annum, compound interest?

Here is given \( p = 256.5 \), \( a = 360.92115 \), \( R = 1.05 \).

To find \( t \) by theorem III. \( R^7 = \frac{a}{p} = 360.92115 \)

1.40710. which being continually divided by \( R = 1.05 \) until nothing remain, the number of the divisions will be 7 = \( t \).

Thus 1.05 \( 1.40710 \times 1.3400, \) and 1.05 \( 1.3400 \)

1.2762, and 1.05 \( 1.2762 \) 1.2155, and so on until it becomes 1.05 \( 1.05 \) 1.05 (1. which will be at the seventh division.

Therefore it will be \( t = 7 \), the number of years required by the question.

INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

See GRAMMAR.

INTERIM, a name given to a formulary, or kind of constitution, inserted into the writings of some ancient authors.

INTERROGATION, or Point of Interrogation, in grammar, a character of this form (?) serving to denote a question.

INTERVAL, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

INTERMENT, See Burial.

INTERROGA TION, or Point of Interrogation, in grammar, a character of this form (?) serving to denote a question.

INTERVAL, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

INTERMENT. See Burial.

INTERROGATION, or Point of Interrogation, in grammar, a character of this form (?) serving to denote a question.

INTERVAL, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

INTERMENT, See Burial.

INTERROGA TION, or Point of Interrogation, in grammar, a character of this form (?) serving to denote a question.

INTERROGA TION, or Point of Interrogation, in grammar, a character of this form (?) serving to denote a question.

INTERVAL, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

INTERMENT, See Burial.
JOANNA, one of the islands of Comoro, situated between the north-west part of Madagascar and Zanguebar, in Africa: E. long. 45°, S. lat. 12°.

INVERSE, is applied to a manner of working the rule of three. See ARITHMETICK, p. 383.

INVERURY, a parliament-town of Scotland, in the county of Aberdeen, situated on the river Don, ten miles west of Aberdeen.

INVESTIGATION, properly denotes the searching or finding anything out by the tracts or prints of the feet; whence mathematicians, schoolmen, and grammarians, come to use the term in their respective researches.

INVESTITURE, in Scots law, the writs which constitute a proper feudal right. See LAW, tit. 10.

INULA, in botany, a genus of the syngenesia polygami superflua class. The receptacle is naked; the pappus is simple; and the anther terminate at the base in two bristles. There are 22 species, of them natives of Britain, viz. the heliunium, or elecampane; the dysenterica, or middle flea-bane; the pulicaria, or small flea-bane; and the eritimoides, or golden simpleire. The root of the elecampane is said to excite urine, and loosen the belly.

INVOCATION, in theology, the act of adoring God, and especially of addressing him in prayer for his assistance and protection.

INVOICE, an account in writing of the particulars of merchandise, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country. See BOOK-KEEPING, p. 618.

INVOLUCRUM, among botanists. See BOTANY, p. 637.

INVOLUTION, in algebra. See ALGEBRA, p. 84.

JOACHIMITES, in church-history, the disciples of Joachim a cistercian monk, who was an abbot of Flora in Calabria, and a great pretender to inspiration.

The Joachimites were particularly fond of certain ternaries: the Father, they said, operated from the beginning till the coming of the Son; the Son, from that time to theirs, which was the year 1260; and from that time the Holy Spirit was to operate in his turn. They also divided everything relating to mankind, to doctrine, and the manner of living, into three classes, according to the three persons in the Trinity.

JOANNA, one of the islands of Comoro, situated between the north-west part of Madagascar and Zanguebar, in Africa: E. long. 45°, S. lat. 12°.

JOB, or Book of Job, a canonical book of the Old Testament, containing a narrative of a series of misfortunes which happened to a man whose name was Job, as a trial of his virtue and patience; together with the conferences he had with his cruel friends, on the subject of his misfortunes, and the manner in which he was restored to safety and happiness. This book is filled with those noble, bold, and figurative expressions, which constitute the very soul of poetry.

Many of the Jewish rabbins pretend that this relation is altogether a fiction: others think it a simple narrative of a matter of fact, just as it happened: while a third sort of critics acknowledge, that the groundwork of the story is true, but that it is written in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining.

The time is not set down in which Job lived. Some have thought that he was much anterior than Moses, because the law is never cited by Job or his friends, and because it is related that Job himself offered sacrifices. Some imagine that this book was not by himself; others say, that Job wrote it originally in Syriac or Arabic, and that Moses translated it into Hebrew: but the rabbins generally pronounce Moses to be the author of it, and many Christian writers are of the same opinion.

JOBBER, in law, a person that buys and sells cattle for others. Hence stock jobbers are persons who buy and sell flocks for other persons.

IOGUIS, among the East-Indians, a kind of hermits, who generally stand under trees, or near their pagods. Some of them go stark naked, holding their arms across over their heads, and continue in that posture all their lives: others lie on the ground, with one leg higher than the other, and their arms raised above their head; and these wretched penitents insensibly lose the use of their arms and legs: some confine themselves in cages, set on the top of a thick flake, fixed in the ground; and these cages are so small, that they put the penitent to prodigious torture: some holding a flabe in one hand, and a kind of shield in the other, go up a kind of crane, where hucking themselves to an iron, which runs a considerable way into their backs, they spring forward into the air, flourishing their fabrics, and launching out into extravagant praisings of their idols: and others plunge into the Ganges, in hopes of being devoured by a crocodile, fancying that by this means they shall obtain the happiness of the next life.

These miserable wretches are considered by the Indians as perfect models of piety and holiness: they are followed by perfons of both sexes, who make a vow of devoting themselves to their service, and are wholly employed in soothing their voluntary sufferings by offering them alms and refreshments. They call the pious to their devotions by ringing a little bell; and when they hold their spiritual conversations, they fit close in a ring, and set up a banner, made of several pieces of stuff, fastened at the end of a stick.

JOHN, or Gospel of St. John, a canonical book of the New Testament, containing a recital of the life, actions, doctrine, and death of our Saviour Jesus Christ, written by St. John the apostle and evangelist.

St. John wrote his Gospel at Ephesus, after his return from the isle of Patmos, at the desire of the Christians of Asia. St. Jerome says, he would not undertake it, but on condition they should appoint a public fast, to implore the assistance of God; and that the fast being ended, St. John, filled with the Holy Ghost, broke out into these words, "In the beginning was the word, &c. The ancients assign two reasons for this undertaking: the first is, because, in the other three gospels, there was wanting the history of the beginning of Jesus Christ's preaching, till the imprisonment of John the Baptist; which, therefore, he applied himself particularly to relate. The second reason was, in order to remove the errors of the Cen- thians, Ebionites, and other sects.
St. John’s Day, the name of two Christian festivals, one observed on June 24, kept in commemoration of the wonderful circumstances attending the birth of St. John the Baptist; and the other on Dec. 27, in honour of St. John the Evangelist.

St. John’s Wort. See Hypericum.

St. John’s, in geography, one of the Philippine islands, situated in 126° E. lon. and 7° N. lat.

St. John’s, is also an island in the bay of St. Lawrence, situated north of New Scotland: W. lon. 65°, N. lat. 49°.

Joinery, the art of working in wood, or of fitting various pieces of timber together.

It is called by the French menuiserie, g. d. small work, to distinguish it from carpentry, which is employed about large and less curious works.

Joint, in general, denotes the juncture of two or more things.

The joints of the human body are called by anatomists articulations. See Anatomy, p. 148.

Jointure, in law, generally signifies a settlement of lands and tenements, made on a woman in consideration of marriage.

Joinville, a town of Champaign, in France, situated on the river Marne: E. lon. 5° 15’, and N. lat. 48° 27’.

Joists, or joists, in architecture, those pieces of timber framed into the girders and sumbers, on which the boards of the floor are laid.

Jonah, or Prophecy of Jonah, a canonical book of the Old Testament; in which it is related, that Jonah was ordered to go and prophecy the destruction of the Ninevites; but that disobediently attempting a voyage another way, he was discovered by the rising of a sudden tempest, and cast into the sea; where he was swallowed up by a whale, which, having lodged him three days and three nights in his belly, disgorged him upon the shore; whereupon being sensible of his peril danger and surprising deliverance, he betook himself to the journey and embassy to which he was appointed; and arriving at Nineveh, the metropolis of Assyria, he, according to his commission, boldly laid open to the inhabitants their sins and miscarriages, and proclaimed their sudden overthrow; upon which the whole city, by prayer and fasting, and a speedy repentance, happily averted the divine vengeance, and escaped the threatened ruin.

Ionia, anciently was a province of the Lesser Asia, or Natolia, bounded by Etolia on the north, Lydia on the east, Caria on the south, and the Archipelago on the west.

Ionic order. See Architecture, p. 352.

Ionic dialect, in grammar, a manner of speaking peculiar to the people of Ionia.

Ionic sect was the first of the ancient sects of philosophers; the others were the Italian and Eleatic. The founder of this sect was Thales, who, being a native of Miletus in Ionia, occasioned his followers to assume the appellation of Ionics; Thales was succeeded by Anaximander, and he by Anaximenes, both of Miletus; Anaxagoras Clazomenus succeeded them, and

Vol. II. Numb. 62. 2

removed his school from Asia to Athens, where Socrates was his scholar. It was the distinguishing tenet of this sect, that water was the principle of all natural things.

Jonk, or Jonque, in naval affairs, is a kind of small ship, very common in the East Indies: these vessels are about the bigness of our fly-boats; and differ in the form of their building, according to the different methods of naval architecture used by the nations to which they belong. Their sails are frequently made of mats, and their anchors are made of wood.

Joshua, a canonical book of the Old Testament, containing a history of the wars and transactions of the person whose name it bears. This book may be divided into three parts; the first of which is a history of the conquest of the land of Canaan; the second, which begins at the twelfth chapter, is a description of that country, and the division of it among the tribes; and the third, comprised in the two last chapters, contains the renewal of the covenant he caused the Israelites to make, and the death of their victorious leader and governor. The whole comprehends a term of seventeen, or, according to others, of twenty-seven years.

Journal, or day-book. See Book-keeping, p. 583.

Journal is also a name common for weekly essays, news-papers, &c. as the Grey’s Inn Journal, the Westminster Journal, the Edinburgh Weekly Journal, &c.

Journeyman, properly one who works by the day only; but it is now used for any one who works under a master, either by the day, the year, or the piece.

Ipecacuanha, in the materia medica, a West-indian root, of which there are two kinds, distinguished by their colour, and brought from different places, but both possessing the same virtues, though in a different degree. The one is grey, and brought from Peru; the other is brown, and is brought from the Brazils, and these are indifferently sent into Europe under the general name of ipecacuana.

These two sorts have been by some supposed to be the roots of two different plants; but this is a mistake; the only difference is, that one grows in a different place, and in a richer and moister soil, and is better supplied with juices than the other.

Ipecacuana is an excellent, mild, and safe emetic; it is also a noble refrigerant; and, given in doses too small to vomit, is the greatest of all remedies for a dysentery. Small doses of ipecacuana are an excellent remedy in diarrhoea of a more simple kind; and in the flor albus we hardly know a better medicine.

Ipecacuana is an excellent, mild, and safe emetic; it is also a noble refrigerant; and, given in doses too small to vomit, is the greatest of all remedies for a dysentery. Small doses of ipecacuana are an excellent remedy in diarrhoea of a more simple kind; and in the flor albus we hardly know a better medicine.

Ipomoea, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped; the stylum is globular, and the capsule has three cells. There are eighteen species, none of them natives of Britain.

Ipswich, a borough and port town of Suffolk, situated on the river Orwel, twenty-four miles south-east of Bury.

Ireland, two members to parliament.
IRELAND, an island of the Atlantic ocean, subject to Great Britain, situated between 5° an 10° W. long. and between 51° and 56° N. lat. being bounded by the Northern ocean on the north, by St. George's channel, which divides it from Great Britain, on the east, and by the Atlantic and Western ocean on the south and west. This country is two hundred and fifty miles long, and one hundred and fifty broad; distant from Holyhead in north Wales fifty miles, and from Galloway in Scotland fifteen miles. It is divided into four large provinces, viz. Ulster on the north, Leinster on the east, Munster on the south, and Connaught on the west.

IRIS, in anatomy. See Anatomy, p. 289.

IRIS, the flower-de-luce, in botany, a genus of the triandria monogynia class. The corolla consists of six divisions, alternately reflected: the stigmata have the appearance of petals. There are twenty-two species, only two of which are natives of Britain, viz. the pseudacorus, or yellow flower-de-luce; and the felicitidifima, or flinking gladdon. The root is cathartic, and recommended in dropsies.

IRON. See Chemistry, p. 82.

IRON-sick, in the sea-language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

IRON-wort., in botany. See Sideritis.

IRON-y, in rhetoric, is when a person speaks contrary to his thoughts, in order to add force to his discourse; whence Quintilian calls it diversiloquium.

IROQUOIS, the name of five nations in North America, in alliance with the British colonies. They are bounded by Canada on the north, by the British plantations of New-York and Pennsylvania on the east and south, and by the lake Ontario on the west.

IRRADIATION, the act of emitting subtile effluvia, like the rays of the sun, every way.

IRTIS, a great river, which runs from north to south through Russia, falls into the river Oby, and makes part of the boundary between Asia and Europe.

IRWIN, a port-town of Scotland, in the bailiwic of Strathclyde, situated at the mouth of the river Irwin, on the frith of Clyde: W. long. 4° 39', N. lat. 55° 25'.

ISABELLA, a fortress of the Austrian Netherlands, situated on the west side of the river Scheld, opposite to Antwerp: in E. long. 4° 30', N. lat. 51° 15'.

ISAIAH, or Prophecy of ISAIAH, a canonical book of the Old Testament. Ifaiah is the first of the four greater prophets, the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood, his father Amos being brother to Azariah king of Judah. The style of this prophet is noble, sublime and didactic. Grocius calls him the Demosthenes of the Hebrews. He had the advantage, above the other prophets, of improving his dictum by conversing with men of the greatest parts and eloquence; and this added a sublimity, force, and majesty to what he said. He impartially reprobated the vices of the age in which he lived, and openly displayed the judgments of God that were hanging over the Jewish nation; at the same time denouncing vengeance on the Assyrians, Egyptians, Ethiopians, Moabites, Edomites, Syrians, and Arabians, who were instrumental in inflicting those judgments.

ISATIS, in botany, a genus of the tetradynamia siliquosa class. The pod is lanceolated, has two valves, and contains but one seed. There are four species, only one of which, viza the tinctoria, or woad, is a native of Britain. It is used by the dyers. See Botany, p. 634.

ISCHIUM, in anatomy. See Anatomy, p. 185.

ISCHURY, in medicine, a disease consisting in an entire supposition of urine. See Medicine.

ISIA, feasts and sacrifices anciently solemnized in honour of the goddes of Isis.

ISIN, in bots. See Sideritis.

ISII, in anatomy. See Anatomy, p. 172.

ISCHYUM, in anatomy. See Anatomy, p. 172.

ISCHYUM, in anatomy. See Anatomy, p. 172.

ISH, in Scots law, signifies expiry: thus we say, The ifh of a leafe. It signifies also to go out: thus we say, Free ifh and entry from and to any place.

ISIA, feasts and sacrifices anciently solemnized in honour of the goddes of Isis.

The Iife were full of abominable impurities, and for that reason those who were initiated were obliged to take an oath of secrecy: they held for nine days luculently; but were so abominable, that the senate abolished them at Rome, under the consulship of Piso and Gabinius.

ISINGLASS. See Ichtyscolia.

ISLAND, a tract of dry land, encompassed with water; in which sense it stands contradistinguished from continent, or terra firma.

ISLE DE DIEU, an island in the bay of Biscay, on the coast of France, situated fourteen miles west of the coast of Poitous.

ISLE of FRANCE, a province of that kingdom, in which the capital city of Paris is situated, being bounded by Picardy on the north, by Champain on the east, by Orleans on the south, and by Normandy on the west.

ISNARDIA, in botany, a genus of the tetradynamia siliquosa class. It has no corolla; the calix consists of four divisions; and the capulis has four cells. There is but one species, a native of France.
ISNY, a free imperial city of Germany, in the circle of Swabia, situated in E. long. 10°, N. lat. 47° 30'.
ISOCHRONAL, is applied to such vibrations of a pendulum, as are performed in the same space of time as all the vibrations or fwingings of the same pendulum are, whether the arches it describes be longer or shorter.
ISOCHRONAL LINE, that in which a heavy body is supposed to descend without any acceleration.
ISOLA, a port-town and bishop's see of the hither Calabria, fifteen miles south of St Severino.
ISOPERIMETRICAL FIGURES, in geometry, are such as have equal perimeters or circumferences.
ISOPYRUM, in botany, a genus of the polyandria class.
ISOLA, a province of the king of Sardinia's dominions. Italy is usually described, however, with Italy, as it is contiguous to Piedmont, and has the same sovereign, being a province of the king of Sardinia's dominions.
IONS, in botany, a seed of the caper plant.
Isthmus, in geography, a narrow neck of land, that joins two continents, or joins a peninsula to the land.
ISTHMUS, in geology, a narrow neck of land, that joins two continents, or joins a peninsula to the land.
ISTHMUS, a port-town and bishop's see of the hither Calabria, fifteen miles south of St Severino.
ISTRIA, a peninsula in the north part of the gulf of Venice, bounded by Carniola on the north; and on the south, east, and west, by the sea.
ITALIAN, the language spoken in Italy.
ITALY, a country situated between seven and nineteen degrees east long. and between thirty-eight and forty-seven degrees north latitude, bounded by Switzerland, and the Alps, which separate it from Germany, on the north; by the gulf of Venice, on the east; by the Mediterranean sea, on the south; and by the same sea and the Alps, which separate it from France, on the west; and if we include Savoy, which lies indeed on the west side of the Alps, between Italy and France, we must extend it a degree farther west: this is usually described, however, with Italy, as it is contiguous to Piedmont, and has the same sovereign, being a province of the king of Sardinia's dominions. Italy is said to resemble a boot, and in length from north to south 500 miles; the breadth is very unequal: in the north, which may be called the top of the boot, it is about 400 miles broad from east to west; in the calf of the leg, or middle, it is about 120 miles broad; and towards the south, about the instep, eighty miles broad; and comprehends the following countries or subdivisions. 1. In the north are the duchies of Savoy, Piedmont, and Montferrat; the territories of Genoa; the duchies of Milan, Mantua, Parma, Modena, and the territories of Venice. 2. In the middle of Italy, are the duchy of Tuscany, the pope's dominions, and the state of Lucca. 3. And in the south is the kingdom of Naples.
ITCH, a cutaneous disease, arising from a corruption of a ftrong lymphatic matter, sometimes attended with mild, sometimes with more obbligating and dangerous symptoms. See Medicine.
JUBILEE, a time of public and solemn festivity among the ancient Hebrews.

This was kept every fifteenth year: it began about autumnal equinox, and was proclaimed by the sound of trumpet throughout all the country. At this time all slaves were released, all debts annihilated, and all lands, houses, wives, and children, however alienated, were restored to their first owners. During this whole year all kind of agriculture was forbidden, and the poor had the benefit of the harvest, vintage, and other productions of the earth, in the same manner as in the sabbatic or seventh year. As this was designed to put the Israelites in mind of their Egyptian servitude, and to prevent their imposing the like upon their brethren, it was not observed by the Gentile profelytes.

The Chriftians, in imitation of the Jews, have likewise established jubilees, which began in the time of pope Boniface VIII. in the year 1300, and are now practised every twenty-five years; but these relate only to the pretended forgivenefs of sins, and the indulgences granted by the church of Rome; together with the privilege of performing a thousand frolics in masquerade.

JUCATAN, or Yucatan, a peninsula of Mexico, situated between 89° and 94° W. long. and between 16° and 21° N. lat.

JUDAISM, the religious doctrines and rites of the Jews. See Jews.

JUDE, or the general epistle of Jude, a canonical book of the New Testament, written against the heretics, who, by their disorderly lives and impious doctrines, corrupted the faith and good morals of the Chriftians. St. Jude draws them in lively colours, as men given up to their passions, full of vanity, concluding themselves by worldly wisdom, and not by the spirit of God. See Palestine.

JUDAISM, the religious doctrines and rites of the Jews. See Jews.

JUDENBURGH, a city of Stiria, in Germany: E. long. 15° 15', N. lat. 47° 22'.

JUDEA. See Palestine.

JUDEA, See Palestine.

JUDENBURGH, a city of Stiria, in Germany: E. long. 15°, N. lat. 47° 22'.

JUDGE, a chief magistrate of the law, appointed to hear caufes, to explain the laws, and to pass sentence.

Book of Judges, a canonical book of the Old Testament, so called from its relating the state of the Israelites under the administration of many illustrious perufons who were called judges, from their being both the civil and military governors of the people, and who were raised up by God upon special occasions, after the death of Josua, till the time of their making a king. In the time of this peculiar policy, there were several remarkable occurrences, which are recorded in this book. It acquaints us with the gross impiety of a new generation which sprang up after the death of Josua,
fl tua, and gives us a short view of the dispensations of heaven towards this people, sometimes relieving and delivering them, and at others severely chastising them by the hands of their enemies.

Judgment, among logicians, a faculty or rather act of the human soul, whereby it compares its ideas, and perceives their agreement or disagreement.

Judgment, in law, the sentence of the judges upon a suit, &c.

Judoigne, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Gheet, thirteen miles south-eacl of Louvain, and sixteen north of Namur.

Ives, or St. Ives, a borough and port-town of Cornwall, situated on the Irish channel: it sends two members to parliament: W. long. 6°, N. lat. 50° 18'.

Jugerum, in Roman antiquity, a square of 120 Roman feet; its proportion to the English acre being as 10000 to 16097.

Jugular, in anatomy, an appellation given to two veins of the neck, which arise from the subclavians.

See Anatomy, part IV.

IVica, or Yvica, the capital of an island of the same name, fifty miles east of Valencia in Spain: E. long. 1°, N. lat. 39°.

Juice, denotes the sap of vegetables, or the liquor of animals.

Juubes, in the materia medica, the name of a fruit of the pulp kind, produced on a tree which Linnaeus makes a species of rhamnus. See Rhamnus.

The juubes have been made a general ingredient in pulpy kind, produced on a tree which Linnaeus makes a species of rhamnus. See Rhamnus.

Jupiter, in astronomy. See Astronomy, p. 441.

Jura, or Vera, a strong city in Italy, in the province of Piedmont, situated on the river Doria, subject to the king of Sardinia: E. long. 45° 22'; N. lat. 45°. 36'.

Jurisprudence, the science of what is just or unjust, or the knowledge of laws, rights, customs, statutes, &c. necessary for the administration of justice.

Jury-mast, whatever is set up in room of a mast that has been lost in a storm or in an engagement, and to which a leaffer yard, ropes, and falls, are fixed.

Jus deliberandi, in Scots law, that right which an heir has, by law, of deliberating for a certain time whether he will represent his predececor. See Law, tit. 27.

Jus devolutum, in Scots law, the right of the church, of presenting a minister to a vacant parifli, in case the heir has, by law, of deliberating for a certain time whether he will represent his predecessor. See Law, tit. 27.

Jus de novo, in Scots law, the right which an heir has, by law, of deliberating for a certain time whether he will represent his predecessor. See Law, tit. 27.

Jus deliberaendi, in Scots law, that right which an heir has, by law, of deliberating for a certain time whether he will represent his predecessor. See Law, tit. 27.

Jus devolutum, in Scots law, the right of the church, of presenting a minister to a vacant parifli, in case the heir has, by law, of deliberating for a certain time whether he will represent his predecessor. See Law, tit. 27.

Jus mariti, in Scots law, the right the husband ac-

Jus relictus, in Scots law, the right the wife has in virtue of the marriage. See Law, tit. 6.
JUSTICIAR, in the old English laws, an officer instituted by William the Conqueror, as the chief officer of state, who principally determined in all cases civil and criminal. He was called in Latin Capitālis Jūsticiarius totius Angliae.—For Justiciar in Scotland, see Law, tit. 3. § 13.

JUSTICIARY, or Court of Justiciary, in Scotland. See Law, tit. 3. § 10.

JUTES, the ancient inhabitants of Jutland, in Denmark.

JUTLAND, a peninsula of Denmark, anciently called Jutland; the south being usually called Slefwic.

KAKENHAUSEN, a city of Livonia, subject to Russia. E. long. 26°, N. lat. 57°.

KALI, in botany. See Sal salis.

KAKOLIN, one of the substances whereof china-ware is made; being no other than a kind of talc reduced to powder, and made into a paste with water.

KAOLIN, one of the substances whereof china-ware is made; being no other than a kind of talc reduced to powder, and made into a paste with water. There are two species, both natives of India. The root of this plant is the galangal, which was formerly used in bitter infusions, but is now neglected in practice.

KALLO, a town of Upper Hungary, situated in a lake twenty miles south east of Tockay. E. long. 26°, N. lat. 57°.

KAMPFERIA, in botany, a genus of the monandria monogynia class. The corolla consists of five segments, three of them being large and open. There are two species, both natives of India. The root of this plant is the galangal, which was formerly used in bitter infusions, but is now neglected in practice.

KAKENHAUSEN, a city of Livonia, subject to Russia: E. long. 26°, N. lat. 57°.

KALI, in botany. See Sal salis.

KALOLIN, a town of Upper Hungary, situated in a lake twenty miles south east of Tockay.

KAOLIN, one of the substances whereof china-ware is made; being no other than a kind of talc reduced to powder, and made into a paste with water.

KAUSBEUREN, an imperial city of Germany, thirty-two miles south of Augsburg: E. long. 10° 45', N. lat. 47° 50'.

KEBLA, an appellation given by the Mahometans to that part of the world where the temple of Mecca is situated, towards which they are obliged to turn themselves when they pray.

KEE, brought up or down in a narrow river by means of the tide, the wind being contrary. To do this, they use to set their fore-course, or fore-top sail and mizzen, that so they may flatten her about; and if she happens to come too near the shore, they let fall a kedge-anchor, with a hawser fastened to it from the ship, in order to turn her head about; which work is called kedging.

KEE, the lowest piece of timber in a ship, running her whole length from the lower part of her stem to the lower part of her stern-post. Into it are all the lower futtocks fastened; and under part of it, a false keel is often used.

KEELSON, a principal timber in a ship, fayed withinside crofs all the floor timbers; and being adjusted to the keel with suitable scarf's, it serves to strengthen the bottom of the ship.

KEEPER of the great seal, is a lord by his office, is styled lord keeper of the great seal of Great-Britain, and is always one of the privy-council. All grants, charters and commissions of the king under the great seal, pass through the hands of the lord-keeper; for without that seal, many of those grants, &c. would be

Tedging, in the sea-language, is when a ship is

Vol. II. No. 62.

2
be of no force; the king being, in the interpretation of the law, a corporation, and therefore passes nothing but by the great seal, which is also said to be the public faith of the kingdom, being in the highest esteem and reputation.

Whenever there is a lord-keeper, he is invested with the same place, authority, preeminence, jurisdiction, or execution of laws, as the lord chancellor of Great-Britain is vested with.

The lord-keeper is constituted by the delivery of the great seal, &c.

Keeper of the privy seal, is also a lord by his office, through whose hands all grants, pardons, &c. pass before they come to the great seal, and even some things pass this officer's hands which do not pass the great seal at all. This officer is also one of the privy council, yet was anciently called clerk of the privy seal. His duty is to put the seal to no grant, &c. without a proper warrant; nor with warrant where it is against law, or inconvenient, but shall first acquaint the king therewith.

Keiserwaert, a strong town of Germany in the circle of Gelderland, and duchy of Berg, situated on the Rhine, twenty-five miles north of Cologne, E. lon. 6° 8', N. lat. 51° 20'.

Kelling, a borough-town of Cornwall, thirteen miles south of Launceston, which sends two members through whose hands all grants, pardons, &c. pass be-fore they come to the great seal, and even some things pass this officer's hands which do not pass the great seal at all. This officer is also one of the privy council, yet was anciently called clerk of the privy seal. His duty is to put the seal to no grant, &c. without a proper warrant; nor with warrant where it is against law, or inconvenient, but shall first acquaint the king therewith.

Kells, in the sea language, doubling in a rope or cable, when handed in and out, so that it does not run free in the block, then it is said to make kelps.

Kelp, a fixed salt, or particular species of pot-ash, procured by burning a species of falticosa. See Sali-cosa.

Kelsa, a town of Scotland, in the shire of Mers, or Roxburgh, situated on the north side the Tweed, twenty-miles south-west of Berwick.

Kempten, a city of Germany, in the circle of Swabia, situated on the river Iler: E. lon. 16° 7', N. lat. 47° 38'.

Kendal, a market-town of Westmoreland, twenty-two miles south-west of Appleby.

Kens, in the sea language, doublings in a rope or cable, when handed in and out, so that it does not run free in the block, then it is said to make kelps.

Kening to a Terce, in Scots law, the dividing or setting off that part of the husband's estate to his reliet which she is entited to lisen to after his death. See Terce.

Kensington, a pleasant village in the county of Middlesex, two miles west of London; where is a royal palace, with large and fine gardens.

Kent, a county bounded by the river Thames on the north, by the sea on the east, by Sussex and the Straits of Dover on the south, and by Surrey on the west.

Kerman, the capital of the province of Kerman, or Carmania, in Persia: E. lon. 56° 30', N. lat. 30°.

Kermes in botany. See Kermes mineral.

Kermes mineral. See Chemistry, p. 140.

Kerry, a county of Ireland, in the province of Munster, bounded by the river Shannon, which divides it from Clare, on the north; by Limeric and Cork, on the east; by another part of Cork, on the south; and by the Atlantic Ocean, on the west.

Kesel, a town of Upper Gueldeland, in the quarter of Roermonde, situated on the river Meuse: E. lon. 6°, N. lat. 51° 25'.

Kestrel, in ornithology. See Falco.

Ketmia, in botany. See Hisiscus.

Kettering, a market-town of Northamptonshire, ten miles north-east of Northampton.

Ketch, in naval architecture, a vessel with two masts. See Ship.

Kevel, in ship-building, a piece of plank said against the quickwork on the quarter-deck, in the shape of a semicircle; about which the running rigging is belaid.

Kexholme, the capital of the province of the same name in Finland, situated on the lake Ladoga, thirty miles north of Petersburg: E. lon. 30°, N. lat. 61° 30'.

Key, a well known instrument for opening and shutting the locks of doors, chests, bureos, and the like.

Key, in music, a certain fundamental note, or tone, to which the whole piece, be it in concerto, sonata, can- tata, &c. is accommodated, and with which it usually begins, but always ends.

Key-stone of an arch, or vault, that placed at the top or vertex of an arch, to bind the two sweeps together.

Kiam, a great river of China, which, taking its rise near the west frontier, crosses the whole kingdom eastward, and falls into the bay or gulph of Nanking, a little below that city.

Kiamsi, a province of China, bounded by that of Nanking on the north, and by that of Canton on the south.

Kidderminster, a market-town twelve miles north of Worcester.

Kidneys, in anatomy. See Anatomy, p. 268.

Kiggelaria, in botany, a genus of the dioecia chambera class. The calyx of both male and female consist of five segments, and the corolla of five petals: the antherae of the male are perforated at the apex:

The female has five styles; the capsule has five valves, one cell, and many seeds. There is but one species, a native of Ethiopia.

Kiddare, the capital of a county of the same name, in Ireland, twenty-seven miles south-west of Dublin.

Kilderkin, a liquid measure, containing two fifths.

Kildare, a province of Ireland, bounded by Queen's County, on the north; by the county of Wexford, on the east; by Waterford, on the south; and by the county of Tipperary, on the west. It is also the name of the capital of that county; and is situated in W. lon. 7° 15', N. lat. 52° 20'.

Kimbolton, a market-town of Huntingdonshire, nine miles south-west of Huntingdon.

King, in the general acceptance of the word, is a person who has a supreme authority, with the power of levying taxes, making laws, and enforcing an obedience to them: but in Britain, which is a limited monarchy,
monarchy, the power of the king is greatly restrained; which is so far from diminishing his honour, that it adds a glory to his crown; for while other kings are absolute monarchs over innumerable multitudes of slaves, the king of England has the distinguished glory of governing a free people, the leaf of whom is protected by the laws: he has great prerogatives, and a boundless power in doing good; and is at the same time only restrained from acting inconsistently with his own happiness, and that of his people. He has all the ensigns of royalty, and all the marks of sovereignty; but while he has the power of making treaties, of sending and receiving ambassadors, of conferring titles of honour, creating privy councilors, officers of state, and judges, and may raise men and arms both for sea and land, he cannot force his subjects to maintain them, or raise one tax by his sole authority: he has the privilege of coinage money, but he cannot force the meanest subject to part with his property; he can pardon a criminal; but he cannot put a subject to death, till he is condemned by his peers: he may at his pleasure call, continue, prorogue, and dissolve parliaments, and without his royal assent no bill in parliament can pass into a law; yet he can neither act contrary to law, nor make new laws by his sole authority; on the contrary, he may even be sued and call in his own courts.

At his coronation, he takes an oath to govern his people according to the statutes agreed on in parliament, to cause law and justice in mercy to be executed in all his judgments; to maintain, as much as in him lies, the laws of God, the true profession of the gospel, and the protestant reformed religion by law established. But though he may mitigate the rigour of the law, and forgive offenders, he cannot pardon murder, where an appeal is stayed of a lord chief justice and three other justices or judges, who are invested with a sovereign jurisdiction over all matters, whether of a criminal or public nature. All crimes against the public good, though they do not injure any particular person, are under the cognizance of this court; and no private subject can suffer any unlawful violence or injury against his person, liberty, or possessions, but a proper remedy is afforded him here; not only for satisfaction of damages sustained, but for the punishment of the offender: and wherever this court meets with an offence contrary to the first principles of justice, it may punish it. It frequently proceeds on indictments found before other courts, and removed by certiorari into this. Persons illegally committed to prison, though by the king and council, or either of the houses of parliament, may be bailed in it; and in some cases, even upon legal commitments. Writs of mandamus are issued by this court, for the restoring of officers in corporations, &c. unjustly turned out, and freemen wrongfully disfranchized.

The court of king's bench is now divided into a crown-side and plea-side, the one determining criminal, and the other civil causes: in the first it determines criminal matters of all kinds, where the king is plaintiff; such as treasons, felonies, murders, rapes, robberies, riots, breaches of the peace, and all other causes that are prosecuted by indictment, information, &c. On the plea-side, it determines all personal actions commenced by bill or writ; as actions of debt, upon the case, detinue, trover, ejectment, trespass, waif, &c. against any person in the custody of the marshal of the court, as every person sued here is supposed to be by law.

The officers of this court on the crown-side are the clerk and serjeant of the crown; and on the side of the pleas there are two chief clerks or prothonotaries, and their serjeant and deputy, the custos brevium, two clerks of the papers, the clerk of the declarations, the signer and sealer of bills, the clerk of the rules, and their seconde and deputy, the cuftos brevium; to which may be added the bailiffs, the marshal of the court, and the serjeant.

Books of Kings, two canonical books of the Old Testament, so called because they contain the history of the kings of Israel and Judah, from the beginning of the reign of Solomon, down to the Babylonish captivity, for the space of near six hundred years.

It is probable that these books were composed by Ezra, who extracted them out of the public records, which were kept of what passed in that nation.

King's county, a county of Ireland, in the province of Leinster, bounded by Westmeath on the north, by the county of Kildare on the east, by Queen's county and Tipperary on the south, and by the river Shannon, which separates it from Galway, on the west.

King's Evil. See Medicine.

King's Fisher. In ornithology. See Alcedo.

Kinghorn, a town of Scotland, on the coast of Fife, nine miles north of Edinburgh.
KINGSTON, a market-town of Surry, situated on the river Thames, twelve miles west of London.

KINGSTON, a port-town of Jamaica, situated on the north side of the bay of Port royal: W. long. 77°, N. lat. 17° 32'.

KINROSS, a town of Scotland, in the shire of Fife, situated on the lake of Loch-Leven, twenty miles north of Edinburgh.

KINSALE, a port-town of Ireland, in the county of Cork and province of Munster, situated on the river Bandon, fourteen miles south of the city of Cork: W. long. 8° 20', and N. lat. 51° 32'.

KIOF, or Kiof, the capital of the Ruffian Ukraine, on the frontiers of Poland: E. long. 30°, and N. lat. 51°.

KIRK, a Saxon term, signifying the same with church.

KIRK SESSIONS, an inferior church judiciary in Scotland, confiting of the ministers, elders, and deacons of a parish.

It regulates matters relating to public worship, catechizing, vibrations, &c. and judges in cases of fornication and lefser scandals.

KIRKALDY, a town of Fifeshire, in Scotland, ten miles north of Edinburgh.

KIRKHAM, a market town of Lancashire, sixteen miles south of Lancaster.

KIRKUDBRIGHT, a parliament-town of Scotland, which ranks with Dumfries, Annan, &c. situated on a bay of the Irish sea, sixty miles west of Carlisle: W. long. 4° 5', and N. lat. 54° 38'.

KIRKWALL, the capital of the Orkney-islands, and situated in that of Pomona, is a parliament-town, which classes with Dingwall, Tain, &c. W. long. 25°, and N. lat. 59° 45'.

KITCHEN-GARDEN, a piece of ground laid out for the cultivation of fruit, herbs, pulfe, and other vegetables used in the kitchen. See Gardening.

KITE. See FALCO.

KNARESBOROUGH, a borough-town in the north riding of Yorkshire, fifteen miles north of York. It sends two members to parliament.

KNAVE, in old law-books, an appellation given to a man-servant, or even to a male child.

KNAVESHIP, in Scots law, one of the names of the small-duties payable in thirlage to the miller’s servants, called fequeles. See Scotts Law, tit. 16.

KNAUTIA, in botany, a genus of the tetrandra monocynia class. The common calix is oblong, simple, and contains five flowers; the proper calix is simple, and above the fruit; the corollule is irregular; and the receptacle is naked. There are two species, none of them natives of Britain.

KNEE, in anatomy, the articulation of the thigh and leg-bones. See Anatomy, part I. &c.

Knee, in a ship, a crooked piece of timber, bent like a knee, used to bind the beams and futtocks together, by being bolted fast into them both. These are used about all the decks.

Carling-Knees, in a ship, those timbers which extend from the sides to the hatch-way, and bear up the deck on both sides.

KNIFE, a well-known instrument, made for cutting.

All sorts of knives are prohibited to be imported.

KNIGHT, among the Romans, a perfon of the second degree of nobility, following immediately that of the senators.

Part of the ceremony whereby this honour was conferred, was the giving of an horfe; for each had an horfe at the public charge, and received the flippend of a horfeman, to serve in the wars.

When the knights were taken in among the senators, they renounced the privilege of having an horfe kept for them at the charge of the public; then it became neceflary, in order to be a knight, that they should have a certain revenue, that their poverty might not disgrace the order; and when they failed of the prescribed revenue, they were expunged out of the list of knights, and thrust down among the Plebeians. Ten thoufand crowns is computed to have been the revenue required.

The knights at length grew fo very powerful, that they became a balance between the power of the senate and people: they neglected the exercises of war, and betook themselves principally to civil employments in Rome.

KNIGHT, in a modern sense, properly signifies a perfon, who, for his virtue and martial prowess, is by the king raised above the rank of gentlemen, into an higher clafs of dignity and honour.

Knighthood was formerly the first degree of honour in the army, and usually conferred with a great deal of ceremony on those who had distinguished themselves by some notable exploit in arms: the ceremonies at their creation have been various; the principal was a box on the ear, and a stroke with a sword on the shoulder; they put on him a shoulder-belt, and a gilt sword, spurs, and other military accoutrements; after which being armed as a knight, he was led to the church in great pomp. Camden describes the manner of making a knight-batchelor among us, which is the lowest, though the most ancient order of knighthood, to be thus: the person kneeling, was gently struck on the shoulder by the prince, and accosted in these words, “Rise, or be a knight, in the name of God.”

KNIGHT is also understood of a perfon admitted into an order, either purely military, or military and religious, instituted by some king or prince, with certain marks and tokens of honour and distinction, as the knights of the garter, knights of the thistle, knights of Malta, the knights of the Holy Ghost, &c.

KNIGHTS-ERRANT, a pretended order of chivalry, much talked of in old romances, being a kind of heroes that travelled the world in search of adventures, redressing wrongs, rescuing damsels, and taking all occasions of signalizing their prowess. This romantic bravery of the old knights was heretofore the chimera of the Spaniards.

KNIGHTS OF THE SHIRE, or KNIGHTS OF PARLIAMENT, in
the British polity, are knights or gentlemen of estate, who are elected, on the king's writ, by the freeholders of every county, to represent them in parliament.

The qualifications of a knight of the shire in England, is to possess £600 a year in a freehold estate; and in Scotland £400 a year. Scots valued rent, or 40 shillings of old extent. Their expenses during their sitting, were, by a statute of Hen. VIII. to be defrayed by the county; but this is now scarce ever required.

**Knights** in a ship, two thick short pieces of wood, commonly carved like a man's head, having four slide- ing in each, three for the halyards, and one for the top-ropes to run in; one of them fland fast bolted on the beams abaft the foremast, and is therefore called the fore-knight, and the other, standing abaft the main main, is called the main knight.

**Knowledge**, is defined, by Mr Locke, to be the perception of the connexion and agreement, or disagreement and repugnancy, of our ideas.

**Konigsburg**, a city of Poland, the capital of ducal Prussia, and of the king of Prussia's Polish dominions, situated on the river Pregel, near a bay of the Baltic sea, seventy miles north-east of Dantizck: E. long. 21°, and N. lat. 54° 40'.

**Koran, or Alcoran.** See Mahometanism.

**Kos**, in Jewish antiquity, a measure of capacity, containing about four cubic inches: this was the cup of blessing, out of which they drank when they gave thanks after solemn meals, like that of the pa'davera.

**Kur**, the ancient Cyrus, a river of Persia, which rises in the mountains of Georgia, and running south-east by Tellis, unite it streams with the river Arras (the ancient Arraxes) and falls into the Caspian sea, south of Baku.

**Kutschta**, among the Calmuc Tartars, the name of their high-priest, or sovereign pontiff; formerly only the deputy of the delai-lama, or high-priest of the Tartars, but at present independent on him.
and Canada, on the fourth; and by Hudson's bay, on the west; situated between 50° and 70° of W. long., and between 50° and 64° of N. lat.

LABRUS, in ichthyology, a genus of fishes belonging to the order of thoracici, the characters of which are these. The teeth are sharp, and the lips are simple and very thick; there are six bony rays in the membrane of the gills, and the opercula are falcate. The rays of the back fin are furnished with a thread-like lamentum behind; the breast fins are sharp-pointed; and the lateral line is straight. There are forty one species of labrus, distinguished by the shape of the tail, fins, colour, &c.

LABURNUM, in botany. See Cytisus.

LABYRINTH, in anatomy. See Anatomy, p. 297.

LACCA, or Lac, in natural history, improperly called gum-lac, a fort of wax of a red colour, collected in the East-Indies by certain insects, and deposited on flicks fastened for that purpose in the earth. It is brought ever, either adhering to the flicks, or in small transparent grains, or in semi-transparent flat cakes: the first is called flick lac, the second feed lac, and the third shell lac. On breaking a piece of flick lac, it appears composed of regular cells like the honey-comb, with small corporcles of a deep red colour lodged in them: these are the young insects, and to these the lac owes its tincture, for when freed from them its colour is very dilute. The shell and feed lacs, which do not exhibit any insects or cellular appearance upon breaking, are supposed to be artificial preparations of the other: the feed lac is said to be the flick lac bruised and robbed of its more soluble parts; and the shell to be the feed lac, melted and formed into cakes. The flick lac therefore is the genuine one, and ought alone to be employed for medicinal purposes. This concrete is of great esteem in Germany and other countries, for laxity and sponginess to the order of reptilia, that carry on this manufacture; but vail quantities of the finest laces have been imported from Flanders.

LAC, milk, among physicians, &c. See Milk.

LAPEPIUM, in botany. See Cytisus.

LACE, in commerce, a work composed of many threads of gold, silver or silk, interwoven the one with the othe", and worked upon a pillow with spindles, according to the pattern designed. The open work being formed with pins, which are placed and displaced as the spindles are moved.

The importation of gold and silver lace is prohibited.

Bone LACE, a lace made of fine linen thread or silk, much in the same manner as that of gold and silver. The pattern of the lace is fixed upon a large round pillow, and pins being stuck into the holes or openings in the pattern, the threads are interwoven by means of a number of bobbins made of bone or ivory, each of which contains a small quantity of fine thread, in such a manner as to make the lace exactly resemble the pattern. There are several towns in England, and particularly in Buckinghamshire, that carry on this manufacture; but vast quantities of the finest laces have been imported from Flanders.

LACEDEMON, the ancient name of Misithra. See Mysithra.

LACerta, the lizard, in zoology, a genus of amphibious animals belonging to the order of reptilia, the characters of which are these: The body is naked, with four feet, and a tail. There are 49 species, viz.

1. The crocodylus, or crocodile, has a compressed jagged tail, five toes on the fore-feet, and four on the hind-feet. This is the largest animal of the lizard kind. One that was dissected at Siam, an account of which was sent to the Royal Academy at Paris, was eighteen feet and a half long, of which the tail was no less than five feet and a half, and the head and neck above two and a half. He was four feet and nine inches in circumference where thickest.

The hinder legs, including the thigh and the paw, were two feet and two inches long; the paws, from the joint to the extremity of the longest claws, were above nine inches. They were divided into four toes; of which three were armed with large claws, the long-claw of which was an inch and a half, and seven lines and a half broad at the root. The fourth toe was without a nail, and of a conical figure; but was covered with a thick skin like shagreen leather. These toes were united with membranes like those of ducks, but much thicker.

The fore-legs had the same parts and conformation as the arms of a man; both within and without; but they were somewhat shorter than those behind. The hands had five fingers, the two last of which had no nails, and were of a conical figure, like the fourth toe on the hind paws. The head was long, and had a little riving at the top; but the reit was flat, and especially towards the extremity of the jaws. It was covered with a skin, which adhered firmly to the skull and to the jaws. The skull was rough and unequal in several places; and about the middle of the forehead there were two bony crests, about two inches high. They were not quite parallel, but separated from each other in proportion as they mounted upwards.

The eye was very small in proportion to the reft of the body, and was fo placed within its orbit, that the outward part, when shut, was only a little above an inch in length, and run parallel to the opening of the jaws.

The nose was placed in the middle of the upper jaw, near an inch from its extremity, and was perfectly round and flat, being two inches in diameter, of a black, soft, spongy substance, not unlike the nose of a dog. The nostrils were in the form of a Greek capital меча, and there were two caruncles which filled and closed them very exactly, and which opened as often as he breathed through the nose. The jaws seemed to shut one within another by means of several apophyses, which...
LAC (859)  LAC

which proceeded from above downwards, and from below upwards, there being cavities in the opposite jaw to receive them. They had twenty-seven dog-teeth in the upper jaw, and fifteen in the lower, with several void spaces between them. They were thick at the bottom, and sharp at the point; being of different sizes, except ten large hooked ones, six of which were in the lower jaw, and four in the upper. The mouth was fifteen inches in length, and eight and a half in breadth where broadest; and the distance of the two jaws, when opened as wide as they could be, was fifteen inches and a half. The skull, between the two crests, was proof against a musket ball, for it only rendered the part a little white that it struck against.

The colour of the body was of a dark brown on the upper part, and of a whitish citron below, with large spots of both colours on the sides. From the shoulders to the extremity of the tail he was covered with large scales of a square form, disposed like parallel girdles, and were fifty-two in number; but those near the tail were not so thick as the rest. In the middle of each girdle there were four protuberances, which became higher as they approached the end of the tail, and composed four rows, of which the two in the middle were lower than the remaining two, forming three channels, which grew deeper the nearer they came to the tail, and were confounded with each other about two feet from its extremity.

The skin was defended with a sort of armour, which, however, was not proof against a musket ball, contrary to what has been commonly said. However, it must be acknowledged, that the attitude in which it was placed might contribute not a little thereto; for probably, if the ball had struck obliquely against the shell, it would have flown off. Those parts of the girdles underneath the belly were of a whitish colour, and were made up of scales of divers shapes. They were about one sixth of an inch in thickness, and were not so hard as those on the back.

This creature lays eggs of the size of those of a goose, to the number of fifty; which the covers over with sand, and leaves to be hatched by the heat of the sun. They are to be met with in the rivers Nile, Niger, and Ganges, besides most other large rivers in the southern parts of Asia, Africa, and America.

The crocodile is very destructive to the lower people of Upper Egypt, often devouring women who come to the river to fetch water, and children playing on the shore or swimming in the river.

2. The caudiverbera, has a depressed pinnatifid tail, and palmated feet. It is larger than the common green lizard, is found in Peru, and has got its name from its beating the ground with its tail. 3. The dracera, has a long tail dentated above, a smooth body, and equal toes. It is a native of America. 4. The superciliosa, has a carinated tail, and the scales on the back and eye-brows are ciliated. It is a native of the Indies. 5. The feu ata, has a subcompressed tail, and a dentated future on the back. It is a native of Asia. 6. The monitor, has a carinated tail, and white eye-like spots on the body. It is a native of the Indies. 7. The principalis, has a carinated tail, a crest on the throat, and a smooth back. It is found in South America. 8. The bicarinata, has a compressed tail with a double carina, and a quadruple carina on the back. It is a native of the Indies. 9. The cor-
dylos has a short verticillated tail, and dentated scales. It is found in Africa and Asia. 10. The itelio, has a verticillated tail, and dentated scales. It is a native of Africa. 11. The mauritania, has a short verticillated tail smooth at the apex. It is found in Mauritania. 12. The azurea, has a short verticillated tail, and sharp pointed scales. It is a native of America. 13. The turca, has a verticillated tail, and a rough grey body. It is a native of the East Indies. 14. The ameiva, has a long verticillated tail, 30 fuc-
te on the belly, and a plaited collar. It is a native of America. 15. The agilis, has a pretty long ver-
ticillated tail, with sharp scales, and a collar formed by scales. This is the common green lizard, and is a native both of Europe and India. 16. The algera, has a pretty long verticillated tail, and a yellow line on each side of the body. It is found in Mauritania. 17. The saps has a long verticillated tail, with a ref-
tected lateral future, and square scales. It is a native of warm climates. 18. The sex-lineata, has a long verticillated tail, and six white lines on the back. It is a native of Carolina. 19. The angulata, has a long hexagonal tail, and sharp carinated scales. It is a native of America.

20. The chamaeleon, has a crooked cylindrical tail.

The head of a large chamaeleon is almost two inches long, and from thence to the beginning of the tail it is four inches and a half. The tail is five inches long, and the feet two and a half. The thickness of the body is different at different seasons; for sometimes from the back to the belly it is two inches, and sometimes but one; for he can blow himself up and contract himself at pleasure. This swelling and contraction is not only of the back and belly, but of the legs and tail.

These different motions are not like those of other animals, which proceed from a dilatation of the breast in breathing, and which rises and falls successively; but they are very irregular, as in tortoises, and frogs. The chamaeleon has continued as it were blown up for two hours together, and then he would grow less and less insensibly; for the dilatation was always more quick and visible than the contraction. In this last state he appeared extremely lean, and the spine of the back was sharp, and all his ribs might be told; likewise the tendons of the arms and legs might be seen very distinctly.

The skin is very cold to the touch; and, notwithstanding he seems so lean, there is no feeling the beating of the heart. The surface of the skin is unequal, and has a grain not unlike flagean, but very soft, because each eminence is as smooth as if it was polished. Some of these are as large as a middling pin's head on the arms, legs, belly, and tail, but on the shoulders and head they are of an oval figure, and a little larger. The funder the throat are ranged in the form of a chap-

LAC
The four feet are all of a less size; and the only difference between them is, that those before are turned backwards, and those behind forwards. There are five toes on each paw, which have a greater resemblance to hands than feet. They are all divided into two, which gives the appearance of two hands to each arm, and two feet to each leg; and though one of these parts have three toes, and the other but two, yet they seem to be all of the same size. These toes lie together under the same skin as in a mitten; however, their shape might be seen through the skin. With these paws the chameleon can lay hold of the small branches of trees in the same manner as a parrot. When he is about to perch, he parts his toes different from birds, because he puts two behind and two before. The claws are little, crooked, very sharp, and of a pale yellow, proceeding but halfway out of the skin, while the other half is hid beneath it. His walk is slower than that of a tortoise, and he seems to move along with an afflictation of gravity. He seems to seek for a proper place to set his feet upon; and when he climbs up trees, he does not trust to his feet like squirrels, but endeavours to find out crests in the bark, that he may get a firmer hold.

His tail is like that of a viper when it is puffed up and round; for otherwise the bones may be seen in the same manner as on the back. He always wraps his tail round the branches of trees, and it serves him as were instead of a fifth hand.

He is a native of Africa and Asia.

21. The gecko, has a cylindrical tail, concave ears, and a wartly body. It is the Indian salamander of Bonnies. "This animal is very frequent in Cairo, (says Haffelquilt) both in the houses and without them. The poison of this animal is very singular, as it exudes from the lobule of the toes. The animal seeks all places and things impregnated with sea salt, and plying over them several times leaves this very noxious poison behind it. In July 1750, I saw two women and a girl, in Cairo, at the point of death, from eating cheese newly salted, bought in the market, and on which this animal had dropped its poison. Once at Cairo, I had an opportunity of observing how acrid the exhalations of the toes of this animal are, as it ran over the hand of a man who endeavoured to catch it; there immediately rose little pustules over all those parts the animal had touched; these were red, inflamed, and filled a little, greatly resembling those occasioned by the stinging of nettles. It emits an odd sound, especially in the night, from its throat, not unlike that of a frog." 22. The scincus, has a cylindrical tail, compressed at the point, and blunt margined toes. This animal is found in Arabia Petraea near the Red Sea, and in Upper Egypt near the Nile. It is much used by the inhabitants of the East as an aphrodisiacum, but not at this time by the Europeans. The flesh of the animal is given in powder, with some stimulating vehicle; broth made of the recent flesh, is likewise used by the Arabs. It is brought from Upper Egypt and Arabia to Alexandria, whence it is carried to Venice and Marseille, and from thence to all the apothecaries shops of Europe. It has been an error, common to almost all authors, to imagine the scincus to be a fish. 23. The orbicularis, has a cylindrical tail.
Fig. 4. *Lacerta Crocodylus* or Crocodile

Fig. 5. *Lacerta Chameleon*

Fig. 6. *Lacerta Basiliscus*

Plate CII.
Xjf America. 29. The umbra, has a long cylindrical tail, a smooth back, and a small teethed crest on the Cape of Good-hope.

47. The agouina, has a very long verticillated tail, some toes on the fore-feet, and a naked porous body. This animal is vulgarly said to live in fire; but it is found to be a

48. The quatuor-lineata, has a long cylindrical tail, four toes on the fore-feet, and a roundish belly. It is a native of Carolina.

45. The bullaris, has a long cylindrical tail, with prickles on the neck and hind part of the head. It is a native of North America.

29. The umbra, has a long cylindrical tail, a callous crest on the nape of the neck, and a streaked back. It is a native of southern climates.

30. The plica, has a long cylindrical tail, a callous crest on the hind-head, and a warty neck. It is a native of the Indies.

31. The marmorata, has a long cylindrical tail, a smooth back, and small teethed crest on the throat. It is a native of Spain.

32. The bullaris, has a long cylindrical tail, and a bladder on the throat, which it blows up when enraged. It is a native of Jamaica.

33. The frumosa has a long cylindrical tail, and a gibbous breast. It is found in South America.

34. The tequifein, has a long cylindrical tail, and a plated future on the side. It is a native of the Indies.

35. The aurata, has a cylindrical tail, and round shining scales like gold. It is found in the islands of Cyprus and Jersey.

36. The nilotica, has a long tail with a triangular edge, and four lines of scales on the back. It is a native of Egypt.

37. The punctata, has a long cylindrical tail, two yellow lines on the back, and is interspersed with black points. It is found in Asia.

38. The lemniscata, has a long cylindrical tail, and eight white lines on the back. It is found in Guinea.

39. The fackata, has a blue cylindrical tail, and five yellow lines on the back. It is a native of Carolina.

40. The chalcides, has a long cylindrical tail, four toes on the fore-feet, and a naked porous body. This animal is vulgarly said to live in fire; but it is found to be a

41. The vulcan, has a cylindrical tail, four toes on the fore-feet, and five yellow lines on the back. It is a native of Guinea.

42. The aquatica, has a tail some-

43. The palutilis, has a lanceolated tail, and four toes on the fore-feet. It inhabits the flagrant waters of Europe.

44. The punctata, has a cylindrical tail, four toes on the fore-feet, and longitudinal rows of white spots on the back. It is a native of Carolina.

45. The quatuor-lineata, has a long cylindrical tail, four toes on the fore-feet, and four yellow lines on the back. It is a native of North America.

46. The salamandra, has a short cylindrical tail, four toes on the fore-feet, and a naked porous body. This animal is vulgarly said to live in fire; but it is found to be a

47. The agouina, has a very long verticillated tail, extremely rigird at the point. It is found at the Cape of Good-hope.

See Plate CII.
all over with gold and precious stones; where, at a distance, they prostrate themselves before him, it not being lawful for any to kiss even his feet. He is called the great lama, or lama of lamases, that is, priest of priests. And to persuade the people that he is immortal, the inferior priests, when he dies, substitute another in his stead, and so continue the cheat from generation to generation. These priests persuade the people, that the lama was raised from death many hundred years ago, that he has lived ever since, and will continue to live for ever.

**LAMB**, in zoology, the young of the sheep kind. See **Ovis**.

**LAMELLÆ**, in natural history, denotes very thin plates, such as the scales of fishes are composed of.

**LAMINÆ**, in physiology, the thin plates whereof many substances consist.

**LAMMENTATIONS**, a canonical book of the Old Testament, written by the prophet Jeremiah. The two first chapters of this book are employed in describing the calamities of the siege of Jerusalem. In the third, the author deplores the persecutions he himself had suffered. The fourth turns upon the desolation of the city and temple, and the misfortune of Zedekiah. The fifth chapter is a prayer for the Jews in their dispersion and captivity; and at the end of all, he speaks of the cruelty of the Edomites, who had insulted Jerusalem in her misery. The first four chapters of the lamentations are an abcedary, every verse or couplet beginning with one of the letters of the Hebrew alphabet, in the alphabetical order.

**LAMINÆ**, in physiology, the thin plates whereof many substances consist.

**LANCET**, a churical instrument, sharp-pointed, and two-edged, chiefly used for opening veins in the operation of phlebotomy, or bleeding; also for laying open abscesses, tumors, &c.

**LANCHANG**, the capital of the kingdom of Laos, in the further India: E. long. 101°, N. lat. 20°.

**LAND**, in the sea-language, makes part of several compound terms; thus land-laid, or to lay the land, is jist to lose fight of it. Land-locked, is when land lies all round the ship, so that no point of the compass is open to the sea; if she is at anchor in such a place, she is said to ride land-locked, and is therefore concluded to ride safe from the violence of winds and tides. Land mark, any mountain, rock, steeple, tree, &c. that may serve to make the land known at sea. Land is shut in, a term used to signify that another point of land hinders the sight of that the ship came from. Land to, or the ship lies land to; that is, she is so far from shore that it can only be just discerned. Land turn, is a wind that in almost all hot countries blows at certain times from the shore in the night. To set the land, that is, to see by the compass how it bears.

**LANDAFF**, a city and bishop's see of Glamorganshire, in south Wales, twenty-six miles north west of Bristol: W. long. 3° 20', N. lat. 51° 33'.

**LANDAU**, a city of Germany, in the circle of the Upper Rhine, and landgrave of Alfac, situated fifteen miles south-west of Spire: E. long. 9°, N. lat. 49° 12'.

**LANDEN**, a town of the Austrian Netherlands, in the province of Brabant, eighteen miles south-east of Louvain, and twenty miles north of Namur.

**LANDGRAVE**, the German name for a count or earl, that has the government of a province, country, or large tract of land.

**LANDGRAVITE**, or **LANDGRAVATE**, the office, authority, jurisdiction, or territory of a landgrave.

**LANDRECY**, a town of the French Netherlands, in the province of Hainault: E. long. 3° 25', N. lat. 50° 3'.

**LANDSCROON**, a port-town of Sweden, in the province of Gotland, and territory of Schonen, situated on the Baltic sea, within the Sound: E. long. 14° 20', N. lat. 55° 42'.

**LANDSHUT**, a city of Germany, and the capital of Lower Bavaria, situated forty miles north-east of Munich: E. long. 12° 6', N. lat. 48° 30'.

**LANDSKIP**,
LANGUAGE, in the most general meaning of the word, signifies any sound uttered by an animal, by which it expresses any of its passions, sensations, or affections; but it is more particularly understood to denote those various modifications of the human voice, by which the several sensations and ideas of one man are communicated to another.

Nature has endowed every animal with powers sufficient to communicate to others of the same species some of its sensations and desires. The organs of most animals are so formed, as readily to perceive and understand (as far as is necessary for their particular species of existence) the voice of those of their own kind; by means of which they assemble together, for the defense or preservation of the species. But as they rise higher in the order of intellectual powers, the powers of expression likewise increase. However, the voice alone, even when endowed with a great extent of modulation, is incapable of conveying all that variety of emotions and sensations, which on many occasions are necessary to be communicated. In all these cases, motion and gesture are called in to supply the defects of the voice. The amorous pigeon does not tryst solely to his plaintive cooing in order to soften the rigour of his reluctant mate, but adds to it the most sublimating and expressive gestures; and the faithful dog, finding his voice alone insufficient to express his joy at meeting with his master, is obliged to recur to a variety of endearing actions. But man—the most distinguished of all the animal creation,—although endowed with a power of voice and expression of countenance and gesture eminently superior to all the creatures of God, finds that all these united are not sufficient to express the infinite variety of ideas with which his mind is stored: for although these may powerfully express the passions and stronger feelings of the mind; yet as they are incapable of expressing the several progressive steps of perception by which his reason ascends from one degree of knowledge to another, he has been obliged to discover, by means of his reasoning faculty, a method of expressing with certainty, and communicating with the utmost facility, every perception of his mind.—With this view, having observed, that besides the power of uttering simple sounds, and the several variations of these into acute or grave, open or shrill, &c. by which his stronger feelings were naturally expressed, he was likewise endowed with a power of flapping or interrupting these sounds, by certain clappings of the lips with one another, and of the tongue with the palate, &c. he has taken advantage of these circumstances, and formed unto himself a language capable of expressing every perception of the mind; for by affixing at all times the same idea to any one sound or combination of sounds thus modified and joined together, it is enabled at any time to excite in the mind of any other person an idea similar to that in his own mind, provided the other person has been previously so far instructed as to know the particular modification of sound which has been agreed upon as the symbol of that idea. Thus man is endowed with two different species of language: one consisting of tones and gestures; which as it is natural to man considered as a definite species of animals, and necessary for the preservation and well-being of the whole, is universally understood by all mankind: thus laughter and mirth universally expresses cheerfulness of mind; while tears, in every part of the globe, discover a heart overflowing with tender sensations; and the humble tone of supplication, or the acute accent of pain, are equally understood by the Huns of America, and by the more refined inhabitants of Europe. The other species of language, as it is entirely artificial, and derives its power from particular compact, (for before any thing can be recognized as the symbol of an idea, several persons must first agree that such an idea must always be denoted by this symbol,) must be different in different parts of the globe; and every distinct form which it may assume, from the different genius of every society who originally formed a particular language for themselves, will be altogether unintelligible to every other body of men, but those belonging to the same society where that language was originally invented, or those who have been at pains to acquire a knowledge of it by means of study.

It is unnecessary for us here to draw any parallel between the nature of these two different species of language; it being sufficiently evident, that the artificial language does not debar the use of the tones and gestures of the natural, but tends to ascertain the meaning of these with greater precision, and consequently to give them greater power. Man must therefore reap many advantages from the use of artificial language, which he could not have enjoyed without it. It is equally plain, that the one, being natural and inspired, must remain nearly the same, without making any progress to perfection; whereas the other, being entirely the invention of man, must have been exceedingly rude and imperfect at first, and must have arrived by slow degrees at greater and greater perfection, as the reasoning faculties acquired vigour and acuteness. It must likewise be subject to perpetual changes, from that variety of incidents which affect all sublunary things: and
and these changes must always correspond with the change of circumstances in the people who make use of that particular language: for when any particular set of ideas become prevalent among any society of men, words must be adopted to express them; and from these the language must assume its character. Hence the reason why the language of all barbarous and uncivilized people is rude and uncultivated; while those nations which have improved their reasoning faculties, and made some progress in the polite arts, have been no less distinguished by the superiority of their language than by their pre-eminence in other respects. — The language of a brave and martial people is bold and nervous, although perhaps rude and uncultivated; while the language of those nations in which luxury and effeminacy prevail, is flowing and harmonious, but devoid of force and energy of expression.

It may be considered as a general rule, that the language of any nation is an exact index of the state of their minds. But as man is naturally an imitative animal, and in matters of this kind never has recourse to invention but through necessity; if by some accident any part of a nation should be separated from that community to which they belonged, after a language had been invented, they would retain the same general sounds and idiom of language with those from whom they were separated; although in process of time these two people, by living in countries of a different nature, or being engaged in different occupations, and leading a different manner of life, might in time lose all knowledge of one another, assume a different national character and opposite dispositions of mind, and form each of them a distinct language to themselves, totally different in genius and style, though agreeing with one another in the fundamental sounds and general idiom: so that if this particular idiom, formed before their separation, should happen to be more peculiarly adapted to the genius of one of these people than the other, that particular people whose natural genius and style of language was not in concord with the idiom which they had adopted, would labour under an inconvenience on this account which they never would be able entirely to overcome; and this inconvenience would prevent their language from attaining such a degree of perfection, as the genius of the people would otherwise naturally have led them to. Thus languages have been originally formed; and thus that happy concord of circumstances which have concurred to raise some languages to that height of perfection which they have attained may be easily accounted for, while many ineffectual efforts have been made to raise other languages to the same degree of excellence.

We shall not here enter upon any fruitless inquiries, with a view to discover if only one language was originally formed, or if any language that we are acquainted with has a greater claim to that much envied pre-eminence than others. We have seen, that the discovery of language is entirely within our reach, and evidently the invention of man; and therefore that the invention of different languages by different societies, is extremely probable. But these different societies, in process of time, behoved to intermix by war or commerce, and their different languages would likewise become mixed. Hence during the succession of many ages, while the principles of language were not understood, many different languages must have been formed, while others may have sunk into oblivion, especially in those early ages before the invention of letters, which alone could preserve their memory. In vain, therefore, would we endeavour to discover the state of those nations or languages of which we have but obscure traces in history. Indeed we have no reason to lament our loss in this particular; for supposing such a discovery could be made, we could derive little advantage from it. The antiquity of a language does not imply any degree of excellence: some nations have made more progress in improving their mental faculties, and refining their language, in a few years, than others have done in many ages. We shall therefore leave this subject, and proceed to make some remarks on the advantages or defects of some of those idioms of language with which we are most intimately acquainted, as this may perhaps lead us to some discoveries of real utility to ourselves.

As the words idiom and genius of a language are often confounded, it will be necessary to inform the reader, that by idiom we would here be understood to mean that general mode of arranging words into sentences which prevails in any particular language; and by the genius of a language we mean to express the particular set of ideas which the words of any language, either from their formation or multiplicity, are most naturally apt to excite in the mind of any one who hears it properly uttered. Thus although the English, French, Italian, and Spanish languages, nearly agree in the same general idiom; yet the particular genius of each is remarkably different: The English is naturally bold, nervous, and strongly articulated; the French is weaker, and more flowing; the Italian more soothing and harmonious; and the Spanish more grave, fonorous, and stately. Now, when we examine the several languages which have been most esteemed in Europe, we find that there are only two distinct idioms among them which are essentially distinguished from one another; and all these languages are divided between these two idioms, following sometimes the one, and sometimes the other, either wholly or in part. The languages which may be said to adhere to the first idiom, are those which in their construction follow the order of nature; that is, express their ideas in the natural order in which they occur to the mind; the subject which occasions the action appearing first; then the action, accompanied with its several modifications; and, last of all, the object to which it has reference. — These may be properly called analogous languages; and of this kind are the English, French, and most of the modern languages in Europe. — The languages which may be referred to the other idiom, are those which follow no other order in their construction than what the taste or fancy of the composer may suggest; sometimes making the object, sometimes the action, and sometimes the modification of the action, to precede or follow the other parts. The confusion which this might occasion is avoided by the particular manner of inflecting their words, by which they are made to refer to the others with which they ought to be connected, in whatever.
ever part of the sentence they occur, the mind being left at liberty to connect the several parts with one another after the whole sentence is concluded. And as the words may be here transposed at pleasure, those languages may be called transpositive languages. To this class we must, in an especial manner, refer the Latin and Greek languages. As each of these idioms has several advantages and defects peculiar to itself, we shall endeavour to point out the most considerable of them, in order to ascertain with greater precision the particular character and excellence of some of those languages, now principally spoken or studied in Europe.

The partiality which our forefathers, at the revival of letters in Europe, naturally entertained for the Greek and Roman languages, made them look upon every distinguishing peculiarity belonging to them, as one of the many causes of the amazing superiority which those languages evidently enjoyed above every other at that time spoken in Europe. This blind deference still continues to be paid to them, as our minds are early prepossessed with these ideas, and as we are taught in our earliest infancy to believe, that to entertain the least idea of our own language being equal to the Greek or Latin in any particular whatever, would be a certain mark of ignorance or want of taste. Their rights, therefore, like those of the church in former ages, remain still to be examined; and we, without exerting our reason to discover truth from falsehood, tamely sit down satisfied with the idea of their undoubted pre-eminence in every respect. But if we look around us for a moment, and observe the many excellent productions which are to be met with in almost every language of Europe, we must be satisfied, that even these are now possessed of some powers which might afford at least a prefunption, that, if they were cultivated with a proper degree of attention, they might, in some respects, be made to rival, if not to excel, those beautiful and justly admired remains of antiquity. Without endeavouring to derogate from their merit, let us, with the cool eye of philosophic reasoning, endeavour to bring before the sacred tribunal of Truth some of those opinions which have been most generally received upon this subject, and rest the determination of the cause on her impartial decision.

The learned reader well knows, that the several changes which take place in the arrangement of the words in every transpositive language could not be admitted without occasioning great confusion, unless certain classes of words were endowed with particular variations, by means of which they might be made to refer to the other words with which they ought naturally to be connected. From this cause proceeds the necessity of several variations of verbs, nouns, and adjectives; which are not in the least essential or necessary in the analogous languages, as we have pretty fully explained under the article Grammar, to which we refer for satisfaction on this head. We shall in this place consider, whether these variations are an advantage or a disadvantage to language.

As it is generally supposed, that every language whose verbs admit of inflection, is on that account much more perfect than one where they are varied by auxiliaries; we shall, in the first place, examine this with some degree of attention; and that what is said on this head may be the more intelligible, we shall give examples from the Latin and English languages. We make choice of these languages, because the Latin is more purely transpositive than the Greek, and the English admits of less inflection than any other language that we are acquainted with.

If any preference be due to a language from the one or the other method of conjugating verbs, it must in a great measure be owing to one or more of these three causes:—Either it must admit of a greater variety of sounds, and consequently more room for harmonious diversity of tones in the language,—or a greater freedom of expression is allowed in uttering any simple idea, by the one admitting of a greater variety in the arrangement of the words which are necessary to express that idea than the other does;—or, lastly, a greater precision and accuracy in fixing the meaning of the person who uses the language, arise from the use of one of these forms above the other!—for, as every other circumstance which may serve to give a diversity to language, such as the general and most prevalent sounds, the frequent repetition of any one particular letter, and a variety of other circumstances of that nature, which may serve to debase a particular language, are not influenced in the least by the different methods of varying the verbs, they cannot be here considered. We shall therefore proceed to make a comparison of the advantages or disadvantages which may accrue to a language by inflecting their verbs, with regard to each of these particulars.

The first particular that we have to examine, is, whether the one method of expressing the variations of a verb admits of a greater variety of sounds. In this respect the Latin seems, at first view, to have a great advantage over the English: for the word amo, amabam, amaveram, amavero, amem, &c. seem to be more different from one another than the English translations of these, I love, I did love, I had loved, I shall have loved, I may love, &c. for, although the syllable am is repeated in every one of the first, yet as the last syllable usually strikes the ear with greater force, and leaves a greater impression than the first, it is very probable that many will think the frequent repetition of the word love will, in the last instance, appear more striking to the ear than the other: we will therefore allow this its full weight, and grant that there is as great, or even a greater difference between the sounds of the different tenses of a Latin verb, than there is between the words that are equivalent to them in English. But as we here consider the variety of sounds of the language in general, before any just conclusion can be drawn, we must not only compare the different parts of the same verb, but also compare the different verbs with one another in each of these languages. And here, at first view, we perceive a most striking distinction in favour of the analogous language over the inflected: for as it would be impossible to form a particular set of inflections different from one another for each particular verb, all those languages which have adopted this method have been obliged to reduce their verbs into a small number of classes; all the words of each of which classes, commonly called conjugations, have the several variations of the modes, tenses, and persons, expressed
expressed exactly in the same manner, which must of necessity introduce a similarity of sounds into the language in general, much greater than where every particular verb always retains its own distinguishing sound. — To be convinced of this, we need only repeat any number of verbs in Latin and English, and observe one which fide the preference with respect to variety of sounds must fall.

The similarity of sounds is here so obvious in the Latin as to be perceived at the first glance: nor can we be surprised to find it so, when we consider, that all their regular verbs, amounting to four thousand or upwards, must all be reduced to four conjugations, and even these differing but little from one another, which must of necessity produce the sameness of sounds which we here perceive; whereas every language that follows the natural order, like the English, instead of these small number of uniform terminations, have almost as many distinct sounds as original verbs in their language.

But if, instead of the present of the indicative mood, we should take almost any other tense of the Latin verb, the similarity of sounds would be still more perceptible, as many of these tenses have the same termination in all the four conjugations, particularly in the imperfect of the indicative, as below.

The second particular by which the different methods of marking the relation of the verbal attributive can affect language, arises from the variety of expressions, which either of these may admit of in uttering the same sentiment. — In this respect likewise the method of conjugating by inflection seems to be deficient. Thus the present of the indicative mood in Latin can at most be expressed only in two ways, viz. scribo, and ego scribo; which ought perhaps in strictness to be admitted only as one: whereas, in English, we can vary it in four different ways, viz. 1st, I write; 2nd, I do write; 3rd, write I do; 4th, write do I. And if we consider the further variation which these receive in power as well as in sound, by having the accent placed on the different words; instead of four, we will find eleven different variations: thus, if I write, with the emphasis upon the I; 2nd, I write, with the emphasis upon the word write. Let any one pronounce these with the different accent necessary, and he will be immediately satisfied that they are not only distinct from each other with respect to meaning, but also with regard

* We are sufficiently aware, that the last variation cannot in strictness be considered as good language; although many examples of this manner of using it in serious compositions, both in poetry and prose, might be easily produced from the best authors in the English language. — But however unjustifiable it may be to use it in serious composition; yet, when judiciously employed in works of humour, this and other forced expressions of the like nature produce a fine effect; by giving a burlesque air to the language, and beautifully contravening it to the purer dictation of solid reasoning. The sagacious Shakespeare has, on many occasions, shewed how successfully these may be employed in composition, particularly in drawing the character of ancient Pistol, in Henry V. Without this liberty, Butler would have found greater difficulty in drawing the inimitable character of Hudibras.—Let this apology suffice for our having inferred this and other variations of the same kind; which, although they may be often improper for serious composition, have fill their use in language.
regard to sound; and the same must be understood of all the other parts of this example.

</table>

None of the Latin tenses admit of more variations than the two above mentioned; nor do almost any of the English admit of fewer than in the above example; and several of these phrasés, which must be considered as exact translations of some of the tenses of the Latin verb, admit of many more. Thus the imperfection of the subjunctive mood, which in Latin admits of the above two variations, admits of English in the following:

1. I might have wrote.
2. Wrote I might have.
3. Have wrote I might.
4. Wrote might have I.
5. I wrote might have.
6. Have wrote might I.
7. Wrote I might have.
8. Wrote I might have.
9. Have wrote I might.
10. Wrote might have I.
11. I wrote might have.
12. Have wrote I might.
13. Wrote might have I.
14. I might have wrote.
15. Wrote might have I.
16. Have wrote I might.
17. Wrote I might have.
18. I wrote might have.
19. Have wrote I might.
20. Wrote I might have.
21. Have wrote I might.
22. Wrote might have I.
23. I wrote might have.
24. Have wrote I might.

And if we likewise consider the variations which may be produced by a variation of the emphasis, they will be as under.

1. I might have wrote.
2. Wrote I might have.
3. Have wrote I might.
4. Wrote might have I.
5. I wrote might have.
6. Have wrote might I.
7. Wrote I might have.
8. Wrote I might have.
9. Have wrote I might.
10. Wrote might have I.
11. I wrote might have.
12. Have wrote I might.
13. Wrote might have I.
14. I might have wrote.
15. Wrote might have I.
16. Have wrote I might.
17. Wrote I might have.
18. I wrote might have.
19. Have wrote I might.
20. Wrote I might have.
21. Have wrote I might.
22. Wrote might have I.
23. I wrote might have.
24. Have wrote I might.

In all twenty four variations, instead of two. If we likewise consider, that the Latins were obliged to employ the same word, not only to express "I might have wrote," but also "I could; I would, or I should have wrote," each of which would admit of the same variations as the word might, we have in all ninety six different expressions in English for the same phrase which in Latin admits only of two, unless they have recourse to other forced turns of expression, which the defects of their verbs in this particular has compelled them to invent.

But, if it should be objected, that the last circumstance we have taken notice of as a defect, can only be considered as a defect of the Latin language, and is not to be attributed to the inflexion of their verbs, seeing they might have had a particular tense for each of these different words might, could; would, and should; we answer, that, even admitting this as correct as valid, the superiority of the analogous language, as such, still remains in this respect as twelve to one. Yet even this concession is greater than ought to have been made: For as the difficulty of forming a sufficient variety of words for all the different modifications which a verb may be made to undergo is too great for any rude people to be able to overcome; we find, that every nation which has adopted this mode of inflexion, not excepting the Greeks themselves, has been obliged to remain satisfied with fewer words than would have been necessary even to effect this purpose, and make the same word serve a double, triple, or even quadruple office, as in the Latin tense which gave rise to these observations: So that however in physical necessity this may not be chargeable upon this particular mode of construction, yet in moral certainty this must always be the case; and therefore we may safely conclude, that the mode of varying verbs by inflexion affords less variety in the arrangement of the words of the particular phrasés, than the method of varying them by the help of auxiliaries.

But if there should still remain any shadow of doubt in the mind of the reader, whether the method of varying the verbs by inflexion, is inferior to that by auxiliaries, with regard to diversity of sounds, or variety of expression; there cannot be the least doubt, but that, with respect to precision, distinctness, and accuracy in expressing any idea, the latter enjoys a superiority beyond all comparison. Thus the Latin verb Amo, may be Englished either by the words *I love*, or *I do love*, and the emphasis placed upon any of the words that the circumstances may require; by means of which, the meaning is pointed out with a force and energy which it is altogether impossible to produce by the use of any single word. The following line from Shakspeare’s Othello may serve as an example:

---Excellent wretch!---

Perdition catch my soul, but I do love thee.

In which the strong emphasis upon the word do, gives it a force and energy which conveys, in an irresistible manner, a most perfect knowledge of the situation of the mind of the speaker at the time—That the whole energy of the expression depends upon this seemingly insignificant word, we may be at once satisfied of, by keeping it away in this manner;

---Excellent wretch!---

Perdition catch my soul, but I love thee.

How poor—how tame—how insignificant is this, when compared with the other! Here nothing remains but a tame assertion, uttered in with a pompous exclamation which could not here be introduced with any degree of propriety. Whereas, in the way that Shakeespere has left it to us, it has a forcible power which nothing can surpass; for, overpowered with the irresistible force of Desdemona’s charms, this strong exclamation is forced from the soul of Othello in spite of himself. Surprised at this tender emotion which brings to his mind all those amiable qualities for which he had so much esteemed her, and at the same time fully impressed with the firm persuasion of her guilt, he bursts out into that seemingly inconsistent exclamation—Excellent wretch! And then he adds in the warmth of his surprize,—thinking it a thing most astonishing that any warmth of affection should still remain in his breast, he even confirms it with an oath,—"Perdition catch my soul, but I do love thee."—"In spite of all the falsehoods with which I know thou hast deceived me—in spite of all the crimes of which I know thee guilty—in spite of all these reasons for which I ought to hate thee—in spite of myself,—still I find that I love,—yes, I do love thee."—We look upon it as a thing altogether impossible to trans-
false the energy of this expression into any language whose verbs are regularly inflected.

In the same manner we might go through all the other tenses, and shew that the same superiorit" is to be found in each —Thus in the perfect tense of the Latins, instead of the simple amavi, we say, I have loved; and by the liberty we have of putting the emphasis upon any of the words which compose this phrase, we can in the most accurate manner fix the precise idea which we mean to excite: for if we say I have loved, with the emphasis upon the word I, it at once points out the person as the principal object in that phrase, and makes us naturally look for a contrast in some other person, and the other parts of the phrase become subordinate to it; —He has loved thee much, but I have loved thee infinitely more." —The Latins too, as they were not prohibited from joining the pronoun with their verb, were also acquainted with this excellence, which Virgil has beautifully used in this verse:

Nos patriam fugimus;
Tu, Tytere, lentis in umbra, &c.

But we are not only enabled thus to distinguish the person in as powerful a manner as the Latins, but can also with the same facility point out any of the other circumstances as principals; for if we say, with the emphasis upon the word Have, "I have loved," it as naturally points out the time as the principal object, and makes us look for a contrast in that peculiarity, I have: -I have loved indeed;—my imagination has been led astray—my reason has been perverted:—but, now that time has opened my eyes, I can smile at those imaginary distresses which once perplexed me." —In the same manner we can put the emphasis upon the other word of the phrase loved, —I have loved.—Here the passion is exhibited as the principal circumstance; and as this can never be excited without some object, we naturally wish to know the object of that passion —"Who! what have you loved?" are the natural questions we would put in his case. "I have loved —Eliza." —In this manner we are, on all occasions, enabled to express, with the utmost precision, that particular idea which we would with to excite, so as to give an energy and perspicuity to the language, which can never be attained by those languages whose verbs are conjugated by inflection; and if to this we add the inconvenience which all inflected languages are subjected to, by having too small a number of tenses, so as to be compelled to make one word on many occasions supply the place of two, three, or even four, the balance is turned still more in our favour. —Thus, in Latin, the same word amabo stands for shall or will love, so that the reader is left to guess from the context which of the two meanings it was most likely the writer had in view. —In the same manner, may or can love are expressed by the same word amem; as is also might, could, would, or should love, by the single word amarem, as we have already observed; so that the reader is left to guess which of these four meanings the writer intended to express; which occasions a perplexity very different from that clear preception which our language allows of, by not only pointing out the different words, but also by allowing us to put the emphasis upon any of them we please, which superadds energy and force to the precision it would have had without that of assistance.

Upon the whole, therefore, after the most candid examination, we must conclude, that the method of conjugating verbs by inflection is inferior to that which is performed by the help of auxiliaries; —because it does not afford such a diversity of sounds, —nor allow such variety in the arrangement of expression for the same thought, —nor give us much distinction and precision in the meaning. —It is, however, attended with one considerable advantage above the other method: for as the words of which it is formed are necessarily of greater length, and more sonorous, than in the analogous languages, it admits of a more flowing harmony of expression; for the number of monosyllables in this last greatly checks that pompous dignity which naturally results from longer words. Whether this single advantage is sufficient to counterbalance all the others with which it is attended, is left to the judgment of the reader to determine: —but we may remark, before we quit the subject, that even this excellence is attended with some peculiar inconveniences, which shall be more particularly pointed out in the sequel.

But perhaps it might still be objected, that the comparison we have made above, although it may be fair, and the conclusion just with regard to the Latin and English languages; yet it does not appear clear, that on that account the method of conjugating verbs by inflection is inferior to that by auxiliaries: —for although it be allowed, that the Latin language is defective in point of tenses; yet if a language were formed which had a sufficient number of inflected tenses to answer every purpose; if it had, for instance, a word properly formed for every variation of each tense; one for I love, another for I do love; one for I shall, another for I will love; one for I might, another for I could, and would, and should love; and so on through all the other tenses; that this language would not be liable to the objections we have brought against the inflection of verbs; and that of course, the objections we have brought are only founded on that account the method of conjugating verbs by inflection is inferior to that by auxiliaries; —for although it is fair to suppose that this language would not be liable to the objections we have brought against the inflection of verbs; and that of course, the objections we have brought are only valid against those languages which have followed that mode and executed it imperfectly. —We answer, that although this would in some measure remedy the evil, yet it would not remove it entirely. For in the first place, unless every verb, or a very small number of verbs, was conjugated in one way, having the sound of the words in each tense, and divisions of tenses, as we may say, different from all the other conjugations,—it would always occasion a sameness of sounds which would in some measure prevent that variety of sounds so proper for a language. And even if this could be effected, it would not give such a latitude to the expression as auxiliaries allow: —for although there should be two words, one for I might, and another for I could love; yet as these are single words, they cannot be varied; whereas, by auxiliaries, either of these can be varied twenty-four different ways, as has been shewn above. —In the last place, no single word can ever express all that variety of meaning which we can do by the help of our auxiliaries and the emphases. I have loved, if expressed by any one word, could only denote at all times one definite meaning; so that, to give it
defence of each of these two methods of varying verbs, in their unintelligible language? But the well known powers of the twenty-four letters, can equal the simplicity or the power of the one method, could be expressed by this unwieldy apparatus? What of ten thousand words would be necessary to form the

time retaining the original method of varying them by tenses in the same manner as the Latins, and at the same instance combined the joint powers of the two: which there had been a people sagacious enough to have united variations of any one verb, and a hundred times that can be attained with the utmost ease, to express all that facility. But how could this be attained, since upwards of ten thousand words would be necessary to form the variations of any one verb, and a hundred times that number would not include the knowledge of the verbs alone of such a language?—How much, therefore, ought we to admire the simple perspicuity of our language, which which enables us, by the proper application of ten or twelve seemingly trifling words, the meaning and use of which can be attained with the utmost ease, to express all that could be expressed by this unwieldy apparatus? What can equal the simplicity or the power of the one method, but the well known powers of the twenty-four letters, the knowledge of which can be obtained with so much ease—and their power knows no limits?—or what can be compared to the fancied perfection of the other, but the transport of it which the Chinese seem to have formed in their unintelligible language?

