Encyclopædia Britannica; OR, A DICTIONARY OF ARTS and SCIENCES, COMPILED UPON A NEW PLAN. IN WHICH The different SCIENCES and ARTs are digested into distinct Treatises or Systems; AND The various TECHNICAL TERMS, &c. are explained as they occur in the order of the Alphabet.

ILLUSTRATED WITH ONE HUNDRED AND SIXTY COPPERPLATES.

By a SOCIETY of GENTLEMEN in SCOTLAND.

IN THREE VOLUMES.

VOL. II.

EDINBURGH:
Printed for A. BELL and C. MACFARQUHAR;
And sold by COLIN MACFARQUHAR, at his Printing-office, Nicolson-street.
M.DCC.LXXI.
CAABA, or CAABAH, properly signifies a square building; but is particularly applied by the Mahometans to the temple of Mecca, built, as they pretend, by Abraham and Ismaël his son. It is towards this temple they always turn their faces when they pray, in whatever part of the world they happen to be.

This temple enjoys the privilege of an asylum for all sorts of criminals; but it is most remarkable for the pilgrimages made to it by the devout Mussulmans, who pay so great a veneration to it, that they believe a single sight of its sacred walls, without any particular act of devotion, is as meritorious, in the sight of God, as the most careful discharge of one's duty, for the space of a whole year, in any other temple.

CAB, an Hebrew dry measure, being the sixtieth part of a seah or fatum, and the eighteenth part of an ephah: A cab contained 2½ pints of our corn measure; a quarter-cab was the measure of dove's dung, or more properly a sort of chick-pease, called by this name, which was sold at Samaria, during the siege of that city, for five shekels.

CABALIST, in French commerce, a factor, or person, who is concerned in managing the trade of another.

CABALLARIA, in middle-age writers, lands held by the tenure of furnishing a horseman, with suitable equipment, in time of war, or when the lord had occasion for him.

CABALLEROS, or CAVALLEROS, are Spanish wools, of which there is a pretty considerable trade at Bayonne, in France.

CABALLINE denotes something belonging to horses: Thus caballine aloes is so called, from its being chiefly used for purging horses; and common brimstone is called sulphur caballinum, for a like reason.

CABBAGE, in botany. See Brassica.

CABBAGE-tree, a name sometimes given to the palm-tree, called by Linnaeus Phoenix. See Phoenix.

CABBAGING, among gardeners, a term used for the knitting of cabbages into round heads.

CABBALA, according to the Hebrew style, has a very distinct signification from that wherein we understand it in our language. The Hebrew cabbala signifies tradition; and the rabbins, who are called cabbalists, study principally the combination of particular words, letters, and numbers, and by this means pretend to discover what is to come, and to see clearly into the sense of many difficult passages in scripture: There are no sure principles of this knowledge, but it depends upon some particular traditions of the ancients; for which reason it is termed cabbala.

The cabbalists have abundance of names, which they call sacred: These they make use of in invoking of spirits, and imagine that they receive great light from them: They tell us, that the secrets of the cabbala were discovered to Moses on mount Sinai; and that these have been delivered down to them from father to son, without interruption, and without any use of letters; for to write them down, is what they are by no means permitted to do. This is likewise termed the oral law, because it passed from father to son, in order to distinguish it from the written laws.

There is another cabbala, called artificial, which consists in searching for abstruse and mysterious significations of a word in scripture, from whence they borrow certain explanations, by combining the letters A which
CABBALISTS, the Jewish doctors who profess the CABBALA, or CABESSE, CABENDA, a port-town of Congo, in Africa, and CABLIDOS, or a long measured at Goa, CAVIDQS, CABIN, in the sea-language, a small room, or apartment, which compose it: this cabbala is divided into three kinds, the gematrie, the notaricon, and the temura or themurah. The first whereof consists in taking the letters of a Hebrew word for ciphers or arithmetical numbers, and explaining every word by the arithmetical value of the letters whereof it is composed. The second sort of cabbala, called notaricon, consists in taking every particular letter of a word for an entire dictionary; and the third, called themurah, i.e. change, consists in making different transpositions or changes of letters, placing one for the other, or one before the other.

Among the Christians likewise, a certain sort of magic is, by mistake, called cabbala, which consists in using improperly certain passages of scripture for magic operations, or in forming magic characters or figures with stars and talismans.

Some visionaries, among the Jews, believe, that Jesus Christ wrought his miracles by virtue of the mysteries of the cabbala.

CABBALISTS, the Jewish doctors who profess the study of the cabbala.

In the opinion of these men, there is not a word, letter, or accent in the law, without some mystery in it. The Jews are divided into two general sects; the Karaites, who refuse to receive either tradition or the letter, or accent in the law, without a divine mystery in the study of the cabbala.

The latter are again divided into two other sects; pure Rabbinists, who explain the scripture, in its natural sense, by grammar, history, and tradition; and cabbalists, who, to discover hidden mythical senses, which they suppose God to have couched therein, make use of the cabbala, and the magical methods above mentioned.

CABECAS, or CABESSE, a name given to the finest foks in the East Indies, as those from 15 to 20 per cent. inferior to them are called barina. The Indian workmen endeavour to pass them off one with the other; for which reason, the more experienced European merchants take care to open the bales, and to examine all the skins one after another. The Dutch distinguish two sorts of cabecas; namely, the Moor cabeca, and the common cabeca. The former is sold at Amsterdam for about 21½ schellinghen Elemilh, and the other for about 18½.

CABENDA, a port-town of Congo, in Africa, and subject to the Portuguese: E. long. 12°, and S. lat. 4°.

CABILIDOS, or CAVIDQS, a long measured at Goa, and in other places of the East Indies belonging to the Portuguese, to measure hulks, linens, &c. and equal to ¼ of the Paris ell.

CABIN, in the sea-language, a small room, or apartment, whereof there are a great many in several parts of a ship; particularly on the quarter-deck, and on each side of the forecastage, for the officers of the ship to lie in.

The great cabin is the chief of all, and that which properly belongs to the captain, or chief commander.

CABINET, or CABINET, the most retired place in the finer part of a building, set apart for writing, studying, or preserving anything that is precious.

A complete apartment consists of a hall, antechamber, chamber, and cabinet, with a gallery on one side. Hence we say, a cabinet of paintings, curiosities, &c. Cabinet also denotes a piece of joiner's workmanship, being a kind of press or chest, with several doors and drawers.

There are common cabinets of oak or of cheesnut, varnished cabinets of China and Japan, cabinets of inlaid work, and some of ebony, or the like scarce and precious woods.

Formerly the Dutch and German cabinets were much esteemed in France, but are now quite out of date, as well as the cabinets of ebony, which came from Venice.

CABIRI, a term in the theology of the ancient Pagans, signifying great and powerful gods; being a name given to the gods of Samothracia. They were also worshipped in other parts of Greece, as Lemnos and Thebes, where the cabiria were celebrated in honour of them; these gods are said to be, in number, four, viz. Axioiros, Axioros, Axiocerfa, and Axiocerfus, and Casmius.

CABIRIA, festivals in honour of the cabiria, celebrated in thebes and Lemnos, but especially in Samothrace, an island consecrated to the cabiria. All who were initiated into the mysteries of these gods, were thought to be secured thereby from storms at sea, and all other dangers. The ceremony of initiation was performed by placing the candidate, crowned with olive-branches, and girded about the loins with a purple riband, on a kind of throne, about which the priests, and perfons before initiated, danced.

CABLAN, the name of a kingdom and city of India, beyond the Ganges.

CABLE, a thick, large, strong rope, commonly of hemp, which serves to keep a ship at anchor.

There is no merchant-ship, however weak, but has at least three cables; namely, the chief cable, or cable of the fleet-anchor, a common cable, and a smaller one.

Cable is also said of ropes, which serve to raise heavy loads, by the help of cranes, pullies, and other engines. The name of cable is usually given to such as have, at least, three inches in diameter; those that are lefs are only called ropes of different names, according to their use.

Every cable, of what thickness soever it be, is composed of three strands; every strand of three ropes; and every rope of three twills: the twill is made of more or less threads, according as the cable is to be thicker or thinner.

In the manufacture of cables, after the ropes are made, they use ficks, which they pass first between the ropes of which they make the strands, and afterwards between the strands of which they make the cable, to the end that they may all twill the better, and be more regularly wound together; and also, to prevent them from twining or intertangling, they hang...
CABLED, in heraldry, a term applied to a cross, Pay is to let more out of the flip. Pay more CkBi.B, To splice is to make two pieces fast together, CABLE, is the greatest cable belonging to CA.-BI.IL, Sheet-anchor cable, is the greatest cable belonging to a ship. Serve or plate the Cable, is to bind it about with ropes, clouts, &c. to keep it from gallung in the hawfe. To splice a Cable, is to make two pieces fast together, by working the several threads of the rope, the one into the other. Pay more Cable, is to let more out of the ship. Pay cheap the cable, is to hand it out apace. Veer more cable, is to let more out, &c. CABLED, in heraldry, a term applied to a cross, sometimes also to a cross covered over with rounds of rope, more properly called a cross-corded. CABLED-flute, in architecture, such flutes as are filled up with pieces, in the form of a cable. CABO DE ISTRIA, the capital of the province of Istria, in the dominion of Venice, situated on the gulf of Venice, about twelve miles south of Trieste: E. long. 14° 20', and N. lat. 45° 50'. CABOCHED, in heraldry, is when the heads of beasts are borne without any part of the neck, full-faced. CABOLETTO, in commerce, a coin of the republic of Genoa, worth about 3 d. of our money. CABUL, the capital of a province of the same name, on the north-west of India. Both the town and province of Cabul were ceded to the Persians in 1739: E. long. 69°, and N. lat. 33° 30'. CABURNS, on ship-board, are small lines, made of spun yarn, to bind cables, seize tackles, or the like. CACACA, a city of Africa, in the kingdom of Fz. CACAGOGA, among ancient physicians, ointments, which, applied to the fundament, procure ftools. Paulus Aegineta directs to boil aluin, mixed with honey, for that purpose. CACALIA, in botany, a genus of the fyngeonia polygania equalis class. The receptacle is naked; the pappus is hairy; and the calyx is cylindrical, oblong, and has a kind of small cup at the bafe. There are 12 species, none of which are natives of Britain. CACALANTHEMUM, in botany, a fynonime of the cacalia. See Cacalia. CACAO, in botany. See Theobroma. CACERES, a town of Eftremadura, in Spain, about seventeen miles south-east of Alcantara: W. long. 6° 45', and N. lat. 39° 12'. CACHAN, a city of Persia, situated in a large plain, about 20 leagues from Isphahan. It is remarkable for its manufactures of gold and silver fluffs, and of fine earthen ware. CACHAO, or Kecho, the capital of the kingdom of Tonquin, situated on the western shore of the river Dorna: E. long. 105°, and N. lat. 22° 30'. CACHECTIC, something partaking of the nature of, or belonging to a cachexy. See Cachexy. CACHEMIRE, or Kachemire, a province of Asia, in the country of the Mogul. The inhabitants are thought to have been originally Jews, because they speak much of Moses and Solomon, whom they believe to have travelled into their country. Cachemire is also the capital of that province, situated in 76° E. long. and 34° 30' N. lat. CACHEXY, in medicine, a vitius flate of the humours and whole habit. See Medicine. CACHRY, in botany, a genus of the pentandria digynia class. The frut is oval and a little angled. There are but two species, viz. the libanotis, a native of Sicily; and the ficula, a native of Sicily and Spain. CACOETHES, in medicine, an epithet applied, by Hippocrates, to malignant and difficult disfempers: when applied to signs or symptoms, it imports what is very bad and threatening; and if given to tumours, ulcers, &c. it denotes a great malignancy. CACTUS, in botany, a genus of the icofandria monogynia class. The calyx confists of one leaf, imbivicated, and above the fruit. The berrv has but one cell, containing many seeds. The species are twenty-three, one of which is the cochineal-plant. See Cochineal. CAD, or Cadre: See Cade. CADARI, or Kadari, a sect of Mahometans, which attributes the adions of men to men alone, and not to the divine decree determining his will; and denies all absolute decrees, and predetermination. Ben Aun calls the cadari, the magi or maniches of the mufful- mans.
CADE, a cag, cad, or barrel. A cade of herrings is a vessel containing the quantity of 500 red herrings, or of sprats 1000.

CADE-LAMB, a young lamb, weaned and brought up by hand in a house.

CADE-OIL, an oil much used in France and Germany: it is prepared from the fruit of a species of cedar, called *oxycedrus*.

CADE-WORM, in zoology, the maggot or worm of a fly, called *phryganea*. See *phryganea*.

CADENCE, in reading, is a falling of the voice below the key-note at the close of every period. In reading, whether prose or verse, a certain tone is assumed which is called the key-note; and in this tone the bulk of the words are founded; but this note is generally lowered towards the close of every sentence.

CADENCE, in music, according to the ancients, is a certain conclusion of a song, or of the parts of a song, which divide it, as it were, into so many numbers or periods. It is when the parts terminate in a chord or note, the ear seeming naturally to expect it; and is much the same in a song, as the period that closes the sentence in a paragraph of discourse.

A cadence is either perfect, consisting of two notes sung after each other, or by degrees conjoined in each of the two parts, and by these means satisfying the ear; or imperfect, when its last measure is not in the octave or unison, but a fifth or third. It is called imperfect, because the ear doth not acquiesce in the conclusion, but expects a continuation of the song. The cadence is said to be broken, when the bass, instead of filling a fifth, as the ear expects, arises a second, either major or minor. Every cadence is in two measures; sometimes it is suspended, in which case it is called a repose, and only consists of one measure, as when the two parts stop at the fifth, without finishing the cadence. With regard to the bass-viol, Mr Rousseau distinguishes two cadences, one with a rest, when the finger, that should shake the cadence, stops a little, before it shakes, on the note immediately above that which requires the cadence; and one without a rest, when the stop is omitted.

CADENCE, in the menage, an equal-measure or proportion, observed by a horse in all his motions; so that his times have an equal regard to one another, the one does not embrace or take in more ground than the other, and the horse observes his ground regularly.

CADIEN, one of the sorts of carpets which the Europeans import from the Levant. They are the worst sort of all, and are sold by the piece from one to two piastras per carpet.

CADET, the younger son of a family, is a term naturalized in our language from the French. At Paris, among the citizens, the cadets have an equal patrimony with the rest. At Caix, in Normandy, the custom, as with us, is to leave all to the eldest, except a small portion to the cadets. In Spain, it is usual for one of the cadets in great families to take the mother's name.

CADET is also a military term denoting a young gentleman who chooses to carry arms in a marching regiment as a private man. His views are, to acquire some knowledge in the art of war, and to obtain a commission in the army. Cadet differs from volunteer, as the former takes pay, whereas the latter serves without any pay.

CADI, or CADH, a judge of the civil affairs in the Turkish empire.

It is generally taken for the judge of a town; judges of provinces being distinguished by the appellation of molla's.

In Biledulgerid in Africa, the cadis decides in spiritual affairs.

CADILESCHER, a capital officer of justice among the Turks, answering to a chief justice among us.

It is said, that this authority was originally confined to the foldiery; but that, at present, it extends itself to the determination of all kinds of law-suits; yet nevertheless subject to appeals.

There are but three cadis in the grand sanior's territories; the first is that of Europe; the second, of Natolia; and the third resides at Grand Cairo. This last is the most considerable: they have their seats in the divan next to the grand vizir.

CADIZ, a city and port-town of Andalusia in Spain, situated on the north-west end of the island of Leon, or Lyon, opposite to Port St Mary on the continent, about sixty miles south-west of Seville, and forty north-west of Gibraltar: W. long. 6° 40, N. lat. 36° 30'.

The island it stands on is in length about eighteen miles; the south-west end is about nine broad, but the other end, where the city stands, not above two. It has a communication with the continent by means of a bridge; and, with the opposite shore, forms a bay of twelve miles long and six broad. About the middle of this bay, there are two head-lands, or promontories, one on the continent, and the other on the island, which advance so near together, that the forts upon them, called the Punta and Matagorda, command the passage; and within these forts is the harbour, which it is impossible for an enemy to enter till he has first taken the forts.

CADIZADELITES, a sect of Mahometans very like the ancient Cadien, and living on the same principles. They shun feasts and diversions, and affect an extraordinary gravity in all their actions; they are continually talking of God, and some of them make a jumble of Christinity and Mahometanism; they drink wine, even in the fast of the ramazan; they love and protect the Christians; they believe that Mahomet is the Holy Ghost, practises circumcision, and justifies it by the example of Jesus Christ.

CADMIA, a metallic substance separated from the ore of zinc by fussion. See *chemistry*, Of *zinc*.

CADORIN, a province of Italy, in the territories of Venice, bounded by the bishopric of Brixen on the north;
CÆMUM, or Coecum, in anatomy, the blind-gut. 

CAIRN, in a general sense, any glutinous substance. 

CALSILIA, in zoology, a genus of serpents belonging to the amphibia class. The caecilia has no scales; it is smooth, and moves by means of lateral rugae or prickles. The upper lip is prominent, and furnished with two tentacula. It has no tail. There are but two species of this serpent, viz. 1. The tentaculata, has 135 rugae. It is about a foot long and an inch in circumference, preserving an uniform cylindrical shape from the one end to the other. The teeth are very small. It has such a resemblance to an eel, that it may easily be mistaken for one; but as it has neither fins nor gills, it cannot be clasped with the fishers. It is a native of America, and its bite is not poisonous. 2. The glutinosa has 340 rugae or prickles above and ten below the anus. It is of a brownish colour, with a white line on the side, and is a native of the Indies. 

CÆCUM, or Coecum, in anatomy, the blind-gut. See p. 260. col. 2. 

CÆMENT, in a general sense, any glutinous substance, capable of uniting and keeping things together in close cohesion: in this sense, under cement, are compre- 

CÆM, or Coecum, in anatomy, the blind-gut. 5 

CÆM, or Coecum, in anatomy, the blind-gut. 

CÆMENTATION, in chemistry, a kind of menstruum composed of fine brick-dust well sifted, resin, and bees-wax, used in mosaics to bind bricks or stones together for some kind of moulding; or in cementing a block of bricks for the carving of capitals, frolis, or the like. There are two sorts, 1. Hot cement, which is the most common, made of resin, bees-wax, brick-dust, and chalk, boiled together. The bricks to be cemented with this kind, must be made hot with the fire, and rubbed to and fro after the cement is spread, in the same manner as joiners do when they glue two boards together. 2. Cold cement, made of Cheshire-cheese, milk, quicklime, and whites of eggs. This cement is less used than the former, and is accounted a secret known but to few bricklayers. 

CÆMENT-POTS, or those used in the cementation of metals, are made of fine potter's clay, and that either pure, or mixed with sand in different proportions. 

CÆMENTATION, in chemistry, the corroding of metals in a dry form, by means of the fumes of acid salts. See Chemistry, Part II. 

CAEN, the capital of a county of the same name in Normandy, situated on the river Orne, about forty-five miles west of Rouen, and thirty south-west of Havre de Grace; W. long. 25°, N. lat. 49° 20'. It has an university, first founded by king Henry VI. of England, in 1431. 

CAERFILLY, a town of Glamorganshire, about five miles north of Landaff; W. long. 3° 15', and N. lat. 51° 35'. 

CÆRITES, or Casritum Tabulæ, in Roman antiquity, tables or registers in which the names of the Casrites were registered. The people of Caere were accounted citizens of Rome, but had no privilege of voting; hence when a Roman citizen was degraded, if a senator, he was expelled the Senate; if a knight, he lost the public horse; and if a plebeian, his name was inserted in the register of the Cærites; that is, he was
was subject to all taxes, but incapable of voting or enjoying any public office.

**CAERLEON** was a market-town of Monmouthshire, situated on the river Tivy, about five miles from the sea.

**CAERNARVEN** was the capital of Caernarvonshire in Wales, situated upon the river Ulice, about sixteen miles south-west of Monmouth: W. long. 3°, N. lat. 51° 40'.

**CAERMARTHEN** was the chief town of Caernarvonshire in Wales, situated upon the river Tivy, about five miles from the sea.

**CAERNARVAN** was a market-town in Caernarvonshire in Wales, situated upon the river Menay.

**CAERWIS**, a market-town in Flintshire, in north Wales, about five miles east of St. Asaph, and four miles west of Flint: W. long. 3° 25', N. lat. 53° 20'.

**CÆSALPINIA**, in botany, a genus of the decandria monogynia class. The calix has five segments, the lowest of which is largest; the corolla consists of five petals; the capsule is of the pod kind. There are four species, all natives of the Indies.

**CÆSALPINOIDES**, in botany, a synonime of the gleditsia. See GLEDITSIA.

**CÆSAR**, in Roman antiquity, a title borne by all the emperors, from Julius Cæsar, to the destruction of the empire. It was also used as a title of distinction, for the intended or presumptive heir of the empire, as King of the Romans is now used for that of the German empire.

This title took its rise from the surname of the first emperor, C. Julius Cæsar, which, by a decree of the senate, all the succeeding emperors were to bear. Under his successor, the appellation of Augustus being appropriated to the emperors, in compliment to that prince, the title Cæsar was given to the second person in the empire, though still it continued to be given to the first; and hence the difference between Caesar used simply, and Cæsar with the addition of Imperator Augustus.

The dignity of Caesar remained the second of the empire, till Alexius Comnenus having elected Nicephorus Melissenus Cæsar, by contract; and it being necessary to confer some higher dignity on his own brother Isaac, he created him Seuflatorocrates, with the precedence over Melissenus; ordering, that in all acclamations, &c. Isaacus Seuflatorocrates should be named the second, and Melissenus Caesar, the third.

**CÆSARIAN operation**, in midwifery. See MIDWIFERY.

**CÆSARIANS, Caesarinus**, in Roman antiquity, were officers or ministers of the Roman emperors: They kept the account of the revenues of the emperors, and took possession in their name, of such things as devolved, or were confiscatted to them.

**CÆSTUS**, in antiquity, a large gantlet made of raw hide, which the wrestlers made use of when they fought at the public games.

This was a kind of leather t'rap, strengthened with lead, or plates of iron, which encompassed the hand, the wrist, and a part of the arm, as well to defend these parts, as to enforce their blows.

**CÆSTUS, or Cæstum**, was also a kind of girdle, made of wool, which the husband untied for his spouse the first day of marriage, before they went to bed.

**CÆSURA**, in the ancient poetry, is when, in the scanning of a verse, a word is divided so, as one part seems cut off, and goes to a different foot from the rest; as,

\[
Menthé nollis, numquam mendiacō profunt. 
\]

where the syllables ri, li, quau, and men, are cæsuras.

**CÆSURE**, in the modern poetry, denotes a reft, or pause, towards the middle of an Alexandrian verse, by which the voice and pronunciation are aided, and the verse, as it were, divided into two hemistichs. See PAUSE.

**CAFFA, in commerce**, painted cotton-cloths manufactured in the E. Indies, and sold at Bengal.

**CAFFA, or Kaffa**, a city and port-town of Crim Tartary, situated on the south-east part of that peninsula: E. long. 37°, N. lat. 44° 55'.

It is the most considerable town in the country, and gives name to the straits of Caffa, which run from the Euxine or Black sea, to the Palus Meotis, or sea of Azoph.

**CAFFILA, a company of merchants or travellers, who join together in order to go with more security thro' the dominions of the Grand Mogul, and through other countries on the continent of the E. Indies.**

The Caffila differs from a caravan, at least in Persia; for the caffila belongs properly to some sovereign, or to some powerful company in Europe; whereas a caravan is a company of particular merchants, each trading upon his own account. The English and Dutch have each of them their caffila at Gambron.

**CAFFILA on the coast of Guzerat or Cambaya, signifies a small fleet of merchant-ships.**

**CAFFRARIA, the country of the Caffers, or Hottentots, in the most southerly part of Africa, lying in the form of a crescent about the inland country of Monomotapa, between 35° S. lat. and the tropic of Capricorn; and bounded on the east, south, and west, by the Indian and Atlantic oceans.**

Most of the sea-coasts of this country are subject to the Dutch, who have built a fort near the most southern promontory, called the Cape of Good-Hope.

**CAGE, an inclosure made of wire, wicker, or the like, interwoven lattice-wire, for the confinement of birds, or wild beasts.**

The cage, in the Roman amphitheatres, was a place wherein savage animals were confined. It was inclosed with iron rails, and open at top, so as to be seen to the bottom by the spectators.

**CAGLI, a town of the province of Urbino, in the pope's territories, about twenty-five miles south of the city of Urbino: E. long. 14° 0', N. lat. 43° 15'.**

**CAGLIARI, the capital of the island of Sardinia, situated on a bay of the sea in the southern part of that island: E. long. 9° 12', N. lat. 39°.**

**CAGUI, in zoology, a synonime of two species of monkey, viz. the jaccchus and cœdipus.** See SIMIA.
CAHERAHI, or AL-CAHERAHI, the capital of Egypt, which we call Grand Cairo. See CAIRO.

CAHLO, the name by which some call the lupus plicis or wolf-fish.

CAHORS, the capital of the territory of Querci, in the province of Guienne in France, situated about forty-five miles north of Toulouse: E. long. 1°, N. lat. 44° 25'.

It is the see of a bishop, and has an university.

CAHYI, a dry measure for corn, used in some parts of Spain, particularly at Seville and at Cadiz. It is near a bushel of our measure.

CAJANABURG, the capital of the province of Cajia, or east Bothnia in Sweden, situated on the north-east part of the lake Cajania, about three hundred miles north-east of Abo: E. long. 27°, N. lat. 63° 30'.

CAJAZZO, a town of the province of Lavoro in the kingdom of Naples, situated about sixteen miles north-east of the city of Naples: E. long. 15°, N. lat. 41° 15'.

CAJEPUT, an oil brought from the E. Indies, which resembles that of cardamoms.

CAIFUM, a city of China, situated in the province of Honan, on the river Croceus, three hundred and fifty miles north-west of Nankin: E. long. 113° 30', and N. lat. 35°.

CAIMACAM, or CAIMACAM, in the Turkish affairs, a dignity in the Ottoman empire, answering to lieutenant, or rather deputy, among us.

There are usually two caimacans, one residing at Constantinople, as governor thereof; the other attending the grand vizir, in quality of his lieutenant, secretary of state, and first minister of his council; and gives audience to ambassadors. Sometimes there is a third caimacan, who attends the sultan; whom he acquaints with any public disturbances, and receives his orders concerning them.

CAIMAN, or CAIMAN-ISLANDS, certain American islands lying south of Cuba, and north-west of Jamaica, between 81° and 86° of W. long. and in 21° of N. lat.

They are most remarkable on account of the fisheries of tortoises, which the people of Jamaica catch here, and carry home alive, keeping them in pens for food, and killing them as they want them.

CAINJANS, or CAJNITES, in church-history, Christian heretics, that sprung up about the year 130, and took their name from Cain, whom they looked upon as their head and father: They said, that he was formed by a celestial and almighty power, and that Abel was made but by a weak one.

This sect adopted all that was impure in the heresy of the gnostics, and other heresies of those times: They acknowledged a power superior to that of the Creator; the former they called Wisdom, the latter, Inferior Virtue: They had a particular veneration for Korah, Abiram, Efau, Lot, the Sodomites, and especially Judas, because his treachery occasioned the death of Jesus Christ: They even made use of a gospel, which bore that sibyl apostle's name.

CAINTO, in botany. See CHRYSOHYLLUM.

CAIRO, or GRAND CAIRO, the capital of Egypt, situated in a plain at the foot of a mountain, about two miles east of the Nile, and 100 miles south of the mouth of that river: E. long. 32°, N. lat. 30°.

The town is ten miles in circumference, and full of inhabitants. The cattle stands on the summit of a hill, at the south end of the town, and is three miles round. The British and other European states have their consuls and factors here, for the protection of trade.

CAIROAN, a town of the kingdom of Tunis in Africa, situated on the river Maghida, about eighty miles south of Tunis: E. long. 9°, N. lat. 36°.

CAINS, a name given to the Greeks in the isle of Crete, who revolt from the Turks to the Venetians.

CAISSON, in the military art, a wooden chest, into which several bombs are put, and sometimes only filled with gun-powder: This is buried under some work whereof the enemy intends to possess themselves, and, when they are masters of it, is fired, in order to blow them up.

CAISSON is also used for a wooden frame or chest, used in laying the foundations of the piers of a bridge.

CAITHNESS. See CAITHNESS.

CAKILE, in botany. See BUNIAS.

CALABA, in botany. See CALOPHYLLUM.

CALABASH TREE, in botany. See CRESCENTIA.

CALABRIA, the most southern part of the kingdom of Naples, situated over against Sicily.

There are two provinces of Calabria called the Higher and Farther Calabria, with respect to the city of Naples; Cosenza being the capital of the former, and Rheggio of the latter.

CALADE, in the menage, the descent or sloping declivity, yet considerably heavy.

This facility of a rising menage ground, being a small eminence of a spungy substance and a lax and cavernous texture, yet considerably heavy.

CALAHORRA, a city of Old Castile in Spain, situated on the river Ebro, near the confines of Navarre, about sixty miles north-west of Saragossa: W. long. 2°, N. lat. 42° 20'.

CALAIS, a port-town of Picardy in France, situated on the English channel, about twenty-two miles south-east of Dover: E. long. 2°, N. lat. 51°.

CALAMANCO, a fort of wooden stuff manufactured in England and in Brabant. It has a fine gloss, and is chequered in the warp, whence the checks appear on the surface, yet considerably heavy.

CALAMINARIS, or LAPIS CALAMINARIS, in natural history, a kind of fofsid, the general ore of zinc, of a spungy substance and a lax and cavernous texture, yet considerably heavy.

It is of no determinate shape or size, but is found in mafles of a very various and irregular figure. It is
CALAMITA is sometimes used for the magnet or

CALAMITAS, in botany, a name given to sty-

and

MEN-

CALAMINT, in botany. See MELISSA, and MENTHA.

CALAMUS or sweet-scented flag, in the ma-

aromaticus,

CALAMITES. See OSTEOCOLLA.

CALAMUS in antiquity, a reed or rush to

fcriptorius,

CALAMUS, in botany, a genus of the hexandria mo-

CHARITELLA, in botany. See STYRAX.

CALANGAY, in ornithology. See PSITTACULA.

CALASIRIS, in antiquity, a linen tunic fringed at the

CALATHUS, in antiquity, a basket, hamper, or pan-

was also a vessel, or pan, for cheese-curd and milk; also the name of a cup for wine, used in sacrifices.

CALATOR, in antiquity, a public servant, and a

freeman, such as a bailiff or crier, a sumner, to sum-

mon courts, synods, and other public assemblies.

CALATRAVA, a city of New Castile, in Spain, forty-eight miles east of Burgos; W. long. 3° 30', N. lat. 42° 36'.

CALCADA, or St Domingo de Calcada, a city of Old Castile, in Spain, forty-eight miles east of Burgos; W. long. 3°, N. lat. 42° 36'.

CALCANEUM, or os CALCIS, in anatomy. See p. 186. col. 1.

CALCAR, in zoology, the trivial name of a species of nautilus. See NAUTILUS.

CALCAR, in glams-making, a sort of oven, or reverbera-
tory furnace, in which, being well heated, the crystal

frit, or bollito, is made.

CALCAR, in geography, a town of the duchy of Cleves, and circle of Westphalia, in Germany: E. long. 5° 50', and N. lat. 51° 45'.

CALCARIUS, in general, denotes something belonging to, or partaking of the nature of calx. See CALX.

CALCARIUS lapis, in natural history, the same with lime-flone. See LIME.

CALCARIUM, in antiquity, a term used to denote the allowance made the soldiers to buy their shoes.

CALCEOLUS, in botany. See CYPRIPIEDUM.

CALCINATION, in chemistry, the reducing of sub-

stances to a calx by fire. See CHEMISTRY.

CALCITRAPA, and CALCITRAPPIDES, in botany. See CENAIARE.

CALCULUS, in natural history, properly denotes a little flone or pebble. See Pebble.