Having thus considered pretty fully the advantages and defects of each of these two methods of varying verbs, we cannot help feeling a secret wish with arise in our mind, that there had been a people sagacious enough to have united the powers of the one method with those of the other;—nor can we help being surprized, that, among the changes which took place in the several languages of Europe after the downfall of the Roman monarchy, none of them did not accidentally stumble on the method of doing it.—From many concurring circumstances, it seems probable, that the greatest part, if not all the Gothic nations that over-ran Italy at that time, had their verbs varied by the help of auxiliaries; and many of the modern European languages which have sprung from them, have so far borrowed from the Latin, as to have some of the tenses of their verbs inflected: yet the English alone have in any infлексe combined the joint powers of the two: which could only be done by forming inflections for the different tenses in the same manner as the Latins, and at the same time retaining the original method of varying them by auxiliaries; by which means either the one or the other method could have been employed as occasion required. But if we proceed one step further, and consider the variety which is produced in the language in general, by the one or the other of these methods, the case is entirely reversed. For as it would have been impossible to form different variations, different from one another, for each case of every noun, they have been obliged to reduce all their nouns into a few general classes, called declensions, and endowed all of those included under each class with the same termination in every case; which produces a like similarity of sounds which the few classes admit of; and even the sounds of these few classes are not so much diversified as they ought to have been, as many of the different cases in the Latin language, as there is no necessity for any constraint, there is almost as great a variety of sounds as there are of nouns. The Latins have only five different declensions, so that all the great number of words of this general order must be reduced to the very small diversity of sounds which these few classes admit of; and even the sounds of these few classes are not so much diversified as they ought to have been, as many of the different cases in the different declensions have exactly the same sounds, as we shall have occasion to remark more fully hereafter.—We might here produce examples to shew the great similarity of sounds between different nouns in the Latin language, and variety in the English, in the same way as we did of the verbs: but as every reader, in the lead acquainted with the powers of ours, there beheld to be three distinct words at least. However, if all this was done:—that is, if there was a distinct conjugation formed for every forty or fifty verbs;—if each of the tenses was properly formed, and all of them different from every other tense as well as every other verb; and these all carried through each of the different persons, so as to be all different from one another;—and if likewise there was a distinct word to mark each of the separate meanings which the same tense could be made to assume by means of the emphasis;—and if all this infinite variety of words could be formed in a distinct manner, different from each other and harmonious;—this language would have powers greater than any that could be formed by auxiliaries, if it were possible for the human powers to acquire such a degree of knowledge as to be able to employ it with facility. But how could this be attained, since upwards of ten thousand words would be necessary to form the variations of any one verb, and a hundred times that number would not include the knowledge of the verbs alone of such a language?—How much, therefore, ought we to admire the simple perspicuity of our language, which which enables us, by the proper application of ten or twelve seemingly trifling words, the meaning and use of which can be attained with the utmost ease, to express all that could be expressed by this unwieldy apparatus? What can equal the simplicity or the power of the one method, but the well known powers of the twenty-four letters, the knowledge of which can be obtained with so much ease—and their power knows no limits?—or what can be compared to the fancied perfection of the other, but the transport of it which the Chinese seem to have formed in their unintelligible language?
acquainted with these two languages, can satisfy himself in this particular, without any further trouble than by marking down any number of Latin nouns. with their translations in English; we thought it unnecessary to dwell longer on this particular.

But if the inflection of nouns is a disadvantage to a language in point of diversity of sounds, it is very much the reverse with regard to the variety it allows in the arranging the words of the phrase. Here, indeed, the Transpositive language shines forth in all its glory, and the Analogous must yield the palm without the smallest dispute. For as the nominative case (or that noun which is the cause of that energy expressed by the verb) is different from the accusative (or that noun upon which the energy expressed by the verb is exerted) these may be placed in any situation that the writer shall think proper, without occasioning the smallest confusion: whereas in the analogous languages, as these two different states of the noun are expressed by the same word, they cannot be distinguished but by their position alone; so that the noun which is the efficient cause must always precede the verb, and that which is the active subject must follow; which greatly cramps the harmonious flow of composition. —Thus the Latins, without the smallest perplexity in the meaning, could say either Brutum amavit Cæsius, or Cæsius amavit Brutum, or Brutum Cæsius amavit, or Cæsius Brutum amavit. As the termination of the word Cæsius always points out that it is in the nominative case, and therefore that he is the person from whom the energy proceeds; and in the same manner, as the termination of the word Brutum points out that it is in the accusative case, and consequently that he is the object upon which the energy is exerted; the meaning continues still distinct and clear, notwithstanding all these several variations: whereas in the English language, we could only say Cæsius loved Brutus, or, by a more forced phraseology, Cæsius Brutus loved: Were we to reverse the case, as in the Latin, the meaning also would be reversed; for if we say Brutus loved Cæsius, it is evident, that, instead of being the person beloved, as before, Brutus now becomes the person from whom the energy proceeds, and Cæsius becomes the object beloved. —In this respect, therefore, the analogous languages are greatly inferior to the transpositive; and indeed it is from this single circumstance alone that they derive their chief excellence.

But although it thus appears evident, that any language, which has a particular variation of its nouns to distinguish the accusative from the nominative case, has an advantage over those languages which have none; yet it does not appear that any other of their cases adds to the variety, but rather the reverse: for, in Latin, we can only say Amor Dei; in English the same phrase may be rendered, either, — the love of God, — of God the love, — or, by a more forced arrangement, God the love of. And as these oblique cases, as the Latins called them, except the accusative, are clearly distinguished from one another, and from the nominative, by the preposition which accompanies them, we are not confined to any particular arrangement with regard to these as with the accusative, but may place them in what order we please, as in Milton’s elegant invocation at the beginning of Paradise Lost:

Of man’s first disobedience, and the fruit
Of that forbidden tree, whose mortal taste
Brought death into the world, and all our wo,
With loss of Eden, till one greater Man
Restore us, and regain the blissful seat,
Sing, heavenly muse.

In this sentence the transposition is almost as great as the Latin language would admit of, and the meaning as distinct as if Milton had begun with the plain language of prose, thus,—“ Heavenly muse, sing of man’s first disobedience,” &c.

Before we leave this head, we may remark, that the little attention which seems to have been paid to this peculiar advantage derived from the use of an accusative case different from the nominative, is somewhat surprising. — The Latins, who had more occasion to attend to this with care than any other nation, have in many cases overlooked it, as is evident from the many instances we meet with in their language where this is not distinguished. For the nominative and accusative are the same in the singular number of all those of the first declension ending in e; as is likewise the case with those in um of the second, in e of the third, and in u of the fourth. In the plural number, there is no distinction between these two cases in those of the second declension ending in u,m, nor in all those of the third, fourth, and fifth, of every termination, the number of which is very considerable. So that their language reap no advantage in this respect from almost one half of their nouns. Nor have any of the modern languages in Europe, however much they may have borrowed from the ancient languages in other respects, attempted to copy from them in this particular; from which perhaps more advantage would have been gained, than from copying all the other supposed excellencies of their language. — But to return to our subject.

It remains that we consider, whether the inflection of nouns gives any advantage over the method of defining them by prepositions, in point of distinctness and precision of meaning. — But in this respect too the analogous language must come off victorious. — Indeed this is the particular in which their greatest excellence consists; nor was it, we believe, ever disputed, but that, in point of accuracy and precision, this method must excel all others, however it may be defective in other respects. — We observed under this head, when speaking of verbs, that it might perhaps be possible to form a language by inflection which should be capable of as great accuracy as in the more simple order of auxiliaries; but this would have been such an infinite labour, that it was not to be expected that ever human powers would have been able to accomplish it. More easy would it have been to have formed the several inflections of the nouns so different from one another, as to have rendered it impossible ever to mistake the meaning. Yet even this has not been attempted. And as we find that those languages which have adopted the method of inflecting their verbs are more imperfect in point of precision than the other, so the same may be said of inflecting the nouns; for, not to mention the energy which
which the analogous languages acquire by putting the accent upon the noun, or its preposition (when in an oblique case), according as the subject may require, to express which variation of meaning no particular variety of words have been invented in any inflected language, they are not even complete in other respects.—The Latin, in particular, is in many cases defective, the same termination being employed in many instances for different cases of the same noun.—Thus the genitive and dative singular, and nominative and vocative plural, of the first declension, are all exactly alike, and can only be distinguished from one another by the formation of the sentences;—as are also the nominative, vocative, and ablative singular, and the dative and ablative plural. In the second, the genitive singular, and nominative and vocative plural, are the same; as are also the dative and ablative singular, and dative and ablative plural; except those in um, whose nominative, accusative, and vocative singular, and nominative, accusative and vocative plural, are alike. The other three declensions agree in as many of their cases as these do; which evidently tends to perplex the meaning, unless the hearer is particularly attentive to, and well acquainted with, the particular construction of the other parts of the sentence; all of which is totally removed, and the clearest certainty exhibited, at once, by the help of prepositions in the analogous languages.

It will hardly be necessary to enter into such a minute examination of the advantages or disadvantages attending the variation of adjectives; as it will appear evident, from what has been already said, that the ending them with terminations similar to, and corresponding with the nouns, must tend still more and more to increase the similarity of sounds in any language, than any of those particulars we have already taken notice of; and were it not for the liberty which they have, in transpositive languages, of separating the adjective from the noun, this must have occasioned such a jingle of similar sounds as behaved to have been most disgusting to the ear: but as it would have been impossible in many cases, in those languages where the verbs and nouns are inflected, to have pronounced the words which ought to have followed each other, unless their adjectives could have been separated from the nouns; therefore, to remedy this inconvenience, they were forced to devise this unnatural method of inflecting them also; by which means it is easy to recognize to what noun any adjective has a reference, in whatever part of the sentence it may be placed.—In these languages, therefore, this inflection, both as to gender, number, and case, becomes absolutely necessary; and, by the diversity which it admitted in the arranging the words of the several phrases, might counterbalance the jingle of similar sounds which it introduced into the language.—But what shall we say of those European nations, who, although professed of a language in every respect different from the transpositive idiom, have nevertheless adopted the variations of their adjectives in the fullest sense? for here they have nothing to counterbalance this disagreeable jingle of similar sounds, so destructive of all real harmony.—In the days of monkish ignorance, when this custom was probably introduced, the clashing of words with one another might be esteemed an ornament; but now that mankind have attained a higher sense of harmony and propriety, in Britain may felicitate ourselves to find, that our language has escaped this mark of barbarity, which so many others are now subjected to.

Having thus examined the most striking particulars in which the transpositive and analogous languages differ, and endeavoured to show the general tendency of every one of the particulars separately, it would not be fair to diminish the subject without considering each of these as a whole, and pointing out their general tendency in that light: for we all know, that it often happens in human inventions, that every part which composes a whole, taken separately, may appear extremely fine; and yet, when all these parts are put together, they may not agree, but produce a jarring and confusion very different from what we might have expected. We therefore imagine a few remarks upon the genius of each of these two distinct idioms of language considered as a whole will not be deemed useless.

Although all languages agree in this respect, that they are the means of conveying the ideas of one man to another; yet as there are an infinite variety of ways in which we might wish to convey these ideas, sometimes by the easy and familiar mode of conversation, and at other times by more solemn addresses to the understanding, by pompous declamation, &c. it may so happen, that the genius of one language may be more properly adapted to the one of these than the other, while another language may excel in the opposite particular. This is exactly the case in the two general idioms of which we now treat.—Every particular in a transpositive language, is peculiarly calculated for that solemn dignity which is necessary for pompous orations. Long sounding words, formed by the inflection of the different parts of speech,—flowing periods, in which the attention is kept awake by the harmony of the sounds, and an expectation of that word which is to unravel the whole,—if composed by a skilful artist, are admirably suited to that solemn dignity and awful grace which constitute the essence of a public harangue. On the contrary, in private conversation, where the mind wishes to unbend itself with ease, these become so many clogs which encumber and perplex. At these moments we wish to transfuse our thoughts with ease and facility—we are tired with every unnecessary syllable—and wish to be freed of the trouble of attention as much as may be. Like our state robes, we would wish today and facility—we are tired with every unneceffary syllable and cloggs which encumber and perplex. At these moments we wish to transfuse our thoughts with ease and facility—we are tired with every unnecessary syllable.
If we consider the effects which these two different characters of language must naturally produce upon the people who employ them, we will soon perceive, that the genius of the analogical language is much more favourable for the most engaging purposes of life, civilizing the human mind by mutual intercourse of thought, than the transposed. For as it is chiefly by the use of speech that man is raised above the brute creation;—as it is by this means he improves every faculty of his mind, and, to the observations which he may himself have made, has the additional advantage of the experience of others with whom he may converse, as well as the knowledge which the human race have acquired by accumulated experience of all preceding ages;—as it is by the enlivening glow of conversation that kindred souls catch fire from one another, that thought produces thought, and each improves upon the other, till they soar beyond the bounds which human reason, if left alone, could ever have aspired to;—we must surely consider that language as the most beneficial to society, which most effectually removes these bars that obstruct its progress. Now, the genius of the analogical language is so easy, so simple and plain, as to be within the reach of every one who is born in the kingdom where it is used, to speak it with facility; even the rudest among the vulgar can hardly fall into any grammatical errors: whereas, in the transposed languages, so many rules are necessary to be attended to, and so much variation is produced in the meaning by the slightest variations in the found, that it requires a study far averse mull surely consider that language as the most beneficial to society, which most effectually removes these bars that obstruct its progress. Now, the genius of the analogical language is so easy, so simple and plain, as to be within the reach of every one who is born in the kingdom where it is used, to speak it with facility; even the rudest among the vulgar can hardly fall into any grammatical errors: whereas, in the transposed languages, so many rules are necessary to be attended to, and so much variation is produced in the meaning by the slightest variations in the found, that it requires a study far above the reach of the illustrious mechanic ever to attain. So that, how perfect ever the language may be when spoken with purity, the bulk of the nation must ever labour under the inconvenience of rudeness and inaccuracy of speech, and all the evils which this naturally produces. Accordingly we find, that in Rome, a man, even in the highest rank, received as much honour, and was as much distinguished among his equals, for being able to converse with ease, as a modern author would be for writing in an easy and elegant style; and Caesar among his contemporaries was as much esteemed for his superiority in speaking the language in ordinary conversation with ease and elegance, as for his powers of oratory, his skill in arms, or his excellence in literary composition. It is needless to point out the many inconveniences that this behaved to produce in a state. It is sufficient to observe, that it naturally tends to introduce a vast distinction between the different orders of men; to fet an impenetrable barrier between those born in a high and those born in a low station; to keep the latter in ignorance and barbarity, while it elevates the former to such a height as mult subject the other to be easily led by every popular demagogue. How far the history of the nations who have followed this idiom of language confirms this observation, every one is left to judge for himself.

Having thus considered Language in general, and pointed out the genius and tendency of the two most distinguished idioms which have prevailed; we shall close these remarks with a few observations upon the particular nature and genius of those language which are now chiefly studied or spoken in Europe.

Of all the nations whose memory history has transmitted to us, none have been so eminently distinguished for their literary accomplishments, as well as acquaintance with the polite arts, as the Greeks; nor are we as yet acquainted with a language posessed of so many advantages, with so few defects, as that which they used, and which continues till to be known by their name.—The necessary connection between the progress of knowledge and the improvement of language has been already explained; so that it will not be surprising to find their progress in the one keep pace with that of the other:—but it will be of utility to point out some advantages which that distinguished people posessed, which other nations, perhaps not less distinguished for talents or taste, have not enjoyed, which has contributed to render their language the most universally admired in ancient as well as in modern times.

As it is probable, that many different societies of men, in the early ages of antiquity, may have found themselves in such circumstances as to be obliged to invent a language to themselves; each would naturally adopt those founds into their language which chance might suggest, or were most agreeable to their perception of harmony, or most consonant to the disposition of mind of the original inventors; in the same manner as we see that each composer of music has a particular species of sounds, for which he is fonder than any other, which will predominate through all his compositions, and give them a certain characteristic tone by which they may be distinguished from that of other composers:—So the language of each particular set of people would have originally a certain characteristic tone of harmony, which would distinguish it from all others; and behaved to be more or less perfect, according to the greater or less degree of that delicate sense of harmony, distinguished by the name of taste, which these original inventors were posessed of. These founds, then, being once established by custom, would become familiar to the ear of the descendents of these particular tribes:—new words would be invented as knowledge increased; but these behoved to be modulated so as to be agreeable to the general tenor of their language, from the necessity of making it consonant as well to the organs of hearing as the organs of speech. Hence it happens, that the characteristic tones of a language are preserved much longer without variation than any other particular relating to it; and if it change at all, the change must be slow and imperceptible. Knowledge after this may increase;—taste may be improved;—it may be perceived that the language is not copious enough to express the ideas, or harmonious enough to please the ear of the composer;—he may readily invent words to supply the deficiency in that respect; but the sounds in a great measure remain without the reach of his power, and he must rest satisfied with these, such as they are, without attempting innovations.——Happy therefore, in this respect, must we deem those nations, whose earliest ancestors have been so fortunate as to adopt no unharmonious founds into their language, whereby they are freed from one bar to the cultivating those refined pleasures which proceed from the use of a delicate taste, which others may perhaps never be able to surmount:—and in this respect no nation was ever so eminently distinguished as the
the Greeks; which no doubt contributed its share to promote that general elegance and harmony of proportion which prevailed in all their arts. The original sounds and fundamental tones of that language are the most harmonious, and the most agreeable to the ear, of any that have hitherto been invented; insomuch, that from this principle alone the sound of their language is agreeable to every nation who have heard it, even when the meaning of the words are not understood; whereas almost all other languages, till they are understood, appear, to an ear which has not been accustomed to them, jarring and discordant. This is the fundamental excellence of that justly admired language; nor have the people failed to improve this to the utmost of their power, by many aids of their own invention. —The Greek language is of the transpositive kind: but a people so lively, so acute, and so loquacious, could ill bear the ceremonious restraint which that mode of language naturally subjected them to; and have therefore, by various methods, freed it in a great measure from the stiffness which that produced. In inflicting their nouns and verbs, they sometimes prefix a syllable, and sometimes add one; which, besides the variety that it gives to the sounds of the language, adds greatly to the distinctness, and admits of a more natural arrangement of the words than in the Latin, and of consequence renders it much fitter for the easiness of private conversation: and indeed, the genius of the people so far prevailed over the idiom of the language, as to render it, in the age of its greatest perfection, capable of being much easier, and requiring much less time for the formation of words, as those languages which have been called analogous. But as those nations who spoke this language were all governed by popular assemblies, and as no authority could be obtained among them but by a skill in rhetoric and the powers of persuasion; it became necessary for every one, who wished to acquire power or consideration in the state, to improve himself in the knowledge of that language, in the use of which alone he could expect honours or reputation. Hence it happened, that while the vivacity of the people rendered it easy, the great men studiously improved every excellence that it could reap from its powers as a transpositive language; so that, when brought to its utmost perfection by the amazing genius of the great Demosthenes, it attained a power altogether unknown to any other language. —Thus happily circumstanced, the Greek language arrived at that envied pre-eminence which it still justly retains. From the progress of arts and sciences; from the gaiety and inventive genius of the people; from the number of free states into which Greece was divided, each of which invented words of its own, all of which contributed to the general stock; and from the natural commutation which took place between these states, which excelled in the greatest degree the talents of the people; it acquired a copiousness unknown to any ancient language, and excelled by few of the moderns. —In point of harmony of numbers, it is altogether unrivalled; and on account of the ease as well as dignity which it admitted of from the caesuras assigned above, it admits of perfection in a greater number of particular kinds of composition than any other language ever known.

—The irresistible force and overwhelming impetuosity of

The Romans, a people of fierce and warlike dispositions, for many ages during the infancy of their republic, more intent on pursuing conquests and military glory, than in making improvements in literature or the fine arts, bestowed little attention to their language. Of a disposition lefs formal and more phlegmatic than the Greeks, they gave themselves no trouble about rendering their language fit for conversation; and it remained strong and nervous, but, like their ideas, was limited and confined. More disposed to command respect by the power of their arms than by the force of persuasion, they despised the more effeminate powers of speech: so that, before the Punic wars, their language was perhaps more revered and uncourtly than any other at that time known. —But after their rival Carthage was destroyed, and they had no longer that powerful curb upon their ambition; when riches flowed in upon them by the multiplicity of that conquests; —luxury began to prevail, the stern austerity of their manners to relax, and selfish ambition to take place of that disinterested love for their country so eminently conspicuous among all orders of men before that period. —Popularity began then to be courted: ambitious men, finding themfelves not possessed of that merit which infected them succeds with the virtuous senate, amased the mob with artful and seductive harangues; and by making them believe that they were possessed of all power, and had their sacred rights encroached upon by the senate, led them about at their pleasure, and got themselves exalted to honours and riches by these ingenuous arts. It was then the Romans first began to perceive the use to which a command of language could be put. —Ambitious men then studied it with care, to be able to accomplish their ends; while the more virtuous were obliged to acquire a skill in this, that they might be able to repel the attacks of their adversaries. —Thus it happened, that in a short time that people, from having entirely neglected, began to study their language with the greatest affiduity; and as Greece happened to be subjected to the Roman yoke about that time, and a friendly intercourse was establisht between those two countries, this greatly conpired to nourish in the
minds of the Romans a taste for that art of which they had lately become so much enamoured. Greece had, long before this period, been corrupted by luxury; their taste for the fine arts had degenerated into unnecessary refinement; and all their patriotism confided in popular harangues and unmeaning declamation. Oratory was then studied as a refined art; and all the subtleties of it were taught by rule, with as great care as the gladiators were afterwards trained up in Rome. But while they were thus idly trying who should be the lord of their own people, the nerves of government were relaxed, and they became an easy prey to every invading power. In this situation they became the subjects, under the title of the allies, of Rome, and introduced among them the same taste for haranging which prevailed among themselves. Well acquainted as they were with the powers of their own language, they set themselves with unwearied assiduity to polish and improve that of their new masters: but with all their assiduity and pains they never were able to make it arrive at that perfection which their own language had acquired; and in the Augustan age, when it had arrived at the summit of its glory, Cicero bitterly complains of its want of copiousness in many particulars.

But as it was the desire of all who studied this language with care, to make it capable of that lately digested dignity and pomp necessary for public harangues; they followed the genius of the language in this particular, and in a great measure neglected those lesser delicacies which form the pleasure of domestic enjoyment: so that, while it acquired more copiousness, more harmony, and precision, it remained stiff and inflexible for conversation; nor could the minute distinction of nice grammatical rules be ever brought down to the apprehension of the vulgar; so that the language spoken among the lower classes of people remained rude and unpolished even till the end of the monarchy. The Huns who over ran Italy, incapable of acquiring any knowledge of such a difficult and abstruse language, never adopted it; and the native inhabitants being made acquainted with a language more natural and easily acquired, quickly adopted that idiom of speech introduced by their conquerors, although they still retained many of those words which the confined nature of the barbarian language made necessary to allow them, to express their ideas.—And thus it was that the language of Rome, that proud mistress of the world, from an original defect in its formation, although it had been carried to a perfection in other respects far superior to any northern language at that time, easily gave way to them, and in a few ages the knowledge of it was lost among mankind: while, on the contrary, the more easy nature of the Greek language has still been able to keep some flight footing in the world, although the nations in which it has been spoken have been subjected to the yoke of foreign dominion for upwards of two thousand years, and their country has been twice ravaged by barbarous nations, and more cruelly depopulated than ever the Romans were.

From the view which we have already given of the Latin language, it appears evident, that its idiom is naturally subjected: nor could it boast of such favourable alleviating circumstances as the Greek, the prevailing sounds of the Latin being far less harmonious to the ear; and although the formation of the words are such as to admit of full and distinct sounds, and so modulated as to lay no restraint upon the voice of the speaker; yet, to a person unacquainted with the language, they do not convey that enchanting harmony so remarkable in the Greek language. The Latin is flatly and solemnly, it does not excite delight; but at the same time it does not charm the ear, so as to make it listen with pleased attention. To one acquainted with the language indeed, the nervous boldness of the thoughts, the harmonious rounding of the periods, the full solemn swelling of the sounds, so distinguishable in the most eminent writers in that language which have been preferred to us, all conspire to make it pleasing and agreeable.—In these admired works we meet with all its beauties, without perceiving any of its defects; and we naturally admire, as perfect, a language which is capable of producing such excellent works.—Yet with all these seeming excellencies, this language is less copious, and more limited in its style of composition, than many modern languages far less capable of precision and accuracy than almost any of these, and infinitely behind them all in point of easiness in conversation. But these points have been so fully proved already, as to require no further illustration.—Of the compositions in that language which have been preferred to us, the orations of Cicero are best adapted to the genius of the language, and we there see it in its utmost perfection. In the philosophical works of that great author we perceive some of its defects; and it requires all the powers of that great man, to render his epistles agreeable, as these have the genius of the language to struggle with.—Next to oratory, history agrees with the genius of this language; and Caesar, in his Commentaries, has exhibited the language in its purest elegance, without the aid of pomp or foreign ornament. Among the Poets, Virgil has best adapted his works to his language. The flowing harmony and pomp of it is well adapted for the epic strain, and the correct delicacy of his taste rendered him perfectly equal to the task. But Horace is the only poet whose force of genius was able to overcome the bars which the language threw in his way, and succeed in lyric poetry. Were it not for the brilliancy of the thoughts, and acuteness of remarks, which so eminently distinguish this author's compositions, his odes would long ere now have sunk into utter oblivion. —But so conscious have all the Roman poets been of the unfitness of their language for easy dialogue; that almost none of them, after Plautus and Terence, have attempted any dramatic compositions in that language. —Nor have we any reason to regret that they neglected this branch of poetry, as it is probable, if they had ever become fond of these, they would have been obliged to have adopted so many unnatural contrivances to render them agreeable, as would have prevented us (who of course would have considered ourselves as bound to follow them) from making that progress in the drama which so particularly distinguishes the productions of modern times. —The modern Italian language, from an inattention quite common in literary subjects, has been usually called a child.
child of the Latin language, and is commonly believed
to be the ancient Latin a little debased by the mixture of
the barbarous language of those people who conquered I-
taly. The truth is, it is directly the reverse: for this
language, in its general idiom, and fundamental princi-
pies, is evidently of the analogous kind, first introduced
by the fierce invaders, although it has borrowed many
of its words, and some of its modes of phraseology, from
the Latin, with which they were so intimately blended
that this could scarcely be avoided; and it has been from
remarking this slight connexion so obvious at first sight,
that superficial observers have been led to draw this gen-
eral conclusion. So contrary to fact.

When Italy was over-run with the Lombards, and the
empire destroyed by these northern invaders, they, as
conquerors, continued to speak their own native language.
Fierce and illiterate, they would not stoop to the servility
of studying a language so clogged with rules, and difficult
of attainment, as the Latin behoved to be to a people al-
together unacquainted with such grammatical distinctions:
while the Romans of necessity were obliged to study the
language of their conquerors, as well to obtain some re-
 lief of their grievances by prayers and supplications, as
to destroy that odious distinction which subsisted between
the conquerors and conquered while they continued as
different people. As the language of their new masters,
although rude and confined, was natural in its order, and
easy to be acquired, the Latins would soon attain a com-
petent skill in it: and as they bore such a proportion to
the whole number of people, the whole language behoved
to partake somewhat of the general sound of the former:
for, in spite of all their efforts to the contrary, the organs
of speech could not at once be made to acquire a perfect
power of uttering any accustomcd sounds; and as the
language of the barbarians behoved to be much less cop-
pious than the Latin, whenever they found themselves at
a loss for a word, they would naturally adopt those which
most readily presented themselves from their new sub-
jects. Thus a language in time was formed, somewhat
resembling the Latin, both in the general tenor of the
sounds, and in the meaning of many words; and as the
barbarians gave themselves little trouble about language,
and in some cases perhaps hardly knew the general ana-
logy of their own language, it is not surprising if their
new subjects should find themselves sometimes at a loss on
that account, or if, in these situations, they followed,
with some occasions, the analogy suggested to them by
their own: which accounts for the strange degree of
mixture of heterogeneous grammatical analogy we meet
with in the Italian as well as Spanish and French lan-
guages.—The Idiom of all the Gothic languages is purely
analogous; and in all probability, before their mixture
with the Latins and other people in their provinces,
the several grammatical parts of speech followed the
plain simple idea which that supposes; the verbs and nouns
were all probably varied by auxiliaries, and their adje-
tives retained their simple unalterable state: but by their
mixture with the Latins, this simple form has been in
many cases altered; their verbs became in some cases
inflected; but their nouns in all these languages still re-
tained their original form; although they have varied
their adjectives, and foolishly clogged their nouns with
gender, according to the Latin idioms. From this het-
erogeneous, and fortuitous (as we may say, because in-
judicious) mixture of parts, results a language posses-
ning almost all the defects of each of the languages of
which it is composed; with few of the excellencies of either:
for it has neither the ease and precision of the analo-
gous, nor the pomp and boldness of the transplanted
languages; at the same time that it is clogged with almost
as many rules, and liable to as great abuses.

These observations are equally applicable to the French,
and Spanish, as to the Italian language.—With regard
to this last in particular, we may observe, that as the
natural inhabitants of Italy, before the last invasion
of the barbarians, were funk and enervated by luxury
and that depreffion of mind and genius which anarchy
always produces; they had become fond of feating and
entertainments, and the enjoyment of sensual pleasures
conflituted their highest delight; and their language par-
took of the same debility as their body.—The barba-
rians too—unaccustomed to the seductions of pleasure
soon fell from their original boldness and intrepidity,
and, like Hannibal's troops of old, were eneravted by
the sensual gratifications into which a nation of conquerors
unaccustomed to the restraint of government freely ind-
dulged.—The softness of the air—the fertility of the
climate—the unaccustomed flow of riches which they at
once acquired,—together with the voluptuous manner
of their conquered subjects,—all conpired to ener-
vate their minds, and render them soft and effeminate.—
No wonder then, if a language new-moulded should at
this juncture partake of the genius of the people who
formed it; and instead of participating of the martial
boldness and ferocity of either of their ancestors, should
be softened and enfeebled by every device which an effemi-
ate people could invent.—The strong consonants which
terminated the words, and gave them life and boldness,
being thought too harfly for the delicate ears of these sons
of sloth, were banifhed their language;—while sonorous
vowels, which could be protraded to any length in muflce,
were substituted in their stead.—Thus the Italian lan-
guage is formed flowing and harmonious, but deftitute
of those nerves which constitute the strength and vigour
of a language; at the same time, the sounds are neither
euough diversified, nor in themselves of such an agreeable
tone, as to afford great pleasure without the aid of mu-
ical notes;—and the small pleasure which this affords is still
lesened by the little variety of measure which the great
similarity of the termination of words occasions.—Hence
it happens, that this language is fitted for excelling in
fewer branches of literature than almost any other;—and
although we have excellent historians, and more than or-
dinary poets, in this language; yet they labour under
great inconveniences from the language in which they
write,—as it wants nerves and lineatenfs for the for-
nar,—and sufficient variety of modulation for the lat-
ter. It is, more particularly on this account, altogether
unfit for an epic poem:—and although attempts have been
made in this way by two men, whose genius, if not
fettered by the language, might have been crowned
with success; yet these, notwithstanding the fame that
with
with some they may have acquired, must, in point of poetic harmony, be deemed defective by every impartial person. Nor is it possible that a language which hardly admits of poetry without rhymes, can ever be capable of producing a perfect poem of great length; and the stanza to which their poets have ever confined themselves, must always produce the most disagreeable effect in a poem where unrestrained pomp or pathos are necessary qualifications. The only species of poetry in which the Italian language can claim a superior excellence, is the tender tone of elegy: and here it remains unrivalled and alone,—the plaintive melody of theounds, and smooth flow of the language, seem perfectly adapted to express that soothing melancholy which this species of poetry requires.—On this account, the plaintive stanzas of the Paflor Fido of Guarini have justly gained to that poem an universal applause; although, unless on this account alone, it is perhaps inferior to almost every other poem of the kind which ever appeared.—We must observe with surprise, that the Italians, who have fettered every other species of poetry with the severest shackles of rhyme, have in this species shewed an example of the most unrestrained freedom; the happy effects of which ought to have taught all Europe the powerful charms attending it: yet with amazement we perceive, that scarce an attempt to imitate them has been made by any poet in Europe except by Milton in his Lycidas; no dramatic poet, even in Britain, having ever adopted the unrestrained harmony of numbers to be met with in this and many other of their best dramatic compositions.

Of all the languages which sprung up from the mixture of the Latins with the northern people on the destruction of the Roman empire, none of them approach so near to the genius of the Latin as the Spanish does. For as the Spaniards have been always remarkable for their military prowess and dignity of mind, their language is naturally adapted to express ideas of that kind. Sonorous and solemn, it admits nearly of as much dignity as the Latin, For conversation, it is the most elegant and courteous language in Europe.—The humane and generous order of chivalry was first invented and kept its footing longest in this nation; and although it run at laft into such a ridiculous excess as defervedly made it fall into universal disrepute, yet it left such a strong tincture of romantic heroism upon the minds of all ranks of people, as made them jealous of their glory, and strongly emulous of cultivating that heroic politeness, which they considered as the highest perfection they could attain. Every man disdained to flatter, or to yield up any point of honour which he possessed: at the same time, he rigorously exacted from others all that was his due. These circunstances have given rise to a great many terms of respect, and courteous condescension, without meanness or flattery, which give their dialogue a respectful politeness and elegance unknown to any other European language. This is the reason why the characters so finely drawn by Cervantes in Don Quixote are still unknown to all but those who understand the language in which he wrote.—Nothing can be more unlike the gentle meekness and humane heroism of the knight, or the native simplicity, warmth of affection, and respectful loquacity of the squire,—than the inconsistent follies of the one, or the impertinent forwardness and disrespectful petulance of the other, as they are exhibited in every English translation.—Nor is it possible to represent so much familiarity, united with such becoming condescension in the one, and safe-guad deference in the other, in any other European language, as is necessary to paint these two admirable characters.

Although this language, from the solemn dignity and majestic elegance of its structure, is perhaps better qualified than any other modern one for the sublime strains of epic poetry; yet as the poets of this nation have all along imitated the Italians by a most servile subjection to rhyme, they never have produced one poem of this fort, which in point of poetry of style deserves to be transmitted to posterity. And in any other species of poetry but this, or the higher tragedy, is it not naturally fitted to excel. But although the drama and other polite branches of literature were early cultivated in this country, and made confidereable progress in it, before the thrill of gain debased their souls, or the desire of universal dominion made them forfeit that liberty which they once so much prized; since they became enervated by an overbearing pride, and their minds enslaved by superstition; all the polite arts have been neglected: so that, while other European nations have been advancing in knowledge, and improving their language, they have remained in a state of torpid inactivity; and their language has not arrived at that perfection which its nature would admit, or the acute genius of the people would have made us naturally expect.

It will perhaps, by some, be thought an unpardonable infult, if we do not allow the French the preference of all modern languages in many respects. But so far milt we pay a deference to truth, as to be obliged to rank it among the poorest languages in Europe.—Every other language has some sounds which can be uttered clearly by the voice: even the Italian, although it wants energy, still possesses diffinutenesses of articulation. But the French is almost incapable of either of these beauties; for in that language the vowels are so much curtained in the pronunciation, and the words run into one another in such a manner, as of necessity to produce an indistinguishniness of articulation. But this language is in a great measure incapable of poetic modulation, and rhyme has been obliged to be sublimated in its stead: so that this poorest of all contrivances which has ever yet been invented to diffuish poetry from prose, admitted into all the modern languages when ignorance prevailed over Europe, has still kept some footing in the greatest part of these, rather through a deference for established customs, than from any necessity.—Yet as the French language admits of so little poetic modulation, rhyme is in some measure necessary to it; and therefore they have adopted, and dignified this poor deviation from prose with the name of Poetry; and, by their blind attachment to this art, have neglected to improve so much as they might have done the small powers for harmony that their language is possessed of; and, by being long accustomed to this false taste, have become fond of it to such a ridiculous excess, as to have all their tragedies,—nay even their comedies, in rhyme. While the poet is obliged to enervate his language, and check the flow of composition, for the
the sake of linking his lines together, the judicious actor finds more difficulty in destroying the appearance of that measure, and preventing the clinking of the rhymes, than in all the rest of his talk.——After this we will not be surprised to find Voltaire attempt an epic poem in this species of poetry; although the more judicious Fenelon in his Telemage had shown to his countrymen the only species of poesy which their language could admit of for any poem which aspired to the dignity of the epic strain,—Madam Despouliers, in her Amours, has shown the utmost extent of harmony to which their language can attain in smaller poems;—indeed in the tenderness of an elegy, or the gravity of a song, it may succeed; but it is so deific of force and energy, that it can never be able to reach the Pindaric, or even perhaps the Lyric strain,—as the intellectual efforts even of the harmonious Roufeau, in his translation of the Psalms of David of this stamp, may fully convince us.

With regard to its power in other species of composition, the sententious rapidity of Voltaire, and the more nervous dignity of Roufeau, afford us no small presumption, that, in a skilful hand, it might acquire so much force, as to transmit to futurity historical facts in a style not altogether unworthy of the subject——in attempts at pathetic declamation, the superior abilities of the composer may perhaps on some occasions excite a great idea, but this is ever cramped by the genius of the language: and although no nation in Europe can boast of so many orations where the sense of the words are foil in fugues, quavers, and indeed, that in modern times, in which so little attention is bestowed on the simple and sublime charms of pathetic expression, it must of course be naturally admitted into the courts of princes, and assemblies of great personages; who, having fewer equals with whom they can associate, are more under a necessity of conversing with strangers, in whose company the tender stimulus of friendship does not so naturally expand the heart to mutual trust or unrestrained confidence. In these circumstances, as the heart remaineth disengaged, conversion must necessarily flag; and mankind in this situation will gladly adopt that language in which they can converse most easily without being deeply interested——One these accounts the French now is, and probably will continue to be reckoned the most polite language in Europe, and therefore the most generally studied and known: nor should we envy them this distinction, if our countrymen would not weaken and enervate their own manly language, by adopting too many of their unmeaning phrases.

The English is perhaps possessed of a greater degree of excellence, blended with a greater number of defects, than any of the languages that we have hitherto mentioned.——As the people of great Britain are a bold, daring, and impetuous race of men; subject to strong passions, and, from the absolute freedom and independence which reigns among all ranks of people throughout this happy isle, little solicitous about controlling these passions:——our language takes its strongest characteristic distinction from the genius of the people; and, being bold, daring, and abrupt, is admirably well adapted to express those great emotions which spring up in an intrepid mind at the prospect of interesting events. Peculiarly happy too in the full and open sound of the vowels, which forms the characteristic tone of the language, and in the strong use of the aspirate H in almost all those words which are used as exclamations, or marks of strong emotions upon interesting occasions, that particular class of words called interjections have, in our language, more of that fulness and unrestrained freedom of tones, in which their chief power consists, and are pushed forth from the inmost recesses of the soul in a more forcible and unrestrained manner, than any other language whatever. Hence it is

* An author of great discernment, and well acquainted with the French language, has lately made the same remark; and as the lofsines of his genius often prevents him from bringing down his illustrutions to the level of ordinary comprehension, he has on this, and many other occasions, been unjustly accused of being fond of paradoxes.——But as music never produces its full effect but when the tones it attunes are in unison with the idea that the words naturally excite, it of necessity follows, that if the words of any language do not admit of that fulness of sound, or of that species of tones, which the passion or affection that may be describ'd by the words would naturally require to excite the same idea in the mind of one who was unacquainted with the language, it will be impossible for the music to produce its full effect, as it will be cramped and confined by the sound of the words;——and as the French language does not admit of those full and open sounds which are necessary for pathetic expression in music, it must of course be unfit for musical composition.——It is true indeed, that in modern times, in which so little attention is bestowed on the simple and sublime charms of pathetic expression, and a fantastical tingling of unmeaning sounds is called music——where the sense of the words is lost in fugues, quavers, and unnecessary repetition of particular syllables,——all languages are nearly equally fitted for it; and among these the French: nor is it to be doubted, that, in the easy gaiety of a song, this language can properly enough admit of all the musical expression which that species of composition may require.
more peculiarly adapted for the great and interesting scenes of the Drama than any language that has yet appeared in the globe.—Nor has any other nation ever arrived at that perfection which the English may justly claim in that respect; for however faulty our dramatic compositions may be in some of the critical niceties which relate to this art,—in nervous force of diction, and in the natural expression of those great emotions which constitute its soul and energy, we claim, without dispute, an unrivalled superiority.—Our language too, from the great intercourse that we have had with almost all the nations of the globe by means of our extensive commerce, and from the eminent degree of perfection which we have attained in all the arts and sciences, has acquired a copiousness beyond what any other modern nation can lay claim to; and even the most partial favourers of the Greek-language are forced to acknowledge, that in this respect it must give place to the English. Nor is it less happy in that facility of construction which renders it more peculiarly adapted to the genius of a free people, than any other form of language.—Of an idiom purely analogous, it has deviated less from the genius of that idiom, and possesses more of the characteristic advantages attending it, than any other language that now exists: for, while others, perhaps by their more intimate connexion with the Romans, have adopted some of their transpositions, and clogged their language with unnecessary letters, we have preferred ourselves free from the contagion, and still retain the primitive simplicity of our language. Our verbs are all varied by auxiliaries (except in the infinse we have already given, which is so much in our favours); our nouns remain free from the perplexing embarrassment of genders, and our pronouns mark this distinction where necessary with the most perfect accuracy; our articles also are of course freed from this unnatural encumbrance, and our adjectives preserve their natural freedom and independence. From these causes, our language follows an order of construction so natural and easy, and the rules of syntax are so few and obvious, as to be within the reach of the most ordinary capacity. So that from this, and the great clearness and distinctness of meaning which this mode of construction necessarily is accompanied with, it is much better adapted for the familiar intercourse of private society, and liable to fewer errors in using it, than any other language yet known; and on this account we may boast, that in no nation of Europe do the lower classes of people speak their language with so much accuracy, or have their minds so much enlightened by knowledge, as those of great Britain.—What then shall we say of the deficiency of those grammarians, who are every day echoing back to one another complaints of the poverty of our language on account of the few and simple rules which it requires in syntax? As jutly might we complain of an invention in mechanics, which, by means of one or two simple movements, obvious to an ordinary capacity, little liable to accidents, and easily put in order by the rudest hand, should pollute the whole powers of a complex machine, which had required an infinite apparatus of wheels and contrary movements, the knowledge of which could only be acquired, or the various accidents to which it was exposed by using it be repaired, by the powers of an ingenious artist, as complain of this characteristic excellence of our language as a defect.

But if we thus enjoy an eminent degree the advantages attending an analogous language; we likewise feel in a considerable measure the defects to which it is exposed; as the number of monosyllables with which it always must be embarrased, notwithstanding the great improvements which have been made in our language since the revival of letters in Europe, prevents in some degree that swelling fulness of sound which so powerfully contributes to harmonious dignity and graceful cadences in literary compositions.—And as the genius of the people of Britain has always been more disposed to the rougher arts of command, than the softer inducements of persuasion, no pains have been taken to correct these natural defects of our language; but on the contrary, by an inattention of which we have hardly a parallel in the history of any civilized nation, we meet with many instances, even within this last century, of the harmony of sound being sacrificed to that brevity so desirable in conversation, as many elegant words have been curtailed, and harmonious syllables suppressed, to substitute in their stead others, shorter indeed, but more barbarous and uncouth. Nay, so little attention have our forefathers bestowed upon the harmony of sounds in our language, that one would be tempted to think, on looking back to its primitive state, that they had on some occasions flidiously debased it.—Our language, at its first formation, seems to have laboured under a capital defect in point of sound, as such a number of S's enter into the formation of our words, and such a number of letters and combinations of other letters assume a similar sound, as to give a general hiss through the whole tenor of our language, which must be exceedingly disagreeable to every unprejudiced ear. We would therefore have naturally expected, that at the revival of letters, when our forefathers became acquainted with the harmonious languages of Greece and Rome, they would have acquired a more correct taste, and endeavoured, if possible, to have diminished the prevalence of this disgusting sound. But so far have they been from thinking of this, that they have multiplied this letter exceedingly. The plurals of almost all our nouns were originally formed by adding the harmonious syllable en to the singular, which has given place to the letter s; and instead of house, formerly, we now say houses. In like manner, many of the variations of our verbs were formed by the syllable eth, which we have likewise changed into the same disagreeable letter; so that, instead of loves, moveth, writeth, walketh, &c. we have changed them into the more modish form of loves, moves, writs, walk, &c.—Our very auxiliary verbs have suffered the same change; and instead of bath and doth, we now make use of has and does. From these causes, notwithstanding the great improvements which have been made in language, within these few centuries, in other respects; yet, with regard to the pleasingness of sound alone, it was perhaps much more perfect in the days of Chaucer than at present: and although custom may have rendered these sounds so familiar to our ear, as not to affect us much; yet to an unprejudiced person, unacquainted with our language, we have
have not the smallest doubt, but the language of Bacon or Sydney would appear more harmonious than that of Robertson or Hume. —This is indeed the fundamental defect of our language, and loudly calls for reformation. Robertfon or Hume. —This is indeed the fundamental causation, and the nervous force which it derives from the acquaintance with the meaning of our words; yet to those which allow in the choice of words proper for the occasion, and the nervous force which it derives from the accent, with the perspicuity and graceful elegance the emphasis befalls upon it, makes this defect be totally overlooked; and we could produce such numerous works of prose which excel in almost every different style of composition as would be tiresome to enumerate; and every reader of taste and discernment will be able to recollect a sufficient number of writings which excel in point of style, between the graceful and becoming gravity so conspicuous in all the works of the author of the Whole Duty of Man, and the animated and nervous diction of Robertson in his history of Charles the fifth, the more flowery stile of Shaftsbury, or the Attic simplicity and elegance of Addison. But although we can equal, if not surpass, every modern language in works of prose, it is in its poetical powers that our language shines forth with the greatest lustre. —The brevity to which we must here necessarily confine ourselves, prevents us from entering into a minute examination of the poetical powers of our own, compared with other languages; otherwife it would be easy to shew, that every other modern language labours under great restraints in this respect which ours is freed from; that our language admits of a greater variety of poetic movements, and diversity of cadence, than any of the admired languages of antiquity; that it distinguishes with the greatest accuracy between accent and quantity, and is poiffed of every other poetic excellence which their languages were capable of: so that we are poiffessed of all the fources of harmony which they could boast; and, besides all these, have one superadded, which is the caufe of greater variety and more forcible expression in numbers than all the rest; that is, the unlimited power given to the emphasis over quantity and cadence; by means whereof, a necessary union between sound and sense, numbers and meaning, in verification, unknown to the ancients, has been brought about, which gives our language in this respect a superiority over all those jointly admired languages. —But as we cannot here further pursue this subject, we shall only observe, that these great and distinguishing excellencies far more than counterbalance the inconveniences that we have already mentioned; and although, in more pleasantness of sounds, or harmonious flow of syllables, our language may be inferior to the Greek, the Latin, Italian and Spanish; yet in point of manly dignity, graceful variety, intuitive definiteness, nervous energy of expression, unconstrained freedom and harmony of poetic numbers, it will yield the palm to none. —Our immortal Milton, slowly rising, in graceful majesty stands up as equal, if not superior in these respects to any poet, in any other language, that ever yet existed; —while Thomson, with more humble aim, in melody more smooth and flowing, softens the soul to harmony and peace: —the plaintive mean of Hammond calls forth the tender tear and sympathetic sigh; while Gray's more soothing melancholy fixes the sober mind to slient contemplation: —more tender still than these, the amiable Shenfon comes; and from his Doric reed, still free from courtly affectation, flows a strain so pure, so simple, and of such tender harmony, as even Arcadian shepherds would be proud to own. But far before the rest, the daring Shakespeare steps forth conspicuous, clothed in native dignity; and, pressing forward with unremitting ardour, boldly lays claim to both dramatic crowns, held out to him by Thalia and Melpomene: —his rivals, far behind, look up, and envy him for these unfading glories; and the admired nations round, with diñant awe, behold and tremble at his daring flight. —Thus the language, equally obedient to all, bends with ease under their hands, whatever form they would have it assume; and, like the yielding wax, readily receives, and faithfully transmits to posterity, those impressions which they have flamped upon it. —Such are the principal outlines of the language of Great Britain, such are its beauties, and such its most capital defects; a language more peculiarly circumstanced than any that has ever yet appeared. —It is the language of a great and powerful nation, whose fleets surround the globe, and whose merchants are in every port; a people admired, or revered by all the world; —and yet it is less known in every foreign country, than any other language in Europe. —In it are written more perfect treatises on every art and science, than are to be found in any other language; —yet it is less fought after or esteemed by the literati in any part of the globe, than almost any of these. Its superior powers for every purpose of language are sufficiently obvious from the models of perfection, in almost every particular, which can be produced in it; —yet it is neglected, despifed, and vilified by the people who use it; and many of those authors who owe almost the whole of their fame to the excellence of the language in which they wrote, look upon that very language with the highest contempt. —Neglected and despifed, it has been trodden under foot as a thing altogether unworthy of cultivation or attention. Yet in spite of all these inconveniences, in spite of the many wounds it has thus received, it still holds up its head, and preserves evident marks of that comeliness and vigour which are its characteristic differentia. Like a healthy oak planted in a rich and fertile soil, it has sprung up with vigour: —and although neglected, and suffered to be over-run with weeds; although exposed to every blast, and unprotected from every violence, it still beareth up under all these inconveniences, and shoots up with a robust healthiness and wild luxuriance of growth. Should this plant, so found and vigorous, be now cleared from those weeds with which it has been so much encumbered: —should every obstacle which now buries it under thick shades, and hides it from the view of every passenger, be cleared away: —should the soil be cultivated with care, and a strong fence be placed around it, to prevent the idle or the wicked from breaking or distorting its branches: —who can tell what additional vigour it would flourish, or what amazing magnitude and perfec-
tion it might at first attain!—How would the artificial world behold, with reverential awe, the majestic gracefulness of that object which they so lately despised!

It sends two members to parliament.

Launch, in the fea language, signifies to put out: as, launch the ship, that is, put her out of the dock; launch aft, or forward, speaking of things that are swallowed in the hold, is, put them more forward:

The root of the saffafra-tree is brought to us in long straight pieces, very light, and of a spongy texture, covered with a rough fungsack bark; outwardly of an ashy colour, inwardly of the colour of rusty iron. It has a fragrant smell, and a sweetish aromatic subacid taste: the bark tasts much stronger than any other part; and the small twigs stronger than the large pieces. As to the virtues of this root, it is a warm aperient and corrobator; and frequently employed, with good success, for purifying and sweetening the blood and juices. For these purposes, infusions made from the rasped root or bark may be drank as tea. In some constipations, these liquors, by their fragrance, are apt, on first taking them, to affect the head; in such cases, they may be advantageously freed from their flavour by boiling; a decoction of saffafra, boiled down to the confidence of an extract, proves simply bitterish and subacidstringent. Hoffman assures us, that he has frequently given this extract to the quantity of a scruple at a time, with remarkable success, for strengthening the tone of the visceras in cachexies; as also in the decline of intermittent fevers, and in hypochondriacal spasms. Saffafra yields in distillation an extremely fragrant oil, of a penetrating pungent taste, so ponderous (notwithstanding the lightness of the drug itself) as to sink in water. Rectified spirit extracts the whole tafs and smell of saffafra: and elevates nothing in evaporation: hence the spirituous extract proves the most elegant and efficacious preparations, as containing the virtue of the root entire.

The only official preparation of saffasra is the essential oil. The saffasra itself is an ingredient in the decoction of the woods and the compound lime waters, and the oil in the elixir guaiacum.

Lausanne, a city of Switzerland, in the canton of Bern, situated on the north side of the lake of Geneva: E. lon. 6° 31', and N. lat. 46° 33'.

Law may be defined, "The command of the sovereign power, containing a common rule of life for the subjects." It is divided into the law of nature, the law of nations, and civil or municipal law.
and comprehends all the duties we owe either to the Supreme Being, to ourselves, or to our neighbour; as reverence to God, self-defence, temperance, honour to our parents, benevolence to all, a strict adherence to our engagements, gratitude, &c. The law of nature, where it either commands or forbids, is immutable, and cannot be controlled by any human authority; but where that law does no more than confer a right, without obliging us to use it, the supreme power may divest us thereof, in whole or in part.

2. The law of nations is also the result of reason, and has God for its author; but it supposes mankind formed into several bodies politic, or states; and comprises all the duties which one state owes to another. These must of necessity be similar to the duties arising between individuals, since both are dictated by reason; so that what is the law of nature when applied to men considered simply as such, is indeed the law of nations when applied to kingdoms or states. From this source proceed the rights of war, the security of ambassadors, the obligations arising from treaties, &c. The particular usages of nations in their mutual correspondence

PRINCIPLES OF THE LAW OF SCOTLAND.

Title I. General Observations.

1. The municipal law of Scotland, as of most other countries, consists partly of statutory or written law, which has the express authority of the legislative power; partly of customary or unwritten law, which derives force from its presumed or tacit consent.

2. Under our statutory or written law is comprehended, (1.) Our acts of parliament: not only those which were made in the reign of James I. of Scotland, and from thence down to our union with England in 1707, but such of the British statutes enacted since the union as concern this part of the united kingdom.

3. The remains of our ancient written law were published by Sir John Skene clerk-regifter, in the beginning of the last century, by licence of parliament. The books of Regiam Majestatem, to which the whole collection owes its title, seem to be a syllabus of Scots law, written by a private lawyer at the command of David I.; and though no express confirmation of that treatise by the legislature appears, it is admitted to have been the ancient law of our kingdom by express statutes. The borough-laws, which were also enacted by the same king, David, and the statutes of William, Alexander II., David II. and the three Roberts, are universally allowed to be genuine. Our parliaments have once and again appointed commissions to revise and amend the Regiam Majestatem, and the other ancient books of our law, and to make their report; but, as no report appears to have been made, nor consequently any ratification by parliament, none of these remains are received, as of proper authority, in our courts; yet they are of excellent use in proving and illustrating our most ancient customs.

4. Our written law comprehends, (2.) The acts of federunt, which are ordinances for regulating the forms of proceeding before the court of seftion in the administration of justice, made by the judges, who have a delegated power from the legislature for that purpose. Some of these acts dip upon matter of right, which declare what the judges apprehend to be the law of Scotland, and what they are to observe afterwards as a rule of judgment.

5. The civil or Roman and canon laws, though they are not perhaps to be deemed proper parts of our written law, have undoubtedly had the greatest influence in Scotland. The powers exercised by our sovereigns and judges have been justified upon no other ground, than that they were conformable to the civil or canon laws; and a special statute was judged necessary, upon the recommendation, to refund such of their constitutions as were repugnant to the Protestant doctrine. From that period, the canon law has been little respected, except in questions of titles, patronages, and some few more articles of ecclesiastical right: But the Roman continues to have great authority in all cases where it is not derogated from by statute or custom, and where the genius of our law suffers us to apply it.

6. Our unwritten or customary law, is that which, without being expressly enacted by statute, derives its force from the tacit consent of king and people; which consent is presumed from the ancient custom of the community. Custom, as it is equally founded in the will of the lawgiver with written law, has therefore the same effects: Hence, as one statute may be explained by another, so a statute may be explained or repealed by the uniform practice of the community, and even go into dispute by a posterior contrary custom. But this power of custom to derogate from prior statutes, is generally confined by lawyers to statutes concerning private right, and does not extend to those which regard public policy.

7. An
7. An uniform tract of the judgments or decisions of the court of seclusion, is commonly considered as part of our customary law; and without doubt, where a particular custom is thereby fixed or proved, such custom of itself constitutes law: But decisions, though they bind the parties litigating, have not, in their own nature, the authority of law in similar cases; yet, where they continue uniform, great weight is justly laid on them. Neither can the judgments of the house of peers of Great Britain reach farther than to the parties in the appeal, since in these the peers act as judges, not as lawyers.

8. Though the laws of nature are sufficiently published by the internal suggestion of natural light, civil laws cannot be considered as a rule for the conduct of life, till they are notified to those whose conduct they are to regulate. The Scots acts of parliament were, by our most ancient custom, proclaimed in all the different shires, boroughs, and baron-courts of the kingdom. But after our statutes came to be printed, that custom was gradually neglected; and at last, the publication of our laws, at the market-crofs of Edinburgh, was declared sufficient; and they became obligatory forty days thereafter. British statutes are deemed sufficiently notified, without formal promulgation; either because the printing is truly a publication, or because every subject is, by a maxim of the English law, party to them, as being present in parliament, either by himself or his representative. After a law is published, no pretence of ignorance can excuse the breach of it.

9. As laws are given for the rule of our conduct, they can regulate future cases only; for past actions, being out of our power, can admit of no rule. Declaratory laws form no exception to this; for a statute, where it is declaratory of a former law, does no more than interpret its meaning; and it is included in the notion of interpretation, that it must draw back to the date of the law interpreted.

10. By the rules of interpreting statute-law received in Scotland, an argument may be used from the title to the act itself, a rubro ad nigrum; at least, where the rubric has been either originally framed, or afterwards adopted by the legislature. The preamble or narrative, which recites the inconveniences that had arisen from the act, the parties inducing the enactment, may also lead a judge to the general meaning of the statute. But the chief weight is to be laid on the statutory words.

11. Laws, being directed to the unlearned as well as the learned, ought to be construed in their most obvious meaning, and not explained away by subtle distinctions; and no law is to suffer a figurative interpretation, where the proper sense of the words is as commodious, and equally fitted to the subject of the statute. Laws ought to be explained so as to exclude absurdities, and in the sense which appears most agreeable to former laws, to the intention of the lawgiver, and to the general frame and structure of the constitution. In prohibitory laws, where the right of acting is taken from a person, solely for the private advantage of another, the consent of him, in whose behalf the law was made, shall support the act done in breach of it; but the consent of parties immediately interested has no effect in matters which regard the public utility of a state. Where the words of a statute are capable but of one meaning, the statute must be observed, however hard it may bear on particular persons. Nevertheless, as no human system of laws can comprehend all possible cases, more may be sometimes meant by the lawgiver than is expressed; and hence certain statutes, where extension is not plainly excluded, may be extended beyond the letter, to similar and omitted cases; others are to be confined to the statutory words.

12. A strict interpretation is to be applied, 1. To correlative statutes, which repeal or restrict former laws, and to statutes which enact heavy penalties, or restrain the natural liberties of mankind. 2. Laws, made on occasion of present exigencies in a state, ought not to be drawn to similar cases, after the pressure is over. 3. Where statutes establish certain solemnities as requisites to deeds, such solemnities are not supposable by equivalents; for solemnities lose their nature, when they are not performed specifically. 4. A statute, which enumerates special cases, is, with difficulty, to be extended to cases not expressed; but, where a law does not descend to particulars, there is greater reason to extend it to similar cases. 5. Statutes, which carry a dispensation or privilege to particular persons or societies, suffer a strict interpretation; because they derogate from the general law, and imply a burden upon the rest of the community. But at no rate can a privilege be explained to the prejudice of those in whose behalf it was granted. As the only foundation of customary law is usage, which confines in fact, such law can go no farther than the particular usage has gone.

13. All statutes, concerning matters specially favoured by law, receive an ample interpretation; as laws for the encouragement of commerce, or of any useful public undertaking, for making effectual the wills of dying persons, for restraining fraud, for the security of creditors, &c. A statute, though its subject-matter should not be a favourite of the law, may be extended to similar cases, which did not exist when the statute was made; and for which, therefore, it was not in the lawgiver's power to provide.

14. Every statute, however unfavourable, must receive the interpretation necessary to give it effect: And, on the other hand, in the extension of favourable laws, scope must not be given to the imagination, in discovering remote resemblances; the extension must be limited to the cases immediately similar. Where there is ground to conclude that the legislature has omitted a case out of the statute purposely, the statute cannot be extended to that case, lest it be ever more similar to the cases expressed.

Tit. 2. Of Jurisdiction and Judges in general.

1. The object of law are persons, things, and actions: among persons, judges, who are invested with jurisdiction, deliberate the first consideration. Jurisdiction is a power conferred upon a judge or magistrate, to take cognizance of, and decide causes according to law, and to carry his sentences into execution. That tract of ground, or district, within which a judge has the right of jurisdiction,
is called his territory: and every act of jurisdiction, exercised by a judge without his territory, either by pronouncing sentence, or carrying it into execution, is null.

2. The supreme power, which has the right of enacting laws, falls naturally to have the right of creating courts, and appointing judges, who may apply these laws to particular cases: But, in Scotland, this right has been always intrusted with the Crown, as having the executive power of the state.

3. Jurisdiction is either supreme, inferior, or mixed. That jurisdiction is supreme, from which there lies no appeal to a higher court. Inferior courts are those whose sentences are subject to the review of the supreme courts, and whose jurisdiction is confined to a particular territory. Mixed jurisdiction partakes of the nature both of the supreme and inferior: thus, the judge of the high court of Admiralty, and the commissaries of Edinburgh, have an universal jurisdiction over Scotland, and they can review the decrees of inferior admirals and commissaries: but since their own decrees are subject to the review of the courts of Seffion or Jurisdiction, they are, in that respect, inferior courts.

4. Jurisdiction is either civil or criminal: by the first, questions of private right are decided; by the other, crimes are punished. But, in all jurisdiction, though merely civil, there is a power inherent in the judge to punish, either corporally, or by a pecuniary fine, those who offend during the proceedings of the court, or who shall afterwards obstruct the execution of the sentence.

5. Jurisdiction is either privative or cumulative. Privative jurisdiction, is that which belongs only to one court, to the exclusion of all others. Cumulative, otherwise called concurrent, is that which may be exercised by any one of two or more courts, in the same cause. In civil cumulative jurisdiction, the private pursuer has the right of election before which of the courts he shall sue: but as, in criminal questions which are prosecuted by a public officer of court, a collision of jurisdiction might happen, through each of the judges claiming the exercise of their right, that judge, by whose warrant the delinquent is first cited or apprehended, (which is the first step of jurisdiction), acquires thereby (jure preventi) the exclusive right of judging in the cause.

6. All rights of jurisdiction, being originally granted in consideration of the fitness of the grantee, were therefore personal, and died with himself. But, upon the introduction of the feudal system, certain jurisdictions were annexed to lands, and descended to heirs, as well as the lands to which they were enfeated: but now all heritable jurisdictions, except those of admiraltry and a small portion referred to barons, are either abolished, or referred and annexed to the crown.

7. Jurisdiction is either proper or delegated. Proper jurisdiction, is that which belongs to a judge or magistrate himself, in virtue of his office. Delegated, is that which is communicated by the judge to another who acts in his name, called a depute or deputy. Where a deputy appoints one under him, he is called a sub-depute. No grant of jurisdiction, which is an office requiring personal qualifications, can be delegated by the grantee to another, without an express power in the grant.

8. Civil jurisdiction is founded, 1. Ratione domicilii, if the defender has his domicile within the judge’s territory. A domicile is the dwelling-place where a person lives with an intention to remain; and custom has fixed it as a rule, that residence for forty daysounds jurisdiction. If one has no fixed dwelling-place, e.g. a soldier, or a travelling-merchant, a personal citation against him within the territory is sufficient to found the judge’s jurisdiction over him, even in civil questions. As the defender is not obliged to appear before a court to which he is not subject, the pursuer must follow the defender’s domicile.

9. It is founded, 2. Ratione rei sitae, if the subject in question lie within the territory. If that subject be immovable, the judge, whose jurisdiction is founded in this way, is the sole judge competent, excluding the judge of the domi le.

10. Where one, who has not his domicile within the territory, is to be sued before an inferior court ratione rei sitae, the court of seffion must be applied to, whose jurisdiction is universal, and who, of course, grants letters of supplement to cite the defender to appear before the inferior judge. Where the party to be sued resides in another kingdom, and has an estate in this, the court of seffion is the only proper court, as the commune forum to all persons residing abroad; and the defender, if his estate be heritable, is considered as lawfully summoned to that court; by a citation at the market-cross of Edinburgh, and pier and shore of Leith: but where a stranger, not a native of Scotland, has only a moveable estate in this kingdom, he is deemed to be so little subject to the jurisdiction of our courts, that action cannot be brought against him till his effects are first attached by a warrant jure preventi, the court of seffion must be applied to, who apply the warrant to the supreme courts of seffion, or admiraltry, or from that within whose territory the subject is situated, at the suit of the creditor.

11. A judge may, in special cases, arrest or secure, the persons of such as have neither domicile nor estate within his territory, even for civil debts. Thus, on the border between Scotland and England, warrants are granted of course by the judge-ordinary of either side, against those who have their domicile upon the opposite side, for arresting their persons, till they give security judicio jlli: and even the persons of citizens or natives may be so secured, where there is just reason to suspect that they are in meditazione fugi, i.e. that they intend suddenly to withdraw from the kingdom; upon which suspicion, the creditor who applies for the warrant must make oath. An inhabitant of a borough-royal, who has furnished one who lives without the borough in meat, cloaths, or other merchandise, and who has no security for it but his own compt-book, may arrest his debtor, till he give security judicio jlli.

12. A judge may be declined, i.e. his jurisdiction disdained judicially, 1. Ratione causa, from his incompetency to the special cause brought before him. 2. Ratione sufficietia judicis; where either the judge himself, or his near kinman, has an interest in the suit. No judge can vote in the cause of his father, brother, or son, either by consanguinity or affinity; nor in the cause of his uncle or nephew by consanguinity.
Prorogated jurisdiction is that which is, by the consent of parties, conferred upon a judge, who, without such consent, would be incompetent. Where a judge is incompetent, every step he takes must be null, till his jurisdiction be made competent by the parties actual submission to it. It is otherwise where the judge is competent, but may be declined by the party upon privilege.

In order to prorogation, the judge must have jurisdiction, such as may be prorogated. Hence, prorogation cannot be admitted where the judge’s jurisdiction is excluded by statute. Yet where the cause is of the same nature with those to which the judge is competent, though law may have confined his jurisdiction within a certain sum, parties may prorogate it above that sum unless where prorogation is prohibited. Prorogation is not admitted in the king’s causes; for the interest of the Crown cannot be hurt by the negligence of its officers.

All judges must at their admission swear, 1. The oath of allegiance, and subscribe the assurance; 2. The oath of abjuration; and lastly, The oath of fidelity administration.

A party who has either properly declined the jurisdiction of the judge before whom he had been cited, or who thinks himself aggrieved by any proceedings in the cause, may, before decree, apply to the court of session to issue letters of advocation for calling the action from before the inferior court to themselves. The grounds therefore, upon which a party may pray for letters of advocation, are incompetency and iniquity. Under incompetency, is comprehended not only defect of jurisdiction, but all the grounds of declining a jurisdiction, in itself competent, arising either from sufficition of the judge, or privilege in the parties. A judge is said to commit iniquity, when he either delays justice, or pronounces sentence, in the exercise of his jurisdiction, contrary to law.

The court of session may not waft their time in trifles, no cause for a sum below twelve pound Sterling can be advocated to the court of session from the inferior judge competent: but if an inferior judge shall proceed upon a cause to which he is incompetent, the cause may be carried from him by advocation, let the subject be ever so inconsiderable.

The King, who is the fountain of jurisdiction, might by our constitution have judged in all causes, either in his own person, or by those whom he was pleased to vest with jurisdiction.

The parliament of Scotland, as our court of the last resort, had the right of reviewing the sentences of all our supreme courts.

By the treaty of union, 1707, the parliaments of Scotland and England are united into one parliament of Great Britain. From this period, the British house of peers, as coming in place of the Scots parliament, is become our court of the last resort, to which appeals lie from all the supreme courts of Scotland: But that court has no original jurisdiction in civil matters, in which they judge only upon appeal! By art. 22. of that treaty, the Scots share of the representation in the house of peers is fixed to sixteen Scots peers elective; and in the house of Commons, to forty-five commoners, of which thirty are elected by the freeholders of counties, and fifteen by the royal boroughs. The Scots privy council was also thereupon abolished, and funk into that of Great Britain, which for the future is declared to have no other powers than the English privy council had at the time of the union.

Court of Session.

A court was erected in 1425, consisting of certain persons to be named by the king, out of the three eftates of parliament, which was vested with the jurisdiction formerly lodged in the privy council, and got the name of the session, because it was ordained to hold annually a certain number of sessions at the places to be specially appointed by the king. This court had a jurisdiction, cumulative with the judge ordinary, in spoliations, and other pollicitory actions, and in debts; but they had no cognizance in questions of property of heritable subjects. No appeal lay from its judgments to the parliament. The judges of this court served by rotation, and were changed from time to time, after having sat forty days; and became so negligent in the administration of justice, that it was at last thought necessary to transfer the jurisdiction of this court to a council to be named by the king, called the daily council.

The present model of the court of session, or college of justice, was formed in the reign of James V. The judges thereof, who are vested with an universal civil jurisdiction, consist of seven churchmen, seven laymen, and a president, whom it behoved to be a prelate; but spiritual judges were in 1584 parzey, and in 1640 totally prohibited. The judges of session have been always received by warrants from the crown. Anciently his Majesty seems to have transferred to the court itself the right of choosing their own president; and in a decree recorded June 26. 1593, the king condescended to present to the lords, upon every vacancy in the bench, a list of three persons, out of which they were to chuse one. But his Majesty soon resumed the exercise of both rights, which continued with the Crown till the usurpation; when it was ordained, that the King should name the judges of the session, by the advice of parliament. After the restoration, the nomination was again declared to be solely in the Sovereign.

Though judges may, in the general cause, be named at the age of twenty-one years, the lords of session must be at least twenty-five. No person can be named lord of session, who has not served as an advocate or principal clerk of session for five years, or as a writer to the signet for ten: and in the case of a writer to the signet, he must undergo the ordinary trials upon the Roman law, and be found qualified two years before he can be named. Upon a vacancy in the bench, the king presents the successor by a letter addressed to the lords, wherein he requires them to try and admit the person presented. The powers given them to reject the presentee upon trial are taken
taken away, and a bare liberty to remonstrate substituted in its place.

7. Besides the fifteen ordinary judges, the king was allowed to name three or four lords of his great council, who might sit and vote with them. These extraordinary lords were suppressed in the reign of Geo. L.

8. Though the jurisdiction of the session be properly limited to civil causes, the judges have always fulfilled themselves as competent to the crime of falsehood. Where the falsehood deserves death or demembration, they, after finding the crime proved, remit the criminal to the court of Justiciary. Special statute has given to the court of session jurisdiction in contraventions of law, burrows, deforcements, and breach of arrestment; and they have been in use to judge in battery pendentite lite, and in ufuury.

9. In certain civil causes, the jurisdiction of the session is exclusive of all inferior jurisdictions; as in declarators of property, and other competitions of heritable rights, provings of the tenor, cessiones honorum, retribution of minors, reductions of decrees or of writings, sales of the estates of minors or bankrupts, &c. In a second class of causes, their jurisdiction can be only exercised in the way of review, after the cause is brought from the inferior court; as in maritime and confidorial cases, which must be pursued in the first instance before the admiral or commissary; and in actions below twelve pounds Sterling, which must be commenced before the judge ordinary. In all civil actions, which fall under neither of these classes, the jurisdiction of the session is concurrent, even in the first instance, with that of the judge ordinary. The session may proceed as a court of equity by the rules of conscience, in abating the rigour of law, and giving aid in proper cases to such as in a Court of Law can have no remedy: and this power is inherent in the supreme court of every country, where separate courts are not established for law and for equity.

Court of Justiciary:

10. The supreme criminal judge was styled the Justiciar; and he had an anciently an universal civil jurisdiction, even in matters of heritage. He was obliged to hold two justice courts or ayres yearly at Edinburgh or Peebles, where all the free-holders of the kingdom were obliged to attend. Besides this universal court, special justice-ayres were held in all the different shires of the kingdom twice in the year. These last having gone into disuse, eight deputies were appointed, two for every quarter of the kingdom, who should make their circuits over the whole in April and October.

11. The office of deputies was suppressed in 1772; and five lords of session were added, as commissioners of Justiciary, to the justice-general and justice-clerk. The justice-general, if present, is constant president of the court, and in his absence the justice-clerk. The kingdom is divided into three districts, and two of the judges are appointed to hold circuits in certain boroughs of each district twice in the year; one judge may proceed to business in the absence of his colleague.

12. By an old statute, the crimes of robbery, rape, murder, and wilful fire raising, (the four pleas of the

Crown), are said to be referred to the King's court of

Crown; but the only crime in which, de praxi, the

jurisdiction of Justiciary became at last exclusive of all

inferior criminal jurisdiction, was that of high treason.

The court of Justiciary, when sitting at Edinburgh, has a power of advocating causes from all inferior criminal judges, and of suspending their sentences.

13. The circuit-court can also judge in all criminal causes which do not infer death or demembration, upon appeal from any inferior court within their district; and has a supreme civil jurisdiction, by way of appeal, in all causes not exceeding twelve pounds Sterling, in which their decrees are not subject to review: but no appeal is to lie to the circuit, till the cause be finally determined in the inferior court.

Court of Exchequer.

14. The court of Exchequer, as the King's chamberlain court, judged in all questions of the revenue. In pursuance of the treaty of Union, that court was abolished, and a new court erected, consisting of the Lord High Treasurer of Great Britain, and a chief Baron, with four other Barons of Exchequer; which Barons are to be made of sergeants at law, English barristers, or Scots advocates of five years standing. This court has a private jurisdiction conferred upon it, as to the duties of customs, excise, or other revenues appertaining to the King or Prince of Scotland, and as to all honours and estates which may accrue to the crown; in which matters, they are to judge by the forms of proceeding used in the English court of Exchequer, under the following limitations; that no debt due to the Crown shall affect the debtor's real estate in any other manner than such estate may be affected by the laws of Scotland, and that the validity of the Crown's titles to any honours or lands shall continue to be tried by the court of Session. The Barons have the powers of the Scots court transferred to them, of pausing the accounts of sheriffs, or other officers who have the execution of writs issuing from, or returnable to the court of Exchequer, and of receiving resignations, and passing signatures of charters, gifts of casuallies, &c. But though all these must pass in Exchequer, it is the court of Session only who can judge of their preference after they are completed.

Admiral Court.

15. The jurisdiction of the Admiral in maritime causes was of old concurrent with that of the Session. The High-admiral is declared the King's Justice-General upon the seas, on fresh water within flood mark, and in all harbours and creeks. His civil jurisdiction extends to all maritime causes, and to questions of charters-parties, freights, salvages, bottomries, &c. He exercises this supreme jurisdiction by a delegate, the judge of the high-court of admiralty; and he may also name inferior deputies, whose jurisdiction is limited to particular districts, and whose sentences are subject to the review of the high court. In causes which are declared to fall under the Admiral's cognizance, his jurisdiction is now sole; in so much that the Session itself, though they may review his decrees by suspention or reduction, cannot.
not carry a maritime question from him by advocation. The Admiral has acquired, by usage, a jurisdiction in mercantile causes, even where they are not strictly maritime, cumulative with that of the judge-ordinary.

16. All our supreme courts have seals or signets, proper to their several jurisdictions. The courts of Seftion and Justiciary used formerly the same signet, which was called the King's, because the writs issuing from thence run in the King's name; and though the Justiciary got at last a separate signet for itself, yet that of the Seftion still retains the appellation of the King's Signet. In this office are sealed summons for citation, letters of execution, and generally whatever passes by the warrant of the Justiciary, or for staying or prohibiting of diligence; and generally whatever passes by the warrant of the Seftion, and is to be executed by the officers of the court. All these must, before sealing, be signed by the writers or clerks of the signet: But letters of diligence, where they are granted in a depending process, merely for probate, though they pass by the signet, must be subscribed by a clerk of Seftion. The clerks of the signet also prepare and subscribe all signatures of charters, or other royal grants, which pass in Exchequer.

Tit. 4. Of the inferior Judges and Courts of Scotland.

Sheriff.

Sheriff, from reeve, governor, and steer, to cut or divide, is the judge ordinary constituted by the Crown over a particular division or county. The Sheriff's jurisdiction, both civil and criminal, was, in ancient times, nearly as ample within his own territory as that of the supreme courts of Seftion and Justiciary was over the whole kingdom.

2. His civil jurisdiction now extends to all actions upon contract, or other personal obligations, forquisitions, pointings of the ground, mail duties, and to all possessory actions, as removing, ejecting, spuillies, &c. to all brevices issuing from the chancery, as of inquest, terce, division, tuition, &c. and even to adjudications of land-estates, when proceeding on the renunciation of the apparent heir. His present criminal jurisdiction extends to certain capital crimes, as theft, and even murder, though it be one of the pleas of the Crown; and he is competent to most questions of public police, and has a cumulative jurisdiction with justices of the peace in all riots and breaches of the peace.

3. Sheriffs have ministerial power, in virtue of which, they return juries, in order to the trial of causes that require juries. The writs for electing members of parliament have been, since the union, directed to the Sheriffs, who, after they are executed, return them to the crown-office from whence they issued. They also execute writs issuing from the court of Exchequer; and in general, take care of all estates, duties, or casualties that fall to the Crown within their territory, for which they must account to the Exchequer.

Lord of Regality.

4. A Lord of Regality was a magistrate, who had a grant of lands from the Sovereign, with royal jurisdiction annexed thereto. His civil jurisdiction was equal to that of a Sheriff; his criminal extended to the four pleas of the crown. He had a right to replead or reclaim all criminals, subject to his jurisdiction, from any other competent court, though it were the Justiciary itself, to his own. He had also right, according to the most common opinion, to the single escheat of all denounced persons residing within his jurisdiction, even though such privilege had not been expressed in the grant of regality.

Stewart.

5. The Stewart was the magistrate appointed by the King over such regality lands as happened to fall to the Crown by forfeiture, &c. and therefore the Stewart's jurisdiction was equal to that of a regality. The two stewartries of Kirkcudbright, and of Orkney and Zetland, make threes or counties by themselves, and send each a representative to parliament.

Bailie.

6. Where lands, not erected into a regality, fell into the King's hands, he appointed a Bailie over them, whose jurisdiction was equal to that of a Sheriff.

7. By the late jurisdiction act 20. Geo. II, all heritable royalties and baileries, and all such heritable territories and stewartries as were only parts of a shire, were dissolved; and the powers formerly vested in them are made to devolve upon such of the King's courts as these powers would have belonged to if the jurisdictions dissolved had never been granted. All territories and stewartries that were not part of a shire, where they had been granted, either heritably or for life, are resumed and annexed to the crown. No High Sheriff or Stewart can hereafter judge personally in any cause. One Stewart or Stewart-depute is to be appointed by the King in every shire, who must be an advocate of three years standing; and after a certain term not yet expired, all commissions to these deputies are to be granted for life.

Prince of Scotland.

8. The appanage, or patrimony, of the Prince of Scotland, has been long erected into a regality-jurisdiction, called the Principality. It is personal to the King's eldest son, upon whose death or succession it returns to the Crown. The prince has, or may have, his own chancery, from which his writs issue, and may name his own chamberlain and other officers for receiving and managing his revenue. The vassals of the Prince are intitled to elect, or to be elected members of Parliament for counties, equally with those who hold of the Crown.

Justices of the Peace.

9. Justices of the Peace are magistrates named by the Sovereign over the several counties of the kingdom, for the special purpose of preserving the public peace. Anciently their power reached little farther than to bind over disorderly persons for their appearance before the Privy Council or Justiciary; afterwards they were authorized to judge in breaches of the peace, and in most of the laws concerning public policy. They may compel workmen or labourers to serve for a reasonable fee, and
they can condemn masters in the wages due to their servants. They have power to judge in questions of highways, and to call out the tenants with their cattle and servants to perform six days work yearly for upholding them.

10. Since the Union, our justices of the peace, over and above the powers committed to them by the laws of Scotland, are authorised to exercise whatever belonged to the office of an English justice of the peace, in relation to the public peace. From that time, the Scots and the English commissions have run in the same style, which contain powers to inquire into, and judge in all capital crimes, witchcrafts, felonies, and several others specially enumerated, with this limitation subjoined, of which justices of the peace may lawfully inquire. Two justices may constitute a court. Special statute has given the cognisance of several matters of excise to the justices, in which their sentences are final.

**Boroughs.**

11. A borough is a body-corporate, made up of the inhabitants of a certain tract of ground erected by the Sovereign, with jurisdiction annexed to it. Boroughs are erected, either to holden of the Sovereign himself, which is the general caií of royal boroughs; or of the superior of the lands erected, as boroughs of regality and barony. Boroughs royal have power, by their charters, to chuse annually certain office-bearers or magistrates; and in boroughs of regality and barony, the nomination of magistrates is, by their charter, lodged, sometimes in the inhabitants, sometimes in the superior Baillies of boroughs have jurisdiction in matters of debt, services, and questions of pollution between the inhabitants. Their criminal jurisdiction extends to petty riots, and reckless fire-raising. The Dean of Guild is that magistrate of a royal borough, who is head of the merchant-company: he has the cognisance of mercantile causes within borough, and the inspection of buildings, that they incroach neither on private property, nor on the public streets; and he may direct insufficient houses to be pulled down. His jurisdiction has no dependence on the court of the borough, or baillie-court.

**Barons.**

12. A Baron, in the large sense of that word, is one who holds his lands immediately of the Crown; and, as such, had, by our ancient constitution, right to a seat in parliament, however small his freehold might have been. The lesser Barons were exempted from the burden of attending the service of parliament. This exemption grew insensibly into an utter disability in all the lesser Barons from sitting in parliament, without election by the country; though no statute is to be found expressly excluding them.

13. To constitute a Baron in the strict law-sense, his lands must have been erected, or at least confirmed by the King, in liberam baroniam: and such Baron had a certain jurisdiction, both civil and criminal, which he might have exercised, either in his own person, or by his bailie.

14. By the late jurisdiction-act, the civil jurisdiction of a Baron is reduced to the power of recovering, from his vassals and tenants, the rents of his lands, and of condemning them in mill services; and of judging in causes where the debt and damages do not exceed 40 s. Sterling. His criminal jurisdiction is, by the same statute, limited to assaults, batteries, and other smaller offences, which may be punished by a fine not exceeding 20 s. Sterling, or by setting the offender in the stocks in the day-time not above three hours; the fine to be levied by poinding, or one month’s imprisonment. The jurisdiction formerly competent to proprietors of mines, coal or salt, was, over their workmen, reserved; and also that which was competent to proprietors who had the right of fairs or markets, for correcting the disorders that might happen during their continuance; provided they shall exercise no jurisdiction inferring the loss of life or demembration.

**Constabularies.**

15. The High Constable of Scotland had no fixed territorial jurisdiction, but followed the court; and had, jointly with the Marischal, the cognisance of all crimes committed within two leagues of it. All other constabularies were dependent on him: These had castles, and sometimes boroughs subject to their jurisdiction, as Dundee, Montrose, &c. and amongst other powers, now little known, they had the right of executing criminal jurisdiction within their respective territories during the continuance of fairs. By the late jurisdiction-act, all jurisdictions of constabulary are dissolved, except that of High Constable.

**Lyon King of Arms.**

16. The office of the Lyon King of Arms was chiefly ministerial, to denounce war, proclaim peace, carry public messages, &c. But he has also a right of jurisdiction, whereby he can punish all who usurp arms contrary to the law of arms, and deprive or suspend messengers, heralds, or pursuivants, (who are officers named by himself;) but he has no cognizance of the damages arising to the private party through the messenger’s fault. Messengers are subiequent to the supreme courts of election and judicature; and their proper business is to execute all the King’s letters either in civil or criminal causes.

17. Our judges had, for a long time, no other salaries or appointments than what arose from the fentence they pronounced. Our criminal judges applied to their own use the fines or forfeits of their several courts; and regalities had a right to the angle fireheat of all persons denounced, who refused within their jurisdiction; and our civil judges got a certain proportion of the sum contained in the decree pronounced. But these were all prohibited upon regular salaries being settled upon our judges.

**Tit. 5. Of Ecclesiastical Persons.**

The Pope, or bishop of Rome, was long acknowledged, over the western part of Chiltendom, for the head of the Christian church. The papal jurisdiction was abolished in Scotland anno 1560. The King was, by act 1669, declared to have supreme authority over all persons,
persons, and in all causes ecclesiastical; but this act was
repealed by 1690, as inconfentful with Presbyterian church-government, which was then upon the point of
being established.

2. Before the reformation from Popery, the clergy was
divided into secular and regular. The secular had a parti-
cular tract of ground given them in charge, within which
they exercised the pastoral office of bishop, prebendary, or
other church officer. The regular clergy had no cure of
souls, but were tied down to residence in their abbacies,
provincies, or other monasteries: And they got the name
of regular, from the rules of mortification to which they
were bound, according to the institution of their several
orders. Upon the vacancy of any benefice, whether fecu-
lar or regular, Commandments were frequently appoint-
et to levy the fruits, as factors or stewards during the
vacancy. The Pope alone could give the higher benefi-
cies in commendam; and at last, from the plenitude of
his power, he came to name commendators for life, and
without any obligation to account. After the reforma-
tion, several abbacies and priories were given by James
VI. in perpetuum commendam, to laics.

3. Upon abolishing the Pope's authority, the regular
clergy was totally suppressed; and, in place of all the
different degrees which distinguished the secular clergy,
we had at first only parochial Prebendaries or Ministeres, and
superintendents, who had the overflight of the church
within a certain dioclet: Soon thereafter the church-
government became episcopal, by Archbishops, Bishops,
&c. and after some intermediate turns, is now Presby-
terian by kirk-feffions, prebyteries, synods, and general
assemblies.

4. Prelate, in our statutes, signifies a Bishop, Abbot,
or other dignified clergyman, who in virtue of his office
had a seat in parliament. Every Bishop had his Chapter,
which consisted of a certain number of the minifters of the
diocefe, by whose assistance he managed the affairs of
the church within that dioclet. The nomination of Bishops to vacant benefices has been in the crown since
1540, though under the appearance of continuing the
ancient right of election, which was in the Chapter.
The confirmation by the Crown under the great seal, of
the Chapter's election, confirmed a right to the spirituality
of the benefice; and a second grant, upon the confecra-
tion of the Bishop-elect, gave a title to the temporality;
but this second grant fell soon into disuse.

5. He who founded or endowed a church was intitled
to the right of patronage thereof, or advocatio ecclesiæ,
whereby, among other privileges, he might present a
churchman to the cure, in case of a vacancy. The pre-
sentee, after he was received into the church, had a right
to the benefice proprio jure; and if the church was parochial, he was called a parson. The Pope claim-
ed the right of patronage of every kirk, to which no
third party could give a special title; and since the re-
formation, the Crown, as coming in place of the Pope,
is considered as universal patron, where no right of pa-
tronage appears in a subject. Where two churches are
united, which had different patrons, each patron prentes
by turns.

6. Gentlemen of estate frequently founded colleges or
collegiate churches, the head of which got the name of
Provost, under whom were certain Prebendaries or Cats-
nons, who had their several italls in the church, where
they sung masses. Others of lesser fortunes founded chap-
lainries, within the precincts of a parochial church; or
altarages, which were donations granted for the singing
of masses for deceased friends at particular altars in a
church. Though all these were suppressed upon the re-
formation, their founders continued patrons of the end-
dowments; out of which they were allowed to provide
bursars, to be educated in any of the universities.

7. Where a fund is gifted for the establishment of a
second minifter in a parth where the cure is thought too
heavy for one, the patronage of such benefice does not
belong to the donor, but to him who was patron of the
church, unless either where the donor has referred to
himself the right of patronage in the donation, or where
he and his successors have been in the constant use of
presenting the second minifter, without challenge from the
patron. The right of prententing incumbents was by
1690, c. 23, taken from patrons, and vested in the he-
ritors and elders of the parth, upon payment to be made
by the heritors to the patron of 600 merks; but it was
again restored to patrons, 10. An. c. 12. with the ex-
ception of the prententions sold in pursuance of the for-
mer act.