CALCULUS, or CALCULUS HUMANUS, in medicine, the flone in the bladder or kidneys. See MEDICINE, and SURGERY.

CALCULUS also denotes a method of computation, so
called from the calculi, or counters, anciently used for this purpose. Hence,

CALCULUS specialis or LITERALIS, is the same

with algebra. See ALGEBRA.

CALCULUS differentialis is a method of differencing quantities, that is, of finding an infinitely small quan-
tity, which being taken an infinite number of times, shall be equal to a given quantity. See FLUXIONS.

CALCULUS exponentialis, among mathematicians, a method of differencing exponential quantities, and fum-
mimg up the differentials of exponential quantities.

CALCULUS INTEGRALIS, or SUMMATURIS, is a method of summing up differential quantities; that is, from a differential quantity given, to find the quantity from whose differencing the given differential results. See FLUXIONS.

CALDARIUM, in the ancient baths, a certain vault, or
or room, made so as to collect the vapours, and produce sweating: whence it signifies a hot house, bagno, stove, or sweating-room.

CALEFACTION, the production of heat in a body from the action of fire, or that impulse impressed by a hot body upon other bodies about it. This word is used in pharmacy, by way of distinction from coction, which implies boiling; whereas calefaction is only heating a thing.

CALENBERG-CASTLE, the capital of a duchy of the same name, in Lower Saxony, in Germany, situated upon the river Leine, about fifteen miles south of Hanover: E. long. 9° 40', and N. lat. 52° 20'.

CALENDAR, a distribution of time, accommodated to the various uses of life, but more especially such as regard civil and ecclesiastical polity. See Astronomy, Of the division of time.

Julian Christian Calendar. See Astronomy, Of the division of time.

Gregorian Calendar. See Astronomy, Of the division of time.

CALENDER, a machine used in manufactories, to press certain woollen and silk-en stuffs, and linens, to make them smooth, even, and glossy, or to give them waves, or water them, as may be seen in mohairs and tabbies. This instrument is composed of two thick cylinders, or rollers, of very hard and polished wood, round which the stuffs to be calendared are wound: these rollers are placed cross-ways between two very thick boards, the lower serving as a fixed base, and the upper moveable, by means of a thick screw, with a rope fastened to a spindle, which makes its axis: the uppermost board is loaded with large stones weighing 20000 lb. or more. It is this weight that gives the polish and makes the waves on the stuffs about the rollers, by means of a shallow indenture or engraving cut in it.

CALENDAS, in Roman antiquity, the first day of each month, so called from the Greek [kalein], to proclaim: it being customary, on these days, to proclaim the number of holy-days in each month.

The Roman method of reckoning the days of their months has something extremely singular in it: instead of computing forwards, in the natural order of the numbers 1, 2, 3, &c. they reckoned backwards, in the manner expressed in the following verses:

*Prima dies mensis calendas eft dixta calendae:*
*Sex Maius, nonas, Julius, October, & Mars;*
*Quattuor at reliqui: habet idus quinque octo;*
*Inde dies reliques omnes dic esse calendas;*
*Quae retro numerant, dices a mensis sequente.*

Hence to find the day of our month answering to that of the calends, to the number of days in the preceding month add two, and from this sum subtracting the number of calends given, the remainder will be the day of our month: thus the fourth of the calends of June is found to answer to the twenty-ninth of May; and so in other cases.

CALENDULA, orMarygold, in botany, a genus of the syngenesia polygamia necessaria elias. The receptacle is naked; it has no pappus; the calix con-
teen of Nabonassar's years, four days, and \( \frac{13}{27} \) ; he, to avoid fractions, quadrupled the golden number, and by that means made a new cycle of seventy-six years; which time being expired, he supposed the lunation, or changes of the moon, would happen on the same day of the month, and hour of the day, that they were on seventy-six years before.

CALIX. See CALYX.

CALIXTINS, in church-history, a feast of Christians, in Bohemia and Moravia; the principal point in which they differed from the church, was the use of the chalice, or communicating in both kinds.

CALIXTINS, is also a name given to those, among the Lutherans, who follow the sentiments of George Calixtus, a celebrated divine, who opposed the opinion of St Augustine, on predestination, grace, and free-will.

CALMA, a kingdom of Tartary, in Asia, to the east of Siberia.

CALLING. See CAULKING.

CALLKS, among fowlers, a sport is also a name given to those, among the CALIXTINS, CALKS are bell made of box, walnut-tree, or Artificial CALLS are bell made of box, walnut-tree, or the like: they are formed of the bigness of an hen's egg, bored through from end to end; about the middle there must be a hole hollowed within, to the bottom; then have a pipe of a swan's quill, and the bone of a cat's foot, opened at one end, which must be conveyed into the hole at the end, and so thrust into the hole at the middle; take afterwards a goose-quill, opened at both ends, and put it in at the other end of the call; blow into the quill, and it will make the like noise as the partridge-cock does.

CALLA, in botany, a genus of the gynandria polyantha. The calyx has five leaves; the petals are yellow and blue; the envelope is wound over the calix and is divided into four or five lobes; the capsule is divided into two or three partitions, each containing two seeds. There is but one species, \( \text{Calla} \).

CALLABAS, a town of Indostan in Asia, upon the road from Surat to Agra.

CALLAO, a port-town in a little island on the coast of Peru, in South America, opposite to Lima: W. long. 76°, and S. lat. 12°.

CALLEN, a town of Ireland, in the county of Kilkenny; N. lat. 52° 25'.

CALLICHTYS, in ichthyology, the trivial name of a species of silurus. See Silurus.

CALLICO, in commerce, a kind of linen manufacture, made of cotton, chiefly in the East Indies, some of which are painted with various flowers of different colours; and others that are never dyed, having a stripe of gold and silver quite through the piece; and at each end they fix a tissue of gold, silver, and silk, intermingled with flowers. This manufacture is brought hither by the East-India company, and is re-exported by merchants to other parts of Europe. The general wear of flained or printed India calicoes in this nation having become a general grievance, and occasioning unspeakable difficulties upon our own manufacturers, they were prohibited by Act 7 Geo. I. cap. vii.

CALLIDRYS, in ornithology, the trivial name of a species of motacilla. See Motacilla.

CALLIGRAPHUS, in antiquity, a copist or scriviner, much practised during the wooing season of partridges, especially for taking cock-partridges; for which they put a hen into a cage, to call and bring them near.

CALLIGONUM, in botany, a genus of the polyandria digynia-clas. The calyx has five leaves; the petals are four; it has two fili; and the capsule is divided into two partitions, each containing two seeds. There is but one species, \( \text{Calligonum} \).

CALLING the house, in the British parliament, is the calling over the members names, every one answering to his own, and going out of the house, in the order in which he is called: this they do, in order to discover whether there be any persons there not returned by the clerk of the crown; or if any member be absent without leave of the house.

CALLIONYMUS, in ichthyology, a genus of fishes belonging to the order of jugulares. The upper lip is doubled up; the eyes are very near each other; the membrane of the gills has fix radii; the operculum is flat; the body is naked; and the belly-fins are at a great distance from each other. There are three species of callionymus, \( \text{Callionymus} \).

CALLING the house, in the British parliament, is the calling over the members names, every one answering to his own, and going out of the house, in the order in which he is called: this they do, in order to discover whether there be any persons there not returned by the clerk of the crown; or if any member be absent without leave of the house.

CALLIONYMUS, in ichthyology, a genus of fishes belonging to the order of jugulares. The upper lip is doubled up; the eyes are very near each other; the membrane of the gills has six radii; the operculum is flat; the body is naked; and the belly-fins are at a great distance from each other. There are three species of callionymus, \( \text{Callionymus} \).
CALLISTEA, in Grecian antiquity, a Leibian festival, wherein the women presented themselves in Juno's temple, and the prize was assigned to the fairest.

There was another of these contentions at the festival of Ceres Eleusinia, among the Parthians, and another among the Eleans, where the most beautiful man was presented with a complete suit of armour, which he consecrated to Minerva, to whose temple he walked in procession, being accompanied with his friends, who adorned him with ribbands, and crowned him with a garland of myrtle.

CALLUS, or callus, in a general sense, any cutaneous, corneous, or osseous hardness, whether natural or preternatural: but most frequently it means the callus generated about the edges of a fracture, provided by nature to preserve the fractured bones, or divided parts, in the situation in which they are replaced by the surgeon.

CALM, in the sea language, is when there is no wind stirring. That tract of sea, to the northward of the equator, between 4° and 10° of latitude, lying between the meridians of Cape Verde, and of the easternmost island of that name, seems to be a place condemned to perpetual calms: the little winds that are being only some sudden uncertain gusts of very small continuance, and less extent. The Atlantic ocean, near the equator, is very much subject, nay, always attended with these calms.

CALMAR, the capital of the province of Gothland, in Sweden, situated on the coast of the Baltic sea, about forty miles north of Carlscroon: E. long. 16°, and N. lat. 56° 40'.

CALMUCKS, certain wandering tribes or hords of Tartars, inhabiting the country north of the Caspian sea, under the protection of Russia.

CALNE, a borough-town of Wiltshire, about twenty miles north of Salisbury, which sends two members to parliament: W. long. 2°, and N. lat. 51° 30'.

CALOGERI, in church-history, monks of the Greek church, divided into three degrees, the novices, called archari; the ordinary professed, called microchemi; and the more perfect, called megalochemi: they are likewise divided into coenobites, anchorites, and recluses. The coenobites are employed in reciting their office from midnight to sun-set; they are obliged to make three genuflexions at the door of the choir, and returning, to bow to the right and to the left, to their brethren. The anchorites retire from the conversation of the world, and live in hermitages, in the neighbourhood of the monasteries; they cultivate a little spot of ground, and never go out but on Sundays and holy-days, to perform their devotions at the next monastery. As for the recluse, they shut themselves up in grottos and caverns, on the tops of mountains, which they never go out of, abandoning themselves entirely to Providence: They live on the alms sent them by the neighbouring monasteries.

CALOMEL, or dulcedine sublimate of mercury, is prepared in the following manner. Take of corrosive sublimate, one pound; purified quicksilver, nine ounces. Having powdered the sublimate, add to it the quicksilver, and digest them together in a mortar, with a gentle sand heat, until they unite; then increasing the heat, let the mixture be sublimed. The sublimed matter, freed from the acrimonious part at top and such mercurial globules as happen to appear distinct in it, is to be reduced into powder, and sublimed again; and this sublimation must be repeated six times. This dulcedine mercury, or calomel, is one of the best preparations for general use. The dose, for raising a salivation, is ten or fifteen grains, taken in the form of a bolus; or pills, every night or oftener, till the pyralsism begins. As an alterant and diaphoretic, it is given in doses of five or six grains, a purgative being occasionally interposed, to prevent its affecting the mouth. It answers however much better when given in smaller quantities, as one, two, or three grains every morning and evening, in conjunction with such substances as determine its action to the skin, as the extract or resin of guaiacum; the patient at the same time keeping warm, and drinking freely of warm diluting liquor. By this method of administering it, obturant, cutaneous, and generall diempers have been successfully cured, without any remarkable increase of the sensible evacuations.

CALOPHYLLUM, in botany, a genus of the polyantha monogynia class. The corolla consists of five petals; the calix has five teeth; and the drupa is globular. There are but two species, viz. the isophyllum, and calaba, both natives of India.

CALOTTE, a cap or coif of hair, satin, or other stuff; an ecclesiastical ornament in most popish churches.

See Cap.

CALOTTE, in architecture, a round cavity or depression, in form of a cup or cup, lathed and plantered, used to diminish the rile or elevation of a moderate chapel, cabinet, alcove, &c. which, without such an expedient, would be too high for other pieces of the apartment.

CALPE, the mountain, at the foot of which, towards the sea, Gibraltar stands. It is half a league in height towards the land, and so steep, that there is no approaching it on that side.

CALQUING, or calking, a term used in printing, &c. where the backside of any design is covered with a black or red colour, and the strokes, or lines, traced through, on a waxed plate, wall, or other matter, by passing lightly over each stroke of the design with a point, which leaves an impression of the colour on the plate or wall.

CALTHA, in botany, a genus of the polyandria monogynia class. It has no calyx; there are five petals; and the capsules are many, containing a great number of seeds. There is but one species, viz. the palustris, or marsh-marigold, a native of Britain.

CALTROP, in botany, the English name of the tribulus. See Tribulus.

CALVARIA,
CALVARIA, in anatomy, the hairy scalp. See p. 141.

Calyculum, in heraldry, a term used for a bundle of arrows, a term also used for a bundle of arrows.

Calvi, a town of the province of Lavoro, in the kingdom of Naples, situated near the sea, about fifteen miles north of the city of Naples: E. long. 14° 43', and N. lat. 41° 15'.

Calvi is also the name of a sea-port in the island of Corsica, situated on a bay, on the west side of the island, about forty miles south-west of Bastia: E. long. 9° 5', and N. lat. 42° 16'.

Calvinists, in church-history, those who follow the opinions of John Calvin, one of the principal reformers of the church, in the XVth century, as the persons of great parts and industry, and of considerable learning; whose doctrine still subsists in its greatest purity at Geneva, where it was first broached, and from whence it was propagated. This is the prevailing religion of the United Provinces. In England, it is confined among the dissenters; and, in Scotland, it is the only orthodox faith.

The Calvinists are great advocates for the absolute freedom of God's decrees, and hold that election and reprobation depend on the mere will of God, without any regard to the merit or demerit of mankind; that he affords to the elect an irrevocable grace, a faith that they cannot lose, which takes away the freedom of will, and necessitates all their actions to virtue.

The Calvinists believe that God foreknew a determinate number, whom he pitched upon to be holy, in order to which he gives them an irrevocable grace, which makes it impossible for them to be otherwise.

Calvities, or Calvitium, in medicine, baldness, or a want of hair, particularly on the occiput, occasioned by the moisture of the head, which should feed it, being dried up, by some disease, old age, or the immoderate use of powder, &c. See Alopecia.

Calumet, a symbol of peace among the Indians; it is a pipe, made of a red stone, like our marble; the head resembles our tobacco-pipes, but larger; and is fixed on a hollow reed, to hold it for smoking; they adorn it with fine wings of several colours, and is the cup of the flower, to whom they present it, especially if they want fair weather, or rain. This pipe is a pass and safe conduct amongst all the allies of the nation who has it given; in all embassies the ambassador carries it as an emblem of peace, and it always meets with a profound regard; for the savages are generally persuaded, that a great misfortune would befall them, if they violated the public faith of the calumet.

Calx, properly signifies lime, but is also used by chemists and physicians for a fine powder remaining after the calcination or corrosion of metals and other mineral substances. See Chemistry.

Calx antimonii. See Chemistry, Of antimony.

Calx nativa, in natural history, a kind of marly earth, of a dead whitish colour, which, if thrown into water, makes a considerable bubbling and hissing noise, and has, without previous burning, the quality of making a cement like lime, or plaster of Paris.

Calx vivae, or quick-lime, that whereon no water has been cast, in contradiction to lime which has been flaked by pouring water on it. See Chemistry, Of lime.

Calx, in anatomy. See Calcanemum.

Calycistæ, an appellation given by Linnaeus to those botanists who have clasped plants according to the different structure of the calyx, or cup of the flower; such was Magnolius.

Calyptra, among botanists, a thin membraneous involucrum, usually of a conic figure, which covers the parts of fructification. The capsules of most of the mollusks have calyptrae. See Botany.

Calyx, among botanists, a general term expressing the cup of a flower, or that part of a plant which surrounds and supports the other parts of the flower.

The cups of flowers are very various in their structure, and on that account distinguished by several names, as perianthium, involucrum, spatha, gluma, &c. See Botany.

Cam, a river, anciently called Grant, which, rising in Hertfordshire, runs north-east by Cambridge, and afterwards continues its course northwards, to the isle of Ely, where it falls into the river Ouse.

Camæa, in natural history, a genus of the semipellucid gems, approaching to the onyx structure, being composed of zones, and formed on a crystalline basis; but having their zones very broad and thick, and laid alternately on one another, with no common matter between; usually less transparent, and more debased with earth, than the onyxes.