8. Patrons were not simply administrators of the
church; for they held the fruits of the vacant benefice
as their own, for some time after the reformation. But
that right is now no more than a truft in the patron, who
must apply them to pious ufe within the parth, at the
fight of the heritors, yearly as they fall due. If he fail,
he loses his right of admiftrating the vacant stipend for
that and the next vacancy. The king, who is exempted
from this rule, may apply the vacant stipend of his church-
es to any pious ufe, though not within the parth. If
one should be ordained to a church, in opposition to the
presentee, the patron, whose civil right cannot be affect-
ed by any sentence of a church-court, may retain the
stipend as vacant. Patrons are to this day intitled to a
seat and burial-place in the churches of which they are
patrons; and to the right of all the teinds of the parth;
not heritably difpofed.

9. That kirks may not continue too long vacant, the
patron must præsent to the prebendary, (formerly to the
Bishop,) a fit perfon for supplying the cure, within fix
months from his knowledge of the vacancy, otherwise
the right of præsentation accrues to the prebendary jure
devoluto. Upon præsentation by the patron, the Bishop
collated or conferred the benefice upon the præsentee by
a writing, in which he appointed certain minifters of the
diocefe to induce or inftitute him into the church; which
induction completed his right, and was performed by
their placing him in the pulpit, and delivering him the
bible and the keys of the church. The bishop collated
to the churches of which himself was patron, pleno jure,
or without præsentation; which he also did in mensal
churches, whose patronages were sunk, by the churches
being appropriated to him, as part of his patrimonie.
Since the revolution, a judicial act of admiflion by the
prebendary, proceeding either upon a præsentation, or up-
on.
on a call from the heritors and elders, or upon their own free volun- 
compleats the minister’s right to the bene- 
10. Soon after the reformation, the Popish churchmen were prevailed upon to resign in the sovereign’s hands, a third of their benefits, which was appropriated, in the first place, for the subsistence of the reformed clergy. To make this fund effectual, particular localities were assigned in every benefice, to the extent of a third, called the assumption of thirds; and for the farther support of ministers, Queen Mary made a grant in their favour of all the small benefits not exceeding 300 merks. Bishops, by the act which restored them to the whole of their benefits, were obliged to maintain the ministers within their diocefes, out of the thirds; and in like manner, the laic titulars, who got grants of the teinds, became bound, by their acceptance thereof, to provide the kirks within their erections in competent stipends.

11. But all these expedients for the maintenance of the clergy having proved ineffectual, a commiiffion of parliament was appointed in the reign of James VI., for planting kirks, and modifying stipends to ministers out of the teinds; and afterwards several other commiiffions were appointed, with the more ample powers of dividing large parishes, erecting new ones, &c. all of which: were, in 1707, transferred to the court of Seffion, with this limitation, that no parff as should be disjoined, nor new-church erected, nor old one removed to a new place, without the consent of three fourths of the heritors, computing the votes, not by their numbers, but by the valuation of their rents within the parff. The Judges of Seffion, when sitting in that court, are considered as a commiiffion of Parliament, and have their proper clerks, macers, and other officers of court, as such.

12. The lowest stipend that could be modified to a minister by the first commiiffion was 500 merks, or five chalders of victual, unless where the whole teinds of the parff did not extend so far: And the highest was 1000 merks, or ten chalders. The parliament 1633 raised the minimum to eight chalders of victual, and proportionably in silver; but as neither the commiiffion appointed by that act, nor any of the subsequent ones, was limited as to the maximum, the commiiffioners have been in ufe to augment stipends considerably above the old maximum, where there is sufficiency of free teinds, and the cure is burdensome, or living expensive.

13. Where a certain quantity of stipend is modified to a minister out of the teinds of a parff, without proportioning that stipend among the several heritors, the decree is called a decree of modification: But where the commiiffioners also fix the particular proportions payable by each heritor, it is a decree of modification and locality. Where a stipend is only modified, it is secured on the whole teinds of the parff, so that the minister can infift against any one heritor to the full extent of his teinds; such heritor being always entitled to relief against the rest, for what he shall have paid above his just share: But where the stipend is also localised, each heritor is liable in no more than his own proportion.

14. Few of the reformed ministers were, at first, provided with dwelling houses: most of the Popish clergy having, upon the first appearance of the reformation, let their manfes in feu, or in long tacks: Ministers therefore got a right, by 1563, to as much of these manfes as would serve them, notwithstanding such feus or tacks: Where there was no parffon’s nor vicar’s manfe, one was to be built by the heritors, at the right of the bishop, (now the Prebiftery,) the charge not exceeding L. 1000 Scots, nor below 500 merks. Under a manfe are comprehended flable, barn, and byre, with a garden; for all which, it is ufual to allow half an acre of ground.

15. Every incumbent is intitled at his entry to have his manfe put into good condition; for which purpose, the prebiftery may appoint a visitation by tradesmen, and order estimates to be laid before them of the sums necessary for the repairing, which they may proportion among the heritors according to their valuations. The prebiftery, after the manfe is made sufficient, ought, upon application of the heritors, to declare it a free manfe, which lays the incumbent under an obligation to uphold it in good condition during his incumbency; otherwife, he or his executors shall be liable in damages; But they are not bound to make up the los arising from the necessary decay of the building by the waste of time.

16. All ministers, where there is any landward or country parff, are, over and above their stipend, intitled to a glebe, which comprehends four acres of arable land, or fifteen fowms of pasture-ground where there is no arable land, (a fowm is what will graze ten sheep or one cow), and is to be defined or marked by the bishop or prebiftery out of fuch kirk lands within the parff as lie nearest to the kirk, and, in default of kirk-lands, out of temporal lands.

17. A right of relief is competent to the heritors, whole lands are set off for the manfe or glebe, against the other heritors of the parff. Manfes and glebes, being once regularly defined, cannot be feued or fold by the incumbent in prejudice of his successors, which is in practice extended even to the cale where such alienation evidently appears profitable to the benefice.

18. Ministers, besides their glebes, are intitled to grafs for a horfe and two cows. And, if the lands, out of which the grafs may be defigned, either lie at a distance, or are not fit for pasture, the heritors are to pay to the minister L. 20 Scots yearly as an equivalent. Ministers have also freedom of foggage, paffurage, fafel, defal, divot, loaning, and free ifh and entry, according to use and wont: What these privileges are, must be determined by the local custom of the several parishes.

19. The legal terms at which stipends become due to ministers are Whitfunday and Michaelmas. If the incumbent be admitted to his church before Whitfunday, till which term the corns are not presumed to be fully sown, he has right to that whole year’s stipend; and, if he is received after Whitfunday, and before Michaelmas, he is intitled to the half of that year; because, tho’ the corns were sown before his entry, he was admitted before the term at which they are presumed to be reap’d. By the fame reason, if he dies or is transported before Whitfunday, he has right to no part of that year; if before Michaelmas, to the half; and if not till after Michaelmas, to the whole.

20. After
20. After the minister's death, his executors have right to the annat; which, in the form of the canon law, was a right referred to the Pope, of the first year's fruits of every benefice. Upon a threatened invasion from England anno 1547, the annat was given by our Parliament, notwithstanding this right in the Pope, to the executors of such churchmen as should fall in battle in defence of their country: But the word annat or ann, as it is now understood, is the right which law gives to the executors of ministers, of half a year's benefice, over and above what was due to the minister himself for his incumbency.

21. The executors of a minister need make up no title to the ann by confirmation: Neither is the right assignable by the minister, or affectable with his debts; for it never belonged to him, but is a mere gratuity given by law to those whom it is presumed the deceased could not sufficiently provide; and law has given it expressly to executors: And if it were to be governed by the rules of succession in executory, the widow, in case of no children, would get one half, the other would go to the next of kin; and where there are children, she would be intitled to a third, and the other two thirds would fall equally among the children. But the court of Session, probably led by the general practice, have in this last case divided the ann into two equal parts, of which one goes to the widow, and the other among the children in capita.

22. From the great confidence that was, in the first ages of Christianity, reposed in churchmen, dying persons frequently committed to them the care of their effuates, and of their orphan children; but these were simply rights of trust, not of jurisdiction. The clergy soon had the address to establish to themselves a proper jurisdiction, not confined to points of ecclesiastical right, but extending to questions that had no concern with the church. They judged, not only in teinds, patronages, testaments, breach of vow, scandal, &c.; but in questions of marriage and divorce, because marriage was a sacrament; in rochers, because they were given in consideration of marriage; in all questions where an oath intervened, on pretence that oaths were a part of religious worship, &c. As churchmen came, by the means of this extensive jurisdiction, to be diverted from their proper functions, they committed the exercise of it to their officials or commissaries: Hence the Commissary-court was called the Bishops' court, and Curia Christianitatis; it is also styled the Confofitorial Court, from Confoftory, a name first given to the court of appeals of the Roman Emperors, and afterwards to the courts of judicature held by churchmen.

23. At the reformation, all episcopal jurisdiction, exercised under the authority of the Bishop of Rome, was abolished. As the course of justice in consistorial causes was thereby stopped, Q. Mary, besides naming a Commissey for every diocese, did, by a special grant, establish a new Commissey-court at Edinburgh, consisting of four judges or commissaries. This court is vested with a double jurisdiction; one diocesan, which is exercised in the special territory contained in the grant, viz. the counties of Edinburgh, Haddington, Linlithgow, Peebles, and a part of Stirling-shire; and another universal, by which the judges confirm the testaments of all who die in foreign parts, and may reduce the decrees of all inferior Commissions, provided the reduction be pur- chased within a year after the decree: Bishops, upon theirroneshipment in the reign of James VI were restored to the right of naming their several Commisseyes.

24. As the clergy, in times of Popery, assumed a jurisdiction independent of the civil power or any secular court, their elections could be reviewed only by the Pope, or judges delegated by him; so that, with regard to the courts of Scotland, their jurisdiction was supreme. But by an act 1560, the appeals from our Bishops courts, that were then depending before the Roman consistory, were ordained to be decided by the court of Session: And by a posterior act 1609, the Session is declared the King's great Confoftory, with power to review all sentences pronounced by the Commisseyes. Nevertheless, since that court had no inherent jurisdiction in consistorial causes, prior to this statute; and since the statute gives them a power of judging only by way of opposition, they have not, to this day, any proper consistorial jurisdiction in the first instance; neither do they pronounce sentence, in any consistorial cause brought from the Commissions, but remit it back to them with instructions. By the practice immediately subsequent to the act before quoted, they did not admit oppositions from the inferior Commissions, till the cause was brought before the Commissions of Edinburgh; but that practice is now in disuse.

25. The Commissions retain to this day an exclusive power of judging in declamators of marriage, and of the nullity of marriage; in actions of divorce and of non-adherence of adultery, bastardy, and confirmation of testaments; because all these matters are still considered to be properly consistorial. Inferior Commissions are not competent to questions of divorce, under which are comprehended questions of bastardy and adherence, when they have a connection with the lawfulneps of marriage, or with adultery.

26. Commissions have now no power to pronounce decrees in absence for any sum above L. 40 Scots, except in causes properly consistorial: but they may authenticate tutorial and curatorial inventories; and all bonds, contracts, &c. which contain a clause for registration in the books of any judge competent, and protests on bills, may be registered in their books.

Tit. 6. Of Marriage.

Persons, when considered in a private capacity, are chiefly distinguished by their mutual relations; as husband and wife, tutor and minor, father and child, master and servant. The relation of husband and wife is constituted by marriage; which is the conjunction of man and wife, vowing to live inseparchably till death.

2. Marriage is truly a contract, and so requires the consent of parties. Ideots, therefore, and forious persons cannot marry. As no person is presumed capable of consent within the years of pupillarity, which, by our law, lasts till the age of fourteen in males, and twelve in females, marriage cannot be contracted by pupils; but if the married pair should cohabit after puberty, such acquiescence
acquiescenc gives force to the marriage. Marriage is
fully perfected by consent; which, without consumma-
tion, founds all the conjugal rights and duties. The
consent requisite to marriage must be de praesenti. A
promise of marriage, (juplicitas Jonfalitia,) may be
refilled from, as long as matters are entire; but if any
thing be done by one of the parties, whereby a prejudice
arises from the non-performance, the party refusing is li-
able in damages to the other. The canons, and after
them our courts of justice, explain a copula subsequent
to a promise of marriage into actual marriage.

3. It is not necessary, that marriage should be cele-
brated by a clergymen. The consent of parties may be
declared before any magistrate, or simply before wit-
nes; And though no formal consent should appear,
marriage is presumed from the cohabitation, or living
together at bed and board, of a man and woman who are
generally reputed husband and wife. One's acknowled-
gment of his marriage to the midwife whom he called to
his wife, and to the minister who baptized his child, was
found sufficient presumptive evidence of marriage, with-
out the aid, either of cohabitation, or of habite and re
pate. The father's consent was, by the Roman law, effent-
tial to the marriage of children in familia: But, by
our law, children may enter into marriage, without the
knowledge, and even against the remonstrances of a fa-
ther.

4. Marriage is forbidden within certain degrees of
blood. By the law of Moses, Lev. c. 18. which is
made ours, seconds in blood, and all remoter degrees,
may lawfully marry. By seconds in blood are meant
first cousins. Marriage in the direct line is forbidden in
infinitum; as it is also in the collateral line, in the spe-
cial case where one of the parties is loco parentis to
the other, as grand uncle, great grand-uncle, &c. with re-
spect to his grand-niece, &c. The same degrees that are
prohibited in consanguinity, are prohibited in affinity;
which is the tie rising from marriage, betwixt one of the
married pair and the blood relations of the other.
Marriage also, where either of the parties is naturally
 unfit for generation, or flands already married to a third
person, is ipso jure null.

5. To prevent bigamy and incestuous marriages, the
church has introduced proclamation of banns; which is
the ceremony of publishing the names and designations of
those who intend to intermarry, in the churches where the
bride and bridegroom reside, after the congregation is as-
sembled for divine service; that all persons who know
any objection to the marriage, may offer it. When the
order of the church is observed, the marriage is called
regular; when otherwise, clandestine.

6. By marriage, a society is created between the mar-
ried pair, which draws after it a mutual communication of
their civil interests, in as far as is necessary for maintain-
ing it. As the society lasts only for the joint lives of
the socii; therefore rights that have the nature of a per-
petuity, which our law fyles heritable, are not brought
under the partnership or communion of goods; as a land-
estate, or bonds bearing a yearly interest: It is only mo-
ovable subjNecks, or the fruits produced by heritable sub-
jects during the marriage, that become common to man
and wife.

7. The husband, as the head of the wife, has the sole
right of managing the goods in communion, which is
called jus maritii. This right is fo absolute, that it
bears but little resemblance to a right of administering a
common subject; for the husband can, in virtue thereof,
directly, or even gift at pleasure, the whole goods falling un-
der communion; and his creditors may affect them for
the payment of his proper debts: So that the jus mari-
tii carries all the characters of an assignation by the wife
to the husband, of her moveable estate. It arises by
jure from the marriage; and therefore needs no other
constitution. But a stranger may convey an estate to a
wife, fo as it shall not be subject to the husband's admi-
nistration; or the husband himself may, in the marriage-
contract, renounce his jus maritii in all or any part of
his wife's moveable estate.

8. From this right are excepted paraphernal goods,
which as the word is understood in our law, comprehends
the wife's wearing apparel, and the ornaments proper to
her person, as necklaces, ear rings, breast or arm jewels,
buckles, &c. These are neither alienable by the hus-
bond, nor affectable by his creditors. Things of pro-
miscuous use to husband and wife, as plate, medals, &c.
may be considered as paraphernal, by the husband's giving them to
the wife, after marriage; but they are paraphernal
only in regard to that husband who gave them to her,
and are esteemed common moveables, if the wife, whose
paraphernalia they were, be afterwards married to a se-
cond husband; unless he shall in the same manner appro-
priate them to her.

9. The right of the husband to the wife's moveable e-
state, is burdened with the moveable debts contracted by
her before marriage: And as his right is universal, fo is
his burden; for it reaches to her whole moveable debts,
though they should far exceed her moveable estate. Yet
the husband is not considered as the true debtor in his
wife's debts. In all actions for payment, she is the pro-
der defender: the husband is only cited for his interest,
that is, as curator to her, and administrator of the society-
goods. As soon therefore as the marriage is dissolved,
and the society goods thereby suffer a division, the hus-
bond is no farther concerned in the share belonging to his
deceased wife; and consequently is no longer liable to
pay her debts, which must be recovered from her repre-
fentatives, or her separate estate.

10. This obligation upon the husband is perpetuated
against him. Where his proper estate, real or personal,
has been affected, during the marriage, by complete legal
diligence; in which case, the husband must, by the com-
mon rules of law, relieve his property from the burden
with which it stands charged: But the utmost diligence
against his perdon, is not sufficient to perpetuate the ob-
ligation; nor even incomplete diligence against his estate.

1. Where his proper estate, real or personal,
has been affected, during the marriage, by complete legal
diligence; in which case, the husband must, by the com-
mon rules of law, relieve his property from the burden
with which it stands charged: But the utmost diligence
against his person, is not sufficient to perpetuate the ob-
ligation; nor even incomplete diligence against his estate.
2. The husband continues liable, even after the wife's
death, in so far as he is lucratus or profited by her e-
state. As he was at no time the proper debtor in his
wife's moveable debts; therefore, though he should be
lucratus, he is, after the dissolution, only liable for
them.
them subdiaries, i.e. if her own separate estate is not sufficient to pay them off.

11. Where the wife is debtor in that sort of debt, which, if it had been due to her, would have excluded the jus maritii, e.g. in bonds bearing interest, the husband is liable only for the bygone interests, and those that may grow upon the debt during the marriage; because his obligations for her debts must be commenfurate to the interest he has in her estate. It is the husband alone who is liable in personal diligence for his wife's debts, while the marriage subsists: The wife, who is the proper debtor, is free from all personal execution upon them while she is vestita viro.

12. The husband by marriage becomes the perpetual curator of the wife. From this right it arises, that no suit can proceed against the wife, till the husband be cited for his interest. All deeds, done by a wife without the husband's consent, are null; neither can she set in any action without the husband's concurrence. Where the husband refuses, or by reason of forfeiture, &c. cannot concur; or where the action is to be brought against the husband himself, for performing his part of the marriage-articles; the judge will authorize her to sue in her own name. The effects arising from this curatorial power discover themselves even before marriage, upon the publication of bans; after which the bride, being no longer suas juris, can contract no debt, nor do any deed, either to the prejudice of her future husband, nor even to her own.

13. If the husband should either withdraw from his wife, or turn her out of doors; or if, continuing in family with her, he should by severe treatment endanger her life; the Commiffaries will authorize a separation a mensa et toro, and give a separate alimony to the wife, suitable to her husband's estate, from the time of such separation, until either a reconciliation or a sentence of divorce.

14. Certain obligations of the wife are valid, notwithstanding her being sub cura mariti; e.g. gr. obligations arising from delict; for wives have no privilege to commit crimes. But if the punishment resolves into a pecuniary mulct, the execution of it must, from her incapacity to fulfill, be suspended till the dissolution of the marriage, unless the wife has a separate estate exempted from the jus maritii.

15. Obligations arising from contract, affect either the person or the estate. The law has been so careful to protect wives, while sub cura mariti, that all personal obligations granted by a wife, though with the husband's consent, as bonds, bills, &c. are null; with the following exceptions: 1. Where the wife gets a separate peculium or stock, either from her father or a stranger, for her own or her children's alimony, she may grant personal obligations in relation to such stock; and by stronger reason, personal obligations granted by a wife are good, when her person is actually withdrawn from her husband's power, by a judicial separation. 2. A wife's personal obligation, granted in the form of a deed inter vivos, is valid, if it is not to take effect till her death. 3. Where the wife is by the husband præposita negositi, entrusted with the management, either of a particular branch of business, or of his whole affairs, all the contracts the husband enters into in the exercise of her præpositura, are effectual, even though they be not reduced to writing, but should arise merely ex re, from furnishings made to her: But such obligations have no force against the wife; it is the husband only, by whose commissio acts, who is thereby obliged.

16. A wife, while she remains in family with her husband, is considered as præposita negotiis domus; and consequently may provide things proper for the family, for the price whereof the husband is liable, though they should be misapplied, or though the husband should have given her money to provide them elsewhere. A husband, who suspects that his wife may hurt his fortune by high living, may use the remedy of inhibition against her; by which all persons are interpell'd from contracting with her, or giving her credit. After the completing of this diligence, whereby the præpositura falls, the wife cannot bind the husband, unless for such reasonable furnishings as he cannot instruct that he provided her with aludate. As every man, and consequently every husband, has a right to remove his managers at pleasure, inhibition may pass at the suit of the husband against the wife, though he should not offer to justify that measure by an actual proof of the extravagance or profufeness of her temper.

17. As to rights granted by the wife affecting her estate; she has no moveable estate, except her paraphernalia; and these she may alien or impignorate, with consent of the husband. She can, without the husband, bequeath by testament her share of the goods in communion; but she cannot dispose of them inter vivos. A wife can lawfully oblige herself, in relation to her heritable estate, with consent of her husband; though her person is in some sense sunk by the marriage, she becomes capable of holding a real estate; and in such obligations, her estate is considered, nor not her person. A husband, though he be curator to his wife, can, by his acceptance or intervention, authorize rights granted by her in his own favour; for a husband's curatorial is not intended only for the wife's advantage, but is considered as a mutual benefit to both.

18. All donations, whether by the wife to the husband, or by the husband to the wife, are revocable by the donor; but if the donor dies without revocation, the right becomes absolute. Where the donation is not perfect, it is not subject to revocation: Thus, a grant made by the husband, in consequence of the natural obligation that lies upon him to provide for his wife, is not revocable, unless in so far as it exceeds the measure of a rational settlement; neither are remuneratory grants revocable, where mutual grants are made in consideration of each other, except where an onerous caufe is simulated, or where what is given sine inde bears no proportion to each other. All voluntary contracts of separation, by which the wife is provided in an yearly alimony, are effectual as to the time past, but revocable either by the husband or wife.

19. As wives are in the strongest degree subject to the influence of their husbands, third parties, in whose favours they had made grants, were frequently vexed with actions of reduction, as if the grant had been extorted from the wife, through the force or fear of the husband.
hundred. To secure the grantees against this danger, ratifications were introduced, whereby the wife, appearing before a judge, declares upon oath, her husband not present, that she was not induced to grant the deed ex vi aut motu. A wife's ratification is not absolutely necessary for securing the grantee: Law indeed allows the wife to bring reduction of any deed she has not ratified, upon the head of force or fear; of which, if she brings sufficient evidence, the deed will be set aside; but if she fails in the proof, it will remain effectual to the receiver.

20. Marriage, like other contracts, might, by the Roman law, be dissolved by the contrary consent of parties; but, by the law of Scotland, it cannot be dissolved till death, except by divorce, proceeding either upon the head of adultery, or of wilful defertion.

21. Marriage is dissolved by death, either within year and day from its being contracted, or after year and day. If it is dissolved within year and day, all rights granted in consideration of the marriage (unless guarded against in the contract) become void, and things return to the same condition in which they stood before the marriage; with this restriction, that the husband is considered as a bona fide possessor, in relation to what he has consumed upon the faith of his right; but he is liable to repay the tocher, without any deduction in consideration of his family expense during the marriage. If things cannot be restored on both sides, equity hinders the re-floring of one party, and not the other.

22. Upon the dissolution of a marriage, after year and day, the surviving husband becomes the irrevocable proprietor of the tocher and the wife, where she survives. She has also right to mournings, suitable to the husband's quality; and to alimony from the day of his death, till the term at which her lterent provision, either legal or conventional, commences. If a living child be procured of the marriage, the marriage has the same effect as if it had subsisted beyond the year. A day is adjudged to the year, in majorem evidentiarn, that it may clearly appear that the year itself is elapsed; and therefore, the running of any part of the day, after the year, has the same effect as if the whole were elapsed. The legal right of courteously competent to the surviving husband is explained below, Tit. xvi. 28.

23. Divorce is such a separation of married persons, during their lives, as leaves them from the nuptial tie, and leaves them at freedom to intermarry with others. But neither adultery, nor wilful defertion, are grounds which must necessarily dissolve marriage; they are only handles, which the injured party may take hold of, to be free. Cohabitation, therefore, by the injured party, after being in the knowledge of the acts of adultery, implies a passing from the injury; and no divorce can proceed, which is carried on by collusion between the parties, lest, contrary to the first institution of marriage, they might defingle themselves by their own consent; and though after divorce, the guilty person, as well as the innocent, may contract second marriages; yet in the case of divorce upon adultery, marriage is by special statute prohibited betwixt the two adulterers.

24. Where either party has deserted from the other for four years together, that other may sue for adherence. If this has no effect, the church is to proceed, first by admonition, then by excommunication; all which previous steps are declared to be a sufficient ground for pursing a divorce. De praxi, the Commisaries pronounce sentence in the adherence, after one year's defertion; but four years must intervene between the first defertion and the decree of divorce.

25. The legal effects of divorce on the head of defertion are, that the offending husband shall restore the tocher, and forfeit to the wife all her provisions, legal and conventional; and on the other hand, the offending wife shall forfeit to the husband her tocher, and all the rights that would have belonged to her, in the case of her survivance. This was also esteemed the rule in divorces upon adultery. But by a decision of the court of Session 1762, founded on a tract of ancient decisions recovered from the records, the offending husband was allowed to retain the tocher.

Tit. 7. Of Minors, and their Tutors and Curators.

1. The stages of life principally distinguished in law are, pupillarity, puberty or minority, and majority. A child is under pupillarity, from the birth till fourteen years of age, if a male, and till twelve, if a female. Minority begins where pupillarity ends, and continues till majority, which, by the law of Scotland, is the age of twenty-one years complete, both in males and females: But minority, in a large sense, includes all under age, whether pupils, or puberes. Because pupils cannot in any degree act for themselves, and minors seldom with discretion, pupils are put by law under the power of tutors, and minors may put themselves under the direction of curators. Tutority is a power and faculty to govern the person, and administer the estate of a pupil. Tutors are either nominate, of law, or dative.

2. A tutor nominate is he who is named by a father, in his testament or other writing, to a lawful child. Such tutor is not obliged to give caution for the faithful discharge of his office; because his fidelity is presumed to have been sufficiently known to the father.

3. If there be no nomination by the father, or if the tutors nominate do not accept, or if the nomination falls by death or otherwise, there is place for a tutor of law. This sort of tutor devolves upon the next agnate; by which we understand he who is nearest related by the father, though females intervene.

4. Where there are two or more agnates equally near to the pupil, who is intitled to the pupil's legal succession falls to be preferred to the others. But as the law suspects, that he may not be over careful to preserve a life which stands in the way of his own interest, this sort of tutor is excluded from the custody of the pupil's person, which is commonly committed to the mother, while a widow, until the pupil be seven years old; and, in default of the mother, to the next cognate, i.e. the nearest relation by the mother. The tutor of law must be at least twenty-five years of age. He is served or declared by a jury of sworn men, who are called upon a brief issu-
ing from the Chancery, which is directed to any judge having jurisdiction. He must give security before he enters upon the management.

5. If no tutor of law demands the office, any person, even a stranger, may apply for a tutory-dative. But because a tutor in law ought to be allowed a competent time to deliberate whether he will serve or not, no tutor-dative can be given till the elapsing of a year from the time at which the tutor of law had first a right to serve. It is the king alone, as the father of his country, who gives tutors-dative, by his court of exchequer; and no gift of tutorial can pass in exchequer, without the citation or consent of the next of kin to the pupil, both by the father and mother, nor till the tutor give security, recorded in the books of exchequer. There is no room for a tutor of law, or tutor-dative, while a tutor nominate can be hoped for: and tutors of law, or dative, even after they have begun to act, may be excluded by the tutor nominate, as soon as he offers to accept, unless he has expressly renounced the office. If a pupil be without tutors of any kind, the court of Session will, at the suit of any kinsman, name a factor (steward) for the management of the pupil's estate.

6. After the years of pupillarity are over, the minor is considered as capable of acting by himself, if he has confidence enough of his own capacity and prudence. The only two cases in which curators are imposed upon minors are, first, where they are named by the father, in a state of health. 2. Where the father is himself alive; for a father is ipso jure, without any service, administrator, that is, both tutor and curator of law to his children, in relation to whatever estate may fall to them during their minority. This right in the father does not extend to grand-children, nor to such even of his immediate children as are forisfamiliated. Neither has it place in subjects which are left by a stranger to the minor, exclusive of the father's administration. If the minor chuses to be under the direction of curators, he must raise and execute a summons, citing at least two of his next of kin, to appear before his own judge-ordinary, upon nine days warning. At the day and place of appearance, he offers to the judge a list of those whom he intends for his curators: such of them as resolve to undertake the office, must sign their acceptance, and give caution; upon which an act of curatory is extracted.

7. These curators are styled ad negotia, to distinguish them from another sort called curators ad litter, who are authorized by the judge to concur with a pupil or minor in actions of law, either where he is without tutors and curators, or where his tutors or curators are parties to the suit. This sort is not obliged to give caution, because they have no intermeddling with the minor's estate: they are appointed for a special purpose; and when that is over, their office is at an end. Women are capable of being tutors and curators, under the following restrictions: 1. The office of a female tutor or curator falls by her marriage, even though the nomination should provide otherwise; 2. No woman can be tutor of law. Pupils are declared incapable of tutorial or curatory. Where the minor has more tutors and curators than one, who are called in the nomination to the joint management, they must all concur in every act of administration; where a certain number is named for a quorum, that number must concur; where any one is named sine quo non, no act is valid without that one's special concurrence. But if they are named without any of these limitations, the concurrence of the majority of the nominees then alive is sufficient.

8. In this, tutorial differs from curatory, that as pupils are incapable of content, they have no person capable of acting; which defect the tutor supplies: but a minor pubes can act for himself. Hence, the tutor subscribes alone all deeds of administration: but in curatory, it is the minor who subscribes as the proper party; the curator does no more than content. Hence also, the persons of pupils are under the power, either of their tutors or of their nearest cognates; but the minor, after pupillarity, has the disposal of his own person, and may reside where he pleases. In most other particulars, the nature, the powers, and the duties of the two offices coincide. Both tutors and curators must, previous to their administration, make a judicial inventory, subscribed by them and the next of kin, before the minor's judge-ordinary, if his whole estate, personal and real; of which, one subscribed duplicate is to be kept by the tutors or curators themselves; another, by the next of kin on the father's side; and a third, by the next of kin on the mother's. If any estate belonging to the minor shall afterwards come to their knowledge, they must add it to the inventory within two months after their attaining possession thereof. Should they neglect this, the minor's debtors are not obliged to make payment to them; they may be removed from their offices as suspected, and they are intitled to no allowance for the sums disbursed by them in the minor's affairs, except the expense laid out upon the minor's entertainment, upon his lands and houses, and upon completing his titles.

9. Tutors and curators cannot grant leases of the minor's lands, to endure longer than their own office; nor under the former rental, without either a warrant from the court of Session, or some apparent necessity.

10. They have power to sell the minor's moveables; but cannot sell their pupil's land estate, without the authority of a judge. But the alienation of heritage by a minor, with consent of his curators, is valid.

11. Tutors and curators cannot, contrary to the nature of their trust, authorise the minor to do any deed for their own benefit; nor can they acquire any debt affecting the minor's estate: and, where a tutor or curator makes such acquisition, in his own name, for a less sum than the right is intitled to draw, the benefit thereof accrues to the minor.

12. By the Roman law, tutorial and curatory, being munera publica, might be forced upon every one who had not a relevant ground of excuse; but, with us, the persons named to these offices may either accept or decline: and where a father, in ligeo pousies, names certain persons both as tutors and curators to his children, though they have acted as tutors, they may decline the office of curator. Tutors and curators having once accepted, are liable in diligence, that is, accountable for the consequences of their neglect in any part of their duty.
duty from the time of their acceptance. They are accountable fungali in solidum, i.e. every one of them is answerable, not only for his own diligence, but for that of his co-tutors; and any one may be sued without citing the rest: But he who is condemned in the whole, has action of relief against his co-tutors.

13. From this obligation to diligence, we may except, 1. Fathers or administratores in law, who, from the presumption that they act to the best of their power for their children, are liable only for actual intoxications. 2. Tutors and curators named by the father, with the special provision, that they shall be liable barely for intoxications, not for omissions; and that each of them shall be liable only for himself, and not in solidum for the co-tutors: But this power of exemption from diligence, is limited to the estate defending from the father himself. Tutors or curators are not intitled to any salary or allowance for pains, unless a salary has been expressly contained in the testator’s nomination; for their office is presumed gratuitous.

14. Though no person is obliged to accept the office of tutor or curator, yet having once accepted, he cannot throw it up or renounce it, without sufficient cause; but, if he should be guilty of misapplying the minor’s money, or fail in any other part of his duty, he may be removed at the suit of the minor’s next in kin, or by a co-tutor, or co-curator. Where the misconduct proceeds merely from indolence, or inattention, the court, in place of removing the tutor, either join a curator with him, or, if he be a tutor-nominate, they oblige him to give caution for his past and future management.

15. The offices of tutorry and curatory expire by the pupil’s attaining the age of puberty, or the minor’s attaining the age of twenty-one years complete; and by the death either of the minor, or of his tutor or curator.

16. Deeds either by pupils, or by minors having curators without their consent, are null; but they oblige the granters, in as far as relates to sums profitably applied to their use. A minor under curators can indeed make a testament by himself; but whatever is executed by him, in the course of that business, especially if he has proximus majorenniti at signing the deed. 4. According to the more common opinion, a minor cannot be restored against his own delicacy or fraud. 2. Restitution is excluded, if the minor, at any time after majority, has approved of the deed, either by a formal ratification, or tacitly by payment of interest, or by other acts inferring approbation. 3. A minor, who has taken himself to business, as a merchant shopkeeper, &c cannot be restored against any deed granted by him, in the course of that business, especially if he was proximus majorenniti at signing the deed.

18. Questions of restitution are proper to the court of Session. Two things must be proved by the minor, in order to the reduction of the deed; 1. That he was minor when it was signed; 2. That he is hurt or lefled by the deed. This lesion must not proceed merely from accident; for the privilege of restitution was not intended to exempt minors from the common misfortunes of life; it must be owing to the imprudence or negligence of the minor, or his curator.

19. A minor cannot be restored against his own delicacy or fraud. 2. Restitution is excluded, if the minor, at any time after majority, has approved of the deed, either by a formal ratification, or tacitly by payment of interest, or by other acts inferring approbation. 3. A minor, who has taken himself to business, as a merchant shopkeeper, &c cannot be restored against any deed granted by him, in the course of that business, especially if he was proximus majorenniti at signing the deed. 4. According to the more common opinion, a minor cannot be restored in a question against a minor, unless some gross unfairness shall be qualified in the bargain.

20. The privilege of restitution does not always die with the minor himself. 1. If a minor succeeds to a minor, the time allowed for restitution is governed by the minority of the heir, not of the ancestor. 2. If a minor succeeds to a major, who was not full twenty-five, the privilege continues with the heir during his minority; but he cannot avail himself of the anni utiles, except in so far as they were unexpired at the ancestor’s death. 3. If a major succeeds to a minor, he has only the quadriennium utile after the minor’s death; and if he succeeds to a major dying within the quadriennium, no more of it can be profitable to him than what remained when the ancestor died.

21. No minor can be compelled to state himself as a defender, in any action, whereby his heritable estate flowing from ascendents may be evicted from him, by one pretending a preferable right.

22. This privilege is intended merely to save minors from the necessity of disputing upon questions of preference; it does not therefore take place, 1. Where the action is pursued on the father’s falsehood or delict. 2. Upon his obligation to convey heritage. 3. On his liquid bond for a sum of money, though such action should have the effect to carry off the minor’s estate by adjudication. 4. Nor in actions pursued by the minor’s superior, upon feudal casualties. 5. This privilege cannot be pleaded in bar of an action which had been first brought against the father, and is only continued against the minor; nor where the father was not in the peaceable possession of the heritable subject at his death. Before the minor can plead it, he must be served heir to his father. The persons of pupils are protected from imprisonment on civil debts.

23. Curators are given, not only to minors, but in general to every one who, either through defect of judgment, or unfitness of disposition, is incapable of reasonable time, from that period, when he is first presumed to have the proper use of his reason, to confer with himself what deeds done in his minority have been truly prejudicial to him.
rightly managing his own affairs. Of the first fort, are idiots and furious persons. Idiots, or *fatai*, are entirely deprived of the faculty of reason. The delirium of the furious person does not consist in the defect of reason, but in an overheated imagination, which obstructs the application of reason to the purposes of life. Curators may be also granted to lunatics, and even to persons dumb and deaf, though they are of sound judgment, where it appears that they cannot exert it in the management of business. Every person, who is come of age, and is capable of acting rationally, has a natural right to conduct his own affairs. The only regular way, therefore, of appointing this sort of curators, is by a jury summoned upon a brief from the chancery; which is not, like the brief of common tutory, directed to any judge-ordinary, but to the judge of the special territory where the person alleged to be fatuous or furious resides; that if he is really of sound judgment, he may have an opportunity to oppose it: And, for this reason, he ought to be made a party to the brief. The curates of idiots and furious persons belongs to the nearest agnate; but a father is preferred to the curator of his furious son, and the husband to that of his furious wife, before the agnate.

24. A claus is inserted in the brief, for inquiring how long the fatuous or furious person has been in that condition; and the verdict to be pronounced by the inquest, is declared a sufficient ground, without farther evidence, for reducing all deeds granted after the period at which it appeared by the proof that the fatuity or furiousness began. But, as fatuous and furious persons are, by their very state, incapable of being obliged, all deeds done by them may be declared void, upon proper evidence of their fatuity at the time of signing, though they should never have been cognized idiots by an inquest.

25. We have some few instances of the Sovereign's giving curators to idiots, where the next agnate did not claim; but such gifts are truly deviations from our law, since they pass without an inquiry into the state of the person upon whom the curatory is imposed. Hence the curator of law to an idiot, serving *quandoconque*, is preferred as soon as he offers himself, before the curator-legate. This sort of curator does not determine by the lucid intervals of the person *s ub cura*; but it expires by his death, or perfect return to a sound judgment; which last ought regularly to be declared by the sentence of a judge.

26. Persons, let them be ever so profuse, or liable to be imposed upon, if they have the exercise of reason, can effectually oblige themselves, till they are fettered by law. Interdiction is a legal restraint laid upon such persons from signing any deed to their own prejudice, without the consent of their curators or interdictors.

27. There could be no interdiction, by our ancient practice, without a previous inquiry into the person's condition. But as there were few who could bear the blame that attends judicial interdiction, however necessary the restraint might have been, voluntary interdiction has received the countenance of law; which is generally executed in the form of a bond, whereby the granter obliges himself to do no deed that may affect his estate, without the consent of certain friends therein mentioned. Though the reasons inductive of the bond should be but gently touched in the recital, the interdiction stands good. Voluntary interdiction, though it be imposed by the sole act of the person interdicted, cannot be recalled at his pleasure: But it may be taken off, 1. By a sentence of the court of Seffion, declaring, either that there was, from the beginning, no sufficient ground for the restraint; or that the party is, since the date of the bond, become *rei j u s pr ovidus*. 2. It falls, even without the authority of the Lords, by the joint act of the person interdicted, and his interdictors, concurring to take it off. 3. Where the bond of interdiction requires a certain number as a quorum, the restraint ceases if the interdictors shall be by death reduced to a lesser number.

28. Judicial interdiction is imposed by a sentence of the court of Seffion. It commonly proceeds on an action brought by a near kinsmen to the party; and sometimes from the *nobile officium* of the court, when they perceive, during the pendency of a suit, that any of the litigants is, from the facility of his temper, subject to imposition. This suit must be taken off by the authority of the same court that imposed it.

29. An interdiction need not be served against the person interdicted; but it must be executed, or published by a messenger, at the market-cross of the jurisdiction where he resides, by publicly reading the interdiction there, after three oysles made for convicting the lieges. A copy of this execution must be affixed to the cross; and thereafter, the interdiction, with its execution, must be registered in the books, both of the jurisdiction where the person interdicted resides, and where his lands lie, or, in the general register of the seffion, within forty days from the publication. An interdiction, before it is registered, has no effect against third parties, though they should be in the private knowledge of it; but it operates against the interdictors themselves, as soon as it is delivered to them.

30. An interdiction, duly registered, has this effect, that all deeds, done thereafter, by the person interdicted, without the consent of his interdictors, affecting his heritable estate, are subject to reduction. Registration, in the general register, secures all his lands from alienation, where-ever they lie; but where the interdiction is recorded in the register of a particular thire, it covers no lands, except those situated in that thire. But persons interdicted have full power to dispose of their moveables, not only by testament, but by present deeds of alienation: And creditors, in personal bonds granted after interdiction, may use all execution against their debtor's person and moveable estate; such bonds being only subject to reduction, in so far as diligence against the heritable estate may proceed upon them.

31. All onerous or rational deeds granted by the person interdicted, are as effectual, even without the consent of the interdictor, as if the granter had been laid under no restraint, but he cannot alter the succession of his heritable estate, by any settlement: let it be ever so rational. No deed, granted with consent of the interdictors, is reducible, though the strongest reason or prejudice to the granter should appear: The only remedy competent, in such case, is an action by the granter against his interdictors,
The law concerning the estate of children falls next to be explained. Children are either born in wedlock, or out of it. All children, born in lawful marriage or wedlock, are presumed to be begotten by the person to whom the mother is married; and consequently to be lawful children. This presumption is so strongly founded, that it cannot be defeated but by direct evidence that the mother's husband could not be the father of the child, e.g. where he is impotent, or was absent from the wife till within six lunar months of the birth. The canonists indeed maintain, that the concurrence of testimony of the husband and wife that the child was not procreated by the husband, is sufficient to elide this legal presumption for legitimacy: but it is an agreed point, that no regard is to be paid to such testimony, if it be made after they have owned the child to be theirs. A father has the absolute right of disposing of his children person, of directing their education, and of moderate chastisement; and even after they become pueri, he may compel them to live in family with him, and to contribute their labour and industry, while they continue there, towards his service. A child who gets a separate flock from the father for carrying on any trade or employment, even though he should continue in the father's house, may be said to be emancipated or forisfamiliiated, in so far as concerns that flock; for the profits arising from it are his own. Forisfamilium, when taken in this sense, is also inferred by the child's marriage, or by his living in a separate house, with his father's permission or goodwill. Children, after their full age of twenty-one years, become, according to the general opinion, their own masters; and from that period are bound to the father only by the natural ties of duty, affection, and gratitude. The mutual obligations between parents and children to maintain each other, are explained afterwards, Tit. 20.

32. Children, born out of wedlock, are styled natural children, or bastards. Bastards may be legitimated or made lawful, either. 1. By the subsequent intermarriage of the mother of the child with the father. And this sort of legitimation, invests the child to all the rights of lawful children. The subsequent marriage, which produces legitimation, is considered by the law, to have been entered into when the child legitimated was begotten; and hence, if he be a male, he excludes, by his right of primogeniture, the sons procreated after the marriage, from the succession of the father's heritage, though these sons were lawful children from the birth. Hence also, those children only can be thus legitimated, who are begotten of a woman whom the father might at that period have lawfully married. 2. Bastards are legitimated by letters of legitimation from the sovereign. See Tit. 29.

34. As to the power of masters over their servants: All servants now enjoy the same rights and privileges with other subjects, unless in so far as they are tied down by...
of which can be brought under the power of any one person, though their use be common to all: Others are by law exempted from private commerce, in respect of the uses to which they are defined. Of this last kind are, 1. Res publicae, as navigable rivers, highways, bridges, &c.: the right of these is vested in the King, chiefly for the benefit of his people, and they are called regalia. 2. Res univcrsitatis, things which belong in property to a particular corporation or society, and whose use is common to every individual in it; but both property and use are subject to the regulations of the society; as town-houses, corporation-halls, market-places, church yards, &c. The lands or other revenue belonging to a corporation do not fall under this class, but are juris privati.

3. Property may be acquired, either by occupation or accession; and transferred by tradition or prescription. But prescription, being also a way of losing property, and continued, under certain restrictions, the doctrine of the Roman law, Quod nullius est, fit occupans; but it can have no room in the feudal plan, by which the King is looked on as the original proprietor of all the lands within his dominions.

4. Even in that sort of moveable goods which are presumed to have once had an owner, this rule obtains by the law of Scotland, Quod nullius est, fit dominus regit. Thus, the right of treasuries hid under ground, is not acquired by occupation, but accrues to the King. Thus also, where one finds stray cattle or other moveables, which have been lost by the former owner, the finder acquires no right in them, but must give public notice thereof; and if within year and day after such notice, the proprietor does not claim his goods, they fall to the King, Sheriff, or other person, to whom the King has made a grant of such ejectments.

5. In that sort of moveables which never had an owner, as wild beasts, fowls, fishes, or pearls found on the shore, the original law takes place, that he who first apprehends, becomes proprietor; in so much, that though the right of hunting, fowling, and fishing, be restrained by statute, under certain penalties, yet all game, even what is caught in contravention of the law, becomes the property of the catcher, unless where the confiscation thereof is made part of the penalty: But whales thrown in or killed on our coasts, belong neither to those who kill them, nor to the proprietor of the grounds on which they are cast, but to the King, providing they are so large as that they cannot be drawn by a wane with six oxen.

6. Accession is that way of acquiring property, by which, in two things which have a connection with, or dependence on one another, the property of the principal thing draws after it the property of its accessor. Thus the owner of a cow becomes the owner of the calf; a house belongs to the owner of the ground on which it stands, though built with materials belonging to, and at the charge of another. The Romans excepted from this rule the case of paintings drawn on another man's board or canvas, in consideration of the excellency of the art; which exception our practice has for a like reason extended to similar cases.

7. Under accession is comprehended specification; by which is meant, a person's making a new species or subject, from materials belonging to another. Where the new species can be again reduced to the matter of which it was made, law considers the former mass as still existing; and therefore, the new species, as an accessory to the former subject, belongs to the proprietor of that subject: But where the thing made cannot be so reduced, as in the case of wine, which cannot be again turned into grapes, there is no place for the fideio juris; and therefore the workmanship draws after it the property of the materials.

8. Though the new species should be produced from the commixtion or confusion of different substances belonging to different proprietors, the same rule holds; but where the mixture is made by the common consent of the owners, such consent makes the whole a common property, according to the shares that each proprietor had formerly in the several subjects. Where things of the same sort are mixed without the consent of the proprietors, which cannot again be separated, e.g. two hogheads of wine, the whole likewise becomes a common property; but in the after-division, regard ought to be had to the different quality of the wines. If the things so mixed admit of a separation, e.g. two flocks of sheep, the property continues distinct.

9. Property is carried from one to another by tradition; which is the delivery of possession by the proprietor, with an intention to transfer the property to the receiver. Two things are therefore requisite, in order to the transmitting of property in this way: 1. The intention or consent of the former owner to transfer it on some proper title of alienation, as sale, exchange, gift, &c. 2. The actual delivery in pursuance of that intention. The first is called the causa, the other the modus transferendi dominii: Which last is so necessary to the acquiring of property, that he who gets the last right, with the first tradition, is preferred, according to the rule, Traditionibus, non nudis peditibus, transferuntur rerum dominia.

10. Tradition is either real, where the ipfa corpora of moveables are put into the hands of the receiver; or symbolical, which is used where the thing is incapable of real delivery, or even when actual delivery is only inconvenient. Where the possession or custody of the subject has been before with him to whom the property is to be transferred, there is no room for tradition.

11. Possession, which is essential both to the acquisition and enjoyment of property, is defined, the detention of a thing, with a design or animus in the detainer of holding it as his own. It cannot be acquired by the sole act of the mind, without real detention; but, being once acquired, it may be continued solo animo. Possession is either natural, or civil. Natural possession is, when one possesses by himself: Thus, we possess lands by cultivating them and reaping their fruits, houses by inhabiting them, moveables by detaining them in our hands. Civil possession is our holding the thing, either by the sole act
of the mind, or by the hands of another who holds it in our name: Thus, the owner of a thing lent possesses it by the borrower; the proprietor of lands, by his tacksman, truelee, or fealver; &c. The same subject cannot be possessed entirely, or in jussidum, by two different persons at one and the same time; and therefore possession by an act of the mind ceases, as soon as the natural possession is so taken up by another, that the former possessor is not suffered to re-enter. Yet two persons may, in the judgment of law, possess the same subject, at the same time, on different rights: thus, in the case of a pledge, the creditor possesses it in his own name, in virtue of the right of impagnation; while the proprietor is considered as possessing, in and through the creditor, in so far as is necessary for supporting his right of property. The same doctrine holds in linters, tacksman, and, generally, in every case where there are rights affecting a subject, distinct from the property.

12. A bona fide possessor is he, who, though he is not really proprietor of the subject, yet believes himself proprietor on probable grounds. A mala fide possessor knows, or is presumed to know, that what he possesses is the property of another. A possessor bona fide acquired right, by the Roman law, to the fruits of the subject possessed, that had been reaped and consumed by himself, while he believed the subjects his own. By our customs, perception alone, without consumption, secures the possessor: Nay, if he have the ground, while his bona fides continued, he is intitled to reap the crop, propter curatum et culturam. But this doctrine does not reach to civil fruits, e.g. the interest of money, which the bona fide receiver must restore, together with the principal, to the owner.

13. Bona fides necessarily ceaseth by the conscientia rei aliciae in the possessor, whether such consciousness should proceed from legal interpellation, or private knowledge: Mala fides is sometimes induced, by the true owner's bringing his action against the possessor, sometimes not till till interpellation, and, in cases uncommonly favourable, not till sentence be pronounced against the possessor.

14. The property of moveable subjects is presumed by the bare effect of possession, until the contrary be proved; but possession of an immovable subject, though for a century of years together, if there is no seisin, does not create even a presumptive right to it: Nulla saflina, nulla terra. Such subject is considered as cadditary, and so accrues to the sovereign. Where the property of a subject is contested, the lawful possessor is intitled to continue his possession, till the point of right be discussed; and, if he has lost it by force or stealth, the judge will, upon summury application, immediately restore it to him.

15. Where a possessor has several rights in his person, affecting the subject possessed, the general rule is, that he may acribe his possession to which of them he pleases; but one cannot acribe his possession to a title other than that on which it commenced, in prejudice of him from whom his title flowed.

Tyt. 9. Of heritable and moveable Rights. For the better understanding the doctrine of this title, it must be known, that by the law of Scotland, and indeed of most nations of Europe, since the introduction of seisin, where ever there are two or more in the same degree of consanguinity to one who dies intestate, and who are not all females, such rights belonging to the deceased as are either properly feudal, or have any resemblance to feudal rights, descend wholly to one of them, who is considered as his proper heir; the others, who have the name of next of kin or executors, must be contented with that portion of the estate which is of a more perishable nature. Hence has arisen the division of rights to be explained under this title: the subjects decreasing to the heir, are styled heritable; and those that fall to the next of kin, moveable.

2. All rights of, or affecting lands, under which are comprehended houses, mills, fisheries, teinds; and all rights of subjects that are fundo asexu, whether completed by seisin or not, are heritable ex sua natura. On the other hand, every thing that moves itself, or can be moved, and in general whatever is not united to land, is moveable; as household-furniture, corns, cattle, cash, arrears of rent and of interest, even though they should be due on a right of annuallent: For though the arrears last mentioned are secured on land, yet being presently payable, they are considered as cash.

3. Debts, (nomina debitorum), when due by bill, promissory note, or account, are moveable. When constituted by bond, they do not all fall under any one head; but are divided into heritable and moveable, by the following rules. All debts constituted by bond bearing an obligation to infeft the creditor in any heritable subject in security of the principal sum and annualrent, or annualrent only, are heritable; but for they not only carry a yearly profit, but are secured upon land.

4. Bonds merely personal, though bearing a clause of interest, are moveable as to succession; i.e. they go not to the heir, but to the next of kin or executors: but they are heritable with respect to the fisk, and to the rights of husband and wife; that is, though, by the general rule, moveable rights fall under the communion of goods consequent upon marriage, and the moveables of denounced persons fall to the crown or seise, yet such bonds do neither, but are heritable in both respects.

5. Bonds taken payable to heirs and assigns, excluding executors, are heritable in all respects, from the definition of the creditor. But a bond, which is made payable to heirs, without mention of executors, descends, not to the proper heir in heritage, though heirs are mentioned in the bond, but to the executor; for the word heir, which is a generic term, points out him who is to succeed by law in the right; and the executor, being the heir in mobilibus, is considered as the person to whom such bond is taken payable. But where a bond is taken to heirs male, or to a series of heirs, one after another, such bond is heritable, because its destination necessarily excludes executors.

6. Subjects originally moveable become heritable: 1. By the proprietor's definition. Thus, a jewel, or any other moveable subject, may be provided to the heir, from the right competent to every proprietor to settle his property on whom he pleases. 2. Moveable rights
rights may become heritable, by the supervening of an
heritable security: Thus, a sum due by a personal bond
becomes heritable, by the creditor's accepting an heritable
right for securing it, or by adjudging upon it.

7. Heritable rights do not become moveable by acces-
sory moveable securities, the heritable right being in such
case the *jus millius*, which draws the other after it.

8. Certain subjects partake, in different respects, of
the nature both of heritable and moveable. Personal
bonds are moveable in respect of succession, but heritable
as to the small, and husband and wife. All bonds, who-
ether merely personal, or even heritable, on which no se
fin has followed, may be affected at the suit of creditors,
either by adjudication, which is a diligence proper to her-
itage; or by arrestment, which is peculiar to moveables.
Bonds excluding executors, though they descendent to the
creditor's heir, are payable by the debtor's executors,
without relief against the heir; since the debtor's succe-
sion cannot be affected by the definition of the creditor.

9. All questions, whether a right be heritable or move-
able, must be determined according to the condition of
the subject at the time of the ancestor's death. If it was
heritable at that period, it must belong to the heir; if
moveable, it must fall to the executor, without regard
to any alterations that may have affected the subject in
the intermediate period between the ancestor's death and
the competition.

**Tit. 10. Of the Constitution of heritable Rights
by Charter and Seisin.**

Heritable rights are governed by the feudal law,
which owed its origin, or at least its first improvements,
to the Longobards; whose kings, upon having penetrated
into Italy, the better to preserve their conquests, made
grants to their principal commanders of great part of
the conquered provinces, to be again subdivided by them
among the lower officers, under the conditions of fidelity
and military service.

2. The feudal constitutions and usages were first re-
duced into writing, about the year 1150, by two lawyers
of Milan, under the title of *Conjunctudines Feudorum*.
None of the German Emperors appear to have expressly
confirmed this collection by their authority; but it is
generally agreed, that it had their tacit approbation, and
was considered as the customary feudal law of all the
countris subject to the empire. No other country has ever
acknowledged these books for their law; but each state
has followed the genius of its own constitution. In feudal
questions, therefore, we are governed, in the first place,
by our own statutes and customs; where these fail us, we
have regard to the practice of neighboring countries, if
the genius of their law appears to be the same with ours;
and should the question still remain doubtful, we may
have recourse to those written books of the feus, as to
the original plan on which all feudal systems have pro-
ceeded.

3. This military grant got the name, *first of beneficium,*
and afterwards of *feudum;* and was defined a gratuitous
right to the property of lands, made under the conditions
of fealty and military service, to be performed to the
grantor by the receiver; the radical right of the lands
still remaining in the grantor. Under lands, in this def-
inition, are comprehended all rights or subjects so con-
ected with land, that they are deemed a part thereof;
as houses, mills, fisheries, jurisdictions, patronages, &c.

4. Allodial goods are opposed to seus; by which are
understood, goods enjoyed by the owner, independent of
a superior. All moveable goods are allodial; lands only
are so, when they are given without the condition of
fealty or homage. By the feudal system, the sovereign,
who is the fountain of feudal rights, refers to himself
the superiority of all the lands of which he makes the
grant; so that, with us, no lands are allodial, except
those of the King's own property, the superiorities which
the King reserves in the property-lands of his subjects,
and manors and glebes, the right of which is comple-
ted by the prebendary's designation, without any feudal
grant.

5. Every person who is in the right of an immovable
subject, provided he has the free administration of his e-
flate, and is not debared by statute, or by the nature of
his right, may dispose of it to another. Nay, a vassal,
though he has only the *dominium utile*, can subfeu his
property to a subvassal by a subaltern right, and thereby
raise a new *dominium directum* in himself, subordinate
to that which is in his superior; and so *in infinitum*.
The vassal who thus subfeu, is called the subvassal's im-
mediate superior, and the vassal's superior is the subvaf-
kal's mediate superior.

6. All persons who are not disabled by law, may ac-
quire and enjoy feudal rights. Papists cannot purchase a
land estate by any voluntary deed. Aliens, who owe al-
legiance to a foreign prince, cannot hold a feudal right
without naturalization; and therefore, where such privi-
lege was intended to be given to favored nations or per-
sons, statutes of naturalization were necessary, either ge-
neral, or special; or at least, letters of naturalization by
the sovereign.

7. Every heritable subject, capable of commerce, may
be granted in feu. From this general rule is ex-
cepted, 1. The annexed property of the Crown, which is
not alienable without a previous dissolution in parlia-
ment. 2. Tailzied lands, which are devisfed under
condition that they shall not be aliened. 3. An estate in
hereditate jacente cannot be effectually aliened by the
heir-apparent (**f. e.** not entered); but such alienation
becomes
becomes effectual upon his entry, the supervening right accruing in that case to the purchaser; which is a rule applicable to the alienation of all subjects not belonging to the vender at the time of the sale.

8. The feudal right, or, as it is called, invelliture, is constituted by charter and seisin. By the charter, we understand that writing which contains the grant of the feudal subject to the vassal, whether it be executed in the proper form of a charter, or of a disposition. Charters by subject-supersiors are granted, either, 1. A me de superiore meo, when they are to be helden, not of the grantor himself, but of his superior. This fort is called a public holding, because vassals were in ancient times publicly received in the superior's court before the pairs curiae or co-vassals. Or, 2. De me, where the lands are to be helden of the grantor. These were sometimes sale rights, from bis, lessor; and sometimes private, because, before the establishment of our records, they were easily concealed from third parties; the nature of base rights, from has, lower: and sometimes private, to be helden at the time of the sale.

9. The first clause in an original charter, which follows immediately after the name and designation of the grantor, is the narrative or recital, which expresses the causes inducive of the grant. If the grant be made for a valuable consideration, it is said to be onerous; if for love and favour, gratuitous. In the dispositive clause of a charter, the subjects made over are described either by special boundaries or march-stones, (which is called a bounding charter), or by such other characters as may sufficiently distinguish them. A charter regularly carries right to no subjects but what are contained in the clause, though they should be mentioned in some other clause of the charter.

10. The clause of tenendas (from its first words, tenendas pradiis terrarum) expresses the particular tenure by which the lands are to be held. The clause of reddendo (from the words, reddendo inde annuatim) specifies the particular duty or service which the vassal is to pay or perform to the superior.

11. The clause of warrandice is that by which the grantor obliges himself that the right conveyed shall be effectual to the receiver. Warrandice is either personal or real. Personal warrandice, where the grantor is only bound personally, is either, 1. Simple, that is, that he shall grant no deed in prejudice of the right; and this fort, which is confined to future deeds, is implied even in dispositions. 2. Warrandice from fact and deed, by which the grantor warrants that the right neither has been, nor shall be hurt by any fact of his. Or, 3. Absolute warrandice contra omnes mortales, whereby the right is warranted against all legal defects in it, which may carry it off from the receiver, either wholly or in part. Where a sale of lands proceeds upon an onerous cause, the grantor is liable in absolute warrandice, though no warrandice be expressed; but in assignments to debts or decrees, no higher warrandice than from fact and deed is implied.

12. Gratuitous grants by the Crown imply no warrandice; and though warrandice should be expressed, the clause is ineffectual, from a presumption, that it has crept in by the negligence of the Crown's officers. But where the Crown makes a grant, not jure corona, but for an adequate price, the sovereign is in the same case with his subjects.

13. Absolute warrandice, in case of eviction, affords an action to the grantee, against the grantor, for making up to him all that he shall have suffered through the defect of the right; and not simply for his indemnification, by the grantor's repayment of the price to him. But as warrandice is penal, and consequently stricti juris, it is not easily presumed, nor is it incurred from every light servitude that may affect the subject, far less does it extend to burdens which may affect the subject posterior to the grant, nor to those imposed by public statute, whether before or after, unless specially warranted against.

14. Real warrandice is either, 1. Express, whereby, in security of the lands principally conveyed, other lands, called warrandice-lands, are also made over, to which the receiver may have recourse in case the principal lands be evicted. Or, 2. Tacit, which is constituted by the exchange or exchangement of one piece of ground with another; for, if the lands exchanged are carried off from either of the parties, the law itself, without any partition, gives that party immediate recourse upon his own first lands, given in exchange for the lands evicted.

15. The chapter concludes with a precept of seisin, which is the command of the superior grantor of the right to his bailie, for giving seisin or possession to the vassal, or his attorney, by delivering to him the proper symbols. Any person, whose name may be inserted in the blank, left in the precept for that purpose, can execute the precept as bailie; and whoever has the precept of seisin in his hands, is presumed to have a power of attorney from the vassal, for receiving possession in his name.

16. A seisin is the instrument or attestation of a notary, that possession was actually given by the superior or his bailie, to the vassal or his attorney; which is considered as necessary a solemnity, as not to be suppliable, either by a proof of natural possession, or even of the special fact that the vassal was duly entered to the possession by the superior's bailie.

17. The symbols, by which the delivery of possession is expressed, are, for lands, earth and stone; for rights of annual rent payable forth of land, it is also earth and stone, with the addition of a penny money; for parcels of ground, a sheaf of corn; for jurisdictions, the book of the court; for patronages, a palm-book, and the keys of the church; for fisheries, net and cable; for mills, clap and happer, &c. The seisin must be taken upon the ground of the lands, except where there is a special dispensation in the charter from the Crown.

18. All seisins must be registered within sixty days after their date, either in the general register of seisins at Edinburgh, or in the register of the particular shire appointed by the act 1617; which, it must be observed, is not, in every case, the shire within which the lands lie.
Seisin necessarily supposes a superior by whom it is given; the right therefore which the sovereign, who acknowledges no superior, has over the whole lands of Scotland, is constitutum, jus corona, without seisin. In several parcels of land, that lie contiguous to one another, one seisin serves for all, unless the right of the several parcels be either held of different superiors, or derived from different authors, or enjoyed by different tenures under the same superior. In discontiguous lands, a separate seisin must be taken on every parcel, unless the sovereign has united them into one tenancy, by a charter of union; in which case, if there is no special place expressed, a seisin taken on any part of the united lands will serve for the whole, even though they be situated in different shires. The only effect of union is, to give the discontiguous lands the same quality as if they had been contiguous, or naturally united; union, therefore, does not take off the necessity of separate seisins, in lands held by different tenures, or the rights of which flow from different superiors, these being incapable of natural union.

21. The privilege of barony carries a higher right than union does, and consequently includes union in it as the lesser degree. This right of barony can neither be given, nor transmitted, unless by the Crown; but the quality of simple union, being once conferred on lands by the sovereign, may be communicated by the vassal to a subvassal. Though part of the lands united or erected into a barony, be held by the vassal to be held on me, the whole union is not thereby dissolved: what remains of fee simple union retains the quality.

22. A charter, not perfected by seisin, is a right merely personal, which does not transfer the property, (see Tit. xx. 1.) and a seisin of itself bears no faith, without its warrant: It is the charter and seisin joined together that constitutes the feudal right, and secures the receiver against the effect of all posterior seisins, even though the charters on which they proceed should be prior to his.

23. No quality which is designed as a lien or real burden on a feudal right, can be efficacious against singular succesors, if it be not inserted in the investiture. If the creditors in the burden are not particularly mentioned, the burden is not real; for no perpetual unknown incumbrance can be created upon lands. Where the right itself is granted with the burden of the sum therein mentioned, or where it is declared void, if the sum be not paid against a day certain, the burden is real; but where the receiver is simply obliged by his acceptance to make payment, the clause is effectual only against him and his heirs.

20. Seisin necessarily supposes a superior by whom it is given; the right therefore which the sovereign, who acknowledges no superior, has over the whole lands of Scotland, is constitutum, jus corona, without seisin. In several parcels of land, that lie contiguous to one another, one seisin serves for all, unless the right of the several parcels be either held of different superiors, or derived from different authors, or enjoyed by different tenures under the same superior. In discontiguous lands, a separate seisin must be taken on every parcel, unless the sovereign has united them into one tenancy, by a charter of union; in which case, if there is no special place expressed, a seisin taken on any part of the united lands will serve for the whole, even though they be situated in different shires. The only effect of union is, to give the discontiguous lands the same quality as if they had been contiguous, or naturally united; union, therefore, does not take off the necessity of separate seisins, in lands held by different tenures, or the rights of which flow from different superiors, these being incapable of natural union.

21. The privilege of barony carries a higher right than union does, and consequently includes union in it as the lesser degree. This right of barony can neither be given, nor transmitted, unless by the Crown; but the quality of simple union, being once conferred on lands by the sovereign, may be communicated by the vassal to a subvassal. Though part of the lands united or erected into a barony, be held by the vassal to be held on me, the whole union is not thereby dissolved: what remains of fee simple union retains the quality.

22. A charter, not perfected by seisin, is a right merely personal, which does not transfer the property, (see Tit. xx. 1.) and a seisin of itself bears no faith, without its warrant: It is the charter and seisin joined together that constitutes the feudal right, and secures the receiver against the effect of all posterior seisins, even though the charters on which they proceed should be prior to his.

23. No quality which is designed as a lien or real burden on a feudal right, can be efficacious against singular succesors, if it be not inserted in the investiture. If the creditors in the burden are not particularly mentioned, the burden is not real; for no perpetual unknown incumbrance can be created upon lands. Where the right itself is granted with the burden of the sum therein mentioned, or where it is declared void, if the sum be not paid against a day certain, the burden is real; but where the receiver is simply obliged by his acceptance to make payment, the clause is effectual only against him and his heirs.

Tit. II. Of the several kinds of Holding.

Feudal subjects are chiefly distinguished by their different manners of holding, which were either ward, blench, feu, or burgage. Ward-holding, which is now abolished by 20. Geo. II. c. 50. was that which was granted for military service. Its proper reddendo was services, or services used and void, by which last was meant the performance of service whenever the superior's occasions required it. As all feudal rights were originally held by this tenure, ward-holding was in duos. Hence, though the reddendo had contained some special service, or yearly duty, the holding was preferred ward, if another holding was not particularly expressed.

2. Feu-holding is that whereby the vassal is obliged to pay to the superior a yearly rent in money or grain, and sometimes also in services proper to a farm, as ploughing, reaping, carriages for the superior's use, &c. merely in acknowledgment of the superiority, nonis alia forma. This kind of tenure was introduced for the encouragement of agriculture, the improvement of which was considerably obstructed by the vassal's obligation to military service. It appears to have been a tenure known in Scotland as far back as leges burgorum.

3. Blanch-holding is that whereby the vassal is to pay to the superior an annual yearly duty, as a penny money, a role, a pair of gilt spurs, &c. merely in acknowledgment of the superiority, nonis alia forma. This duty, where it is a thing of yearly growth, if it be not demanded within the year, cannot be exacted thereafter; and where the words, si potatur tantum, are subjoined to the reddendo, they imply a release to the vassal, whatever the quality of the duty may be, if it is not asked within the year.

4. Burgage holding is that, by which boroughs-royal hold of the sovereign the lands which are contained in their charters of erection. This, in the opinion of Craig, does not constitute a separate tenure, but is a species of ward-holding; with this particularity, that the vassal is not a private person, but a community: And indeed, watching and warding, which is the usual service contained in the reddendo of such charters, might be properly enough said, some centuries ago, to have been of the military kind. As the royal borough is the King's vassal, all burgage-holders hold immediately of the Crown: The magistrates therefore, when they receive the resignations of the particular burgesses, and give seisin to them, act, not as superiors, but as the King's bailies specially authorized thereto.

5. Feudal objects, granted to churches, monasteries, or other societies for religious or charitable uses, are said to be mortified, or granted ad manum mortorum: either because all casualties must necessarily be loit to the superior, where the vassal is a corporation, which never dies; or because the property of these subjects is granted to a dead hand, which cannot transfer it to another. In lands mortified in times of Popery to the church, whether granted to prelates for the benefit of the church, or in furore eleemosynarum; the only services pretable by the vassal were prayers, and singing of masses for the souls of the deceased, which approaches nearer to ward-holding than ward. The purposes of such grants having been, upon the reformation, declared superfluous, the lands mortified were annexed to the Crown: But mortifications...
T. 12. Of the Casualties due to the Superior.

The right of the superior continues unimpaired, notwithstanding the feudal grant, unless in so far as the dominium utile, or property, is conveyed to his vassal. The superiority carries a right to the services and annual duties contained in the reddendo of the vassal's charter. The duty payable by the vassal is a debitum fundi; i.e., it is recoverable, not only by a personal action against himself, but by a real action against the lands.

1. Besides the constant fixed rights of superiority, there are others, which, because they depend upon uncertain events, are called casualties.

2. The casualties proper to a ward holding, while that tenure subsists, were ward, recognition, and marriage, which it is now unnecessary to explain, as by the late statutes 20 and 25 Geo. II. for abolishing ward-holdings, the tenure of the lands helden ward of the Crown or Prince is turned into blench, for payment of one penny Scots yearly. The landed duty in money, viz. short, or cattle, in place of all services, is conveyed to his vassal.

3. The casualties proper to a feuholding, while that tenure subsists, are feu holding, the fee duty, and the feudal covenant. The feudal covenant is a condition implied in the feudal right, and not as a condition of feudal tenure. The feudal covenant is a condition implied in the feudal right, and not as a condition of feudal tenure,

4. The only casualty, or rather forfeiture, proper to feu-holdings, is the loss or tinfelof the feu-right, by the failure to renew the investiture after his ancestor's death. Yet where there is no conventional irritancy in the feu-right, the vassal is allowed to purge the legal irritancy at the bar; that is, he may prevent the forfeiture, by making payment before sentence: but where the legal irritancy is fortified by a conventional, he is not allowed to purge, unless where he can give a good reason for the delay of payment.

5. The casualties common to all holdings are, non-entry, relief, livery, escheat, disclaim, and purpresture. Non-entry is that casualty which arises to the superior out of the rents of the feudal subject, through the heir's neglecting to renew the investiture after his ancestor's death. The superior is intitled to this casualty, not only where the heir has not obtained himself infeft, but where his retour is set aside upon nullities. The heir, from the death of the ancestor, till he be cited by the superior in a process of general declarator of non-entry, looses only the returned duties of his lands, (see next parag.) and he forfeits these, though his delay should not argue any contempt of the superior, because the casualty is considered to fall, as a condition implied in the feudal right, and not as a penalty of transgression: But, where the delay proceeds not from the heir, but from the superior, nothing is forfeited.

6. For understanding the nature of returned duties, it must be known, that these were anciently a general valuation of all the lands in Scotland, designed both for regulating the proportion of public subsidies, and for ascertaining the quantity of non-entry and relief-duties payable to the superior, which appears, by a contract between K. R. Bruce and his subjects anno 1327, preferred in the library of the faculty of advocates, to have been settled at least as far back as the reign of Alexander III. This valuation became in the course of time, by the improvement of agriculture, and perhaps also by the heightening of the nominal value of our money, from the reign of Robert I. downwards to that of James III. much too low a standard for the superior's casualties: Wherefore, in all services of heirs, the inquest came at last to take proof likewise of the present value of the lands contained in the brief (quantum nunc valent) in order to fix these casualties. The shift was called the old, and the other the new extent. Though both extents were ordained to be specified in all returns made to the Chancery upon briefs of inquest; yet by the appellation of returned duties in a question concerning casualties, the new extent is always understood. The old extent continued the rule for levying public subsidies, till a tax was imposed by new proportions, by several acts made during the usurpation. By two acts of Cromwell's parliament, held at Westminister 1656, imposing taxation on Scotland, the rates laid upon the several counties are precisely fixed. The subsidy granted by the act of convention 1667, was levied on the several counties, nearly in the same proportion that were fixed by the usurper in 1656; and the sums to which each county was subjected were subdivided among the individual land-holders in that county, according to the valuations already settled, or that should be settled by the commission appointed to carry that act into execution. The rent fixed by these valuations is commonly called the valued rent; according to which, the feudal tax, and most of the other public burdens, have been levied since that time.

7. In feu-holdings, the feu-duty is retoured as the rent, because the feu-duty is presumed to be, and truly was at first, the rent. The superior therefore of a feuholding gets no non-entry, before citation in the general declarator; for he would have been intitled to the yearly feu-duty, though the fee had been full, i.e., though there had been a vassal infeft in the lands. The superior of tenements gets the fifth part of the returned duty as non-entry, because the law considers teinds to be worth a fifth part of the rent. In rights of annualrent which are holden of the granter, the annualrenter becomes his debtor's vassal; and the annuelrent contained in the right is retoured to the blanch or other duty contained in the right before declarator.

8. It is because the returned duty is the presumed rent, that the non-entry is governed by it. If therefore no retour of the lands in non-entry can be produced, nor any evidence brought of the returned duty, the superior is intitled to the real, or at least to the valued rent, even before citation. In lands formerly holden ward of the King, the heir, in place of the returned duties, is subjected only to the annual payment of one per cent. of the valued rent.

9. The heir, after he is cited by the superior in the action of general declarator, is subjected to the full rents till...
till his entry, because his neglect is less excusable after
citation. The decree of declarator, proceeding on this
action, intitles the superior to the possession, and gives
him right to the rents, downward from the citation. As
this sort of non-entry is properly penal, our law has al-
ways restricted it to the retoured duties, if the heir had
a probable excuse for not entering.

10. Non-entry does not obtain in burgage-holdings,
because the incorporation of inhabitants holds the whole
incorporated subjects of the King; and there can be no
non-entry due in lands granted to communities, because
there the vassal never dies: This covers the right of par-
ticulars from non-entry; for if non-entry be excluded
with regard to the whole, it cannot obtain with regard
to any part. It is also excluded, as to a third of the
lands, by the terre, during the widow's life; and as to
the whole of them, by the courtey, during the life of the
husband. But it is not excluded by a precept of seisin
granted to the heir, till seisin be taken thereon.

11. Relief is that casualty which intitles the supe-
rior to an acknowledgment or consideration from the heir,
for receiving him as vassal. It is called relief, because,
by the entry of the heir, his fee is relieved out of the
hands of the superior. It is not due in feu-holdings
flowing from subjects, unless where it is expressed in the
charter by a special clause for doubling the feu-duty at
the entry of an heir; but in feu rights, holden of the
crown, it is due, though there should be no such clause
in the charter. The superior can recover this casualty,
either by a paying of the ground, as a debitum fundi,
or by a personal action against the heir. In blanch and
feu-holdings, where this casualty is expressly stipulated,
year's blanch or feu-duty is due in name of relief, be-
side the current year's duty payable in name of blanch or
feu farm.

12. Escheat (from esceoir, to happen or fall) is that
forfeiture which falls through a person's being denoun-
ced rebel. It is either single or liferent. Single escheat,
though it does not accrue to the superior, must be ex-
plained in this place, because of its coincidence with lifer-
rent.

13. After a debt is constituted, either by a formal de-
eree, or by registration of the ground of debt, which to
the special effect of execution, is in law accounted a
decree; the creditor may obtain letters of horning, issuing
from the signet, commanding messengers to charge the
defender to pay or perform his obligation, within a day
certain. Where horning proceeds on a formal decree of the Se-
dition, the time indulged by law to the debtor is
fifteen days; if upon a decree of the commiss of teinds
or admiral, it is ten; and upon the decrees of all inferior
judges, fifteen days. Where it proceeds on a re-
gistered obligation, which specifies the number of days,
that number must be the rule; and, if no precise num-
ber be mentioned, the charge must be given on fifteen
days, which is the term of law, unless where special fla-
tute interposes; as in bills, upon which the debtor may
be charged on six days.

14. The messenger must execute these letters (and in-
deed all summons) against the debtor, either personally,
or at his dwelling house; and, if he get not access to
the house, he must strike six knocks at the gate, and
thereafter affix to it a copy of his execution. If pay-
ment be not made within the days mentioned in the
horning, the messenger, after proclaiming three nightes
at the market-crofs of the head borough, of the debtor's
domicile, and reading the letters there, blows three blaits
with a horn, by which the debtor is understood to be
proclaimed rebel to the King for contempt of his au-
thority; after which, he must affix a copy of the execu-
tion to the market-crofs: This is called the publication
of the diligence, or a denunciation at the horn. Where
the debtor is not in Scotland, he must be charged on fix-
ty days, and denounced at the market crofs of Edinburgh,
and pier and shore of Leith.

15. Denunciation, if registered within fifteen days,
either in the Sheriff's books, or in the general register,
drew after it the rebel's single escheat, i.e., the forfeiture
of his moveables to the Crown. Persons denounced re-
bels have not a persona flandi in judicio; they can nei-
er sue nor defend in any action. But this incapacity,
being unfavourable, is personal to the rebel, and cannot
be pleaded against his allegiance.

16. Persons cited to the court of Judicary may be
also denounced rebels, either for appearing there with
too great a number of attendants; or, if they fail to ap-
pear, they are declared fugitives from the law. Single
escheat falls without denunciation, upon sentence of
death pronounced in any criminal trial; and by special
flutute, upon one's being convicted of certain crimes,
thought not capital; as perjury, bigamy, defenses.
ence of arrestment, and usury. By the late act abo-
lifting wardholdings, the casualties both of single and
liferent escheat are discharged, when proceeding upon
denunciation for civil debts; but they still continue,
when they arise from criminal causes. All moveables
belonging to the rebel at the time of his rebellion,
(whether proceeding upon denunciation, or sentence in
a criminal trial), and all that shall be afterwards ac-
quired by him until relaxation, fall under single escheat.
Bonds bearing interest, because they continue heritable
quad fijicum, fall not under it; nor such fruits of her-
itables as become due after the term next ensuing.
the rebellion, these being reserved for the liferent
escheat.

17. The King never retains the right of escheat to
himself, but makes it over to a donatory, whose gift is
not perfected, till, upon an action of general declarator,
it be declared that the rebel's escheat has fallen to the
crown by his denunciation, and that the right of it is now
transferred to the purfuer by the gift in his favour:
Every creditor therefore of the rebel, whose debt was
contracted before rebellion, and who has used diligence
before declarator, is preferable to the donatory. But
the escheat cannot be affected by any debt contracted,
nor by any voluntary deed of the rebel after rebellion.

18. The rebel, if he either pays the debt charged for,
or suspends the diligence, may procure letters of relaxa-
tion from the horn, which, if published in the same place,
and registered fifteen days thereafter in the same register
with the denunciation, have the effect to restore him to
his former state; but they have no retrospect, as to the
moveables
moveables already fallen under escheat, without a special clause for that purpose.

19. The rebel, if he continues unrelaxed for year and day after rebellion, is construed to be civilly dead: And therefore, where he holds any feudal right, his superiors, as being without a vassal, are entitled, each of them, to the rents of such of the lands belonging to the rebel as holds of himself, during all the days of the rebel’s natural life, by the casualty of different escheat; except where the denunciation proceeds upon treason or proper rebellion, in which case the lizenet falls to the King.

20. It is that estate only, to which the rebel has a proper right of lizenet in his own person, that falls under his different escheat.

21. Though neither the superior nor his donatory can enter into possession in consequence of this casualty, still decree of declarator; yet that decree, being truly declaratory, has a retrospect, and does not so properly confer a new right, as declare the right formerly constituted to the superior, by the civil death of his vassal. Hence, all charters or heritable bonds, though granted prior to the rebellion, and all adjudications, though led upon debts contracted before that period, are ineffectual against the different escheat, unless feizin be taken thereon within year and day after the grantor’s rebellion.

22. Here, as in single escheat, no debt contracted after rebellion can hurt the donatory. nor any voluntary right granted after that period, though in security or satisfaction of prior debts.

23. Disclamation is that casualty whereby a vassal forfeits his whole feu to his superior, if he disowns or disclaims him without ground, as to any part of it. Purpresture draws likewise a forfeiture of the whole feu after it, and is incurred by the vassal’s increasing upon any part of his superior’s property, or attempting, by building, inclosing, or otherwise, to make it his own. In both these feudal delinquencies, the least colour of excuse faves the vassal.

24. All grants from the crown, whether charters, gifts of casualties, or others, proceed on signatures which pass the signet. When the King resided in Scotland, all signatures were superscribed by him; but, on the accession of James VI. to the crown of England, a cachet or seal was made, having the King’s name engraved on it, in pursuance of an act of Privy Council, April 4, 1603, with which all signatures were to be afterwards sealed, that the Lords of exchequer were impowered to pass; and these powers are transferred to the court of Exchequer, which was established in Scotland after the union of the two kingdoms in 1707. Grants of higher consequence, as remissions of crimes, gifts proceeding upon forfeiture, and charters of novum munus, must have the King’s sign-manual for their warrant.

25. If lands holding of the Crown were to be conveyed, the charter passed, before the union of the kingdoms in 1707, by the great seal of Scotland; and now by a seal substituted in place thereof. Grants of church dignities, during episcopacy, passed also by the great seal; and the commissions to all the principal officers of the Crown, as Justice Clerk, King’s Advocate, Solicitor, &c.
4. Salmon-fishing is likewise a right understood to be reolved by the Crown, if it be not expressly granted; but forty years possession thereof, where the lands are either erected into a barony, or granted with the general clause of fisheries, established as the full right of the salmon fishing in the vassal. A charter of lands, within which any of the king's forests lie, does not carry the property of such forest to the vassal.

5. All the subject's, which were by the Roman law accounted res publica, as rivers, high ways, ports, &c. are, since the introduction of fees, held to be inter regalias, or in patrimonio principis; and hence incroachment upon a highway is said to infringe purpureum. No person has the right of a free port without a special grant, which implies a power in the grantee to levy anchorage and store dues, and an obligation upon him to uphold the same. The right of a free port without a special grant, which is the right of a free port without a special grant, which may be excluded from the grant of lands. But if the lands in the grant are marked out by special limits, the vassal is circumcised by the tenor of his own right, which excludes every subject without these limits from being pertinent of the lands. A right possessed under an express instrument is preferable, ceperis paribus, to one possessed only as pertinent. Where neither party is infeft per expressum, the mutual promises, by an action of marriage and duties before the Sheriff, are reckoned sequestrations, or small places of strength, originally built for the defence of the country, either against foreign invasions, or civil commotions; but these now pass with the lands in every charter.

6. The vassal acquires right by his grant, not only to the lands specially contained in the charter, but to those that have been possession forty years as pertinent thereof. But, 1. If the lands in the grant are marked out by special limits, the vassal is circumcised by the tenor of his own right, which excludes every subject without these limits from being pertinent of the lands. 2. A right possessed under an express instrument is preferable, ceperis paribus, to one possessed only as pertinent. Where neither party is infeft per expressum, the mutual promises, by an action of marriage and duties before the Sheriff, are reckoned sequestrations, or small places of strength, originally built for the defence of the country, either against foreign invasions, or civil commotions; but these now pass with the lands in every charter.

7. As barony is a nomen universitas, and unites the several parts contained in it into one individual right, the general conveyance of a barony carries with it all the different tenements of which it consists, though they should not be specially enumerated, (and this holds, even without erection into a barony, in lands that have been united under a special name,) Hence likewise, the possession by the vassal of the smallest part of the barony lands preserves to him the right of the whole.

8. The vassal is intitled, in consequence of his property, to levy the rents of his own lands, and to recover them from his tenants by an action for rent before his own court; and from all other poisselors and intrummers, by an action of mals and duties before the Sheriff. He can also remove from his lands, tenants who have no leases, and he can grant tacks or leases to others. A tack is a contract of location, whereby the use of land or any other immovable subject, is let to the leahee or tacksmen for a certain yearly rent, either in money, the fruits of the ground, or services. It ought to be reduced into writing, as it is a right concerning lands; tacks therefore, that are given verbally, to endure for term of years, are good against neither party, for more than one year. An obligation to grant a tack is as effectual against the grantor, as a formal tack. A liferent, having a temporary property in the fruits, may grant tacks to endure for the term of his own liferent.

9. The tacksmen's right is limited to the fruits which spring up annually from the subject set, either naturally, or by the industry of the tacksmen; he is not therefore intitled to any of the growing timber above ground, and far less to the minerals, coal, clay, &c. under ground, the use of which confuses the substance. Tacks are, like other contracts, personal rights in their own nature, and consequently ineffectual against singular successors in the lands; but, for the encouragement of agriculture, they were, by act 1449, declared effectual to the tacksmen for the full time of their endurance, into whose hands forever the lands might come.

10. To give a written tack the benefit of this statute, it must mention the special tack duty payable to the proprietor, which though small, if it be not arbitrary, secures the tacksmen; and it must be followed by possession, which supplies the want of a seisin. If a tack does not express the term of entry, the entry will commence at the next term after its date, agreeable to the rule, Quod purum debetur, pretenti die debetur. If it does not mention the inn, i.e. the term at which it is to determine, it is good for one year only; but, if the intention of parties to continue it for more than one year, should appear from any clause in the tack, it is sustained for two years as the minimum. Tacks granted to perpetuity, or with an indefinite inn, have not the benefit of the statute. Tacks of houses within borough do not fall within this act.

11. Tacks necessarily imply a delectus personae, a choice by the fetter of a proper person for his tenant. Hence the conveyance of a tack, which is not granted to affignees, is ineffectual without the landlord's consent. A right of tack, though it be heritable, falls under the jus maritii, because it cannot be separated from the marriage, and implements of tillage, which are moveable subjects. A tack therefore granted to a single woman without the liberty of affigning, falls by her marriage, because the marriage, which is a legal conveyance thereof to the husband, cannot be anulled. This implied exclusion of assignees, is however limited to voluntary, and does not extend to necessary assignments, as an adjudication of a tack by the tacksmen's creditor; but a tack, expressly excluding assignees, cannot be carried even by adjudication. But the tacksmen may sublet, unless subtenants are expressly excluded; and liferent tacks, because they import a higher degree of right in the tacksmen, than tacks for a definite term, may be assigned, unless assignees be specially excluded.

12. If neither the fetter nor tacksmen shall properly discover their intention to have the tack dissolved at the term fixed for its expiration, they are understood, or presumed, to have entered into a new tack upon the same terms with the former, which is called tacit relocation, and continues till the landlord warns the tenant to remove, or the tenant renounces his tack to the landlord: This obtains also in the case of moveable tenants, who poiffess from year to year without written tacks.

13. In tacks of land, the fetter is commonly bound to put
put all the houses and office houses, necessary for the farm, in good condition at the tenant's entry; and the tenant must keep them and leave them so at his removal. But in tacks of houses, theetter must not only deliver to the tenant the subjekt set, in tentable repair at his entry, but uphold it in that repair during the whole years of the tack.

14. If the inclemency of the weather, inundation, or calamity of war, should have brought upon the crop an extraordinary damage (plus quam tolerabile), the landlord had, by the Roman law, no claim for any part of the tack-duty; If the damage was more moderate, he might exact the full rent. It is no where defined, what degree of fertility or devastation makes a loss not to be borne; but the general rule of the Roman law seems to be made ours. Tenants are obliged to pay no public burdens, to which they are not expressly bound by their tacks, except mill-services.

15. Tacks may be evacuated during their currency: 1. In the same manner as feu-rights, by the tacksmen's running in arrear of their tack-duty for two years together. This irritancy may be prevented by the tenant's making payment at the bar before sentence. 2. Where the tenant either runs in arrear of one year's rent, or leaves his farm uncultivated at the usual season; in which case he may be ordained to give security for the arrears, and for the rent of the five following crops, if the tack shall subsist so long; otherwise, to remove, as if the tack were at an end. 3. Tacks may be evacuated at any time, by the mutual consent of parties.

16. The landlord, when he intends to remove a tenant whose tack is expiring, or who possesse with a tack, must, upon a precept signed by himself, warn the tenant forty days preceding the term of Whitfunday, at or immediately preceding the inth, personally, or at his dwelling house, to remove at that term, with his family and effects. This precept must be also executed on the ground of the lands, and thereafter read in the parish-church where the lands lie, after the morning service, and affixed to the most patent door thereof. Whitfunday, though it be a moveable feast, is, in questions of removing, fixed to the 15th of May. In warnings from tenements within borough, it is sufficient that the tenant be warned forty days before the inth of the tack, whether it be Whitfunday or Martinmas; and in these the ceremony of chalking the door is sufficient as warning, when proceeding upon a verbal order from the proprietor.

17. This process of warning was precisely necessary for founding an action of removing against tenants, till act of securant of the court of Session, Dec. 14, 1756, which leaves it in the option of the proprietor, either to use the former method, or to bring his action of removing before the Judge ordinary; which, if it be called forty days before the said term of Whitfunday, shall be held as equal to a warning. Where the tenant is bound, by an express clause of his tack, to remove at the inth without warning, such obligation is, by the said act, declared to be a sufficient warrant for letters of horning, upon which, if the landlord charge his tenant forty days before the said Whitfunday, the judge is authorized to eject him within six days after the term of removing expressed in the tack.

18. Actions of removing might, even before this act of securant, have been pursued without any previous warning. 1. Against vicious poisseurs, i.e. persons who had seized the possession by force, or who, without any legal title, had intruded into it, after the last poisseur had given it up. 2. Against poisseurs who had a naked tolerance. 3. Against tenants who had run in arrear of rent, during the currency of their tacks. 4. Against such as had fold their lands, and yet continued to possess after the term of the purchaser's entry. Upon the same ground; warning was not required, in removing against poisseurs of liferented lands, after the death of the liferenter who died in the natural possession: But if he possessed by tenants, these tenants could not be disturbed in their possession till the next Whitfunday, that they might have time to look out for other farms; but they might be compelled to remove at that term, by an action of removing, without warning.

19. A landlord's title in a removing, let it be ever so lame, cannot be brought under question by a tenant whose tack flows immediately from him; but, if he is to inflict against tenants not his own, his right must be perfected by infeftment, unless it be such as requires no infenm, i.e. serce, &c.

20. The defender, in a removing, must, before offering any defence which is not instantly verified, give security to pay to the settor the violent profits, if they should be awarded against him. These are so called, because the law considers the tenant's possession after the warning as violent. They are imitated, in tenements within borough, to double the rent; and in lands, to the highest profits the pursuer could have made of them, by poisfelling them either by a tenant, or by himself.

21. If the action of removing shall be passed from, or if the landlord shall, after using warning, accept of rent from the tenant, for any term subsequent to that of the removal, he is presumed to have changed his mind, and tacit relocation takes place. All actions of removing against the principal or original tackman, and decrees thereupon, if the order be used, which is set forth supra, § 17, are, by the act of securant 1755, declared to be effectual again the assignees to the tack, or subtenants.

22. The landlord has, in security of his tack-duty, over and above the tenant's personal obligation, a tacit pledge or hypothec, not only in the fruits, but in the cattle pasturing on the ground. The corn, and other fruits, are hypothecated for the rent of that year whereof they are the crop; for which they remain affected, though the landlord should not use his right for years together.

23. The whole cattle on the ground, considered as a quantity, are hypothecated for a year's rent, one after another successively. The landlord may apply this hypothec payment of the past year's rent, at any time within three months from the last conventional term of payment, after which it ceases for that year. As the tenant may increase the subject of this hypothec, by purchasing oxen, sheep, &c. fo he can impair it, by selling part of his flock; but if the landlord supposes the tenant's management, he may, by sequestration or paying, make his right, which was before general upon the whole flock, special upon every individual. A superior has also a hypo-
pothee for his feu-duty, of the same kind with that just explained.

24. In tacks of houses, breweries, shops, and other tenements, which have no natural fruits, the furniture and other goods brought into the subject set are hypothecated to the landlord for one year's rent. But the tenant may by sale impair this hypothec, as he might that of cattle in rural tenements; and indeed, in the particular case of a shop, the tenant rents it for no other purpose, than as a place of sale.

A vassal may transmit his feu either to universal succes-
sors, as heirs; or to singular successors, i.e. those
who acquire by gift, purchase, or other singular title. This last fort of transmission is either voluntary, by disposition; or necessary, by adjudication.

2. By the first feudal rules, no superior could be compelled to receive any vassal in the lands, other than the heir expressed in the investiture; for the superior alone had the power of ascertaining to what order of heirs the fee granted by himself was to descend. But this right of refusal in the superior did not take place, 1. In the case of creditors apprizers or adjudgers, whom superiors were obliged to receive upon payment of a year's rent. 2. In the case of purchasers of bankrupt estates, who were put on the same footing with adjudgers. The Crown refuses no voluntary dissenee, on his paying a compoition to the exchequer of a sixteenth part of the valued rent. Now superiors are directed to enter all singular successors (except incorporations) who shall have got from the vassal a disposition, containing procuratory of resignation; they always receiving the fees or casualties that law entitles them to on a vassal's entry, i.e. a year's rent.

3. Base rights, i.e. dispositions to be holden of the dissenee, are transmissions only of the property, the superiority remaining as formerly. As this kind of right might, before establishing the registries, have been kept quite concealed from all but the granter and receiver, a public right was preferable to it, unless cloathed with possession. But as this distinction was no longer necessary after the establishment of the records, all infeftments are declared preferable, according to the dates of their several registra-
tions; without respect to the former distinction of base and public, or of being cloathed and not cloathed with possession.

4. Public rights, i.e. dispositions to be holden of the granter's superior, may be perfected either by confirmation or resignation; and therefore, they generally contain both precept of seisin and procuratory of resignation. When the receiver is to complete his right in the first way, he takes seisin upon the precept; but such seisin is ineffectual without the superior's confirmation; for the dissenee cannot be deemed a vassal, till the superior receive him as such, or confirm the holding. By the usual style in the transmission of lands, the disposition contains an obligation and precept of infeftment, both a me and de me, in the option of the dissenee; upon which, if seisin is taken indefinitely, it is construed in favour of the dissenee to be a base infeftment, because a public right is null without confirmation. But, if the receiver shall afterwards obtain the superior's confirmation, it is considered as if it had been from the beginning a public right.

5. Where two several public rights of the same subject are confirmed by the superior, their preference is governed by the dates of the confirmations, not of the infeftments confirmed; because it is the confirmation which compleats a public right.

6. Though a public right becomes, by the superior's confirmation, valid from its date; yet if any hind impediment intervene betwixt that period and the confirmation, to hinder the two from being conjoined, e.g. if the granter of a public right should afterwards grant a base right to another, upon which seisin is taken before the superior's confirmation of the first, the confirmation will have effect only from its own date; and consequently the base right first compleated, will carry the property of the lands preferable to the public one.

7. Resignation is that form of law, by which a vassal surrenders his feu to his superior; and it is either ad perpetuam remanentiam, or in favorem. In resignations ad remanentiam, where the feu is resigned, to the effect that it may remain with the superior, the superior, who before had the superiourity, acquires, by the resignation, the property also of the lands resigned: and as his infeftment in the lands still subsisted, notwithstanding the right by which he had given his vassal the property; therefore, upon the vassals resignation, the superior's right of property revives, and is consolidated with the superiority, without the necessity of a new infeftment; but the instrument of resignation must be recorded.

8. Resignations in favorem are made, not with an intention that the property resigned should remain with the superior, but that it should be again given by him, in favour either of the resigner himself, or of a third party; consequently the fee remains in the resigner, till the person in whose favour resignation is made gets his right from the superior perfeded by seisin. And because resignations in favorem, are but incompleat personal deeds, our law has made no provision for recording them. Hence, the first seisin on a second resignation is preferable to the last seisin upon the first resignation; but the superior, accepting a second resignation, whereupon a prior seisin may be taken in prejudice of the first resigna-
tory, is liable in damages.

9. By our former decisions, one who was vested with a personal right of lands, i.e. a right not compleat-
ed by seisin, effectually divested himself by dispensing it to another; after which, no right remained in the dissenee, which could be carried by a second disposition, because a personal right is no more than a jus obligationis, which may be transferred by any deed sufficiently expressing the will of the granter. But this doctrine, at the same time that it rendered the security of the records extremely uncertain, was not truly applicable to such rights as required seisin to complete them; and therefore it now obtains, that the granter even of a personal right of lands, is not so devoid of conveying the right to one person, but that he may effectually make it over afterwards to anoter;
Tit. 15. Of redeemable Rights.

An heritable right is said to be redeemable, when it contains a right of reverion, or return, in favour of the person from whom the right flows. Reversions are either legal, which arise from the law itself, as in adjudications, which law declares to be redeemable within a certain term after its date; or conventional, which are constituted by the agreement of parties, as in wadsets, rights of annuallent, and rights in security. A wadset (from wad or pledge) is a right, by which lands, or other heritable subjects, are impregnated by the proprietor to his creditor, in security of his debt; and, like other heritable rights, is perfected by seisin. The debtor, who grants the wadset, and has the right of reverison, is called the reverfer; and the creditor, receiver of the wadset, is called the wadsetter.

Wadsets, by the present practice, are commonly made out in the form of mutual contracts, in which one party sells the land, and the other grants the right of reverison. When the right of reverison is thus incorporated in the body of the wadset, it is effectual without registration; because the fingular seisin in the wadsetter is, in that case, sufficiently certified of the reverison, though it be not registered, by looking into his own right, which bears it in gremio. But where the right of reverison is granted in a separate writing, it is ineffectual against the singular seisin of the wadsetter, unless it be registered in the regifter of seifs within 60 days after the date of the seisin upon the wadset.

1. Rights of reverison are generally esteemed reriti juris; yet they go to heirs, though heirs should not be mentioned, unless there be some clause in the right, discovering the intention of parties, that the reverison should be personal to the reverfer himself. In like manner, though the right should not express a power to redeem from the wadsetter's heir, as well as from himself, redemption will be competent against the heir. All our lawyers have affirmed, that reverisons cannot be assigned, unless they are taken to assignees; but from the favour of legal diligence, they may be adjudged.

2. Reversions commonly leave the reverfer at liberty to redeem the lands quodcumque, without restriction in point of time; but a clause is adjointed to some reversions, that if the debt be not paid against a determinate day, the right of reverison shall be irrevocable, and the lands shall become the irredeemable property of the wadsetter. Nevertheless, the irritancy being penal, as in wadsets, the sum lent falls always short of the value of the lands, and the right of redemption is by indulgence continued to the reverfer, even after the term has expired, while the irritancy is not declared. But the reverfer, if he does not take the benefit of this indulgence, within forty years after the lapse of the term, is cut out of it by prescription.

3. If the reverfer would redeem his lands, he must use an order of redemption against the wadsetter: the first step of which is premonition (or notice given under form of instrument) to the wadsetter, to appear at the time and place appointed by the reverfer, then and there to receive payment of his debt, and then upon to renounce his right of wadset. In the voluntary redemption of a right of wadset holden bare, a renunciation duly registered re-establishes the reverfer in the full right of the lands. Where the wadset was granted to be holten of the grantor's superior, the superior must receive the reverfer, on payment of a year's rent, if he produce a disposition from the wadsetter, containing procuratory of renunciation. If, at executing the wadset, the superior has granted letters of regress, i.e., an obligation again to enter the reverfer upon redemption of the lands, he will be obliged to receive him, without payment of the year's rent. But letters of regress will not have this effect against singular successors in the superiority, if they are not registered in the register of reverisons. All wadsets that remain personal rights, are extinguished by simple discharges, though they should not be recorded.

4. If the wadsetter either does not appear at the time and place appointed, or refuses the redemption-money, the reverfer must confign it under form of instrument, in the hands of the person thereto appointed in the right of reverison; or, if no person be named, in the hands of the clerk to the bills, a clerk of seisin, or any responsible person. An instrument of confignation, with the confignatory's receipt of the money configned, compleats the order of redemption, stops the farther currency of interest against the reverfer, and founds him in an action for declaring the order to be formal, and the lands to be redeemed in consequence of it.

5. After decree of declarator is obtained, by which the lands are declared to return to the debtor, the confignated money, which comes in place of the lands, becomes the wadsetter's, who therefore can charge the confignatory upon letters of horning to deliver it up to him; but, because the reverfer may, at any time before decree, pass from his order, as one may do from any other step of diligence, the confignated sums continue to belong to the reverfer, and the wadsetter's interest in the wadset continues heritable till that period.

6. If the wadsetter chuses to have his money rather than the lands, he must require from the reverfer, under form of instrument, the sums due by the wadset, in terms of the right. The wadset sums continue heritable, notwithstanding requisition, which may be passed from by the wadsetter even after the reverfer has configned the redemption money in consequence thereof.

7. Wadsets are either proper or improper. A proper wadset is that whereby it is agreed, that the use of the land shall go for the use of the money; so that the wadsetter takes his hazard of the rents, and enjoys them without accounting, in satisfaction or in solutum of his interest.

8. In an improper wadset, the reverfer, if the rent should fall short of the interest, is taken bound to make up the deficiency; if it amounts to more, the wadsetter is obliged to impute the excessence towards extinction of the capital: And, as soon as the whole sums, principal and interest, are extinguished by the wadsetter's possession,
property in the debtor, may be extinguished without retrenching the payment of his part interest: And in a conquest of a requisition, or by a charge upon letters of hornbook, according as the right is drawn.

If the wafsetter be intitled by his right to enjoy the rents without accounting, and if at the sametime the wafsetter be subjected to the hazard of their deficiency, such contract is fully declared furious; and also in all proper wafsets wherein any unreasonable advantage has been taken of the debtor, the wafsetter must, during the not requisition of the sum lent, either quit his possession to the debtor, upon his giving security to pay the interest, or subject himself to account for the surplus-rents, as in improper wafsets.

Infeftments of annualrent, the nature of which has been explained, are also redeemable rights. A right of annualrent does not carry the property of the lands, but it creates a real nexus or burden upon the property, for payment of the interest or annualrent contained in the right; and consequently, the bygone interests due upon it are debita fundi. The annualrenter may therefore either infilt in a real action for obtaining letters of poinding the ground, or sue the tenant in a personal action towards the payment of his past interest. And in a competition for those rents, the annualrenter's preference will not depend on his having ufed a poinding of the ground, for his right was compleated by the seifin; and the power of poinding the ground, arising from that antecedent right, is merum facultatis, and need not be exercized, if payment can be otherwise got. As it is only the interest of the sum lent which is a burden upon the lands, the annualrenter, if he wants his principal sum, cannot recover it either by poinding or by a personal action against the debtor's tenants, but must demand it from the debtor himself, on his personal obligation in the bond, either by requisition, or by a charge upon letters of hornbook, according as the right is drawn.

Rights of annualrent, being feervitudes upon the property, and consequently consistent with the right of property in the debtor, may be extinguished without renunciation.

Infeftments in security are another kind of redeemable rights (now frequently ufed in place of rights of annualrent) by which the receivers are infelt in the lands themselves, and not simply in an annualrent forth of them, for security of the principal sums, interest, and penalty, contained in the rights. If an infeftment in security be granted to a creditor, he may thereupon enter into the immediate poision of the lands or annualrent for his payment. They are extinguished as rights of annualrent.

All rights of annualrent, rights in security, and generally whatever constitutes a real burden on the fee, may be the ground of an adjudication, which is preferable to all adjudications, or other diligences, intervening between the date of the right and of the adjudication deduced on it; not only for the principal sum contained in the right, but also for the whole past interest contained in the adjudication. This preference arises from the nature of real debts, or debita fundi; but in order to obtain it for the interest of the interest accumulated in the adjudication, such adjudication must proceed on a process of poinding the ground.

Servitude is a burden affecting lands, or other heritable subjects, whereby the proprietor is either restrained from the full use of what is his own, or is obliged to suffer another to do something upon it. Servitudes are either natural, legal, or conventional. Nature itself may be said to constitute a servitude upon inferior tenements, whereby they must receive the water that falls from those that stand on higher ground. Legal servitudes are established by statute or custom, from considerations of public policy; among which may be numbered the constraints laid upon the proprietors of tenements within the city of Edinburgh. There is as great a variety of conventional servitudes, as there are ways by which the exercise of property may be restrained by passion in favour of another.

Servitudes constituted by grant, where the will of the party burdened is expressed in writing, or by prescription, where his consent is presumed from his acquiescence in the burden for 40 years. A servitude constituted by writing, or grant, is not effectual against the grantor's singular successors, unless the grantee has been in the use or exercise of his right; but they are valid against the grantor and his heirs, even without use. In servitudes that may be acquired by prescription, forty years exercise of the right is sufficient, without any title in writing, other than a charter and seisin of the lands, to which the servitude is claimed to be due.

Servitudes constituted by grant are not effectual in a question with the superior of the tenement burdened with the servitude, unless his consent be exhibited; for a superior cannot be hurt by his vassal's deed: But, where the servitude is acquired by prescription, the consent of the superior, whose right afforded him a good title to interrupt, is implied. A servitude by grant, though followed only by a partial possession, must be governed, as to its extent, by the tenor of the grant; but a servitude by prescription is limited by the measure or degree of the use had by him who prescribes; agreeably to the maxim, tantum praescriptum quantum poefium.

Servitudes are either predial or personal. Predial servitudes are burdens imposed upon one tenement, in favour of another tenement. That to which the servitude is due is called the dominant, and that which owes it is called the servient tenement. No person can have right to a predial servitude, if he is not proprietor of some dominant tenement that may have benefit by it; for that right is annexed to a tenement, and so cannot pass from one person to another, unless some tenement goes along with it.

Servitudes are divided into rural servitudes, or of lands; and urban servitudes, or of houies. The rural servitudes of the Romans were iter, ultus, vie, aquaductus, aquaeauflus, and jus pacendi pecoris. Similar servitudes may be constituted with us, of a foot, road, horse road, cart-road, dams, and aqueducts; watering of cattle, and palurage. The right of a highway is not a servitude constituted in favour of a particular tenement, but is a right common to all travellers. The care

Tit. 16. Of Servitudes.
of high-ways, bridges, and ferries, is committed to the sheriffs, justices of peace, and commissioners of supply in each thire.

6. Common pasturage, or the right of feeding one's cattle upon the property of another, is sometimes constituted by a general clause of pasturage in a charter or disposition, without mentioning the lands burdened; in which case, the right comprehends whatever had been formerly appropriated to the lands dispofed out of the grantor's own property, and likewise all pasturage due to them out of other lands. When a right of pasturage is given to several neighbouring proprietors, on a moor or common belonging to the grantor, indefinite as to the number of cattle to be pastured, the extent of their several rights is to be proportioned according to the number that each of them can fodder in winter upon his own dominant tenement.

7. The chief servitudes of houses among the Romans were those of support, viz. signi immittendi, and oneris ferendi. The first was the right of fixing in our neighbour's wall a joist or beam from our house; the second was that of reposing the weight of one's house upon his neighbour's wall.

8. With us, where different floors or stories of the same house belong to different persons, as is frequent in the city of Edinburgh, the property of the house cannot be made to be entirely divided; the roof remains a common roof to the whole, and the area on which the house stands supports the whole; so that there is a communication of property, in consequence of which the proprietor of the ground floor must, without the constitution of any servitude, uphold it for the support of the upper, and the owner of the highest floor must uphold that as a cover to the lower. Where the highest floor is divided into garrets among the several proprietors, each proprietor is obliged, according to this rule, to uphold that part of the roof which covers his own garret.

9. No proprietor can build, so as to throw the rain-water falling from his own house, immediately upon his neighbour's ground, without a special servitude, which is called servitium alius non tollendi; but, if it falls within his own property, though at a small distance from the march, the owner of the inferior tenement must receive it.

10. The servitudes altius non tollendi, et non officiendi luminibus vel prospexitui, restrain proprietors from raising their houses beyond a certain height, or from making any building whatsoever that may hurt the light or prospect of the dominant tenement. These servitudes cannot be constituted by prescription alone; for, though a proprietor should have built his house ever so low, or should not have built at all upon his grounds for forty years together, he is presumed to have done so for his own conveyency or profit; and therefore cannot be barred from afterwards building a house on his property, or raising it to what height he pleases, unless he be tied down by his own consent.

11. We have two predial servitudes to which the Romans were strangers; viz. that of fewel or thatch, and of thirlage. The first is a right, by which the owner of the dominant tenement may turn up peats, turfs, seals, or divots, from the ground of the servient, and carry them off either for fewel, or thatch, or the other uses of his own tenement.

12. Thirlage is that servitude, by which lands are thirled, or thirled, to a particular mill, and the pothead- ors bound to grind their grain there, for payment of certain multures and sequels, at the agreed price of grinding. In this servitude, the mill is the dominant tenement, and the lands thirled (which are called also the thirle or thirlage) the servient. Multure is the quantity of grain or meal payable to the proprietor of the mill, or to the miller his tacksmen. The sequels are the small quantities given to the servants, under the name of knaveship, bannock, and lock or gowpen. The quantities paid to the mill by the lands not thirled, are generally proportioned to the value of the labour, and are called out-town or out-sucken multures; but those paid by the thirle are ordinarily higher, and are called in-town or in-sucken multures.

13. Thirlage may be constituted by a land-holder, when, in the disposition of certain lands, he thirls them to his own mill; or when, in the disposition of a mill, he thirls his own lands to the mill dispensed, or when, in letting his lands, he makes it a condition in the tacks. The grant of a mill with the general clause of multures, without specifying the lands thirled, conveys the thirlage of all the lands formerly thirled to that mill, whether they were the property of the granter, or of a third party.

14. A less formal constitution serves to thirle barony-lands to the mill of the barony, than is necessary in any other thirlage; which perhaps proceeds from the effects of the union between the two. Hence, if a man makes over the mill of a barony, cum mularis, or cum asfrittit multuris, it infers an thirlage of the barony lands to the mill conveyed, even of such as had been before sold to another for a certain duty pro omni alto onere. But if, prior to the baron's conveyance of his mill cum mularis, he had sold any part of the barony-lands to another cum mularis, the first purchaser's lands are not thirled by the posterior grant; for a right of lands with the multures, implies a freedom of those lands from thirlage.

15. Thirlage is either, 1. Of grindable corns; or, 2. Of all growing corns; or, 3. Of the invetta et illata, i. e. of all the grain brought within the thirle, though of another growth. Where the thirlage is of grindable grain, it is in practice restricted to the corns which the tenants have occasion to grind, either for the support of their families, or for other uses; the surplus may be carried out of the thirle unmanufactured, without being liable in multure. Where it is of the grana crescentia, the whole grain growing upon the thirle is thirled, with the exceptions, 1. Of seed and horse-corn, which are destined to uses inconsistent with grinding; and, 2. Of the farm-dues due to the landlord, if they are deliverable in grain not ground. But, if the rent be payable in meal, flour, or malt, the grain of which these are made must be manufactured in the dominant mill.

16. The thirlage of invetta et illata is seldom constituted but against the inhabitants of a borough or village, that they shall grind all the unmanufactured grain they import thither at the dominant mill. Multure, therefore, cannot be exacted in a thirlage of invetta et illata, for
flour or oat-meal brought into the servient tenement, unless the importer brought it in grain, and grinding it at another mill. The same grain that owes mulature, as *granum crescent*, to the mill in whose thirl it grew, if it shall be afterwards brought within a borough where the *inoeeta et illata* are thirled, must pay a second mulure to the proprietor of that dominant tenement; but, where the right of these two thirlages is in the same proprietor, he cannot exact both. Where lands are thirled of general terms, without expressing the particular nature in the servitude, the lightest thirlage is presumed, from the favour of liberty; but in the affiliation of a borough or village, where there is no growing grain which can be the subject of thirlage, the affiliation of *inoeeta et illata* must be necessarily understood.

17. Thirlage, in the general case, cannot be established by prescription alone, for *ii quae sunt mera facultatis non praebibitur*; but where one has paid for forty years together the heavy infunken mulures, the flightest title in writing will subject his lands. Thirlage may be, contrary to the common rule, constituted by prescription alone, 1. Where one pays to a mill a certain sum, or quantity of grain yearly, in name of mulure, whether he grinds at it or not (called dry mulure.) 2. In mills of the King's property; which is constituted *jure corone*, without titles in writing; and, where he derives right from another, his titles are more liable to be lost. This is extended in practice to mills belonging to church-lands, where thirty years possession is deemed equivalent to a title in writing, from a presumption that their rights were destroyed at the reformation. Though thirlage itself cannot be constituted by mere possession, the proportion of mulure payable to the dominant tenement may be so fixed.

18. The possessors of the lands affrighted, are bound to uphold the mill, repair the dam dykes and aqueducts, and bring home the millstones. These services, though not expressed in the constitution, are implied.

19. Servitudes, being restraints upon property, are *sulti juris*: They are not therefore presumed, if the acts upon which they are claimed can be explained consistently with freedom; and, when servitudes are constituted, they ought to be used in the way least burdensome to the servient tenement. Hence, one who has a servitude of peats upon his neighbour's moats, is not at liberty to extend it for the use of any manufacture which may require an extraordinary expense of fuel; but must confine it to the natural uses of the dominant tenement.

20. Servitudes are extinguished. 1. Confusione, when the same person is both proprietor of the dominant and servient tenements; for *res sua nemini servit*, and the use the proprietor thereafter makes of the servient tenement is not *jure servitutis*, but is an act of property.

21. Personal servitudes are those by which the property of a subject is burdened, in favour, not of a tenement, but of a person. The only personal servitude known in our law, is usufruct or servitude; which is a right to use and enjoy a thing during life, the substance of it being preserved. A servitude cannot therefore be constituted upon things which perish in the use; and though it may upon subjects which gradually wear out by time, as household-furnitures, &c. yet, with us, it is generally applied to heritable subjects. He, whose property is burdened, is usually called the feisin.

22. Servitudes are divided into conventional and legal. Conventional servitudes are either simple, or by reservation. A simple servitude, or by a separate constitution, is that which is granted by the proprietor in favour of another: And this fort, contrary to the nature of predial servitudes, requires feisin in order to affect singular successors; for a servitude of lands is, in strict speech, not a servitude, but a right resembling property, which constitutes the liferenter vassal for life; and singular successors have no way of discovering a servitude-right, which perhaps is not yet commenced, but by the records; whereas, in predial servitudes, the confiant use of the dominant tenement makes them public. The proper right of servitude is intransferrable, *offus ususque servitudinis inheret*: When the profits of the servient subject are transmitted to another, the right becomes merely personal, for it intitles the assignee to the rent, not during his own life, but his co-tenant's, and is therefore carried by simple assignation, without seisin.

23. A servitude by reservation, is that which a proprietor refers to himself in the same writing by which he conveys the fee to another. It requires no seisin; for the granter's former seisin, which virtually included the servitude, still subsists as to the servitude which is expressly reserved. In conjunct infeftments taken to husband and wife, the wife's right of conjunct fee resolves, in the general case, into a servitude.

24. Servitudes by law, are the terce and the courtey. The terce (*tertia*) is a servitude competent by law to widows, who have not accepted of special provisions, in the third of the heritable subjects, in which their husbands died intestate; and takes place only where the marriage has subsisted for year and day, or where a child has been born alive of it.

25. The terce is not limited to lands, but extends to teinds, and to servitudes and other burdens affecting lands; thus, the widow is intitled, in the right of her terce, to a servitude of the third of the sums secured, either by rights of annalrent, or by rights in security. In improper wadsets, the terce is a third of the sum lent: In those that are proper, it is a third of the wadset-lands; or in case of redemption, a third of the redemption money. Neither rights of reversion, superiority, nor patronage, fall under the terce; for none of these have fixed profits, and so are not proper subjects for the widow's subsistence; nor tacks, because they are not feudal rights. Burgage tenements are also excluded from it, the reason of which is not so obvious. Since the husband's seisin is both the measure and security of the terce, such debts or diligences alone, as exclude the husband's seisin, can prevail over it.

26. Where a terce is due out of lands burdened with
a prior terce still subsisting, the second terce has only right to a third of the two thirds that remain unaffected by the first terce. But upon the death of the first widow, whereby the lands are disburdened of her terce, the lesser terce becomes enlarged, as if the first had never existed. A widow, who has accepted of a special provision from her husband, is thereby excluded from the terce, unless such provision shall contain a clause that she shall have right to both.

27. The widow has no title of possession, and so cannot receive the rents in virtue of her terce, till she be served to it; and in order to this, she must obtain a brief out of the chancery, directed to the Sheriff, who calls an inquest, to take proof that she was wife to the deceased; and that the deceased died intestate in the subjects contained in the brief. The service or sentence of the jury, finding these points proved, does, without the necessity of a return to the chancery, intitle the wife to enter into the possession; but she can only possess the heir pro indiviso, and so cannot remove tenants, till the heir sells his wife's estate, or divides the lands between her and the heir. In this division, after determining by lot or kavil, whether to begin by the sun or the shade, i.e. by the east or the west, the sheriff sets off the two first acres for the heir, and the third for the widow. Sometimes the division is executed, by giving one entire farm to the widow, and two of equal value to the heir. The widow's right is not properly constituted by this service; it was constituted before, by the husband's seisin, and fixed by his death; the service only declares it, and so intitles her to the third part of the rents retro to her husband's death, preferable to any rights that may have affected the lands in the intermediate period between that and her own service. The relief, if she was reputed to be lawful wife to the deceased, must be served, notwithstanding any objections by the heir against the marriage, which may be afterwards tried by the commissary.

28. Courtevy is a liferent given by law, to the surviving husband, of all his wife's heritage in which she died intestate, if there was a child of the marriage born alive: A marriage, though of the longest continuance, gives no right to the courtevy, if there was no issue of it. The child born of the marriage must be the mother's heir: If she had a child of a former marriage, who is to succeed to her estate, the husband has no right to the courtevy while such child is alive: so that the courtevy is due to the husband, rather as father to an heir, than as husband to an heiress. Heritage is here opposed to conquest, and so is to be understood only of the heritable rights to which the wife succeeded as heir to her ancestors, excluding what she herself had acquired by singular titles.

29. Because the husband enjoys the liferent of his wife's whole heritage, on a lucrative title, he is considered as her temporary representative, and so is liable in payment of all the yearly burdens chargeable on the subject, and of the current interest of all her debts, real and personal, to the value of the yearly rent he enjoys by the courtevy. The courtevy needs no solemnity to its constitution: That right, which the husband had to the rents of his wife's estate, during the marriage, jure mariti, is continued with him after her death, under the name of courtevy, by an act of the law itself. As in the terce, the husband's seisin is the ground and measure of the wife's right; so in the courtevy, the wife's seisin is the foundation of the husband's; and the two rights are, in all other respects, of the same nature; if it is not that the courtevy extends to bargains, holdings, and to superiorities.

30. All liferenters must use their right falsa rei substantiae: Whatever therefore is part of the fee itself, cannot be encroached on by the liferenter, e.g., woods or growing timber, even for the necessary uses of the liferented tenement. But, where a coppice or silva cedux has been divided into hags, one of which was in use to be cut annually by the proprietor, the liferenter may continue the former yearly cuttings; because these are considered as the annual fruits the subject was intended to yield, and so the proper subject of a liferent.

31. Liferenters are bound to keep the subject liferented in proper repair. They are also burdened with the alimony of the heir, where he has not enough for maintaining himself. The bare right of appearance founds the action against the liferenter. It is a burden personal to the liferenter himself, and cannot be thrown on his adjudging creditors, as coming in his place by their diligence. Liferenters are also subjected to the payment of the yearly cesse, stipends, &c., falling during their right, and to all other burdens that attend the subject liferented.

32. Liferent is extinguished by the liferenter's death. That part of the rents which the liferenter had a proper right to, before his death, falls to his executors: the reft, as never having been in bonis of the deceased, goes to the heir. Martinmas and Whitunday are, by our custom, the legal terms of the payment of rent: Consequently, if a liferenter of lands survives the term of Whitunday, his executors are intitled to the half of that year's rent, because it was due the term before his death; and if he survives the Martinmas, they have right to the whole. If the liferenter, being in the natural possession, and having first sowed the ground, should die, even before the Whitunday, his executors are intitled to the whole crop, in respect that both feed and industry were his. In a liferent of money constituted by a moveable bond, the executors have a right to the interest, down to the very day of the liferenter's death, where no terms are mentioned for the payment thereof; but in the case of an heritable bond, or of a money liferent secured on land, the interests of liferenter and heir (or of heir and executor, for the same rules serve to fix the interests of both) are both governed by the legal terms of land-rent, without regard to the conventional.

Tit. 17. Of Tithes.

1. Tithes, or tithes, are that liquid proportion of our rents or goods, which is due to churchmen, for performing divine service, or exercising the other spiritual functions proper to their several offices. Most of the canons affirm, that the precise proportion of a tenth, not only of the fruits of the ground, but of what is acquired by personal industry, is due to the Christian clergy, of divine right, which they therefore call the proper patrimony
trimony of the church; though it is certain that tithes, in their infancy, were given, not to the clergy alone, but to lay-monks who were called pauperes, and to other indigent persons. Charles the Great was the first secular Prince who acknowledged this right in the church. It appears to have been received with us, as far back as David I.

2. The person employed by a cathedral church or monastery to serve the cure in any church annexed, was called a vicar, because he held the church, not in his own right, but in the right or vice of his employers; and so was removable at pleasure, and had no share of the benefice, other than what they thought fit to allow him. But, in the course of time, the appellation of vicar was limited to those who were made perpetual, and who got a stated share of the benefice for their incumbency; from whence arose the distinction of benefices into parfonages and vicarages.

3. Parsonage-teinds are the teinds of corn; and they are so called because they are due to the parson or other titular of the benefice. Vicarage-teinds are the small teinds of calves, lint, hemp, eggs, &c. which were commonly given by the titular to the vicar who served the cure in his place. The first fort was universally due, unless in the case of their infeudation to laics, or of a pontifical exemption; but, by the customs of almost all Christendom, the latter teinds were not demanded where they had not been in use to be paid. By the practice of Scotland, the teinds of animals, or of things produced from animals, as lambs, wool, calves, are due though not accustomed to be paid; but roots, herbs, &c. are not tithable, unless use of payment be proved: neither are personal teinds, i.e. the tenth of what one acquires by his own industry, acknowledged by our law; yet they have been found due, when supported by 40 years possession.

4. The parson who was entitled to the teind of corn, made his right effectual either by accepting of a certain number of teind-bolls yearly from the proprietor, in satisfaction of it; or more frequently, by drawing or separating upon the field his own tenth part of the corns, after they were reaped, from the flock or the remaining nine tenths of the crop, and carrying it off to his own granaries; which is called drawn teind.

5. After the reformation, James VI. considered himself as proprietor of all the church-lands; partly because the purposes for which they had been granted were declared superfluous; and partly, in consequence of the resignations which he, and Q. Mary his mother, had procured from the beneficiaries: and even as to the teinds, tho' our reformed clergy also claimed them as the patrimony of the church, our sovereign did not submit to that doctrine farther than extended to a competent provision for ministers. He therefore erected or secularized several abbeys and priories into temporal lordships; the grantees of which were called sometimes lords of erection, and sometimes titulars, as having by their grants the same title to the erected benefices, that the monasteries had formerly.

6. As the Crown's revenue suffered greatly by these erections, the temporality of all church-benefices (i.e. church lands) was, by 1587, c. 20. annexed to the crown. That statute excepts from the annexation such benefices as were established before the reformation in laymen, whose rights the legislature had no intention to weaken. Notwithstanding this statute, his Majesty continued to make farther erections, which were declared null by 1592, c. 119. with an exception of such as had been made in favour of lords of parliament, since the general act of annexation in 1587.

7. K. Charles I. soon after his succession, raised a reduction of all these erections, whether granted before or after the act of annexation, upon the grounds mentioned at length by Mr. Forbes in his treatise of tithes, p. 159. At last the whole matter was referred to the King himself by four several submissions or compromizes, in which the parties on one side were the titulars and their tackmen, the bishops with the inferior clergy, and the royal boroughs, for the interest they had in the teinds that were gifted for the provision of ministers, schools, or hospitals within their boroughs; and, on the other part, the proprietors who wanted to have the leading of their own teinds. The submission by the titulars contained a surrender into his Majesty's hands of the superiorities of their several erections.

8. Upon each of these submissions his Majesty pronounced separate decrees arbitral, dated Sept. 2. 1629, which are subjoined to the acts of parliament of his reign. He made it lawful to proprietors to sue the titulars for a valuation, and if they thought fit for a sale also, of their teinds, before the commissions named or to be named for that purpose. The rate of teind, when it was possessed by the proprietor jointly with the flock, for payment of a certain duty to the titular, and so did not admit a separate valuation, was fixed at a fifth part of the constant yearly rent, which was accounted a reasonable farogatus, in place of a tenth of the increase. Where it was drawn by the titular, and consequently might be valued separately from the flock, it was to be valued as its extent should be ascertained upon a proof before the commissions; but in this last valuation, the King directed the fifth part to be deducted from the proved teind, in favour of the proprietor, which was therefore called the King's ease. The proprietor suing for a valuation gets the leading of his own teinds as soon as his suit commences; providing he does not allow prostitution to be extracted against him for not infilling.

9. Where the proprietor infilled also for a sale of his teinds, the titular was obliged to sell them at nine years purchase of the valued teind-duty. If the pursuer had a tack of his own teinds, not yet expired; or if the defender was only a proctor of the teinds, and so could not give the pursuer an heritable right; an abatement of the price was to be granted accordingly by the commissions.

10. There is no provision in the decrees arbitral, for selling the teinds granted for the support of the crown, universities, schools or hospitals; because these were to continue, as a perpetual fund, for the maintenance of the persons or societies to whom they were appropriated; and they are expressly declared not subject to sale, by 1690. c. 30.—1693, c. 23. By the last of these acts, it is also provided...
vided, that the teinds belonging to bishops, which had then fallen to the crown, upon the abolishing of episcopacy, should not be subject to sale as long as they remained with the Crown not disposed of; nor those which the the proprietor, who had right both to flock and teind, referred to himself, in a sale or feu of the lands. But, though none of these teinds can be sold, they may be valued.

11. The King, by the decrees arbitral, declared his own right to the superiorities of erection which had been assigned to him by the submission, referring to the titulars the feu-duties thereof, until payment by himself to them of one thousand marks Scots for every chalder of feu virtual, and for each hundred marks of feu-duty, which right of redeeming the feu-duties was afterwards renounced by the Crown. If the church-vassal should consent to hold his lands of the titular, he cannot thereafter recus to the Crown as his immediate superior.

12. In explaining what the constant rent is, by which the teind must be valued, the following rules are observed. The rent drawn by the proprietor, from the sale of subjects, that are more properly parts of the land than of the fruits, e.g. quarries, minerals, mooves, &c. is to be deducted from the rental of the lands; and also the rent of supernumerary houses, over and above what is necessary for agriculture; and the additional rent that may be paid by the tenant, in consideration of the proprietor's undertaking any burden that law imposes on the tenant, e.g. upholding the tenant's houses, because none of these articles are paid properly on account of the fruits. Orchards must also be deducted, and mill-rent, because the profits of a mill arise from industry; and the corns manufactured there suffer a valuation, as rent payable by the tenant; and therefore ought not to be valued a second time against the titular as mill-rent. The yearly expense of culture ought not to be deducted; for no rent can be pruduced without it: But, if an improvement of rent is made at an uncommon expense, e.g. by draining a lake, the proprietor is allowed a reasonable abatement on that account.

13. Notwithstanding the several ways of misapplying parochial teinds in the times of popery, some few benefits remained entire in the hands of the parsons. The ministers planted in these, after the reformation, continued to have the full right to them, as proper beneficiaries; but a power was afterwards granted to the patron, to redeem the whole teind from such beneficiaries, upon their getting a competent stipend modified to them; which teind so redeemed, the patron is obliged to sell to the proprietor, at fix years purchase.

14. Some teinds are more directly subject to an allocation for the minifier's stipend, than others. The teinds, in the hands of the lay titular, fall first to be allocated, who, since he is not capable to serve the cure in his own person, ought to provide one who can; and if the titular, in place of drawing the teind, has fet it in tack, the tack-duty is allocated: This fort is called free teind. Where the tack-duty, which is the titular's intereft in the teinds, falls short, the tack itself is burdened, or, in other words, the surplus teind over and above the tack-duty: But, in this case, the commissioners are empowered to recompense

Vol. II. Numb. 65. 2

the tacksmen, by prorogating his tack for such a number of years as they shall judge equitable. Where this like-wise proves deficient, the allocation falls on the teinds, heritably conveyed by the titular, unless he has warranted his grant against future augmentations; in which case, the teinds of the lands belonging in property to the titular himself must be allocated in the first place.

15. Where there is sufficiency of free teinds in a parish, the titular may allocate any of them he shall think fit for the minifier's stipend, since they are all his own; unless there has been a previous decree of locality: And this holds, though the stipend should have been paid immorally out of the teinds of certain particular lands. This right was frequently abused by titulars, who, as soon as a proprietor had brought an action of sale of his teinds, allocated the purfuer's full teind for the stipend, whereby such action became ineffectual: It was therefore provided, that after citation in a sale of teinds it shall not be in the titular's power to allocate the purfuer's teinds solely, but only in proportion with the other teinds in the parish.

16. Minifers glebes are declared free from the payment of teind. Lands cum decimis inuitis are also exempted from teind. But in order to exempt lands from payment of teind, it is necessary that the proprietor prove his right thereto, cum decimis inclusis, as far back as the above act of annexation 1587.

17. Teinds are debita frutuum, not fundi. The action therefore for bygone teinds is only personal, against those who have intermeddled, unless where the titular is infeft in the lands, in security of the valued teind-duty. Where a tenant is, by his tack, bound to pay a joint duty to his landlord for flock and teind, without distinguishing the rent of each, his defence of a bona fide payment of the whole to the landlord has been sustained in a suit at the instance of a laic titular, but repelled where a churchman was purfuer. In both cafes the proprietor who receives such rent is liable as intermeddler.

18. In tacks of teinds, as of lands, there is place for tacit relocation; to stop the effed of which, the titular must obtane and execute an inhibition of teinds against the tacksmen, which differs much from inhibition of lands (explained under the next title), and is intended merely to interpel or inhibit the tacksmen from farther intermeddling. This diligence of inhibition may also be used at the suit of the titular, against any other poifessor of the teinds; and if the tackman or poifessor shall intermeddle after the inhibition is executed, he is liable in a spulcie.

19. Lands and teinds pass by different titles: A disposition of lands therefore, though granted by one who has also right to the teind, will not carry the teind, unless it shall appear from special circumstances that a sale of both was designed by the parties. In lands cum decimis inclusis, where the teinds are consolidated with the flock, the right of both must necessarily go together in all cafes.

Tit. 18. Of Inhibitions.

The constitution and transmission of feudal rights being explained,
explained, and the burdens with which they are chargeable, it remains to be considered, how these rights may be affected at the suit of creditors, by legal diligence. Diligences are certain forms of law, whereby a creditor endeavours to make good his payment, either by affecting the person of his debtor, or by securing the subjects belonging to him from alienation, or by carrying the property of these subjects to himself. They are either real or personal. Real diligence is that which is proper to heritable or real rights; personal, is that by which the person of the debtor may be secured, or his personal estate affected. Of the first we have two, viz. Inhibition and Adjudication.

2. Inhibition is a personal prohibition, which passes by letters under the signet, prohibiting the party inhibited to contract any debt, or do any deed, by which any part of his lands may be aliened or carried off, in prejudice of the creditor inhibiting. It must be executed against the debtor, personally, or at his dwelling house, as summonses, and thereafter published and registered in the same manner with interdictions, (see Tit. vii. 30.)

3. Inhibition may proceed, either upon a liquid obligation, or even on an action commenced by a creditor for making good a claim not yet sustained by the judge; which last is called inhibition upon a depending action. The summons, which constitutes the dependence, must be executed against the debtor before the letters of inhibition pass the signet; for no suit can be said to depend against one, till he be cited in it as a defender: But the effect of such inhibition is suspended, till decree be obtained in the action against the debtor; and in the same manner, inhibitions on conditional debts have no effect, till the condition be purified. Inhibitions are not granted, without a trial of the cause, when they proceed on conditional debts. And though, in other cases, inhibitions now pass of course, the Lords are in use to stay, or recall them, either on the debtor's showing cause why the diligence should not proceed, or even ex officio where the ground of the diligence is doubtful.

4. Though inhibitions, by their uniform style, disable the debtor from selling his moveable as well as his heritable estate, theireffect has been long limited to heritage, from the interruption that such an embargo upon moveables must have given to commerce; so that debts contracted after inhibition may be the foundation of diligence, against the debtor's person and moveable estate. An inhibition secures the inhibiter against the alienation, not only of the lands that belonged to his debtor when he was inhibited, but of those that he shall afterwards acquire; but no inhibition can extend to such after-purchases as lie in a jurisdiction where the inhibition was not registered; for it could not have extended to theehe, tho' they had been made prior to the inhibition.

5. This diligence only strikes against the voluntary debts or deeds of the inhibited person: it does not restrain him from granting necessary deeds, e. g. such as he was obliged to grant anterior to the inhibition, since he might have been compelled to grant thee before the inhibiter had acquired any right by his diligence. By this rule, a wadsetter or annuelrenter might, after being inhibited, have effectually renounced his right to the reverfer on payment, because law could have compelled him to it; but to secure inhibitors against the effect of such alienations, it is declared by act of sedent of the court of Seffion, Feb. 19. 1650, that, after intimation of the inhibition to the reverfer, no renunciation or grant of redemption shall be sustained, except upon declarator of redemption brought by him, to which the inhibiter must be made a party.

6. In an inhibition is a diligence simply prohibitory, so that the debt, on which it proceeds, continues personal after the diligence; and consequently, the inhibitor, in a question with anterior creditors whose debts are not struck at by the inhibition, is only preferable from the period at which his debt is made real by adjudication: And where debts are contracted on heritable security, though posterior to the inhibition, the inhibiter's debt, being personal, cannot be ranked with them; he only draws back from the creditors ranked the sums contained in his diligence. The heir of the person inhibited is not restrained from alienation, by the diligence used against his auncel; for the prohibition is personal, affecting only the debtor against whom the diligence is used.

7. Inhibitions do not, of themselves, make void the posterior debts or deeds of the person inhibited; they only afford a title to the use of the diligence to set them aside, if he finds them hurtful to him: And even where a debt is actually reduced ex capitio inhibitionis, such reduction, being founded solely in the inhibiter's interest, is profitable to him alone, and cannot alter the natural preference of the other creditors.

8. Inhibitions may be reduced, upon legal nullities, arising either from the ground of debt, or the form of diligence. When payment is made by the debtor to the inhibiter, the inhibition is said to be purged. And even where a debt is struck at by the inhibition, may, upon making payment to the inhibiter, compel him to assign the debt and diligence in his favour, that he may make good his payment the more effectually against the common debtor.

Tit. 19. Of Comprifings, Adjudications, and Judicial Sales.

Heritable rights may be carried from the debtor to the creditor, either by the diligence of appriving (now adjudication), or by a judicial sale carried on before the court of Seffion. Appriving, or compriving, was the sentence of a sheriff, or of a messenger who was specially constituted sheriff for that purpose, by which the heritable rights belonging to the debtor were sold for payment of the debt due to the apprivor; so that appriving were, by their original constitution, proper sales of the debtor's lands, to any purchaser who offered. If no purchaser could be found, the sheriff was to apprise or tax the value of the lands by an inquest, (whence came the name of appriving), and to make over to the creditor lands to the value of the debt.

2. That creditors may have access to affect the estate of their deceased debtor, though the heir should stand off from entering, it is made lawful (by 1540, c. 106) for any creditor to charge the heir of his debtor to enter to his ancestor, year
year and day being past after the ancestor's death, within forty days after the charge; and, if the heir fails, the creditor may proceed to apprize his debtor's lands, as if the heir had been entered. Custom has explained this statute, that the creditor may charge the heir, immediately after the death of his ancestor, provided letters of apprising be not raised till after the expiry both of the year and of the forty days next ensuing the year, within which the heir is charged to enter. But this statute relates only to such charges on which apprising is to be led against the ancestor's lands; for, in those which are to be barely the foundation of a common summons or process against the heir, action will be sustained if the year be elaps'd from the ancestor's death before the execution of the summons, though the forty days should not be also expired. Though the statute authorizes such charges against majoris only, practice has also extended it against minors, and the rule is extended to the case where the heir is the debtor. One must, in this matter, distinguish between a general and a special charge. A general charge serves only to fix the representation of the heir who is charged, so as to make the debt his, which was formerly his ancestor's: But a special charge makes up for the want of a service, explained Tit. xxvii. 25. and states the heir, fictione juris, in the right of the subject to which he is charged to enter. Where therefore the heir is the debtor, a general charge for fixing the representation against him is unnecessary, since the only concern of the creditor is, that his debtor make up titles to the ancestor's estate, which is done by a special charge: But where the deceased was the debtor, the creditor must first charge his heir to enter in general, that it may be known whether he is to represent the debtor; if he does not enter within forty days, the debt may be fixed against him by a decree of constitution, on which he must be charged to enter heir in special, upon forty days more; and these must be elaps'd before the creditor can proceed to apprise.

3. Apprising in course of time underwent several changes in their form and effect, till at length, by act 1672, c. 19. adjudications were substituted in their place, which directed to proceed against debtors by way of action before the court of Session. By that statute, such part of the debtor's lands is to be adjudged as is equivalent to the principal sum and interest of the debt, with the composition due to the superior and expenses of infenfment, and a fifth part more in respect the creditor is obliged to take land for his money. The debtor must deliver to the creditor a valid right of the lands to be adjudged, or tranfumps thereof, renounce the possession in his favour, and ratify the decree of adjudication: And law considers the rent of the lands as precisely commensurate to the interest of the debt; so that the adjudger lies under no obligation to account for the surplus rents. To this, which is called a special adjudication, the legal or time within which the debtor may redeem, is declared to be five years; and the creditor attaining possession upon it can use no farther execution against the debtor, unless the lands be evicted from him.

4. Where the debtor does not produce a sufficient right to the lands, or is not willing to renounce the possession, and ratify the decree, (which is the case that has most frequently happened), the statute makes it lawful for the creditor to adjudge all right belonging to the debtor in the same manner, and under the same reversion of ten years, as he could, by the former laws, have apprized it. In this last kind, which is called a general adjudication, the creditor must limit his claim to the principal sum, interest, and penalty, without demanding a fifth part more. But no general adjudication can be instituted on, without libelling in the summons the other alternative of a special adjudication; for special adjudications are introduced by the statute in the place of apprisings; and it is only where the debtor refuses to comply with the terms, thereof that the creditor can lead a general adjudication.

5. Abbreviates are ordained to be made of all adjudications, which must be recorded within sixty days after the date of the decree. In every other respect, general adjudications have the same effects that appraisings had; adjudgers in possession are accountable for the surplus rents; a citation in adjudications renders the subject liti- guous; superiors are obliged to enter adjudgers; the legal of adjudications does not expire during the debtor's minority, &c. Only it may be observed, that though appraisings could not proceed before the term of payment, yet where the debtor is 'vagens ad inopiam, the court ex nobili officio admit adjudication for the debt before it be payable. But this sort being found solely in equity, subjects merely as a security, and cannot carry the property to the creditor by any length of time.

6. There are two kinds of adjudication, which took place at the same time with appraisings, and still obtain; viz. adjudications on a decree cognitionis causa, otherwise called contra hereditatem jaecentem, and adjudications in implement. Where the debtor's apparent heir, who is charged to enter, formally renounces the succession, the creditor may obtain a decree cognitionis causa; in which, though the heir renouncing is cited for the sake of form, no sentence condemnatory can be pronounced against him, in respect of his renunciation; the only effect of it is to subject the hereditas jacens to the creditor's diligence.

7. Adjudications contra hereditatem jaecentem, carry not only the lands themselves that belonged to the deceased, but the rents thereof fallen due since his death; for these, as an accessory to the estate belonging to the deceased, would have descended to the heir if he had entered, which rule is applied to all adjudications led on a special charge. This sort of adjudication is declared redeemable within seven years, by any co-adjudging creditor, either of the deceased debtor, or of the heir renouncing. The heir himself, who renounces, cannot be restored against his renunciation, nor consequently redeem, if he be not a minor. But even a major may redeem indirectly, by granting a simulâe bond to a confident person; the adjudication upon which, when conveyed to him/herself, is a good title to redeem all other adjudications against the lands belonging to his ancestor.

8. Adjudications in implement are deduced against those who have granted deeds without procuratory of reparation or precept of seisin, and refuse to divest themselves;
to the end that the subject conveyed may be effectually vested in the grantee. These adjudications may be also directed against the heir of the grantor, upon a charge to enter. Here there is no place for a legal reversion; for, as the adjudication is led for completing the right of a special subject, it must carry that subject as irredeemably as if the right had been voluntarily completed.

9. All adjudications led within year and day of that one which has been made first effectually by seisin (where seisin is necessary) or exact diligence for obtaining seisin, are preferable pari passu. The year and day runs from the date of the adjudication, and not of the seisin or diligence for obtaining it. After the days of that period, they are preferable according the their dates. All the co adjudicators within the year are preferable pari passu as if one adjudication had been led for all their debts. This makes the seisin or diligence on the first adjudication a common right to the refl, who must therefore be refunded to the owner of that diligence his whole expence laid out in carrying on and completing it. And though that first adjudication should be redeemed, the diligence upon it still subsists as to the refl. This pari passu preference, however, does not destroy the legal preference of adjudications led on debita funda. See Tit. xv. 15. Nor does it take place in adjudications in implement.

10. Before treating of judicial sales of bankrupts estates, the nature of sequestration may be shortly explained, which is a diligence that generally usher's in actions of sale. Sequestration of lands is a judicial act of the court of Sessio, whereby the management of an estate is put into the hands of a factor or steward named by the court, who gives security, and is to be accountable for the rents to all having interest. This diligence is competent, either where the right of the lands is doubtful, if it be applied for before either of the competitors has attained possession; or where the estate is heavily charged with the debts: But, as it is an unfavourable diligence, it is not admitted, unless that measur shall appear necessary for the security of creditors. Subjects, not brought before the court by the diligence of creditors, cannot fall under sequestration; for it is the competition of creditors which alone founds the jurisdiction of the court to take the disputed subject into their possession.

11. The court of Sessio who decrees the sequestration has the nomination of the factor, in which way they are directed by the recommendation of the creditors. A factor appointed by the Sessio, though the proprietor had not been infeft in the lands, has a power to remove tenants. Judicial factors must, within six months after extralcing their factor, make up a rental of the estate, and a list of the arrears due by tenants, to be put into the hands of the clerk of the procès, as a charge against themselves, and a note of such alterations in the rental as may afterwards happen; and must also deliver to the clerk annually a scheme of their accounts, charge and discharge, under heavy penalties. They are, by the nature of their office, bound to the same degree of diligence that a prudent man attends in his own affairs; they are accountable for the interest of the rents, which they either have, or by diligence might have recovered, from a year after their falling due. As it is much in the power of those factors to take advantage of the necessities of creditors, by purchasing their debts at an undervalue, all such purchases made either by the factor himself, or to his behoof, are declared equivalent to an acquittance or extinction of the debt. No factor can warrantably pay to any creditor, without an order of the court of Sessio; for he is, by the tenor of his commission, directed to pay the rents to those who shall be found to have belt right to them. Judicial factors are intitled to a salary, which is generally stated at five per cent. of their intromissions; but it is seldom affirmed till their office expires, or till their accounting; that the court may modify a greater or smaller salary, or none. In proportion to the factor's integrity and diligence. Many cases occur, where the court of Sessio, without sequestration, name a factor to preserve the rents from perilling; e.g. where an heir is deliberating whether to enter, where a minor is without tutors, where a succession opens to a person refusing abroad; in all which cases, the factor is subjected to the rules laid down in act of sedentum, Feb. 13. 1730.

12. The word bankrupt is sometimes applied to persons whose funds are not sufficient for their debts; and sometimes, not to the debtor, but to his estate. The court of Sessio are empowered, at the suit of any real creditor, to try the value of a bankrupt's estate, and sell it for the payment of his debts.

13. No process of sale, at the suit of a creditor, can proceed without a proof of the debtor's bankruptcy, or at least that his lands are so charged with debts, that no prudent persons will buy from him; and therefore the summons of sale must comprehend the debtor's whole estate. The debtor, or his apparent heir, and all the real creditors in possession, must be made parties to the suit; but it is sufficient if the other creditors be called by an edictal citation. The summons of sale contains a conclusion of ranking or preference of the bankrupt's creditors. In this ranking, first and second terms are assigned to the whole creditors for exhibiting in court (or producing) their rights and diligences; and the decree of certification proceeding thereupon, against the writings not produced, has the same effect in favour of the creditors who have produced their rights, as if that decree had proceeded upon an action of reduction-improvement. See Tit. xxx. 5. The ranking of these creditors must be concluded by an extrated decree, before the actual sale. The irredeemable property of the lands is adjudged by the court to the highest offerer at the sale. The creditors receiving payment must grant to the purchaser absolute warrandice, to the extent of the sum received by them; and the lands purchased are declared disbursed of all debts or deeds of the bankrupt, or his ancestors, either on payment of the price by the purchaser to the creditors according to their preference, or on confignation of it, in case of their refusal, in the hands of the magistrates of Edinburgh: The only remedy provided to such creditors as judge themselves hurt by the sale of division of the price, even though they should be minors, is an action for recovering their share of the price against the creditors who have received it.

14. The expense of these proceedings is defbursed by the factor out of the rents in his hands; by which the whole
whole burden of such expence falls upon the posteriors creditors.

15. Apparent heirs are intitled to bring actions of sale of the estates belonging to their ancestors, whether bankrupt or not; the expence of which ought to fall upon the pursuer, if there is any excrefcence of the price, after payment of the creditors.

16. As process of ranking and sale are designed for the common interefl of all, the creditors, no diligence carried on or completed during their pendency ought to give any preference in the competition; pendente lite, null innovandum.

17. It is a rule in all real diligences, that where a creditor is preferable on several different subjedts, he cannot give any preference in the competition. It is not material to such a creditor to draw his whole payment out of any one fund, he may apply his debt so as may best secure himself; but that inequality will be rectified, as to the posteriors creditors, who had likewise, by their rights and diligences, affected the subjedts out of which he drew his payment, by obliging him to assign in their favour his right upon the separate subjedts which he did not use in the ranking; by which they may recur against these separate subjedts for the shares which the debt preferred might have drawn out of them. As the obligation to assign is founded merely in equity, the catholic creditor cannot be compelled to it, if his assigning shall weaken the preference of any separate debt vested in himself, affecting the special subjedt sought to be assigned. But if a creditor upon a special subjedt shall acquire from another a catholic right, or a catholic creditor shall purchase a debt affecting a special subjedt, with a view of creating to the special debt a higher degree of preference than was naturally due to it, by an arbitrary application of the catholic debt, equity cannot protect him from assigning in favour of the creditor excluded by such application, especially if, prior to the purchase, the subjedt had become litigious by the process of ranking; for transmissions ought not to hurt creditors who are no parties to them, nor to give the purchaser any new right, which was not formerly in himself or his cedent.

Tit. 20. Of Obligations and Contracts in general.

The law of heritable rights being explained, moveable rights fall next to be considered, the doctrine of which depends chiefly on the nature of Obligations. An obligation is a legal tie, by which one is bound to pay or perform something to another. Every obligation on the person obliged, implies an opposite right in the creditor, so that what is a burden in regard to the one is right with the other; and all rights founded on obligation are called personal. There is this essential difference between a real and a personal right, that a jus in re, whether of property, or of an inferior kind as servitude, entitles the person vested with it to possess the subjedt as his own; or if he is not in possession, to demand it from the possessors; whereas the creditor in a personal right has only jus ad rem, or a right to compel the debtor to fulfill his obligation; without any right in the subjedt itself, which the debtor is bound to transfer to him. One cannot oblige himself, but by a present act of the will. A bare resolution therefore, or purpose to be obliged, is alterable at pleasure.

2. Obligations are either, first, merely natural, where one person is bound to another by the law of nature, but cannot be compelled by any civil action to the performance. Thus, though deeds granted by a minor having curators, without their consent, are null, yet the minor is naturally obliged to perform such deeds; and parents are naturally obliged to provide their children in reasonable patrimony. Natural obligations intitle the creditor to retain what he has got in virtue thereof, without being subjected to restore it. 2. Obligations are merely civil, which may be sued upon by an action, but are elided by an exception in equity; this is the case of obligations granted through force or fear, &c. 3. Proper or full obligations, are those which are supported both by equity and the civil function.

3. Obligations may be also divided into, 1. Pure, to which neither day nor condition is adjested. These may be exacted immediately. 2. Obligations (ex die), which have a day adjested to their performance. In these, dies flatum cedit, fed non venit; a proper debt arises from the date of the obligation, because it is certain that the day will exsist; but the execution is suspended, till the lapse of that day. 3. Conditional obligations; in which there is no proper debt (dies non cedit) till the condition be fulfilled, because it is possible the condition may exist; and which therefore are said to create only the hope of a debt; but the granter, even of these, has no right to refile. An obligation, to which a day is adjested that possibly may never exist, implies a condition; dies incertus pro conditione habetur. Thus, in the case of a provision to a child, payable when he attains to the age of fourteen, if the child dies before that age, the provision falls. 4. Obligations, when considered with regard to their cause, were divided by the Romans, into those arising from contract, quasi contract, delict, and quasi-delict. But there are certain obligations, even full and proper ones, which cannot be derived from any of these sources, and to which Lord Stair gives the name of obedienc. Such as the obligation on parents to alimone or maintain their children; which arises singly from the relation of parent and child, and may be enforced by the civil magistrate. Under parents are comprehended the mother, grandfather, and grandmother, in their proper order. This obligation on parents extends to the providing of their issue in all the necessaries of life, and giving them suitable education. It ceases, when the children can earn a livelihood by their own industry; but the obligation on parents to maintain their indigent children, and reciprocally on children to maintain their indigent parents, is perpetual. This obligation is, on the father's death, transferred to the eldest son, the heir of the family; who, as representing the father, must alimone his younger brothers and sisters: The brothers are only intitled to alimony, till their age of twenty-one, after which they are presumed able to do for themselves; but the obligation
to maintain the filters continues till their marriage. In persons of lower rank, the obligation to alimment the filters ceases after they are capable of subsisting by any service or employment.

5. All obligations, arising from the natural duty of restitution, fall under this class: Thus, things given upon the view of a certain event, must be restored, if that event does not afterwards exist: Thus also, things given ob turpem causam, where the turpitude is in the receiver and not in the giver, must be restored. And on the same principle, one upon whose ground a house is built or repaired by another, is obliged, without any covenant, to restore the expense laid out upon it, in so far as it has been productive to him.

6. A contract is the voluntary agreement of two or more persons, whereby something is to be given or performed upon one part, for a valuable consideration, either present or future, on the other part. Consent, which is implied in agreement, is excluded. 1. By error in the essentials of the contract, for in such case, the party does not properly contract, but errors or is deceived; And this may be also applied to contracts which take their rise from fraud or imposition. 2. Consent is excluded by such a degree of restraint upon any of the contracting parties, as extends the agreement; for where violence or threatening are used against a person, his will has really no part in the contract.

7. Loan or mutuum is that contract which obliges a person, who has borrowed any fungible subject from another, to restore to him as much of the same kind, and of equal goodness. Whatever receives its estimation in number, weight, or measure, is a fungible, as corn, wine, current coin, &c. The only proper subjects of this contract are things which cannot be used, without either their extinction or alienation; hence, the property of the thing lent is necessarily transferred by delivery to the borrower, who consequently must run all the hazards, either of its deterioration or its perishing, according to the rule, res perit suo domino. Where the borrower neglects to restore, at the time and place agreed on, the estimation of the thing lent must be made according to its price at that time and in that place; because it would have been worth so much to the lender, if the obligation had been duly performed. If there is no place nor time stipulated for, the value is to be stated according to the price that the commodity gave when and where it was demanded. In the loan of money, the value put on it by public authority, and not its intrinsic worth, is to be considered. This contract is obligatory only on one part; for the lender is subjected to no obligation: The only action therefore that it produces, is pointed against the borrower, that he may restore as much in quantity and quality as he borrowed, together with the damage the lender may have suffered through default of due performance.

8. Commodate is a species of loan, gratuitous on the part of the lender, where the thing lent may be used, without either its perishing or its alienation. Hence, in this sort of loan, the property continues with the lender; the only right the borrower acquires in the subject is its use, after which he must restore the individual thing that he borrowed: Consequently, if the subject perishes, it perishes to the lender, unless it has perished by the borrower's fault. What degree of fault or negligence makes either of the contracting parties liable to the other in damages, is comprehended under the following rules. Where the contract gives a mutual benefit to both parties, each contracter is bound to adhere a middle fort of diligence, such as a man of ordinary prudence uses in his affairs. Where only one of the parties has benefit by the contract, that party must use exact diligence; and the other who has no advantage by it is accountable only for done, or for gross omissions which the law determines to be done. Where one employs less care on the subject of any contract which implies an exuberant trust, than he is known to employ in his own affairs, it is considered as done.

9. By these rules, the borrower in the contract of commodate must be exactly careful of the thing lent, and restore it at the time fixed by the contract, or after that use is made of it for which it was lent: If he puts it to any other use, or neglects to restore it at the time covenanted, and if the thing perishes thereafter, even by mere accident, he is bound to pay the value. On the other part, the lender is obliged to restore to the borrower such of the expenses disbursed by him on that subject, as arose from any uncommon accident, but not those that naturally attend the use of it. Where a thing is lent gratuitously, without specifying any time of redelivery, it constitutes the contract of precarium, which is revocable at the lender's pleasure, and, being entered into from a personal regard to the borrower, ceases by his death.

10. Depositum is a contract, by which one who has the custody of a thing committed to him (the depositary), is obliged to restore it to the depositor. If a reward is bargained for by the depository for his care, it resolves into the contract of location. As this contract is gratuitous, the depositary is only answerable for the consequences of gross neglect; but after the deposit is redeemed, he is accountable even for casual misfortunes. He is intitled to a full indemnification for the losses he has sustained by the contract, and to the recovery of all sums expended by him on the subject.

11. An obligation arises without formal pact, barely by a traveller's entering into an inn, ship, or stable, and there depositing his goods, or putting up his horses; whereby the innkeeper, shipsmaster, or stabler, is accountable, not only for his own acts and those of his servants, (which is an obligation implied in the very exercise of these employments), but of the other guests or passengers; and, indeed, in every case, unless where the goods have been lost damnos fatales, or carried off by pirates or housebreakers. Not only the masters of ships but their employ- ers, are liable each of them for the share that he has in the ship; but by the present custom of trading nations, the goods brought into a ship must have been delivered to the master or mate, or entered into the ship-books. Carriers fall within the intention of this law; and practice has extended it to vintners within borough. The extent of the damage sustained by the party may be proved by his own oath in liem.

12. Sequestration, whether voluntarily confented to by the parties, or authorized by the judge, is a kind of deposit;
deposit; but as the office of sequestration, to whose care the subject in dispute is committed, is not considered as gratuitous, he cannot throw it up at pleasure, as a common depository may do; and he is liable in the middle degree of diligence. Confinnement of money is also a deposit. It may be made, either where the debt is called in question by the debtor, as in suspensions; or where the creditor refuses to receive his money, as in wadsets, &c. The risk of the confined money lies on the confignor, where he ought to have made payment, and not con- signation, or has configned only a part; or has chosen for consignatory, a person neither named by the parties nor of good credit. The charger, or other creditor, runs the risk, if he has charged for sums not due, or has without good reason refused payment, by which refusal the confignation became necessary. It is the office of a con- signatory, to keep the money in safe custody, till it be called for: If therefore he puts it out at interest, he must run the hazard of the debtor's insolvency; but, for the same reason, though he should draw interest for it, he is liable in none to the consignor.

13. Pledge, when opposed to wadset, is a contract, by which a debtor puts into the hands of a creditor a special moveable subject in security of the debt, to be re- delivered on payment. Where a security is established by law to the creditor, upon a subject which continues in the debtor's possession, it has the special name of an hypothec. Tradesmen and ship carpenters have an hypothec on the house or ship repaired, for the materials and other charges of reparation; but not for the expense of building a new ship. Owners of ships have an hypothec on the cargo for the freight, heritors on the fruits of the ground, and landlords on the inspueta et illita, for their rents. Writers also, and agents, have a right of hypothec, or more properly of retention, in their constituent's writings, for their claim of pains and disbursements. A creditor cannot, for his own payment, sell the subject impignorated, without applying to the judge-ordinary for a warrant to put it up to public sale or roup; and to this application the debtor ought to be made a party.

Tit. 21. Of Obligations by Word or Writ.

The appellation of verbal may be applied to all obligations to the constitution of which writing is not essential, which includes both real and consensual contracts; but as these are explained under separate titles, obligations by word, in the sense of this article, must be restricted, either to promises, or to such verbal agreements as have no special name to distinguish them. Agreement implies the intervention of two different parties, who come under mutual obligations to one another. Where nothing is to be given or performed but on one part, it is properly called a promise, which, as it is gratuitous, does not require the acceptance of him to whom the promise is made. An offer, which must be distinguished from a promise, implies something to be done by the other party; and consequently is not binding on the offerer, till it be accepted, with its limitations or conditions, by him to whom the offer is made; after which, it becomes a proper agreement.

2. Writing must necessarily intervene in all obligations and bargains concerning heritable subjects, though they should be only temporary; as tacks, which, when they are verbal, last but for one year. In these no verbal agreement is binding, though it should be referred to the oath of the party; for, till writing is exhibited, law gives both parties a right to refuse, as from an unfinished bargain; which is called loco panis. If, upon a verbal bargain of lands, part of the price shall be paid by him who was to purchase, the interventus rei, the actual payment of money, creates a valid obligation, and gives a beginning to the contract of sale: And in general, where ever matters are no longer entire, the right to refuse seems to be excluded. An agreement, whereby a real right is passed from, or restricted, called paullum liberatorium, may be perfected verbally; for freedom is favourable, and the purpose of such agreement is rather to dissolve than to create an obligation. Writing is also essential to bargains made under condition that they shall be reduced into writing; for in such cases, it is pars contrac- tral, that, till writing be exhibited, both parties shall have liberty to withdraw. In the same manner, verbal or nuncupative testaments are rejected by our law; but verbal legacies are sustained, where they do not exceed L. 100 Scots.

3. Anciently, when writing was little used, deeds were executed by the party appending his seal to them; in presence of witnesses. For preventing frauds that might happen by appending seals to false deeds, the subscription also of the granter was afterwards required, and, if he could not write, that of a notary. As it might be of dangerous consequence, to give full force to the subscription of the parties by initials, which is more easily counterfeited; our practice, in order to sustain such subscription, seems to require a proof, not only that the granter used to subscribe in that way, but that de facto he had subscribed the deed in question; at least, such proof is required, if the instrumental witnesses be still alive.

4. As a further check, it was afterwards provided that all writings carrying any heritable right, and other deeds of importance, be subscribed by the principal parties, if they can subscribe; otherwise, by two notaries, before four witnesses specially designed. The subsequent practice extended this requisite of the designation of the witnesses to the case where the parties themselves subscribed. Custom has confirmed obligations for sums exceeding L. 100 Scots, to be obligations of importance. In a divisible obligation, ex gr. for a sum of money, though exceeding L. 100, the subscription of one notary is sufficient, if the creditor restricts his claim to L. 100: But, in an obligation indivisible, e. g. for the performance of a fact, if it be not subscribed in terms of the statute, it is void. When notaries thus attest a deed, the attestation or docquet must specially express that the granter gave them a mandate to sign: nor is it sufficient that this be mentioned in the body of the writing.

5. In every deed, the name of him who writes it, with his dwelling place or other mark of distinction, must be inserted. The witnesses must both subscribe as witness, and their names and designations be inserted in the body of the deed: And all subscribing witnesses must know the granter, and either see him subscribe, or hear
him acknowledge his subscription; otherwise they are declared punishable as accessary to forgery. Deeds, decrees, and other securities, consisting of more than one sheet, may be written by way of book, in place of the former custom of putting together the several sheets, and signing the joinings on the margin; provided each page be signed by the granter, and marked by its number; and the telling clause expires the number of pages.

6. Instruments of feisin are valid, if subscribed by one notary, before a reasonable number of witnesses; which is extended by practice to instruments of renunciation. Two witnesses are deemed a reasonable number to every deed that can be executed by one notary. It is not necessary, that the witnesses to a notorial instrument, or execution, see the notary or messenger sign; for they are called as witnesses to the transaction which is attested, and not to the subscription of the person attesting.

7. A new requisite has been added to certain deeds since the union, for the benefit of the revenue: They must be executed on flamped paper, or parchment, paying a certain duty to the crown. Charters, instruments of renunciation, feisins, and returns of lands held of a subject, are charged with 2 f. 3 d. of duty: Bonds, tacks, contracts, and other personal obligations, paid at first 6 d. to which a farther duty of 1 s. has since added. Bills of exchange are drawn by a person in one country to his correspondent in another; and they have that name, because it is the exchange, or the value of money in one place compared with its value in another, that generally determines the precise extent of the sum contained in the draft. The creditor in the bill is sometimes called the payee, or porteur. As parties to bills are of different countries, questions concerning them ought to be determined by the received custom of trading nations, unless where special statute interposes. For this reason, bills of exchange, though their form admits not of witnesses, yet prove their own dates, in questions either with the heir, or creditors of the debtor; but this doctrine is not extended to inland bills payable to the drawer himself.

11. A bill is valid, without the designation, either of the drawer, or of the person to whom it is made payable: It is enough, that the drawer's subscription appears to be truly his; and one's being payee of a bill marks him out to be the creditor, if he bears the name given in the bill to the creditor: Nay, though the person drawn on should not be designated, his acceptance presumes that it was he whom the drawer had in his eye. Bills drawn blank, in the creditor's name, fall under the statutory nullity; for though indorsements of bills are excepted from it, bills themselves are not. Not only the person drawn upon must sign his acceptance, but the drawer must sign his draught, before any obligation can be formed against the acceptor: Yet it is sufficient in practice, that the drawer signs, before the bill is produced in judgment; though it should be after the death both of the creditor and acceptor. A creditor in a bill may transmit it to another by indorsement, though the bill should not bear to his order; by the same rule that other rights are transferrable by assignation, though they do not bear to assignees.

12. The drawer, by signing his draught, becomes liable for the value to the creditor in the bill, in case the person drawn upon either does not accept, or after acceptance does not pay; for he is presumed to have received value from the creditor at giving him the draught, though it should not bear for value received: But, if the drawer was debtor to the creditor in the bill before the draught, the bill is presumed to be given towards payment of the debt, unless it expressly bears for value. The person drawn upon, if he refuse to accept, while he has the drawer's money in his hands, is liable to him in damages. As a bill presumes value from the creditor, indorsement presumes value from the indorser; who therefore, if he cannot obtain payment from the acceptor, has recourse against the indorser, unless the bill be indorsed in these words, without recourse.

13. Payment of a bill, by the acceptor, acquits both the drawer and him at the hands of the creditor; but it intitles the acceptor, if he was not the drawer's debtor, to an action of recouvre against him; and, if he was, to
where the bill does not bear value in the hands of the person drawn upon, it is presumed that he is not the drawer's debtor, and consequently he has recourse against the drawer, ex mandato.

14. Bills, when indorsed, are considered as so many bags of money delivered to the onerous indorsee; which therefore carry right to the contents, free of all burdens that do not appear on the bills themselves. Hence, a receipt or discharge, by the original creditor, if granted on a separate paper, does not exempt the acceptor from payment to the indorsee; hence also, no ground of compensation competent to the acceptor against the original creditor can be pleaded against the indorsee: But, if the debtor shall prove, by the oath of the indorsee, that he paid not the full value for the indorsement, the indorsee is justly considered as but a name; and therefore all exceptions, receivable against the original creditor, will be sustained against him.

15. Bills must be negotiated by the possessor, against the person drawn upon, within a prorogation time, in order to preserve recourse against the drawer. In bills payable so many days after sight, the creditor has a discretionary power of fixing the payment somehow sooner or later, as his occasions shall require. Bills payable on a definite day, need not be presented for acceptance till the day of payment, because that day can neither be prolonged nor shortened by the time of acceptance. For the same reason, the acceptance of bills, payable on a precise day, need not be dated: But, where a bill is drawn payable so many days after sight, it must; because there the term of payment depends on the date of the acceptance.

16. Though bills are, in strict law, due the very day on which they are made payable, and may therefore be protested on the day thereafter; yet there are three days immediately following the day of payment, called days of grace, within any of which the creditor may protest the bill: But if he delay protesting till the day after the last day of grace, he loses his recourse. Where a bill is protested, either for not acceptance, or not payment, the dishonour must be notified to the drawer or indorser, within three polls at farthest. This strictness of notification is confined to such bills as may be protested by the possessor upon the third day of grace: Where therefore bills are indorsed after the days of grace are expired, the indorsee is left more at liberty, and does not lose his recourse, though he should not take a formal protest for not payment, if, within a reasonable time, he shall give the indorser notice of the acceptor's refusing to pay. Not only does the possessor, who neglects strict notification, lose his recourse against the drawer, where the person drawn upon becomes afterwards bankrupt, but though he should continue solvent; for he may, in that case, recover payment from the debtor, and so is not to be indulged in an unnecessary process against the drawer, which he has tacitly renounced by his negligence. Recourse is preferred against the drawer, though the bill should not be duly negotiated, if the person drawn upon was not his debtor; for there the drawer can qualify no prejudice by the neglect of diligence, and he ought not to have drawn on one who owed him nothing.

17. The privileges superadded to bills by statute, that.tho', by their form, they can have no clause of registration, yet, if duly protested, they are registrable within six months after their date in case of not acceptance, or in six months after the term of payment in the case of not payment; which registration is made the foundation of summary diligence, either against the drawer or indorser in the case of not acceptance, or against the acceptor in case of not payment. This is extended to inland bills, i.e. bills both drawn and made payable in Scotland. After acceptance, summary diligence lies against no other than the acceptor; the drawer and indorser must be pursued by an ordinary action. It is only the principal sum in the bill, and interest, that can be charged for summarily: The exchange, when it is not included in the draught, the re-exchange incurred by suffering the bill to be protested and returned, and the expense of diligence, must all be recovered by an ordinary action; because these are not liquid debts, and so must be previously constituted.

18. Bills, when drawn payable at any considerable distance of time after date, are denied the privileges of bills; for bills are intended for currency, and not to lie as a security in the creditor's hands. Bills are not valid which appear ex facie to be donations. No extrinsic stipulation ought to be contained in a bill which deviates from the proper nature of bills; hence, a bill to which a penalty is adjointed, or with a clause of interest from the date, is null. Inland precepts drawn, not for money the medium of trade, but for fungibles, are null, as wanting writer's name and witnesses. It is not an agreed point whether promissory notes, without writer and witnesses, unless holograph are probative. This however is certain, that they at no rate intitle to the privileges of bills.

19. As for the solemnities essential to deeds signed in a foreign country, when they come to receive execution in Scotland, it is a general rule, that no laws can be of authority beyond the dominions of the lawmaker. Hence, in strictness, no deed, though perfected according to the law of the place where it is signed, can have effect in another country where different solemnities are required to a deed of that sort. But this rigour is so softened ex committate, by the common consent of nations, that all personal obligations granted according to the law of that country where they are signed, are effectual everywhere, which obtains even in obligations to convey heritage. Conveyances themselves, of heritable subjects, must be perfected according to the law of the country where the heritage lies, and from which it cannot be removed.

20. A writing, while the grantor keeps it under his own power or his doer's, has no force; it becomes obligatory, only after it is delivered to the grantee himself, or found in the hands of a third person. As to which last, the following rules are observed: A deed found in the hands of one, who is doer both for the grantor and grantee, is presumed to have been put in his hands as doer for the grantee. The presumption is also for delivery, if the deed appears in the hands of one who is a stranger to both. Where a deed is deposited in the hands of a third person, the terms of deposition may be proved by the oath of the depostary, unless where they are
Tit. 22. Of Obligations and Contracts arising from Consent, and of accessory Obligations.

Contracts confensual, i.e. which might, by the Roman law, be perfected by sole consent, without the intervention either of things or of writing, are sale, permutation, location, society, and mandate. Where the subject of any of these contracts is heritable, writing is necessary.

2. Sale is a contract, by which one becomes obliged to give something to another, in consideration of a certain price in current money to be paid for it. Things confinutally in hope, may be the subject of this contract, as the draught of a net. Commodities, where their importation or use is absolutely prohibited, cannot be the subject of sale; and even in run goods, no action lies against the vendor for non-delivery, if the buyer knew the goods were run.

3. Though this contract may be perfected before delivery of the subject, the property remains till then with the vendor. See Tit. viii. 9. Yet till delivery, the hazard of its deterioration falls on the purchaser, because he has all the profits arising from it, after the sale. On the other hand, the subject itself percusses to the vendor; if it should perish through his fault, or after his undue delay to deliver it. 2. If a subject is sold as a fungible, and not as an individual, or corpus, e.g. a quantity of farm-wheat, sold without distinguish the parcel to be delivered from the rest of the farm. 3. The periculum lies on the vendor till delivery, if he be obliged by a special article in the contract to deliver the subject at a certain place.

4. Location is that contract, where an hire is stipulated for the use of things, or for the service of persons. He who lets his work or the use of his property to hire, is the locatur or lese; and the other, the conductor or lessee. In the location of things, the lessee is obliged to deliver the subject, fitted to the use it was let for; and the lessee must preserve it carefully, put it to no other use, and, after that is over, restore it. Where a workman or artificer lets his labour, and if the work is either not performed according to contract, or if it be insufficient, even from mere unskilfulness, he is liable to his employer in damages, for he ought not, as an artificer, to have undertaken a work to which he was not equal. A servant hired for a certain term, is intitled to his full wages, though from sickness or other accident he should be disabled for a part of his time; but, if he die before the term, his wages are only due for the time he actually served. If a master dies, or without good reason turns off, before the term, a servant who eats in his house, the servant is intitled to his full wages, and to his maintenance till that term. And, on the other part, a servant who without ground deferts his service, forfeits his wages and maintenance, and is liable to his master in damages.

5. Society or copartnership is a contract, whereby the several partners agree concerning the communication of losses and gain arising from the subject of the contract. It is formed by the reciprocal choice that the partners make of one another; and so is not constituted in the case of co-heirs, or of several legatees in the same subject. A copartnership may be so constituted, that one of the partners shall, either from his sole right of property in the subject, or from his superior skill, be intitled to a certain share of the profits, without being intitled to any part of the loss; but a society, where one partner is to bear a certain proportion of losses, without being intitled to any share of the profits, is justly reprobated. All the partners are intitled to shares of profit and loss proportioned to their several flocks, where it is not otherwise covenanted.

6. As partners are united, from a delectus persona, in a kind of brotherhood, no partner can, without a special power contained in the contract, transfer any part of his share to another. All the partners are bound in solidum by the obligation of any one of them, if he subscribe by the firm or social name of the company; unless it be a deed that falls not under the common course of administration. The company-effects are the company property of the society intituted to its debts; so that no partner can claim a division thereof, even after the society is dissolved, till these are paid: And, consequently, no creditor of a partner can, by diligence, carry to himself the property of any part of the common flock, in prejudice of a company-creditor: but he may, by assent of a partner, secure his debtor's share in the company's hands, to be made forthcoming to him at the close of the copartnership, in so far as it is not exhaustd by the company debts.

7. Society being founded in the mutual confidence among the socii, is dissolved, not only by the renunciation, but by the death of any one of them, if it be not otherwise specially covenanted. A partner, who renounces upon unfair views, or at a critical time, when his withdrawing may be fatal to the society, looses his partners from all their engagements to him, while he is bound to them for all the profits he shall make by his withdrawing.
ing, and for the loss arising thereby to the company. Not only natural, but civil death, e. g. arising from a sentence inflicting capital punishment, makes one incapable to perform the duties of a partner, and consequent-ly dissolves the society. In both cases, of death and renunciation, the remaining partners may continue the copartnership, either expressly, by entering into a new contract; or tacitly, by carrying on their trade as formerly.

Public trading companies are now every day constituted, with rules very different from those which either obtained in the Roman law, or at this day obtain in private societies. The proprietors or partners in these, though they may transfer their shares, cannot renounce; nor does their death dissolve the company, but the share of the deceased descends to his representative.

8. A joint trade is not a partnership, but a momentary contract, where two or more persons agree to contribute a sum, to be employed in a particular course of trade, the produce whereof is to be divided among the adventurers, according to their several shares, after the voyage is finished. If, in a joint trade, that partner who is intrusted with the money for purchasing the goods, shoud, in place of paying them in cash, buy them upon credit, the furnishor who followed his faith alone in the sale, has no recourse against the other adventurers; he can only recover from them what of the buyer's share is yet in their hands. Where any one of the adventurers, in a joint trade, becomes bankrupt, the others are preferable to his creditors, upon the common stock, as long as it continues undivided, for the relief of all the engagements entered into by them on account of the adventure.

9. Mandate is a contract, by which one employs another to manage any business for him; and by the Roman law, it must have been gotituous. It may be constituted tacitly, by one's suffer-ing another to act in a certain branch of his affairs, for a tract of time together, without challenge. The mandator is at liberty not to accept of the mandate; and, as his powers are solely founded in the mandant's commission, he must, if he undertakes it, strictly adhere to the directions given him: Nor is it a good defence, that the method he followed was more rational; for in that his employer was the proper judge. Where no special rules are prescribed, the mandator, if he acts prudently, is secure, whatever the success may be; and he can sue for the recovery of all the expenses reasonably disbursed by him in the execution of his office.

10. Mandates may be general, containing a power of administering the mandant's whole affairs; but no mandate implies a power of disposing gratuitously of the constituent's property; nor even of selling his heritage for an adequate price: But a general mandatory may sell such of the moveables as must otherwise perish. No mandatory can, without special powers, transfer doubtful claims belonging to his constituent, or refer them to arbitrators.

11. Mandates expire. 1. By the revocation of the employer, though only tacit, as if he should name another mandator, for the same business. 2. By the renunciation of the mandatory; even after he has executed part of his commission, if his office be gratuitous. 3. By the death, either of the mandant or mandatory; but if matters are not entire, the mandate continues in force, notwithstanding such revocation, renunciation, or death.