1. One species of the camæa is the dull-looking onyx, with broad black and white zones; and is the camæa of the moderns, and the Arabian onyx: This species is found in Egypt, Arabia, Persia, and the East Indies. 2. Another species of the camæa is the dull, broad-zoned, green and white camæa, or the jasper-cameo of the Italians: It is found in the East Indies, and in some parts of America. 3. The third is the hard camæa, with broad white and cheetnut-coloured veins. 4. The hard camæa, with bluish, white, and flesh-coloured broad veins, being the larnyx of Pliny's time, only brought from the East Indies.

Camæeu, a term in painting, when there is only one colour, the lights and shades being of gold, or on a golden and azure ground. It is chiefly used to represent bafto-relievos.

Camaldulians, a religious order founded by St. Romuald, in a little plain, on the mount Apennine, called Camaldalia, situated in the state of Florence.

The manner of life first enjoined this order was, that they dwelt in separate cells, and met together only at the time of prayer; some of them, during the two lents of the year, observed an inviolable silence; and others, for the space of an hundred days. On Sundays and Thursdays they fed on herbs, and the rest of

Plate LIX.
the week only on bread and water. These constitutions were, however, a little moderated some time afterwards. This hermitage is now accounted very rich.

CAMARA, in botany. See LANTANA.

CAMARANA, an island of Arabia in the Red sea, situated in 15° N. lat.

CAMBAIA, a city of the province of Cambia, or Guzerat, in the higher peninsula of India; it is a very large city, and had once a great trade, now removed to Surat: E. long. 72°, and N. lat. 23° 30'.

CAMAYES, in commerce, cotton linens made at Benzar, in the higher peninsula of India; it is a very large city, containing about six thousand inhabitants.

CAMBRICKS, a species of very fine white linen, made of flax at Cambray. This manufacture, especially cambricks, which took their name from hence.

CAMBRIDGE, the capital of Cambridgeshire, situated upon the river Cam, about fifty-five miles north of London, and sixty north-east of Oxford. Cambridge is most remarkable on account of its university, which consists of sixteen colleges, wherein are educated about fifteen hundred students. There are fourteen parishes in the town, which is said to contain about six thousand inhabitants.

New CAMBRIDGE, a town of New England, about three miles west of Boston; likewise remarkable for an university, consisting of three colleges: W. long. 70° 4', and N. lat. 42°.

CAMEL, in zoology. See CAMELUS.

CAMELFORD, a borough-town of Cornwall, about twenty miles west of Launceston: W. long. 5°, and N. lat. 50° 40'.

It sends two members to parliament.

CAMELIA, in botany, a genus of the monodelphia class. The calix is imbricated, and consists of many leaves, the anterior of which are longest. There is but one species, viz. the japonica, a native of China and Japan.

CAMERON, in botany. See LANTANA.

CAMEL, in zoology. See CAMELUS.

CAMELET, or CAMLET, a plain stuff, composed of a warp and woof, which is manufactured on a loom, with two tredles, as linens and flannels are.

There are camblets of several sorts, some of goat's hair, both in the warp and woof; others, in which the warp is of hair, and the woof half hair and half flax; others again, in which both the warp and the woof are of wool; and lastly, some of which the warp is of wool and the woof of thread. Some are dyed in thread, others are dyed in the piece, others are marked or mixed; some are striped, some are glazed or watered, and some figured.

Camblets are proper for several uses, according to their different kinds and qualities; some serve to make garments both for men and women; some for bed-curtains; others for household-furniture, &c.

CAMBODIA, the capital of a kingdom of the same name in India, beyond the Ganges: E. long. 104°, N. lat. 12° 20'.

The kingdom of Cambodia extends from 9° to 15° of N. lat. being bounded by the kingdom of Laos on the north, Cochin-china on the east, the Indian ocean on the south, and by the bay of Sam on the west.

CAMBRAY, a city in the French Netherlands, situated on the river Schelde, near its source: E. long. 3° 15', and N. lat. 50° 15'.

It is a large and well-built city, considerable for its linen manufacture, especially camblets, which took their name from hence.

CAMBRICKS, a species of very fine white linen, made of flax at Cambray.

CAMBRIDGE, the capital of Cambridgeshire, situated upon the river Cam, about fifty-five miles north of London, and sixty north-east of Oxford.

Cambridge is most remarkable on account of its university, which consists of sixteen colleges, wherein are educated about fifteen hundred students. There are fourteen parishes in the town, which is said to contain about six thousand inhabitants.

New CAMBRIDGE, a town of New England, about three miles west of Boston; likewise remarkable for its university, consisting of three colleges: W. long. 70° 4', and N. lat. 42°.
CAMERARIA, in botany, a genus of the pentandria. CAMERATA, in optics, a machine representing visions. When enraged by their driver, they throw out from their mouth a liquor which corrodes and makes the skin rise into blisters.

CAMERATED, among builders, the same with vaulted or arched.

CAMERET-BAY, in the province of Brittany in France, forms the harbour of Brest. See BREST.

CAMERINO, a town of the ecclesiastical state in Italy.

CAMERLINGO, according to Ducange, signified formerly the pope's or emperor's treasurer: At present, camerlingo is nowhere used, but at Rome, where it notes the cardinal who governs the ecclesiastical state, and administers justice. It is the most eminent office at the court of Rome, because he is at the head of the treasury. During a vacation of the papal chair, the cardinal camerlingo publishes edicts, coins money, and exerts every other prerogative of a sovereign prince; he has under him a treasurer-general, auditor-general, and twelve prelates called clerks of the chamber.

CAMERONIANS, a party of presbyterians, which sprung up in Scotland in the reign of king Charles II. They affirmed that the king had forfeited his right to the crown, by breaking the solemn league and covenant, which were the terms on which he received it. They pretended both to dethrone and excommunicate him; and broke out into an open rebellion. Upon the revolution, they were reconciled to the kirk, and their preachers submitted to the general assembly of the church of Scotland, in 1690. That sect is now greatly declined. They are few in number, and split into many parties.

CAMERON, or Frounce, in hores. See Frounce.

CAMILLI, and Camilla, in Roman antiquity, a certain number of boys and girls, who assisted in the sacrifices to the gods, but more especially attended the flamens dialls.

CAMIS, or Kamis, in the Japanese affairs, denote the defecd souls of illustrious personages, believed to intercede themselves in the welfare of their countrymen: In which sense they answer to the defecd heroes of antiquity. See Hero.

CAMISARDS, a name given by the French to the Calvinists of the Cevennes, who formed a league, and took up arms in their own defence, in 1658.

CAMLETINE, a slight stuff, made of hair and coarse silk, in the manner of camblet. It is now out of fashion.

CAMMIN, a port-town of Brandenburg-Pomerania in Germany, situated on the eastern mouth of the river Oder, about thirty miles north of Stettin: E. long. 15°, N. lat. 54°.

CAMP, the ground upon which an army pitch their tents. It is marked out by the quarter-master general, who appoints every regiment their ground.

The chief advantages to be minded in chosing a camp for an army, are, to have it near the water, in a country of forage, where the soldiers may find wood for dressing their victuals; that it have a free communication with garrisons, and with a country from whence it may be supplied with provisions; and, if possible, that it be situated on a rising ground, in a dry gravelly soil. Besides these advantages of the ground ought to be considered, as marshes, woods, rivers, and inclosures; and if the camp be near the enemy, with no river or marsh to cover it, the army ought to be intrenched. An army always encamps in a strong enemy; and generally in two lines, running parallel about five hundred yards distance; the horse and dragoons, on the wings, and the foot in the centre: Sometimes a body of two, three, or four brigades is encamped behind the two lines, and is called the body of reserve. The artillery and bread-wagons are generally encamped in the rear of the two lines. A battalion of foot is allowed eighty or an hundred paces for its camp; and thirty or forty for an interval betwixt one battalion and another. A squadron of horse is allowed thirty for its camp, and thirty: for an interval, and more if the ground will allow it.

The disposition of the Hebrew encampment was at first laid out by God himself. Their camp was of a quadrangular form, surrounded with an inclosure of the height of ten hands-breadth. It made a square of twelve miles in compass about the tabernacle; and within this was another, called the Levites camp. The Greeks had also their camps, fortified with gates and ditches. The Lacedemonians made their camp of a round figure, looking upon that as the most perfect and defendible of any form: We are not, however, to imagine, that they thought this form so efficient to a camp, as never to be dispensed with when the circumstance of the place required it. Of the rest of the Grecian camps, it may be observed, that the most valiant of the soldiers were placed at the extremities, the rest in the middle. Thus we learn from Homer, that
that Achilles and Ajax were polled at the ends of the camp before Troy, as bulwarks on each side of the reef of the prince.

The camps of the Romans were generally of an exact square form, or else oblong; though this, without doubt, was often accommodated to the situation of the place. They were always fortified, and a very exact discipline maintained in them, in order to prevent surprises from the enemy.

Camp is also used, by the Siamese, and some other nations in the E. Indies, as the name of the quarters which they assign to the foreigners who come to trade with them.

In these camps, every nation forms, as it were, a particular town, where they carry on all their trade, not only keeping all their ware-houses and shops there, but also live in these camps with their whole families. The Europeans, however, are so far indulged, that at Siam, and almost everywhere else, they may live either in the cities or suburbs, as they shall judge most convenient.

Campagna, in geography. See Campania.

Campaign, in the art of war, denotes the space of time that an army keeps the field, or is incamped, in opposition to quarters.

Campagna, a city of the hither principate in the kingdom of Naples: situated about thirty-five miles south-east of the city of Naples: E. long. 15° 30', N. lat. 4° 45'.

Campania, or Campagna di Roma, a province of the pope's territories in Italy, extending from the city of Rome south-east, as far as the frontiers of the kingdom of Naples.

Campaniform, or campanulated, an appellation given to flowers resembling a bell.

Campanula, or bell-flower, in botany, a genus of the pentandria monogynia clafs. The corolla is campaniform or bell-shaped, the bottom of which is closed with five valvulous nectarias; the stigma is trifid; and the capulcule is below the flower, and opens at the sides. There are forty-one species of campanula, only nine of which are natives of Britain, viz. the rotundifolia, or lesser round-leaved bell-flower; the patula, or field bell-flower; the uniflora, or mountain bell-flower; the rapunculus, or rampions; the latifolia, or giant throat-wort; the tracheluna, great throat-wort, or Canterbury bells; and the glomerata, lesser throat-wort, or Canterbury-bells.

Campbell-town, a parliament-town in Argyleshire in Scotland, situated on the eastern shore of Kintire, about ten miles west of the island of Arran: W. long. 5° 10', N. lat. 55° 35'.

Campden, a market-town in Gloucestershire, about eighteen miles north-east of Gloucester: W. long. 1° 50', and N. lat. 52°.

Campeachy, or Campeche, a town of the province of Yucatan, on the bay or gulf of Mexico: W. long. 93°, N. lat. 19°.

Campowych, in botany. See Hæmatoxylum.

Campden, a market-town, in the province of Overeyssel, in the united Netherlands, near the mouth of the river Ijssel, about forty-two miles north-east of Amsterdam: E. long. 5° 40', and N. lat. 52° 35'.

Campor, or Camphire, a solid concrete juice extracted from the wood and roots of the laurus camphora, which grows in Japan. The camphor is extracted in the same way by which we extract essential oils. As it first sublimes from the wood, it appears brownish, composed of semipellucid grains mixed with dirt. In this state it is exported by the Dutch, and purified by a second sublimation; after which it is reduced to leaves, probably by fusion in close vessels, and in this form it is sold to us. Pure camphor is very white, pellucid, somewhat unctuous to the touch; of a bitterish, aromatic, acrid taste, yet accompanied with a sense of coolness. It has a fragrant smell, somewhat like that of rosemery, but much stronger. It is totally volatile and inflammable; soluble in vinous spirits, oils, and mineral acids; but not in water, alcaline liquors, or the vegetable acids. Camphor is esteemed one of the most efficacious diaphoretics, and has long been celebrated in fevers, malignant and epidemic distempers. In delirium, where opiates fail of procuring sleep, this medicine frequently succeeds.

Artificial Camphor is prepared with gum-sandarach and white vinegar distilled, kept twenty days in horned dung, and afterwards exposed a month to the sun to dry, at the end of which the camphor is found in form of the crust of a white loaf. This is also called juniper-gum, and maffic.

Camphor-tree. See Laurus.

Camphorata, in botany. See Polycnemum.

Camphor, in botany. See Laurus.

Camphor, in botany. See Laurus.

Camphora, in botany. See Polycnemum.

Campion, in botany. See Laurus.

Camphor, in botany. See Laurus.

Camp, in the sea-language, as can-pump, a vessel, where with seamen pour water into the pump to make it go.

Can-buoy, a larger size of buoy, used to discover dangerous
dangerous rocks and shelves, by being placed over them.

CANADA. See Hook.

CANADA, or New France, an extensive tract of North America, bounded by New Britain and the British colonies on Hudson’s bay, on the north; by the river of St Lawrence, the Iroquois, or five Indian nations, the Huron and Illinois lakes, on the east and south; and by unknown lands, on the west. Its chief town is Quebec.

Canal of communication, an artificial cut in the ground, supplied with water from rivers, springs, &c. in order to make a navigable communication betwixt one place and another.

The particular operations necessary for making artificial navigations depend upon a number of circumstances. The situation of the ground; the vicinity or connection with rivers; the ease or difficulty with which a proper quantity of water can be obtained; these and many other circumstances necessarily produce great variety in the structure of artificial navigations, and augment or diminish the labour and expense of executing them. When the ground is naturally level, and unconnected with rivers, the execution is easy, and the navigation is not liable to be disturbed by floods; but, when the ground rises and falls, and cannot be reduced to a level, artificial methods of raising and lowering vessels must be employed; which likewise vary according to circumstances.

A kind of temporary sluices are sometimes employed for raising boats over falls or shoals in rivers by a very simple operation. Two posts or pillars of masonry, with grooves, are fixed, one on each bank of the river, at some distance below the shoal. The boat having passed these posts, planks are let down across the river by pulleys into the grooves, by which the water is dammed up to a proper height for allowing the boat to pass up the river over the shoal.

The Dutch and Flemings at this day, sometimes when obstructed by cascades, form an inclined plane or rolling-bridge upon dry land, along which their vessels are drawn from the river below the cascade into the river above it. This, it is said, was the only method employed by the ancients, and is still used by the Chinese, who are said to be entirely ignorant of the nature and utility of locks. These rolling-bridges consist of a number of cylindrical rollers which turn easily on pivots, and a mill is commonly built near by, so that the same machinery may serve the double purpose of working the mill and drawing up vessels.

A lock is a basin placed lengthwise in a river or canal, lined with walls of masonry on each side, and terminated by two gates, placed where there is a cascade or natural fall of the country; and so constructed, that the basin being filled with water by an upper sluice to the level of the waters above, a vessel may ascend through the upper gate; or the water in the lock being reduced to the level of the water at the bottom of the cascade, the vessel may descend through the lower gate; for when the waters are brought to a level on either side, the gate on that side may be easily opened.

But as the lower gate is strained in proportion to the depth of water it supports, when the perpendicular height of the water exceeds 12 or 13 feet, more locks than one become necessary. Thus, if the fall be 17 feet, two locks are required, each having 8½ feet fall; and if the fall be 26 feet, three locks are necessary, each having 8 feet 8 inches fall. The side-walls of a lock ought to be very strong. Where the natural foundation is bad, they should be founded on piles and platforms of wood: They should likewise flop outward, in order to resist the pressure of the earth from behind.

Plate LX. Fig. 1. A perspective view of part of a canal: the vessel L, within the lock A C.—Fig. 2. Section of an open lock: the vessel L about to enter.—Fig. 3. Section of a lock full of water: the vessel L raised to a level with the water in the superior canal.—Fig. 4. Ground section of a lock. L, a vessel in the inferior canal. C, the under gate. A, the upper gate. G H, a subterraneous passage for letting water from the superior canal run into the lock. K F, a subterraneous passage for water from the lock, to the inferior canal.