12. The favour of commerce has introduced a tacit mandate, by which matters of ships are empowered to contract in name of their exercitors or employers, for repairs, ship-provisions, and whatever else may be necessary for the ship or crew; as to oblige, not themselves only, but their employers. Whoever has the actual charge of the ship is deemed the master, though he should have no commission from the exercitors, or should be substituted by the master in the direction of the ship without their knowledge. Exercitors are liable, whether the master has paid his own money to a merchant for necessaries, or has borrowed money to purchase them. The furnishor or lender must prove that the ship-needed repairs, provisions, &c. to such an extent; but he is under no necessity to prove the application of the money or materials to the ship's life. If there are several exercitors, they are liable in solidum. In the same manner the undertaker of any branch of trade, manufacture, or other land-negotiation, is bound by the contracts of the initiators whom he sets over it, in so far as relates to the subject of the preposture.

13. Contracts and obligations, in themselves imperfect, receive strength, by the contracter or his heirs doing any act thereafter which imports an approbation of them, and consequently supplies the want of an original legal consent. This is called homologation; and it takes place even in deeds intrinsically null; whether the nullity arises from the want of statutory solemnities, or from the incapacity of the granter. It cannot be inferred, 1. By the act of a person who was not in the knowledge of the original deed; for one cannot approve what he is ignorant of 2. Homologation has no place where the act or deed which is pleaded as such can be ascribed to any other cause; for an intention to come under an obligation is not presumed.

14. Quasi-contracts are formed without explicit consent, by one of the parties doing something that by its nature either obliges him to the other party, or the other party to him. Under this class may be reckoned turoty, the entry of an heir, negotiorum gestio, indebiti solutio, communion of goods between two or more common proprietors, and mercium jactus levans noctis causit. Negotiorum gestio forms those obligations which arise from the management of a person's affairs in his absence, by another, without a mandate. As such manager acts without authority from the proprietor, he ought to be liable in exact diligence, unless he has from friendship interposed in affairs which admitted no delay; and he is accountable for his intromissions with interest. On the other
other part, he is intitled to the recovery of his necessary obligations in which he may have bound himself in consequence of the management.

15. *Indebiti solutio,* or the payment to one of what is not due to him, if made through any mistake, either of fact, or even of law, founds him who made the payment in an action against the receiver for repayment (*conditio indebiti.*) This action does not lie, 1. If the sum paid was due *ex aequitate,* or by a natural obligation; for the obligation to restore is founded solely in equity, or by a natural obligation; of fault, or even of law, founds him who made the payment knew that nothing was due; for *qui consulit quod non debebat,* præsumit donare.

16. Where two or more persons become common proprietors of the same subject, either by legacy, gift or purchase, without the view of co-partnership, an obligation is thereby created among the proprietors to communicate the profit and loss arising from the subject, while it remains common: And the subject may be divided at the suit of any having interest. This division, where the question is among the common proprietors, is according to the valuation of their respective properties: But, where the question is between the proprietors and those having servitudes upon the property, the superfice is only divided, without prejudice to the property. Commonties belonging to the King, or to royal boroughs, are not divisible. Lands lying runrig, and belonging to different proprietors, may be divided, with the exception of borough and incorporated acres; the execution of which is committed to the judge-ordinary, or justices of the peace.

17. The throwing of goods overboard, for lightening a ship in a storm, creates an obligation, whereby the owners of the ship and goods saved are obliged to contribute for the relief of those whose goods were thrown overboard, that all may bear a proportional loss of the goods ejected for the common safety. In this contribution, the ship's provisions suffer no estimation. A master who has cut his mast, or parted with his anchor, to save the ship, is intitled to this relief; but if he has lost them by the storm, the loss falls only on the ship and freight. If the ejection does not save the ship, the goods preserved from shipwreck are not liable in contribution. Ejection may be lawfully made, if the master and a third part of the mariners judge that measure necessary, though the owner of the goods should oppose it: And the goods ejected are to be valued at the price that the goods of the same sort which were saved shall be afterwards sold for.

18. There are certain obligations, which cannot subsist by themselves, but are accesseos to, or make a part of other obligations. Of this sort are *fidejusfion,* and the obligation to pay interest. Cautionry, or *fidejusfion,* is that obligation by which one becomes engaged as security for another, that he shall either pay a sum, or perform a deed.

19. A cautioner for a sum of money may be bound, either simply as cautioner for the principal debtor, or conjunctly and severally for and with the principal debtor. The first has, by our customs, the *benficium ordinis,* or of *fidejusfion,* by which the creditor is obliged to disburse the proper debtor, before he can insist for payment against the cautioner. Where one is bound as full debtor with and for the principal, or conjunctly and severally with him, the two obligants are bound equally in the same obligation, each *in solidum*; and consequently, the cautioner, though he is but an accessory, may be sued for the whole, without either disputing, or even citing the principal debtor. Cautioners for performance of acts by another, or for the faithful discharge of an office, e. g. for factors, tutors, &c. cannot by the nature of their engagement be bound conjunctly and severally with the principal obligant, because the fact to which the principal is bound cannot possibly be performed by any other. In such engagements, therefore, the failure must be previously constituted against the proper debtor, before action can be brought against the cautioner, for making up the lops of the party suffering.

20. The cautioner, who binds himself at the desire of the principal debtor, has an *aetio mandati,* or of relief against him, for recovering the principal and interest paid by himself to the creditor, and for necessary damages; which action lies *de jure,* though the creditor should not assign to him on payment. As relief against the debtor is implied in *fidejusfory* obligations, the cautioner, where such relief is cut off, is no longer bound: Hence, the defence of prescription frees the cautioner, as well as the principal debtor.

21. But, 1. Where the cautioner is interposed to an obligation merely natural, the relief is restricted to the sums that have really turned to the debtor's profit. 2. A cautioner who pays without citing the debtor, loses his relief, in so far as the debtor had a relevant defence against the debt, in whole or in part. Relief is not competent to the cautioner, till he either pays the debt, or is discharged for it; except, 1. Where the debtor is expressly bound to deliver to the cautioner his obligation cancelled, against a day certain, and has failed; or, 2. Where the debtor is *bursarius,* in which case the cautioner may, by proper diligence, secure the debtor's funds for his own relief, even before payment or discharge.

22. A right of relief is competent *de jure* to the cautioner who pays against his co-cautioners, unless where the cautioner appears to have renounced it. In consequence of this implied relief, a creditor, if he shall grant a discharge to any one of the cautioners, must, in demanding the debt from the others, deduct that part, as to which he has cut off their relief by that discharge. Where a cautioner in a bond signs a bond of corroboration, as a principal obligant with the proper debtor, and with them a new cautioner, the cautioner in the new bond is intitled to a total relief against the first cautioner, at whose desire he is presumed to be bound.

23. Cautionery is also judicial, as in a suspension. It is sufficient to loose the cautioner, that when he became bound, the suspender had good reason to suspend, e. g. if the charger had at that period no title, or had not then performed his part, though the sums of suspension should be afterwards taken off. In all maritime causes, where the parties are frequently foreigners, the defender must give caution *fidejusfio* et *judicatum solvi:* Such cautioner gets free by the death of the defender before sentence;
sentence; but he continues bound, though the cause
should be carried from the admiral to the court of secession.
This sort of caution is only to be exacted in causes strictly
maritime.

24. It happens frequently, that a creditor takes two
or more obligants bound to him, all as principal debtors,
without subjunction. Where they are so bound, for the
performance of facts that are in themselves indivisible,
they are liable each for the whole, or singuli in solidum.
But, if the obligation be for a sum of money, they are
only liable pro rata; unless 1. Where they are in
express words bound conjunctly and severally; or 2. In
the case of bills or promissory notes. One of several ob-
ligants of this fort, who pays the whole debt, or fulfills
the obligation, is intitled to a proportional relief against
the rest; in such manner, that the loss must, in every case,
fall equally upon all the solvant obligants.

25. Obligations for sums of money are frequently ac-
companied with an obligation for the annual rent or in-
terest thereof. Interest (in juris) is the profit due, by the
developer of a sum of money, to the creditor, for the use
of it. The canon law considered the taking of interest as
unlawful: the law of Moses allowed it to be exacted
from strangers; and all the reformed nations of Europe
have found it necessary, after the example of the Romans,
to authorize it at certain rates fixed by statute. Soon aft
the reformation, our legal interest was fixed at the
rate of ten per cent. per annum; from which time, it has
c. 16. it was brought to five per cent. and has continued
at that rate ever since.

26. Interest is due, either by law, or by pactum. It
is due by law, either from the force of statute, under
which may be included acts of secession, or from the na-
ture of the transaction. Bills of exchange, and inland
bills, though they should not be protested, carry interest
from their date in case of non acceptance; or from the
day of their falling due, in case of acceptance and non pay-
ment. Where a bill is accepted, which bears no term of
payment, or which is payable on demand, no interest is
due till demand be made of the sum. The legal voucher
of which is a notorial protest. Interest is due by a debtor
after denunciation, for all the sums contained in the di-
gress, even for that part which is made up of interest.
Some paid by cautioners on distress, carry interest, not
only as to the principal sum in the obligation, but as to
the interest paid by the cautioner. Names named by
the court of secession are liable for interest by a special act
of secession; see Tit. xix. 10.

27. It arises ex lege, or from the nature of the tran-
action, that a purchaser in a sale is liable in interest for
the price of the lands bought from the term of his entry,
though the price should be arrested in his hands, or to
the seller should not be able to deliver to him a sufficient
proviso or title to the lands; for no purchaser can in e-
quity enjoy the fruits of the lands, while at the same time
he retains the interest of the price; But lawful configna-
tion of the price made by a purchaser, upon the refusal of
the perfons having right to receive it, a propos the currency
of interest. Where one intermeddles with money be-
longing to another which carries interest, he ought to re-

28. Interest is due by express pactum, where there is
a clause in a bond or obligation, by which money is made
to carry interest. An obligation is not lawful, where it
is agreed on, that the yearly interest of the sum lent, if
it should not be paid punctually as it falls due, shall be
accumulated into a principal sum bearing interest; but an
obligation may be lawfully granted, not only for the sum
truly lent, but for the interest to the day at which the
obligation is made payable, whereby the intermediate
interest is accumulated into a principal sum from the term
of payment. Interest may be also due by implied pactum:
Thus, where interest upon a debt is by a letter promiss
for time paid, such promise implies a pactum for interest
as long as the debt remains unpaid; thus also, the use of
payment of interest promises a pactum, and when interest
is expressed for one term, it is presumed to be bargained
for till payment.

29. The subject matter of all obligations confults ei-
ther of things, or of facts. Things exempted from com-
merce cannot be the subject of obligation. See Tit. viii.
2. et seq. One cannot be obliged to the performance of
a fact naturally impossible; nor of a fact in itself immoral,
but for that is also in the judgment of law impossible. Since
impossible obligations are null, no penalty or damage can
be incurred for non-performance; but it is otherwise, if
the fact be in itself possible, though not in the debtor's
power; in which case the rule obtains, locum faciit in-
praefabilis facit damnum et interesse.

30. An obligation, to which a condition is adjo-
cted, either naturally or morally impossible, is in the general
case null; for the parties are presumed not to have been
serious. But such obligation is valid, and the condition
thereof held pro non scripta, 1. In testaments; 2. In o-
bligations, to the performance of which the grantor lies
under a natural tie, as in bonds of provision to a child.
Where an obligation is granted under a condition, lawful
but unfavourable, e. g. that the creditor shall not marry
without the consent of certain friends, no more weight
is given to the condition than the judge thinks reasonable.
A condition, which is in some degree in the power of the
creditor himself, is held as fulfilled, if he has done all he
could to fulfil it. Implement or performance cannot be
demanded in a mutual contract, by that party who himself
decides, or cannot fulfil the counterpart.

31. Donation, so long as the subject is not delivered
to the donee, may be justly ranked among obligations;
and it is that obligation which arises from the mere good
will and liberality of the grantor. Donations imply no
warrandice, but from the future acts of the donor.
They are hardly revocable by our law for ingratitude,
though it should be of the poorest kind: Those betwixt
man and wife are revocable by the donor, even after
the death of the donee; but remunerator grants, not be-
ing truly donations, cannot be so revoked. That special
sort of donation, which is constituted verbally, is called a
promiss. The Roman law intitled all donors to the be-

Vol. II. No. 65. 2°

vescium
OBLIGATIONS may be dissolved by performance or implement, content, compensation, novation, and confusion. 1. By specific performance: Thus, an obligation for a sum of money is extinguished by payment. The creditor is not obliged to accept of payment by parts, unless where the sum is payable by different divisions. If a debtor in two or more separate bonds to the same creditor, made an indefinite payment, without ascribing it, at the time, to any one of the obligations, the payment is applied, 1. To interest, or to sums not bearing interest. 2. To the sums that are least secured, if the debtor thereby incurs no rigorous penalty. But, 3. If this application be penal on the debtor, c. g. by suffering the legal of an adjudication to expire, the payment will be so applied as to save the debtor from that forfeiture. Where one of the debts is secured by a caution, the other not, the application is to be so made, ceteris paribus, that both creditor and cautioner may have equal justice done to them.

2. Payment made by the debtor upon a mistake in fact, to one whom he believed, upon probable grounds, to have the right of receiving payment, extinguishes the obligation. But payment made to one, to whom the law denies the power of receiving it, has not this effect; as if a debtor, feized by letters of citation, should make payment to the messenger; for ignorancia juris neminem excusat. In all debts, the debtor, if he be not interpellled, may safely pay before the term, except in tacks, duties or feu-duties; and the payment whereof, before the terms at which they are made payable, is confirmed to be collusive, in a question with a creditor of the landlord or superior. Payment is in dubio presumed, by the voucher of the debt being in the hands of the debtor; chirographum, apud debitorem repertum, presumitur solutum.

3. Obligations are extinguished by the consent of the creditor, who, without full implement, or even any implement, may renounce the right constituted in his own favour. Though a discharge or acquittance, granted by one whom the debtor bona fide took for the creditor, but who was not, extinguishes the obligation, if the satisfaction made by the debtor was real; yet where it is imaginary, the discharge will not screen him from paying to the true creditor the debt that he had made no prior satisfaction for. In all debts which are constituted by writing, the extinction, whether it be by specific performance, or bare content, must be proved, either by the oath of the creditor, or by a discharge in writing; and the same solemnities which law requires in the obligation, are necessary in the discharge: But, where payment is made, not by the creditor himself, but by the creditor's intromission with the rents of the debtor's estate, or by delivery to him of goods in name of the debtor, such delivery or intromission, being falsi, may be proved by witnesses, though the debt should have been not only constituted by writing, but made real on the debtor's lands by adjudication.

4. A discharge, though it should be general, of all that the grantor can demand, extends not to debts of an uncommon kind, which are not presumed to have been under the grantor's eye. This doctrine applies also to general assignations. In annual payments, as of rents, feu-duties, interest, &c. three consecutive discharges by the creditor, of the yearly or termly duties, presume the payment of all preceedings. Two discharges by the ancestor, and the third by the heir, do not infer this presumption, if the heir was ignorant of the ancestor's discharges. And discharges by an administrator, as a factor, tutor, &c. presume only the payment of all preceding duties incurred during his administration. This presumption arises from repeating the discharges thrice successively; and fo does not hold in the case of two discharges, though they should include the duties of three or more terms.

5. Where the same person is both creditor and debtor to another, the mutual obligations, if they are for equal sums, are extinguished by compensation; if for unequal, still the lesser obligation is extinguished, and the greater diminished, as far as the concourse of debt and credit goes. To found compensation, 1. Each of the parties must be debtor and creditor at the same time. 2. Each
of them must be debtor and creditor in his own right.

3. The mutual debts must be of the same quality: Hence, a sum of money cannot be compensated with a quantity of corns; because, till the prices are fixed, at which the corns are to be converted into money, the two debts are incommerurable. Lastly, compensation cannot be admitted, where the mutual debts are not clearly ascertained, either by a written obligation, the sentence of a judge, or the oath of the party. Where this requires but a short discussion, sentence for the purifier is delayed for some time, ex aequitate, that the defendant may make good his ground of compensation. Where a debt for fungibles is ascertained in money, by the sentence of a judge, the compensation can have no effect farther back than the liquidation, because, before sentence, the debts were incommerurable: But where a debt for a sum of money is, in the course of a suit, constituted by the oath of the debtor, the compensation, after it is admitted by the judge, operates retro, in so far as concerns the currency of interest, to the time that, by the parties acknowledgment, the debt became due; for, in this case, the debtor's oath is not what creates the debt, or makes it liquid; it only declares that such a liquid sum was truly due before. Compensation cannot be offered after decree, either by way of suspension or reduction; unless it has been formerly pleaded, and unjustly repelled. Decrees in absence are excepted.

6. The right of retention, which bears a near resemblance to compensation, is chiefly competent, where the mutual debts, not being liquid, cannot be the ground of compensation; and it is sometimes admitted ex aequitate, in liquid debts, where compensation is excluded by statute: Thus, though compensation cannot be pleaded after decree, either against a creditor or his assignee; yet, if the original creditor should become bankrupt, the debtor, even after decree, may retain against the assignee, till he gives security for satisfying the debtor's claim against the cedent. This right is frequently founded in the expense disbursed or work employed on the subject retained, and so arises from the mutual obligations incumbent on the parties. But retention may be sustained, though the debt due to him who claims it does not arise from the nature of the obligation by which he is debtor: Thus, a factor on a land estate may retain the sums levied by him in consequence of his factory, not only till he be paid of the disbursements made on occasion of such estate, but also till he be discharged from the separate engagements he may have entered into on his constituent's account.

7. Obligations are dissolved by novation, whereby one obligation is changed into another, without changing either the debtor or creditor. The first obligation being thereby extinguished, the cautioners in it are released, and all its consequences discharged; so that the debtor remains bound only by the last. As a creditor to whom a right is once constituted, ought not to lose it by implication, novation is not easily presumed, and the new obligation is continued to be merely corroborative of the old; but, where the second obligation expressely bears to be in satisfaction of the first, these words must necessarily be explained into novation. Where the creditor accepts of a new debtor, in place of the former who is discharged, this method of extinction is called delegation.

8. Obligations are extinguished confused, where the debt and credit meet in the same person, either by succession or singular title, e. g. when the debtor succeeds to the creditor, or the creditor to the debtor, or a stranger to both, for one cannot be debtor to himself. If the succession, from which the confusion arises, happens afterwards to be divided, so as the debtor and creditor come again to be different persons; the confusion does not produce an extinction, but only a temporary suspension of the debt.

Tit. 24. Of Assignations.

Heritable rights, when they are clothed with inheritance, are transmitted by disposition, which is a writing containing procuratory of resignation and precept of seisin; but those which either require no seisin, or on which seisin has actually followed, are transmissible by simple assignation. He who grants the assignation, is called the cedent; and he who receives it, the assignee or cessionary: If the assignee conveys his right to a third person, it is called a translation; and if he assigns it back to the cedent, a retrocession. Certain rights are, from the uses to which they are defined, incapable of transmission, as alimentary rights: Others cannot be assigned by the person involved in them, without special powers given to him, as tacks, reversions: The transmission of a third fort, is not presumed to be intended, without an express conveyance; as of paraphernal goods, which are so proper to the wife, that a general assignation by her to her husband, or all that did or should belong to her at her decease, does not comprehend them. A litterent-right is, by its nature, incapable of a proper transmission; but its profits may be assigned, while it subsists.

2. Assignations must only be delivered to the assignee, but intimating by him to the debtor. Intimations are considered as so necessary for completing the conveyance, that in a competition between two assignations, the last, if first intimated, is preferred.

3. Though, regularly, intimation to the debtor is made by an instrument, taken in the hands of a notary, by the assignee or his procurator; yet the law admits equipollencies, where the notice of the assignation given to the debtor is equally strong. Thus, a charge upon letters of horning at the assignee's instance, or a suit brought by him against the debtor, supplies the want of intimation; these being judicial acts, which expose the conveyance to the eyes both of the judge and of the debtor; or the debtor's promise of payment by writing to the assignee, because that is in effect corroborating of the original debt. The assignee's possession of the right, by entering into payment of the rents or interest, is also equal to an intimation; for it imports, not only notice to the debtor, but his actual compliance: But the debtor's private knowledge of the assignation is not sustained as intimation.

4. Certain conveyances need no intimation. 1. Indorations of bills of exchange: for these are not to be fet-tered with forms, introduced by the laws of particular states. 2. Bank-notes are fully conveyed by the bare delivery.
delivery of them; for as they are payable to the bearer, their property must pass with their possession. 3. An adjudication, which is a judicial conveyance, and marriage, which is a legal one, carry the full right of the subjects thereby conveyed, without intimation: nevertheless, as there is nothing in these conveyances which can of themselves put the debtor in malafide, he is therefore in tutu dication, which is a judicial conveyance, and marriage, their property must pass with their possession. 3. Adjudication, till the marriage or adjudication be notified to him. Assignments of moveable subjects, though they be intimated, if they are made retenta possessione, (the cedent retaining the possession), cannot hurt the cedent's creditors; for such rights are presumed, in all questions with creditors, to be collusive, and granted in trust for the cedent himself.

5. An assignment carries to the assignee the whole right of the subject conveyed, as it was in the cedent; and consequently, he may use diligence, either in his cedent's name while he is alive, or in his own.

6. After an assignment is intimated, the debtor cannot prove payment, or compensation, by the oath of the cedent, who has no longer any interest in the debt; unless the matter has been made litigious by an action commenced prior to the intimation: But the debtor may refer to the oath of the assignee, who is in the right of the debt, that the assignment was gratuitous, or in trust for the cedent; either of which being proved, the oath of the cedent will affect the assignee. If the assignment be in part onerous, and in part gratuitous, the cedent's oath is good against the assignee, only in so far as his right is gratuitous. All defences competent against the original creditor in a moveable debt, which can be proved otherwise than by his oath, continue relevant against even an onerous assignee; whose right can be no better than that of his author, and must therefore remain affected with all the burdens which attended it in the author's person.

Tit. 25. Of Arrestments and Pounding.

The diligences, whereby a creditor may affect his debtor's moveable subjects, are arrestment and pounding. By arrestment is sometimes meant the securing of a criminal's person till trial; but as it is understood in the rubric of this title, it is the order of a judge, by which he who is debtor in a moveable obligation to the arrester's debtor, is prohibited to make payment or delivery till the debt due to the arrester be paid or secured. The arrester's debtor is usually called the common debtor; because, where there are two or more competing creditors, he is debtor to all of them. The person in whose hands the diligence is used, is styled the arrester.

2. Arrestment may be laid on, by the authority either of the supreme court, or of an inferior judge. In the first case, it proceeds either upon special letters of arrestment, or on a warrant contained in letters of horning; and it must be executed by a messenger. The warrants granted by inferior judges are called precepts of arrestment, and they are executed by the officer proper to the court. Where the debtor to the common debtor is a pupil, arrestment is properly used in the hands of the tutor, as the pupil's administrator: This doctrine may perhaps extend to other general administrators, as commissioner, &c. But arrestment, used in the hands of a factor or steward, cannot found an action of forthcoming without calling the confittuent. Where the debtor to the common debtor is a corporation, arrestment must be used in the hands of the directors or treasurer, who represent the whole body. Arrestment, when it is used in the hands of the debtor himself, is inept; for that diligence is intended only as a restraint upon third parties.

3. All debts, in which one is personally bound, though they should be heritably secured, are grounds upon which the creditor may arrest the moveable estate belonging to his debtor. Arrestment may proceed on a debt, the term of payment whereof is not yet come, in case the debtor be vergent ad inopiam. If a debt be not yet constituted by decree or registration, the creditor may sue and execute a summons against his debtor for payment, on which pending action arrestment may be used, in the same manner as inhibition, which is called arrestment upon a dependent. If one's ground of credit be for the performance of a fact, or if his depending process be merely declaratory, without a conclusion of payment or delivery, such claims are not admitted to be sufficient grounds for arrestment.

4. Moveable debts are the proper subject of arrestment; under which are comprehended conditional debts, and even depending claims. For lessening the expense of diligence to creditors, all bonds which have not been made properly heritable by seisin are declared arrestable. But this does not extend to adjudications, wadlets, or other personal rights of lands, which are not properly debts. Certain moveable debts are not arrestable. 1. Debts due by bill, which pass from hand to hand as bags of money. 2. Future debts; for though inhibition extends to adquirenda as well as adquifita, yet arrestment is limited, by its warrant, to the debt due at the time of serving it against the arrester. Hence, an arrestment of rents or intereft carries only those that have already either fallen due, or at least become current. Claims, depending on the issue of a suit, are not considered as future debts; for the sentence, when pronounced, has a retrospective to the period at which the claim was first founded. The like doctrine holds in conditional debts. 3. Alimentary debts are not arrestable; for these are granted on personal considerations, and are not communicable to creditors; but the past intereft due upon such debt may be arrested by the person who has furnished the alimony. One cannot secure his own effects to himself for his maintenance, fo as they shall not be affectable by his creditors. Salaries annexed to offices granted by the king, and particularly those granted to the judges of the Seffion, and the fees ofervants, are considered as alimentary funds; but the surplus fee, over and above what is necessarry for the servant's personal uses, may be arrested.

5. If, in contempt of the arrestment, the arrester shall make payment of the sum, or deliver the goods arrested, to the common debtor, he is not only liable criminally for breach of arrestment, but he must pay the debt again to the arrester. Arrestment is not merely prohibitory, as inhibitions are; but is a step of diligence which founds the user in a subsequent action, whereby the property of the
the subject arrested may be adjudged to him: It therefore does not, by our later practice, fall by the death of the arrester, but continues to subsist, as a foundation for an action of forthcoming against his heir, while the subject arrested remains in medio. Far less is arrestment lost, either by the death of the arrester, or of the common debtor.

6. Where arrestment proceeds on a depending action, it may be loosed by the common debtor’s giving security to the arrester for his debt, in the event it shall be found due. Arrestment founded on decrees, or on registred obligations, which in the judgment of law are decrees, cannot be loosed, but upon payment or configuration; except,

1. Where the term of payment of the debt is not yet come, or the condition has not yet exfiltr. 2. Where the arrestment has proceeded on a registred contract, in which the debts or mutual obligations are not liquid. 3. Where the decree is suspended, or turned into a libel; for, till the suspension be discharged, or the pending action concluded, it cannot be known whether any debt be truly due. A loosing takes off the nexus, which had been laid on the subject arrested; so that the arrester may thereafter pay safely to his creditor, and the cautioner is substituted in place of the arrestment, for the arrester’s security: Yet the arrester may be further intitled to the subject arrested while the subject continues with the arrester, pursues him in a forthcoming, notwithstanding the loosing.

7. Arrestment is only an inchoated or begun diligence; to perfect it, there must be an action brought by the arrester against the arresee, to make the debt or subject arrested forthcoming. In this action, the common debtor must be called for his interdict, that he may have an opportunity of contesting to the lawfulness or extent of the debt, on which the diligence proceeded. Before a forthcoming can be pursued, the debt due by the common debtor to the arrester, must be liquidated; for the arrester can be further intitled to the subject arrested than to the extent of the debt due to him by the common debtor. Where the subject arrested is a sum of money, it is, by the decree of forthcoming, directed to be paid to the purifier towards satisfying his debt; where goods are arrested, the judge ordains them to be exposed sale, and the price to be delivered to the purifier. So that in either case, decrees of forthcoming are judicial assignations to the arrester of the subject arrested.

8. In all competitions, regard is had to the dates, not of the grounds of debt, but of the diligences proceeding upon them. In the competition of arrestments, the preference is governed by their dates, according to the priority even of hours, where it appears with any certainty which is the first. But, as arrestment is but a begun diligence, therefore if a prior arrester shall neglect to insist in an action of forthcoming for such a time as may be reasonably construed into a defeition of his begun diligence, he looses his preference. But, as dereliction of diligence is not cally presumed, the distance of above two years, between the first arrestment and the decree of forthcoming, was found not to make such a mora as to intitle the posterior arrester to a preference. This rule of preference, according to the dates of the several arrestments, holds, by our present practice, whether they have proceeded on a decree, or on a dependence; on debts not yet payable, or on debts already payable; provided the pendency shall have been closed, or the debt have become payable, before the issue of the competition.

9. In the competition of arrestments with assignations, an assignation by the common debtor, intimated before arrestment, is preferable to the arrestment. If the assignation is granted before arrestment, but not intimated till after it, the arrester is preferred.

10. Poinding is that diligence affecting moveable subjects, by which their property is carried directly to the creditor. No poinding can proceed till a charge be given to the debtor to pay or perform, and the days there of be expired, except poindings against vassals for feu-duties, and poindings against tenants for rent, proceeding upon the landlord’s own decree; in which the ancient custom of poinding without a previous charge continues. A debtor’s goods may be poind by one creditor, though they have been arrested before by another; for arrestment being but an imperfect diligence, leaves the right of the subject still in the debtor, and so cannot hinder any creditor from using a more perfect diligence, which has the effect of carrying the property directly to himself.

11. No cattle pertaining to the plough, nor instruments of tillage, can be poind in the time of labouring or tilling the ground, unless where the debtor has no other goods. By labouring time is understood, that time, in which that tenant, whose goods are to be poind, is ploughing, though he should have been earlier or later than his neighbours; but summer-fallowing does not fall under this rule.

12. In the execution of poinding, the debtor’s goods must be apprized, first on the ground of the lands where they are laid hold on, and a second time at the market-crofts of the jurisdiction, by the stated apprizers thereof; or, if there are none, by persons named by the messenger or other officer employed in the diligence. Next, the messenger must, after public intimation by three oyeles, declare the value of the goods according to the second apprization, and require the debtor to make payment of the debt, including interest and expenses. If payment shall be offered to the creditor, or in his absence to his lawful attorney; or if, in case of refusal by them, confirmation of the debt shall be made in the hands of the judge ordinary or his clerk, the goods must be left with the debtor; if not, the messenger ought to adjudge and deliver them over, at the apprized value, to the use of the diligence towards his payment: And the debtor is intitled to a copy of the warrant and executions, as a voucher that the debt is discharged in whole or in part by the goods poinded.

13. Minifters may poind for their stipends, upon one apprization on the ground of the lands; and landlords were always in use to poind for, for their rents. Apprization of the goods at the market-crofts of the next royal borough, or even of the next head-borough of flyearthy or regality, though these jurisdictions be abolished, is declared as sufficient as if they were carried to the head-borough of the shire. Poinding, whether it be considered as a sentence, or as the execution of a sentence, must be
proceeded in between fun-rising and fun-setting; or at
least it must be finisht before the going off of day-
light. The powers of the officer employed in the execu-
tion of pointings, are not clearly defined by custom, in
the case of a third party claiming the property of the goods
to be pointed. This is certain, that he may take the
oath of the claimant, upon the verity of his claim; and
if from thence it shall appear that the claimant’s title is
collusive, he ought to proceed in the diligence; but, if
there remains the least doubt, his safest course is to deliver
the goods to the claimant, and to express in his execution
the reasons why pointing did not proceed.

14. Any person who takes a pointing *via falsi*, on
groundless pretences, is liable, both criminally, in the
pains of deforcement, (see Tit xxxiii. 15.) and civilly,
in the value of the goods which might have been pointed
by the creditor.

Prescription, which is a method, both of esta-
bling and of extinguishing property, is either positive
or negative. Positive prescription is generally defined,
as the Roman *usucaupio*, the acquisition of property (it
should rather be, when applied to our law, the securing it
against all further challenge) by the possessor’s continuing
his possession for the time which law has declared suffi-
cient for that purpose: Negative, is the loss or amissa-
ion of a right, by neglecting to follow it forth, or use it, during
the whole time limited by law. The doctrine of prescription,
which is, by some writers, condemned as contrary to jus-
tice, has been introduced, that the claims of negli-
gent creditors might not sullbut for ever, that property
might be at last fixed, and forgeries discouraged, which
the difficulty of detecting must have made exceeding fre-
quently, if no length of time had limited the legal effect
of writings.

2. Positive prescription was first introduced into our
law by 1617. c. 12. which enacts, that whoever shall have
possessed his lands, annuities, or other heritages, peace-
ably, in virtue of infestments, for forty years continually
after their dates, shall not thereafter be dispossessed in his
right by any person pretending a better title. Under he-
ritages are comprehended every right that is *fundo an-
nexum*, and capable of continual possession. Continued
possession, if proved as far back as the memory of man,
prefumes possession upwards to the date of the infestments.
The whole course of possession must by the act be found-
ed on seifins, and consequently no part thereof on the
bare right of apparency; but forty years possession, with-
out seifins, is sufficient in the prescription of such heritable
rights as do not require seifin, but only a sufficient title of property, the possessor is secured.

4. The negative prescription of obligations, by the
lapse of forty years, was introduced into our law long
before the positive, by 1469, c. 29—1474, c. 55. This
prescription is now amplified by the foreaid act 1617,
which has extended it to all actions competent upon heri-
table bonds, reversions, and others whatsoever; unless
where the reversions are either incorporated in the body
of the wadset-right, or regisfed in the register of rever-
sions; And reversions fo incorporated, or registred, are
not only exempted from the negative prescription, but
they are an effectual bar against any person from pleading
the positive.

5. A shorter negative prescription is introduced by fla-
tute, in certain rights and debts. Actions of spuulzie,
ejection, and others of that nature, must be pursued
within three years after the commission of the fact on
which the action is founded. As in spuulzes and ejections,
the purfuer was intitled, in odium of violence, to a proof
by his own oath in *litem*, and to the violent profits a-
against the defender, the statute meant only to limit thefe
special privileges by a three years prescription, without
cutting off the right of action, where the claim is restric-
ted to simple restitution. Under the general words, and
others of that nature, are comprehended all actions
where the purfuer is admitted to prove his libel by his
own oath in *litem*.

6. Servants fees, house-rents, mens ordinaries, (*i.e.
mony due for board,* ) and merchants accounts, fall un-
der the triennial prescription, by 1579, c. 83. There
is also a general clause subjoined to this statute, of *other
the like debts*, which includes alimentary debts, wages
due to workmen, and accounts due to writers, agents,
or procurators. These debts may by this act, be proved
after the three years, either by the writing or oath of the
debtor; so that they prescribe only as to the mean of
proof by witnesses; but after the three years, it beho
the creditor to refer to the debtor’s oath, not only the
constitution, but the subsistence of the debt. In the pre-
scription of house-rents, servants fees, and alimony, each
term's
term's rent, fee, or alimony, runs a separate course of prescription; so that in an action for these, the claim will be reftrained to the arrears incurred within the three years immediately before the citation: But, in accounts, prescription does not begin till the last article; for a single article cannot be called an account. Actions of removing must also be pursued within three years after the warning. Reductions of erroneous returns, prescribe, if not pursued within twenty years.

7. Ministers' stipends and multures prescribe in five years after they are due; and arrears of rent, five years after the tenant's removing from the lands. As the prescription of mails and duties was introduced in favour of poor tenants, that they might not suffer by neglecting to preserve their discharges, a proprietor of lands subject to a tenant, who had obtained a lease of all the tenant's lands from the landlord, is not intitled to plead it, nor a feaman of one's whole estate, who had by the lease a power of removing tenants. Bargains concerning moveables, or sums of money which are proveable by witnesses, prescribe in five years after the bargain. Under these are included sales, locations, and all other confessional contracts, to the constitution of which writing is not necessary. But all the above mentioned debts, after the five years, be proved, either by the oath or the writing of the debtor; of which above, § 6. A quinquennial prescription is established in arrearsments, whether on decrees or depending actions: The first prescribe in five years after using the arrearsment, and the last in five years after sentence is pronounced on the depending action.

8. No person binding for or with another, either as cautioner or co-principal, in a bond or contract for a sum of money, continues bound after seven years from the date of the bond, provided he has either a clause of relief in the bond, or a separate bond of relief, intimated to the creditor, at his receiving the bond. But all diligence used within the seven years against the cautioner, shall stand good. As this is a public law, intended to prevent the bad consequences of rash engagements, its benefit cannot, before the lapse of the seven years, be removed by the cautioner. As it is correlative, it is strictly interpreted: Thus bonds bearing a mutual clause of relief pro rata, fall not under it; nor bonds of corroboration, nor obligations, where the condition is not purifed, or the term of payment not come within the seven years; because no diligence can be used on these. The statute excludes all cautions for the faithful discharge of offices; these not being obligations in a bond or contract for sums of money. And practice has denied the benefit of it to all judicial cautioners, as cautioners in a suspension. Actions of count and reckoning, competent either to minors against their tutors or curators, or vice versa, prescribe in ten years after the majority or death of the minor.

9. Holograph bonds, missive letters, and books of account, not attested by witnesses, prescribe in twenty years, unless the creditor shall thereafter prove the verity of the subscription by the debtor's oath. It is therefore sufficient to save from the effect of this prescription, that the constitution of the debt be proved by the party's oath, after the twenty years; whereas in stipends, merchants accounts, &c. not only must be proved by writing or the debtor's oath, after the term of prescription. Some lawyers extend this prescription of holograph writings to all obligations for sums not exceeding £100 Scots, which are not attested by witnesses; because though these are in practice fulfilled, yet they ought not to have the same duration with deeds attested by witnesses. Though in the short prescriptions of debts, the right of action is forever lost, if not exercised within the time limited; yet where action was brought on any of those debts, before the prescription was run, it subsisted, like any other right, for forty years. As this defeated the purpose of the acts establishing these prescriptions, all proceedings upon warnings, spurries, ejections, or arrears; or for payment of the debts contained in act 1669, c. 9. are by the said act, joined with 1685, c. 14. declared to prescribe in five years, if not wakened within that time; see Tit. 30.

10. Certain obligations are lost by the lapse of less than forty years, without the aid of statute, where the nature of the obligation, and the circumstances of parties, justify it: Thus, bills which are not intended for lating securities, produce no action, where the creditor has been long silent, unless the subsistence of the debt be proved by the debtor's oath; but the present time is not fixed by practice. Thus also, a receipt for bills granted by a writer to his employer, not instilled upon for twenty three years, was found not productive of an action. The prescriptions of the restitution of minors, of the benefit of inventory, &c. are explained in their proper places.

11. In the positive prescription, as established by the act 1617, the continued possession for forty years, proceeding upon a title of property not chargeable with falseness, secures the possessor against all other grounds of challenge, and so presumes bona fides, presumptions juris et de jure. In the long negative prescription, bona fides in the debtor is not required: The creditor's neglecting to instil for so long a time, is construed as an abandoning of his debt, and so is equivalent to a discharge. Hence, though the subsistence of the debt should be referred to the debtor's own oath, after the forty years, he is not liable.

12. Prescription runs de momento in momentum: The whole time defined by law must be completed. Before a right can be either acquired or lost by it; so that interruption, made on the last day of the fortieth year, breaks its course. The positive prescription runs against the Sovereign himself, even as to his annexed property, but it is generally thought he cannot suffer by the negative: He is secured against the negligence of his officers, in the management of proceedings by express statute, 1660, c. 14. The negative, as well as the positive prescription, runs against the church, though churchmen have but a temporary interest in their benefices. But because the rights of benefices to their stipends are liable to accidents, through the frequent change of incumbents, thirteen years possession does, by a rule of the Roman chancery which we have adopted, found a presumptive title in the beneficiary: But this is not properly prescription; for if by titles recovered, perhaps out of the incumbent's own hands,
hands, it shall appear that he has possessed tithes, or other subjects, to a greater extent than he ought, his possession will be restricted accordingly. This right must not be confounded with that established in favour of churchmen, which is confined to church lands and rents, and constitutes a proper prescription, upon a possession of thirty years.

13. The clause in the act 1617, saving minors from prescription, is extended to the positive, as well as to the negative prescription; but the exception of minority is not admitted in the case of hospitals for children, where there is a continual succession of minors, that being a casus insititus. Minors are expressly excepted in several of the short prescriptions, as 1579, c. 81.—1669, c. 9; but where law leaves them in the common case, they must be subject to the common rules.

14. Prescription does not run contra non valentem agentes, against one who is barred, by some legal incapacity, from pursuing; for in such case, neither negligence nor dereliction can be imputed to him. This rule is, by a favourable interpretation, extended to wives who ex reversione maritali forbear to pursue actions competent to them against their husbands. On the same ground, prescription runs only from the time that the debt or right could be sued upon. Thus, inquisition precedes only from the publication of the deed granted to the inhibitor's prejudice; and in the prescription of removings, the years are computed only from the term at which the defender is warned to remove. Neither can prescription run against persons who are already in possession, and so can gain nothing by a pursuit. Thus, where a person, who has two adjudications affecting the same lands, is in possession upon one of them, prescription cannot run against the other during such possession.

15. Certain rights are incapable of prescription: 1. Things that law has exempted from commerce. 2. Reserva facultatis, e.g. a faculty to change a subject with debts, to revoke, &c. cannot be lost by prescription, for debts may, by their nature, be exercised at any time: Hence, a proprietor's right of using any act of property on his own grounds, cannot be lost by the greatest length of time. 3. Exceptions competent to a person for eliding an action, cannot prescribe, unleas the exception is founded on a right productive of an action, e.g. compenfation; such right must be infilled on, within the years of prescription. 4. Obligations of yearly pensions or payments, though no demand has been made on them for forty years, do not suffer a total prescription, but still subsist as to the arrears fallen due within that period; because prescription cannot run against an obligation, till it be payable, and each year's pension or payment is considered as a separate debt.

16. No right can be lost non utendo by one, unleas the effect of that prescription be to establish it in another. Hence the rule arises, juris sanguinis non quam prescribitur. Hence also, a proprietor of land cannot lose his property by the negative prescription, unless he who objects it can himself plead the positive. On the same ground, a superior's right of feu-duties cannot be lost non utendo; because being inherent in the superiority, it is truly a right of lands that cannot suffer the negative prescription, except in favour of one who can plead the positive; which the valsal cannot do, being defult of a title. This rule applies also to parsonage tithes, which are an inherent burden upon all lands not specially exempted; and from which therefore the person liable cannot prescribe an immunity, by bare non-payment: But such vicarage tithes as are only due where they are established by usage, may be lost by prescription. In all these cases, though the radical right cannot suffer the negative prescription, the bygone duties, not demanded within the forty years, are lost to the proprietor, superior, or titular.

17. Prescription may be interrupted by any deed, whereby the proprietor or creditor uses his right or ground of debt. In all interruptions, notice must be given to the possessor of the subject, or the debtor, that the proprietor or creditor intends to sue upon his right. All writings whereby the debtor himself acknowledges the debt, and all processes for payment brought or diligences used against him upon his obligation, by harrassment, interdiction, &c. must be effectual to interrupt prescription.

18. Interruptions, by citation upon libelled summonses, where they are not used by a minor, prescribe, if not renewed every seven years: But where the appearance of parties, or any judicial act has followed thereupon, it is no longer a bare citation, but an action which subsists for forty years. Citations for interrupting the prescription of real rights must be given by messengers; and the summonses, on which such citations proceed, must pass the signet upon a bill, and be registered within sixty days after the execution, in a particular register appointed for that purpose: And where interruption of real rights is made in fact, an instrument must be taken upon it, and recorded in the said register; otherwise it can have no effect against singular successeurs.

19. Interruption has the effect to cut off the course of prescription, so that the person prescribing can avail himself of no part of the former time, but must begin a new course, commencing from the date of the interruption. Minority therefore is no proper interruption; for it neither breaks the course of prescription, nor is it a document or evidence taken by the minor on his right: It is a personal privilege competent to him, by which the operation of the prescription is indeed suspended during the years of minority, which are therefore discounted from it, but it continues to run after majority, and the years before and after the minority may be conjoined to complete it. The same doctrine applies to the privilege arising from one's incapacity to act.

20. Diligence used upon a debt, against any one of two or more co-obligants, preserves the debt itself, and so interrupts prescription against all of them; except in the special case of co-obligants, who are not affected by any diligence used against the principal debtor. In the same manner, a right of annualler, constituted upon two separate tenements, is preferred as to both from the negative prescription, by diligence used against either of them. But whether such diligence has also the effect to hinder the possessor of the other tenement by singular titles from the benefit of the positive prescription, may be doubted.
Tit. 27. Of Succession in heritable Rights.

SINGULAR successors are those who succeed to a person yet alive, in a special subject by singular titles; but succession, in its proper sense, is a method of transmitting rights from the dead to the living. Heritable rights descend by succession to the heir properly so called; moveable rights, to the executors, who are sometimes said to be heirs in moveables. Succession is either by special designation, which descends to those named by the proprietor himself; or legal, which devolves upon the persons whom the law marks out for successors, from a presumption, that the proprietor would have named them, had he made a designation. The first is in all cases preferred to the other, as presumption must yield to truth.

2. In the succession of heritage, the heirs at law are otherwise called heirs general, heirs whatsoever, or heirs of line; and they succeed by the right of blood, in the following order. First, descendents sons are preferred to daughters, and the eldest son to all the younger. Where there are daughters only, they succeed equally, and are called heirs-portioners. Falling immediate descendents, grand-children succeed; and in default of them, great-grandchildren; and so on in infinitum; preferring, as in the former case, males to females, and the eldest male to the younger.

3. Next after descendents, collaterals succeed; among whom the brothers german of the deceased have the first place. But as, in no case, the legal succession of heritage is, by the law of Scotland, divided into parts, unless where it descends to females; the immediate younger brother of the deceased excludes the eldest, according to the rule, heritage defends. Where the deceased is himself the youngest, the succession goes to the immediate elder brother, as being the least deviation from this rule.

If there are no brothers german, the sisters german succeed equally; then brothers consanguinean in the same order as brothers german; and failing them, their grand-child, consanguinean equally. Next, the father succeeds after him; his brothers and sisters, according to the rules already explained; then the grand-father; failing him, his brothers and sisters; and so upwards, as far back as propinquity can be proved. Though children succeed to their mother, a mother cannot to her child; nor is there any succession by our law through the mother of the deceased; in so much that one brother uterine, i.e. by the mother only, cannot succeed to another, even in that estate which flowed originally from their common mother.

4. In inheritance there is a right of representation, by which one succeeds, not from any title in himself, but in the place of, and as representing some of his deceased ascendants. Thus, where one leaves a younger son, and a grandchild by his eldest, the grandchild, though farther removed in degree from the deceased than his uncle, excludes him, as coming in place of his father the eldest son. Hence arises the distinction between succession in capita, where the division is made into as many equal parts as there are capita or heirs, which is the case of heirs portioners; and succession in stirpes, where the re-

moters heirs draw no more among them than the share belonging to their ascendent or stirpes, whom they represent; an example of which may be figured in the case of one who leaves behind him a daughter alive, and two grand-daughters by a daughter deceased. In which case the two grand-daughters would succeed equally to that half which would have belonged to their mother had she been alive.

5. In the succession of heirs portioners, indivisible rights, e.g. titles of dignity, fall to the eldest sister. A single right of superiority goes also to the eldest; for it hardly admits a division, and the condition of the vassal ought not to be made worse by multiplying superiors upon him. Where there are more such rights, the eldest may perhaps have her election of the best, but the younger sisters are entitled to a recom pense, in so far as the divisions are unequal; at least, where the superiorities yield a constant yearly rent. The principal seat of the family falls to the eldest, with the garden and orchard belonging to it, without recompense to the younger sisters; but all other houses are divided amongst them, together with the lands on which they are built, as parts and 1erminals of these lands.

6. Those heritable rights, to which the deceased did himself succeed as heir to his father or other ancestor, get sometimes the name of heritage in a strict sense, in opposition to the feuda nova, or feus of conquest, which he had acquired by singular titles, and which descend, not to his heir of line, but of conquest. This distinction obtains only, where two or more brothers or uncles, or their issue, are next in succession; in which case the immediate younger brother, as heir of line, succeeds to the proper heritage, because that descends; whereas the conquest descends to the immediate elder brother. It has no place in female succession, which the law divides equally among the heirs-portioners. Where the deceased was the younger brother, the immediate elder brother is heir both of line and of conquest. An estate, disposed by a father to his eldest son, is not conquest in the son's person, but heritage; because the son would have succeeded to it, though there had been no disposition. The heir of conquest succeeds to all rights affecting land, which require feisin to perfect them. But teinds go to the heir of line; because they are merely a burden on the fruits, not on the land. Tacks do not fall under conquest, because they are complete rights without feisin; nor personal bonds taken to heirs excluding executors.

7. The heir of line is entitled to the succession, not only of subjects properly heritable, but to that sort of moveables called heirship, which is the best of certain kinds. This doctrine has been probably introduced, that the heir might not have a house and estate to succeed to, quite dismembered by the executor. In that sort which goes by pairs or dozens, the best pair or dozen is the heirship. There is no heirship in fungibles, or things estimated by quantity, as grain, hay, current money, &c. To intitle an heir to this privilege, the deceased must have been either, 1. A Prelate; 2. A Baron, i.e. one who holds infief at his death in lands, though not erected into a barony; or even in a right of annuitant; Or, 3. A burgess; not an honorary one, but a trading burgess, of a royal borough, or at least one intituled to enter bur-
gefs, in the right of his ancieft. Neither the heir of conquest, nor of tailzie, has right to heirhip-moveables.

8. As to succession by definition, no proprietor can settle any heritable estate, in the proper form of a testament; not even bonds excluding executors, though these are not heritable ex sua natura: But, where a testament is in part drawn up in the style of a deed inter vivos, such part of it may contain a settlement of heritage, though executors should be named in the testamentary part.

The common method of settling the succession of heritage is by disposition, contract of marriage, or simple procuratory of resignation: And, though a disposition settling heritage should have neither precept nor procuratory, it founds an action against the heir of line to complete his titles to the estate; and thereafter divest himself in favour of the disponent. The appellation of tailzie, or entail, is chiefly used in the case of a land estate, which is settled heritable ex sua natura: But, where a testament is in conquest, nor of tailzie, has right to heirship-moveables. 

9. Titles to the estate; and thereafter divert himself in favour of the disponent. That it shall not be lawful to the heirs to contract debts on a long series of heirs, substituted one after another. The perfon first called in the tailzie, is the institute; the rest, the heirs of tailzie, or the substitutes.

9. Tailzies, when considered in relation to their several degrees of force, are either, 1. Simple definitions: 2. Tailzies with prohibitory clauses. 3. Tailzies with prohibitory, resolutive, and irritant clauses. That is a simple definition, where the persons called to the succession are substituted one after another, without any restraint laid on the exercise of their property. The heirs, therefore, succeeding to such estate, are absolute heirs, and consequently may alter the destination at pleasure.

10. In tailzies with clauses prohibitory, e.g. declaring that it shall not be lawful to the heirs to contract debts or alien the lands in prejudice of the succession, none of the heirs can alien gratuitously. But the members of entail may contract debts which will be effectual to the creditors, or may dispose of the estate for onerous causes. In both these forts, the maker himself may alter the tailzie; except, 1. Where it has been granted for an onerous cause, as in mutual tailzies; or, 2. Where the maker is expressly disabled, as well as the institute or the heirs.

11. Where a tailzie is guarded with irritant and resolutive clauses, the estate entailed cannot be carried off by the debt, or deed, of any of the heirs succeeding thereto, in prejudice of the substitutes. It was long doubted, whether such tailzies ought to be effectual, even where the superior's consent was adhibited; because they sunk the property of estates, and created a perpetuity of liferents. They were first explicitly authorized by 1685, c. 22. By this statute, the entail must be registered in a special register establishef for that purpose; and the irritant and resolutive clauses must be inserted, not only in the procuratories, precepts, and seifins, by which the tailzies are first constituted, but in all the after-conveyances thereof; otherwise they can have no force against singular susceptible. But a tailzie, even without these requisites, is effectual against the heir of the granter, or against the institute who accepts of it.

12. An heir of entail has full power over the entailed estate, except in so far as he is expressly fettered; and as entails are an unfavourable restraint upon property, and a frequent snare to trading people, they are juris: so that no prohibition or irritancies are to be inferred by implication.

13. An heir, who counteracts the directions of the tailzie, by aliening any part of the estate, charging it with debt, &c. is said to contravene. It is not the simple contracting of debt that infrers contravention; the lands entailed must be actually adjudged upon the debt contracted. An heir may, where he is not expressly barred, settle rational provisions on his wife and children, without incurring contravention.

14. When the heirs of the last person specially called in a tailzie come to succeed, the irritancies have no longer any person in favour of whom they can operate; and consequently, the fee, which was before tailzie, becomes simple and unlimited in the person of such heirs. The King may purchase lands within Scotland, notwithstanding the strictest entail; and where the lands are in the hands of minors or fatuous persons, his Majesty may purchase them from the curators or guardians. And heirs of entail may fall to their vallads the superiorities belonging to the entailed estate; but in all these cases, the price is to be settled in the same manner that the lands or superiorities sold were settled before the sale.

15. Rights, not only of land-estates, but of bonds, are sometimes granted to two or more persons in conjunct fee. Where a right is so granted to two strangers, without any special clause adjested to it, each of them has an equal interest in the fee, and the part of the deceased descends to his own heir. If the right be taken to the two jointly, and the longest liveth and their heirs, the several shares of the conjunct heirs are affectable by their creditors during their lives; but, on the death of any one of them, the survivor has the fee of the whole, in so far as the share of the predeceased remains free, after payment of his debts. Where the right is taken to the two in conjunct fee, and to the heirs of one of them, he to whose heirs the right is taken, is the only heir; the right of the other relieves into a simple liferent: Yet where a father takes a right to himself and his son jointly, and to the son's heirs, such right being gratuitous is not understood to strip the father of the fee, unless a contrary intention shall plainly appear from the tenor of the right.

16. Where a right is taken to a husband and wife, in conjunct fee and liferent, the husband, as the persona dignior, is the only heir: The wife's right resolves into a liferent, unless it be presumable, from special circumstances, that the fee was intended to be in the wife. Where a right of moveables is taken to husband and wife, the heirs of both succeed equally, according to the natural meaning of the words.

17. Heirs of provision are those who succeed to any subject, in virtue of a provision in the invenititure, or other deed of settlement. This appellation is given most commonly to heirs of a marriage. These are more favourably regarded than heirs by simple definition, who have only the hope of succession; for heirs of a marriage, because their provisions are constituted by an onerous contract, cannot be disappointed of them by any gratuitous deed of the father. Nevertheless, as their right is only a right of succession, which is not designed to restrain the father
father from granting onerous or rational deeds, he 
continues to have the full power of telling the subjeft, or 
charging it with debts, unless a proper right of credit be 
given to the heir by the marriage contract, e. g. if the 
father should oblige himself to infect the heir in the lands, 
or make payment of the sum provided against a day cer- 
tin, or when the child attains a certain age, &c. for 
such rights, when perfected by infefition, or secured by 
diligence, are effectual against all the posterior deeds of 
the father, even onerous

19. Though all provisions to children, by a marriage-
contract conceived in the ordinary form, being merely 
rights of succession, are postponed to every onerous 
debt of the grantor, even to those contracted posterior to the 
provisions; yet where a father executes a bond of provi-
tion to a child actually existing, whether such child be 
the heir of a marriage or not, a proper debt is thereby 
created, which, though it be without doubt gratuitious, 
is not only effectual against the father himself and his 
heirs, but is not reducible at the instance even of his 
prior onerous creditors, if he was solvent at the time of 
granting it. A father may, notwithstanding a first mar-
rriage-contract, fettle a jointure on a second wife, or pro-
vide the children of a second marriage; for such settle-
ments are deemed onerous; but where they are exorbit-
ant, they will be restricted to what is rational: And in 
all such settlements, where the provisions of the first mar-
rriage-contract are incroached upon, the heirs of that 
marriage have recourse against the father, in case he should 
afterwards acquire a separate estate, which may enable 
him to fulfil both obligations.

19. Where heritable rights are provided to the heirs 
of a marriage, they fall to the eldest son, for he is the 
heir at law in heritage. Where a sum of money is so 
provided, the word heir is applied to the subject of the 
provision, and so marks out the executor, who is the heir 
in moveables. When an heritable right is provided to 
the bairns (or issue) of a marriage, it is divided equally 
among the children, if no division be made by the father; 
for such division is cut off the exclusive right of the lega-
l heir. No provision granted to bairns, gives a special 
right of credit to any one child, as long as the father 
lives: The right is granted familiae; so that the whole 
mull indeed go to one or other of them; but the father 
haves a power inherent in him, to divide it among them, 
in such proportions as he thinks best; yet so as none 
of them may be entirely excluded, except in extraordinary 
cases.

20. A clause of return is that, by which a sum in a 
bond or other right, is, in a certain event, limited to 
return to the grantor himself, or his heirs. When a 
right is granted for onerous caufes, the creditor may de-
feat the clause of return, even gratuitously. But, where 
the sum in the right flows from the grantor, or where 
there is any other reasonable cause for the provision of 
return in his favour, the receiver cannot disappoint it gra-
uitously. Yet since heirs far, the sum may be either 
allotted by him for an onerous caufe; or affected by his creditors.

21. An heir is, in the judgment of law, eadem per-
fons cum defuncto, and so represents the deceased uni-
versally, not only in his rights, but in his debts: In the 
first view, he is said to be heir ultra vires in the second 
pasive. From this general rule are excepted, heirs sub-
stituted in a special bond, and even substituted in a dispo-
sition nominis honorum, to take effect at the grantor’s 
death; for such substitutes are considered as singular 
successors, and their right as an universal legacy, which 
does not suffer the legatee ultra vires.

22. Before an heir can have an active title to his an-
celor’s rights, he must be entered by service and return. 
He who is intitled to enter heir, is, before his actual en-
try, called apparent heir. The bare right of apparen-
ty carries certain privileges with it. An apparent heir may 
defend his ancestor’s titles against any third party who 
brings them under challenge. Tenants may safely pay 
him their rents; and after they have once acknowledged 
him by payment, he may compel them to continue it; 
and the rents not uplifted by the apparent heir belong to 
his executors, upon his death.

23. As an heir is, by his entry, subjected universally 
to his ancestor’s debts, apparent heirs have therefore a 
year (annus deliberandi) allowed to them from the 
ancestor’s decease, to deliberate whether they will enter 
or not; till the expiring of which, though they may be 
charged by creditors to enter, they cannot be sued in 
in any process founded upon such charge. Though de-
claratory actions, and others which contain no personal 
conclusion, may be pursued against the apparent heir, 
without a previous charge; action does not lie even upon 
these, within the year, if the heir cannot make the proper 
defences without incurring a passive title. But judicial 
valids, commenced against an ancestor, may be continued 
upon a citation of the heir, without waiving the year of 
deliberating. This annus deliberandi is computed, in 
the case of a posthumous heir, from the birth of such 
heir. An apparent heir, who by immixing with the es-
state of his ancestor, is as much subjected to his debts as 
if he had entered, can have no longer a right to deli-
berate whether he will enter or not.

24. All services proceed on briefs from the chancery, 
which are called briefs of inquest, and have been long 
known in Scotland. The judge, to whom the brief is 
directed, is required to try the matter by an inquest of 
fifteen sworn men. The inquest, if they find the claim 
verified, must declare the claimant heir to the decea-
fed. This annus deliberandi is computed, in the 
cafe of a posthumous heir, from the birth of such 
heir. An apparent heir, who by immixing with the es-
state of his ancestor, is as much subjected to his debts as 
if he had entered, can have no longer a right to deli-
berate whether he will enter or not.

25. The service of heirs is either general or special. 
A general service veils the heir in the right of all heri-
table subjects, which either do not require seisin, or 
which have not been perfected by seisin in the person of 
the ancestor. A special service, followed by seisin, veils 
the heir in the right of the special subjects in which the 
ancestor died intestate.

26. If an heir, doubtful whether the estate of his an-
celor be sufficient for clearing his debts, shall at any 
time within the annus deliberandi, exhibit upon oath a 
full inventory of all his ancestor’s heritable subjects, to the 
clerk of the shire where the lands lie; or, if there is no 
heritage requiring seisin, to the clerk of the shire where 
he died; and if, after the same is subscribed by the shel-
riff or sheriff depute, the clerk, and himself, and registered in the sheriff’s books, the extract thereof shall be registered within forty days after expiry of the annus du liberandi in the general register appointed for that purpose; his subsequent entry will subject him no farther than to the value of such inventory. If the inventory be given up and registered within the time prescribed, the heir may serve on it, even after the year.

27. Creditors are not obliged to acquiesce in the value of the estate given up by the heir; but, if they be real creditors, may bring the estate to a public sale, in order to discover its true value; since an estate is always worth what can be got for it. An heir by inventory, as he is, in effect, a trustee for the creditors, must account for that value to which the estate may have been improved since the death of the ancestor, and he must communicate to all the creditors the estate he has got in transcacing with any one of them.

28. Practice has introduced an anomalous sort of entry, without the interposition of an inquest, by the sole consent of the superior, who, if he be satisfied that the person applying to him is the next heir, grants him a precept (called of claire confat, from the first words of its recital), commanding his bailie to infeft him in the subjects that belonged to his ancestor. These precepts are, no doubt, effectual against the superior who grants them, and his heirs; and they may, when followed by feisin, affect a title of preemption: But as no person can be declared an heir by private authority, they cannot bar the true heir from entering after twenty years, as a legal entry would have done. Of the same nature is the entry by haip and staple, commonly used in burgage tenements of houses; by which the bailie, without calling an inquest, cognosces or declares a person heir, upon evidence brought before himself; and, at the same time, invests him in the subject, by the symbol of the haip and staple of the door. Charges given by creditors to apparent heirs to enter, stand in the place of an actual entry, so as to support the creditor’s diligence.

29. A general service cannot include a special one; since it has no relation to any special subject, and carries only that class of rights on which feisin has not proceeded; but a special service implies a general one of the same kind or character, and consequently carries even such rights as have not been perfected by feisin. Service is not required to establish the heir’s right in titles of honour, or offices of the highest dignity; for these descend jure fanginius.

30. An heir, by mixing with his ancestor’s estate without entry, subjects himself to his debts, as if he had entered; or, in our law-phrased, incurs a passive title. The only passive title by which an apparent heir becomes liable universally for all his ancestor’s debts, is gestio pro herede, or his behaving as none but an heir has right to do. Behaviour as heir is—inferred, from the apparent heir’s intention, after the death of the ancestor, with any part of the lands or other heritable subjects belonging to the deceased, to which he himself might have completed an active title by entry.

31. This passive title is excluded, if the heir’s intromission be by order of law; or if it be founded on fingu-
36. An apparent heir, who is cited by the ancestor’s creditor in a process for payment, if he offers any peremptory defence against the debt, incurs a passive title; for he can have no interest to object against it, but in the character of heir. In the same manner, the heir’s not renouncing upon a charge to enter heir, infers it: But the effect of both these is limited to the special debt pursued for, or charged upon. This passive title, which is inferred from the heir’s not renouncing, has no effect till decree passes against him; and even a renunciation offered after decree, if the decree be in abeyance, will intitle the heir to a suspension of all diligence against his person and estate, competent upon his ancestor’s debts.

37. By the principles of the feudal law, an heir, when he is to complete his titles by special service, must necessarily pass over his immediate ancestor; e. g. his father, if he was not infeste; and serve heir to that ancestor who was last vest and feized in the right, and in whose hereditas jucconi the right must remain, till a title be connected thereto from him. As this bore hard upon creditors, who might think themselves secure in contracting with a person whom they law for some time in the possession of an estate, and from thence conclude that it was legally vested in him; it is therefore provided, that every person, passing over his immediate ancestor who had been three years in possession, and serving heir to one more remote, shall be liable for the debts and deeds of the person interjected, to the value of the estate to which he is served. This being correetory of the feudal maxims, has been strictly interpreted, so as not to extend to the gratuitous deeds of the person interjected, nor to the estate where the interjected person was a naked heir, and possessed only civilly through the liberent.

38. Our law, from its jealousy of the weakness of mankind while under sickness, and of the importunity of friends on that occasion, has declared that all deeds affecting heritage, if they be granted by a person on deathbed, (i.e. after contracting that sickness which ends in death), to the damage of the heir, are ineffectual, except where the debts of the granter have laid him under a necessity to alien his lands. As this law of deathbed is founded solely in the privilege of the heir, deathbed-deeds, when confented to by the heir, are not reducible. The term properly opposed to death-bed is liege poufle, by which is understood a state of health; and it gets that name, because persons in health have the legitima poftelar, or lawful power of disposing of their property at pleasure.

39. The two extremes being proved, of the granter’s sicknefs immediately before signing, and of his death following it, though at the greatest distance of time, did, by our former law, found a presumption that the deed was granted on deathbed, which could not have been elided, but by a positive proof of the granter’s convalescence; but now the allegation of deathbed is also excluded, by his having lived fifty days after signing the deed. The legal evidence of convalescence is the granter’s having been, after the date of the deed, at kirk or market unsupported; for a proof of either will secure the deed from challenge. The going to kirk or market must be performed, when people are met together in the church or churchyard for any public meeting, civil or ecclesiastical, or in the market place at the time of public market. No other proof of convalescence is receivable, because at kirk and market there are always present unsuspected witnesses, which we can hardly be sure of in any other place.

40. The privilege of setting aside deeds ex capite let., is competent to all heirs, not to heirs of line only, but of conquest, taile, or provision; not only to the immediate, but to remoter heirs, as soon as the succession opens to them. But, where it is confented to or ratified by the immediate heir, it is secured against all challenge even from the remoter. Yet the immediate heir cannot, by any antecedent writing, renounce his right of reduction, and thereby give strength to deeds that may be afterwards granted in leito to his hurt; for no private renunciation can authorize a person to act contrary to a public law; and such renunciation is presumed to be executed through the fear of exheredation. If the heir should not use this privilege of reduction, his creditor may, by adjudication, transfer it to himself, or he may without adjudication, reduce the deed, libelling upon his interest as creditor to the heir: But the granter’s creditors have no right to this privilege, in regard that the law of death-bed was introduced, not in behalf of the granter himself, but of his heir.

41. The law of death-bed strikes against dispositions of every subject to which the heir would have succeeded, or from which he would have had any benefit, had it not been so disposed. Deathbed-deeds granted in consequence of a full or proper obligation in liege poufle, are not subject to reduction; but, where the antecedent obligation is merely natural, they are reducible. By stronger reason, the deceased cannot, by a deed merely voluntary, alter the nature of his estate on deathbed to the prejudice of his heir, so as from heritable to make it moveable; but if he should, in liege poufle, exclude his apparent heir, by an irrevocable deed containing reserved faculties, the heir cannot be heard to quarrel the exercise of these faculties on deathbed.

42. In a competition between the creditors of the deceased and of the heir, our law has justly preferred the creditors of the deceased, as every man’s estate ought to be liable, in the first place, for his own debt. But this preference is, by the statute, limited to the case where the creditors of the deceased have used diligence against their debtor’s estate, within three years from his death; and therefore the heir’s creditors may, after that period, affect it for their own payment. All dispositions by an heir, of the ancestor’s estate, within a year after his death, are null, in so far as they are hurtful to the creditors of the ancestor. This takes place, though these creditors should have used no diligence, and even where the dispositions are granted after the year: It is thought they are inefficacious against the creditors of the deceased who have used diligence within the three years.

Tit. 28. Of Succession in Moveables.

In the succession of moveable rights, it is an universal rule,
rule, that the next in degree to the deceased (or next of kin) succeeds to the whole; and if there are two or more equally near, all of them succeed by equal parts, without that prerogative, which takes place in heritage, of the eldest son over the younger, or of males over females. Neither does the right of representation, explained Tit. xxvii. 4. obtain in the succession of moveables, except in the single case of a competition between the full blood and the half blood; for a niece by the full blood will be preferred before a brother by the half blood, though the is by one degree more remote from the deceased than her uncle. Where the estate of a person deceased confinls partly of heritage, and partly of moveables, the heir in the heritage has no share of the moveables, if there are others as near in degree to the deceased as himself: But where the heir, in such case, finds it his interest to renounce his exclusive claim to the heritage, and betake himself to his right as one of the next of kin, he may collate or communicate the heritage with the others, who in their turn must collate the moveables with him; so that the whole is thrown into one mass, and divided equally among all of them. This doctrine holds, not only in the line of descendents, but of collaterals; for it was introduced, that the heir might in no case be worse than the other next of kin.

2. One may settle his moveable estate upon whom he pleases, excluding the legal successor, by a testament; which is a written declaration of what a person wills to be done with his moveable estate after his death. No testamentary deed is effectual, till the death of the testator; who may therefore revoke it at pleasure, or make a new one, by which the first loses its force; and hence testaments are called, lait or latter wills. Testaments, in their strict acceptation, must contain a nomination of executors, i.e. of persons appointed to administer the succession according to the will of the deceased: Yet nothing hinders one from making a settlement of moveables, in favour of an universal legatee, though he should not have appointed executors; and on the other part, a testament where executors are appointed, is valid, though the person who is to have the right of succession should not be named. In this last case, if the executor nominated be a stranger, i.e. one who has no legal interest in the moveable estate, he is merely a trustee, accountable to the next of kin; but he may retain a third of the dead’s part (explained § 6.) for his trouble in executing the testament; in payment of which, legacies, if any be left, must be imputed. The heir, if he be named executor, has right to the third as a stranger; but if one be named, who has an interest in the legal succession, he has no allowance, unless such interest be less than a third.

3. A legacy is a donation by the deceased, to be paid by the executor to the legatee. It may be granted, either in the testament, or in a separate writing. Legacies are not due till the granter’s death; and consequently they can transmit no right to the executors of the legatee, in the event that the granter survives him.

4. Legacies, where they are general, i.e. of a certain sum of money indefinitely, give the legatee no right in any one debt or subject; he can only insist in a personal action against the executor, for payment out of the testator’s effects. A special legacy, i.e. of a particular debt due to the deceased, or of a particular subject belonging to him, is of the nature of an alienation, by which the property of the special debt or subject vests, upon the testator’s death, in the legatee, who can therefore directly sue the debtor or possessor: Yet as no legacy can be claimed till the debts are paid, the executor must be cited in such process, that it may be known, whether there are free effects sufficient for answering the legacy. Where there is not enough for payment of all the legacies, each of the general legatees must suffer a proportional abatement: But a special legatee gets his legacy entire, though there should be nothing over for payment of the rest; and on the contrary, he has no claim, if the debt or subject bequeathed should perish, whatever the extent of the free executry may be.

5. Minors, after puberty, can tell without their curators, wives without their husbands, and persons interdicted without their interdictors; but bailards cannot tell, except in the cases afterwards set forth, Tit. xxix. 3. As a certain share of the goods, falling under the communion that is consequent on marriage, belongs, upon the husband’s decease, to his widow, jure relativa, and a certain share to the children, called the legitime, portion-natural, or bairns part of gear; one who has a wife or children, though he be the absolute administrator of all these goods during his life, and consequently may alien them by a deed inter vivos in loco possess, even gratuitously, if no fraudulent intention to disappoint the wife or children shall appear, yet cannot impair their shares gratuitously on deathbed; nor can he dispose of his moveables to their prejudice by testament, though it should be made in loco possess; since testaments do not operate till the death of the testator, at which period the division of the goods in communion have their full effect in favour of the widow and children.

6. If a person deceased leaves a widow, but no child, his testament, or, in other words, the goods in communion, divide in two; one half goes to the widow, the other is the dead’s part, i.e. the absolute property of the deceased, on which he can tell, and which falls to his next of kin, if he dies intestate. Where he leaves children, one or more, but no widow, the children get one half as their legitime; the other half is the dead’s part, which falls also to the children, if the father has not testified upon it. If he leaves both widow and children, the division is tripartite; the wife takes one third by herself; another falls, as legitime, to the children equally among them, or even to an only child, though he should succeed to the heritage; the remaining third is the dead’s part. Where the wife predeceases without children, one half is retained by the husband, the other falls to her next of kin: Where the children, the division ought also to be bipartite, by the common rules of society, since no legitime is truly due on a mother’s death; yet
yet it is in practice tripartite; two thirds remain with the
surviving father, as if one third were due to him proprio
suo nomine, and another as administrator of the legitime for
his children; the remaining third, being the wife's share,
goes to her children, whether of that or any former mar-
riage, for they are all equally her next of kin.
7. Before a testament can be divided, the debts owing
by the deceased are to be deducted; for all executory must
be free. As the husband has the full power of burden-
ing the goods in comminution, his debts affect the whole,
and so left the legitime and the share of the relict, as
well as the dead's part. His funeral charges, and the
mournings and alimony due to the widow, are considered
as his proper debts; but the legacies, or other gratuitous
rights, granted by him on deathbed, affect only the dead's
part. Bonds bearing interest, due by the deceased, cannot
diminith the relict's share, because such bonds, when
due to the deceased, do not increase it. The funeral
charges of the wife predeceasing, fall wholly on her exec-
utors who have right to her share. Where the deceased
leaves no family, neither husband, wife, nor child, the
testament suffers no division, but all is the dead's part.
8. The whole issue of the husband, not only by that
marriage which was dissolved by his death, but by any
former marriage, has an equal interest in the legitime;
otherwife the children of the first marriage would be cut
out, as they could not claim the legitime during their fa-
ther's life. But no legitime is due, 1. Upon the death of
a mother. 2. Neither is it due to grandchildren, up-
ward to the third degree, i. e. to such as, by having renounced
the legitime, are no longer considered as in familta, and
so are excluded from any further share of the moveable
colle que than they have already received.
9. As the right of legitime is strongly founded in na-
ture, the renunciation of it is not to be inferred by im-
plication. Renunciation by a child of his claim of legi-
time has the same effect as his death, in favour of the
other children intitled thereto; and consequently the share
of the renouncer divides among the rest; but he does not
the eby lose his right to the dead's part, if he does not
also renounce his share in the father's execution. Nay,
his renunciation of the legitime, where he is the only
younger child, has the effect to convert the whole subject
thereof into dead's part, which will therefore fall to the
renouncer himself as next of kin, if the heir be not will-
ing to collate the legitime with him.
10. For preserving an equality among all the children,
who continue intitled to the legitime, we have adopted
the Roman doctrine of collatio honorum; whereby the
card, who has got a provision from his father, is obliged
to collate it with the others, and impute it towards his
own share of the legitime; but if, from the deed of pro-
vision, the father shall appear to have intended it as a
preceduum to the child, collation is excluded. A child
is not bound to collate an heritable subject provided to
him, because the legitime is not impaired by such provi-
sion. As this collation takes place only in questions am-
ong children who are intitled to the legitime, the relict
is not bound to collate donations given her by her hus-
band, in order to increase the legitime; and on the other
part, the children are not obliged to collate their provis-
ions, in order to increase her share.
11. As an heir in heritage must complete his titles by
entry, so an executor is not vested in the right of the
moveable estate of the deceased without confirmation,
confirmation is a sentence of the Commissary or Bishop's
court, impowering an executor, one or more, upon ma-
kincg inventory of the moveables pertaining to the deceased,
to recover, posses, and administer them, either in behalf
of themselves, or of others interested therein. Testa-
ments must be confirmed in the commissariat where the
deceased had his principal dwelling house at his death.
If he had no fixed residence, or died in a foreign coun-
try, the confirmation must be at Edinburgh, as the com-
mis e forum; but if he went abroad with an intention to
return, the commissariat within which he resided, before
he left Scotland, is the only proper court.
12. Confirmation proceeds upon an edit, which is af-
fixed on the door of the parish church where the decea-
ded dwelt, and serves to intimate to all concerned the day
of confirmation, which must be nine days at least after
publishing the edit. In a competition for the office of
executor, the Commissary prefers primo loco, the per-
son named to it by the deceased himself, whose nomination
he ratifies or confirms, without any previous decer-
niture; this is called the confirmation of a testament-testa-
mentary. In default of an executor named by the de-
ceased, universal dispoonees are by the present practice
preferred; after them, the next of kin; then the relict;
then creditors; and lastly, special legatees. All these
must be decreed executors, by a sentence called a de-
cree-dative; and if afterwards they incline to confirm, the
Commissary authorizes them to administer, upon their
making inventory, and giving security to make the sub-
ject thereof forthcoming to all having interest; which is
called the confirmation of a testament-dative.
13. A creditor, whose debtor's testament is already
confirmed, may sue the executor, who holds the office
for all concerned, to make payment of his debt. Where
there is no confirmation, he himself may apply for the
office, and confirm as executor creditor; which intitles
him to sue for, and receive the subject confirmed, for his
own payment. And where one applies for a confirmation,
as executor-creditor, every co-creditor may apply to be
conjoined with him in the office. As this kind of confir-
mation is simply a form of diligence, creditors are ex-
empted from the necessity of confirming more than the a-
mount of their debts.
14. A creditor, whose debt has not been constituted,
or his claim not closed by decree, during the life of his
debtor, has no title to demand directly the office of exec-
cutor gua creditor; but he may charge the next of kin
who stands off, to confirm, who must either renounce
within twenty days after the charge, or be liable for the
debt; and if the next of kin renounces, the pursuer may
conclude his debt, and obtain a decree cognitio in cause,
against the hereditas jacent of the moveables, upon which
he may confirm as executor creditor to the deceased.
Where one is creditor, not to the deceased, but to his
next of kin who stands off from confirming, he may af-
sess the moveables of the deceased, by obtaining himself
decreed
decerned executor-dative to the deceased, as if he were creditor to him, and not to his next of kin.

15. Where an executor has either omitted to give up any of the effects belonging to the deceased in inventory, or has estimated them below their just value, there is place for a new confirmation, ad omisit vel male appretiata, at the suit of any having interest; and if it appears that he has not omitted or undervalued any subject dedi or déja été, the Commissary will ordain the subjects omitted, or the difference between the estimations in the principal testament and the true values, to be added thereto; but if done shall be presumed, the whole subject of the testament ad omisit vel male appretiata, will be carried to him who confirms it, to the exclusion of the executor in the principal testament.

16. The legitime and relift’s share, because they are rights arising ex lege, operate ipso jure, upon the father’s death, in favour of the relift and children: and consequently pass from them, though they should die before confirmation, to their next of kin. Whereas the dead’s part, which falls to the children or other next of kin in the way of succession, remains, if they should die before confirming, in bonis of the first deceased; and so does not descend to their next of kin, but may be confirmed by the person who, at the time of confirmation, is the next of kin to the first deceased. Special assignations, though neither intimated, nor made public, during the life of the grantor, carry to the assignee the full right of the subjects assigned, without confirmation. Special legacies are really assignations, and so fall under this rule. The next of kin, by the bare possession of the ipsa corpora movables, acquires the property thereof without confirmation, and transmits it to his executors.

17. The confirmation of any one subject by the next of kin as it proves his right of blood, has been adjudged to carry the whole executors out of the testament of the deceased, even what was omitted, and to transmit all to his own executors. The confirmation of a stranger, who is executor nominated, as it is merely a court for the next of kin, has the effect to establish the right of the next of kin to the subjects confirmed, in the same manner as if himself had confirmed them.

18. Executory, though it carries a certain degree of representation of the deceased, is properly an office: Executors therefore are not subjected to the debts due by the deceased, beyond the value of the inventory; but, at the same time, they are liable in diligence for making the inventory effectual to all having interest. An executor creditor who confirms more than his debt amounts to, is liable in diligence for what he confirms. Executors are not liable in interest, even upon such bonds recovered by them as carried interest to the deceased, because their office obliges them to retain the sums they have made effectual, in order to a distribution thereof among all having interest. This holds though they should again lend out the money upon interest, as they do it at their own risk.

19. There are certain debts of the deceased called privileged debts, which were always preferable to every other. Under that name are comprehended, medicines furnished to the deceased on death-bed, physicians fees during that period, funeral charges, and the rent of his house, and his servant’s wages for the year or term current at his death. These the executors are in safety to pay on demand. All the other creditors, who either obtain themselves confirmed, or who cite the executor already confirmed, within fix months after their debtor’s death, are preferred, pari passu, with those who have done more timely diligence; and therefore no executor can either retain for his own debt, or pay a testamentary debt. So as to exclude any creditor, who shall use diligence within the six months, from the benefit of the pari passu preference; neither can a decree for payment of debt be obtained, in that period, against an executor, because, till that term be elapsed, it cannot be known how many creditors may be intitled to the fund in his hands. If no diligence be used within the six months, the executor may retain for his own debt, and pay the residue primo ventienti. Such creditors of the deceased as have used diligence within a year after their debtor’s death, are preferable on the subject of their testament to the creditors of his next of kin.

20. The only passive title in moveables is vitious intromission, which may be defined an unwarrantable intermeddling with the moveable estate of a person deceased, without the order of law. This is not confined, as the passive titles in heritage are, to the persons interested in the succession, but strikes against all intrumitters whatever. Where an executor confirmed, intromits with more than he has confirmed, he incurs a passive title, fraud being in the common case presumed from his not giving up in inventory the full subject intermeddled with. Vitiuous intromission is also presumed, where the repositories of a dying person are not sealed up, as soon as he becomes incapable of sense, by his nearest relations; or, if he dies in a house not his own, they must be sealed by the master of such house, and the keys delivered to the judge-ordinary, to be kept by him, for the benefit of all having interest.

21. The passive title of vitious intromission does not take place where there is any probable title or circumstance that takes off the presumption of fraud. In consequence of this rule, necessary intromission, or suffectio causa, by the wife or children, who only continue the possession of the deceased, in order to preserve his goods for the benefit of all concerned, infers no passive title. And upon the same principle, an intrumitter, by confirming himself executor, and thereby subjecting himself to account, before action be brought against him on the passive titles, purges the vitiosity of his prior intromission: And where the intromitter is one who is interested in the succession, e.g. next of kin, his confirmation, at any time within a year from the death of the deceased, will exclude the passive title, notwithstanding a prior citation. As this passive title was intended only for the security of creditors, it cannot be sued upon by legatees; and since it arises ex delitto, it cannot be pleaded against the heir of the intrumitter. As in delicis, any one of many delinquents may be subjected to the whole punishment, so any one of many intrumitters may be sued in solidum for the purfuer’s debt, without calling the rest; but the intrumitter who pays, has an action of relief against the others for their share of it. If the intrumitters are sued jointly,
I.

28. The whole of a debtor's estate is subjected to the payment of his debts; and therefore, both his heirs and executors are liable for them, in a question with creditors; but as succession is by law divided into the heritable and the moveable estate; each of these, ought, in a question between the several successors, to bear the burdens which naturally affect it. Action of relief is accordingly competent to the heir who has paid a moveable debt, against the executor; and vice versa. This relief is not cut off by the deceased's having disposed either his land-estate or his moveables, with the burden of his whole debts; for such burden is not to be construed as an alteration of the legal succession, but merely as a farther security to creditors, unless the contrary shall be presumed from the special style of the disposition.

Tit. 29. Of last Heirs and Bastards.

By our ancient practice, feudal grants taken to the vassal, and to a special order of heirs, without settling the last termination upon heirs whatsoever, returned to the superior, upon failure of the special heirs therein contained, but now that fees are become patrimonial rights, the superior is, by the general opinion, held to be fully divested of such grant, and the right descends to the vassal's heirs at law. And even where a vassal dies, without leaving any heir who can prove the remotest propriety to him, it is not the superior, as the old law held, but the King, who succeeds as last heir, both in the heritable and moveable estate of the deceased, in consequence of the rule, Quod nullius est, cedit domino Regi.

2. If the lands, to which the King succeeds, be helden immediately of himself, the property is consolidated with the superiority, as if restitution had been made in the Sovereign's hands. If they are held of a subject, the King, who cannot be vassal to his own subject, names a donoraty; who, to complete his title, must obtain decree of declarator; and thereafter he is prefered to the superior, by letters of presentation from the King under the under-secure, in which the superior is charged to enter the donatory. The whole estate of the deceased is, in this case, subjected to his debts, and to the widow's legal provisions. Neither the King nor his donatory is liable beyond the value of the succession. A person who has no heir to succeed to him, cannot alien his heritage in leto, to the prejudice of the King, who is intitled to set aside such deed, in the character of ultimus heres.

3. A bastard can have no legal heirs, except those of his own body; since there is no succession but by the father, and a bastard has no certain father. The King therefore succeeds to him, failing his lawful issue, as lait heir. Though the bastard, as absolute proprietor of his own estate, can dispose of his heritage in liene poffile, and of his moveables by any deed inter vivos; yet he is disabled, ex defectu natalium, from bequeathing by testament, without letters of legitimation from the Sovereign. If the bastard has lawful children, he may test, without such letters, and name tutors and curators to his issue.
Reduction-improbation is an action, whereby a person who may be hurt or affected by a writing, inuits for producing or exhibiting it in court, in order to have it set aside, or its effect ascertained, under the certification that the writing, if not produced, shall be declared false and forged. This certification is a fiction of law, introduced that the production of writings may be more effectually forced, and therefore it operates only in favour of the pursuer. Because the summons in this action proceeds on alleged grounds of falsehood, his Majesty's Advocate, who is the public prosecutor of crimes, must concur in it.

4. As the certification in this process draws after it so heavy consequences, two terms are assigned to the defenders for production. After the second term is elapsed, intimation must be made judicially to the defender, to satisfy the production within ten days; and till these are expired, no certification can be pronounced. Certification cannot pass against deeds recorded in the books of Seffion, if the defender shall, before the second term, offer a condensation of the dates of their registration, unless falsehood be objected; in which case, the original must be brought from the record to the court. But an extract from the inferior court is no bar to certification; the principal writing must be laid before the court of Seffion on a proper warrant.

5. In an action of simple reduction the certification is only temporary, declaring the writings called for, null, until they are produced; so that they recover their full force after production, even against the pursuer himself; for which reason, that process is now seldom used. Because its certification is not so severe as in reduction-improbation, there is but on term assigned to the defender for producing the deeds called for.

6. The most usual grounds of reductions of writings are, the want of the requisite solemnities; that the grantor was minor, or interdicted, or inhibited; or that he signed the deed on death-bed, or was compelled or frightened into it, or was circumvented; or that he granted it in prejudice of his lawful creditors.

7. In reductions on the head of force, or fear, or fraud and circumstance, the pursuer must libel the particular circumstances from which his allegation is to be proved. Reduction is not competent upon every degree of force or fear; it must be such as would shake a man of constancy and resolution. Neither is it competent, on that fear which arises from the just authority of husbands or parents over their wives or children, nor upon the fear arising from the regular execution of lawful diligence by caption, provided the deeds granted under that fear relate to the ground of debt contained in the diligence; but if they have no relation to that debt, they are reducible ex metu.

8. Alienations granted by debtors after contracting of lawful debts, in favour of conjunct or confident persons, without just and necessary causes, and without a just price really paid, are null. One is deemed a prior creditor, whose relation to the grantee is so near, as to bar them from judging in his cause. Confident persons are those who appear to be in the grantor's confidence, by being employed in his affairs, or about his person; as a doer, steward, or domestic servant.

9. Rights, though gratuitous, are not reducible, if the grantor had, at the date thereof, a sufficient fund for the payment of his creditors. Provisions to children are, in the judgment of law, gratuitous; so that their effect, in a question with creditors, depends on the solvency of the grantor: But settlements to wives, either in marriage contracts, or even after marriage, are onerous, in so far as they are rational; and consequently are not reducible, even though the grantor was insolvent. This rule holds also in rational tochers contracted to husbands: But it must, in all cases, be qualified with this limitation; if the insolvency of the grantor was not publicly known; for if it was, fraud is presumed in the receiver of the right, by contracting with the bankrupt.

10. The receiver of the deed, if he be a conjunct or confident person, must attract or support the onerous cause of his right, not merely by his own oath, but by some circumstances or admixtures. But where a right is granted to a stranger, the narrative of it expressing an onerous cause, is sufficient per se to secure it against reduction.