X and Y (fig. 1.) are the two flood-gates, each of which consists of two leaves, resting upon one another, so as to form an obtuse angle, in order the better to resist the pressure of the water. The first (X) prevents the water of the superior canal from falling into the lock; and the second (Y) dams up and contains the water in the lock. These flood-gates ought to be very strong, and to turn freely upon their hinges. In order to make them open and shut with ease, each leaf is furnished with a long lever A b, A b; C b, C A. They should be made very tight and close, that as little water as possible may be lost.

By the subterraneous passage G H (fig. 2, 3, & 4) which descends obliquely, by opening the sluice G, the water is let down from the superior canal D, into the lock, where it is kept and retained by the gate C when shut, till the water in the lock comes to be on a level with the water in the superior canal D; as represented, fig. 3. When, on the other hand, the water contained by the lock is to be let out, the passage G H must be shut by letting down the sluice G, the gate A must be also shut, and the passage K F opened by raising the sluice K: A free passage being thus given to the water, it descends through K F, into the inferior canal, until the water in the lock is on a level with the water in the inferior canal B; as represented, fig. 2.

Now, let it be required to raise the vessel L (fig. 2.) from the inferior canal B, to the superior one D; if the lock happens to be full of water, the sluice G must be shut, and also the gate A, and the sluice K opened, so that the water in the lock may run out till it is on a level with the water in the inferior canal B. When the water in the lock comes to be on a level with the water at B, the leaves of the gate C are opened by the levers C b, which is easily performed, the water on each side of the gate being in equilibrium; the vessel then fails into the lock. After this the gate C, and the sluice...
flucts K are shut, and the fluce G opened, in order to fill the lock, till the water in the lock, and consequently the vessel, be upon a level with the water in the upper canal D; as is represented in fig. 3. The gate A is then opened, and the vessel passes into the canal D.

Again, let it be required to make a vessel ascend from the canal D, into the inferior canal B. If the lock is empty, as in fig. 2, the gate C and fluce K must be shut, and the upper fluce G opened, so that the water in the lock may rise to a level with the water in the upper canal D. Then open the gate A, and let the vessel pass through into the lock. Shut the gate A and the fluce G; then open the fluce K, till the water in the lock be on a level with the water in the inferior canal; then the gate C is opened, and the vessel passes along into the canal B, as was required.

It is almost needless to spend time in enumerating the many advantages which necessarily result from artificial navigations. Their utility is now so apparent, that most nations in Europe give the highest encouragement to undertakings of this kind wherever they are practicable. The advantages of navigable canals did not escape the observation of the ancients. From the most early accounts of society we read of attempts to cut through large isthmuses, in order to make a communication by water, either between different nations, or distant parts of the same nation, where land-carriage was long and expensive. Herodotus relates, that the Cnidian, a people of Caria in Asia Minor, designed to cut the Isthmus which joins that part of the continent; but were superstitious enough to give up the undertaking, because they were interdicted by an oracle. Several Kings of Egypt attempted to join the Red-sea to the Mediterranean. Cleopatra was exceedingly fond of this project. Solomon II. emperor of the Turks, employed 50,000 men in this great work. This canal was complicated under the caliphate of Omar, but was afterwards allowed to fall into disrepair; so that it is now difficult to discover any traces of it. Both the Greeks and Romans intended to make a canal across the Isthmus of Corinth, which joins the Morea and Achaia, in order to make a navigable passage by the Ionian sea into the Archipelago. Demetrius, Julius Caesar, Caligula, and Nero, made several unsuccessful efforts to open this passage. But, as the ancients were entirely ignorant of the use of water-locks, their whole attention was employed in making level cuts, which is probably the principal reason why they so often failed in their attempts. Charlemagne formed a design of joining the Rhine and the Danube, in order to make a communication between the ocean and the Black-sea, by a canal from the river Almutz which discharges itself into the Danube, to the Reditz, which falls into the Maine, and this last falls into the Rhine near Mayence: For this purpose he employed a prodigious number of workmen; but he met with so many obstacles from different quarters, that he was obliged to give up the attempt.

The French at present have many fine canals: That of Briare was begun under Henry IV. and finished under the direction of cardinal Richelieu in the reign of Lewis XIII. This canal makes a communication between the Loire and the Seine by the river Loing. It extends eleven French great leagues from Briare to Montargis. It enters the Loire a little above Briare, and terminates in the Loing at Cepci. There are forty-two locks on this canal.

The canal of Orleans, for making another communication between the Seine and the Loire, was begun in 1675, and finished by Philip of Orleans, regent of France, during the minority of Lewis XV. and is furnished with twenty locks. It goes by the name of the canal of Orleans; but it begins at the village of Combleux, which is a small French league from the town of Orleans.

But the greatest and most useful work of this kind is the junction of the ocean with the Mediterranean by the canal of Languedoc. It was proposed in the reign of Francis I. Henry IV. and was undertaken and finished under Lewis XIV. It begins with a large reservoir 4000 paces in circumference, and 24 feet deep, which receives many springs from the mountain Noire. This canal is about 64 leagues in length, is supplied by a number of rivulets, and is furnished with 104 locks, of about eight feet each. In some places it passes over bridges of vast height; and in others it cuts through solid rocks for 1000 paces. At one end it joins the river Garonne near Tholoufe, and terminates at the other in the lake Tau, which extends to the port of Cetta. It was planned by Francis Riquet in the 1660, and finished before his death, which happened in the 1680.

In the Dutch, Austrian, and French Netherlands, there is a very great number of canals; that from Bruges to Oltend carries vessels of 200 tons.

The Chinese have also a great number of canals; that which runs from Canton to Pekin, extends about 325 miles in length, and was executed about 800 years ago.

It would be an endless task to describe the numberless canals in Holland, Russia, Germany, &c. We shall therefore confine ourselves to those that are either already finished, or at present executing in our own country.

As the promoting of commerce is the principal intention of making canals, it is natural to expect that their frequency in any nation should bear some proportion to the trade carried on in it, providing the situation of the country will admit of them. The present state of England and Scotland confirms this observation. Though the Romans made a canal between the Nyne, a little below Peterborough, and the Witham, three miles below Lincoln, which is now almost entirely filled up, yet it is not long since canals were revived in England. They are now however become very numerous, particularly in the counties of York, Lincoln, and Cheshire. Most of the counties betwixt the mouth of the Thames and the Brifol channel are connected together either by natural or artificial navigations; those upon the Thames and Isis reaching within about twenty miles of those upon the Severn. The duke of Bridgewater's canal in Cheshire runs twenty-seven miles on a perfect level; but at Barton it is carried by a very high aqueduct bridge, over the Irwell, a navigable river; so that it is common for vessels to be passing at the same time both under and above the bridge.
bridge. It is likewise cut some miles into the hills, where the Duke's coal mines are wrought.

Though a navigable communication between the rivers Forth and Clyde in Scotland had been long talked of, it was never considered with a view to execution till the year 1761, when the ground was surveyed by Mr Smeaton, at the desire of the trustees for fisheries and manufactures in Scotland. From Mr Smeaton's survey and report, the practicability of this canal was fully demonstrated. But, after the scheme became an object of general attention, it was found that a canal of larger dimensions than the one originally proposed would be productive of still greater advantages to the nation. Mr Smeaton was therefore directed to make a second survey, and to report to the intended proprietors an estimate of the expense of making a canal 24 feet broad at bottom, 64 at top, containing seven feet deep of water, and extending from the Forth to the Clyde, a distance of about 51 miles, with a collateral branch to the town of Glasgow, which is about six miles, and another from Bainsford to the river Carron below Carron-works, making in all about 37 miles. This report was approved of, an act of parliament was obtained, and the canal is now cutting upon this very plan. It begins at the Holemerrie in the mouth of the Carron, and terminates at Dunmuir-burn-foot on the river Clyde, about seven miles below Glasgow. Above seven miles are already cut, from the Holemerrie westward; a number of hands are likewise employed at the point of partition in Dollater-bog, and the whole is expected to be finished in five years. At the point of partition, which is 168 feet above the level of the sea at low water, a very large reservoir is to be made for supplying the canal; and the vessels are to be raised and lowered by means of 41 locks. Where the course of the canal is intersected by burns or rivers, it is to be carried over them by aqueduct-bridges; three of these bridges will be large, and require considerable labour and expense, viz. one over the Grangeburn, one over Bony-mill-burn, and a third over the Kelvin in the Glasgow branch. The expense of executing the whole is computed to be about £50,000.

Sea-vessels, about 20 feet wide and 60 feet long, and carrying 70 or 80 tons, may pass along by this canal from the one frith to the other. But it will admit a carrying 70 or 80 tons, may pass along by this canal from the one frith to the other. But it will admit a

CANCALIER, in falconry, is when a light-brown hawk, in her swooping, turns two or three times upon the wing, to recover herself, before the feizes.

CANCELLI, a term used to denote lattice-windows, or those made of cross-bars, disposed lattice-wise; it is also used for rails or balusters, inclosing the communion-table, a court of justice, and the like, and for the net-work in the inside of hollow bones.

CANCER, or Crab, in zoology, a genus of insects belonging to the order of Insecta aptera. The generic characters are these: They have eight legs, (feifon ten or fix), besides the two large claws which answer the purpose of hands. They have two eyes at a considerable distance from each other, and for the most part supported by a kind of pedunculi or foot-stalks; the eyes are likewise elongated and moveable. They have two clawed palpi; and the tail is jointed. There are no less than 87 species of cancer, distinguished principally by the length of their tails and the margins of their breasts. This genus includes the lobster, shrimp, &c.

CANCER, in medicine, a roundish, unequal, hard, and livid tumour, generally feared in the glandulous parts of the body, supposed to be so called, because it appears at length, with turgid veins shooting out from it, so as to resemble, as it is thought, the figure of a crab-fish; or, as others say, because, like that fish, where it has once got, it is scarce possible to drive it away. See Medicine, and Surgery.

CANCER, in astronomy, one of the twelve signs of the zodiac, represented on the globe in the form of a crab, and thus marked (♋) in books.

Tropic of Cancer, in astronomy, a lesser circle of the sphere parallel to the equator, and passing through the beginning of the sign cancer.

CANCHEIRIZANTE, or Cancellerizzato, in the Italian music, a term signifying a piece of music that begins at the end, being the retrograde motion from the end of a song, &c. to the beginning.

CANDAROR, the capital of a territory of the same name, subject to Persia: E. long. 67°, and N. lat. 33°.

CANDIA, the modern name of Crete, an island situated...
in the Mediterranean sea, between 22° and 27° E. long., and between 35° and 36° N. lat.

There is no river of any consequence in the whole island, which is watered by a multitude of rivulets; whereof Lethe is one. Here too is mount Ida, so much celebrated in the writings of the ancients.

CANDIA, or MUTIUM, is the capital of the above island, situated on its northern coast, in 25° E. long., and 35° 30' N. lat.

CANDIDATE, a person who aspires to some public office.

In the Roman commonwealth, they were obliged to wear a white gown, during the two years of their soliciting for a place. This garment, according to Plutarch, they wore without any other cloaths, that the people might not suspect they concealed money for purchasing votes; and also, that they might the more easily show to the people, the fears of those wounds they had received in fighting for the defence of the commonwealth.

CANDIDATI MILITIS, an order of soldiers, among the Romans, who served as the emperor's bodyguards, to defend him in battle. They were the tallest and strongest of the whole troops, and most proper to inspire terror. They were called candidati, because cloathed in white, either that they might be more conspicuous, or because they were considered in the way of preferment.

CANDISH, a province of the hither India, bounded by Chitor and Malva, on the north; by Orixa, on the east; by Decan, on the south; and by Guzarat, on the west: It is subject to the Mogul.

CANDLE, a small taper of tallow, wax, or spermaceti; the wick of which is commonly of several threads of cotton, spun and twisted together.

A tallow-candle, to be good, must be half sheep, and half bullocks tallow; for hogs tallow makes the candle gutter, and always gives an offensive smell, with a thick black smoke. The wick ought to be pure, sufficiently dry, and properly twisted; otherwise the candle will emit an unconstant vibratory flame, which is both prejudicial to the eyes, and insufficient for the distinct illumination of objects.

There are two sorts of tallow-candles; the one dipped, the other moulded: The former are the common candles; the others are the invention of the flower Bregue at Paris.

As to the method of making candles, in general; After the tallow has been weighed, and mixed in the due proportions, it is cut into very small pieces, that it may melt the sooner; for the tallow in lumps, as it comes from the butchers, would be in danger of burning or turning black, if it were left too long over the fire. Being perfectly melted and skimmed, they pour a certain quantity of water into it, proportionable to the quantity of tallow. This serves to precipitate, to the bottom of the vessel, the impurities of the tallow, which may have escaped the skimmer. No water, however, must be thrown into the tallow designed for the three first dips; because the wick, being still quite dry, would imbibe the water, which makes the candles crackle in burning, and renders them of bad use. The tallow, thus melted, is poured into a tub, through a coarse sieve of horse-hair, to purify it still more, and may be used after having stood three hours. It will continue fit for use twenty-four hours in summer, and fifteen in winter.

The wicks are made of linen cotton, which the tallow-candlers buy in skins, and which they wind up into bottoms or cluds. Whence they are cut out, with an instrument contrived on purpose, into pieces of the length of the candle required; then put on the sticks or broaches, or else placed in the moulds, as the candles are intended to be either dipped or moulded. Wax-candles are made of a cotton or flaxen wick, slightly twisted, and covered with white or yellow wax. Of these, there are several kinds; some of a conical figure, used to illuminate churches, and in processions, funeral ceremonies, &c. See Taper.

Others of a cylindrical form, used on ordinary occasions.

The first are either made with a ladle or the hand.

To make wax candles with the ladle.

The wicks being prepared, a dozen of them are tied by the neck, at equal distances, round an iron circle, suspended directly over a large bason of copper tinned, and full of melted wax: A large ladle full of this wax is poured gently on the tops of the wicks one after another, and this operation continued till the candle arrive at its defined bigness; with this precaution, that the three first ladles be poured on at the top of the wick, the fourth at the height of the fifth at ¼, the fifth at ¼, and the sixth at ¼, in order to give the candle its pyramidal form. Then the candles are taken down, kept warm, and rolled and smoothed upon a walnut tree table, with a long square instrument of box, smooth at the bottom.

As to the manner of making wax-candles by the hand, they begin to soften the wax, by working it several times in hot water, contained in a narrow, but deep caldron. A piece of the wax is then taken out, and diposed by little and little, around the wick, which is hung on a hook in the wall, by the extremity opposite to the neck; so that they begin with the big end, diminishing till as they descend towards the neck. In other respects, the method is nearly the same as in the former cafe. However, it must be observed, that in the former case, water is always used to moisten the several instruments, to prevent the wax from flicking; and in the latter, oil of olives, or lard, for the hands, &c. The cylindrical wax-candles are either made, as the former, with a ladle, or drawn. Wax-candles drawn, are so called, because actually drawn in the manner of wire, by means of two large rollers of wood, turned by a handle, which turning backwards and forwards several times, passes the wick through melted wax contained in a brazen bason, and at the same time through the holes of an instrument like that used for drawing wire fastened at one side of the bason.