11. All voluntary payments or rights made by a bankrupt to one creditor, to disappoint the more timeous diligence of another, are reducible at the instance of that creditor who has used the prior diligence. A creditor, though his diligence be but begun by citation, may insist in a reduction of all posterior voluntary rights granted to his prejudice; but the creditor who neglects to complete his begun diligence within a reasonable time, is not entitled to reduce any right granted by the debtor, after the time that the diligence is considered as abandoned.

12. A prohibited alienation, when conveyed by the receiver to another who is not privy to the fraud, subsists in the person of the bona fide purchaser. In the case of moveable rights, this nullity is receivable by exception; but it must be declared by reduction, where the right is heritable.

13. By act 1696, c. 5. all alienations by a bankrupt, within sixty days before his bankruptcy, to one creditor in preference to another, are reducible, at the instance of such co-creditors as had not used the least step of diligence. A bankrupt is there described by the following characters: diligence used against him by horning and caption; and insolvency, joined either with imprisonment, retiring to the sanctuary, abounding, or forcibly defending himself from diligence. It is sufficient that a caption is raised against the debtor, though it be not executed; provided he has retired to flan it. It is provided, that all heritable bonds or rights on which seisin may follow, shall be reckoned, in a question with the grantor's other creditors upon this act, to be of the date of the seisin following thereon. But this act was found to relate only to securities for former debts, and not to nova debita.

14. Actions are divided into rei persequatoria, and paenae. By the first, the pursuer inflicts barely to recover the subject that is his, or the debt due to him; and this includes
includes the damage sustained; for one is as truly a sufferer in his patrimonial interest by that damage, as by the loss of the subject itself. In penal actions, which always arise ex delictis, something is also demanded by way of penalty.

15. Actions of spoilation, ejection, and intrusion, are penal. An action of spoilation is competent to one dispossessed of a moveable subject violently, or without order of law, against the person dispossessing; not only for being restored to the possession of the subject, if extant, or for the value, if it be destroyed, but also for the violent profits, if in case the action be brought within three years from the spoilation. Ejection and intrusion are, in heritable subjects, what spoilation is in moveables. The difference between the two is, that in ejection, violence is used; whereas the intruder enters into the void possession, without either a title from the proprietor, or the warrant of a judge. The actions arising from all the three are of the same general nature.

16. The action of contravention of law-borrows is also penal. It proceedeth on letters of law-borrows, (from borgh a cautioner), which contain a warrant to charge the party complained upon, that he may give security, not to hurt the complainer in his person, family, or estate. These letters do not require the previous citation of the party complained upon, because the caution which the law requires is only for doing what is every man's duty; but, before the letters are executed against him, the complainer must make oath that he dreads bodily harm from him. The penalty of contravention is ascertained to a special sum, according to the offender's quality; the half to be applied to the suit, and the half to the complainer. Contravention is not incurred by the uttering of reproachful words, where they are not accompanied, either with acts of violence, or at least a real injury; and as the action is penal, it is elided by any probable ground of excuse.

17. Penalties are the consequences of delict, or transgression; and as no heir ought to be accountable for the delict of his ancestor, farther than the injured person has really suffered by it, penal actions die with the delinquent, and are not transmissible against heirs. Yet the action, if it has been commenced, and litigated in the delinquent's lifetime, may be continued against the heir, though the delinquent should die during the dependence. Some actions are rei persequaritae on the part of the pursuer, when he imputeth for simple restitution; which yet may be penal in respect of the defender; e.g., the action on the passive title of vitious intromission, by which the pursuer frequently recovers the debt due to him by the deceased, though it should exceed the value of the goods intermeddled with by the defenders.

18. The most celebrated division of actions in our law, is into petitory, possessory, and declaratory. Petitory actions are those, where something is demanded from the defender, in consequence of a right of property, or of credit in the pursuer: Thus, actions for restitution of moveables, actions of paining, of forthcoming, and indeed all personal actions upon contracts or quasi contracts, are petitory. Possessory actions are those which are founded, either upon possession alone, as spoilizies; or upon possession joined with another title, as removing; and they are competent either for getting into possession, for holding it, or for recovering it; analogous to the interdictions of the Roman law, quorum bonorum, uti possidetis, and unde vi.

16. An action of molestation is a possessory action, competent to the proprietor of a land-estate, against those who disturb his possession. It is chiefly used in questions of commonalty, or of controverted marches. Where a declarator of property is conjoined with a process of molestation, the feisin alone is competent to the action. Actions on brieves of perambulation, have the same tendency with molestations, viz. the settling of marches between contumins lands.

20. The action of mails and duties is sometimes petitory, and sometimes possessory. In either case, it is directed against the tenants and natural possessors of land-estates, for payment to the pursuer of the rents remaining due by them for past crops, and of the full rent for the future. It is competent, not only to a proprietor whose right is perfected by seisin, but to a simple disposer, for a disposition of lands includes a right to the mails and duties; and consequently to an adjudger, for an adjudication is a judicial disposition. In the petitory action, the pursuer, since he founds upon right, not possession, must make the proprietor, from whom the tenants derive their right, party to the suit; and he must support his claim by titles of property or diligences, preferable to those in the person of his competitor. In the possessory, the pursuer, who libels that he, his ancestors or authors, have been seven years in possession, and that therefore he has the benefit of a possessory judgment, need produce no other title than a seisin, which is a title sufficient to make the possession of heritage lawful; and it is enough, if he calls the natural possessors, though he should neglect the proprietor. A possessory judgment founded on seven years possession, in consequence either of a seisin or a tack, has this effect, that though one should claim under a title preferable to that of the possessor, he cannot compete with him in the possession, till a formal process of reduction he shall obtain the possessor's title declared void.

21. A declaratory action is that, in which some right is craved to be declared in favour of the pursuer, but nothing sought to be paid or performed by the defender, such as declarators of marriage, of irritancy, of expiry of the legal reversion, &c. Under this class may be also comprehended reificatory actions, which, without any personal conclusion against the defender, tend simply to set aside the rights or writings labelled, in consequence of which a contrary right or immunity arises to the pursuer. Decrees upon action that are properly declaratory confer no new right; they only declare what was the pursuer's right before, and so have a retrospective to the period at which that right first commenced. Declarations, because they have no personal conclusion against the defender, may be pursued against an apparent heir without a previous charge given him to enter to his ancestor; unless where special circumstances require a charge.

22. An action for proving the tenor, whereby a writing, which is destroyed or amissed, is endeavoured to be revised, is in effect declaratory. In obligations that are extinguishable
extinguishable barely by the debtor's retiring or canceling them, the pursuer, before a proof of the tenor is admitted, must condescend on such a casus amissiun, or accident by which the writing was destroyed, as he swears it was lost when in the creditor's possession; otherwise bonds that have been cancelled by the debtor on payment, might be reared up as still subsisting against him: But in writings which require contrary deeds to extinguish their effect, as affirmations, dispositions, charters, &c. it is sufficient to libel that they were lost, even casus fortuito.

23. Regularly, no deed can be revived by this action, without some admindle in writing, referring to that which is libelled; for no written obligation ought to be raised up barely on the testimony of witnesses. If these admindicles afford sufficient conviction, that the deed libelled did once exist, the tenor is admitted to be proved without somes adminicle in writing, referring to that which it stood formerly. Upon the pursuer's death, his representative, in the same condition in which it stood previously, is entitled to the same rents. In the case of several arrestments used in his hands for the same debt; or by tenants in the case of several adjudgments, all of whom claim right to the same rents. In those competitions, any of the competitors may bring an action of double or multiple poinding in name of the tenants, or other debtors, without their consent, or even though they should disclaim the process; since the law has introduced it as the proper remedy for getting such competitions determined: And while the subject in controversy continues in medio, any third person who conceives he has a right to it, may, though he should not be cited as a defendant, produce his titles, as if he were an original party to the suit, and will be admitted for his interest in the competition.

24. The action of double or multiple poinding may be also reckoned declaratory. It is competent to a debtor, who is distressed, or threatened with distress, by two or more persons claiming right to the debt, and who therefore brings the several claimants into the field, in order to debate and settle their several preferences, that so he may pay securely to him whose right shall be found preferable. This action is daily pursued by an arrestee, in the case of several arrestments used in his hands for the same debt; or by tenants in the case of several adjudgments, all of whom claim right to the same rents. In these competitions, any of the competitors may bring an action of multiple-poinding in name of the tenants, or other debtors, without their consent, or even though they should disclaim the process; since the law has introduced it as the proper remedy for getting such competitions determined: And while the subject in controversy continues in medio, any third person who conceives he has a right to it, may, though he should not be cited as a defendant, produce his titles, as if he were an original party to the suit, and will be admitted for his interest in the competition.

25. Certain actions may be called accessary, because they are merely preparatory or subservient to other actions. Thus, exhibitions ad deliberandum, at the instance of an heir against the creditors or custodiers of his ancestor's writings, are intended only to pave the way for future processes. An action of transference is also of this sort, whereby an action during the pendency of which the defender happens to die, is craved to be transferred against his representative, in the same condition in which it stood formerly. Upon the pursuer's death, his heir may insist in the cause against the defender, upon producing, either a retour or a confirmed testament, according as the subject is heritable or movable. Transferences being but incidental to other actions, can be pronounced by that inferior judge alone before whom the principal cause depended; but, where the representatives of the deceased live in another territory, it is the supreme court which must transfer. Obligations may be now registered summarily after the creditor's death; which before was not admitted, without a separate process of registration, to which the granter was neceressary to be made a party.

26. A process of wakening is likewise accessary. An action is said to sleep, when it lies over, not inculled in for a year, in which case its effect is suspended; but even then it may, at any time within the years of prescription, be revived or wakened by a summons, in which the pursuer recites the last step of the process, and concludes that it may be again carried on as if it had not been discontinued. An action that stands upon any of the inchoate rolls cannot sleep; nor an action in which decree is pronounced, because it has got its full completion. Consequently the decree may be extracted after the year, without the necessity of a wakening.

27. An action of transumpt falls under the same clause. It is competent to thefe, who have a partial interest in writings that are not in their own custody, against the possessors thereof, for exhibiting them, that they may be transsumed for their behoof. Though the ordinary title in this process be an obligation by the defender to grant transumpts to the pursuer, it is sufficient if the pursuer can show that he has an interest in the writings; but, in this case, he must transum them on his own charges. Actions of transumpt may be pursued before any judge-ordinary. After the writings to be transsumed are exhibited, full duplicates are made out, collated, and signed, by one of the clerks of court, which are called transumpts, and are as effectual as an extract from the register.

28. Actions proceeded anciently upon brieves issuing from the chancery, directed to the judicatory or judge-ordinary, who tried the matter by a jury, upon whole verdict judgment was pronounced: And to this day, we retain certain brieves, as of inquest, terce, ideology, totary, perambulation, and perhaps two or three others: But summons were, immediately upon the institution of the College of Justice, introduced in the place of brieves. A summons, when applied to actions pursued before the jefision, is a writ in the King's name, issuing from his sigil upon the pursuer's complaint, authorizing messengers to cite the defender to appear before the court, and make his defences; with certification if he fail to appear, that decree will be pronounced against him in terms of the certification of the summons.

29. The days indulged by law to a defender, between his citation and appearance, to prepare for his defence, are called inducias legales. If he is within the kingdom, twenty one and six days, for the first and second diets of appearance, must be allowed him for that purpose; and if out of it, sixty and fifteen. Defenders residing in Orkney or Zetland must be cited on forty days. In certain summons which are priviledged, the inducias are shortened: Spuizies and ejections proceed on fifteen days; wakenings
wakenings and transferences, being but incidental, on six; see the list of privileged summonses, in act of federunt June 29, 1672. A summons must be executed, i.e., served against the defender, so as the last diet of appearance may be within a year after the date of the summons; and it must be called within a year after that diet, otherwise it falls for ever. Offence against the authority of the court, acts of malversation in office by any member of the college of justice, and acts of violence and oppression committed during the dependence of a suit by any of the parties, may be tried without a summons, by a lamenary complaint.

30. Where an action is in part penal, e.g., a removing spoliation, &c., a pursuer who restrains his demand to, and obtains decree merely for restitution, cannot thereafter bring a new process for the violent profits. Yet the same fact may be the foundation both of a criminal and civil action, because these two are intended for different purposes; the one for satisfying the public justice, the other for indemnifying the private party: And though the defender should be absolved in the criminal trial, for want of evidence, the party injured may bring an action ad civilum effectum, in which he is intitled to refer the libel to the defender's oath.

31. One libel or summons may contain different conclusions on the same ground of right, recifitory, declaratory, peremptory, &c., if they be not repugnant to each other: Nay, though different sums be due to one, upon different grounds of debt, or even by different debtors, the creditor may insist against them all in the same summons.

32. Defences are pleas offered by a defender for eliding an action. They are either dilatory, which do not enter into the cause itself, and so can only procure an abatement, &c., or peremptory, which entirely cut off the pursuer's right of action. The first, because they relate to the forms of proceeding, must be offered in limine judicii, and all of them at once. But peremptory defences may be proponed at any time before sentence.

33. A cause, after the parties had litigated it before the judge, was laid by the Romans to be liticecontested. By liticecontestation a judicial contract is understood to be entered into by the litigants, by which the action is perpetuated against heirs, even when it arises ex delitto. By our law, liticecontestation is not formed till an act is extracted, admitting the libel or defences to proof.

Tit. 31. Of Probation.

All allegations by parties to a suit, must be supported by proper proof. Probation is either by writing, by the party's own oath, or by witnesses. In the case of allegations, which may be proved by either of the three ways, a proof is said to be admitted prou de jure; because, in such case, all the legal methods of probations are competent to the party: If the proof he brings by writing be lame, he may have recourse either to witnesses or to his adversary's oath; but, if he should first take himself to the proof by oath, he cannot thereafter use any other probation, for the reason assigned § 3, and, on the contrary, a pursuer, who has brought a proof by witnesses, on an extracted act, is not allowed to resort to the oath of the defender. Single combat, as a sort of appeal to Providence, was, by our ancient law, admitted as evidence, in matters both civil and criminal. It was afterwards restricted to the cause of such capital crimes where no other proof could be had; some traces of this blind method of trial remained even in the reign of J. VI. who, by 1600. c. 12. might authorise duels on weighty occasions.

2. As obligations or deeds signed by the party himself, or his ancestors or authors, must be, of all evidence, the least liable to exception; therefore every debt or allegation may be proved by proper evidence in writing. The solemnities essential to probative deeds have been already explained, Tit. xxii. 3. et seq. Books of account kept by merchants, tradefmen, and other dealers in business, though not subscribed, are probative against him who keeps them; and, in case of furnishings by a shop-keeper, such books, if they are regularly kept by him, supported by the testimony of a single witness, afford a jures plena probatio in his favour, which becomes full evidence by his own oath in supplemment Notorial instruments and executions by messengers bear full evidence, that the solemnities herein set forth were used, not to be invalidated otherwise than by a proof of falsehood; but they do not prove any other extrinsic facts therein averred, against third parties.

3 Regularly, no person's right can be proved by his own oath, nor taken away by that of his adversary; because there are the bare averments of parties in their own favour. But, where the matter in issue is referred by one of the parties to the oath of the other, such oath, though made in favour of the deponent himself, is decisive of the point; because the reference is a virtual contract between the litigants, by which they are understood to put the issue of the cause upon what shall be depoied: And this contract is strictly regarded, that the the party who refers to the oath of the other cannot afterwards, in a civil action, plead upon any deed against the party depoing, inconsistent with his oath. To obviate the fears that may be laid for perjury, he, to whose oath of verity a point is referred, may refuse to depose, till his adversary swear that he can bring no other evidence in proof of his allegation.

4. A defender, though he cannot be compelled to swear to facts in a libel properly criminal; yet may, in trespas, where the conclusion is limited to a fine, or to damages. In general, an oath of party cannot either hurt or benefit third parties; being, as to them, res inter alios acta.

5. An oath upon reference, is sometimes qualified by special limitations restricting it. The qualities which are admitted by the judge as part of the oath, are called intrinsic; those which the judge rejects or separates from the oath, extrinsic. Where the quality makes a part of the allegation which is relevantly referred to oath, it is intrinsic. Thus, because a merchant, suing for furnishings after the three years, must, in order to make a relevancy, offer to prove by the defender's oath, not only the delivery of the goods, but that the price is still due; there-

Vol. II. Num. 66. 2
fore, though the defender should acknowledge upon oath his having received the goods, yet, if he adds, that he paid the price, this last part, being a denial that the debt subsists, is intrinsic, since it is truly the point referred to oath. Where the quality does not import an extinguition of the debt, but barely a counter-claim, or mutua petitio, against the pursuer, it is held as extrinsic, and must be proved aliunde. Neither can a defender who in his oath admits the constitution of a debt, get off by adjoining the quality of payment, where the payment ought by its nature to be vouched by written evidence.

6. Oaths of verity are sometimes deferred by the judge to either party, ex officio; which because they are not founded on any implied contract between the litigants, are not finally decisive, but may be traversed on proper evidence afterwards produced. These oaths are commonly put by the judge for supplying a lame or imperfect proof, and are therefore called oaths in supplement. See 9. 2.

7. To prevent groundless allegations, oaths of calumny have been introduced, by which either party may demand his adversary's oath, that he believes the fact contained in his libel or defences to be just and true. As this is an oath, not of verity, but only of opinion, the party who puts it to his adversary, does not renounce other proba-
tion; and therefore no party is bound to give an oath of calumny, on recent facts of his own, for such oath is really an oath of verity. These oaths have not been so frequent since the act of federunt, Feb. 1. 1715, whereby any party, against whom a fact shall be alleged, is obliged, without making oath, to confess or deny it; and in case of calumnious denial, is subjected to the expense that the other party has thereby incurred.

8. In all oaths, whether of verity or calumny, the citation carries, or at least implies, a certification, that if the party does not appear at the day assigned for deposing, he shall be held pro confesso; from a presumption of his consciousnes, that the fact upon which he declines to swear makes against him; but no party can be held pro confesso, if he be in the kingdom, without a previous personal citation used against him. Though an oath which resolves into a non memini, cannot be said to prove any point; yet where one fo deposes upon a recent fact, to which he himself was privy, his oath is considered as a dissimulating of the truth, and he is held pro confesso, as if he had refused to swear.

9. An oath in litem, is that which the judge defers to a pursuer, for ascertaining either the quantity or the value of goods which have been taken from him by the defender without order of law, or the extent of his damages. An oath in litem, as it is the affirmation of a party in his own behalf, is only allowed where there is proof that the other party has been engaged in some illegal act, or where the public policy has made it necessary, see Tit. xx. 11. This oath, as to the quantities, is not admitted, where there is a concourant testimony of witnesses brought in proof of it. When it is put as to the value of goods, it is only an oath of credulity; and therefore it has always been subject to the modification of the court.

10. The law of Scotland rejects the testimony of witnesses, 1. In payment of any sum above L. 100 Scots, all which must be proved either scripto vel juramento. 2. In all gratuitous promises, though for the smallest trifle. 3. In all contracts, where writing is either essential to their constitution, (see Tit. xxii. 2) or where it is usually adhitted, as in the borrowing of money. And it is a general rule, subject to the restrictions mentioned in the next §, that no debt or right, once constituted by writing, can be taken away by witnesses.

11. On the other part, probary by witnesses is admitted to the extent of L. 100 Scots, in payments, nuncupative legacies, and verbal agreements which contain mutual obligations. And it is received to the highest extent, 1. In all bargains which have known engagements naturally arising from them, concerning movable goods.

12. No person, whose near relation to another bars him from being a judge in his cause, can be admitted as a witnes for him; but he may, against him, except a wife or child, who cannot be compelled to give testimony against the husband or parent, ob reverentiam perfonee, et metum perjurii. Though the witnesses, whose propinquity to one of the parties is objected to, as nearly related to the other, the objection flounds good.

13. The testimony of infamous persons is rejected, i.e. persons who have been guilty of crimes that law declares to infer infamy, or who have been declared infamous by the sentence of a judge; but infamia facti does not disqualify a witnesses. Pupils are inhabile witnesses; being, in the judgment of law, incapable of the impreffions of an oath. The testimony of women is seldom admitted, where other witnesses can be had. And in general witnesses otherwise exceptionable may, where there is a penury of witnesses arising from the nature or circumstances of the fact, be received cum nota; that is, their testimony, though not quite free from suspicion, is to be conjoined with the other evidence, and to have such weight given it as the judge shall think it deserves.

14. All witnesses, before they are examined in the cause, are purged of partial counsel; that is, they must declare, that they have no interest in the suit, nor have given advice how to conduct it; that they have got neither bribe nor promise, nor have been instructed how to depo- se; and that they bear no enmity to either of the parties. These, because they are the points put to a witness before his making oath, are called initialis testimonii. Where a party can bring present proof of a witness's partial counsel, in any of the above particulars, he ought to offer it before the witnesses be sworn; but, because such objection, if it cannot be instantly verified, will be no bar to the examination, law allows the party in that case to protest.
protest for reprobator, before the witness is examined; e. e. that he may be afterwards allowed to bring evidence of his enmity, or other inabilitiy. Reprobator is competent even after sentence, where pretention is duly entered; but in that case, the party infiling mult confign L. 100 Scots, which he forfeits if he succumb. This action must have the concurrence of the King’s Advocate, because the conclusion of it imports perjury; and for this reason, the witness must be made a party to it.

15. The interlocutory sentence or warrant, by which parties are authorized to bring their proof, is either by way of act, or of incident diligence. In an act, the Lord Ordinary who pronounces it, is no longer judge in the cause; but in an incident diligence, which is commonly granted upon special points, that do not exhaust the cause, the Lord ordinary continues judge. If a witness does not appear at the day fixed by the warrant of citation, a second warrant is granted of the nature of a caption, containing a command to messengers to apprehend and bring him before the court. Where the party to whom a proof is granted, brings none within the term allowed by the warrant, an interlocutor is pronounced, circumscribing the term, and precluding him from bringing evidence thereafter. Where evidence is brought, if it be upon an act, the Lord Ordinary on the acts, after the term for proving is elapsed, declares the proof concluded, and thereupon a flate of the cause is prepared by the Ordinary on concluded causes, which must be judged by the whole Lords; but if the proof be taken upon an incident diligence, the import of it may be determined by the Lord Ordinary in the cause.

16. Where facts do not admit a direct proof, presumptions are received as evidence which, in many cases, make as convincing a proof as the direct. Presumptions are conclusions deduced from facts known or proved, which infer the certainty, or at least a strong probability, of another fact to be proved. This kind of probation is therefore called artificial, because it requires a reasoning to infer the truth of the point in question, from the facts that already appear in proof. Presumptions are either, 1. juris et de jure; 2. juris; or 3. boninis or judicis. The first sort obtains, where statute or custom establishes the truth of any point upon a presumption; and it is so strong, that it rejects all proof that may be brought to elude it in special cases. Thus, the testimony of a witness, who forwardly offers himself without being cited, is, from a presumption of his partiality, rejected, let his character be ever so fair; and thus also, a minor, because he is by law presumed incapable of conducting his own affairs, is, upon that presumption, disabled from acting without the consent of his curators, though he should be known to behave with the greatest prudence. Many such presumptions are fixed by statute.

17. Presumptiones juris are those, which our lawbooks or decisions have establisht, without founding any particular consequence upon them, or statuting fuper presumption. Most of this kind are not proper presumptions inferred from positive facts, but are founded merely on the want of a contrary proof; thus, the legal presumptions for freedom, for life, for innocence, &c. are in effect so many negative propositions, that servitude, death, and guilt, are not to be presumed, without evidence brought by him who makes the allegation. All of them, whether they be of this fort, or proper presumptions, as they are only conjectures formed from what commonly happens, may be elided, not only by direct evidence, but by other conjectures, affording a stronger degree of probability to the contrary. Presumptiones boninis or judicis, are those which arise daily from the circumstances of particular cases; the strength of which is to be weighed by the judge.

18. A fictio juris differs from a presumption. Things are presumed, which are likely to be true; but a ficlion or law assumes for truth what is either certainly false, or, at least, is as probably false as true. Thus, an heir is seigned or considered in law as the same person with his ancestor. Fictions of law must, in their effects, be always limited to the special purposes of equity, for which they were introduced; see an example, Tit. xxx. 3.

Tit. 32. Of Sentences and their Execution.

Property would be most uncertain, if debateable points might, after receiving a definitive judgment, be brought again in question, at the pleasure of either of the parties: Every statute has therefore affixed the character of final to certain sentences or decrees, which in the Roman law are called res judicatix, and which exclude all review or rehearing.

2. Decrees of the court of Session, are either in foro contradicitorio, where both parties have litigated the cause, or in absence of the defender. Decrees of the Session in foro cannot, in the general case, be again brought under the review of the court, either on points which the parties neglected to plead before sentence (which we call competent and omitted), or upon points pleaded and found insufficient (proposed and repelled.) But decrees, though in foro, are revivable by the court, where either they labour under essential nullities; e. g. where they are ultra petita, or not conformable to their grounds and warrants, or founded on an error in calcul, &c.; or where the party against whom the decree is obtained has thereafter recovered evidence sufficient to overturn it, of which he knew not before.

3. As parties might formerly reclaim against the sentences of the session, at any time before extrading the decree, no judgment was final till extract; but now, a sentence of the inner-houfe, either not reclaimed against within fix fiderunt-days after its date, or adhered to upon a reclaiming bill, though it cannot receive execution till extract, makes the judgment final as to the court of Session. And, by an order of the house of Lords, March 24, 1725. no appeal is to be received by them from sentences of the Session after five years from extrading the sentence; unless the person entitled to such appeal be minor, clothed with a husband, num compex mentis, imprisoned, or out of the kingdom. Sentences pronounced by the Lord Ordinary have the same effect, if not reclaimed against, as if they were pronounced in presence; and all petitions against the interlocutor of an Ordinary must be preferred within eight fiderunt-days after signing such interlocutor.
4. Decrees, in absence of the defender, have not the force of res judicata as to him; for where the defender does not appear, he cannot be said to have subjected himself by the judicial contract which is implied in litisconsolation. A party therefore may be restored against these, upon paying to the other his costs in recovering them. The sentences of inferior courts may be reviewed by the court of Session, before decree, by adroction, and after decree, by suspention or reduction; which two last are also the methods of calling in question such decrees of the Session itself as can again be brought under the review of the court.

5. Reduction is the proper remedy, either where the decree has already received full execution by payment, or where it decrees nothing to be paid or performed, but simply declares a right in favour of the pursuer. Suspention is that form of law by which the effect of a sentence-condemnatory, that has not yet received execution, is stayed or postponed, till the cause be again considered. The first step towards suspention is a bill preferred to the Lord Ordinary on the bills. This bill, when the desire of it is granted, is a warrant for issuing letters of suspention which pass the signet; but, if the prefenter of the bill shall not, within fourteen days after passing it, expedite the letters, execution may proceed on the sentence. Suspensions of decrees in foro cannot pass, but by the whole Lords in time of seffion, and by three in vacation time; but other decrees may be suspended by any one of the judges.

6. As suspention has the effect of staying the execution of the creditor's legal diligence, it cannot, in the general case, pass without caution given by the suspender to pay the debt, in the event it shall be found due. Where the suspender cannot, from his low or suspected circumstances, procure unquestionable security, the Lords admit juratory caution, i.e. such as the suspender swears is the best he can offer; but the reasons of suspention are, in that case, to be considered with particular accuracy at passing the bill. Decrees in favour of the clergy, of universities, hospitals, or parish school masters, for their stipends, rents, or salaries, cannot be suspended, but upon production of discharges, or on confignation of the funds charged for. A charger, who thinks himself secure without a cautioner, and wants dispatch, may, where a suspention of his diligence is sought, apply to the court to get the reasons of suspention summarily discussed on the bill.

7. Though he, in whose favour the decree suspended is pronounced, be always called the charger, yet a decree may be suspended before a charge be given on it. Nay, suspention is competent even where there is no decree, for putting a stop to any illegal act whatsoever: Thus, a building, or the exercise of a power which one assumes unwarrantably, is a proper subject of suspention. Letters of suspention are considered merely as a prohibitory diligence; so that the suspender, if he would turn provoker, must bring an action of reduction. If upon applying the letters of suspention, the reasons shall be sustained, a decree is pronounced, suspending the letters of diligence on which the charge was given simpliciter; which is called a decree of suspention, and takes off the effect of the decree suspeded. If the reasons of suspention be repelled, the court find the letters of diligence orderly proceeded, i.e. regularly carried on; and they ordain them to be put to farther execution.

8. Decrees are carried into execution, by diligence, either against the perfon, or against the estate of the debtor. The first step of personal execution is by letters of horning, which pass, by warrant of the court of Session, on the decrees of magistrates of boroughs, sheriffs, admirals and commissaries. If the debtor does not obey the will of the letters of horning within the days of the charge, the charger, after denouncing him rebel, and requiring the horning, may apply for letters of caption, which contain a command, not only to meffengers, but to magistrates, to apprehend and imprison the debtor. All meffengers and magistrates, who refuse their assistance in executing the caption, are liable subfidiarie for the debt; and such subfidiarie action is supported by the execution of the meffenger employed by the creditor, expressing that they were charged to concur, and would not. Letters of caption contain an express warrant to the meffenger, in case he cannot get access, to break open all doors, and other lock fall places.

9. Law secures peers, married women, and pupils, against personal execution by caption upon civil debts. No caption can be executed against a debtor within the precincts of the King's palace of Holyroodhouse: But this privilege of sanctuary afforded no security to criminals, as that which was by the canon law, conferred on churches and religious houses. Where the personal presence of a debtor, under caption, is necessary in any of our supreme courts, the judges are empowered to grant him a protection, for such time as may be sufficient for his coming and going, not exceeding a month.

10. After a debtor is imprisoned, he ought not to be indulged the benefit of the air, not even under a guard; for creditors have an interest, that their debtors be kept under close confinement, that, by the fqualor carceris, they may be brought to pay their debt. And any magistrate or jailor, who shall suffer the prisoner to go abroad, without a proper attestation, upon oath, of the dangerous state of his health, is liable subfidiarie for the debt. Magistrates are in like manner liable, if they shall suffer a prisoner to escape, through the insufficiency of their prison: But, if he shall escape under night, by the use of instruments, or by open force, or by any other accident which cannot be imputed to the magistrates or jailors, they are not chargeable with the debt; provided they shall have, immediately after his escape, made all possible search for him. Regularly, no prisoner for debt upon letters of caption, though he should have made payment, could be released without letters of suspention, containing a charge to the jailor to fet him at liberty; because the creditor's dischage could not take off the penalty incurred by the debtor for contempt of the King's authority: But to save unnecessary expense to debtors in small debts, jailors are empowered to let go prisoners where the debt does not exceed 200 merks Scots, upon production of a discharge, in which the creditor conveys to his releafe.
11. Our law, from a consideration of compassion, allows insolvent debtors to apply for a release from prison, upon a cessio honorum, i.e. upon their making over to the creditors all their estate, real and personal. This must be inscribed for, by way of action, to which all the creditors of the prisoner ought to be made parties. The prisoner must, in this action, which is cognizable only by the court of Session, exhibit a particular inventory of his estate, and make oath that he has no other estate than is therein contained, and that he has made no conveyance of any part of it, since his imprisonment, to the hurt of his creditors. He must also make oath, whether he has granted any disposition of his effects before his imprisonment, and condescend on the persons to whom, and on the cause of granting it; that the court may judge, whether, by any collusive practice, he has forfeited his claim to liberty.

12. A fraudulent bankrupt is not allowed this privilege; nor a criminal who is liable in an affrayment or indemnification to the party injured or his executors, though the crime itself should be extinguished by a pardon. A disposition granted on a cessio honorum is merely in farther security to the creditors, not in satisfaction or in solutum of the debts. If, therefore, the debtor shall acquire any estate after his release, such estate may be attached by his creditors, as if there had been no cessio, except in so far as is necessary for his subsistence. Debtors, who are set free on a cessio honorum, are obliged to wear a habit proper to debtors or bankrupts. The Lords are prohibited to dispense with this mark of ignominy, unless, in the summons and process of cessio, it be libelled, sustained, and proved, that the bankruptcy proceeds from misfortune. And bankrupts are condemned to submit to the habit, even where no suspicion of fraud lies against them, if they have been dealers in an illicit trade.

13. Where a prisoner for debt declares upon oath, before the magistrate of the jurisdiction, that he has not wherewith to maintain himself, the magistrate may set him at liberty, if the creditor, in consequence of whole diligence he was imprisoned, does not aliment him within ten days after intimation made for that purpose. But the magistrate may, in such case, detain him in prison, if he chuses to bear the burden of the aliment, rather than release him. The statute authorizing this release, which is usually called the act of grace, is limited to the case of prisoners for civil debts.

14. Decrees are executed against the moveable estate of the debtor by arrestment or pouding; and against his heritable estate, by inhibition, or adjudication. If one be condemned, in a removing or other process, to quit the possession of lands, and refuses, notwithstanding a charge, letters of ejection are granted of course, ordaining the sheriff to eject him, and to enter the tenant of the decree into possession. Where one opposes by violence the execution of a decree, or of any lawful diligence, which the civil magistrate is not able by himself and his officers to make good, the execution is enforced manu militari.

15. A decree-arbital, which is a sentence proceeding on a submission to arbiters, has some affinity with a judicial sentence, though in most respects the two differ. A submission is a contract entered into, by two or more parties who have disputable rights or claims, whereby they refer their differences to the final determination of an arbiter or arbiters, and oblige themselves to acquiesce in what shall be decided. Where the day within which the arbiters are to decide, is left blank in the submission, practice has limited the arbiters power of deciding to a year. As this has proceeded from the ordinary words of style, empowering the arbiters to determine betwixt and the day of next to come; therefore, where a submission is indefinite, without specifying any time, like all other contracts or obligations, itsubsists for forty years. Submissions, like mandates, expire by the death of any of the parties-submitters before sentence. As arbiters are not vested with jurisdiction, they cannot compel witnesses to make oath before them, or have writers of writings to exhibit them; but this defect is supplied by the court of Session, who, at the suit of the arbiters, or of either of the parties, will grant warrant for citing witnesses, or for the exhibition of writings. For the same reason, the power of arbiters is barely to decide; the execution of the decree belongs to the judge. Where the submitters consent to the registration of the decree-arbital, performance may be enforced by summary diligence.

16. The power of arbiters is wholly derived from the consent of parties. Hence, where their powers are limited to a certain day, they cannot pronounce sentence after that day. Nor can they subject parties to a penalty higher than that which they have agreed to in the submission. And where a submission is limited to special claims, sentence pronounced on subjects not specified in the submission is null, as being ultra vires compromissi.

17. But, on the other part, as submissions are designed for a most favourable purpose, the amicable composing of differences, the powers thereby conferred on arbiters receive an ample interpretation. Decrees-arbital are not reducible upon any ground, except corruption, bribery, or falsehood.

The word crime, in its most general sense, includes every breach, either of the law of God, or of our country; in a more restricted meaning, it signifies such transgressions of law as are punishable by courts of justice. Crimes were, by the Roman law, divided into public and private. Public crimes were those that were expressly declared such by some law or constitution, and which, on account of their more atrocious nature and hurtful consequences, might be prosecuted by any member of the community. Private crimes could be pursued only by the party injured, and were generally punished by a pecuniary fine to be applied to his use. By the law of Scotland, no private party, except the person injured, or his next of kin, can accuse criminally; but the King's Advocate, who in this question represents the community, has a right to prosecute all crimes in vindictam publicam, though the party injured should refuse to concur. Smaller offences, as petty riots, injuries, &c. which do not
and the public vengeance, passe generally by the application of delicts, and are punished either by fine or imprisonment.

2. The essence of a crime is, that there be an intention in the actor to commit it; for an action in which the will of the agent has no part, is not a proper object either of rewards or punishments: Hence arise the rule, crimen dolo contrahitur. Simple negligence does not therefore constitute a proper crime. Yet where it is extremely gross, it may be punished arbitrarily. Far less can we reckon in the number of crimes, those committed by an idiot or furious person: But lesser degrees of fault, which only darken reason, will not afford a total defence, though they may arise from the pena ordinaria. Actions committed in drunkenness are not to be considered as involuntary, seeing the drunkenness itself, which was the first cause of the action, is both voluntary and criminal.

3. On the same principle, such as are in a state of infancy, or in the confines of it, are incapable of a criminal action, done not being incident to that age; but the precise age at which a person becomes capable of doe, being fixed neither by nature nor by statute, is by our practice to be gathered by the judge, as he best can, from the understanding and manners of the person accused. Where the guilt of a crime arises chiefly from statute, the actor, if he is under the age, can hardly be found guilty; but, where nature itself points out its deformity, he may, if he is prominus pubertati, be more easily presumed capable of committing it: Yet, even in that case, he will not be punished pena ordinaria.

4. One may be guilty of a crime, not only by perpetrating it himself, but by being accessory to a crime committed by another; which last is by civilians styled ape et consilio, and, in our law-phrase, art and part. A person may be guilty, art and part, either by giving advice or counsel to commit the crime; or, 2. By giving warrant or mandate to commit it; or, 3. By actually assisting the criminal in the execution. It is generally agreed by doctors, that, in the more atrocious crimes, the adviser is equally punishable with the criminal; and that, in the lighter, the circumstances arising from the adviser's lesser age, the jocular or careless manner of giving advice, &c. may be received as pleas for softening the punishment. One who gives mandate to commit a crime, as he is the first spring of action, seems more guilty than the person employed as the instrument in executing it; yet the actor cannot excuse himself under the pretence of orders which he ought not to have obeyed.

5. Affilience may be given to the compitter of a crime, not only in the actual execution, but previous to it, by furnishing him, intentionally, with poison, arms, or the other means of perpetrating it. That sort of assistance which is not given till after the criminal act, and which is commonly called abetting, though it be of itself criminal, does not infer art and part of the principal crime; as if one should favour the escape of a criminal knowing him to be such, or conceal him from justice.

6. Those crimes that are, in their conseqences, most hurtful to society, are punished capitaliy, or by death; others escape with a lesser punishment, sometimes fixed by statute, and sometimes arbitrary, i.e. left to the discretion of the judge, who may exercise his jurisdiction, either by fine, imprisonment, or a corporal punishment. Where the punishment is left, by law, to the discretion of the judge, he can in no case extend it to death. The single effect of the criminal falls on conviction, in all capital trials, though the sentence should not express it.

7. Certain crimes are committed more immediately against God himself; others, against the state; and a third kind, against particular persons. The chief crime in the first class, cognizable by temporal courts, is blasphemy, under which may be included atheism. This crime consists in the denying or vilifying the Deity, by speech or writing. All who curse God or any of the persons of the blessed Trinity, are to suffer death, even for a single act; and those who deny him, if they persist in their denial. The denial of a providence, or of the authority of the holy Scriptures, is punishable capitaliy for the third offence.

8. No prosecution can now be carried on for witchcraft or conjuration. But all who undertake, from their skill in any occult science, to tell fortunes, or discover stolen goods, are to suffer imprisonment for a year, and in the pillory four times in that year, and find surety for their future good behaviour.

9. Some crimes against the state are levelled directly against the supreme power, and strike at the constitution itself; others discover such a contempt of law, as tends to baffle authority, or slacker the reins of government. Treason, crimen majestatis, is that crime which is aimed against the majesty of the state; and can be committed only by those who are subjects of that state either by birth or residence. Soon after the union of the two kingdoms in 1707, the laws of treason, then in force in England, were made ours by 7. An. c. 21. both with regard to the facts constituting that crime, to the forms of trial, the corruption of blood, and all the penalties and forfeitures consequent on it.

10. It is high treason, by the law of England, to imagine the death of the King, Queen-consort, or of the heir apparent of the crown; to levy war against the King, or adhere to his enemies; to counterfeit the King's coin, or his great or privy seal; to kill the chancellor, treasurer, or any of the twelve judges of England, while they are doing their offices; which last article is by the forenamed act 7. An. applied to Scotland, in the case of slinking any judge of the Seiffion or of Jucliciary in judgment. Those who wath, clip, or lighten the proper money of the realm, who advisedly affirm by writing or printing, that the Pretender has any right to the crown, that the King and Parliament cannot limit the succession to it, or who hold correspondence with the Pretender or any person employed by him, are also guilty of treason.

11. The forms of proceeding in the trial of treason, whether against Peers or Commons, are set forth in a small treatise, published by order of the house of Lords in 1709, and joined to a collection of statutes concerning treason. By the conviction upon this trial the whole estate of the traitor forfeits to the crown. His blood is also corruptible, so that, on the death of an ancestor, he cannot inherit;
herit; and the estate which he cannot take, falls to the immediate superior as escheat, ob defecium hereditis, without distinguishing whether the lands hold of the crown, or of a subject. No attainer for treason shall, after the death of the Pretender and all his issues, hurt the right of any person, other than that of the offender, during his natural life; The rights of creditors and other third parties in the case of forfeiture on treason, must be determined by the law of England.

12. Misprision of treason, from Mesprendre, is the overlooking or concealing of treason. It is inferred by one's bare knowledge of the crime, and not discovering it to a magistrature or other person intimated by his office to take examinations; though he should not in the least degree attend to it. The foresaid act 7 An. makes the English law of misprision ours. Its punishment is, by the law of England, perpetual imprisonment, together with the forfeiture of the offender's moveables, and of the profits of his heritable estate, during his life; that is, in the style of our law, his single and different escheat.

13. The crime of sedition consits in the raising commotions or disturbances in the state. It is either verbal or real. Verbal sedition, or leaping making, is inferred from the uttering of words tending to create discord between the King and his people. It is punished either by imprisonment, fine, or banishment, at the discretion of the judge. Real sedition is generally committed, by convoking together any considerable number of people, without lawful authority, under the pretence of redressing some public grievance, to the disturbing of the public peace. Those who are convicted of this crime are punished by the confiscation of their goods; and their lives are at the King's will. If any persons, to the number of twelve, shall assemble, and being required by a magistrate or constable to disperse, shall nevertheless continue together for an hour after such command, the persons disobeying shall suffer death and the confiscation of moveables.

14. Judges, who, willfully or through corruption, use their authority as a cover to injustice or oppression, are punished with the loss of honour, fame, and dignity. Under this head, may be classed theftbute (from bastre, compensation), which is the taking a consideration in money or goods from a thief to exempt him from punishment, or connive at his escape from justice. A sheriff or other judge, guilty of this crime, forfeits his life and goods. And even a private person, who takes thefthbute, suffers as the principal thief. The buying of disputed claims, concerning which there is a pending process, by any judge or member either of the Seillon, or of an inferior court, is punished by the loss of the delinquent's office, and all the privileges thereto belonging.

15. Deforcement is the opposition given, or refusal made, to meffengers or other officers, while they are employed in executing the law. The court of Seillon is competent to this crime. It is punishable with the confiscation of moveables, the one half to the King, and the other to the creditor at whose suit the diligence was used. Armed persons, to the number of three or more, affilling in the illegal running, landing, or exporting of prohibited or uncustomed goods, or any who shall resist, wound, or maim any officer of the revenue in the execution of office, are punishable with death and the confiscation of moveables.

16. Breach of arrestment, (see Tit. xxv. 5,) is a crime of the same nature with deforcement, as it imports a contempt of the law and of our judges. It subjects to an arbitrary corporal punishment, and the escheat of moveables; with a preference to the creditor for his debt, and for such farther sum as shall be modified to him by the judge. Under this head of crimes against good government and police, may be reckoned the forbidding of markets; that is, the buying of goods intended for a public market, before they are carried there; which for the third criminal act, infers the escheat of moveables; as also flying tomland in forbidden time, destroying plough-graith in time of tillage, flying or houghing horses or cows in time of harvest, and destroying or spoiling growing timber; as to the punishment of which, see statutes 1503, c. 72,—1587, c. 82, and 1693, c. 16—1. Geo. 1. St. 2. c. 48.

17. Crimes against particular persons may be directed, either against life, limb, liberty, chattties, goods, or reputation. Murder is the wilful taking away of a person's life, without a necessary cause. Our law makes no distinction between premeditated and sudden homicide; both are punished capitally. Caufal homicide, where the actor is in some degree blameable, and homicide in self-defence, where the just bounds of defence have been exceeded, are punished arbitrarily; but the slaughter of night-thieves, house-breakers, affillants in masterful predations, or rebels denounced for capital crimes, may be committed with impunity. The crime of demembra-
tion, or the cutting off of a member, is joined with that of murder; but in practice, its punishment has been restricted to the escheat of moveables, and an affliction or indemnification to the party. Mutilation, or the disabling of a member, is punished at the discretion of the judge.

18. Self-murder is as highly criminal as the killing our neighbour; and for this reason, our law has, contrary to the rule, criminis morte extinquitur, allowed a proof of the crime, after the offender's death, that his single escheat might fall to the King or his donatory. To this end, an action must be brought, not before the Justiciary, but the Seillon, because it is only intended ad civilem efficium, for proving and declaring the self murder; and the next of kin to the deceased must be made a party to it.

19. The punishment of parricide, or of the murder of a parent, is not confined, by our law, to the criminal himself. All his potterly in the right line are declared incapable of inheriting; and the succession devolves on the next collateral heir. Even the curving or beating of a parent infers death, if the person guilty be above fifteen years; and an arbitrary punishment, if he be under it. A presumptive or flatutory murder is constituted by 1690, c. 21, by which any woman who shall conceal her pregnancy, during its whole course, and shall not call for, or make use of help in the birth, is to be reputed the murderer, if the child be dead, or ambling. This act was intended to discourage the unnatural practice of wom
men making away with their children begotten in fornication, to avoid church-censures.

20. Duelling, is the crime of fighting in single combat, on previous challenges given and received. Fighting in a duel, without licence from the King, is punishable by death; and whatever person, principal or second, shall give a challenge to fight a duel, or shall accept a challenge, or otherwise engage therein, is punished by banishment and escheat of moveables, though no actual fighting should ensue.

21. Haimfecken, (from haim, home, and fecken, to seek or pursue,) is the assaulting or beating of a person in his own house. The punishment of this crime is no where defined, except in the books of the Majestiy, which make it the same as that of a rape; and it is, like rape, capital by our practice. The assault must be made in the proper house of the person assaulted, where he lies and rises daily and nightly, so that neither a public house, nor even a private, where one is only tranfiently, falls within the law.

22. Any party to a law-suit, who shall slay, wound, or otherwise invade his adversary, at any period of time between executing the summons and the compleat execution of the decree, or shall be accessory to such invasion, shall lose his caufe. The sentence pronounced on this trial, against him who has committed the battery, is not subje& to reduction, either on the head of minority, or any other ground whatever: And if the person prosecu- ted for this crime shall be denounced for not appearing, his inferent, as well as single escheat, falls upon the declination.

23. The crime of wrongful imprisonment is inferred, by granting warrants of commitment in order to trial, proceeding on informations not subscribed, or without expressing the cause of commitment; by receiving or detaining prisoners on such warrants; by refusing to a prisoner a copy of the warrant of commitment; by detaining him in close confinement, above eight days after his commitment; by not releasing him on bail, where the crime is bailable; and by transporting persons out of the kingdom, without either their own consent, or a lawful sentence. The persons guilty of a wrongful imprisonment, are punished by a pecuniary mulct, from L. 6000 down to L. 400 Scots, according to the rank of the person detained; and the judge or other person guilty, is over and above subjected to pay to the person detained a certain sum per diem, proportioned to his rank, and is declared incapable of public trust. All these penalties may be inflicted for by a summary action before the session, and are subject to no modification.

24. Adultery, is the crime by which the marriage-bed is polluted. This crime could, neither by the Roman nor Jewish law, be committed, but where the guilty woman was the wife of another: By ours, it is adultery, if either the man or woman be married. We distinguish between simp[le adultery, and that which is notorious or manifest. Open and manifest adulterers, who continue incorrigible, notwithstanding the censures of the church, are punished capitaly. This crime is distinguished by one or other of the following characters; where there is infue procreated between the adulterers; or where they keep bed and company together notoriously; or where they give scandal to the church, and are, upon their obstinate refusing to listen to their admonitions, excommunicated. The punishment of simple adultery, not being defined by statute, is left to the discretion of the judge; but custom has made the falling of the single escheat one of its penalties.

25. Bigamy, is a person's entering into the engagements of a second marriage, in violation of a former marriage-vow still subsisting. Bigamy, on the part of the man, has been tolerated in many states, before the establishment of Christianity, even by the Jews themselves; but it is prohibited by the precepts of the gospel, and it is punished by our law, whether on the part of the man, or of the woman, with the pains of perjury.

26. Incest, is committed by persons who stand within the degrees of kindred forbidden in Lev. xviii. and is punished capitally. The same degrees are prohibited in affinity, as in consanguinity, Lev. xvi. 13. et seq. As this crime is repugnant to nature, all children, whether lawful or natural, stand on an equal footing: Civis ratio civilia jura corrumpere potest, non vero naturalia. It is difficult indeed to bring a legal proof of a relation merely natural, on the side of the father; but the mother may be certainly known without marriage.

27. There is no explicit statute making rape, or the ravishing of women, capital; but it is plainly supposed in act 16 12, c. 4, by which the ravisher is exempted from the pains of death, only in the case of the woman's subsequent consent, or her declaration that she went off with him of her own free-will; and even then, he is to suffer an arbitrary punishment, either by imprisonment, confiscation of goods, or a pecuniary fine.

28. Theft is defined, a fraudulent intermeddling with the property of another, with a view of making gain. Our ancient law proportioned the punishment of the theft to the value of the goods stolen; heightening it gradually, from a flight corporal punishment to a capital, if the value amounted to thirty-two pennies Scots, which in the reign of David I. was the price of two sheep. In several later acts, it is taken for granted, that this crime is capital. But where the thing stolen is of small value, we consider it, not as theft, but as pickery, which is punished either corporally or by banishment. The breaking of orchards, and the cutting of green wood, is punished by a fine, which rises as the crime is repeated.

29. Theft may be aggravated into a capital crime, though the value of the thing stolen be trifling; as theft twice repeated, or committed in the night, or by landed men; or of things set apart for sacred uses. The receivers and concealers of stolen goods, knowing them to be such, suffer as thieves. Those who barely harbour the perfon of the criminal within forty-eight hours either before or after committing the crime, are punished as partakers of the theft. Such as sell goods belonging to thieves or lawless persons, and dare not themselves come to market, are punished with banishment and the escheat of moveables.

30. Theft attended with violence, is called robbery; and in our old statutes, rief or soughtrief, under which class may be included forning, or the taking of meat and drink by force, without paying for it, Stouthrief came

A
it is not punished capitally, but by farther than the private right of the parties.

concludes the cause, the perfon perjured is liable to a to call on God to attest a falsehood. Though an oath, tend performance when he swears, and so cannot be said intended by the swearer; and therefore reasonable allowances ought to be given to forgetfulness or misapprehension, according to his age, health, and other circumstances. The breach of a promissory oath does not infer this crime; for he who promises on oath, may sincerely intend performance when he swears, and so cannot be said to call on God to attest a falsehood. Though an oath, however false, if made upon reference in a civil question, concludes the cause, the person perjured is liable to a criminal trial; for the effect of the reference can go no farther than the private right of the parties.

35. Notwithstanding the mischiefous consequnces of perjury to society, it is not punished capitally, but by confiscation of moveables, imprisonment for a year, and

infamy. The court of Seffion is competent to perjury incidenter, when in any examination upon oath, taken in a cause depending before them, a person appears to have sworn falsely; but in the common cause, that trial is proper to the Julliciary. Subornation of perjury consists in tampering with persons who are to swear in judgment, by directing them how they are to depose; and it is punished with the pains of perjury.

36. The crime of seffionate, from seffio, includes every fraud which is not dilftinftlyd by a special name; but is chiefly applied to conveyances of the fame numerical right, granted by the proprietor to different disponees. The punishment of seffionate must necessarily be arbitrary, to adapt it to the various natures and different aggravations of the fraudulent acts. The perons guilty of that kind of it, which consists in granting double conveyances, are by our law declared infamous, and their lives and goods at the King's mercy. The cognizance of fraudulent bankruptcy is appropriated to the court of Seffion, who may inflict any punishment on the offender, that appears proportioned to his guilt, death excepted.

37. The crime of ufury, before the reformation, consihted in the taking of any interest for the use of money; and now in taking an higher rate of interest than is authorized by law. It is divided into usura manifesfa, or direct; and usura coverta, or covered. One may be guilty of the first kind, either where he covenants with the debtor for more than the lawful interest on the loan-money; or where one receives the interest of a sum before it is due, since thereby he takes a consideration for the use of money before the debtor has really got the use of it. Where a debt is clogged with an uncertain condition, by which the creditor runs the hazard of losing his sum, he may covenant for a higher interest than the legal, without the crime of usury; for there, the interest is not given merely in consideration of the use of the money, but of the danger undertaken by the creditor.

38. Covered usury, is that which is committed under the mask, not of a loan, but of some other contract; e.g. a fale, or an improper waflet. And in general, all obligations entered into with an intention of getting more than the legal interest for the use of money, however they may be disguised, are ufurious. As a farther guard against this crime, the taking more than the legal interest for the forbearance of payment of money, merchandise, or other commodities, by way of loan, exchange, or other contrivance whatever; or the taking a bribe for the loan of money, or for delaying its payment when lent, is declared usury. Where usury is proved, the usurious obligation is not only declared void, but the creditor, if he has received any unlawful profits, forfeits the treble value of the sums or goods lent. Ufury, when it is to be purged criminally, must be tried by the Julliciary; but where the libel concludes only for voiding the debt or restitution, the seffion is the proper court.

39. Injury, in its proper acceptation, is the reproaching or affronting our neighbour. Injuries are either verbal or real. A verbal injury, when directed against a private person, consists in the uttering contumelious words, which tend to expose our neighbour's character by making him little or ridiculous. It does not seem that the twit-
tong one with natural defects, without any farcical reflections, though it be inhuman, falls under this description, as thefie imply no real reproach in the juft opinion of mankind. Where the injurious expressions have a tendency to blacken one's moral character, or fix some particular guilt upon him, and are deliberately repeated in different companies, or handed about in whispers to confidents, it then grows up to the crime of slander: and where a perfon's moral character is thus attacked, the animus injuriandi is commonly inferred from the injurious words themselves, unless special circumstances be offered to take off the presumption; ex. gr. that the words were uttered in judgment in one's own defence, or by way of information to a magistrate, and had some foundation in fact. Though the cognizance of slander is proper to the commiffaries, who, as the judices Christi anni, are the only judges of scandal; yet for some time past, bare verbal injuries have been tried by other criminal judges, and even by the Seffion. It is punifhed either by a fine, proportioned to the condition of the persons injuring and injured, and the circumstances of time and place; or if the injury import scandal, by publicly acknowledging the offence; and frequently the two are conjoined. The calling one a bankrupt is not, in strict speech, a verbal injury, as it does not affeX

A W.

for any crime, without a warrant in writing expressing the caufe, and proceeding upon a subscribed information, unles in the cafe of indignities done to judges, riots, and the other offences specially mentioned in 1701, c. 6. Every prisoner committed in order to trial, if the crime of which he is accused be not capital, is entitled to be releafe upon bail, the extent of which is to be mo- dified by the judge, not exceeding 12000 merks Scots for a Nobleman, 6000 for a landed gentleman, 2000 for any other gentleman or burguf, and 600 for any other inferior perfon. That perfon who, either from the nature of the crime with which they are charged, or from their low circumstances, cannot procure bail, may not lie for ever in prifon untied, it is lawful to every fuch prifoners, to apply to the criminal judge, that his trial may be brought on. The judge muft, within twenty-four hours after fuch application, issue letters di- rected to magiftrates, for intimating to the prosecutor to fix a diet for the prifoner's trial, within forty days after the intimation, under the pain of wrongful imprisonment: And if the prosecutor does not infift within that time, or if the trial is not finifhed in forty days more, when carried on before the Jufticiary, or in thirty, when before any other judge; the prifoner is, upon a fecound application, fettling forth that the legal time is elapfed, entitled to his freedom, under the fame penalty.

42. No perfon can be imprifoned in order to afl Trim trial.
so served, and the day of appearance. When the trial proceeds upon criminal letters, the private prosecutor must give security, at raising the letters, that he will report them duly executed to the Justiciary, in terms of 1535, c. 35; and the defender, if he be not already in prisoù, is, by the letters, required to give caution, within a certain number of days after his citation, for his appearance upon the day fixed for his trial: and if he gives none within the days of the charge, he may be denounced rebel, which infers the forfeiture of his moveables.

45. That part of the indictment, or of the criminal letters, which contains the ground of the charge against the defender, and the nature or degree of the punishment he ought to suffer, is called the libel. All libels must proceed upon criminal letters, the private prosecutor.

46. The defender, in a criminal trial, may raise letters of excuseation, for citing witnesses in proof of his defences against the libel, or of his objections against any of the jury or witnesses; which must be executed, to the same day of appearance, with that of the indictment or criminal letters.

47. The diets of appearance, in the court of Justiciary, are peremptory: the criminal letters must be called on the very day to which the defender is cited; and hence, if no accuser appears, their effect is lost, infania perit, and new letters must be raised. If the libel, or any of the executions, fail to the prosecutor appear in form, or if he be deficient of the proof, from the abscinding of a necessary witness, the court will, upon a motion made by him, deset the diet pro loco et tempo; after which new letters become also necessary. A defender, who does not appear on the day to which he is cited, is declared fugitive; in consequence of which, his single ejectment falls. The defender, after his appearance in court, is called the pannel.

48. The two things to be chiefly regarded in a criminal libel, are, 1. The relevancy of the facts. i.e. their sufficiency to infer the conclusion; 2. Their truth. The consideration of the first belongs to the judge of the court; that of the other, to the jury or assize. If the facts labelled be found irrelevant, the pannel is dismissed from the bar; if relevant, the court remits the proof thereof to be determined by the jury; which must consist of 15 men picked out by the court from a greater number not exceeding 45, who have been all summoned, and given in lift to the defender at serving him with a copy of the libel.

49. Crimes cannot, like debts, be referred to the defender’s oath; for no person is compellable to swear against himself, where his life, limb, liberty, or estate is concerned, nor even in crimes which infer infancy; because one’s good name is, in right estimation, as valuable as his life. There is one exception however to this rule in trying the crime of usury, which may be proved by the usurer’s own oath, notwithstanding the rule, nemo tenetur jurare in suum turpitudinem. Crimes therefore are in the general cafe proveable only by the defender’s free confession, or by writing, or by witnesses. No extrajudicial confession, unless it is adhered to by the pannel in judgment, can be admitted as evidence.

50. All objections relevant against a witness in civil cafes, are also relevant in criminal. No witnesses is admitted, who may gain or lose by the event of the trial. Socii criminis, or associates in the same crime, are not admitted against one another, except either in crimes against the state, as treason; in occult crimes, where other witnesses cannot be had, as forgery; or in thefts or depredations committed in the Highlands. The testimony of the private party injured may be received against the pannel, where the King’s Advocate is the only prosecutor, if, from the nature of the crime, there must needs be a penury of witnesses, as in rape, robbery, &c.

51. After all the witnesses have been examined in court, the jury are shut up in a room by themselves, where they must continue, excluded from all correspondence, till their verdict or judgment be subscribed by the foreman (or chancellor), and clerk; and according to this verdict, the court pronounces sentence either abolishing or condemning. It is necessary, by the law of Scotland, that a jury should be unanimous in finding a person guilty; the narrowest majority is as sufficient against the pannel, as for him, Juries cannot be punished on account of an erroneous verdict, either for or against the pannel.

52. Though the proper business of a jury be to inquire into the truth of the facts found relevant by the court, for which reason they are sometimes called the inquest; yet, in many cases, they judge also in matters of law or relevancy. Thus, though an objection against a witness should be repelled by the court, the jury are under no necessity to give more credit to his testimony than they think just; and in all trials of art and part, where special facts are not labelled, the jury, if they return a general verdict, are indeed judges, not only of the truth, but of the relevancy of the facts that are sworn to by the witnesses. A general verdict, is that which finds, in general terms, that the pannel is guilty or not guilty, or that the libel or defences are proved or not proved. In a special verdict, the jury finds certain facts proved, the import of which is to be afterwards considered by the court.

53. Criminal judges must now suspend for some time, the execution of such sentences as affect life or limb, that condemned criminals, whose cases deserve favour, may have access to apply to the king for mercy. No sentence of any court of judicature, south of the river Forth, importing either death or disembarkation, can be executed in less than thirty days; and, if north of it, in less than forty days; after the date of the sentence. But corporal punishments, less than death or disembarkation, e.g. whipping, pillory, &c. may be inflicted eight days after sentence on this side Forth, and twelve days after sentence beyond it.

54. Crimes are extinguished, 1. By the death of the criminal; both because a dead person can make no defence, so that his trial is truly a judging upon the hearing
of one side; and because, though his guilt should be ever so notorious, he is after death carried beyond the reach of human penalties: Such trials therefore can have no effect, but to punish the innocent heir, contrary to that most equitable rule, culpa temt suo adoreret. 2. Crimes may be extinguished by a remission from the Sovereign. But a remission, though it secures the delinquent from the public resentment, the exercise of which belongs to the Crown, cannot cut off the party injured from his claim of damages, over which the Crown has no prerogative. Whoever therefore founds on a remission, is liable in damages to the private prosecutor, in the same manner, as if he had been tried and found guilty. Even general acts of indemnity passed in parliament, though they secure a against such penalties as law inflict upon the criminal, merely *per modum penae*, yet do not against the payment of any pecuniary fine, which is given by statute to the party injured, nor against the demand of any claim competent to him in name of damages.

55. Lesser injuries, which cannot be properly said to affect the public peace, may be extinguished, either by the private party's expressly forgiving them, or by his being reconciled to the offender, after receiving the injury. Hence arises the rule, *dissimulatione tollitur injuria*. But where the offence is of a higher nature, the party injured, though he may pass from the prosecution, in so far as his private interest is concerned, cannot preclude the King's Advocate, or Procurator-fiscal, from inflicting *ad vindictam publicam*.

56. Crimes are also extinguished by prescription, enter into the choir, nor are present at the chapters; nor do they make any other vow, except of confrancy and obedience. In nunneries, there are also lay-sisters.

**LAZ**

**LAYBURROWS**, in Scots Law. See Law, Tit. xxx. 16.

**LAWLESS COURT**, a court said to be held annually on King's hill, at Rochford, in Essex, on the Wednesday morning after Michaelmas day, at cock-crowing, where they whisper, and have no candle nor any pen and ink, but only a coal. Persons who owe suit, or service, and do not appear, forfeit their rent every hour they are missing.

This servile attendance, Camden informs us, was imposed on the tenants for conspiring at the like unseasonable time to raise a commotion. The court belongs to the honour of Raleigh, and to the earl of Warwick; and is called lawlesfs, from its being held at an unlawful hour.

**LAWN**, a spacious plain in a park, or adjoining to a noble seat.

**LAWSONIA**, in botany, a genus of the octandria monogynia class. The calyx consists of four segments, and the corolla of four petals; the stamina are disposed in pairs; and there are four capsules containing a great many seeds. There are two species, both natives of India.

**LAWYER** signifies a counsellor, or one that is learned or skilled in the law.

**LAY BROTHERS**, among the Romanists, those pious, but illiterate persons, who devote themselves, in some convent, to the service of the religious. They wear a different habit from that of the religious, but never which operates by the mere lapse of time, without any act, either of the Sovereign or of the private sufferer. Crimes prescribe in twenty years; but in particular crimes, the prescription is limited by statute to a shorter time. No person can be prosecuted upon the act against wrongful imprisonment, after three years. High treason, committed within his Majesty's dominions, suffers likewise a triennial prescription, if indictment be not found against the traitor within that time. All actions, brought upon any penal statute made or to be made, where the penalty is appropriated to the Crown, expire in two years after committing the offence; and where the penalty goes to the Crown or other persecutor, the persecutor must sue within one year, and the Crown within two years after the year ended. Certain crimes are, without the aid of any statute, extinguished by a shorter prescription than twenty years. By our old law, in the cafes of rape, robbery, and hame-suck, the party injured was not heard, after a silence of twenty four hours; from a presumption, that persons could not be so grossly injured, without immediately complaining; And it is probable, that a prosecution for these crimes, if delayed for any considerable time, would be cast even at this day, or at least the punishment restricted. Lesser injuries suffer also a short prescription; law presuming forgivenes, from the nature of the offence, and the silence of the party. The particular space of time sufficient to establish this presumption must be determined by the judge, according to circumstances.

**LAZULI**, or Lapis Lazuli, in natural history, one of the ores of copper, the basis of which is a crystalline matter, coloured with that elegant blue which copper gives to all alkaline liquors.

The
The lapis lazuli is found in many parts of the world; but that of Asia and Africa is much superior both in beauty and real value to the Bohemian and German kind, which is too often sold in its place.

Its great use, before the polishing as a gem, is the making the fine blue used in painting called ultramarine, which is obtained from it by calcination.

LEAD. See Chemistry, p. 84, 186.

LEAF, folium, in the natural history of plants. See Botany, feft. 2.

LEAF, in clocks and watches, an appellation given to the notches of their pinions. See Watch.

LEAGUE, a measure of length, containing more or less geometrical paces, according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, being a land-measure mostly peculiar to the French and Germans, contains three thousand geometrical paces, or three English miles.

League also denotes an alliance or confederacy between princes and states for their mutual aid, either in attacking some common enemy, or in defending themselves.

LEAK, among seamen, is a hole in the ship through which the water comes in. To spring a leak, is paid of a ship that begins to leak. To stop a leak, is to fill it with a plug wrapt in oakum and well tarr'd, or putting in a tarpawling clout to keep the water out; or nailing a piece of sheet-lead upon the place.

LEAKAGE, the rate of a vessel that leaks, or lets water or other liquid ouze in or out.

LEAKAGE, in commerce, is an allowance of 12 per cent. in the customs, allowed to importers of wines for the expense of keeping them in the custom-house till th'half of it is wasted: then put in an ounce of the finest lake, the like quantity of brazil in powder, one ounce of alum, and half an ounce of sal ammoniac; mix them well, and keep them stirring over a gentle fire about two hours; and so use the liquid part, to colour or tinge the skins.

To colour leather blue. Take one part of chalk, and another of wood-ashes, and make of them a good lye; then strain out the fine liquor, and let it in a vessel over the fire, and put into it turmeric in powder, and a little saffron; and let it simmer, till it becomes pretty thick; then let it be cooled, to be used as occasion requires.

To make white leather blue. Take a quart of elder-berries, strain the juice, and boil it with an ounce of powder of alum, and half an ounce of indigo, or small-blue, and bruht over the leather with a fine brush dipped in it three times, suffering it to dry between whiles, and the business will be effected.

To colour Spanish leather, &c. Take that which the Dutch call pomplemelch, warm it, and rub the leather with it; then take of Venice tot appelen; and having pounded it small, put a quantity of water to it, and let it oftent over a gentle fire; then press out the water, and rub or wash out the skin in it; repeating the same several times; and after that, take the finest shoemakers black, and rub the skin over with it, having in the melting added a little vitriol or copperas; and letting it dry, take goose or hog's grease, and with a woollen cloth rub the skin over for a good while, where there is a good fire to supple it, and afterwards rub it over with your hands, till it disappear; or instead of grease, you may use linseed or train-oil, and so in case of any other colour, according to the colours you design.

Dying of Leather.

A reddish colour. First wash the skins in water, and wring them out well, and afterwards wet them with a solution of tartar and bay-salt in fair water, and wring them out again; then to the former dissolution add ashes of crab-hells, and rub the skins very well with this; afterwards, wash them in common water, and wring them out; then wash them with tincture of madder in the solution of tartar and alum and the crab-shell ashes: and if they prove not red enough after all, wash them with the tincture of brazil.

A pure yellow. Take of fine aloes two ounces, of lineeed-oil four pounds; dissolve or melt; then strain the liquor, and befmake the skins with it, and being dry varnish them over.
An orange. Boil sweet-berry in alum water: but for a deep orange, use turmeric-root.

Blue. Boil elder-berries, or dwarf elder, in water; then simmer or wash the skins with it; wring them out; then boil the berries as before in a solution of alum water, and wet the skins in the same water once or twice; dry them, and they will be very blue.

A pure blue colour. For each skin take indigo one ounce; put it into boiling water, let it stand one hour; then warm it a little, and with a brush-pencil before the skin twice over.

Purple. Dissolve red-alum in warm water, wet the skins with it, dry them; then boil rasper brazil well in water; let it stand to cool: do this three times, and afterwards rub the dye over the skins with your hand; and when they are dry, polish them.

Green. Take sap-green and alum-water, of each a sufficient quantity; mix and boil them a little; if you would have the colour darker, add a little indigo.

Proeesses for dying Leather Red and Yellow, as practised in Turkey; with directions for preparing and tanning the skins, as communicated by Mr Philippo, a native of Armenia, who received from the Society for the Encouragement of Arts, &c. one hundred pounds, and also the gold medal of the Society, as a reward for discovering this secret.

1. First preparation of the skins, both for Red and Yellow Leather, by dressing them in lime. Let the skins, drenched with the lime, be first laid to soak in clean water for three days; let them then be broken over the flesh side, put into fresh water for two days longer, and afterwards hung up to drain half an hour. Let them now be broken again on the flesh side, limed in cold lime on the same side, and doubled together with the grain side outward. In this state they must be hung up within doors over a frame for five or six days, till the hair be loose; which must be then taken off, and the skins returned into the lime-pit, for about three weeks. Take them out, and let them be well worked flesh and grain, every fifth or seventh day during that time: after which, let them be washed ten times in clear water, changing the water at each washing. They are next to be prepared in drench, as below mentioned.

2. Second preparation of the skins; for both the Red and Yellow Dyer by drenching. After squeezing the water out of the skins, put them into a mixture of bran and water, warm as new milk, in the following proportions, viz. about three pounds of bran for five skins, and water sufficient to make the mixture moderately fluid, which will be about a gallon to each pound of bran. In this drench let the skins lie three days; at the end of which time they must be well worked, and afterwards returned into the drench two days longer. They must then be taken out and rubbed between the hands; the water squeezed from them, and the bran scraped off clear from both sides of the skins. After this they must be again walked ten times in clear water, and the water squeezed out of them. Thus far the preparatory process of all the skins, whether intended to be dyed red or yellow, is the same; but afterwards those which are to be dyed red, must be treated as follows.

3. Preparation in honey and bran of the skins that are to be dyed red. Mix one pound of honey with three pints of luke-warm water, and stir them together till the honey is dissolved. Then add two double handfuls of bran; and taking four skins (for which the above quantity of the mixture will be sufficient) work them well in it one after another. Afterwards fold up each skin separately into a round form, with the flesh side inwards, and lay them in an earthen pan, or other proper vessel; if in the summer, by the side of each other; but in the winter, on the top of each other. Place the vessel in a sloping position, so that such part of the fluid as may spontaneously drain from the skins, may drain from them. An acid fermentation will then rise in the liquor, and the skins will swell considerably. In this state they must continue for seven or eight days; but the moisture that drains from them, must be poured off, once or twice a day, as occasion may require. After this a further preparation in salt is necessary; and which must be performed in the following manner.

4. Preparation in salt, of the skins to be dyed red. After the skins have been fermented in the honey and bran, as abovementioned, let them be taken out of that mixture on the eighth or ninth day, and well rubbed with dry common sea-salt, in the proportion of about half a pound to each skin; the salt must be well rubbed and worked with them. This will make them contract again, and part with a further considerable quantity of moisture; which must be squeezed out by drawing each skin separately through the hands. They must next be feraped clean on both sides from the bran, superfluous salt, and moisture that may adhere to them. After which, dry salt must be brushed over the grain side, and well rubbed in with the hands. They are then to be doubled with the flesh side outwards, lengthways from neck to tail, and a little more dry salt must be thinly brushed over the flesh side, and rubbed in; for the two last operations about a pound and a half of salt will be sufficient for each skin. They must then be put, thus folded on each other, between two clean boards, placed sloping, breadths ways; and a heavy weight laid on the upper board, in order gradually to press out what moisture they will thus part with. In this state of pressure, they must be continued two days or longer, till it is convenient to dye them, for which they will then be duly prepared.

5. Preparation of the Red Dye, in a proper proportion for four skins. Put eight gallons of water into a copper, with seven ounces of Shenan *, tied up in a linen bag.

Light * Shenan is a drug much used by dyers in the East; and may easily be procured at any of the ports of Syria and Africa, in the Levant. It is the Eastern jointed calli, called by botanists felicornia; and grows in great plenty in those and other parts of the East. There is a smaller species of the felicornia on our coast, which, from its great affinity with the Shenan, might be presumed to have the same qualities. On some trials, however, it has not appeared to answer the intention
Light a fire under a copper, and when the water has boil-
ed about a quarter of an hour, take out the bag of shenan,
and put into the boiling fluid or lixivium, 1½, two drams
of alum; 2dly, two drams of pomegranate bark; 3dly
three quarters of an ounce of turmeric; 4thly, three
ounces of cochineal; 5thly, two ounces of loaf sugar.
Let the whole mixture boil about five minutes, then cover
the fire, and take out a quart of liquor, putting it into a
flat earthen pan; and when it is as cold as new milk,
take one skin, folded lengthways, the skin side outwards,
and dip it in the liquor, rubbing it gently with the hands.
Then taking out the skin, hang it up to drain, and throw
away the superfluous dye. Proceed in the same manner
with the remaining three skins; repeating the operation
on each skin separately, eight times, squeezing the skins
by drawing them through the hands before each fresh dipp-
ing. Lay them now on one side of a large pan, let slop-
ing, to drain off as much of the moisture as will run from
them without pressure, for about two hours, or till they
are cold; then tan them as below directed.

6. Tanning the Red Skins. Powder four ounces of
the white galls, finely powdered, with two quarts of clean
water. The skins are then to be separately doubled
lengthways; rolled up with the flesh side outwards, laid
in the mixture, and close pressed down on each other,
in which state they must continue two whole days. On
the third day let them be again worked in the tan; and
afterwards scraped clean from the galls, with an ivory or
brass instrument (for no iron must touch them.) They
must then be put into a fresh tan, made of two pounds of
galls finely powdered, with about three quarts of water,
and well worked therein fifteen times. After this they
must be doubled, rolled up as before, and laid in the se-
cond tan for three days. On the third day a quarter of
a pound of white sea-salt must be worked into each skin;
and the skins doubled up as before, and returned into the
tan, till the day following, when they are to be taken
out, and well washed six times in cold water; and four
times in water lukewarm. The water must be then well
squeezed out, by laying the skins under pressure, for a
half hour an hour, between two boards, with a weight
of about two or three hundred pounds laid upon the up
permolt board, when they will be ready for the dye.

9. Preparation of the Yellow Dye, in the proper pro-
portion for four skins. Mix fix ounces of cajiari gehira*,
or dgehira, or the berries of the eastern rhamnus, with
the same quantity of alum, and pound them together till
they be fine, in a marble or brass mortar, with a brass
pebble. Then dividing the materials thus powdered,
to three equal parts of four ounces each, put one of
those three parts into about a pint and a half of water, in
a china or earthen vessel; and stir the mixture together.
Let the fluid stand to cool, till it will not scald the hand.
Then spreading one of the skins flat on a table, in a warm
room, with the grain side up, pour a fourth part
of the tinting liquor, prepared as above directed, over
the upper or grain side, spreading it equally over the skin
with the hand, and rubbing it well in. Afterwards do
the like with the other three skins, for which the mixture
first made will be sufficient.

This operation must be repeated twice more on each skin
separately, with the remaining eight ounces of the powder
of the berries, and alum, with the abovementioned due
proportions of hot water, put to them as before directed.
The skins, when dyed, are then to be hung up against a wooden
frame, without being folded, with the grain side out-
wards, about three quarters of an hour to drain, when
they must be carried to a river or stream of running water,
and well washed therein six times or more. After this,
they must be put under pressure for about an hour, till
the water be well squeezed out; afterwards the skins must
be hung up to dry in a warm room.

This being done, the skins are to be dressed and grained
as before directed for those dyed red; except the oiling,
which must be omitted.

Gilding
Gilding of Leather. Take plain of the whites of eggs, or gum-water, and with a brush rub over the leather with either of them; then lay on the gold or silver, and letting them dry, burnish them. See the articles Gilding and Burnishing.

To dress or cover leather with silver or gold. Take brown red, grind or move it on a stone with a muller, adding water and chalk; and when the latter is dissolved, rub, or lightly dawb the leather over with it, till it looks a little whitish; and then lay on the leaf, silver or gold, before the leather is quite dry, laying the leaves a little over each other, that there may not be the leaf part uncovered; and when they have well clofed with the leather, and are sufficiently dried on, and hardened, rub them over with an ivory polisher, or the fore-tooth of a horse.

LEAF, a piece of four dough, used to ferment and render light a much larger quantity of dough or paste.

LECHEA, in botany, a genus of the triandria trigynia class. The calix consists of three leaves, and the corolla of three linear petals; and the capsule is three, with three valves, and one seed. There are two species, both natives of Canada.

LECTICA, in Roman antiquity, a vehicle in which people were carried in a reclining posture.

LECTISTERNIUM, a religious feast or banquet of the ancient Romans. In times of public danger or calamity, or of thanksgiving for some happy event, the republic ordered solemn feasts to be made for the gods; and this solemnity was called lecisternium, because on this occasion they spread tables, and placed beds around them, on which their heavenly guests were to lie and eat.

LECTURERS, in England, are an order of preachers in parish-churches, distinct from the rector or vicar. They are chosen by the vestry, or chief inhabitants of the parish, and are usually the afternoon preachers.

LEDSEA, a large market town, in the west riding of York, twenty miles west of York; it has a very great woolen trade.

LEEDS, a large market town, in the west riding of Yorkshire, situated on the river Aire, twenty miles south-west of Leeds. See AYLIUM.

LEERDAM, a town in the province of Holland, seven miles north-east of Dort: E. long. 5°, N. lat. 51° 50'.

LEERWICK, a town of Scotland, in Mainland, one of the islands of Shetland, in the county of Orkney: W. long. 30', N. lat. 61° 20'.

LEES, are the more gross and ponderous parts of liquors, which, being separated by fermentation, fall to the bottom.

LEET, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the Crown, from whence it is derived to inferior persons.

LEEWARD, at sea, the side opposite to that on which the wind blows.

LEEWARD-ISLANDS, in America, a name given to the Caribbees.

LEG, in anatomy. See Anatomy, Part I. and II. &c.

LEGACY, in Scots law, a donation by one person to another, to be paid by the giver's executor after his death. See Law, Tit. xxviii. 3.

LEGATEE, in Scots law, the person to whom a legacy is provided.

LEGATE, a cardinal or bishop, whom the pope sends as his ambassador to sovereign princes.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGEND, any idle or ridiculous story told by the Romans concerning their saints, and other persons, in order to support the credit of their religion.

The legend was originally a book used in the old Roman churches, containing the stories to be read at divine service; hence the lives of the saints and martyrs came to be called legends, because chapters were read out of them at matins, and in the refectories of religious houses. Among thefe the golden legend, which is a collection of the lives of the saints, was received by the church with great applause, which it maintained for two hundred years; though it is full of ridiculous and romantic fancies, that the Romans themselves are now ashamed of it.

LEGER-LINE, in music, one added to the staff of five lines, when the ascending or descending notes run very high or low; there are sometimes many of these lines both above and below the staff, to the number of four or five.

LEGGIARDO, or Leggiardamente, in music, signifies to play or sing in a lively, brisk, and gay manner.

LEGHORN, or Livorno, a port town of Italy, in the duchy of Tuscany, situated on the Tuscany sea, forty miles west of Florence: E. long. 11°, N. lat. 43° 20'.

LEGION, in Roman antiquity, a body of foot which consisted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thousand; though Plutarch affores
LEGISLATOR, a law giver, or person who establishes the polity and laws of a state. Such was Moses, among the Jews; Lycurgus, among the Lacedæmonians, &c.

LEGITIMATION, an act whereby illegitimate children are rendered legitimate.

LEGITIME, in Scots law, that share of the moveable effects belonging to a husband and wife, which upon the husband’s death falls to the children. See Law, Tit. xxviii. 5.

LEGUME. See Botany, p. 637.

LEGUMINOUS, an appellation given to all plants whose fruit is a legume.

LEICESTER, the county-town of Leicestershire. It sends two members to parliament. W. long. 1° 5’, and N. lat. 52° 40’.

LEMINGEN, a town of Germany, seventeen miles south of Worms.

LEINSTE, a province of Ireland, the capital of which is Dublin.

LEIPSIC, a rich and populous city of Germany, in the circle of Upper Saxony and province of Misnia: E. long. 12° 40’, N. lat. 51° 20’.

LEITH, a port-town of Scotland, about two miles north of Edinburgh.

LEMBOURG, Leopolis, a city of Poland, and capital of the province of Red Russia: E. long. 24°, N. lat. 49°.

LEMA, in mathematics, a proposition which serves previously to prepare the way for the more easy apprehension of the demonstration of some theorem, or construction of some problem.

LEMA, in botany, a genus of the monoeia diandria clafs. The calix of both male and female confils of one leaf; neither of them have any corolla; the female has one styulus, and the capule consis of one cell. There are four species, three of which are natives of Britain, viz. the trifulca, or ivy-leaved duck’s-meat; the minor, or leaf duck’s meat; and the pyriform, or greater duck’s-meat.

LENNOS, an iland of the Archipelago, situated forty-miles south-west of the entrance of the Hellefpond: E. lon. 26°, N. lat. 29°.

LEMON, in botany. See Citrus.

LEMONADE, a liquor prepared of water, sugar, and lemon or citron juice: it is very cooling and grateful.

LEMUR, in zoology, a genus of quadrupeds belonging to the order of primates, which are these: There are four fore-teeth in the upper jaw, the intermediate ones being remote; and six long, compressed, parallel teeth in the under jaw; the dog-teeth are folitary, and the grinders are somewhat labiated. There are five species, viz.

Vol. II. No. 67.

LEN (965)

LENS, in dioptics, properly signifies a small roundish glafs, of the figure of a lentil; but is extended to any optic glafs, not very thick, which either collects the rays of light into a point, in their passage through it,
or disperses them further apart, according to the laws of refraction. See Optics.

LENT, a solemn time of fasting in the Christian church, observed as a time of humiliation before Easter, the great festival of our Saviour's resurrection.

Those of the Roman church, and some of the Protestant communion, maintain, that it was always a fast of forty days, and, as such, of apostolical institution. Others think it was only of ecclesiastical institution, and that it was variously observed in different churches, and grew by degrees from a fast of forty hours, to a fast of forty days. This is the sentiment of Morton, bishop Taylor, du Maulin, Daillee, and others.

LEPTISCUS, in botany. See PISTACIA.

LEO, in zoology. See Felis.

LEO, in astronomy. See ASTRONOMY, p. 467.

ST. LEO, a town and bishop's see of Italy, twenty miles north-west of Urbino.

LEON, the capital of the province of Leon, in Spain, situated on the river Esla: W. long. 6° 5', N. lat. 43°.

Leon is also the capital of the province of Nicaragua, in Mexico, situated at the west end of the Lake Nicaragua: W. long. 91°, N. lat. 11° 30'.

ST. LEONARD, a town of France, in the province of Guiennes, and territory of Limousin: E. long. 1° 45', N. lat. 45° 50'.

ST. LEONHART, a town of Germany, in the circle of Austria, and duchy of Carinthia: E. long. 15°, N. lat. 47°.

LEONTICE, in botany, a genus of the hexandria monogynia class. The corolla consists of six petals, and the nectarium of six leaves inserted into the unguis of the corolla, and having an open limbus; and the calyx has six deciduous leaves. There are four species, none of them natives of Britain.

LEONTINI, a town of Sicily, twenty miles north-west of Syracuse.

LEONTODON, in botany, a genus of the fyngeena polygama equalis class. The receptacle is naked; the calyx is calcinated; the pappus is simple; and the floeulci are in a simple series. There are nine species, three of them natives of Britain, viz. the taraxacum, or dandelion; the dittander, or rough dandelion; and the amemnale, or yellow devil's-bit. The root of the taraxacum is esteemed a good cathartic.

LEONURUS, LION'S TAIL, in botany, a genus of the didynamia gymnosperma class. The anthers are interferred with thinning glands. There are five species, only one of them, viz. the cardiaeca, or mother-wort, is a native of Britain.

LEOPARD. See Felis.

LEOPARD'S BANE, in botany. See DORONICUM.

LEPANTO, a port-town of European Turkey, eighty miles west of the Isthmus of Corinth; whence the golph of Lepanto takes its name.

LEPASTRUM, in natural history, a genus of felenite, comporte of plates disposed in the form of a radiated star.

LEPIDIUM, in botany, a genus of the tetradyamnia filiculafa class. The pod is margined, cordated, and contains many seeds. There are 17 species, three of them natives of Britain, viz. the latifolium, or dittander; the runderale, narrow-leaved wild cerefs, or dittander; and the petrseum, or mountain dittander.

LEPIDOPTERA, in zoology, an order of insects, composed of four wings, which are covered with imbricated squamae. See Natural History.

LEPIUM, in natural history, a genus of fossils of the harder gypsum, composed of very small particles, and of a less glittering hue.

There is only one species of this genus, being one of the least valuable and most impure of the class of gypsums. It is of an extremely rude, irregular, coarse and uneven structure; a little soft to the touch, of a very dull appearance, and of different degrees of a greyish white. It is burnt in plaster for the coarser works; it calcines very slowly and unequally, and makes but a very coarse and ordinary plaster.

LEPROSY, a foul cutaneous disease, appearing in dry, white, thin, scurfy lesions, either on the whole body, or only some part of it, and usually attended with a violent itching and other pains. See Medicine.

LEPTODECORHOMBES, in natural history, a genus of fossils of the order of the felenitae; consisting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

Of this genus there are only five known species. 1. A thin, fine, pellucid, and slender streaked one, with transversus ftrize, found in considerable quantities in the strata of clay in most parts of England, particularly near Haddington in Oxfordshire. 2. A thin, dull-looking opaque, and slender streaked one, more scarce than the former, and found principally in Leicestershire and Staffordshire. 3. A thin fine streaked one, with longitudinal ftrize, found in the clay-pits at Richmond; and generally lying at great depths. This has often on its top and bottom a very elegant smaller rhomboide, described by four regular lines. 4. A rough kind, with thick transversae ftrize, and a scabrous surface, very common in Leicestershire and Yorkshire. And, 5. A very short kind, with thick plates, common in the clay-pits of Northamptonshire and Yorkshire.

LEPTOPOLYGINGLIMI, in Natural History, a genus of fossils of the order of the felenitae; consiting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

LEPTODEROCORHOMBES, in natural history, a genus of fossils of the order of the felenitae; consisting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

LEPTOPOLYRINGLIMI, in Natural History, a genus of fossils of the order of the felenitae; consisting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

LEPTOPOLYRINGLIMI, in Natural History, a genus of fossils of the order of the felenitae; consisting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

LEPTOPOLYRINGLIMI, in Natural History, a genus of fossils of the order of the felenitae; consisting of ten planes, each so nearly equal to that opposite to it as to make but a very coarse and ordinary plaster.

LEP (967) LER

the nostrils; the length of the body is generally about a foot and a half; and the colour of the hair is reddish, int rippled with white. The hare is naturally a timid animal. He sleeps in his form, or seat, during the day, and feeds, copulates, &c. in the night. In a moon-light evening, a number of them are sometimes seen sporting together, leaping and pursuing each other: But the least motion, the falling of a leaf, alarms them; and then they all run off separately, each taking a different route. They are extremely swift in their motion, which is a kind of gallop, or a succession of quick leaps. When pursued, they always take to the higher grounds: as their fore feet are much shorter than the hind ones, they run with more ease up hill than down hill. The hare is endowed with all those instincts which are necessary for his own preservation. In winter he changes a form exposed to the south, and in summer to the north. He conceals himself among vegetables of the same colour with himself. Mr. Pouilloux says, that he observed a hare, as soon as he heard the sound of the horn, or the noise of the dogs, although at a mile's distance, rise from her seat, swim across a rivulet, then lie down among the rushes, and by this means evade the scent of the dogs. After being chased for a couple of hours, a hare will sometimes pull another from his form, and lie down in it himself. When hard pressed, the hare will mingle with a flock of sheep, run up an old wall and conceal himself among the grubs on the top of it, or cross a river severally times at small distances. He never runs against the wind, or straight forward; but constantly doubles about, in order to make the dogs lose their scent.

It is remarkable, that the hare, although ever so frequently pursued by the dogs, seldom leaves the place where she was brought forth, or even the form in which she usually is. It is common to find them in the same place next day, after being long and keenly chased the day before. The females are more grosfs than the males, and have less strength and agility; they are likewise more timid, and never allow the dogs to approach so near their form before rifing as the males. They likewise practice more arts, and double more frequently, than the males.

The hare is diffused almost over every climate; and, notwithstanding they are everywhere hunted, their species never diminishes. They are in a condition of propagating the first year of their lives; the females go with young about 30 days, and produce four or five at a time; and as soon as they have brought forth, they again admit the embraces of the male; so that they may be said to be always pregnant. The eyes of the young are open at birth; the mother suckles them about 20 days, after which they separate from her and procure their own food. The young never go far from the place where they were brought forth; but still they live solitary, and make forms about thirty paces distant from each other: Thus, if a young hare be found any where, you may almost be certain of finding several others within a very small distance. The hare is not so savage as his manners would indicate. He is gentle, and susceptible of a kind of education. He is pretty easily tamed, and will even show a kind of attachment to the people of the house: But still this attachment is not so strong or lasting as to engage him to become altogether domestic; for although taken when very young, and brought up in the house, he no sooner arrives at a certain age, than he takes the first opportunity of recovering his liberty and flying to the fields. The hare lives about seven or eight years. He feeds upon grass, and other vegetables. His flesh is excellent food. See Plate CIII. fig. 2.

2. The culmiculus, or rabbit, has a very short tail, and naked ears. The rabbit, though it has a great resemblance to the hare, is very different in his manners; and they have such a rooted antipathy to one another, that no art can engage them to have any sexual intercourse. The fecundity of the rabbit is still greater than that of the hare; they multiply so prodigiously in some countries, that the product of the hedges is hardly sufficient to maintain them. They devour herbage of all kinds, roots, grain, fruits, &c. They are in a condition for producing at the age of six months; like the hare, the female is almost constantly in season; she goes with young about 30 days, and brings forth from four to eight at a litter. A few days before littering, she digs a new hole in the earth, not in a straight line, but in a zigzag form; the bottom of the hole she enlarges every way; she then pulls off a great quantity of hair from her belly, of which she makes a kind of bed for her young. During the two first days after birth, she never leaves them, but when pressed with hunger, and then she eats quickly and returns: In this manner she fuckles and attends her young for six weeks. All this time, both the hole and the young are concealed from the male; sometimes when the female goes out, in order to deceive the male, she fills up the mouth of the hole with earth mixed with her own urine. But when the young ones begin to come to the mouth of the hole, and to eat such herbs as the mother brings to them, the father seems to know them; he takes them between his paws, smooths their hair, and cares for them with great fondness. The rabbit is supposed not to be a native of the northern parts of Europe, but to have been originally brought from Greece and Spain. The rabbit lives about seven years, and his flesh is good. Their colour is various, some of them being red, others white, but the most general colour is grey. See Plate CIII. fig. 3.

3. The capensis, has a tail about the length of his head, and red legs. It is a native of the Cape of Good Hope.

4. The brasiliensis has no tail. It is found in South America.

LEPFUS, in astronomy. See Astronomy, p. 487.

LERIA, a city and bishop's see of Portugal: W. long. 9° 15', and N. lat. 39° 30'.

LERIDA, a city and bishop's see of Catalonia in Spain: E. long. 5', N. lat. 41° 20'.

LERINS, two islands on the coast of Provence, five or six miles south of Antibes, called St. Margaret and St. Honorat.

LERNEA, the Sea-hare*, in zoology, a sea-insect of the order of the gymnarthria, the body of which is of an oblong cylindrical figure, and is perforated in the forehead; the tentacula resemble ears. See Gymnarthria.
LE ROY LE VEUT, the king's affent to public bills. See the articles BILL, STATUTE, and PARLIAMENT.

LESBOIS, or METELIN, an island of the Archipelago, sixty miles north-west of Smyrna. Its chief town is Callao.

LESCAR, a city and bisho. p's fee of France, forty miles east of Bayonne.

LESCARD, a borough-town of Cornwall, fifteen miles west of Launceston, which sends two members to parliament.

LESSINES, a town of the Austrian Netherlands, fourteen miles north of Mons.

LESTWITHIEL, a borough-town of Cornwall, twenty-three miles south-west of Launceston, which sends two members to parliament.

LETHERGY, in medicine. See MEDECINE.

LETHALIS, in the ancient mythology, one of the rivers of Hades, having, according to poetical fiction, the peculiar quality of making those who drank of them forget every thing that was past.

LETRIM, or LEITRIM, a county of Ireland, in the province of Connaught; bounded by Fermanagh on the north, by Cavan on the east, by Roscommon on the south, and by Sligo on the west.

LETTER, a character used to express one of the simple sounds of the voice; and as the different simple sounds are expressed by different letters, these, by being differently compounded, become the visible signs or characters of all the modulations and mixtures of sounds used to express our ideas in a regular language.

LETTER, in law, is a writing by which one person authorizes another to do some lawful act in his stead; as, to give seizin of lands, to receive debts, sue a third person, &c.

The nature of this instrument is to transfer to the person to whom it is given, the whole power of the maker, to enable him to accomplish the act intended to be performed. It is either general or special; and sometimes it is made revocable, which is when a bare authority is only given; and sometimes it is irrevocable, as where debts, &c. are assigned from one person to another. It is generally held, that the power granted to the attorney must be strictly purfued; and that where it is made to three persons, two cannot execute it. In most cases, the power given by a letter of attorney determines upon the death of the person who gave it. No letter of attorney made by any seaman, &c. in any ship of war, or having letters of marque, or by their executors, &c. in order to empower any person to receive any share of prizes, or bounty-money, shall be valid, unless the same be made revocable, and for the use of such seamen, and be signed and executed before, and attested by, the captain and other of the signing officers of the ship, or the mayor or chief magistrate of some corporation.

LETTER of war, or marque, a letter granted to one of the king's subjects, under the privy seal, empowering him to make reprisals for what was formerly taken from him by the subjects of another state contrary to the law of mart. See the article MARQUE.

LETTERS-PATENT, arc writings sealed with the great seal; so called, because they are open, with the seal affixed to them. These are granted to authorize a man to do or enjoy what of himself he could not do.

LETTUCE, in botany. See LACTUC.

LEVANT, a name given to the east part of the Mediterranean sea, bounded by Natolia or the lesser Asia on the north, by Syria and Palestine on the east, by Egypt and Barca on the south, and by the island of Candia and the other part of the Mediterranean on the west.

LEVATOR, in anatomy, a name given to several muscles. See ANATOMY, Part II.

LEUCADENDRON, in botany, a genus of the tetrandria monogynia class. The flower has two petals, one of them being divided into segments; the receptacle is somewhat hairy; it has no proper calyx; and the anthers are joined together. There are 15 species, none of them natives of Britain.

LEUCOCOUM, the great snow-drop, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped, and divided into six segments; and the stigma is simple. There are three species, none of them natives of Britain.

LEUCOMA, in surgery, a distemper of the eye, otherwife called albugo. See ALBUGO and MEDECINE.

LEUCOPHLEGMA, in medicine, a kind of dropsy, otherwise called anusarca. See ANASARCA and MEDICINE.

LEVEL, an instrument wherewith to draw a line parallel to the horizon, by means of which the true level, or the difference of ascent or descent between several places, may be found for conveying water, draining lands, &c.

There are several instruments of different contrivance and matter, invented for the perfection of leveling; all of which, for the practice, may be reduced to those that follow.

Air Level, that which shews the line of level by means of a bubble or air inclosed with some liquor in a glass-tube of an indeterminate length and thickness, whose two ends are hermetically sealed. When the bubble fixes itself at a certain mark, made exactly in the middle of the tube, the plane or ruler wherein it is fixed is level. When it is not level, the bubble will rise to one end. This glass-tube may be set in another of brass, having an aperture in the middle, whence the bubble of air may be observed. The liquor where-with the tube is filled, is oil of tartar, or aqua secundana; those not being liable to freeze as common water, nor to rarefaction and condensation, as spirit of wine is. There is one of these instruments with sights, being an improvement upon that last described, which, by the addition of more apparatus, becomes more commodious and exact. It consists of an air level, (see Plate CIV, fig. 1.) n° 1. about eight inches long, and seven or eight lines in diameter, set in a brass-tube.
2. with an aperture in the middle, C. The tubes are carried in a strong straight ruler, a foot long; at whose ends are fixed two sights, 3, 3, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass crossing each other at right angles; in the middle whereof is drilled a very little hole, through which a point on a level with the instrument is defcribed. The brass-tube is fastened on the ruler by means of two screws, one whereof, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards a level. The top of the ball and socket is rivetted to a little ruler that springs, one end whereof is fastened with screws to the great ruler, and at the other end has a screw, 5, serving to raise and depress the instrument when nearly level.

This instrument, however, is yet less commodious than the following one; because though the holes be ever so small, yet they will still take in too great a space to determine the point of level precisely.

This instrument consists of an air level, with telescope sights: this level (ibid. n° 2.) is like the last, with this difference, that instead of plain sights, it carries a telescope to determine exactly a point of level at a good distance. The telescope is a little brass-tube, about fifteen inches long, fastened on the same ruler as the level. At the end of the tube of the telescope, marked 1, enters the little tube 1, carrying the eye-glass and an hair horizontally placed in the focus of the object-glass, 2; which little tube may be drawn out, or pushed into the great one, for adjusting the telescope to different sights: at the other end of the telescope is placed the object-glass. The screw 3, is for raising or lowering the little fork, for carrying the hair, and making it agree with the bubble of air, when the instrument is level; and the screw 4, is for making the bubble of air, D or E, agree with the telescope: the whole is fitted to a ball and socket. M. Huygens is said to be the first inventor of this level, which has this advantage, that it may be inverted by turning the ruler and telescope half round; and if then the hair cut the same point that it did before, the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying it upon or parallel to the base or ruler, when there is occasion to take the level of remote objects.

Dr Defagullers contrived an instrument, by which the difference of level of two places, which could not be taken in less than four or five days with the bell telescope-levels, may be taken in as few hours. The instrument is as follows: to the ball C (ibid. n° 3.) is joined a recurve tube B A, with a very fine bore, and a small bubble at top, A, whose upper part is open. It is evident from the make of this instrument, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and tube when the instrument is set upright. If the air at C, be so expanded with heat, as to drive the liquor to the top of the tube, the cavity A will receive the liquor, which will come down again and settle at D, or near it, according to the level of the place where the instrument is, as soon as the air at C returns to the same temperatrum as to heat and cold. To preserve the same degree of heat, when the different observations are made, the machine is fixed in a tin vessel E F, filled with water up to g h, above the ball, and a very sensible thermometer has also its ball under water, than one may observe the liquor at D, in each experiment, when the thermometer stands at the same height as before. The water is poured out when the instrument is carried, which one may do conveniently by means of the wooden frame, which is set upright by the three screws S, S, S, ibid. n° 4. and a line and plummet P, n° 5. At the back part of the wooden frame, from the piece at top K, hangs the plummet P, over a brass point at N ; M m are brackets, to make the upright board K N continue at right angles with the horizontal one at N. N° 6, represents a front view of the machine, supposing the fore part of the tin-vessel transparent; and here the brassocket of the recurve tube, into which the ball is screwfed, has two wings at I I, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge when the water is poured in as high as g h.

After the Dr had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball at A, n° 3, in carrying the instrument from one place to another, some of it would adhere to the sides or the ball A, and upon its deficient in making the experiment, so much might be left behind, that the liquor would not be high enough at D, to shew the difference of the level; therefore, to prevent that inconvienency, he contrived a blank screw, to shut up the hole at A, as soon as one experiment is made, that in carrying the machine, the air in A may balance that in C, so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument, in going from one place to another. Now, because one experiment may be made in the morning, the water may be so cold, that when a second experiment is made at noon the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time before it comes to be as cold as it is likely to be at the warmest part of that day, observe and set down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at D; then screw on the cape at A, pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometer is come to the same degree as before, open the screw at top, and observe the liquor in the barometer.

The doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each, tenth of an inch answering to a foot in height. The Dr made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains, (though with a proper allowance for the decreasing density of the air, it will do very well,) but for heights that want to be known in gardens, plantations, and the conveyance of water, where an experiment that answers two or three feet in a distance of twenty miles, will render this a very useful instrument.
Artillery Foot-Level is in form of a square, having its two legs or branches of an equal length; at a juncture whereof is a little hole, whence hangs a thread and plummet playing on a perpendicular line in the middle of a quadrant. It is divided into twice 45 degrees from the middle, *ibid.* n° 7.

This instrument may be used on other occasions, by placing the ends of its two branches on a plane; for when the thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level. To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height, by means of the plummet, whose thread will give the degree above the level.

Carpenters and Paviour’s Level, consists of a long ruler, in the middle whereof is fitted, at right angles, another somewhat bigger, at the top of which is fastened a line, which, when it hangs over a fiducial line at right angles with the base, shows that the said base is horizontal. Sometimes this level is all of one board. *Ibid.* n° 8.

Gunner’s Level, for levelling cannons and mortars, consists of a triangular brass-plate, about four inches high, *ibid.* 9. at the bottom of which is a portion of a circle, divided into 45 degrees; which number is sufficient for the highest elevation of cannons and mortars, and for giving shot the greatest range: on the center of this segment of a circle is screwed a piece of brass, by means of which it may be fixed or screwed at pleasure; the end of this piece of brass is made so as to serve for a plummet and index, in order to show the different degrees of elevation of pieces of artillery. This instrument has also a brass-foot, to set upon cannons or mortars, so, as when those pieces are horizontal, the instrument will be perpendicular. The foot of this instrument is to be placed on the piece to be elevated, in such a manner, as that the point of the plummet may fall on the proper degree: this is what they call levelling the piece.

Mason’s Level, is composed of three rules, so joined as to form an isosceles-rectangle, somewhat like a Roman A; at the vertex whereof is fastened a thread, from which hangs a plummet, that passes over a fiducial line, marked in the middle of the base, when the thing to which the level is applied is horizontal; but declines from the mark, when the thing is lower on one side than on the other.

Plumb, or Pendulum-Level, that which shows the horizontal lines by means of another line perpendicular to that described by a plummet or pendulum. This instrument, *ibid.* n° 10, consists of two legs or branches, joined together at right angles, whereof that which carries the thread and plummet is about a foot and a half long; the thread is hung towards the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, so that it may hang free every where: but towards the bottom, where there is a little blade of silver, whereon is drawn a line perpendicular to the telescope, the said cavity is covered by two pieces of brass, making as it were a kind of cafe, left the wind should agitate the thread; for which reason the silver blade is covered with a glass G, to the end that it may be seen when the thread and plummet play upon the perpendicular: the telescope is fastened to the other branch of the instrument, and is about two feet long: having an hair placed horizontally across the focus of the object-glass, which determines the point of the level. The telescope must be fitted at right angles to the perpendicular. It has a ball and socket, by which it is fastened to the foot, and was invented by M. Picard.

Reflecting Level, that made by means of a pretty long surface of water representing the same object inverted which we see erected by the eye, so that the point where these two objects appear to meet is a level with the place where the surface of the water is found. This is the invention of M. Mariotte.

There is another reflecting level consisting of a mirror of steel, or the like, well polished, and placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must make an angle of 45° with the telescope, in which case the perpendicular line of the said telescope is converted into a horizontal line, which is the same with the line of level. This is the invention of M. Cassini.

Water-Level, that which shows the horizontal line by means of a surface of water or other liquid, founded on this principle, that water always places itself level. See the article Fluid.

The most simple is made of a long wooden trough, or canal, whose sides are parallel to the base, so that being equally filled with water, its surface shows the line of level. This is the chorobates of the ancients. See Chorobata.

It is also made with two cups fitted to the two ends of a pipe, three or four feet long, about an inch in diameter, by means whereof the water communicates from the one to the other cup; and this pipe being moveable on its stand by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extreme of the pipe with wax or pitch. Into the pipe is poured some common or coloured water, which shows itself through the cylinders, by means whereof the line of level is determined; the height of the water, with respect to the center of the earth, being always the same in both cylinders: this level, though very simple, is yet very commodious for levelling small distances.

Level of Mr Huygens’s invention, consists of a telescope a, *ibid.* n° 11. in form of a cylinder, going through a ferril, in which it is fastened by the middle. This ferril has two flat branches b b, one above, and the other below; at the ends whereof are fastened little moving pieces, which carry two rings, by one of which the telescope is suspended to an hook at the end of the screw 3, and by the other a pretty heavy weight is suspended, in order to keep the telescope in equilibrio. This weight hangs in the box 5, which is almost filled with linseed oil, oil of walnuts, or other matter that
LEVELLING, the art of finding a line parallel to the
E, and then to sink the bottom of the canal at B as
much below E as A is below D. But this will not
give the true level: for according to Cassini’s calculation,
at the distance of 5078 feet the apparent level is seven
inches above the true; and therefore, to make a true level,
B must be sunk seven inches lower than the apparent level
directs; so that if A be four feet below D, B must be
four feet seven inches below the mark E. We have here
mentioned the error which will arise from placing the
level at one end of the line to be levelled, and shown how
to correct it; but in most cases it is better to take a flat-
tion in the middle of the line to be levelled: thus, if the
points H and B are to be levelled, place the instrument
in the middle at A, and setting up sticks perpendicular at
H and B, make marks upon each stick where the appa-
rent level points, as E and F; those points are level:
and if you sink H as much below F, as B is below E,
HAB will be a true level.

The operation of levelling is as follows: suppose the
height of the point A, (ibid. n° 3.) on the top of a
mountain above that of the point B, and at the foot
thereof, be required. Place the level about the middle
distance between the two points as in D, and stakes in A
and B; and let there be persons instructed with signals
for raising and lowering, on the said stakes, little marks
of pailéboard or other matter, the level being placed ho-
izontally by the bubble, &c. Look towards the staff
AE, and cause the mark so raised to be lowered till the
middle, upper edge, or other most conspicuous part, ap-
pear in the visual ray. Then measuring exactly the per-
pendicular height of the point E above the point A, which
suppose six feet four inches; set that down in your book:
then turn the level horizontally about, that the eye-plates
of the telescope may be still next the eye when you look
the other way; if you have only plain sights, the instru-
ment need not be turned; and cause the person at the
staff B, to raise or lower his mark, till some conspicuous
part of it fall in the visual ray, as at C: then measure
the perpendicular height of C above B, which suppose
sixteen feet six inches: set this also down in the book a-
bove the other number of the first observation; subtrac-
t the one from the other, the remainder will be ten feet
two inches, which is the difference of the level between
A and B, or the height of the point A above the point B.

If the point D, where the instrument is fixed, be in
the middle between the two points A and B, there will
be no necessity for reducing the apparent level to the true
level; the visual ray in that case being raised equally a-
bore the true level. If it be further required to know
whether there be a sufficient defect for conveying water
from the spring A (ibid. n° 4.) to the point B. Here,
in regard the distance from A to B is considerable, it is
required that several operations be made. Having then
chosen a proper place for the first station, as at I, set up
a staff in the point A, near the spring, with a proper
mark to slide up and down the staff, as L, and measure
the distance from A to I, which suppose two thousand
yards. Then the level being adjusted in the point I, let
the mark L be raised and lowered till such time as you
spy some conspicuous part of it through the telescope or
sights of the level, and measure the height AL, which
suppose thirteen feet five inches. But in regard the dis-
fance AI is two thousand yards, you must have recourse

LEV (971) LEV
to your table for a reduction, subtracting eleven inches, which will leave the height of AL twelve feet six inches, and this note down in your book. Now turn the level horizontally about, so that the eye-glass of the telescope may be towards A, and fixing up another staff at H, cause the mark G to be moved up and down till you spy some conspicuous part through the telescope or sights. Measure the height HG, which suppose seven yards one foot two inches. Measure likewise the distance of the points IH, which suppose one thousand three hundred yards; for which distance four inches eight lines must be subtracted from the height HG, which consequently will only leave seven yards nine inches four lines, to be taken down in your book. This done, remove the level forwards to some other eminence, as E, whence the staff H may be viewed; and also another staff at D, near the place whither the water is to be conveyed. The level being again adjusted in the point E, look back to the staff H; and managing the mark as before, the visual ray will give the point F. Measure the height HF, which suppose eleven feet six inches. Measure likewise the distance HE, which suppose a thousand yards, for which there is two inches nine lines of abatement; which being taken from the height HF, there will remain eleven feet three inches three lines; which enter in your book. Lastly, turning the level to look at the next staff D, the visual ray will give the point D. Measure the height of D from the ground, which suppose eight feet three inches. Measure also the distance from the station E to B, which suppose nine hundred yards, for which distance there are two inches three lines of abatement; which being taken from the height BD, there will remain eight feet nine lines; which enter as before.

For the manner of entering down observations in your book, obverse, that when a proper place or station for the level between the two points has been pitched upon, write down the two heights observed at that station in two different columns, viz. under the first column, those observed in looking through the telescope when the eye was from the spring, or towards the point, which we may call back sights; and under the second column, those observed when the eye was next the spring, which we call foresights. Having summed up the heights of each column separately, subtract the lesser from the greater, the remainder will be the difference of the level between the points A and B. If the distance of the two points be required, add all the distances measured together; and dividing the difference of height by the yards of the distances, for each two hundred yards you will have a descent of about two inches nine lines.

Dr. Halley suggests a new method of levelling, performed wholly by means of the barometer, in which the mercury is found to be suspended to so much the less height, as the place is farther remote from the center of the earth; whence the different heights of the mercury in two places give the difference of level. This method has been put in practice by some of the French academy.
LIBRARY, an edifice or apartment defined for holding books; and the tail of the male terminates in a kind of hooked forceps. There are 21 species, chiefly distinguished by their colour.

LIBER, among botanists, denotes the rind or inner bark of trees.

LIBERIA, in Roman antiquity, a festival observed on the sixteenth of the calends of April, at which time the youth laid aside their juvenile habit for the toga virilis, or habit peculiar to grown men.

LIBERTUS, in Roman antiquity, a person who from being a slave had obtained his freedom.

The difference between the liberti and libertini was this: the liberti were such as had been actually made free themselves, and the libertini were the children of such persons.

LIBERTY, in general, denotes a state of freedom, in contradistinction to slavery.

According to Cicero, liberty is the power of living as a man pleases, or without being controlled by another.

In a legal sense, liberty signifies some privilege that is held by charter or prescription.

LIBRA, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

LIBRA, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

LIBRARY, an edifice or apartment defined for holding a considerable number of books placed regularly on shelves; or, the books themselves lodged in it.

The first who erected a library at Athens was the tyrant Pisistratus, which was transported by Xerxes into Persia, and afterwards brought back by Seleucus Nicanor to Athens. Plutarch says, that under Eumenes there was a library at Pergamus that contained 200,000 books. That of Ptolemy Philadelphia, according to A. Gallus, contained 700,000, which were all burnt by Caesar's soldiers. Constantine and his successors erected a magnificent one at Constantinople, which in the eighth century contained 500,000 volumes; and among the rest, one in which the Iliad and Odyssey were written in letters of gold, on the guts of a serpent: but this library was burnt by order of Leo Haurus. The most celebrated libraries of ancient Rome, were the Ulpinian and the Palatine, and in modern Rome that of the Vatican. The foundation of the Vatican library was laid by pope Nicholas, in the year 1450; it was afterwards deftoyed in the facking of Rome by the confible of Bourbon, and restored by pope Sixtus V. and has been considerably enriched with the ruins of that of Heidelberg, plundered by count Tilly in 1682. One of the most complete libraries in Europe, is that erected by Cosimo de Medicis; though it is now exceeded by that of the French king, which was begun by Francis I. augmented by cardinal Richelieu, and completed by M. Colbert. The emperor's library at Vienna, according to Lambecius, consists of 80,000 volumes, and 15,940 curious medals. The Bodleian library at Oxford exceeds that of any university in Europe, and even those of any of the sovereigns of Europe, except the emperor's and the French king's, which are each of them older by a hundred years. It was first opened in 1602, and has since been increased by a great number of benefactors: indeed the Medicean library, that of Beffarian at Venice, and those just mentioned, exceed it in Greek manuscripts; but it outdoes them all in Oriental manuscripts; and as to printed books, Ambrofian at Milan, and that of Wolfenbuttel, are two of the most famous, and yet both are inferior to the Bodleian. The Cotton library consists wholly of manuscripts, particularly of such as relate to the history and antiquities of Britain; which, as they are now bound, make about 1000 volumes.

In Edinburgh there is a good library belonging to the university, well furnished with books; which are kept in good order, and cloistered up with wire-doors, that none but the keeper can open, and are now lent out only upon configuration of the price; a method much more commodious than the multitude of chains used in other libraries. There is also a noble library of books and manuscripts belonging to the faculty of Advocates.

LICENTIATE, one who has obtained the degree of a licence.

The greatest number of the officers of justice in Spain, are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. Among us, a licentiate usually means a physician who has a licence to practice, granted by the college of physicians.

LICHER, in ancient geography, a large extent of Africa, lying south-west of Egypt.

LICENCE, in law, an authority given to a person to do some lawful act.

LICENTIATE, one who has obtained the degree of a licence.

The greatest number of the officers of justice in Spain, are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. The greatest number of the officers of justice in Spain, are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. Among us, a licentiate usually means a physician who has a licence to practice, granted by the college of physicians.

LICENTIATE, one who has obtained the degree of a licence.
LIEUTENANT, an officer who supplies the place and discharges the office of a superior in his absence. Of these, some are civil, as the lords-lieutenants of kingdoms, and the lord-lieutenants of counties; and others are military, as the lieutenant general, lieutenant general of the artillery, lieutenant colonel, lieutenant of the artillery of the tower, lieutenants of horse, foot, ships of war, &c.

Lord Lieutenant of Ireland, is properly a vicerey, and has all the state and grandeur of a king of England, except being served upon the knee. He has the power of making war and peace, of becalming all the offices under the government, of dubbing knights, and of pardoning all crimes except high treason; he also calls and prorogues the parliament, but no bill can pass without the royal assent. He is abdicated in his government by a privy council; and, on his leaving the kingdom, he appoints the lords of the regency, who govern in his absence.

Lieutenant-general, is an officer next in rank to the general: in battle, he commands one of the wings; in a march, a detachment, or a flying camp; also a quarter, at a siege, or one of the attacks, when it is his day of duty.

LIFE, is peculiarly used to denote the animated Hate of living creatures, or the time that the union of their soul and body lasts.

Ligament, in anatomy, a strong compact substance, serving to join two bones together. See Anatomy.

Ligation, in surgery, is a chord, band, or string; or the binding any part of the body with a chord, band, fillet, &c., whether of leather, linen, &c.

Ligatures are used to extend and replace bones that are broken or dislocated; to tie the patients down in lithotomy and amputations; to tie upon the veins in phlebotomy, or the arteries in amputations, or in large wounds; to secure the splints that are applied to fractures; to tie up the processes of the peritonaeum, with the spermatic vessels in castration; and, lastly, in taking off warts or other excrescences by ligature.

Light, in physiology, certain subtle particles of matter, capable of exciting in us the sensation of colours. See Optics.

Lightening, the bursting of fire from a cloud or the earth. See Electricity.
LIMBURG, the capital of a duchy of the same name, in the Austrian Netherlands, twenty miles south-east of Liege; E. long. 6° 5', and N. lat. 50° 37'.

LIMF^+. See Chemistry, p. 76.

LIMINGTON, or Lemington, a borough town of Limning, the art of painting in water-colours, in con-

LIMOSELLA, in botany, a genus of the didynamia angio-

LINARIA, in ornithology. See Fringilla.

LIMPET. See Patella.

LINCOLN, the capital city of the county of Lincoln.

LINCOLN, in the Austrian Netherlands, twenty miles south-east of Liege; E. long. 6° 5', and N. lat. 50° 37'. It sends two members to parliament.

LINE, in geometry, a quantity extended in length only, without any breadth or thickness. It is formed by the flux or motion of a point. See Fluxions, and Geometry.

Line, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

Line of battle, is also understood of the disposition of a fleet on the day of the engagement, on which occasion the vessels are usually drawn up as much as possible in a straight line, as well to gain and keep the advantage of the wind, as to run the same board.

Ship of the Line, a vessel large enough to be drawn up in the line, and to have a place in a sea-fight.

LINE, in genealogy, a series or succession of relations in various degrees, all descending from the same common father.

LINE also denotes a French measure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot. Geometricians conceive the line subdivided into six points. The French line answers to the English barley corn.

LINES, in heraldry, the figures used in armories, to divide the shield into different parts, and to compose different figures. These lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines.

LINEA ALBA, in anatomy. See Anatomy, p. 192.

LINEAMENT, among painters, is used for the outlines of a face.

LINEAR NUMBERS, in mathematics, such as have relation to length only; such is a number which represents one side of a plane figure. If the plane figure be a square, the linear number is called a root.

LINEAR PROBLEM, that which may be solved geometrically by the intersection of two right lines. This is called a simple problem, and is capable but of one solution.

LINEN. See Linnen.

LING, in ichthyology. See Gadus.

LINGEN, a town of Germany, in the circle of Westphalia, capital of a county of the same name, situated on the river Ems, forty five miles north of Munster.

LINGUATULA, in ichthyology. See Pleuro-

LINIMENT, in pharmacy, a composition of a confection somewhat thinner than an unguent, and thicker than an oil, used for anointing different parts of the body in various intentions.

The materials proper for composing of a liniment, are oils, fats, balsams, and whatever enters the composition of unguents and plasters.

LINLITHGOW, a town of Scotland, in the county of Lothian, capital of the county of Linlithgow, situated sixteen miles west of Edinburgh.

LINNÆA, in botany, a genus of the didynamia angio-

feeds.
feeds. There is but one species, a native of Sweden.
LINNEN, in commerce, a well-known kind of cloth, chiefly made of flax. See Flax.

In order to succeed in the linen-manufacture, one set of people should be confined to the plowing and preparing the soil, sowing and covering the feed, to the weeding, pulling, rippling, taking care of the new feed, and watering and grafting the flax, till it is lodged at home: others should be concerned in the drying, breaking, fcutching, and heckling the flax, to fit it for the spinners; and others in spinning and reeling it, to fit it for the weaver; others should be concerned in taking due care of the weaving, bleaching, beetling, and finishing the cloth for the market. It is reasonable to believe, that if these several branches of the manufacture were carried on by distinct dealers in Scotland and Ireland, where our home-made linens are manufactured, the several parts would be better executed, and the whole would be afforded cheaper, and with greater profit.

LINNET, in ornithology. See Fringilla.

LINSEED, the seed of the plant linum. Linseed bruised and steeped in water, gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtues to it.

LINT. See Linnen and Flax.

LINTEL, in architecture, a piece of stone or timber set of people should be confined to the plowing and preparing the soil, sowing and covering the feed, to the weeding, pulling, rippling, taking care of the new feed, and watering and grafting the flax, till it is lodged at home: others should be concerned in the drying, breaking, fcutching, and heckling the flax, to fit it for the spinners; and others in spinning and reeling it, to fit it for the weaver; others should be concerned in taking due care of the weaving, bleaching, beetling, and finishing the cloth for the market. It is reasonable to believe, that if these several branches of the manufacture were carried on by distinct dealers in Scotland and Ireland, where our home-made linens are manufactured, the several parts would be better executed, and the whole would be afforded cheaper, and with greater profit.

LINNET, in ornithology. See Fringilla.

LINSEED, the seed of the plant linum. Linseed bruised and steeped in water, gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtues to it.

LIFT. See Linnen and Flax.

LINT, the feed of the plant linum. Linseed bruised and steeped in water, gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtues to it.

LIP. See Anatomy.

LIQUIDAMBER, in botany, a genus of the monoecia class. The calyx consists of two leaves, and the corolla of five petals; the capsule has five valves, and ten cells; and the style is solitary. There are 22 species, five of them natives of Britain, viz., the satyrifimum, or common flax; the perenne, or blue flax; the tenuifolium, or narrow-leaved wild flax; the catharticum, or purging flax; and the radiola, least flax. See Chemistry, p. 84.

LIQUOR, a name signifying any fluid substance.

LIQUORIC. See Glycyrrhiza.

LIRIODENDRON, the tulip-tree, in botany, a genus of the polyandria polygynia class. The calyx consists of three leaves, and the corolla of nine petals; and the seeds are imbricated upon a strobilus. There are two species, both natives of America. This tree yields a fragrant resin, called liquidambar, which refolves and opens obstructions.

LISP, in commerce, the bordure of cloth, or of fluff; used on various occasions; but chiefly by gardeners for securing their wall-trees.

LISTANY, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession, saying, We fee thee to hear us, good Lord, &c.

LITCHFIELD, a city of Staffordshire, one hundred and fifty miles north-west of London, and twelve south-east of Stafford. The city and Coventry have one bishop between them; it sends two members to parliament.

LITERATI, in general, denotes men of learning, but is more particularly used by the Chinese for such persons as are able to read and write their language.

LITHANTHRAX, pit-coal, in natural history, a genus of fossils, defined to be solid, dry, opake, inflammable substances, found in large strata, splitting horizontally more easily than in any other direction, of a glossy hue, soft and friable, not fusible, but easily inflammable, and leaving a large residuum of ashes. Of this genus there are three species: 1. The hard, dumpy, black coal, known by the name of Scotch coal. 2. The hard, glossy, black coal, known by the same name. 3. The friable, glossy, black coal, called Newcastle-coal, as being chiefly dug about that town.

LITANY, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession, saying, We see thee to hear us, good Lord, &c.

LONCELLES, in heraldry, a term used for several lions borne in the same coat of arms.

LIP, in anatomy. See Anatomy, p. 303.

LIPPOXYLIA, fainting, in medicine, may arise from several causes, as too violent exercise, suppression of the meatus or other accustomed evacuations, &c. See Medicine.

LIPPIA, in botany, a genus of the didynamia angiospermae class. The calyx consists of four roundish, erect, and membranaceous teeth; the capsule is straight, has two valves, one cell, and two seeds. There are two species, none of them natives of Britain.

LIQUIDAMBER, in botany, a genus of the monocotyledon class. The calyx has four leaves; it has no corolla, but numerous filaments: the calyx of the male consists of four leaves in the form of a globe; it has no corolla, but a couple of stigmas; and the capsules, which are numerous, are round, with a double valve, and contains many seeds. There are two species, both natives of America. This tree yields a fragrant resin, called liquidambar, which resolves and opens obstructions.

LIQUOR, a name signifying any fluid substance.

LIQUORIC. See Glycyrrhiza.

LIRIODENDRON, the tulip-tree, in botany, a genus of the polyandria polygynia class. The calyx consists of three leaves, and the corolla of nine petals; and the seeds are imbricated upon a strobilus. There are two species, both natives of America. This tree yields a fragrant resin, called liquidambar, which resolves and opens obstructions.
LITUIDA, in natural history, the name of a large class of fossils, including the flint and pebble kinds.

The lithuida are defined to be stones of a debased crystalline matter, covered by, and surrounded with, an opake crust, and frequently of great beauty, and considerable brightness within, though of but a slight degree of transparency, approaching to the nature of the semi pellucid genus, and like them found in not very large mafs.

LITHOGINESIA, a term used by some authors for the formation of stones. See STONE.

LITHOMARGA, Stonemarle, a name given by some authors to a sparry subblance highly debased by earth, which is found in great plenty in the caves of the Hart's foreft in Germany, and used there.

LITHONTRPTICS, medicines which either break, or are supposed to have the virtue of breaking, stones in the urinary passages. See MEDICINE.

LITHOPHYTA, the name of Linnaeus's third order of vernes. See Natural History.

LITHOSPERMUM, Gromwell, in botany, a genus of species of fossil coral, composed of a great number of tubes and slender columns, sometimes round, sometimes angular, joined nicely to one another, and of a ftrack or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens.

LITHOSTROTION, in natural history, a name of a class of fossils, including the flint and pebble kinds.

LITHOTOMY, in surgery, cutting for the stone. See Medicine.

LITHUANIA, a province of Poland, bounded by Sa- moitia, Livonia, and part of Ruffia, on the north; by another part of Russia, on the east; by Volhinia and Polefia, on the south; and by Prussia and Pola- chia, on the weft.

LIVONIA, a province of Russia, 160 miles long, and 120 broad; bounded by the gulf of Finland, on the north; by Ingria and great Novagorod, on the east; by Lithuania and Courland, on the south; and by the Baltic, on the west; its chief towns are Narva, Revel, and Riga.

LIVONICA TERRA, a kind of fine bole used in the shops of Germany and Italy. These earths are both dug out of the same pit, in the place from whence they have their name, and in some other parts of the world. They are generally brought to us made up into little cakes, and sealed with the impress of a church and an escutcheon with two crofs keys. In Spain and Portugal they are much ufed, sometimes singly, sometimes mixed together, and are good in fevers and in fluxes of all kinds.

LIVRE, a French money of account, containing twenty sols.

LIXIVIOUS, an appellation given to salts obtained from burnt vegetables by lotion.

LIXIVIUM, in pharmacy, &c. a ley, obtained by pouring some liquor upon the ashes of plants; which is more or less powerful, as it has imbibed the fixed salts contained in the ashes.

LIZZARD, in zoology. See Lacerta.

LZARD, in geography, a cape, or promontory of Cornwall, fifteen miles south of Falmouth: W. long. 5° 47', N. lat. 49° 50'.

LOACH, in ichthyology. See Cobitis.

LOADSTONE. See Magnet.

LOAMS, in natural history, are defined to be earths composed of dissimilar particles, hard, stiff, dense, and hard and rough to the touch; not easily ductile while moist, readily diffusable in water, and composed of sand and a tough rivid clay. Of these loams, some are whitish, and others brown or yellow.

LOBE, in anatomy, any fleshy protuberant part, as the lobes of the lungs, lobes of the ears, &c.

LOBELIA, in botany, a genus of the syngestia mono- gynia class. The calix consists of five segments, and the corolla of one irregular petal; and the capsule has two and sometimes three cells. There are 26 species, only one of them a native of Britain, viz. the dortinana, or water gladiate.

LOCAL, in law, something fixed to the freehold, or tied to a certain place: thus real actions are local, since they must be brought in the country where they lie: and local customs are those peculiar to certain countries and places.
**Local medicines**, those defined to act upon particular parts; such are fomentations, epithems, velicatories, &c.

**Decree of Locality**, in Scots law, a decree proportioning a minister's stipend among the different persons liable in payment of it. See Law, Tit. v. 13.

**Locatellus's balsam**, in pharmacy, a celebrated balsam, the preparation whereof is directed in the Edinburgh dispensatory thus: Take of yellow-wax, one pound; oil olive, a pint and a half; Venice turpentine, a pound and a half; balsam of Peru, two ounces; dragon's blood, one ounce: melt the wax in the oil over a gentle fire; then add the turpentine; and having taken them from the fire, mix in the balsam of Peru and dragon's blood, keeping them continually stirring till grown cold.

This balsam is used in internal bruises and hemorraghes, erosions of the intefines, ulcerations of the lungs, dysenteries, and in some coughs and asthma.

**Lochia**, in medicine, a flux from the uterus, consequent to delivery. See Midwifery.

**Lochmaben**, a town of Scotland, fifteen miles east of Dumfries.

**Lock**, a well-known instrument used for fastening doors, chests, &c. generally opened by a key.

**Lockman**, an officer in the isle of Man, who executed the orders of the government, much like our under sheriff.

**Locrida**, a town of Turkey in Europe, seventy miles from Durazzo: E. long. 21°, N. lat. 41.

**Locus geometricus**, denotes a line, by which a local or indeterminate problem is solved.

A locus is a line, any point of which may equally solve an indeterminate problem. Thus, if a right line suffice for the conclusion of the equation, it is called *locus ad rectum*; if a circle, *locus ad circulum*; if a parabola, *locus ad parabolam*; if an ellipse, *locus ad ellipfis*; and of the rest of the conic sections.

**Loculum**, among botanists, denotes a cell, or cavity, or the cavity in a chest, generally opened by a key.

**Locust**, in zoology. See Gryllus.

**Log** (978) **Log**

* In the water. See Plate CIII. fig. 4.

**Logarithmic curve**. If on the line AN (Plate CIII. fig. 5.) both ways indefinitely extended, be taken, A C, C E, E G, G I, I L, on the right hand; and also Ag, g P, &c. on the left, all equal to one another: and if at the points P g, A, C, E, G, I, L, be erected to the right line A N, the perpendiculars P S, g d, A B, C D, E F, G H, I K, L M, which let be continually proportional, and represent numbers, viz. A B, 1; C D, 10; E F, 100, &c. then shall we have two progressions of lines, arithmetical and geometrical: for the lines A C, A E, A G, &c. are in arithmetical progression, or as 1, 2, 3, 4, 5, &c. and so represent the logarithms to which the geometrical lines A B, C D, E F, &c. do correspond. For since A G is triple of the first line A C, the number G H shall be in the third place from unity, if C D be in the first; so likewise shall L M be in the fifth place, since A L = 5 A C. If the extremities of the proportions S, d, B, D, F, &c. be joined by right lines, the figures S B M L will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

If the parts A C, C E, E G, &c. be bisected in the points, e, g, i, l, and there be again raised the perpendiculars e d, e f, g h, i k, l m, which are mean proportions between A B, C D; C D, E F, &c., then there will arise a new series of proportions, whose terms, beginning from A which immediately follows unity, are double of those in the first series, and the difference of the terms is become less, and approach nearer to a ratio of equality than before. Likewise, in this new series, the right lines A L, A e, express the distances of the terms L M, c d, from unity, viz. since A L is ten times greater than A e, L M shall be the tenth term of the series from unity; and because A e is three times greater than A e, L M will be the third term of the series if A e be the first, and there shall be two mean proportions between A B and A e, and between A B and L M there will be nine mean proportions. And if the extremities of the lines B d, D f, F h, &c. be joined by right lines, there will be a new polygon made, consisting of more but shorter sides than the last.

If, in this manner, mean proportions be continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as to be greater than any given number, or to be infinite; and every side of the polygon so increased, as to become less than any given right line; and consequently the polygon will be changed into a curve-lined figure; for any curve-lined figure may be conceived as a polygon, whose sides are infinitely small and infinite in number. A curve described after this manner, is called logarithmetrical.

It is manifest from this description of the logarithmic curve, that all numbers at equal distances are continually proportional. It is also plain, that if there be four numbers, A B, C D, I K, L M, such that the distance between the first and second be equal to the distance between the third and the fourth, let the distance from the second to the third be what it will, the numbers will be proportional. For because the distances A C, I L, are equal, A B shall be to the increment D s, as I K is to the increment M T. Wherefore,
fore, by composition, $AB : DC : : IK : ML$. And, contrariwise, if four numbers be proportional, the distance between the first and second shall be equal to the distance between the third and fourth.

The distance between any two numbers, is called the logarithm of the ratio of those numbers; and, indeed, do not measure the ratio itself, but the number of terms in a given series of geometrical proportions, proceeding from one number to another, and defines the number of equal ratios by the composition whereof the ratio of numbers is known.

LOGARITHMS, are the indexes or exponents (mostly whole numbers and decimal fractions, confining of seven places of figures at least) of the powers or roots (chiefly broken) of a given number; yet such indexes or exponents, that the several powers or roots they express, are the natural numbers, 1, 2, 3, 4, 5, &c. to 10 or 100000, &c. (as, if the given number be 10, and its index be assumed 1,000,000, then the 0,000,000 root of 10, which is 1, will be the logarithm of 1; the 0,301036 root of 10, which is 2, will be the logarithm of 2; the 0,477121 root of 10, which is 3, will be the logarithm of 3; the 0,120920 root of 10, the logarithm of 4; the 0,405465 root of 10 the logarithm of 11; the 0,903194 root of 10 the logarithm of 12, &c.) being chiefly contrived for ease and expedition in performing of arithmetical operations in large numbers, and in trigonometrical calculations; but they have likewise been found of extensive service in the higher geometry, particularly in the method of fluxions. They are generally founded on this consideration, that if there be any row of geometrical proportional numbers, as 1, 2, 4, 8, 16, 32, 64, 128, 256, &c. or 1, 10, 100, 1000, 10000, &c. and as many arithmetical proportional numbers adapted to them, or set over them, beginning with 0,

then will the sum of any two of these arithmetical proportional numbers, added together, be that arithmetical proportional which answers to or stands over the geometrical proportional, which is the product of the two geometrical proportional over which the two assumed arithmetical proportional numbers stand; again, if these arithmetical proportional numbers be subtracted from each other, the remainder will be the arithmetical proportional standing over that geometrical proportional which is the quotient of the division of the two geometrical proportional numbers belonging to the two first assumed arithmetical proportional numbers; and the double, triple, &c. of any one of the arithmetical proportional numbers, will be the arithmetical proportional standing over the square, cube, &c. of that geometrical proportional which the assumed arithmetical proportional stands over, as well as the $\frac{1}{2}, \frac{1}{3}, \&c.$ of that arithmetical proportional will be the geometrical proportional answering to the square root, cube root, &c. of the arithmetical proportional over it; and from hence arises the following common, though lame and imperfect definition of logarithms; viz.

“That they are so many arithmetical proportional, answering to the same number of geometrical ones.” Whereas, if any one looks into the tables of logarithms, he will find, that these do not all run on in an arithmetical proportion, nor the numbers they answer to in a geometrical one; these last being themselves arithmetical proportional. Dr Wallis, in his history of algebra, calls logarithms the indexes of the ratios of numbers to one another. Dr Halley, in the philosophical transactions, n° 216, says, they are the exponents of the ratios of unity to numbers. So also Mr Cotes, in his Harmonia Mensurarum, says, they are the numerical measures of ratios. But all these definitions convey but a very confused notion of logarithms. Mr Maclaurin, in his Treatise of Fluxions, has explained the natural and geneal of logarithms agreeably to the notion of their first inventor lord Naper. Logarithms then, and the quantities to which they correspond, may be supposed to be generated by the motion of a point; and if this point moves over equal spaces in equal times, the line described by it increases equally.

Again a line decreases proportionally, when the point that moves over it describes such parts in equal times as are always in the same constant ratio to the lines from which, at the beginning of those lines, from a given term in that line. In like manner, a line may increase proportionally, if in equal times the moving point describes spaces proportional to its distances from a certain term at the beginning of each time. Thus, in the first case, let $ac$ (Plate CIV. fig. 3.) be to $a o, o d, o e, &c.$ in equal parts of the time; and suppose the point $p$ describes an uniform motion, while the point $p$ describes a line inconstant ratio. If we now suppose a point $p$ describing the line AG (ibid. n° 4.) with an uniform motion, while the point $p$ describes a line increasing or decreasing proportionally, the line $AP$, described by $P$, with this uniform motion, in the same time, becomes equal to $op$, is the logarithm of $op$. Thus $AC$, $AD, AE, &c.$ are the logarithms of $ac, ad, ae, &c.$ respectively; and $oa$ is the quantity whose logarithm is supposed equal to nothing.

We have here abstracted from numbers, that the doctrine may be the more general; but it is plain, that if $A C, AD, AE, &c.$ be supposed, 1, 2, 3, &c. in arithmetic progression, then $ac, ad, ae, &c.$ will be in geometric progression; and that the logarithm of $oa$, which may be taken for unity, is nothing.

Lord Naper, in his first scheme of logarithms, supposed, that while $op$ increases or decreases proportionally, the uniform motion of the point $P$, by which the logarithm of $op$ is generated, is equal to the velocity of $p$ at $a$; that is, at the time of time when the logarithms begin to be generated.
generated. Hence logarithms, formed after this model, are called Naper's Logarithms, and sometimes Natural Logarithms.

When a ratio is given, the point $p$ describes the difference of the terms of the ratio in the same time. When a ratio is duplicate of another ratio, the point $p$ describes the difference of the terms in a double time. When a ratio is triplicate of another, it describes the difference of the terms of that ratio in a time equal to the sum of the times in which it describes the differences of the terms of the simple ratios of which it is compounded. And what is here said of the times of the motion of $P$, in those times, with its uniform motion.

Hence the chief properties of logarithms are deduced. They are the measures of ratios. The excess of the logarithm of the antecedent above the logarithm of the consequent measures the ratio of those terms. The measure of the ratio of a greater quantity to a less is positive; as this ratio, compounded with any other ratio, increases it. The ratio of equality, compounded with any other ratio, neither increases nor diminishes it; and its measure is nothing. The measure of the ratio of a less quantity to a greater is negative; as this ratio, compounded with any other ratio, diminishes it. The ratio of any quantity $A$ to unity, compounded with the ratio of unity to $A$, produces the ratio of $A$ to $A$, or the ratio of equality; and the measures of those two ratios destroy each other when added together; so that when the one is considered as positive, the other is to be considered as negative. By supposing the logarithms of quantities greater than $oa$ (which is supposed to represent unity) to be positive, and the logarithms of quantities less than it to be negative, the same rules serve for the operations by logarithms, whether the quantities be greater or less than $oa$. When $op$ increases proportionally, the motion of $p$ is perpetually accelerated; for the spaces $ac, cd, de, &c.$ that are described by it in any equal times that continually succeed after each other, perpetually increase in the same proportion as the lines $oa, oc, od, &c.$ When the point $p$ moves from $a$ towards $o$, and $op$ decreases proportionally, the motion of $p$ is perpetually retarded; for the spaces described by it in any equal times that continually succeed after each other, decrease in this case in the same proportion as $op$ decreases.

If the velocity of the point $p$ be always as the distance $op$, then this line increase or decrease in the manner supposed by lord Naper; and the velocity of the point $p$ being the fluxion of the line $op$, will always vary in the same ratio as this quantity itself. This, we presume, will give a clear idea of the genesis, or nature of logarithms; but for more of this doctrine, see Maclaurin's Fluxions.

Construction of Logarithms.

The first makers of logarithms had in this a very laborious and difficult task to perform; they first made choice of their scale or system of logarithms, that is, what set of arithmetical progressions should answer to such a set of geometrical ones, for this is entirely arbitrary; and they chose the decuple geometrical progressions, 1, 10, 100, 1000, 10000, &c. and the arithmetical one, 0, 1, 2, 3, 4, &c. or 0,000000; 1,000000; 2,000000; 3,000000; 4,000000, &c. as the most convenient. After this they were to get the logarithms of all the intermediate numbers between 1 and 10, 10 and 100, 100 and 1000, 1000 and 10000, &c. But first of all they were to get the logarithms of the prime numbers 3, 5, 7, 11, 13, 17, 19, 23, &c. and when these were once had, it was easy to get those of the compound numbers made up of the prime ones, by the addition or subtraction of their logarithms.

In order to this, they found a mean proportion between 1 and 10, and its logarithm will be $\frac{1}{4}$ that of 10; and so given, then they found a mean proportional between the number first found and unity, which mean will be nearer to 1 than that before, and its logarithm will be $\frac{1}{2}$ of the former logarithm, or $\frac{1}{4}$ of that of 10; and having in this manner continually found a mean proportional between 1 and the last mean, and bisected the logarithms, they at length, after finding 54 such means, came to a number $0.000000000000012781914932003235426$ near to 1 as not to differ from it so much as $0.000000000000000055511152312782702$, and found its logarithm to be $0.000000000000000012781914932003235335$ to be the difference whereby 1 exceeds the number of roots or mean proportionals found by extraction; and then, by means of these numbers, they found the logarithms of any other numbers whatsoever; and that after the following manner: between a given number, whose logarithm is wanted, and 1, they found a mean proportional, as above, until at length a number (mixed) be found, such a small matter above 1, as to have 1 and 15 cyphers after it, which are followed by the same number of significant figures; then they said, as the last number mentioned above is to the mean proportional thus found, so is the logarithm above, viz. $0.00000000000000001278191493200323442$, to be nearer to 1 than that before, and its logarithm will be between the number first found and unity, which mean will be the logarithm of the mean proportional between the quantities above 1 and 1; by the addition or subtraction of their logarithms, will be the logarithm of the given number. And this was the method Mr. Briggs took to make the logarithms. But if they are to be made only seven places of figures, which are enough for common use, they had only occasion to find 25 mean proportionals, or, which is the same thing, to extract the $10^{th}$ root of 10. Now having the logarithms of 3, 5, and 7, they easily got those of 2, 4, 6, 8 and 9; for since $2^3=8$, the logarithm of 2 will be the difference of the logarithms of 10 and 5, the logarithm of 4 will be two times the logarithm of 2, the logarithm of 6 will be the sum of the logarithm of 2 and 3, and the logarithm of 9 double the logarithm of 3. So also having found the logarithms of 13, 17 and 19, and also of 23 and 29, they did easily get those of all the numbers between 10 and 30, by addition and subtraction only; and so having found the logarithms of other prime numbers, they got those of other numbers compounded of them.
But since the way above hinted at, for finding the logarithms of the prime numbers is so intolerably laborious and troublesome, the more skilful mathematicians that came after the first inventors, employing their thoughts about abbreviating this method, had a vastly more easy and short way offered to them from the contemplation and menfuration of hyperbolic spaces contained between the portions of an asymptote, right lines perpendicular to it, and the curve of the hyperbola: for if ECN (Plate CIII. fig. 6. n° 1.) be an hyperbola, and AD, AQ the asymptotes, and AB, AP, AQ, &c. taken upon one of them, be represented by numbers, and the ordinates BC, PM, QN, &c. be drawn from the severall points B, P, Q, &c. to the curve, then will the quadrilinear spaces BCMP, PMNQ, &c. viz. their numerical measures be the logarithms of the quotients of the division of AB by AP, AP by AQ, &c. since when AB, AP, AQ, &c. are continual proportions, the said spaces are equal, as is demonstrated by several writers concerning conic sections.

Having said that these hyperbolic spaces, numerically expressed, may be taken for logarithms, we shall next give a specimen, from the great Sir Ifaac Newton, of the method how to meafure these spaces, and consequently of the confusion of logarithms.

Let CA (ibid. n° 2.) = AF be = 1, and AB = Ab = x; then will 1 + x be = BD, and 1 - x = bd; and putting these expressions into series, it will be 1 + x = 1 - x + x^2 - x^3 + x^4 - x^5, &c. and 1 - x = 1 + x + x^3 + x^5 + x^7, &c. and thus it will be x = 1 + x^3 + x^5 + x^7, &c. and the area AFDB = x + x^3 + x^5 + x^7 + x^9, &c. and the sum bd DB = x + 3x^2 + 3x^3 + x^4, &c. and the sum of the areas belonging to the ratios 1, 0.8, and (that is, inscribing upon the parts of the abscissas 1, 0.8, and 1, 0.9) viz. 0.405465, &c. and the total = 0.18232, &c. and the area = 0.10536, &c.

From these areas thus found, others may be easily had from addition and subtraction only. For since 1.2 x 1.2 = 2, the sum of the areas belonging to the ratios 1.2 and 1.2 (that is, inscribing upon the parts of the abscissas 1.2, 0.8; and 1.2, 0.9) viz. 0.405465, &c. and the total = 0.18232, &c. and the area = 0.10536, &c.

Sum = 0.28768, &c.

If the parts AD and AD of this area be added separately, and the leffer DA be taken from the greater dA, we shall have AD - AD = x^3 + x^5 + x^7 + x^9, &c. = Vol. H. Numbr. 67. 2

0.0100503358535014, for the terms reduced to decimals will stand thus:

</table>

0.0100503358535014.

Now if this difference of the areas be added to, and subtracted from their sum before found, half the aggregate, viz. 0.1053605156578263 will be the greater area AD, and half the remainder, viz. 0.0953101798043249, will be the leffer area AD.

By the fame tables, thefe areas AD and AD, will be obtained also when AB = Ab are fuppofed to be or CB = 1.01, and CB = 0.99, if the numbers are but duly transferred to lower places, as

Sum = 0.20000066667066694 = area BD.

0.000100000000000 = first |
| 500000000000000 = second |
| 333333333333333 = third |

0.000100000000000 = area AD - AD.

Half the aggregate 0.0100503358535014 = AD, and half the remainder, viz. 0.009999999999999, there will be obtained AD = 0.00100000000333333, and AD = 0.00099999999666667.

After the fame manner, if AB = Ab, be = 0.2, or 0.02, or 0.002, these areas will arise.

Ad = 0.2231435513142097, and

Ad = 0.1823215576939546, or

Ad = 0.2020207073175194, and

Ad = 0.109802672961797, or

Ad = 0.002002, and AD = 0.001.

From these areas thus found, others may be easily had from addition and subtraction only. For since 1.2 x 1.2 = 2, the sum of the areas belonging to the ratios 1.2 and 1.2 (that is, inscribing upon the parts of the abscissas 1.2, 0.8; and 1.2, 0.9) viz.

0.405465, &c. and the total = 0.18232, &c. and the area = 0.10536, &c.

Sum = 0.28768, &c.
when CG is = 3. Also, since \( \frac{1}{0.8} \times 2 = 3 \), the sum
1.0986122, &c., of the areas belonging to \( \frac{1}{0.8} \) and 2, will be the area of AFGH, when CG = 3. Again, since \( 2x^2 \frac{1}{0.8} = 5 \), and 2x5 = 10; by adding Ad = 0.2231, &c., AD = 0.1053, &c., and AD = 0.1523, &c., together, their sum is 0.5108, &c., and this added to 1.0986, &c., the area of AFGH, when CG = 3. You will have
1.0983791214341004 = AFGH, when CG is 3; and adding that of 2 to this, gives 2.30258509490457 = AFGH, when CG is equal to 10; and since x = 10, adding that of 2 to this, gives 2.30258509490457

The value of the logarithm 2.3025850, &c., of 10, and the index 2, be added; or, which is the same thing, if it be multiplied by its reciprocal 0.4342944819032518, the value of the subtangent of the logarithmic curve, to which Briggs's logarithms are adapted, we shall have the true tabular logarithms of 98, 99, 100, 101, 102. These are to be interpolated by ten intervals, and then we shall have the logarithms of all the numbers between 980 and 1000; between all between 980 and 1000, being again interpolated by ten intervals, the table will be as it were constructed. Then from these we are to get the logarithms of all the prime numbers, and their multiples less than 100, which may be found easily and expeditiously—the loga-

The two first terms \( \frac{dx}{2n} \) of this series, being sufficient for the construction of a canon of logarithms, even to 14 places of figures, provided the number, whose logarithm is to be found, be less than 1000; which cannot be very troublesome, because \( x \) is either 1 or 2: yet it is not necessary to interpolate all the places by help of this rule, since the logarithms of numbers, which are produced by the multiplication or division of the number last found, may be obtained by the numbers whose logarithms were had before, by the addition or subtraction of their logarithms. Moreover, by the difference of their logarithms, and by their second and third differences, if necessary, the void places may be supplied more expeditiously; the rule aforegoing being to be applied only where the continuation of some full places is wanted, in order to obtain these differences.

By the same method rules may be found for the interpolation of logarithms, when of three numbers the logarithm of the lesser and of the middle number are given, or of the middle number and the greater; and this although the numbers should not be in arithmetical progression. Also by pursuing the steps of this method, rules may be easily discovered for the construction of artificial sines and tangents, without the help of the natural tables. Thus far the great Newton, who says, in one of his letters to Mr Leibnitz, that he was so much delighted with the construction of logarithms, at his first sitting out in those studies, that he was ashamed to tell how many places of figures he had carried them at that time: and this was before the year 1666; because, he says, the plague made him lay aside those studies, and think of other things.

Dr. Keil, in his Treatise of Logarithms, at the end of his Commandine's Euclid, gives a series, by means of which may be found easily and expeditiously the logarithms of large numbers. Thus, let \( z \) be an odd number, whose logarithm is sought: then shall the numbers \( z - 1 \) and \( z + 1 \) be even, and accordingly their logarithms, and the difference of the logarithms will be had, which let be called \( y \). Therefore, also the logarithm of a number, which is a geometrical mean between \( z - 1 \) and \( z + 1 \), will
will be given, viz. equal to half the sum of the logarithms. 

Now the series \(y \times \frac{1}{4}, + \frac{1}{24}, + \frac{181}{15120}, + \frac{252002}{1310} \), etc. shall be equal to the logarithm of the ratio, which the geometrical mean between the numbers \(x - 1\) and \(x + 1\), has to the arithmetical mean, viz. to the number \(x\). If the number exceeds 1000, the first term of the series, viz. \(\sqrt[\infty]{x}\), is sufficient for producing the logarithm to 13 or 14 places of figures, and the second term will give the logarithm to 20 places of figures. But if \(x\) be greater than 

\[0.0000000000542813\]  
and if the logarithm of the geometrical mean, viz. 

\[4.301051709302416\]  
be added to the quotient, the sum will be 

\[4.201051709845230\text{=}\text{the logarithm of} \ 20001.\]

Wherefore it is manifest that to have the logarithm to 14 places of figures, there is no necessity of continuing out the quotient beyond 6 places of figures. But if you have a mind to have the logarithm to 10 places of figures only, the two first figures are enough. And if the logarithms of the numbers above 20000 are to be found by this way, the labour of doing them will mostly consist in setting down the numbers. This series is easily deduced from the consideration of the hyperbolic spaces aforesaid. The first figure of every logarithm towards the left hand, which is separated from the rest by a point, is called the index of that logarithm; because it points out the highest or remotest place of that number from the place of unity in the infinite scale of proportionals towards the left hand: thus, if the index of the logarithm be 1, it shews that its highest place towards the left hand is the tenth place from unity; and therefore all logarithms which have 1 for their index, will be found between the tenth and hundredth place, in the order of numbers. And for the same reason all logarithms which have 2 for their index, will be found between the hundredth and thousandth place, in the order of numbers, &c. Whence universally the index or characteristic of any logarithm is always less than the number of figures in whole numbers, which answer to the given logarithm; and, in decimals, the index is negative.

As all systems of logarithms whatever, are composed of similar quantities, it will be easy to form, from any system of logarithms, another system in any given ratio; and consequently to reduce one table of logarithms into another of any given form. For as any one logarithm in the given form, is to its correspondent logarithm in another form, so is any other logarithm in the given form, to its correspondent logarithm in the required form; and hence we may reduce the logarithms of Lord Napier into the form of Briggs's, and contrariwise. For as 2.30258392, etc. lord Napier's logarithm of 10, is to 1.000000000000000, Mr Briggs's logarithm of 10; so is any other logarithm in lord Napier's form, to the correspondent tabular logarithm in Mr Briggs's form; and because the two first numbers constantly remain the same; if lord Napier's logarithm of any one number be divided by 2.30258, etc. or multiplied by 4.342974, etc. the ratio of 1.000000, etc. to 2.30258, etc. as is found by dividing 1.000000, etc. by 2.30258, etc. the quotient in the former, and the product in the latter, will give the correspondent logarithm in Briggs's form, and the contrary. And, after the same manner, the ratio of natural logarithms to that of Briggs's, will be found=86838963806.

The use and application of logarithms.

It is evident, from what has been said of the construction of logarithms, that addition of logarithms must be the same thing as multiplication in common arithmetick; and subtration in logarithms the same as division: therefore, in multiplication by logarithms, add the logarithms of the multiplicand and multiplier together, their sum is the logarithm of the product.

Example. Multiplidand 8.5 .0.1294189  
Multiplier 10 1.0000000  
Product 85 1.9294189

And in division, subtract the logarithm of the divisor from the logarithm of the dividend, the remainder is the logarithm of the quotient.

Example. Dividend 9712 8 3.9873444  
Divisor 456 2.6589468  
Quotient 21.3 1.3283796

To find the complement of a logarithm.

Begin at the left hand, and write down what each figure wants of 9, only what the last significant figure wants of 10; so the complement of the logarithm of 456, viz. 2.6589468, is 7.3410352.

In the rule of three. Add the logarithms of the second and third terms together, and from the sum subtract the logarithm of the first, the remainder is the logarithm of the fourth. Or, instead of subtracting a logarithm, add its complement, and the result will be the same.

To raise powers by logarithms.

Multiply the logarithm of the number given, by the index of the power required, the product will be the logarithm of the power sought.

Example. Let the cube of 32 be required by logarithms. The logarithm of 32=1.5051500, which multiplied by 3, is 4.5154500, the logarithm of 32768, the cube of 32. But in raising powers, viz. squaring, cubing,
To find mean proportionals between any two numbers.

Subtract the logarithm of the least term from the logarithm of the greatest, and divide the remainder by a number more by one than the number of means desired; then add the quotient to the logarithm of the least term (or subtract it from the logarithm of the greatest) continually, and it will give the logarithms of all the mean proportionals required.

Example. Let three mean proportionals be sought, between 106 and 100.

\[
\begin{align*}
\text{Logarithm of 106} & = 2.0253058 \\
\text{Logarithm of 100} & = 2.0000000 \\
\text{Divide by 4} & = 0.006326475 \\
\text{Logarithm of the least term 100 added} & = 2.0000000 \\
\text{Logarithm of the first mean} & = 101.4673846 \\
\text{Logarithm of the second mean} & = 102.0563014 \\
\text{Logarithm of the third mean} & = 104.4670483 \\
\text{Logarithm of the greatest term 106} & = 2.0253059.
\end{align*}
\]

LOGIC.

LOGIC, the art of thinking and reasoning justly; or, it may be defined the science or history of the human mind, inasmuch as it traces the progress of our knowledge from our first and most simple through all their different combinations, conceptions, and all those numerous deductions that result from variously comparing them one with another.

The precise business of logic, therefore, is to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to attain the attainment of truth and knowledge. It lays open those errors and mistakes we are apt, through inattention, to run into; and teaches us how to distinguish between truth, and what only carries the appearance of it. By this means we grow acquainted with the nature and force of the understanding; see what things lie within its reach; where we may attain certainty and demonstration; and when we must be contented with probability.

This science is generally divided into four parts, viz. Perception, Judgment, Reasoning, and Method. This division comprehends the whole history of the sensations and operations of the human mind. But we must refer the reader for the first part, viz. Perception, and Ideas, to Metaphysics, where it will be more conveniently and fully treated, and confine ourselves in this place to the three last, viz. Judgment, Reasoning, and Method.

PART I. Of JUDGMENT.

The mind being furnished with ideas, its next step in the way to knowledge is, the comparing these ideas together, in order to judge of their agreement or disagreement. In this joint view of our ideas, if the relation is such, as to be immediately discoverable by the bare inspection of the mind; the judgments thence obtained are called intuitive; for in this case, a mere attention to the ideas compared, suffices to let us see, how far they are connected or disjoined. Thus, that the whole is greater than any of its parts, is an intuitive judgment, nothing more being required to convince us of its truth, than an attention to the ideas of whole and part.

And this too is the reason, why we call the act of the mind forming these judgments, intuition; as it is indeed no more, than an immediate perception of the agreement or disagreement of any two ideas.

But it is to be observed, that our knowledge of this kind respects only our ideas, and the relations between them; and therefore can serve only as a foundation to such reasonings as are employed in investigating these relations. Now many of our judgments are conversant about facts, and the real existence of things, which cannot be traced by the bare contemplation of our ideas. It does not follow, because I have the idea of a circle in my mind, that therefore a figure answering to that idea, has a real existence in nature. I can form to myself the notion of a centaur, or golden mountain, but never imagine on that account, that either of them exist. What then are the grounds of our judgment in relation to facts? Experience and testimony. By experience we are informed of the existence of the several objects which surround us, and operate upon our senses. Testimony is of a wider extent, and reaches not only to objects beyond the present sphere of our observation, but also to facts and
and transactions, which being now past, and having no
longer any existence, could not without this conveyance,
have fallen under our cognizance.

Here then we have three foundations of human judg-
ment, from which the whole system of human
may with ease and advantage be derived. First, intu-
tion, which respects our ideas themsefes, and their re-
lations, and is the foundation of that species of reasoning,
which we call demonstration. For whatever is deduced
from our intuitive perceptions, by a clear and connective
series of proofs, is said to be demonstrated, and produ-
ces absolute certainty in the mind. Hence the knowledge
obtained in this manner, is what we properly term sci-
ence; because in every step of the procedure, it carries its
own evidence along with it, and leaves no room for doubt
or hesitation. And, what is highly worthy of notice, as
the truths of this class express the relations between our
ideas, and the same relations must ever and invariably
subsist between the same ideas, our deductions in the way
of science, constitute what we call eternal, necessary, and
immutable truths. If it be true that the whole is equal
to all its parts, it must be so unchangeably; because the
relation of equality being attached to the ideas them-
sefes, must ever intervene where the same ideas are com-
pared. Of this nature are all the truths of natural reli-
gion, morality, and mathematicks, and in general, what-
ever may be gathered from the bare view and consideration
of our ideas.

The second ground of human judgment is experience;
from which we infer the existence of those objects that
surround us, and fall under the immediate notice of our
fenses. When we see the fun, or call our eyes towards
a building, we not only have ideas of these objects within
ourselves, but ascribe to them a real existence out of
the mind. It is also by the information of the fenses, that
we judge of the qualities of bodies: as when we say
that snow is white, fire hot, or steel hard. For as we
are wholly unacquainted with the internal structure
and constitution of the bodies that produce these sensations
in us, and are unable to trace any connection between that
structure and the sensations themselves, it is evident, that
we build our judgments altogether upon observation, a-
scribing to bodies such qualities, as are answerable to the
perceptions they excite in us. But this is not the only
advantage derived from experience; for we are likewise
indebted to it for all our knowledge regarding the co-
existence of sensible qualities in objects, and the opera-
tions of bodies one upon another. Ivory, for instance, is
hard and elastic; this we know by experience, and in-
deep by that alone. For being altogether strangers to
the true nature both of elas CTICY and hardnes we can-
not by the bare contemplation of our ideas determine,
how far the one necessarily implies the other, or whether
there may not be a repugnance between them. But when
we observe them to coexist both in the same object, we are
then affured from experience, that they are not incom-
patible; and when we also find that a stone is hard and
not elastic, and that air though elastic is not hard, we also conclude upon the same foundation, that the ideas
are not necessarily conjoined; but may exist sepa-
rately in different objects. In like manner with regard
to the operations of bodies one upon another, it is evi-
dent, that our knowledge this way, is all derived from
observation. Aqua regia dissolves gold, as has been
found by frequent trial, nor is there any other way of
arriving at the discovery. Naturalists may tell us if they
please, that the parts of aqua regia are of a texture apt
to inunctuate between the corpuscles of gold, and thereby
loosen and shake them asunder. If this is a true account
of the matter, we believe it will notwithstanding be al-
lowed, that our conjecture in regard to the conformation
of these bodies is deduced from the experiment, and not
the experiment from the conjecture. It was not from
any previous knowledge of the internal structure of a-
quA regia and gold, and the aptness of their parts to act
or be acted upon, that we came by the conclusion above
mentioned. The internal constitution of bodies is in a
manner wholly unknown to us: and could we even sur-
mount this difficulty, yet as the separation of the parts
of gold, implies something like an active force in the mon-
strum, and we are unable to conceive how it comes to
be possessed of this activity; the effect must be owned to
be altogether beyond our comprehension. But when re-
peated trials had once confirmed it, infomuch that it was
admitted as a fait established in natural knowledge, it
was then easy for men, to spin out theories of their own
invention, and contrive such a structure of parts, both for
gold and aqua regia, as would suft give to explain the
phenomenon, upon the principles of that system of phi-
losophy they had adopted.

From what has been said it is evident, that as intuition
is the foundation of what we call scientific knowledge,
so is experience of natural knowledge. For this last, being wholly
taken up with objects of sense, or those bodies that con-
stitute the natural world; and their properties, as far as
we can discover them, being to be traced only by a long
and painful series of observations, it is apparent, that in
order to improve this branch of knowledge, we must be-
take ourselves to the method of trial and experiment.

But though experience is what we may term the im-
mediate foundation of natural knowledge, yet with re-
spect to particular persons, its influence is very narrow
and confined. The bodies that surround us are numer-
ous, many of them lie at a great distance, and some
quite beyond our reach. Life is too short, and so crowded
with cares, that but little time is left for any single man
to employ himself in unfolding the mysteries of nature.
Hence it is necessary to admit many things upon the te-
stimony of others, which by this means becomes the foun-
dation of a great part of our knowledge of body. No
man doubts of the power of aqua regia to dissolve gold,
though perhaps he never himself made the experiment.
In these therefore and such like cases, we judge of the
facts and operations of nature, upon the mere ground of
testimony. However, as we can always have recourse to
experience, where any doubt or scruple ariees, this is
justly considered as the true foundation of natural philo-
 sophy; being indeed the ultimate support upon which our
affent rests, and whereto we appeal, when the highest de-
gree of evidence is required.

But there are many facts that will not allow of an ap-
pel to the senses, and in this case testimony is the true
and only foundation of our judgments. All human actions of whatever kind, when considered as already past, are of the nature here described: because having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of such as had sufficient opportunities of arriving at the truth. Testimony therefore is justly accounted a third ground of human judgment; and as from the other two we have deduced scientific and natural knowledge, so may we from this derive historical; by which we mean, not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

Of affirmative and negative propositions.

While the comparing of our ideas, is considered merely as an act of the mind, assembling them together, and joining or disjoining them according to the result of its preceptions, we call it judgment; but when our judgments are put into words, they then bear the name of propositions. A proposition therefore is a sentence expressing some judgment of the mind, whereby two or more ideas are affirmed or denied. As to a proposition having terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the subject of the proposition. The idea affirmed or denied, as also the term answering it is called the predicate. Thus in the proposition, God is omnipotent; God is the subject, it being of him that we affirm omnipotence; and omnipotent is the predicate, because we affirm the idea expressed by that word to belong to God.

But as in propositions, ideas are either joined or disjoined; it is not enough to have terms expressing those ideas, unless we have also some words to denote their agreement or disagreement. That word in a proposition which connects two ideas together, is called the copula; and if a negative particle be annexed, we thereby mean not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

When the mind joins two ideas, we call it an affirmative judgment; when it separates them, a negative; and as any two ideas compared together, must necessarily either agree or not agree, it is evident, that all our judgments fall under these two divisions. Hence likewise, the propositions expressing these judgments, are all either affirmative or negative.

Hence we see the reason of the rule commonly laid down by logicians; that in all negative propositions, the negation ought to affect the copula. For as the copula, when placed by itself, between the subject and the predicate, manifestly binds them together; it is evident, that in order to render a proposition negative, the particle of negation must enter it in such manner, as to destroy this union. In a word, then only are two ideas disjoined in a proposition, when the negative particle may be so referred to the copula, as to break the affirmation included in it, and undo that connection it would otherwise establish. When we say, for instance, No man is perfect; take away the negation, and the copula of itself plainly unites the ideas in the proposition. On the contrary, in this sentence; The man who departs not from an upright behaviour, is beloved of God; the predicate beloved of God, is evidently affirmed of the subject an upright man; so that notwithstanding the negative particle, the proposition is still affirmative. The reason is plain; the negation here affects not the copula, but making properly a part of the subject, serves with other terms in the sentence, to form one complex idea, of which the predicate beloved of God, is directly affirmed.

Of universal and particular propositions.

The next considerable division of proposition, is into universal and particular. Our ideas, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once; hence the terms expressing these ideas, must be in like manner universal. (See Metaphysics.) If therefore we suppose any general term to become the subject of a proposition, it is evident, that whatever is affirmed of the abstract idea belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus when we say, Men are mortal; we consider mortality, not as confined to one or any number of particular men, but as what may be affirmed without reftiction of the whole species. By this means the proposition becomes as general as the idea which makes the subject of it, and indeed derives its universality entirely from that idea, being more or less so, according as this may be extended to more or fewer individuals. But these general terms sometimes enter a proposition in their full latitude, as in the example given above; and sometimes appear with a mark of limitation. In this last case we are given to understand, that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition,
All men, implies only a certain number of individuals, comprehended under it, if it denotes a proper species; and to all the several species, and their individuals, if it marks that the predicate agrees to all the individuals comprehended under a single term. Hence the power of beginning motion, may be affirmed of all the several species of animals.

A particular proposition has in like manner some general term for its subject, but with a mark of limitation added, to denote, that the predicate agrees only to some of the individuals comprehended under a species, or to one or more of the species belonging to any genus, and not to the whole universal idea. Thus, some stones are heavier than iron; some men have an uncommon share of prudence. In the latter of these propositions, the subject some men, implies only a certain number of individuals, comprehended under a single species. In the former, where the subject is a genus, that extends to a great variety of different classes, some stones may not only imply any number of particular stones, but also several whole species of stones; inasmuch as there may be not a few, with the property there described. Hence we see, that a proposition does not cease to be particular, by the predicate’s agreeing to a whole species, unless that species singly and distinctly considered, makes also the subject of which we affirm or deny.

There is still one species of propositions that remains to be described; and which the more deserve our notice, as it is not yet agreed among logicians to which of the two classes mentioned above they ought to be referred, I mean singular propositions; or those where the subject is an individual. Of this nature are the following: Sir Isaac Newton was the inventor of fluxions; This book contains many useful truths. What occasions some difficulty, as to the proper rank of these propositions, is, that the subject being taken according to the whole of its extention, they sometimes have the same effect in reasoning, as universals. But if it be considered, that they are in truth the most limited kind of particular propositions, and that no proposition can with any propriety be called universal, but where the subject is some universal idea; we shall not be long in determining to which class they ought to be referred. When we say, Some books contain useful truths; the proposition is particular, because the general term appears with a mark of restriction. If therefore we say, This book contains useful truths; it is evident that the proposition must be still more particular, as the limitation implied in the word this is of a more confined nature than in the former case.

We see therefore, that all propositions are either affirmative or negative; nor is it less evident, that in both cases they may be universal or particular. Hence arises that celebrated fourfold division of them, into universal, affirmative, and universal negative, particular affirmative, and particular negative; which comprehends indeed all their varieties. The use of this method of distinguishing them will appear more fully afterwards, when we come to treat of reasoning and syllogism.

Of absolute and conditional propositions.

The objects about which we are chiefly conversant in this world, are all of a nature liable to change. What may be affirmed of them at one time, cannot often at another; and it makes no small part of our knowledge, to distinguish rightly these variations, and trace the reasons upon which they depend. For it is observably, that amidst all the vicissitudes of nature, some things remain constant and invariable; nor are even the changes, to which we see others liable, effected, but in consequence of uniform and steady laws, which when known, are sufficient to direct us in our judgments about them. Hence philosophers, in distinguishing the objects of our perception into various classes, have been very careful to note, that some properties belong essentially to the general idea, so as not to be separable from it, but by destroying its very nature: while others are only accidental, and may be affirmed or denied of it in different circumstances. Thus, solidity, a yellow colour, and great weight, are considered as essential qualities of gold; but whether it shall exist as an uniform conjoined mass, is not alike necessary. We see that, by a proper menstruum, it may be reduced to a fine powder; and that intense heat will bring it into a state of fusion.

From this diversity in the several qualities of things, arises a considerable difference as to the manner of our judging about them. For all such properties as are inseparable from objects, when considered as belonging to any genus or species, are affirmed absolutely and without reference of that general idea. Thus we say, Gold is very heavy, a stone is hard, animals have a power of self-motion. But in the case of mutable or accidental qualities, as they depend upon some other consideration, distinct from the general idea; that also must be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very susceptible of a rolling motion; the proposition while it remains in the general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion, flows from the figure of the stone; which, as it may vary infinitely, our judgment then only becomes applicable and determinate, when the particular figure, of which volatility is a consequence, is also taken into the account. Let us then bring in this other consideration, and the proposition will run as follows: Stones of a spherical form, are easily put into a rolling motion. Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.
The consideration of propositions, respecting the manner in which the predicate is affirmed of the subject, gives rise to the division of them into absolute and conditional. Absolute propositions are those, wherein we affirm some property inseparable from the idea of the subject, and which therefore belongs to it in all possible cases; as, "God is infinitely wise." Virtue tends to the ultimate happiness of man. But where the predicate is not necessarily connected with the idea of the subject, unless upon some consideration distinct from that idea, there the proposition is called conditional. The reason of the name is taken from the supposition annexed, which is of the nature of a condition, and may be expressed as such. Thus, If a stone is exposed to the rays of the sun, it will contract some degree of heat. If a river runs in a very declining course, it will convey the water with more facility.

There is not any thing of greater importance in philosophy, than a due attention to this division of propositions. If we are careful never to affirm things absolutely, but where the ideas are inseparably connected; and if in our other judgments, we distinctly mark the conditions which determine the predicate to belong to the subject, we shall be the less liable to mistake in applying general truths to the particular concerns of human life. It is owing to the exact observance of this rule, that mathematicians have been so happy in their discoveries, and that they demonstrate of magnitude in general, may be applied with ease in all obvious occurrences.

The truth is, particular propositions are then known to be true, when we can trace their connection with universals; and it is accordingly the great business of science, to find out general truths, that may be applied with safety in all obvious instances. Now the great advantage arising from determining with care the conditions upon which one idea may be affirmed or denied of another, is this; that thereby particular propositions really become universal, may be introduced with certainty into our reasoning, and serve as standards to conduct and regulate our judgments. To illustrate this by a familiar instance. If we say, Some water acts very forcibly; the proposition is particular; and as the conditions on which this forcible action depends, are not mentioned, it is as yet uncertain in what cases it may be applied. Let us then supply the conditions, and the proposition will run thus: Water conveyed in sufficient quantity, along a steep descent, acts very forcibly. Here we have an universal judgment, inasmuch as the predicate forcible action, may be ascribed to all water under the circumstances mentioned. Nor is it less evident, that the proposition in this new form is of easy application; and in fact we find, that men do apply it, in instances where the forcible action of water is required; as in corn-mills, and many other works of art.

Of simple and compound propositions.

Hitherto we have treated of propositions, where only two ideas are compared together. These are in the general called simple; because having but one subject and one predicate, they are the effect of a simple judgment, that admits of no subdivision. But if several ideas offer themselves to our thoughts at once, whereby we are led to affirm the same thing of different objects, or different things of the same object; the propositions expressing these judgments are called compound: because they may be resolved into as many others as there are subjects or predicates in the whole complex determination of the mind. Thus: God is infinitely wise, and infinitely powerful. Here there are two predicates, infinite wisdom, and infinite power, both affirmed of the same subject; and accordingly, the proposition may be resolved into two others, affirming these predicates severally, in like manner in the proposition, neither kings nor people are exempt from death; the predicate is denied of both subjects, and may therefore be separated from them, in distinct propositions. Nor is it less evident, that if a complex judgment consists of several subjects and predicates, it may be resolved into as many simple propositions as are the number of different ideas compared together. Riches and honours are apt to elate the mind, and increase the number of our desires. In this judgment, there are two subjects and two predicates, and it is at the same time apparent, that it may be resolved into four distinct propositions. Riches are apt to elate the mind. Riches are apt to increase the number of our desires. And so of honours.

Logicians have divided these compound propositions into a great many different classes; but not with a due regard to their proper definition. Thus, conditionals, causals, relatives, &c. are mentioned as so many distinct species of this kind, though in fact they are no more than simple propositions. To give an instance of a conditional: If a stone is exposed to the rays of the sun, it will contract some degree of heat. Here we have but one subject and one predicate; for the complex expression, a stone exposed to the rays of the sun, constitutes the proper subject of this proposition, and is no more than one determinate idea. The same thing happens in causals, Rehoboam was unhappy because he followed evil counsel. There is here an appearance of two propositions, arising from the complexity of the expression, but when we come to consider the matter more nearly, it is evident, that we have but one subject and predicate. The pursuit of evil counsel brought misery upon Rehoboam. It is not enough therefore, to render a proposition compound, that the subject and predicate are complex notions, requiring sometimes a whole sentence to express them: For in this case, the comparison is still confined to two ideas, and constitutes what we call a simple judgment. But where there are several subjects, or predicates, or both, as the affirmation or negation may be alike extended to them all, the proposition expressing such a judgment, is truly a collection of as many simple ones as there are different ideas compared. Confounding ourselves therefore to this more strict and just notion of compound propositions, they are all reducible to two kinds, viz. copulatives and disjunctives.

A copulativc proposition is, where the subjects and predicates are so linked together, that they may be all severally affirmed or denied one of another. Of this nature are the examples of compound propositions given above. Riches and honours are apt to elate the mind, and increase the number of our desires. Neither kings nor people are exempt from death. In the first of these, the two
two predicates may be affirmed severally of each subject, whence we have four distinct propositions. The other furnishes an example of the negative kind, where the same predicate being disjoined from both subjects, may be also denied of them in separate propositions.

The other species of compound propositions are those called disjunctives; in which, comparing several predicates with the same subject, we affirm that one of them necessarily belongs to it, but leave the particular predicate undetermined. If any one, for example, says, *This world either exists of itself, or it is the work of some all-wise and powerful cause;* it is evident, that one of the two predicates must belong to the world; but as the proposition determines not which, it is therefore of the kind we call disjunctive. Such too are the following. *The sun either moves round the earth, or it is the centre about which the earth revolves. Friendship finds men equal, or makes them so.* It is the nature of all propositions of this class, supposing them to be exact in point of form, that upon determining the particular predicate, the rest are of course to be removed; or if all the predicates but one are removed, that one necessarily takes place. Thus in the example given above; if we allow the world to be the work of some wise and powerful cause, we of course deny it to be self-existent; or if we deny it to be self-existent, we must necessarily admit that it was produced by some wise and powerful cause. Now this particular manner of linking the predicates together, so that the establishing of one displaces all the rest, or the excluding all but one necessarily establishes that one, cannot otherwise be effected than by means of disjunctive particles. And hence it is, that propositions of this class take their name from these particles, which make so necessary a part of them, and indeed constitute their very nature considered as a distinct species.

Of the division of propositions into self-evident and demonstrable.