Makers of candles are not to use melting-houses, without due entry thereof at the excise-office, on pain
Candle is also a term in medicine, and is reckoned a
silk made by Moses to be placed in the Jewish tabernacle.
This ceremony was prohibited in England, by
an order of council in 1548.
Candies, in geography, the capital of the island of Cey-
and the red from the muscovado.
CANDY, in pharmacy, the act of preferring simples in
bran, and to excite the spirits.
Medicated Candle, or Bougie, in surgery, a small
thick of wax in form of a candle, which surgeons in-
to the urethra properly dis tended. Their
function, therefore, should be proportioned to the
diameter of that canal. The compound bougies are
loaded with some medicine capable of producing a
supuration, or of destroying cariousities and excre-
cences in the urethra. See Surgery.
Candle. Sale or auction by inch of candle, is when a
small piece of candle being lighted, the bidders are
allowed to bid for the merchandize that is selling;
but when the candle is out, the commodity is
adjudged to the last bidder.
There is also an excommunication by inch of can-
dle; when the sinner is allowed to come to repentance
while a lighted candle continues burning; but after it
is consumed, he remains excommunicated to all intents
and purposes.
Candleberry-tree, in botany. See Myrica.
CANDLEMAS, a feast of the church held on the fe-
cnd day of February, in honour of the purification of
the Virgin Mary. It is borrowed from the prac-
tice of the ancient Christians, who on that day used
abundance of lights both in their churches and pro-
cessions, in memory, as is supposed, of our Saviour's
being, on that day, declared by Simeon, "to be a
light to lighten the Gentiles." In imitation of this
custom, the Roman catholics, on this day, consecrate
all the tapers and candles which they use in their
churches during the whole year. At Rome, the pope
performs that ceremony himself, and distributes wax-
candles to the cardinals and others, who carry them
in procession through the great hall of the pope's pa-
lace. This ceremony was prohibited in England, by
an order of council in 1548.
Candlestick, an instrument to hold a candle,
made in different forms, and of all sorts of matter.
The golden candlestick was one of the sacred uten-
sils made by Moses to be placed in the Jewish tabernac-
ule. It was made of hammered gold, a talent in
weight. It consisted of seven branches, supported by
a bafe or foot. These branches were adorned at equal
distances with six flowers like lilies, and with as many
bowls and knobs placed alternately. Upon the flock
and fixed branches of the candlestick, were the golden
lamps, which were immovable, wherein were put oil
and cotton.
There were seven lamps lighted every evening, and
extinguished every morining. The lamps had their
tongs or snuffers to draw the cotton in or out, and
dishes underneath them to receive the sparks and drops-
ings of the oil. This candlestick was placed in the
antichamber of the sanctuary on the south-side, and
burned to illuminate the altar of perfume, and the ta-
bale of the shew-bread. When Solomon had built the
temple of the Lord, he placed in it ten golden can-
dlesticks, of the same form as that described by Mo-

tes, five on the north, and five on the south-side of
the holy. But after the Babylonish captivity, the gol-
den candlestick was again placed in the temple, as it
had been before in the tabernacle by Moses. This fa-
cred utensil, upon the destruction of the temple by
the Romans, was lodged in the temple of Peace, built
by Vespasian; and the representation of it is still to be
seen on the triumphal arch at the foot of mount Pala-
tine, on which Vespasian's triumph is delineated.
Water Candlestick, a kind of fountain, the spout of
which is raised upon a pedestal in form of a large
balustrade, which carries a small basin like a table or
stand, from which the water falls into a larger basin,
level with the alleys in a garden.
CANDY, in geography, the capital of the island of Cey-
lon, situated in the middle of the island: E. long. 79°,
N. lat. 8°.
Candy, or Sugar Candy, a preparation of sugar, made
by melting and crystallizing it six or seven times over,
to render it hard and transparent. It is of three
kinds, white, yellow, and red. The white comes
from the loaf-sugar, the yellow from the cassinado,
and the red from the muscovado.
CANDYING, in pharmacy, the act of preferring simples
in substance, by boiling them in sugar.
The performance of this originally belonged to the
apothecaries, but is now become a part of the business
of a confectioner.
CANE, in botany. See Arundo.
Cane denotes also a walking-stick. It is customary to
adorn it with a head of gold, silver, agate, &c. Some
are without knots, and very smooth and even; others
are full of knots, about two inches distant from each other.
These last have very little elasticity, and will
not bend so well as the others.
Canes of Bengal, are the most beautiful which the
Europeans bring into Europe. Some of them are so
fine, that people work them into vases or bowls,
which being varnished over in the inside with black or
yellow lacca, will hold liquids as well as glasses or
china-ware does, and the Indians use them for that
purpose.
Cane is also the name of a long measure, which differs
according to the several countries where it is used.
At Naples, the cane is equal to 7 feet 3\1 inches

Spaniel
English measure: The cane of Tholouse and the upper Languedoc is equal to the vare of Arragon, and contains 5 feet 8½ inches; at Montpellier, Provence, Dauphine, and the lower Languedoc, to 6 English feet 5½ inches.

CANE, a sea-port town on the north side of Candia, esteemed the second in the island. It is a pretty good harbour, but the fortifications are out of repair: E. long. 24°, N. lat. 35° 36'.

CANICULA, in ichthyology, the trivial name of a species of Squalus. See Squalus.

CANICULA, or Caniculus, in astronomy. See As- 

stronomy, Of fixed stars. / It is also a name given to one of the stars of the constellation canis major, called the dog-star, and by the Greeks, Sirius.

CANICULAR days, commonly called dog-days, a certain number of days preceding and ensuing the heliacal raising of canicula, or the dog-star, in the morning. The Ethiopians and Egyptians began their year at the rising of the dog-star, reckoning to its rise again the next year, which is called the annus canarius. The Romans supposed it to be the cause of the sultry weather usually felt in the dog-days; and therefore sacrificed a brown dog every year at its rising, to appease its wrath.

The dog-days begin towards the end of July, and end the beginning of September.

CANINE, whatever partakes of, or has any relation with the nature of a dog. Thus, 

CANINE teeth, are two sharp-edged teeth in each jaw; one on each side, placed between the incisors and molares.

CANIS, or Dog, in zoology, a genus of quadrupeds, Vol. II, No. 31. belonging to the order of ferae. The characters of the dog are these: He has six fore-teeth in the upper jaw, those in the sides being longer than the intermediate ones, which are lobated; in the under jaw there are likewise six fore-teeth, those on the sides being lobated. He has six grinders in the upper, and seven in the lower jaw. The teeth called dog-teeth are four, one on each side, both in the lower and upper jaw; they are sharp-pointed, bent a little inward, and stand at a distance from any of the rest.

There are nine species of this genus, viz. 1. The familiaris, or domestic dog, is distinguished from the other species, by having its tail bent to the left side; which mark is singular, that perhaps the tail of no other quadruped is bent in this manner. Of this species there are a great number of varieties. Linnaeus enumerates eleven, and Bouffon gives figures of no less than twenty-seven, viz. the molosius, or mastiff, which is about the size of a wolf, with the sides of the lips hanging down, and a full robus body. The large Danish dog, differs only from the former in being fuller in the body, and generally of a larger size. The grey-hound is likewise the same with the mastiff; but its make is more slender and delicate. Indeed the difference between these three dogs, although perfectly distinguishable at first sight, is not greater than that between a Dutchman, a Frenchman, and an Italian. The shepherd's dog, the wolf-dog, and what is commonly called the Siberian dog, to which may be joined the Lapland dog, the Canada dog, and, in general, all those which have flat ears and a pointed snout, are all one kind, differing only in thickness, the roughness or smoothness of their skin, the length of their legs, and tails. The hound, or beagle, the terrier, the braque, or short-tailed setting-dog, and the spaniel, may be considered as the same kind: they have the same form and the same instincts; and differ only in the length of their legs, and size of their ears, which in each of them are long, soft, and pendulous. The bull-dog, the small Danish dog, the Turkish dog, and the Iceland dog, may likewise be considered as the same kind: they have the same form and the same instincts; and differ only in the appearance taking their nere merely from climate. For instance, the Turkish dog, which has no hair, is nothing else but the small Danish dog transplanted to a warm climate, which makes the hair fall off. A dog of any kind loses its hair in very warm climates. But this is not the only change which arises from difference of climate. In some countries, the voice is changed; in others, dogs become altogether silent. In some climates, they lose the faculty of barking, and howl like wolves, or yelp like foxes. Warm climates even change their form and instincts: They turn ill-shaped, and their ears become flat and pointed. It is only in temperate climates that dogs preserve their natural courage, audacity, and sagacity.

In order to give an idea of the different kinds of dogs, in different climates, and of the varieties produced by the commixtures, we shall give an explanation of Bouffon's genealogical tree, See Plate LXI, fig. 1. This tree is constructed in the form of a geographical chart, in which the situation of the different climates to which the particular...
cular dogs belong, is observed as accurately as the nature of the thing will admit.

The shepherd's dog is the stump of the tree. This dog, when transported to Lapland, or any very cold climate, assumes an ugly appearance, and its legs become short. But in Britain, Russia, Siberia, &c. where the cold is not so rigorous, and the people are more civilized, he arrives at greater perfection, both in form and vigour. The same shepherd's dog, when brought up in a country fully civilized, as Britain or France, loses his savage air, his ftrait ears, his thick long hair, and becomes what is called a bull-dog, a mastiff, a beagle, or hound. Thefe changes, Boufson attributes to the influence of the climate, the manners of the people, &c. The mastiff and the bull-dog have their ears still partly ftrait, or half-pendent, and resemble in their manners and languid disposition the dog from which they derive their origin. The beagle or hound prefers lefs of the appearance of its origin than the other two; its ears are long and entirely pendent; the softness, the tractability, the timidity of this dog, Boufson considers as fo many proofs of its great degeneracy, or rather of that perfection which it acquires by culture, and living among a civilized people.

The hound, the small spotted setting-dog, and the terrier, are all of the same family; for all the three kinds are often produced at the same litter, although the female hound had been covered only by one of thefe kinds.

When the hound is transported to Spain, or Barbary, where almost every animal has fine, long, downy hair, it is changed into a water hound, or spaniel. And the small and large spaniel, which differ only in the tail, when carried to Britain, are changed from a white to a black colour, and become what is called the large and small mangrel dogs.

The mastiff, when carried to the north, is changed into the large Danois dog; and when transported to the south, it becomes a grey-hound. The large grey-hounds come from the Levant; those of a lesre fize come from Italy; and the Italian grey-hounds, when brought to Britain, become what the French call levrons, that is, grey-hounds of the least fize.

The great Danois dog, when carried to Ireland, the Ukraine, Tartary, &c. is changed into the Irish dog, which is the largest of all dogs.

The bull-dog, when carried from Britain to Denmark, becomes the small Danois dog; and this small Danois dog, when transported into a warm climate, lores its hair, and is changed into the Turkifh dog.

All these races or families, with their varieties, are produced by the influence of climate, food, and education; the other kinds marked in the tree are not pure or fiftine families, but are produced by the commixture of the other families. These magrel dogs, with the particular parents which produce them, are marked out in the tree by dotted lines. For example.

The grey-hound and mastiff produce the magrel grey-hound, which is likewise called the grey-hound with wolf's hair. The large Danois dog and the large spaniel produce the Calabrian dog; which is a beautiful dog, with long buflhy hair, and of a larger fize than the mastiff. The spaniel and the small Danois dog produce the lion-dog, which is a very rare kind. It is needless to give more examples, as they can easily be traced from the dotted lines in the tree.

Having thus traced the varieties of the dog, and the probable sources of these varieties, we shall now give an account of his nature and infirmities.

From the structure of the teeth, it might be concluded a priori that the dog is a carnivorous animal. He does not however eat indiscriminately every kind of animal substance. There are some birds, as the cowlins and ruffins, which the water-dog will lay hold of with keenness, but will not bring out of the water, because its smell is exceedingly offensive to him. He will not eat the bones of a goose, crow, or hawk: But he devours even the putrid flesh of most other animals. He is possessed of such strong digestive powers, as to draw nourishment from the hardest bones. When flesh cannot be procured, he will eat fish, fruits, succulent herbs, and bread of all kinds. When opprefled with fhowfens, to which he is very fubjeft, especially in the beginning of summer, in order to procure a puke, he eats the leaves of the quicen herbs, the bearded wheat-grafs, or the rough cock's-foot-grafs, which gives him immediate relief. When he steals a piece of flesh, as confions of the immorality of the action, he runs off with his tail hanging and bent in between his feet.

His drink is water, which he takes in small quantities at a time, by licking with his tongue. He is in some measure obliged to lick in this manner, otherwise his nose would be immersed in the water.

His excrements are generally hard fobals, which, especially after eating bones, are white, and go by the name of album gra-curn among physicians. This album gra-curn was for a long time in great repute as a feptic; but it is now entirely disregarded. He does not throw his excrements promifcuously upon every thing that happens to be in the way, but upon ftones, trunks of trees, or barren places. This is a wise infliution of nature; for the excrements of a dog destroyn almost every vegetable or animal substance. They are of such a putrid nature, that if a man's fhoef touches them when recently expelled, that particular part will rot in a few days. He observes the fame method in making his urine, which he throws out at a fide. It is remarkable, that a dog will not pafs a stone or a wall againft which any other dog has piffed, without following his example, although a hundred should occur in a few minutes, in fo much, that it is astonishing how fuch a quantity can be secreted in fo short a time.

The dog is an animal not only of quick motion, but remarkable for travelling very long journeys. He can easily keep up with his master, either on foot or horse-back, for a whole day. When fatigued, he does not sweat, but lolls out his tongue. Every kind of dog can swim; but the water-dog excels in that article.

The dog runs round when about to lie down, in order to discover the most proper situation. He lies generally on his breast, with his head turned to one side, and sometimes with his head above his two fore-feet. He sleeps little, and even that does not seem to be very quiet; for he often
often flirts, and seems to hear with more acuteness in sleep than when awake. They have a tremulous motion in sleep, frequently move their legs, and bark, which is an indication of dreaming.

Dogs are possessed of the sensation of smelling in a high degree. They can trace their mazer by the smell of his feet in a church, or in the streets of a populous city. This sensation is not equally strong in every kind. The hound can trace game, or his master's steps, twenty-four hours afterwards. He barks more lavishly the nearer he approaches the fowls, unless he be beat and trained to silence.

With regard to the propagation of dogs; the females admit the males before they are twelve months old. They remain in season ten, twelve, or even fifteen days, during which time they will admit a variety of males. They come in season generally twice in the year, and more frequently in the cold than in the hot months. The male discovers the condition of the female by the smell; but the female admits him the first fix or seven days. One coitus will make her conceive a great number of young; but, when not restrained, she will admit several dogs every day: she seems to have no choice or predilection, except in favour of dogs: From this circumstance, it sometimes happens, that a small female, who has admitted a maffiff, perishes in bringing forth her young. During the time of copulation, these animals cannot separate themselves, but remain united for long as the erection subsists. This is owing to the structure of the parts. The dog has not only a bone in his penis, but in the middle of the corpus cavernosum there is a large hollow, which is blown up in the time of erection to a considerable bulk. The female, on the other hand, has a larger clitoris than perhaps any other animal; besides a large firm protuberance rises in the time of copulation, and remains perhaps longer than that of the male, and prevents him from retiring till it subside: Accordingly, after the act of copulation is over, the male turns about in order to reft himself on his legs, and remains in that position till these parts turn flaccid. The female goes with young about nine weeks. They generally bring forth from fix to twelve puppies. Those of a small size bring forth five, four, and sometimes but two. They continue to copulate and bring forth during life, which lasts generally about fourteen or fifteen years. The wholes are commonly blind, and cannot open their eyes till the tenth or twelfth day. In the fourth month, they lose some of their teeth, which are soon succeeded by others.

The dog has such a strong resemblance to the wolf and the fox, that he is commonly suppos'd to be the production of one or other of these animals tam'd and civilized. Bonfifon informs us, that he kept a young dog and a young wolf together till they were three years of age, without their discovering the least inclination to copulate. He made the same experiment upon a dog and a fox; but their antipathy was rather increased when the female was in season. From these experiments he concludes, that dogs, wolves, and foxes, are perfectly distinct species of animals.

With regard to the natural disposition of the dog: In a savage state, he is fierce, cruel, and voracious; but, when civilized and accustomed to live with men, he is possessed of every amiable quality. He seems to have no other desire than to please and protect his master. He is gentle, obedient, submissive, and faithful. Those dispositions, joined to his almost unbounded sagacity, justly claim the esteem of mankind. Accordingly no animal is so much cared for or respected: He is so delicate, and so much formed to please, that he assumes the very air and temper of the family in which he resides.

An animal endowed with such uncommon qualities, must answer many useful purposes. His fidelity and vigilance are daily employed to protect our persons, our flocks, or our goods. The acuteness of his smell gains him employment in hunting; in some parts of Siberia, he is trained to draw carriages from one inn to another; and the negroes eat dogs flesh with great relish.

The dog is liable to many disaeases, as the scab, madness, &c and he seldom wants the tania or tape-worm in his guts, especially if he drinks dirty water. See Plate LXI. and LXII.