When any proposition is offered to the view of the mind, if the terms in which it is expressed are understood; upon comparing the ideas together, the agreement or disagreement asserted is either immediately perceived, or found to lie beyond the present reach of the understanding. In the first case, the proposition is said to be self-evident, and admits not of any proof, because a bare attention to the ideas themselves produces full conviction and certainty; nor is it possible to call in anything more evident, by way of confirmation. But where the connection or repugnance comes not so readily under the inspection of the mind, there we must have recourse to reasoning; and if by a clear series of proofs we can make out the truth propounded, insomuch that self-evidence shall accompany every step of the procedure, we are then able to demonstrate what we assert, and the proposition itself is said to be demonstrable. When we affirm, for instance, *that it is impossible for the same thing to be and not to be;* whoever understands the terms makes use of, perceives at first glance the truth of what is asserted; nor can he by any efforts bring himself to believe the contrary. The proposition therefore is self-evident, and such that it is impossible by reasoning to make it plainer; because there is no truth more obvious, or better known, from which as a consequence it may be deduced. But if we say, *This world had a beginning;* the assertion is indeed equally true, and stands not forth with the same degree of evidence. We find a great difficulty in conceiving how the world could be made out of nothing; and are not brought to a free and full consent, until by reasoning we arrive at a clear view of the absurdity involved in the contrary supposition. Hence this proposition is of the kind we call demonstrable, inasmuch as its truth is not immediately perceived by the mind, but yet may be made appear by means of others more known and obvious, whence it follows as an unavoidable consequence.

From what has been said it appears, that reasoning is employed only about demonstrable propositions, and that our intuitive and self-evident perceptions are the ultimate foundation on which it rests.

Self-evident propositions furnish the first principles of reasoning; and it is certain, that if in our researches we employ only such principles as have this character of self-evidence, and apply them according to the rules to be afterwards explained, we shall be in no danger of error in advancing from one discovery to another. For this we may appeal to the writings of the mathematicians, which being conducted by the express model here mentioned, are an incontestable proof of the firmness and stability of human knowledge, when built upon so sure a foundation. For not only have the propositions of this science stood the test of ages; but are found attended with that invincible evidence, as forces the assent of all who duly consider the proofs upon which they are established.

First then it is to be observed, that they have been very careful in ascertaining their ideas, and fixing the significance of their terms. For this purpose they begin with definitions, in which the meaning of their words is so distinctly explained, that they cannot fail to excite in the mind the very fame ideas as are annexed to them by the writer. And indeed the clearness and irresistible evidence of mathematical knowledge is owing to nothing so much as this care in laying the foundation. Where the relation between any two ideas is accurately and justly traced, it will not be difficult for another to comprehend that relation, if, in setting himself to discover it, he brings the very same ideas into comparison. But if, on the contrary, he affixes to his words ideas different from those that were in the mind of him who first advanced the demonstration; it is evident, that, as the same ideas are not compared, the same relation cannot subsist, insomuch that a proposition will be rejected as false, which, had the terms been rightly understood, must have appeared unexceptionably true. A square, for instance, is a figure bounded by four equal right lines, joined together at right angles. Here the nature of the angles makes no less a part of the idea, than the equality of the sides; and many properties demonstrated of the square flow entirely from its being a rectangular figure. If therefore we suppose a man, who has formed a partial notion of a square, comprehending only the equality of its sides without regard to the angles, reading some demonstration that implies also this latter consideration; it is plain he would reject it as not universally true, in as much as it could not be applied where the sides were joined together.
either at unequal angles. For this last figure, answering
still to his idea of a square, would be yet found without
the property assigned to it in the proposition. But if he
comes afterwards to correct his notion, and render his
idea complete, he will then readily own the truth and
justness of the demonstration.

We see therefore, that nothing contributes so much to
the improvement and certainty of human knowledge, as
the having determinate ideas, and keeping them fixed
and invariable in all our discourses and reasonings about
them. And on this account it is, that mathematicians
always begin by defining their terms, and distinctly un-
folding the notions they are intended to express. Hence
such as apply themselves to these studies, having exactly
the same ideas of things, and bringing always the very
fame ideas into comparison, readily discern the relations
between them.

When they have taken this first step, and made known
the ideas whose relations they intend to investigate; their
next care is, to lay down some self-evident truths, which
may serve as a foundation for their future reasonings.
And here indeed they proceed with remarkable circum-
spection, admitting no principles but what flow im-
mEDIATELY from their definitions, and necessarily force them-

selves upon the mind. Thus a circle is a figure formed
by a right line, moving round some fixed point in the
same plane. The fixed point round which the line is
supposed to move, and where one of its extremities ter-

minates, is called the centre of the circle. The other
extremity, which is conceived to be carried round, until
it returns to the point whence it first set out, describes a
curve running into itself, and termed the circumference.
All right lines drawn from the centre to the circumference,
are called radii. From these definitions compared,
red, geometers derive this self-evident truth, That the
radii of the same circle are all equal one to another.

We now observe, that, in all propositions, we either
affirm or deny some property of the idea that constitutes
the subject of our judgment, or we maintain that some-
thing may be done or effected. The first sort are called
speculative propositions, as in the example mentioned a-
bove, the radii of the same circle are all equal one to
another. The others are called practical, for a reason
too obvious to be mentioned; thus, that a right line
may be drawn from one point to another, is a practical
proposition, inasmuch as it expresses that something may
be done.

From this twofold consideration of propositions arises
the twofold division of mathematical principles into axioms
and postulates. By an axiom they understand any self-
evident speculative truth: as, that the whole is greater
than its parts; that things equal to one and the same
things are equal to one another. But a self-evident prac-
tical proposition is what they call a postulate. Such are
those of Euclid: That a finite right line may be continued
directly forwards: That a circle may be described about
any centre with any distance. And as, in an axiom, the
agreement or disagreement between the subject and pre-
dicate must come under the immediate inspection of the
mind; so, in a postulate, not only the possibility of the
thing asserted must be evident at first view, but also the
manner in which it may be effected. For where this
manner is not of itself apparent, the proposition comes
under the notion of the demonstrable kind, and is treated
as such by geometrical writers. Thus, to draw a right
line from one point to another, is assumed by Euclid as
a postulate, because the manner of doing it is so obvious
as to require no previous teaching. But then it is not
equally evident, how we are to construct an equilateral
triangle. For this reason he advances it as a demonstra-
tional proposition, lays down rules for the exact performance,
and at the same time proves, that if these rules are fol-

owed, the figure will be justly described.

This leads us to take notice, that as self-evident truths
are distinguished into different kinds, according as they
are speculative or practical; so it is also with demonstra-
tional propositions. A demonstrable speculative proposition,
is by mathematicians called a theorem. Such is the 47th
proposition of the first book of the Elements, viz that
in every right-angled triangle, the square described upon
the side subtending the right-angle is equal to both the
squares described upon the sides containing the right-
angle. On the other hand, a demonstrable practical
proposition, is called a problem; as where Euclid teaches
us to describe a square upon a given right-line.

It may not be amiss to add, that besides the four kinds
of propositions already mentioned, mathematicians have
also a fifth, known by the name of corollaries. These
are usually subjoined to theorems, or problems, and differ
from them only in this; that they flow from what is
there demonstrated, in so obvious a manner, as to disco-
very their dependence upon the proposition whence they
are deduced, almost as soon as proposed. Thus Euclid
having demonstrated, that in every right-lined triangle
all the three angles taken together are equal to two right
angles; adds by way of corollary, that all the three
angles of any one triangle taken together are equal to all
the three angles of any other triangle taken together;
which is evident at first sight; because in all cases they are
equal to two right ones, and things equal to one and the
same thing are equal to one another.

The scholia of mathematicians are indifferently an-
exed to definitions, propositions, or corollaries; and
answer the same purposes as annotations upon a classical
author. For in them occasion is taken to explain what-
ever may appear intricate and obscure in a train of rea-

oning; to answer objections; to teach the application
and uses of propositions; to lay open the original and
history of the several discoveries made in the science;
and in a word, to acquaint us with all such particulars as
deserve to be known, whether considered as points of
curiosity or profit.

**Part II. Of Reasoning.**

It often happens, in comparing ideas together, that
their agreement or disagreement cannot be discerned at first
view, especially if they are of such a nature as not to
admit of an exact application one to another. When, for
instance,
instance, we compare two figures of a different make, in order to judge of their equality or inequality, it is plain, that by barely considering the figures themselves we cannot arrive at an exact determination; because, by reason of their disfiguring forms, it is impossible to put them together, as that their several parts shall mutually coincide. Here then it becomes necessary to look out for some third idea, that will admit of such an application as the present case requires; wherein if we succeed, all difficulties vanish, and the relation we are in quest of may be traced with ease. Thus right-lined figures are all reducible to figures, by means of which we can measure their areas, and determine exactly their agreement or disaffreement in point of magnitude.

But how can any third idea serve to discover a relation between two others, by being compared severally with these others? for such a comparison enables us to see how far the ideas with which this third is compared are connected or disjoined between themselves. In the example mentioned above, of two right-lined figures, if we compare each of them with some square whose area is known, and find the one exactly equal to it, and the other less by a square inch, we immediately conclude, that the area of the first figure is a square inch greater than that of the second. This manner of determining the relation between any two ideas, by the intervention of some third with which they may be compared, is that which we call reasoning. The great art lies, in finding out such intermediate ideas, as, when compared with the others in the question, will furnish evident and known truths, because it is only by means of them that we arrive at the knowledge of what is hidden and remote.

Hence it appears, that every act of reasoning necessarily includes three distinct judgments; two wherein the ideas whose relation we want to discover are severally compared with the middle idea, and a third wherein they are themselves compared or disjoined according to the result of that comparison. Now, as, in the first part of logic, our judgments, when put into words, were called propositions; so here, in the second part, the expressions of our reasonings are termed syllogisms. And hence it follows, that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. When a reasoning is thus put into words, and appears in form of a syllogism, the intermediate idea makes use of to discover the agreement or disaffreement we search for is called the middle term; and the two ideas themselves, with which this third is compared, go by the name of the extremes.

But as these things are best illustrated by examples; let us, for instance, set ourselves to inquire, whether men are accountable for their actions. As the relation between the ideas of man and accountableness, comes not within the immediate view of the mind, our first care must be, to find out some third idea, that will enable us the more easily to discover and trace it. A very small measure of reflection is sufficient to inform us, that no creature can be accountable for his actions, unless we suppose him capable of distinguishing the good from the bad. Nor is this alone sufficient. For what would it avail him to know good from bad actions, if he had no freedom of choice, nor could avoid the one and pursue the other? hence it becomes necessary to take in both confederations in the present case. It is at the same time equally apparent, that where-ever there is this ability of distinguishing good from bad actions, and of pursuing the one and avoiding the other, there also a creature is accountable. We have then got a third idea, with which accountableness is inseparably connected, viz. reason and liberty; which are here to be considered as making up one complex conception. Let us now take this middle idea, and compare it with the other term in the question, viz. man; and we all know by experience, that it may be affirmed of him. Having thus, by means of the intermediate idea, formed two several judgments, viz. that man is possessed of reason and liberty; and that reason and liberty imply accountableness; a third obviously and necessarily follows, viz. that man is accountable for his actions. Here then we have a complete act of reasoning, in which there are three distinct judgments; two that may be styled previous, in as much as they lead to the other, and arise from comparing the middle idea with the two ideas in the question: the third is a consequence of these previous acts, and flows from combining the extreme ideas between themselves. If we now put this reasoning into words, it exhibits what logicians term a syllogism, and runs thus:

Every creature possessed of reason and liberty is accountable for his actions.

Man is a creature possessed of reason and liberty.

Therefore man is accountable for his actions.

In this syllogism there are three several propositions, expressing the three judgments implied in the act of reasoning, and so disposed as to represent distinctly what passes within the mind in tracing the more distant relations of its ideas. The two first propositions answer the two previous judgments in reasoning, and are called the premises, because they are placed before the other. The third is termed the conclusion, as being gained in consequence of what was asserted in the premises. The terms expressing the two ideas whose relation we inquire after, and as here man and accountableness, are in general called the extremes; and the intermediate idea, by means of which the relation is traced, viz. a creature possessed of reason and liberty, takes the name of the middle term. Hence it follows, that by the premises of a syllogism we are always to understand the two propositions where the middle term is severally compared with the extremes; for these constitute the previous judgments. Where the truth we are in quest of is by reasoning deduced. The conclusion is that other proposition, in which the extremes themselves are joined or separated, agreeably to what appears upon the above comparison.

The conclusion is made up of the extreme terms of the syllogism; and the extreme, which serves as the predicate of the conclusion, goes by the name of the major term; the other extreme, which makes the subject in the same proposition, is called the minor term. From this distinction of the extremes, arises also a distinction between the premises, where these extremes are severally compared with the middle term. That proposition which compares the greater extreme, or the predicate of the conclusion, with the middle term, is called the major proposition;
Jition. When a syllogism is proposed in due form, the
for his actions, gives what we call the major proposition. In
reaforing to be an act or operation of the mind, dedu-
carded with the middle term in the first of the two premis,
estioa is, Man is accountable for his actions. For here
vious from the syllogism already given, where the con-
icted, with the same
in the second of the premis, Man is a creature possessed of reason and liberty is accountable
the subject of the conclusion, viz. man, connected with the same
middle term, whence it is known to be the minor propo-
When a syllogism is proposed in due form, the
major proposition is always placed first, the minor next,
and the conclusion last.

These things premised, we may in the general define
reasoning to be an act or operation of the mind, dedu-
ing some unknown proposition from other previous ones
that are evident and known. These previous propositions,
in a single act of reasoning, are only two in number; and
it is always required that they be of themselves apparent
to the understanding, in so much that we attend to and
perceive the truth of them as soon as proposed. In the
syllogism given above, the premises are supposed to be
self-evident truths, otherwise the conclusion could not be
inferred by a single act of reasoning. If, for instance,
in the major, every creature possessed of reason and liberty
is accountable for his actions, the connection between the
subject and predicate could not be perceived by a bare at-
tention to the ideas themselves; it is evident, that this
proposition would not least require a proof than the con-
clusion deduced from it. In this case a new middle term
must be sought for, to trace the connection here supposed;
and this of course furnishes another syllogism, by which
having established the proposition in question, we are then,
and not before, at liberty to use it in any succeeding train
of reasoning. And should it so happen, that in this second
effay there was still some previous proposition whose
truth did not appear at first sight, we must then have re-
course to a third syllogism in order to lay open that truth
to the mind; because, so long as the premises remain un-
certain, the conclusion built upon them must be so too.
When by conducting our thoughts in this manner, we at
last arrive at some syllogism, where the previous proposi-
tions are intuitive truths; the mind then rests in full
security, as perceiving that the several conclusions it has
passed through stand upon the immovable foundation of
self-evidence, and when traced to their source terminate
in it.

We see, therefore, that in order to infer a conclusion
by a single act of reasoning, the premises must be intuitive
propositions. Where they are not, previous syllogisms
are required; in which case reasoning becomes a compli-
cated act, taking in a variety of successive steps. This
frequently happens in tracing the more remote relations
of our ideas, where many middle terms being called in,
the conclusion cannot be made out, but in consequence of
a series of syllogisms following one another in a train.
But although in this concatenation of propositions, those
that form the premises of the last syllogism are often
considerably removed from self-evidence; yet if we trace
the reasoning backwards, we shall find them the conclu-
sions of previous syllogisms, whose premises approach
nearer and nearer to intuition, in proportion as we ad-
advance, and are found at last to terminate in it. And if,
after having thus unravelled a demonstration, we take it
the contrary way; and observe how the mind, setting out
with intuitive perceptions, couples them together to form
a conclusion; now, by introducing this conclusion into an-
other syllogism, it still advances one step farther; and so
proceeds, making every new discovery subserve to its
future progress; we shall then perceive clearly, that
reasoning, in the highest exercise of that faculty, is no
more than an orderly combination of those simple acts
which we have already so full explained.

Thus we see, that reasoning, beginning with first
principles, riles gradually from one judgment to another,
and connects them in such a manner, that every stage of
the progress brings intuitive certainty along with it.
And now at length we may clearly understand the defini-
tion given above of this differentiating faculty of the hu-
man mind. Reason is the ability of deducing unknown
truths from principles or propositions that are already
known. This evidently appears by the foregoing account,
where we see, that no proposition is admitted into a
syllogism, to serve as one of the previous judgments on
which the conclusion rests, unless it is itself a known and
established truth, whose connection with self-evident prin-
ципes has been already traced.

Of the several kinds of reasoning; and first of that by
which we determine the genera and species of things.

All the aims of human reason may be reduced to these
two: 1. To rank things under those universal ideas to
which they truly belong; and, 2. To ascribe to them their
several attributes and properties in consequence of that
distribution.

One great aim of human reason is, to determine the
genera and species of things. Now, as in universal pro-
positions we affirm some property of a genus or species,
it is plain, that we cannot apply this property to partic-
ular objects, till we have first determined whether they
are comprehended under that general idea of which the
property is affirmed. Thus there are certain properties
belonging to all even numbers, which nevertheless can-
not be applied to any particular number, until we have
first discovered it to be of the species expressed by that
general name. Hence reasoning begins with referring things
to their several divisions and classes in the scale of our
ideas; and as these divisions are all distinguished by pecu-
lar names, we hereby learn to apply the terms ex-
pressing general conceptions to such particular objects as
come under our immediate observation.

Now, in order to arrive at these conclusions by which
the several objects of perception are brought under gene-
ral names, two things are manifestly necessary. First,
that we take a view of the idea itself denoted by that ge-
neral name, and carefully attend to the distinguishing
marks which serve to characterize it. Secondly, that we
compare this idea with the object under consideration,
observing diligently wherein they agree or differ. If
the
the idea is found to correspond with the particular object; we then without hesitation apply the general name; but if no such correspondence intervenes, the conclusion must necessarily take a contrary turn. Let us, for instance, take the number eight, and consider by what steps we are led to pronounce it an even number. First then we call to mind the idea signified by the expression an even number, viz. that it is a number divisible into two equal parts. We then compare this idea with the number eight, and, finding them manifestly to agree, see at once the necessity of admitting the conclusion. Thrice several judgments therefore, transferred into language, and reduced to the form of a syllogism, appear thus:

Every number that may be divided into two equal parts is an even number.

The number eight may be divided into two equal parts. Therefore the number eight is an even number.

Here it may be observed, that where the general idea to which particular objects are referred is very familiar to the mind, this reference, and the application of the general name, seem to be made without any apparatus of reasoning. When we see a horse in the fields, or a dog in the street, we readily apply the name of the species; habit, and a familiar acquaintance with the general idea, suggesting it instinctually to the mind. We are not however to imagine on this account, that the understanding departs from the usual rules of just thinking. A frequent repetition of acts begotten a habit; and habits are attended with a certain promptness of execution that prevents our observing the several steps and gradations by which any course of action is accomplished. But in other instances, where we judge not by pre-contracted habits, as when the general idea is very complex, or less familiar to the mind; we always proceed according to the form of reasoning established above. A goldsmith, for instance, who is in doubt as to any piece of metal, whether it be of the species called gold; first examines its properties, and then comparing them with the general idea signified by that name, if he finds a perfect correspondence, no longer hesitates under what clafs of metals to rank it.

But the great importance of this branch of reasoning, and the necessity of care and circumspection in referring particular objects to general ideas, is still farther evident from the practice of the mathematicians. Every one who has read Euclid knows, that he frequently requires us to draw lines through certain points, and according to such and such directions. The figures thence resulting are often squares, parallelograms, or rectangles. Yet Euclid never supposes this from their bare appearance, but always demonstrates it upon the strictest principles of geometry. Nor is the method he takes in any thing different from that described above. Thus, for instance, having defined a square to be a figure bounded by four equal sides, joined together at right angles; when such a figure arises in any construction previous to the demonstration of a proposition, he yet never calls it by that name, until he has shewn that its sides are equal, and all its angles right ones. Now this is apparently the same form of reasoning we have before exhibited, in proving eight to be an even number.

VOL. II. No 68.

Having thus explained the rules by which we are to conduct ourselves in ranking particular objects under general ideas, and shewn their conformity to the practice and manner of the mathematicians; it remains only to observe, that the true way of rendering this part of knowledge both easy and certain, is, by habituating ourselves to clear and determinate ideas, and keeping them steadily annexed to their respective names. For as all our aim is, to apply general words aright; if these words stand for invariable ideas, that are perfectly known to the mind, and can be readily distinguished upon occasion, there will be little danger of mistake or error in our reasonings. Let us suppose, that by examining any object, and carrying our attention successively from one part to another, we have acquainted ourselves with the several particulars observable in it. If among these we find such as constitute some general idea, framed and settled beforehand by the understanding, and distinguished by a particular name; the resemblance, thus known and perceived, necessarily determines the species of the object, and thereby gives it a right to the name by which that species is called. Thus four equal sides, joined together at right angles, made up the notion of a square. As this is a fixed and invariable idea, without which the general name cannot be applied, we never call any particular figure a square, until it appears to have these several conditions; and contrariwise, where-ever a figure is found with these conditions, it necessarily takes the name of a square. The name will be found to hold in all our other reasonings of this kind; where nothing can create any difficulty but the want of settled ideas. If, for instance, we have not determined within ourselves the precise notion denoted by the word manslaughter; it will be impossible for us to decide, whether any particular action ought to bear that name: because however nicely we examine the action itself, yet being strangers to the general idea with which it is to be compared, we are utterly unable to judge of their agreement or disagreement. But if we take care to remove this obstacle, and distinctly trace the two ideas under consideration, all difficulties vanish, and the resolution becomes both easy and certain.

Thus we see, of what importance it is, towards the improvement and certainty of human knowledge, that we accustom ourselves to clear and determinate ideas, and a steady application of words.

Of Reasoning, as it regards the powers and properties of things, and the relations of our general ideas.

We come now to the second great end which men have in view in their reasonings, namely, The discovering and ascribing to things their several attributes and properties. And here it will be necessary to distinguish between reasoning as it regards the sciences, and as it concerns common life. In the sciences, our reason is employed chiefly about universal truths, it being by them alone that the bounds of human knowledge are enlarged. Hence the division of things into various classes, called otherwise genera and species. For these universal ideas, being set up as the representatives of many particular things, whatever is affirmed of them may be also affirmed of all the individuals to which they belong. Murder, for instance,
LOGIC

is a general idea, representing a certain species of human actions. Reason tells us that the punishment due to it is death. Hence every particular action coming under the notion of murder, has the punishment of death allotted to it. Here then we apply the general truth to some obvious instance, and this is what properly constitutes the reasoning of common life. For men, in their ordinary transactions and intercourse one with another, have for the most part to do only with particular objects. Our friends and relations, their characters and behaviour, the constitution of the several bodies that surround us, and the uses to which they may be applied, are what chiefly engage our attention. In all these we reason about particular things; and the whole result of our reasoning is, the applying the general truths of the sciences to the ordinary transactions of human life. When we see a viper, we avoid it. Wherever we have occasion for the forcible action of water, to move a body that makes considerable resistance, we take care to convey it in such a manner that it shall fall upon the object with impetuosity. Now all this happens in consequence of our familiar and ready application of these two general truths. The bite of a viper is mortal. Water falling upon a body with impetuosity, acts very forcibly towards setting it in motion. In like manner, if we set ourselves to consider any particular character, in order to determine the share of praise or dispraise that belongs to it, our great concern is, to ascertain exactly the proportion of virtue and vice. The reason is obvious. A just determination in all cases of this kind depends entirely upon an application of these general maxims of morality: Virtuous actions deserve praise. Vicious actions deserve blame.

Hence it appears, that reasoning, as it regards common life, is no more than the ascribing the general properties of things to those several objects with which we are more immediately concerned, according as they are found to be that particular division or class to which the properties belong. The steps then by which we proceed are manifestly these. First, we refer the object under consideration to some general idea or class of things. We then collect the several attributes of that general idea. And lastly, ascribe all those attributes to the present object. Thus, in considering the character of Sempronius, if we find it to be of the kind called virtuous; when we at the same time reflect, that a virtuous character is deserving of esteem, it naturally and obviously follows that Sempronius is so too. These thoughts put into a syllogism, in order to exhibit the form of reasoning here required, run thus.

Every virtuous man is worthy of esteem.
Sempronius is a virtuous man.
Therefore Sempronius is worthy of esteem.

By this syllogism it appears, that before we affirm any thing of a particular object, that object must be referred to some general idea. Sempronius is pronounced worthy of esteem, only in consequence of his being a virtuous man. Hence we see the necessary connection of the various parts of reasoning, and the dependence they have one upon another. The determining the genera and species of things is, as we have said, one exercise of human reason; and here we find, that this exercise is the first in order, and previous to the other, which consists in ascribing to them their powers, properties, and relations. But when we have taken this previous step, and brought particular objects under general names; as the properties we ascribe to them are no other than those of the general idea, it is plain, that in order to a successful progress in this part of knowledge, we must thoroughly acquaint ourselves with the several relations and attributes of these our general ideas. When this is done, the other part will be easy, and require scarce any labour of thought, as being no more than an application of the general form of reasoning rephrased in the foregoing syllogism. Now as we have already sufficiently shown how we are to proceed in determining the genera and species of things, all that is farther wanting towards a due explanation of it is, to offer some considerations as to the manner of investigating the general relations of our ideas. This is the highest exercise of the powers of the understanding, and that by means whereof we arrive at the discovery of universal truths, inasmuch that our deductions in this way constitute that particular species of reasoning which we have before said regards principally the sciences.

But that we may conduct our thoughts with some order and method, we shall begin with observing, that the relations of our general ideas are of two kinds. Either such as immediately discover themselves, upon comparing the ideas one with another; or such as, being more remote and distant, require art and contrivance to bring them into view. The relations of the first kind furnish us with intuitive and self-evident truths; those of the second are traced by reasoning and a due application of intermediate ideas. It is of this last kind that we are to speak here, having dispatched what was necessary with regard to the other in the former part. As therefore, in tracing the more distant relations of things, we must always have recourse to intervening ideas, and are more or less successful in our researches, according to our acquaintance with these ideas, and ability of applying them; it is evident, that to make a good reasoner, two things are principally required. Firstly, an extensive knowledge of those intermediate ideas, by means of which things may be compared one with another. Secondly, the skill and talent of applying them happily, in all particular instances that come under consideration.

In order to our successful progress in reasoning, we must have an extensive knowledge of those intermediate ideas by means of which things may be compared one with another. For as it is not every idea that will answer the purpose of our inquiries, but such only as are peculiarly related to the objects about which we reason, so as, by a comparison with them, to furnish evident and known truths; nothing is more apparent, than that the greater variety of conceptions we can call into view, the more likely we are to find some among them that will help us to the truths here required. And indeed it is found to hold in experience, that in proportion as we enlarge our views of things, and grow acquainted with a multitude of different objects, the reasoning faculty gathers strength. For by extending our sphere of knowledge, the mind acquires a certain force and penetration, as being accustomed to examine the several appearances of its ideas, and observe what light they cast one upon another.
This is the reason, why, in order to excel remarkably in any one branch of learning, it is necessary to have at least a general acquaintance with the whole circle of arts and sciences. The truth is, all the various divisions of human knowledge are very nearly related among themselves, and in innumerable instances serve to illustrate and set off each other. And although it is not to be denied, that, by an obstinate application to one branch of study, a man may make considerable progress and acquire some degree of eminence in it; yet his views will be always narrow and contracted, and he will want that masterly discernment, which not only enables us to pursue our discoveries with ease, but also, in laying them open to others, to spread a certain brightness around them. But when our reasoning regards a particular science, it is farther necessary, that we more nearly acquaint ourselves with whatever relates to that science. A general knowledge is a good preparation, and enables us to proceed with ease and expedition, in whatever branch of learning we apply to. But then in minute and intricate questions of any science we are by no means qualified to reason with advantage, until we have perfectly mastered the science to which they belong.

We come now to the second thing required, in order to a successful progress in reasoning, namely, the skill and talent of applying intermediate ideas happily in all particular instances that come under consideration. Use and exercise are the best instructors in the present case. And therefore the true way to acquire this talent is, by being much conversant in those sciences where the art of reasoning is allowed to reign in the greatest perfection. Hence it was that the ancients, who so well understood the manner of forming the mind, always began with mathematicks, as the foundation of their philosophical studies. Here the understanding is by degrees habituated to truth, contracts indefinably a certain fondness for it, and learns never to yield its assent to any proposition, but where the evidence is sufficient to produce full conviction. For this reason Plato has called mathematical demonstrations the catharticks or purgatives of the soul, as being the proper means to cleanse it from error, and restore that natural exercise of its faculties, in which just thinking consists.

If therefore we would form our minds to a habit of reasoning closely and in train, we cannot take any more certain method, than the exercising ourselves in mathematical demonstrations, so as to contract a kind of familiarity with them. Not that we look upon it as necessary that all men should be deep mathematicians, but that, having got the way of reasoning which that study necessarily brings the mind to, they may be able to transfer it to other parts of knowledge, as they shall have occasion.

But although the study of mathematicks be of all others the most useful to form the mind, and give it an early relish of truth, yet ought not other parts of philosophy to be neglected. For there also we meet with many opportunities of exercising the powers of the understanding: and the variety of subjects naturally leads us to observe all those different turns of thinking that are peculiarly adapted to the several ideas we examine and the truths we search after. For this purpose, besides the study of mathematicks, we ought to apply ourselves diligently to the reading of such authors as have distinguished themselves for strength of reasoning, and a just and accurate manner of thinking. For it is observable, that a mind exercised and refioned to truth, seldom relapses into a bare contemplation of the arguments offered by others, but will be frequently exercising its own strength, and purging its discoveries upon the plan it is most accustomed to. Thus we inestimably contract a habit of tracing truth from one stage to another, and of investigating those general relations and properties, which we afterwards ascribe to particular things, according as we find them comprehended under the abstract ideas to which the properties belong.

Of the forms of Syllogisms.

Hitherto we have contented ourselves with a general notion of syllogisms, and of the parts of which they consist. It is now time to enter a little more particularly into the subject, to examine their various forms, and lay open the rules of argumentation proper to each. In the syllogisms mentioned in, we may observe, that the middle term is the subject of the major proposition, and the predicate of the minor. This disposition, though the most natural and obvious, is not however necessary; it frequently happening, that the middle term is the subject in both the premises, or the predicate in both; and sometimes directly contrary, the predicate in the major, and the subject in the minor. Hence the distinction of syllogisms into various kinds, called figures by logicians. For figure, according to their use of the word, is nothing else but the order and disposition of the middle term in any syllogism. And as this disposition is fourfold, so the figures of syllogisms thence arising are four in number.

When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure. If, on the other hand, it is the predicate of both the premises, the syllogism is said to be in the second figure. Again, in the third figure, the middle term is the subject of the two premises. And lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the fourth figure.

But besides this fourfold distinction of syllogisms, there is also a farther subdivision of them in every figure, arising from the quantity and quality, as they are called, of the propositions. By quantity we mean the consideration of propositions as universal or particular; by quality, as affirmative or negative. Now as, in all the several dispositions of the middle term, the proposition of which a syllogism consists may be either universal or particular, affirmative or negative; the due determination of these, and so putting them together as the laws of argumentation require, constitute what logicians call the moods of syllogisms. Of these moods there are a determinate number to every figure, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

The division of syllogisms according to mood and figure,
If it appears that the consequent ought to be rejected, we ought also to admit the consequent. In like manner the antecedent always expresses some condition, which necessarily implies the antecedent; we allow of that condition, and therefore bound to reject also the antecedent. For as the antecedent must always contain some certain and general condition, which necessarily implies the consequent; for otherwise the proposition itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is affirmed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but if we reject the consequent, we are in like manner bound to reject also the antecedent. For as the antecedent always expresses some condition, which necessarily implies the truth of the consequent; by admitting the antecedent we allow of that condition, and therefore ought also to admit the consequent. In like manner if it appears that the consequent ought to be rejected, the antecedent evidently must be so too; because the admitting of the antecedent would necessarily imply the admission also of the consequent.

There are two ways of arguing in hypothetical syllogisms, which lead to a certain and unavoidable conclusion. As for the major is always a conditional proposition, containing of an antecedent and a consequent; if the minor admits the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the modus ponens, in as much as by it the whole conditional proposition both antecedent and consequent is established. Thus:

**If God is infinitely wise, and acts with perfect freedom,**

*Therefore he does nothing but what is best.*

In this example, the major is conditional, and therefore the syllogism itself is termed conditional. Thus:

**If there is a God, he ought to be worshipped.**

*Therefore he ought to be worshipped.*

In this example, the major is conditional, and therefore the syllogism itself is also of the kind called by that name. All conditional propositions are made up of two distinct parts: one expressing the condition upon which the predicate agrees or disagrees with the subject, as in this now before us, *if there is a God;* the other joining or disjoining the said predicate and subject, as here, *he ought to be worshipped.* The first of these parts, or that which implies the condition, is called the antecedent; the second, where we join or disjoin the predicate and subject, has the name of the consequent.

In all propositions of this kind, supposing them to be exact in point of form, the relation between the antecedent and consequent must ever be true and real; that is, the antecedent must always contain some certain and genuine condition, which necessarily implies the consequent; for otherwise the proposition itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is affirmed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but if we reject the consequent, we are in like manner bound to reject also the antecedent. For as the antecedent always expresses some condition, which necessarily implies the truth of the consequent; by admitting the antecedent we allow of that condition, and therefore ought also to admit the consequent. In like manner if it appears that the consequent ought to be rejected, the antecedent evidently must be so too; because the admitting of the antecedent would necessarily imply the admission also of the consequent.

There are two ways of arguing in hypothetical syllogisms, which lead to a certain and unavoidable conclusion. For as the major is always a conditional proposition, containing of an antecedent and a consequent; if the minor admits the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the modus ponens, in as much as by it the whole conditional proposition both antecedent and consequent is established. Thus:

**If God were not a being of infinite goodness, neither would he consult the happiness of his creatures.**

*But God does consult the happiness of his creatures; therefore he is a being of infinite goodness.*

These two species take in the whole class of conditional syllogisms, and include all the possible ways of arguing that lead to a legitimate conclusion; because we cannot here proceed by a contrary process of reasoning, that is, from the removal of the antecedent to the removal of the consequent, or from the establishing of the consequent to the establishing of the antecedent. For although the antecedent always expresses some real condition, which once admitted necessarily implies the consequent, yet it does not follow that there is therefore no other condition; and if so, then, after removing the antecedent, the consequent may still hold, because of some other determination that infers it. When we say: *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat;* the proposition is certainly true; and admitting the antecedent, we must also admit the consequent. But as there are other ways by which a stone may gather heat, it will not follow, from the ceasing of the before-mentioned condition, that therefore the consequent cannot take place. In other words, we cannot argue: *But the stone has not been exposed to the rays of the sun; therefore neither has it any degree of heat.* In as much as there a great many other ways by which heat might have been communicated to it. And if we cannot argue from the removal of the antecedent to the removal of the consequent, no more can we from the admission of the consequent to the admission of the antecedent; because as the consequent may flow from a great variety of different suppositions, the allowing of it does not determine the precise supposition, but only that some one of them must take place. Thus, in the foregoing proposition, *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat;* admitting the consequent, viz. that it has contracted a certain degree of heat, we are not therefore bound to admit the antecedent, that it has been some time exposed to the rays of the sun, because there are many other causes whence that heat may have proceeded. These two ways of arguing, therefore, hold not in conditional syllogisms.

As from the major's being a conditional proposition, we obtain the species of conditional syllogisms; so where it is,
LOGIC

is a disjunctive proposition, the syllogism to which it belongs is also called disjunctive, as in the following example:

The world is either self-existent, or the work of some finite, or of some infinite being.

But it is not self-existent, nor the work of a finite being. Therefore it is the work of an infinite being.

Now a disjunctive proposition is that where, of several predicats, we affirm one necessarily to belong to the subject, to the exclusion of all the rest, but leave that particular one undetermined. Hence it follows, that as soon as we determine the particular predicate, all the rest are of course to be rejected; or if we reject all the predicates but one, that one necessarily takes place. When therefore, in a disjunctive syllogism, the several predicates are enumerated in the major; if the minor establishes any one of these predicates, the conclusion ought to remove all the rest; or if, in the minor, all the predicates but one are removed, the conclusion must necessarily establish that one. Thus, in the disjunctive syllogism given above, the major affirms one of three predicates to belong to the earth, viz. self-existence, or that it is the work of a finite or that it is the work of an infinite being. Two of these predicates are removed in the minor, viz. self-existence, and the work of a finite being. Hence the conclusion necessarily ascribes to it the third predicate, and affirms that it is the work of an infinite being. If now we give the syllogism another turn, inasmuch that the minor may establish one of the predicates, by affirming the earth to be the production of an infinite being; then the conclusion must remove the other two, ascertaining it to be neither self-existent, nor the work of a finite being. These are the forms of reasoning in this species of syllogisms, the judiciousness of which appears at first sight; and that there can be no other, is evident from the very nature of a disjunctive proposition.

In the several kinds of syllogisms hitherto mentioned, the parts are complete, that is, the three propositions of which they consist are represented in form. But it often happens, that some one of the premises is not only an evident truth, but also familiar and in the minds of all men; in which case it is usually omitted, whereby we have an imperfect syllogism, that seems to be made up of only two propositions. Should we, for instance, argue in this manner:

Every man is mortal.
Therefore every king is mortal.

the syllogism appears to be imperfect, as confuting but two propositions. Yet it is really complete, only the minor [Every king is a man] is omitted, and left to the reader to supply, as being a proposition so familiar and evident, that it cannot escape him.

These seemingly imperfect syllogisms are called enthymemes, and occur very frequently in reasoning, especially where it makes a part of common conversation. Nay, there is a particular elegance in them; because, not displaying the argument in all its parts, they leave somewhat to the exercise and invention of the mind. By this means we are put upon exerting ourselves, and seem to share in the discovery of what is proposed to us. Now this is the great secret of fine writing, so to frame and put together our thoughts, as to give full play to the reader's imagination, and draw him insensibly into our very views and course of reasoning. This gives a pleasure not unlike to that which the author himself feels in composing. It besides shortens discourse, and adds a certain force and vivacity to our arguments, when the words in which they are conveyed favour the natural quickness of the mind in its operations, and a single expression is left to exhibit a whole train of thoughts.

But there is another species of reasoning with two propositions, which seems to be complete, in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind from which it follows syllogistically. This happens between propositions where the connection is such that the admission of one necessarily and at the first sight implies the admission also of the other. For if it so falls out, that the proposition on which the other depends is self-evident, we content ourselves with barely affirming it, and infer that other by a direct conclusion. Thus, by admitting an universal proposition, we are forced also to admit of all the particular propositions comprehended under it, this being the very condition that constitutes a proposition universal. If then that universal proposition chances to be self-evident, the particular ones follow of course, without any farther train of reasoning. Whoever allows, for instance, that things equal to one another are equal to one another, we may at the same time allow, that two triangles, each equal to a square whose side is three inches, are also equal between themselves. This argument therefore,

Things equal to one another are equal to one another.
Therefore these two triangles, each equal to the square of a line of three inches, are also equal between themselves.

is complete in its kind, and contains all that is necessary towards a just and legitimate conclusion. For the first or universal proposition is self-evident, and therefore requires no farther proof. And as the truth of the particular is inseparably connected with that of the universal, it follows from it by an obvious and unavoidable consequence.

Now in all cases of this kind, where propositions are deduced one from another, on account of a known and evident connection, we are said to reason by immediate consequence. Such a coherence of propositions, manifest at first sight, and forcing itself upon the mind, frequently occurs in reasoning. Logicians have explained at some length the several suppositions upon which it takes place, and allow of all immediate consequences that follow in conformity to them. It is however observable, that these arguments, though seemingly complete, because the conclusion follows necessarily from the single proposition that goes before, may yet be considered as real enthymemes, whose major, which is a conditional proposition, is wanting. The syllogism but just mentioned, when represented according to this view, will run as follows:

If things equal to one another are equal to one another; these two triangles, each equal to a square whose side is three inches, are also equal between themselves.
But things equal to one and the same thing, are equal to one another; therefore also those triangles, &c., are equal between themselves.

This observation will be found to hold in all immediate conclusions whatsoever, inasmuch that they are in fact no more than enthymemes of hypothetical syllogisms. But then it is particular to them, that the ground on which the conclusion rests, namely, its coherence with the minor, is of itself apparent, and seen immediately to flow from the rules and reasons of logic.

This is a way of arguing, in which a great number of propositions are so linked together, that the predicate of one becomes continually the subject of the next following, until at last is what is known by the name of a sorites. This is a way which the conclusion rests, namely, its coherence with the preceding, and the subject of the last. Of this kind is the following argument.

God is omnipotent.

An omnipotent being can do every thing possible. He that can do every thing possible, can do whatever involves not a contradiction.

Therefore God can do whatever involves not a contradiction.

This particular combination of propositions, may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests. The reason is, because the sorites itself may be resolved into as many simple syllogisms as there are middle terms in it; where this is found universally to hold, that when such a resolution is made, and the syllogisms are placed in train, the conclusion of the last in the series is also the conclusion of the first proposition, and the predicate of the last. Of this kind is the following argument.

God is omnipotent.

An omnipotent being can do every thing possible. He that can do every thing possible, can do whatever involves not a contradiction.

Therefore God can do whatever involves not a contradiction.

This way of arguing, where we infer universally concerning any idea what we had before affirmed or denied separately of all its several subdivisions and parts, is called reasoning by induction. Thus if we suppose the whole tribe of animals, subdivided into men, beasts, birds, insects, and fishes, and then reason concerning them after this manner: All men have a power of beginning motion; all beasts, birds, and insects, have a power of beginning motion; all fishes have a power of beginning motion; therefore all animals have a power of beginning motion: the argument is an induction. When the subdivisions are just, so as to take in the whole general idea, and the enumeration is perfect, that is, extends to all and every of the inferior classes or parts; there the induction is compleat, and the manner of reasoning by induction is apparently conclusive.

The last species of syllogisms we shall take notice of, is that commonly distinguished by the name of a dilemma. A dilemma is an argument, by which we endeavour to prove the absurdity or falsehood of some affirmation. In order to this we assume a conditional proposition, the antecedent of which is the affirmation to be disproved, and the consequent a disjunctive proposition, enumerating all the possible suppositions upon which that affirmation can take place. If then it appears, that all the several suppositions ought to be rejected, it is plain that the antecedent or assertion itself must be so too. When therefore such a proposition as that before-mentioned is made the major of any syllogism; if the minor rejects all the suppositions contained in the consequent, it follows necessarily, that the conclusion ought to reject the antecedent, which, as we have said, is the very affirmation to be disproved. This particular way of arguing is that which logicians call a dilemma; and from the account here given of it, it appears, that we may in the general define it to be a hypothetical syllogism, where the consequent of the major is a disjunctive proposition, which is wholly taken away or removed in the minor. Of this kind is the following:

If God did not create the world perfect in its kind, it must
must either proceed from want of inclination, or from want of power.

But it could not proceed either from want of inclination, or from want of power:

Therefore he created the world perfect in its kind; or, which is the same thing, It is absurd to say that he did not create the world perfect in its kind.

The nature then of a dilemma is universally this. The major is a conditional proposition, whose consequent contains all the several suppositions upon which the antecedent can take place. As therefore these suppositions are wholly removed in the minor, it is evident that the antecedent must be fo too; infomuch that we here always argue from the removal of the consequent to the removal of the antecedent. That is, a dilemma is an argument in the modus tollens of hypothetical syllogisms, as logicians speak. Hence it is plain, that if the antecedent of the major is an affirmative proposition, the conclusion of the dilemma will be negative; but if it is a negative proposition, the conclusion will be affirmative.

Of Demonstration.

Having dispatched what seemed necessary with regard to the forms of syllogisms, we shall now explain their use and application in reasoning. We have seen, that in all the different appearances they put on, we still arrive at a just and legitimate conclusion: now it often happens, that the conclusion of one syllogism becomes a previous proposition in another, by which means great numbers of them are sometimes linked together in a series, and truths are made to follow one another in train. And as in such a concatenation of syllogisms, all the various ways of reasoning that are truly conclusive may be with safety introduced; hence it is plain, that in deducing any truth from its first principles, especially where it lies at a considerable distance from them, we are at liberty to combine all the several kinds of arguments above explained, according as they are found best to suit the end and purpose of our inquiries. When a proposition is thus, by means of syllogisms, collected from others more evident and known, it is laid to be proved; so that we may in the general define the proof of the proposition to be a syllogism, or series of syllogisms, collecting that proposition from known and evident truths. But more particularly, if the syllogisms of which the proof consists admit of no premises but definitions, self-evident truths, and propositions already established, then is the argument so constituted called a demonstration; whereby it appears, that demonstrations are ultimately founded on definitions and self-evident propositions.

All syllogisms whatsoever, whether compound, multi-form, or defective, are reducible to plain simple syllogisms in some one of the four figures. But this is not all. Syllogisms of the first figure in particular, admit of all possible conclusions: that is, any proposition whatsoever, whether an universal affirmative, or universal negative, a particular affirmative, or particular negative, which fourfold division embraces all their varieties; any one of these may be inferred, by virtue of some syllogism in the first figure. By this means the syllogisms of all the other figures are reducible also to syllogisms of the first figure, and may be considered as standing on the same foundation with them. We cannot here demonstrate and explain the manner of this reduction. It is enough to take notice, that the thing is universally known and allowed among logicians, to whose writings we refer such as desire farther satisfaction in this matter. This then being laid down, it is plain, that any demonstration whatsoever may be considered as composed of a series of syllogisms, all in the first figure. For since all the syllogisms that enter the demonstration are reducible to syllogisms of some one of the four figures, and since the syllogisms of all the other figures are farther reducible to syllogisms of the first figure, it is evident, that the whole demonstration may be resolved into a series of these last syllogisms. Let us now, if possible, discover the ground upon which the conclusion rests, in syllogisms of the first figure; because, by so doing, we shall come at an universal principle of certainty, whence the evidence of all demonstrations in all their parts may be ultimately derived.

The rules then of the first figure are these. The middle term is the subject of the major proposition, and the predicate of the minor. The major is always an universal proposition, and the minor always affirmative. Let us now see what effect these rules will have in reasoning. The major is an universal proposition, of which the middle term is the subject, and the predicate of the conclusion the predicate. Hence it appears that, in the major, the predicate of the conclusion is always affirmed or denied universally of the middle term. Again, the minor is an affirmative proposition, whereas the subject of the conclusion is the subject, and the middle term the predicate. Here then the middle term is affirmed of the subject of the conclusion; that is, the subject of the conclusion is affirmed to be comprehended under, or to make a part of the middle term. Thus then we see what is done in the premises of a syllogism of the first figure. The predicate of the conclusion is univerally affirmed or denied of some idea. The subject of the conclusion is affirmed to be or to make a part of that idea. Hence it naturally and unavoidably follows, that the predicate of the conclusion ought to be affirmed or denied of the subject.

To illustrate this by an example, we shall resume one of the former syllogisms.

Every creature possessed of reason and liberty is accountable for his actions.

Man is a creature possessed of reason and liberty.

Therefore man is accountable for his actions.

Here, in the first proposition, the predicate of the conclusion, accountable, is affirmed of all creatures that have reason and liberty. Again, in the second proposition, man, the subject of the conclusion, is affirmed to be or to make a part of the class of creatures. Hence the conclusion necessarily and unavoidably follows, viz. that man is accountable for his actions; because if reason and liberty be that which constitutes a creature accountable, and man has reason and liberty, it is plain he has that which constitutes him accountable. In like manner, where the major is a negative proposition, or denies the predicate of the conclusion universally of the middle term, as the minor always afferts the subject of the conclusion, to be or make a part of that middle term, it is no less evident, that the predicate of the
the conclusion ought in this case to be denied of the subject. So that the ground of reasoning in all syllogisms of the first figure is manifestly this: Whatever may be affirmed universally of any idea, may be affirmed of every or any number of particulars comprehended under that idea. And again: Whatever may be denied universally of any idea, may be in like manner denied of every or any number of its individuals. These two propositions are called by logicians the dictum de omni, and dictum de nullo, and are indeed the great principles of syllogistic reasoning, inasmuch as all conclusions whatsoever either rest immediately upon them, or upon propositions deduced from them. But what adds greatly to their value is, that they are really self-evident truths, and such as we cannot gainay without running into an express contradiction. To affirm, for instance, that no man is perfect, and yet argue that some men are perfect; or to say that all men are mortal, and yet that some men are not mortal, is to assert a thing to be and not to be at the same time.

And now we may affirm, that in all syllogisms of the first figure, if the premises are true, the conclusion must needs be true. If it be true that the predicate of the conclusion, whether affirmative or negative, agrees universally to some idea, and if it be also true that the subject of the conclusion is a part of or comprehended under that idea, then it necessarily follows, that the predicate of the conclusion agrees also to the subject. For to assert the contrary, would be to run counter to some one of the two principles before established; that is, it would be to maintain an evident contradiction. And thus we are come at last to the point we have been all along endeavouring to establish, namely, That every proposition which can be demonstrated is necessarily true. For as every demonstration may be resolved into a series of syllogisms all in the first figure, and as, in any one of these syllogisms, if the premises are true, the conclusion must be so too; it evidently follows, that if all the several premises are true, all the several conclusions are so, and consequently the conclusion also of the last syllogism, which is always the proposition to be demonstrated. Now that all the premises of a demonstration are true, will easily appear from the very nature and definition of that form of reasoning. A demonstration is a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions previously established. Definitions are identical propositions, wherein we connect the description of an idea with the name by which we choose to have that idea called; and therefore as to their truth there can be no dispute. Self-evident propositions appear true of themselves, and leave no doubt or uncertainty in the mind. Propositions before established are no other than conclusions gained by one or more steps from definitions and self-evident principles, that is, from true premises, and therefore must needs be true. Whence all the previous propositions of a demonstration being manifestly true, the last conclusion or proposition to be demonstrated must be so too. So that demonstration not only leads to certain truth, but we have here also a clear view of the ground and foundation of that certainty. For as, in demonstrating, we may be said to do nothing more than combine a series of syllogisms together, all resting on the same bottom; it is plain, that one uniform ground of certainty runs through the whole, and that the conclusions are every where built upon some one of the two principles before established as the foundation of all our reasoning. These two principles are easily reduced into one, and may be expressed thus. Whatever predicate, whether affirmative or negative, agrees universally to any idea, the same must needs agree to every or any number, of individuals comprehended under that idea.

And thus we have reduced the certainty of demonstration to one simple and universal principle, which carries its own evidence along with it, and which is indeed the ultimate foundation of all syllogistic reasoning.

Demonstration therefore serving as an infallible guide to truth, and standing on so sure and unalterable a basis, we may now venture to assert, that the rules of logic furnish a sufficient criterion for the distinguishing between truth and falsehood. For since every proposition that can be demonstrated is necessarily true, he is able to distinguish truth from falsehood, who can with certainty judge when a proposition is duly demonstrated. Now a demonstration is nothing more than a concatenation of syllogisms, all whose premises are definitions, self-evident truths, or propositions previously established. To judge therefore of the validity of a demonstration, we must be able to distinguish, whether the definitions that enter it are genuine, and truly descriptive of the ideas they are meant to exhibit; whether the propositions assumed without proof as intuitive truths have really that self-evidence to which they lay claim; whether the syllogisms are drawn up in due form, and agreeable to the laws of argumentation; in fine, whether they are combined together in a just and orderly manner, so that no demonstrable propositions serve any where as premises, unless they are conclusions of previous syllogisms. Now it is the business of logic, in explaining the several operations of the mind, fully to instruct us in all these points. It teaches the nature and end of definitions, and lays down the rules by which they ought to be framed. It unfolds the several species of propositions, and distinguishes the self-evident from the demonstrable. It delineates also the different forms of syllogisms, and explains the laws of argumentation proper to each. In fine, it describes the manner of combining syllogisms, so as that they may form a train of reasoning, and lead to the successive discovery of truth. The precepts of logic therefore, as they enable us to judge with certainty when a proposition is duly demonstrated, furnish a sure criterion for the distinguishing between truth and falsehood.

But perhaps it may be objected, that demonstration is a thing very rare and uncommon, as being the prerogative of but a few sciences, and therefore the criterion here given can be of no great use. But where ever, by the bare contemplation of our ideas, truth is discoverable, there also demonstration may be attained. Now that is an abundantly sufficient criterion, which enables us to judge with certainty in all cases where the knowledge of truth comes within our reach; for with discoveries, that lie beyond the limits of the human mind, we have properly no business. When a proposition is demonstrated, we are certain of its truth. When, on the contrary, our ideas
ideas are such as have no visible connection nor repugnance, and therefore furnish not the proper means of tracing their agreement or disagreement, there we are sure that scientific knowledge is not attainable. But where there is some foundation of reasoning, which yet amounts not to the full evidence of demonstration, there the precepts of logic, by teaching us to determine aright of the degree of proof, and of what is still wanting to render it full and complete, enable us to make a due estimate of the measures of probability, and to proportion our affent to the grounds on which the proposition stands.

And this is all we can possibly arrive at, or even so much as hope for, in the exercise of faculties so imperfect and limited as ours.

We conclude it may not be improper to take notice of the distinction of demonstration into direct and indirect. A direct demonstration is, when beginning with definitions, self-evident propositions; or known and allowed truths, we form a train of syllogisms, and combine them in an orderly manner, continuing the series through a variety of successive steps, until at last we arrive at a syllogism, whose conclusion is the proposition to be demonstrated. Proofs of this kind leave no doubt or uncertainty behind them, because all the several premises being true, the conclusions must be so too, and of course the very last conclusion or proposition to be proved. The other species of demonstration is the indirect, or, as it is sometimes called, the apogogical. The manner of proceeding here is, by assuming a proposition which directly contradicts that we mean to demonstrate, and thence by a continued train of reasoning, in the way of a direct demonstration, deducing some absurdity or manifest untruth. For hereupon we conclude that the proposition assumed was false, and thence again, by an immediate consequence, that the proposition to be demonstrated is true. Thus Euclid, in his third book, being to demonstrate, that circles which touch one another inwardly have not the same centre, assumes the direct contrary to this, viz. that they have the same centre, and thence by an evident train of reasoning proves that a part is equal to the whole. That supposition therefore, leading to this absurdity, he concludes to be false, viz. that circles touching one another inwardly have the same centre, and thence again immediately infers that they have not the same centre.

Now because this manner of demonstration is accounted by some not altogether so clear and satisfactory, we shall therefore endeavour here to shew, that it equally with the other leads to truth and certainty. Two propositions are said to be contradictory one of another, when that which is asserted to be in the one is asserted not to be in the other. Thus the propositions, circles that touch one another inwardly have not the same centre, and circles that touch one another inwardly have not the same centre, are contradictory; because the second affords the direct contrary of what is asserted in the first. Now in all contradictory propositions this holds universally, that one of them is necessarily true, and the other necessarily false. For if it be true, that circles which touch one another inwardly have not the same centre, it is unavoidably false that they have the same centre. On the other hand, if it be false that they have the same centre, it is necessarily true that they have not the same centre. Since therefore it is impossible for them to be both true or both false at the same time, it unavoidably follows, that one is necessarily true, and the other necessarily false. This then being allowed, if any two contradictory propositions are assumed, and one of them can by a clear train of reasoning be demonstrated to be false, it necessarily follows that the other is true. For as the one is necessarily true, and the other necessarily false, when we come to discover which is the false proposition, we thereby also know the other to be true.

Now this is precisely the manner of an indirect demonstration. For there we assume a proposition, which directly contradicts that we mean to demonstrate; and having by a continued series of proofs shewn it to be false, thence infer that its contradictory, or the proposition to be demonstrated, is true. As therefore this last conclusion is certain and unavoidable, let us next inquire, after what manner we come to be satisfied of the falsehood of the assumed proposition, that so no possible doubt may remain as to the force and validity of demonstrations of this kind. The manner then is plainly this. Beginning with the assumed proposition, we, by the help of definitions, self-evident truths, or propositions already established, continue a series of reasoning in the way of a direct demonstration, until at length we arrive at some absurdity or known falsehood. Thus Euclid, from the supposition that circles touching one another inwardly have the same centre, deduces that a part is equal to the whole. Since therefore, by a due and orderly process of reasoning, we come at last to a false conclusion, it is manifest that all the premisses cannot be true. For were all the premisses true, the last conclusion must be so too. Now as to all the other premisses made use of in the course of reasoning, they are manifest and known truths by supposition, as being either definitions, self-evident propositions, or truths previously established. The assumed proposition is that only as to which any doubt or uncertainty remains. That alone therefore can be false, and indeed, from what has been already shewn, must unavoidably be so. And thus we see, that in indirect demonstrations, two contradictory propositions being laid down, one of which is demonstrated to be false, the other, which is always the proposition to be proved, must necessarily be true; so that here, as well as in the direct way of proof, we arrive at a clear and satisfactory knowledge of truth.

This is universally the method of reasoning in all apopogogical or indirect demonstrations; but if any proposition is assumed, from which in a direct train of reasoning we can deduce its contradictory, the proposition so assumed is false, and the contradictory one true. For if we suppose the assumed proposition to be true, then since all the other premisses that enter the demonstration are also true, we shall have a series of reasoning, confuting wholly of true premisses; whence the last conclusion or contradictory of the assumed proposition must be true likewise. So that by this means we should have two contradictory propositions both true at the same time, which is manifestly impossible. The assumed proposition therefore, thence this absurdity flows, must necessarily be false, and consequently its contradictory, which is true.
here the proposition deduced from it, must be true. If then any proposition is proposed to be demonstrated, and we assume the contradictory of that proposition, and thence directly infer the proposition to be demonstrated, by this very means we know that the proposition so inferred is true. For since from an assumed proposition we have deduced its contradictory, we are thereby certain that the assumed proposition is false; and if so, then its contradictory, or that deduced from it, which in this case is the same with the proposition to be demonstrated, must be true.

We have a curious instance of this in the twelfth proposition of the ninth book of the elements. Euclid there proposes to demonstrate, that in any series of numbers, rising from unity in geometrical progression, all the prime numbers that measure the last term in the series will also measure the next after unity. In order to this, he assumes the contradictory of the proposition to be demonstrated, namely; that some prime number measuring the last term in the series, does not measure the next after unity; and thence, by a continued train of reasoning, proves, that it actually does measure it. Hereupon he concludes the assumed proposition to be false; and that which is deduced from it, or its contradictory, which is the very proposition he proposed to demonstrate, to be true. Now that this is a just and conclusive way of reasoning, is abundantly manifest from what we have so clearly established above.

Having thus sufficiently evinced the certainty of demonstration in all its branches, and shewn the rules by which we ought to proceed, in order to arrive at a just conclusion, according to the various ways of arguing made use of; it is needless to enter upon a particular consideration of those several species of false reasoning, which logicians distinguish by the name of sophisms. He that thoroughly understands the form and structure of a good argument, will of himself readily discern every deviation from it. And although sophisms have been divided into many classes, which are all called by sounding names, that therefore carry in them much appearance of learning; yet are the errors themselves so very palpable and obvious, that it is lost labour to write for a man capable of being misled by them. Here, therefore, we shelve to conclude this second part of logic, and shall in the next part give some account of method, which, though inapplicable from reasoning, is nevertheless always considered by logicians as a distinct operation of the mind; because its influence is not confined to the mere exercise of the reasoning faculty, but extends in some degree to all the transactions of the understanding.

PART III. Of Method.

Of method in general, and the division of it into analytick and synthetick.

We have now done with the two first operations of the mind, whose office it is to search after truth, and enlarge the bounds of human knowledge. There is yet a third, which regards the disposal and arrangement of our thoughts, when we endeavour so to put them together that their mutual connection and dependence may be clearly seen. This is what logicians call method, and place always the last in order in explaining the powers of the understanding; because it necessarily supposes a previous exercise of our other faculties, and some progress made in knowledge, before we can exert it in any extensive degree.

In this view it is plain, that we must be beforehand well acquainted with the truths we are to combine together; otherwise how could we discern their several connections and relations, or so dispose of them as their mutual dependence may require? But it often happens, that the understanding is employed, not in the arrangement and composition of known truths, but in the search and discovery of such as are unknown. And here the manner of proceeding is very different. We assemble at once our whole stock of knowledge relating to any subject; and, after a general survey of things, begin with examining them separately and by parts. Hence it comes to pass, that whereas, at our first setting out, we were acquainted only with some of the grand strokes and outlines of truth, by thus purifying her through her severall windings and receffes we gradually discover those more inward and finer touches whence she derives all her strength, symmetry, and beauty. And here it is, that when, by a narrow scrutiny into things, we have unravelled any part of knowledge, and traced it to its first and original principles, inasmuch that the whole frame and contexture of it lies open to the view of the mind; here it is, that taking it the contrary way, and beginning with these principles, we can so adjust and put together the parts, as the order and method of science requires.

But as these things are best understood when illustrated by examples: let us suppose any machine, for instance a watch, presented to us, whose structure and composition we are as yet unacquainted with, but want if possible to discover. The manner of proceeding in this case is, by taking the whole to pieces, and examining the parts separately one after another. When by such a scrutiny we have thoroughly informed ourselves of the frame and contexture of each, we then compare them together, in order to judge of their mutual action and influence. By this means we gradually trace out the inward make and composition of the whole, and come at length to discern, how parts of such a form, and so put together, as we found in unravelling and taking them allover, constitute that particular machine called a watch, and contribute to all the several motions and phenomena observable in it. This discovery being made, we can take things the contrary way, and, beginning with the parts, so dispose and connect them, as their several uses and structures require, until at length we arrive at the whole itself, from the unravelling of which these parts resulted.

And as it is in tracing and examining the works of art, so it is in a great measure in unfolding any part of human knowledge. For the relations and mutual habits of things do not always immediately appear upon comparing them one with another. Hence we have recourse to intermediate ideas, and by means of them are furnished with
with those previous propositions, that lead to the conclusion we are in quest of. And if it do happen, that the previous propositions themselves are not sufficiently evident, we endeavour by new middle terms to ascertain their truth, still tracing things backward in a continued series, until at length we arrive at some fyllogism where the premises are first and self-evident principles. This done, we become perfectly satisfied as to the truth of all the conclusions we have passed through, in as much as they are now seen to stand upon the firm and immovable foundation of our intuitive perceptions. And as we arrived at this certainty by tracing things backward to the original principles whence they flow, so may we at any time renew it by a direct contrary process, if, beginning with these principles, we carry the train of our thoughts forward, until they lead us by a connected chain of proofs to the very last conclusion of the series.

Hence it appears, that in disposing and putting together our thoughts, either for our own use, that the discoveries we have made may at all times lie open to the review of the mind, or where we mean to communicate and unfold these discoveries to others, there are two ways of proceeding equally within our choice. For we may to propound the truths relating to any part of knowledge, as they pretended themselves to the mind in the manner of investigation, carrying on the series of proofs in a reverse order, until they at last terminate in first principles: or, beginning with these principles, we may take the contrary way, and from them deduce, by a direct train of reasoning, all the several propositions we want to establish. This diversity in the manner of arranging our thoughts gives rise to the twofold division of method established among logicians. For method, according to the use of the word, is nothing else but the order and disposition of our thoughts relating to any subject. When truths are so proposed and put together, as they were or might have been discovered, this is called the analytic method, or the method of resolution; in as much as it traces things backward to their source, and resolves knowledge into its first and original principles. When, on the other hand, they are deduced from these principles, and connected according to their mutual dependence, infomuch that the truths first in order tend always to the demonstration of those that follow,

LOHOCH, or Loch, in pharmacy, a composition of a middle confidence between a soft electuary and a syrup, principally used in disorders of the lungs.

There are several kinds of lohochs, denominated from the principal ingredient that enters into their composition. The common lohoch is made thus: take of fresh drawn oil of sweet almonds, and of pectoral or balsamic syrup, one ounce; white sugar, two drams; mix, and make them into a lohoch.

LOINS, in anatomy, the two lateral parts of the umbilical region of the abdomen. See Anatomy.

LOIRE, the largest river in France, rises in the mountains of the Cevennes, and, after running a course of about five hundred miles, falls into the bay of Bifcay.

LOLIUM, DANDEL, in botany, a genus of the triandria

digynia class. The involucrum consists of one leaf; it has no calix; and the flopula consists of many flowers. There are three species, two of them natives of Britain, viz. the perenne, or perennial dandel-grass; and the temulentum, or annual dandel-grass.

LOMBARDY, a kingdom which comprehended almost all Italy. It was erected by the Longobards, or Lombards, a German nation, about the year 598, and lasted till Charlemain put an end to it about the year 760.

LOMCOND, a lake in the county of Lenox, in Scotland, which runs almost the whole length of the county.

LONCHITIS, spleen-wort, in botany, a genus of the cryptogamia filicum class of plants, the fructifications of which are arranged into united series, and disposed separately under the families of the leaves.
LONGISSMUS DORSI, in anatomy. See Anatomy.

LONGIMETRY, the art of measuring lengths, both

LONGFORD, a county of Ireland, in the province of

LONGEVITY, length of life.

LONDONDERRY, a city of Ireland, in the province

LONDON, the metropolis of Great Britain, where the

LONG, an epithet given to whatever exceeds the usual

LONGITUDE of a star, in astronomy, an arch of the
ecliptic, intercepted between the beginning of aries, and
the point of the ecliptic cut by the star's circle of longitude.

LONGITUDE of a place. See Geography.

In the philosophical transactions, n° 1, we have an account of a successful experiment in finding the longitude at sea, made with two pendulum-watches by major Holmes, in a voyage from the coast of Guinea homewards. This and some other successes encouraged Monsieur Huygens so far, that, after he had improved the structure of these watches, he published an account at large for the shewing how and in what manner these watches are to be used in finding the longitude at sea, with directions for adjusting of them and keeping a journal by them; which account the curious reader may see at large in the Philosophical transactions, n° 47.

The chief objection against pendulum clocks and watches, is the effects that heat and cold have upon the spring and pendulum, which make the spring in watches draw stronger at some times than at other times, and causes the pendulum to lengthen and shorten, according as the weather is hotter or colder; but these effects are so regular, that without doubt they may be accounted for.

But the most ingenious and successful machines for this purpose have been invented by Mr. John Harrison, who, at different times, contrived three different time-pieces for determining the longitude at sea.

The first of Mr. Harrison's machines was tried in May 1736, when it was put on board a man of war, and by its exact measure of time, in its return from Lisbon, corrected an error of almost a degree and an half in the computations of the reckoning of a ship. In 1739, Mr. Harrison finished his second machine, which, from various experiments made upon it, was sufficiently regular and exact for finding the longitude of a ship within the nearest limits proposed by parliament. Upon the success of this, Mr. Harrison, in 1744, undertook a still more advantageous machine, which he finished in 1758, when he applied to the commissioners of longitude for orders to make a trial of that instrument to some part in the West Indies, as directed by the statutes for the discovery of the longitude at sea. In consequence of this application, Mr. Harrison received orders for his son to proceed from Portsmouth to Jamaica, in one of his majesty's ships of war, with his third instrument, in November 1761; and the commissioners having directed that every requisite step and precaution should be taken, for making, with care, the proper experiments, and ascertaining their accuracy, not only going to Jamaica, but in the return, it appears, from the calculations made from the experiments in going to Jamaica, that the difference between the longitude, as found by the time-piece, and calculated by the observations of the transit of mercury in 1743 at Jamaica and London, is five seconds of time, which at Jamaica is little more than a geographical mile.

During the voyage, Mr. Harrison's time-piece corrected the ship's reckoning, which sometimes erred about a degree and a half: and in going from Madeira.
LOPHIOUS, in zoology, a genus of the brachiopterous order of fishes; the head and body are both of a depressed form; there are a number of fleshy prominences or appendages surrounding the whole body of the fish.

There are three species.

LORANTHUS, in botany, a genus of the hexandrous monogynia class. The margin of the calyx is entire; the corolla consists of six segments folded backwards; and the berry contains one seed. There are five species, none of them natives of Britain.

LORD, a title of honour, given to those who are noble, either by birth or creation; in this sense it amounts to much the same as peer of the realm, or lord of Parliament. This title is, by courtesy, also given to all the sons of dukes and marquises, and to the eldest sons of earls; and it is also a title of honour bestowed on those who are honourable by their employments, as lord advocate, lord chamberlain, lord chancellor, &c.

LORETTO, a city of Italy, in the marquisate of Ancona, in the pope's territories, 145 miles east of Rome. This place is famous for the chamber of the blessed Virgin, which, according to the Roman Catholic traditions, was brought by angels from Palestine to Dalmatia, and from thence transported over to Italy, and fixed at Loreto.

LORN, the north part of Argyllshire in Scotland, bounded by Lochabar on the north, by Broadalbin on the east, by the rest of Argyllshire on the south, and by the sea on the west.

LORRAIN, a duchy formerly belonging to the circle of the Upper Rhine in Germany, but now united to the crown of France. It is bounded by the duchy of Luxemburg on the north; by Alsatia, the duchy of Deux ponts, and the palatinate of the Rhine, on the east; by the county of Burgundy, on the south; and by Champaign, on the west.

LOTHIAN, a county of Scotland, bounded by the frith of Forth on the north; by the Berwick sea, on the east; by Clydesdale, Tweedale, and Merse, on the south; and by Stirling, on the west. The capital of this county is Edinburgh.

LOTION is, strictly speaking, such washing as concerns beautifying the skin, by cleansing it of those deformities which a disempered blood sometimes throws upon it, or rather are made by a preternatural secretion: for according to Quincy, generally those dislempers of the skin, commonly accounted signs of a soul blood, are, from those faults which are natural in the best constitution, thrown off by the cutaneous glands, which ought to be washed away through the kidney; so that instead of those insignificant and ridiculous tribes of sweeteners, which in this case are frequently used, promoting the urinary discharge, or rectifying that of the skin by proper washes, frictions, or ointments, or both together, is the only way to get rid of such disorders.

LOTTERY, a kind of public game at hazard, frequent in Britain, France, and Holland, in order to raise money for the service of the state; being appointed with the authority of parliament, and managed by commissioners appointed by the lords of the treasury for that purpose. It consists of several numbers of blanks and prizes, which are drawn out of wheels, one
of which contains the numbers, and the other the corre-

sponding blanks or prizes.

LOTUS, in botany, a genus of the diadelphla decandria

class. The legumen is cylindrical; the wings are con-
invent above; and the calyx is tubular. There are 17

species, only one of which, viz. the corniculata, or

birds-foot trefoil, is a native of Britain.

LOVAGE, in botany. See Ligusticum.

LOVE APPLE. See Solanum.

LOUIS, or Knights of St. Louis, the name of a mi-
litary order in France, instituted by Louis XIV. in 1693.

Their collars are of a flame colour, and pass from left
to right; the king is their grand master. There are in

it eight grand croffes, and twenty-four commanders;

the number of knights is not limited. At the time of

their institution, the king charged his revenue with a

fund of three hundred thousand livres for the penfions

of the commanders and knights.

LOUWISANA, or New France, a country of north A-
merica, bounded by the river and lake of Illinois on

the north, North Carolina on the east, and the gulph
of Mexico on the south.

LOUSE, in zoology. See Pediculus.

LOUTH, a county of Ireland, in the province of Lein-

ger aff, by the Irish Channel on the south, by Eall Meath on

the north by that of Tome; on the eaft, by the Bothnis

church, obferved on the 18th of October.

Luke wrote with the affiftance of St. Paul.

Some think it was properly St. Paul's gofpel, and

that when that apoftle fpeaks of his gofpel, he means

what is called St. Luke's. Irenaeps fays, that St. Luke

thus, the lues gallica, or venerea, fignifies the venereal
difeafe. See Medicine.

LUES, among phyficians, is, in general, ufed for a
difeafe of any kind; but, in a more particular fenfe,
is reftrained to contagious and peftilential difeafes:

thus, the lues gallica, or venerea, fignifies the venereal
difeafe. See Medicine.

LUCCA, the capital of the Republic of the fame name
in Italy, frituated twelve miles eafth of the Tuscan sea:

E. long. 11° 20', N. lat. 45° 45'.

LUCERN, the capital of the canton of the fame name in

Switzerland, frituated on the lake Lucern, to which it
gives its name: E. long. 8° 12', N. lat. 47°.

LUCERNE, in botany. See Medicago. For the
culture of lucerne, see Agriculture, p. 65.

LUC, a town of Provence, in France, twenty-three

miles north-east of Toulon.

LUCA, or St. Lucar, a port-town of Spain, in the
province of Andalusia: W. long. 6° 38', N. lat. 36° 42'.

St. Lucar is alfo a town of Andalusia, in Spain: W.
long. 8° 12. N. lat. 37° 20.

St. Lucar is alfo the name of another town of Spain,

fifteen miles weft of Seville.

LUCARNO, a town of the duchy of Milan, frituated

on the lake of Maggiore, but fubjedt to Switzerland.

LUCCA, the capital of the republic of the fame name
in Italy, frituated twelve miles eafth of the Tuscan sea:

E. long. 11° 20', N. lat. 45° 45'.

LUCERN, the capital of the canton of the fame name in

Switzerland, frituated on the lake Lucern, to which it
gives its name: E. long. 8° 12', N. lat. 47°.

LUCERNE, in botany. See Medicago. For the
culture of lucerne, see Agriculture, p. 65.

LUCIA ISLANDS, one of the Caribbee islands in Ame-
rica, frituated seventy miles north-west of Barbadoes,
being twenty-two miles long, and eleven broad.

St. Lucia, one of the Cape Verd islands in Africa,
lying in W. long. 25°, N. lat. 16° 30'.

LUCIOPERCA, in ichthyology. See Perca.

LUCIUS, in ichthyology. See Esox.

LOZENGE, in heraldry, a rhombus, or figure of equal

sides and four cells, with many seeds. There are

two fcpecies, none of them natives of Britain.

LOZENGE, in heraldry, a rhombus, or figure of equal

sides and four cells, with many seeds. There are

48 fcpecies, principally di-

flinglyd by their colour.

LOZENGE, in heraldry, a rhombus, or figure of equal

sides and four cells, with many seeds. There are

48 fcpecies, principally di-

flinglyd by their colour.

LOZENGE, in heraldry, a rhombus, or figure of equal

sides and four cells, with many seeds. There are

48 fcpecies, principally di-

flinglyd by their colour.

LOXIA, in zoology, the name of a genus of birds of the

order of the falieres; the diflinguishing characters of

which are, that the tongue is plain, equal and whole;

the beak large, thick, and thort, and crooked and con-

vex both ways. There are 48 fcpecies, principally di-

flinglyd by their colour.

LOXIA, in zoology, the name of a genus of birds of the

order of the falieres; the diflinguishing characters of

which are, that the tongue is plain, equal and whole;

the beak large, thick, and thort, and crooked and con-

vex both ways. There are 48 fcpecies, principally di-

flinglyd by their colour.

LOXIA, in zoology, the name of a genus of birds of the

order of the falieres; the diflinguishing characters of

which are, that the tongue is plain, equal and whole;

the beak large, thick, and thort, and crooked and con-

vex both ways. There are 48 fcpecies, principally di-

flinglyd by their colour.
LUMBAGO, in medicine, denotes a pain about the loins, as that preceding fevers, agues, and the rheumatism.

LUMBARIS, a name given to the arteries and veins which spread over the loins. See Anatomy.

LUMBRICAL, a name given to four muscles of the fingers, and to as many of the toes. See Anatomy, part II.

LUMBRICUS, the earth-worm, in zoology, a genus of insects belonging to the order of veines intestinalia. The body is cylindrical, annulated, with an elevated belt near the middle. There is but one species of this animal. It lives under ground, and feeds upon the seeds and roots of plants. It comes above ground in the night, or during rain, for the purpose of copulation. For the effects of these animals in the human body, and the method of expelling them, see Medicine.

LUMME, in ornithology. See COLUMBUS.

LUNA, in astronomy, the moon. See Astronomy.

LUMRITICUS, in falmony, a device of leather, in the form of fingers, and to as many of the toes. See Anatomy, part II.

LUNAR, something belonging to the moon; thus we say, lunar month, lunar year, &c.

LUNARIA, honesty, in botany, a genus of the tetradyamina filiculae class. The filicula, or pod, is entire, elliptical, and compressed; with plain, equal, parallel valves. There are two species, none of them natives of Britain.

LUNATIC, a person affected with lunacy. See Medicine.

LUND, or LUNDEN, a city of Sweden, in the province of Gothland, the capital of the territory of Schonen, situated thirty miles east of Copenhagen.

LUNDY, a little island in the mouth of the Bristol-channel: W. long. 40° 50', N. lat. 51° 25'.

LUNENBURG, the capital of the duchy of the same name, thirty miles south-east of Hamburg: E. long. 10° 20', N. lat. 53° 35'.

LUNGS. See Anatomy, p. 280.

LUNG WORT, in botany. See Pulmonaria.

UNISOLAR YEAR, in chronology, the space of 352 common years; found by multiplying the cycle of the sun by that of the moon.

LUNULA, in geometry, a plane figure like a crescent or half moon.

LUPERCALIA, a festival of the ancient Romans in honour of the god Pan, observed on the 15th of February, and so called from luperci, the priests of that fabulous deity.

LUPINUS, in botany, a genus of the diadelphia decandra class. The calix consists of two lips; five of the anthers are oblong, and the other five round; and the pod is corymbose. There are seven species, none of them natives of Britain.

LUPULUS, in botany, &c. See Humulus.

LUPUS, in zoology. See Canis.

LUPUS MARINUS. See Anarrichas.

LUPUS, in astronomy. See Astronomy, p. 487.

LURE, in falmony, a device of leather, in the form of a bird, with two wings stuck with feathers, and baited with a piece of flesh; wherewith to reclaim or call back a hawk, when at a considerable distance.

LUSATIA, a marquisate of Upper Saxony, bounded by Brandenburg, on the north; by Silesia, on the east; by Bohemia, on the south; and by the duchy of Saxony, on the west: it is subject to the king of Poland.

LUSTRE, the gloss or brightness appearing on any thing, particularly on manufactures of silk, wool, or fluff. It is likewise used to denote the composition or manner of giving that gloss.

The lustre of silk is given them by washing in soap, then clear water, and dipping them in alum water cold. To give fluffs a beautiful lustre, for every eight pounds of fluff allow a quarter of a pound of linseed; boil it half an hour, and then strain it through a cloth, and let it stand till it is turned almost to a jelly; afterwards put an ounce and a half of gum to diffuse twenty four hours; then mix the liquor, and put the cloth into this mixture; take it out, dry it in the shade, and press it. If once doing is not sufficient, repeat the operation. Carriers give a lustre to black leather firit with juice of bar-berrys, then with gum arabic, als, vinegar, and flanders-glue, boiled together. For coloured leather, they use the white of an egg beaten in water. Moroccons have their lustre from juice of bar-berrys and lemon or orange. For hats, the lustre is frequently given with common water, sometimes a little black dye is added: the same lustre serves for furs, except that for very black furs they sometimes prepare a lustre of galls, copperas, Roman alum, ox's marrow, and other ingredients.

LUSTRUM, in Roman antiquity, a general muster and review of all the citizens and their goods, which was performed by the cenfors every fifth year, who afterwards made a solemn lustration. See Lustration.

LUTE, is also a musical instrument with strings.

The lute consists of four parts, viz. the table; the body or belly, which has nine or ten fides; the neck, which has nine or ten fops or divisions, marked with strings; and the head, or cros, where the ferev for raising and lowering the strings to a proper pitch of tone are fixed. In the middle of the table there is a rofe or paffage for the found; there is also a bridge: that the strings are fastened to, and a piece of ivory between.
between the head and the neck to which the other extremities of the strings are fitted. In playing, the strings are struck with the right hand, and with the left the fops are pressed. The lutes of Bologna are esteemed the best, on account of the wood, which is said to have an uncommon disposition for producing a sweet sound.

LUTHERANS, the Christians who follow the opinions of Martin Luther, one of the principal reformers of the church in the sixteenth century. This sect took its rise from the diffilfe taken at the indulgences which were granted in 1517, by pope Leo X. to those who contributed towards finishing St. Peter's church at Rome. John Stuptize, vicar general of the Auguflines in Germany, was the first who took occasion to declare against these abuses, for which purpose he made use of Martin Luther, the most learned of all the Auguflines. Luther was a native of Eisleben, in the county of Mansfield in Saxony, and taught divinity at the university of Wirtemberg: he mounted the pulpit, and declaimed vehemently against the abuse of indulgences, and even fixed ninety-five propositions upon the church-doors of Wirtemberg, in order to their being considered and examined in a public conference; against those John Tetzel, a Dominican, published a hundred and six propositions at Francfort upon the Oder; and by virtue of his office of inquisitor, ordered those of Luther to be burnt; when his adherents, to revenge the affront, publicly burnt at Wirtemberg those of Tetzel. Thus war was declared between the Dominicans and Auguflines, and soon after between the Roman catholic and the Lutheran party. In 1520, Luther sent his book De Libertate Christiana, to the pope; in which he grounds justification upon faith alone, without the assistance of good works; and afferts, that Christian liberty rescues us from the bondage of human traditions, and particularly the slavery of papal impostions; and afterwards, in a remonftrance written in high Dutch, he proceeded to deny the authority of the church of Rome. He was the same year excommunicated by the pope; upon which Luther caus'd a large fire to be made without the walls of Wirtemberg, threw the pope's bull into it with his own hands, together with the decreetals, extravgants, and Clementines; and this example was followed by his disciples in other towns. The next year the emperor Charles V. ordered his books to be burnt; and put him under the ban of the empire as a heretic and schismatic; and about this time king Henry VIII. of England wrote against him in defence of the seven sacraments, to which Luther wrote a reply.

The elector of Saxony, who had for some time kept him concealed in his castle of Wetzburg, now gave him leave to reform the churches of Wirtemberg as he thought fit; when this reformer propofed, that the bishops, abbots, and monks, should be expelled; that all the lands and revenues of the bishoprics, abbeys, and monasteries, should befeath to the refpective princes; and that all the convents of mendicant friars should be turned into public schools and hospitals: this year, Luther had the satisfaction to see a league contracted between Guflavus king of Sweden, and Frederick king of Denmark, who both agreed to establish Lutheranism in their dominions; and now Luther's perfusion, which from the Upper Saxony had spread into the northern provinces, began to be perfectly settled in the duchies of Lunenburgh, Brunfwick, Mecklenburgh, and Pomerania, and in the archbishoprics of Magdeburgh and Bremen; in the towns of Hamburg, Wifmar, RoStock, and along the Baltic as far as Livonia and Prufia. Luther maintained the doctrine of confubfitution; and at a general one at Ratibfon for reconciling both parties, the divines could agree to no more than five or six articles concerning justification, free-will, original sin, baptism, good works, and epiftopacy.

LUTHERN, in architecture, a kind of window over the corniche, in the roof of a building; flanding perpendicular over the naked of a wall, and serving to illustrate the upper flory. Lutherns are of various forms, as square, femi-circular, round, called bulls-eyes, flat arches, &c.

LUTON, a market town, fourteen miles south of Bedford.

LUTRA, in zoology. See Mustela.

LUXATION, in surgery, is when any bone is moved out of its place, or articulation, so as to impede or destroy its proper motion or office. See Surgery.

LUXEMBURG, the capital of the duchy of the same name, situated an hundred miles south-east of Brufels, is a small but strong forts: E. long. 6° 8', N. lat. 49° 45'.

LYBIA, a name anciently given to all the coast of Barbary, especially that part lying westward of Egypt.

LYCEUM, in Grecian antiquity, an academy situated upon the banks of the Iliffus at Athens. It was composed of porticoes and walks, where Ariflotle taught philosophy; walking there constantly every day till the hour of anointing; whence he and his followers were called peripatetics.

LYCHNIS, in botany, a genus of the decandria pentagynia class. The calix consists of one oblong smooth leaf, and the corolla of five unguiculated petals, with a bifid limbus; and the capsule has three cells. There are seven species, three of them natives of Britain, viz. the flos cuculi, meadow-pinks, or cuckow-flower; the vicaria, or red German catchfly; and the dioica, or white campion.

LYCIUM, in botany, a genus of the petandria monogygynia class. The corolla is tubular, the falk being shut up by the beard of the filaments; and the berry has two cells. There are three species, none of them natives of Britain.

LYCODONTES, in natural history, the petrified teeth of the lupus-pisces, or wolf-fish, frequently found fossil. They are of different shapes; but the most common kind rise into a semiobicular form, and are hollow within, somewhat resembling an acorn-cup: this hollow is found sometimes empty, and sometimes filled with the stratum in which it is immerfed. Many of them have an outer circle, of a different colour from the rest.

LYCO-
LYCOPERDON, in botany, a genus of the cryptogamia fungis class: It is roundish, and replete with farinaceous seeds. There are ten species, five of them natives of Britain, viz. the tuber, or solid puff balls; the cervinum, or branny puff-ball; the bovista, or common puff-ball; the tellatum, or star puff-ball; the sordidatum, or turret puff-ball; and the pedunculatum, or stalked puff-ball.

LYCOPODIUM, in botany, a genus of the cryptogamia musci class. The anther is double-valved, and fertile; the calyptra is wanting. There are 24 species, of which six are natives of Britain, viz. the clavatum, or common club mosses; the inundatum, or marsh club-mosses; the alpinum, or mountain club-mosses; the filago, or fir club-mosses; and the felaginoides, or prickly club-mosses.

LYCOPSIS, in botany, a genus of the pentandria monogynia class. The tube of the corolla is incurvated. There are seven species, only one of which, viz. the arvensis, or small wild buglars, is a native of Britain.

LYCOPUS, in botany, a genus of the diandria monogynia class. The corolla consists of six segments, one of them emarginated; the stamens are distant; and there are four seeds. There are two species: only one of them, viz. the europaeus, or water-horehound, is a native of Britain.

LYDIA, an ancient province of Lower Asia, in which was the city of Philadelphia.

LYGEUM, in botany, a genus of the triandria monogynia class. The spathe consists of one leaf; there are two corollae above the same germen; and the nut has two cells. There is but one species, a native of Spain.

LYDIA, an ancient province of Lower Asia, in which was the city of Philadelphia.

LYCHEUM, in botany, a genus of the triandria monogynia class. See Anatomy, Part III.

LYNCH, in zoology. See Felis.

LYONS, the capital of the Lyonesse, a province of France, bounded by Orleans and Burgundy on the north, by la Breffe and Dauphine on the east, by Languedoc and Guittene on the south, and by another part of Guittene and Orleans on the west. This city lies upon the confluence of the rivers Rhone and Saone, in Lat. 4° 55', and N. lat. 5° 50'. Next to Paris, it is esteemed the place of greatest trade in France.

LYRA, in ichthyology. See Callionymus.

LYRE, a musical instrument of the string-kind, much used by the ancients.

LYRE, in astronomy. See Astronomy, p. 486.

LYRIC, in general, signifies something sung or played on the lyre: but it is more particularly applied to the ancient odes and stanzas, answering to our airs and songs, and may be played on instruments. This species of poetry was originally employed in celebrating the praises of gods and heroes, though it was afterwards introduced into feasts and public diversions.

LYSIMACHIA, in botany, a genus of the pentandria monogynia class. The calyx is rounded; and the capsule is roundish, with a sharp point, and contains ten valves. There are eleven species, five of them natives of Britain, viz. the vulgaris, or yellow willow-herb; the thiriflora, or tufted loose-strife; the nemorum, or yellow pimpernel of the woods; the nummularia, or money-wort; and the tenella, or purple money-wort.

LYTHRUM, in botany, a genus of the dodecandria monogynia class. The calyx consists of twelve segments; and the corolla of six petals inserted into the calyx; and the capsule has two cells and many seeds. There are ten species, two of them natives of Britain, viz. the salicaria, or purple spiked loose-strife; and the hyssopifolia, or small hedge-hyssop.
ERRATA.