2. The second species of this kind is the lupus or wolf, which is distinguished from the dog by having its tail turned inward. The wolf is larger and fiercer than a dog. His eyes sparkle, and there is a great degree of fury and wildness in his looks. He draws up his claws when he walks, to prevent his tread from being heard. His neck is short, but admits of very quick motion to either side. His colour is generally blackish. Like most ferocious animals, he can bear hunger a very long time; but, at last, when the appetite for victuals becomes intolerable, he grows perfectly furious, and will attack men, horses, dogs, and cattle of all kinds; even the graves of the dead are not proof against his rapacity. This circumstance is finely described, in the following lines.

By wintry famine round'd,——
Cruel as death, and hungry as the grave!
Burning for blood! bony, and ghastly, and grim!
Assembling wolves in raging troops descend;
And, pouring o'er the country, bear along.
Keen as the north-wind sweeps the gloomy snow.
The god-like face of Man avails him nought.
Here bleeds, a hapless child, undistinguish'd prey.

Nor can the bull his awful front defend;
Or shake the murthering savages away.
Rapacious at the mother's throat they fly,
And tear the crying infant from her breast.

The generous lion stands in mother's gaze,
Ever beauty, force divine! at whose bright glance
The whomp highway hounds in soft'd gaze,
Here bleeds, a hapless undistinguish'd prey.

Thomson's Winter.
parts of the continent to this day. This country, a few centuries ago, was much infested with them. So late as the year 1457, there is an act of parliament obliging all the gentlemen and tenants in the different shires of Scotland, to rise, properly armed, four times in the year, in order to destroy the wolves. But they are now so effectually rooted out, that not one of them has been seen wild, even in the highlands, for a century past. See Plate LXII. fig. 5.

3. The hyaena, has a ftrait jointed tail, with the hair of its neck erect, small naked ears, and four toes on each foot. It is about the size of a fox, and its head resembles that of a boar. The hairs on the back are about a span long, erect, and black at the points, and the eyes are near each other. The hyaena is a native of India and Africa. He digs holes in the earth like a fox, where he retires from danger. He is very fond of human flesh, which he digs out of church-yards in the night. When irritated, he lays hold of a weapon, or any thing that offends, and keeps it fast in his teeth, which makes him an easy prey to hunters.

4. The vulpes, or fox, has a ftrait tail, white at the point. His body is yellowish, or rather straw-coloured; his ears are small and erect; his lips are whitish, and his fore-feet are black. From the bafe of the tail, a fragrant, and to others extremely disagreeable. The Prong scent is emitted, which to some people is very pleasant. Foxes are near each other. The hyaena is a native of India and Africa. He digs holes in the earth like a fox, where he retires from danger. He is very fond of human flesh, which he digs out of church-yards in the night. When irritated, he lays hold of a weapon, or any thing that offends, and keeps it fast in his teeth, which makes him an easy prey to hunters.

5. The alopex, or field-fox, is every way the same with the common fox, except in the point of the tail, which is black.

6. The lagopus, or white fox, has a ftrait tail, and the apex of different colours. The legs are very hairy. It inhabits the mountains of Lapland and Siberia.

7. The aureus, or jackall, is a native of the East Indies. There is no genuine description of this animal. They assemble in large troops in the night, in several parts of Asia, and make a hideous howling noise. When one calls, he is answered by numbers even at great distances; so that in a short time the whole woods reound with their noise. This noise rouses all the other wild animals, as lions, tygers, &c. who take advantage of the general consternation, and devour the weaker animals. This circumstance has probably given rise to the notion of the jackall's being the lion's provider. They hide themselves in holes during the day, and go in quest of their prey in the night: They sometimes fall upon children, and devour them when no assistance is near.

8. The Mexicanus, has a smooth crooked tail. The body is ash-coloured, variegated with yellow spots. It is a native of Mexico, and is called the mountain-cat by Seba.

9. The thous, has a smooth crooked tail. The upper part of his body is grey, and the belly is white. He is about the size of a large cat, and is found at Surinam.

Canius, the dog-fish, a name given to several species of squalus. See Squalus.

Canius major, in astronomy, a constellation of the southern hemisphere.

Canius minor, Caniculus, or Canicula, in astronomy, a constellation of the northern hemisphere.

Canker, a disease incident to trees, proceeding chiefly from the nature of the soil. It makes the bark rot and fall. If the canker be in a bough, cut it off; in a large bough, at some distance from the tree; and in a small one, close to it: But for over-hot ground, the mold is to be cooled about the roots with pond mud, and cow-dung.

Canna, in botany, a genus of the monandria monogynia class. There are four species of this plant, all natives of the Indies.

Cannabis, hemp, in botany, a genus of the dicotyledonous class. The calix of the male is divided into five segments, and it has no corolla. The calix of the female consists of one leaf, open at the side; it has two flymes; and the nut or capsule consists of two valves. There is but one species, viz. the sativa, or common hemp, a native of India. For the method of cultivating and preparing hemp, see Flax, and Hemp.

Cannacorus, in botany. See Canna.

Cannel-coal, a substance which has a long time, though with very little reason, been confounded, both by authors and druggists, with jet. It is dug up in many parts of England in great abundance, particularly in Lancashire, where it is burnt as common fuel. It is worked into toys and utensils of various kinds, under the name of jet. In medicine, it is said to be good in the colic; but the present practice takes no notice of it.

Cannon, in the military art, an engine or fire-arm for throwing iron, lead, or stone bullets, by force of gunpowder.

Cannons at first were called bombardae, from the noise they made. They had likewise the name of culverin, basiliik, &c. from the beasts that were represented upon them; and the Spaniards, from devotion, gave them the name of saints; witnesses the twelve apostles which Charles V. ordered to be cast at Malaga, for his expedition to Tunis.

The metal of which cannons are composed, is either iron, or which is more usual, a mixture of copper, tin, and brass; the tin being added to the copper,
per, to make the metal more dense and compact; so that the better and heavier the copper is, the less tin is required. Some to an hundred pounds of copper, add ten of tin, and eight of brass; others ten of tin, five of brass, and ten of lead. The fieur Bercou pretends, that when old pieces of metal are used, the founder ought to add to one hundred weight of that metal, twenty-five pounds of good copper, and five pounds of tin. Braudius describes a method of making cannon of leather; and it is certain the Swedes made use of such in the long war of the last century; but thes burft too easily to have much effect. With regard to iron cannon, they are not capable of so much resistance as those of brass; but as they are less expensive, they are often used on board of ships, and also in several fortified places.

Cannons are distinguished by the diameters of the balls they carry. The rule for their length is, that it be such as that the whole charge of powder be on fire, before the ball quit the piece. If it be too long, the quantity of air to be drawn out before the ball, will give too much resistance to the impulse; and that impulse ceasing, the friction of the ball against the surface of the piece will take off from the motion.

In former days, cannon were made much longer than they are now; but experience has taught us, that a ball moves with a greater impetus through a less space than a greater; and accordingly it is found, that an iron ball of forty-eight pound weight goes farther from a short cannon, than another ball of ninety-six pound out of a longer piece; whereas, in other respects, it is certain, the larger the bore and ball, the greater the range.

It is found too, by experience, that of two cannons of equal-bore, but different lengths, the longer requires a greater charge of powder than the shorter. The ordinary charge of a cannon is, for the weight of its gun-powder to be half that of its ball.

We shall here subjoin a table exhibiting the names of the several cannon, their length, their weight, and that of their ball.

Cannon are likewise distinguished according to the diameter of their mouth, or calibre. This calibre is divided, in consequence of an order from the king of France, into thirty-six parts, in order to determine by these parts the dimensions of the different moulds for cannon. We hope the reader, then, will not be dissatisfied to find an account of the dimensions of the several parts of cannon of five different calibres, as they are regulated by that order of the king of France, on Oct. 7, 1732, in the following table:

</table>
CANNULLA, in surgery, a tube made of different metals, principally of silver and lead, but sometimes of iron. They are introduced into hollow ulcers, in order to facilitate a discharge of pus or any other substance; or into wounds, either accidental or artificial, of the large cavities, as the thorax or abdomen; they are used in the operation of branchotomy, and by some, after cutting for the flux, as a drain for the urine.

Other cannulas are used for introducing cauteries, either actual or potential, in hollow parts, in order to guard the parts adjacent to that to be cauterized, from injury. They are of various figures; some being oval, some round, and others crooked.

CANOE, a small boat, made of the trunk of a tree, bored hollow; and sometimes also of pieces of bark fewed together.

It is used by the natives of America to go a-fishing in the sea, or upon some other expedition, either by sea, or upon the rivers and lakes.

CANON, commonly called prebendary, a person who possesses a prebend, or revenue allotted for the performance of divine service in a cathedral or collegiate church. Originally, canons were only priests, or inferior ecclesiastics, who lived in community, residing near the cathedral church to assist the bishop, depending entirely on his will, supported by the revenues of his bishops, and living in the same house as his domestics or counsellors, &c. By degrees these communities of priests, shewing off their dependence, formed separate bodies; in time they freed themselves from their rules, and at length ceased to live in a community. It is maintained, that the colleges of canons, which have been introduced into each cathedral, were not in the ancient church, but are of modern appointment.

In the Roman church, when a person is promoted to the office of a canon, he must be presented in a very ceremonious manner to the chapter, who assemble in the cathedral, in order to receive him: he kisses the altar thrice, after which he goes and takes his place in the choir; he afterwards makes his confession of faith aloud, and swears to observe the ordinances of the church and his holiness the pope: being thus solemnly inducted, he is impowered to assist at the chapter, to chant the office of the choir, &c.

Canons are of various kinds, as,

Cardinal-Canons, those attached, or, as the Latins call it, incardinati, to a church, as a priest is to a parish.

Domicilary-Canons, young canons, who, not being in orders, had no right in any particular chapters.

Expectantius-Canons were such as, without having any revenue or prebend, had the titles and dignities of canons, a voice in the chapter, and a place in the choir, till such time as a prebend should fall.

Foreign Canons, such as did not officiate in the canons to which they belonged. To these were opposed missionary canons.
The ecclesiastical jurisdiction of the see of Rome in England, was founded on the canon-law; and this created quarrels between kings and several archbishops and prelates, who adhered to the papal usurpation.

Beside the foreign canons, there were several laws and constitutions made here for the government of the church; but all these received their force from the royal assent: And if, at any time, the ecclesiastical courts did, by their sentence, endeavour to enforce obedience to such canons, the courts at common law, upon complaints made, would grant prohibitions. The authority vested in the church of England of making canons, was ascertained by a statute of Henry VIII. commonly called the act of the clergy's submission; by which they acknowledged, that the congregation had been always assembled by the king's writ: so that though the power of making canons reposed in the clergy met in convocation, their force was derived from the authority of the king's assenting to, and confirming them.

The old canons continued in force till the reign of James I. when the clergy being assembled in convocation, the king gave them leave to treat and consult upon canons; which they did, and presented them to the king, who gave them the royal assent: These were a collection out of the several preceding canons and injunctions. Some of these canons are now obsolete. In the reign of Charles I. several canons were passed by the clergy in convocation.

CANONESS, in the Romish church, a woman who enjoys a prebend, affixed, by the foundation, to maids, without their being obliged to renounce the world, or make any vows.

CANONIZATION, a ceremony in the Romish church, by which persons deceased are ranked in the catalogue of the saints. It succeeds beatification. See Beatification.

Before a beatified person is canonized; the qualifications of the candidate are strictly examined into, in some consistory held for that purpose; after which one of the consistorial advocates, in the presence of the pope and cardinals, makes the panegyric of the person who is to be proclaimed a saint, and gives a particular detail of his life and miracles: Which done, the holy father decrees his canonization, and appoints the day.

On the day of canonization, the pope officiates in white, and their eminences are dressed in the same colour. St Peter's church is hung with rich tapestry, upon which the arms of the pope, and of the prince or state requiring the canonization, are embroidered in gold and silver. An infinite number of lights blaze all round the church, which is crowded with pious souls, who wait, with a devout impatience, till the new saint has made his public entry, as it were, into paradise, that they may offer up their petitions to him, without danger of being rejected.

The following maxim, with regard to canonization, is now observed, though it has not been followed a-bove a century, viz. not to enter into the inquiries prior to canonization, till fifty years, at least, after the death of the person to be canonized. By the ceremony of canonization, it appears, that this rite of the modern Romans, has something in it very like the apotheosis or deification of the ancient Romans, and in all probability owes its rise to it; at least, several ceremonies of the same nature are conspicuous in both.

CANONOR, a town on the Malabar coast, in the Hither India: E. long. 75°, N. lat. 10°.

Here the Dutch have a fort and factory, which they took from the Portuguese in 1663.

CANONRY, the benefice filled by a canon. It differs from a prebend, in that the prebend may subsist without the canonicate; whereas the canonicate is inseparable from the prebend; again, the rights of suffrages, and other privileges, are annexed to the canonicate, and not to the prebend.

CANOPUS, in astronomy, a star of the first magnitude in the rudder of Argo, a constellation of the southern hemisphere. See Astronomy, Of the fixed stars.

CANTABRICA, in botany, a synonym of a species of convolvulus. See Convulvulus.

CANTALIERS, in architecture, pieces of wood framed into the front or other sides of a house, to suspend the mouldings and eyes over it.

CANTAR, or Cantaro, in commerce, a weight used in Italy, particularly at Leghorn, to weigh all sorts of merchandizes.

There are three sorts of cantari, or quintals, one weighs 150 pounds, the other 151, and the third 160: The first serves to weigh alum and cheese, the second is for sugar, and the third for wool and codfish.

Cantar is also a measure of capacity used at Cochin, and containing four rubis.

CANTATA, in music, a song or composition, intermixed with recitatives, airs, and different movements, chiefly intended for a single voice, with a thorough bass, though sometimes for other instruments.

The cantata, when performed with judgment, has something in it very agreeable; the variety of the movement not clogging the ear, like other compositions. It was first used in Italy, then in France, whence it passed to us.

CANTERBURY, the capital city of Kent, fifty-five miles east of London, and sixteen north-west of Dover: E. long. 1° 15', N. lat. 51° 16'.

It is a county of itself, and the see of an archbishop, who is primate and metropolitan of all England. It is a large, populous, and trading city; has a good silk manufactury, and sends two members to parliament.

CANTERBURY-BELL, in botany. See Campanula.

CANTHARIS, in zoology, a genus of insects belonging to the order of insecta coleoptera. The feelers of this genus are setaceous; the breast is margined, and shorter than the head; the elytra, or wing-cases, are flexible; and the sides of the belly are plaited and papillous. Linnaeus enumerates 27 species of the cantharis, most of them to be found in different parts of Europe.
CANZONE, in music, signifies, in general, a song.

CANTON, in geography, denotes a small country, or district, constituting a distinct government: such are the cantons of Switzerland.

CANTO, in music, the treble, or at least the higher part of a piece.

This word more properly signifies the first treble, unless the word secondo, for the second, or ripieno, for the treble of the grand chorus, be added.

CANTON, in geography, denotes a small country, or district, constituting a distinct government: such are the cantons of Switzerland.

CANTON is also the name of a large, populous, and wealthy city and port-town of China, situated on the river Ta, about fifty miles from the Indian ocean: E. long. 112° 30', N. lat. 23° 25'.

It is a fortified place, within the walls of which no Christians are permitted to enter, notwithstanding their great trade thither; it being from thence that they import all manner of Chinese goods, as china-ware, tea, cabinets, raw and wrought silks, gold-duff, &c.

CANTONING, in the military art, is the allotting distinct and separate quarters to each regiment of an army; the town where they are quartered, being divided into so many cantons, or divisions, as there are regiments.

CANTRED, or Cantref, signifies an hundred villages, being a British word, compounded of the adjective cant, i.e. hundred, and tref, a town or village.

In Wales, some of the countries are divided into cantredes, as in England into hundreds.

CANVAS, in commerce, a very clear unbleached cloth of hemp, or flax, woven very regularly in little squares.

It is used for working tapestry with the needle, by pasing the threads of gold, silver, silk, or wool, through the intervals or squares.

CANVAS is also a coarse cloth of hemp, unbleached, somewhat clear, which serves to cover women's stays, also to stiffen men's cloaths, and to make some other of their wearing-apparel, &c.

CANVAS is also a very coarse cloth made of hemp, unbleached, serving to make towels, and anfwering other domestic purpofes. It is also used to make fails for shipping, &c.

CANVAS is used among the French, for the model and first words, where an air or piece of muflc is composed, and given to a poet to regulate and finifh.

CANATUS, in ornithology, the trivial name of a species of tringa. See Tringa.

CANZONE, in music, signifies, in general, a song where some little figures are introduced: But it is sometimes used for a sort of Italian poem, usually pretty long, to which music may be composed in the style of a cantata. If this term be added to a piece of instrumental music, it signifies much the fame as cantata: If placed in any part of a sonata, it implies the same meaning as allegro, and only denotes that the part to which it is prefixed, is to be played or sung in a brisk and lively manner.

CANZONETTA, a diminutive of canzone, denoting a little short song: The canzonette neapolitane have two strains, each whereof is sung twice over, as the vaudevilles of the French: The canzonette siciliane are a species of jigg, the measure whereof is usually twelve eights, and fix eights, and sometimes both, as rondaeus.

CAP, a part of drefs made to cover the head, much in the figure thereof.

The use of caps and hats is referred to the year 1449, the first seen in these parts of the world being at the entry of Charles VII. into Rouen: from that time they began to take place of the hoods, or cha- peroons, that had been used till then. When the cap was of velvet, they called it morier; when of wool, simply bonnet. None but kings, princes, and knights, were allowed the use of the morier. The cap was the head-dres of the clergy and graduates: Church-men and members of universities, students in law, physic, &c. as well as graduates, wear square caps in most universities. Doctors are distinguished by peculiar caps, given them in assuming the doctorate. Pal- quier says, that the giving the cap to students in the universities, was to denote that they had acquired full liberty, and were no longer subject to the rod of their superiors, in imitation of the ancient Romans, who gave a pileus or cap to their slaves, in the ceremony of making them free. The cap is also used as a mark of infamy in Italy. The Jews are distinguished by a yellow cap at Lucca, and by an orange one in France.

Cape of Good-Hope: See Good-Hope.

CAPE, in geography, an high land running out with a point, into the sea, as Cape-Nord, Cape-Horn, the Cape of Good-Hope, &c.

Cape of Good-Hope: See Good-Hope.

CAPE-coast-castle, the principal Britifh fort and settlement on the gold-coast of Guinea, situated under the meridian of London, in 5° N. lat.

CAPELLA, in astronomy, a bright fixed star in the constellation auriga.

CAPELLA, in astronomy, a bright fixed star in the constellation auriga.

CAPEL, in botany. See Capparis.

CAPEQUIN, a town of Ireland, in the county of Waterford, and province of Munster, situated on the river Blackwater: W. long. 7° 50', and N. lat. 52° 5'.

CAPHER, a duty which the Turks raise on the Chriftians, who carry or fend merchandifes from Aleppo to Jerusalem, and other places in Syria.

This duty of caphar was firft imposed by the Chriftians themselves, when they were in poftiffion of the Holy land, for the maintenance of the troops, which were planted in difficult paffes, to obferve the Arabs, and prevent their incursions. It is still continued, and much increafed by the Turks, under pretence of defend ing the Chriftians againft the Arabs, with whom, never-
nevertheless, they keep a secret intelligence, favouring their excursions and plunder.

CAPI-AGA, or Capou-agassi, a Turkish officer, who is, as it were, grand-master of the seraglio.

He is the first in dignity and repute of all the white eunuchs, and is always near the Grand Signior's person. It is he who introduces embassadors to audience; and all great affairs pass through his hands before they come to that of the prince.

CAPIAS, in law, a writ of two sorts, one before judge and the other after: That before judgment is called capias ad reflexandum, where an original is sued out, &c. to take the defendant, and make him answer the plaintiff; and that after judgment is the capias ad prediction, &c.

CAPIGI, in the Turkish affairs, the name of certain inferior officers belonging to the seraglio, to the number of five hundred, whose business is to assist the janitors in guarding the first and second gate of that palace; whence also the name capighi, which signifies a gate.

CAPILLAMENT, in a general sense, signifies a hair, whence the word is applied to several things, which, on account of their length or their fineness, resemble hairs: as,

CAPILEMENTS OF THE NERVES, in anatomy, the fine fibres, or filaments, whereof the nerves are composed.

CAPILLARY, in general sense, an appellation given to things on account of their extreme fineness, or resembling hair.

CAPILLARY TUBES, in physics, little pipes whose canals are extremely narrow, their diameter being only a half, third, or fourth of a line. See Hydrostatics.

CAPILLUS VENERIS, in botany. See Adiantum.

CAPITAL, in geography, denotes the principal city of a kingdom, province, or state.

CAPITAL, among merchants, traders, and bankers, signifies the sum of money which individuals bring to make up the common stock of a partnership.

CAPITAL CRIME, such a one as subjects the criminal to capital punishment, that is, the loss of life.

CAPITAL, in architecture, the uppermost part of a column or pilaster, serving as the head, or capping, and placed immediately over the shaft, and under the entablature. See Architecture.

CAPITANATE, a province of the kingdom of Naples, situated on the gulf of Venice, and having the province of Molise on the north, and the Principate on the south.

CAPITANIA, in geography, an appellation given to the twelve governments established by the Portuguese in the Brazils.

CAPITATION, a tax or impost raised on each person in consideration of his labour, industry, office, rank, &c. It is a very ancient kind of tribute. The Latins call it tributum, by which taxes on persons are distinguished from taxes on merchandize, which were called vetigalia.

Capitations are never practised among us but in exigencies of state. In France, the capitation was introduced by Lewis XIV. in 1695, and is a tax very different from the taille, being levied from all persons whether they be subject to the taille or not. The clergy pay no capitation, but the princes of the blood are not exempted from it.

CAPITOL, in antiquity, a castle on the Mons Capitolinus at Rome, where there was a temple dedicated to Jupiter, in which the senate anciently assembled. The capitol consisted of three parts; a nave, sacred to Jupiter; and two wings, the one consecrated to Juno, and the other to Minerva: It was ascended to by stairs; the frontispiece and sides were surrounded with galleries, in which those who were honored with triumphs entertained the senate at a magnificent banquet, after the sacrifices had been offered to the gods.

Both the inside and outside were enriched with infinite ornaments, the most distinguished of which was the statue of Jupiter, with his golden thunder-bolt, his sceptre, and crown. In the capitol also were a temple to Jupiter the guardian, and another to Juno, with the mint; and on the descent of the hill was the temple of Concord.

This beautiful edifice contained the most sacred deposits of religion, such as the ancylia, the books of the fylbs, &c.

CAPITOLINE GAMES, annual games instituted by Camillus, in honour of Jupiter Capitolinus, and in commemoration of the capitol's not being taken by the Gauls. Plutarch tells us, that a part of the ceremony consisted in the public crew's putting up the Heturians to sale by auction: They also took an old man, and, tying a golden bulla about his neck, exposed him to the public derision. Festus says, they also dressed him in a pretexa. There was another kind of capitoline games, instituted by Domitian, wherein there were rewards and crowns bestowed on the poets, champions, orators, historians, and musicians. These last capitoline games were celebrated every five years, and became so famous, that instead of calculating time by lustra, they began to count by capitoline games, as the Greeks did by olympiads. It appears, however, that this custom was not of long continuance.

CAPITOL, in geography, an appellation given to the chief magistrates of Tholouse, on account of their meeting in a place called the Capitol: They are eight in number, are chosen annually, and have each the government of a capitoulate, or precinct, like the wards of London.

CAPITULATION, in military affairs, a treaty made between the garrison or inhabitants of a place besieged, and the besiegers, for the delivering up the place on certain conditions.

The most honourable and ordinary terms of capitulation are, to march out at the breach, with arms and baggage, drums beating, colours flying, a match lighted at both ends, and some pieces of cannon, waggons and convoys for their baggage, and for the sick and wounded.

CAPITULATION, in the German polity, a contract which the emperor makes with the electors, in the name of all the princes and states of the empire, before he is declared emperor, and which he ratifies before
fore he is raised to that sovereign dignity. The principal points which the emperor undertakes to observe, are, 1. To defend the church and the empire. 2. To observe the fundamental laws of the empire. And, 3. To maintain and preserve the rights, privileges, and immunities of the electors, princes, and other states of the empire, specified in the capitulation. These articles and capitulations are presented to the emperor by the electors only, without the concurrence of the other states, who have complained from time to time of such proceedings; and in the time of the Westphalian treaty, in 1648, it was proposed to elaborate in the following diet, upon a way of making a perpetual capitulation; but the electors have always found means of eluding the execution of this article. In order however to give some satisfaction to their adversaries, they have inserted in the capitulations of the emperors, and in that of Francis I. in particular, a promise to use all their influence to bring the affair of a perpetual capitulation to a conclusion. Some German authors own, that this capitulation limits the emperor's power; but maintain that it does not weaken his sovereignty: Though the most part maintain, that he is not absolute, because he receives the empire under conditions which fix bounds to an absolute authority.

CAPNIDES, in botany, the trivial name of a species of Fumaria. See Fumaria.

CAPON, a cock-chicken, gelded as soon as left by the dam, or as soon as he begins to crow. They are of use either to lead chickens, ducklings, pheasants, &c. and defend them from the kites and buzzards; or to feed for the table, they being reckoned more delicate than either a cock or a hen.

CAPPA CIA, a town of the hither principate, in the kingdom of Naples. It is a bishop's see, and situated about fifty-five miles south-east of the city of Naples: E. long. 15° 20', and N. lat. 40° 40'.

CAPPARIS, in botany, a genus of the polyantris monocotyledonous class. The calyx consists of four cortaceous leaves; the corolla consists of four petals; the stamens are long; and the capsule is fleshy within, unilocular, and supported by a pedunculus. There are ten species, none of which are natives of Britain.

CAPRA, or Goat, a genus of quadrupeds belonging to the order of Pecora. The horns are hollow, turned upwards, erect, and scabrous. There are eight fore teeth in the under jaw, and none in the upper; and they have no dog-teeth. This genus consists of twelve species, viz.

1. The hircus, or common goat, with arched carinat horns, and a long beard. The goat of Angora is only a variety of this species; its hair is white, and hangs down to the feet; and the ears are plain and pendent. The common goat is a native of the eastern mountains. See Plate LXIII.

The goat is an animal of more sagacity than the sheep. Instead of having an antipathy at mankind, they voluntarily mingle with them, and are easily tamed. Even in uninhabited countries, they betray no savage dispositions. In the year 1668, an English vessel having put in to the island of Bonovita, two negroes came aboard, and offered gratis to the captain as many goats as he pleased. The captain expressed his astonishment at this offer. But the negroes replied, that there were only twelve persons in the island; that the goats had multiplied to such a degree, that they were become extremely troublesome; and that, instead of having any difficulty in catching them, they followed the men wherever they went, and were so obstinately officious, that they could not get quit of them upon any account whatever.

Goats are sensible of carelessness, and capable of a considerable degree of friendship. They are strong, more agile, and less timid than sheep. They have a lively, capricious, and wandering disposition; are fond of high and solitary places; and frequently sleep upon the very points of rocks. They are more easily supported than any other animal of the same size; for there is hardly an herb or the bark of a tree, which they will not eat with pleasure. Neither are they liable to so many diseases as sheep: They can bear heat and cold with less inconvenience. The actions and movements of animals depend more upon the force and variety of their sensations, than the structure of their bodies: The natural constancy and fancifulness of goats is accordingly expressed by the irregularity of their actions: They walk, stoop, run, jump, chew, and hide themselves, as it were by mere caprice, and without any other cause than what arises from the natural vivacity of their temper.

The buck will copulate when he is a year old, and the female when she is seven months. But as this is rather premature, they are generally restrained till they be eighteen months or two years. The buck is baulk, beautiful, and vigorous; one is sufficient to serve 150 females. A buck for propagation should be large, handsome, and about two years of age; his neck should be short and fleshy; his head flender; his ears pendant; his thighs thick; his limbs firm; his hair black, thick, and soft; and his beard should be long, and bushy. The females are generally in season from September to the end of November. The time of going with young is five months. They generally produce one kid, sometimes two, seldom three, and never more than four; and continue fruitful till they be seven years of age: But a buck is seldom kept after he is five.

Goat's flesh is not so good as mutton: The rank smell of the buck does not proceed from the flesh, but from the skin.

The food of this animal costs next to nothing, as it lives mostly upon such plants as are rejected by other cattle, and can support itself even upon the most barren mountains. But their produce is valuable. Cheese is made of their milk, which besides is reckoned good in consumptions, and other diseases. Their flesh, tallow, hair, and hides, are all useful and saleable commodities.

The food of this animal costs next to nothing, as it lives mostly upon such plants as are rejected by other cattle, and can support itself even upon the most barren mountains. But their produce is valuable. Cheese is made of their milk, which besides is reckoned good in consumptions, and other diseases. Their flesh, tallow, hair, and hides, are all useful and saleable commodities.

2. The ibex, has large knotty horns reclin'd upon its back, is of a yellowish colour, and its beard is black. This species is a native of Crete; and is like-wise to be met with in the mountains of some of the northern parts of Europe.

3. The
CAPRICORN, in zoology. See Mordella.

CAPRI, or Caprea, a city and island at the entrance of the gulf of Naples, about twenty miles south of that city: E. long. 14° 50', and N. lat. 40° 45'.

The island is only four miles long, and one broad; the city is a bishop's seat, situated on a high rock, at the well end of the island.

CAPRICORN, in botany. See Ficus.

CAPRIFICUS, in botany. See Ficus.

CAPRIFICATION, a method used in the Levant, for ripening the fruit of the domestic fig-tree, by means of infects bred in that of the wild fig-tree.

It is said, that these figs will never come to maturity, unless wounded by the insects depositing their eggs. Possibly the reason of this effect, may be their lacering the vessels of the fruit, and thereby deriving thither a greater quantity of nutritious juice.

Plumbs and pears, wounded in the same manner, are found to ripen soonest, and the pulp about the wound has a more exquisite taste than the rest.

CAPRIFICUS, in botany. See Ficus.

CAPRIFOLIUM, in botany. See Lonicera.

CAPRIMULGUS, Goat-sucker, or Fern-owl, in ornithology, a genus of birds belonging to the order of passerines. The beak is incurvated, small, tapering, and depressed at the base; the hairs at the mouth, which it opens very wide, are placed in a row. There are two species, viz. the Europasus, with the tubes of the nostrils hardly visible. It is a native of Europe, and feeds upon moths and nocturnal insects. This bird is said to suck goats in the night. See Pl. 63. 2. The Americanus, has the tubes of the nostrils very conspicuous. This is a night-bird, and is found in America.

CAPROLES, in the menage, leaps that a horse makes in the same place, without advancing, in such a manner, that when he is at the height of the leap, he jerks out with his hinder legs even and near. It is the most difficult of all the high menage. It differs from a croupade in this, that in a croupade the horse does not shew his heels; and from a seashare, because in this he does not jerk out. To make a horse work well at caprioles, he must be put between two pillars, and taught to raise first his fore-quarters, and then his hind quarters, while his fore are yet in the air, for which end you must give the whip and the poinson.

CAPRICORN-beetle. See Cerambyx.

CAPRICORN, in astronomy, one of the twelve signs of the zodiac.

Tropic of Capricorn, a lesser circle of the sphere, which is parallel to the equinoctial, and at 23° 30' distance from it southwards.

CAPRICATION, a method used in the Levant, for ripening the fruit of the domestic fig-tree, by means of infects bred in that of the wild fig-tree.

It is said, that these figs will never come to maturity, unless wounded by the insects depositing their eggs. Possibly the reason of this effect, may be their lacering the vessels of the fruit, and thereby deriving thither a greater quantity of nutritious juice.

Plumbs and pears, wounded in the same manner, are found to ripen soonest, and the pulp about the wound has a more exquisite taste than the rest.

CAPRIFICUS, in botany. See Ficus.

CAPRIFOLIUM, in botany. See Lonicera.

CAPRIMULGUS, Goat-sucker, or Fern-owl, in ornithology, a genus of birds belonging to the order of passerines. The beak is incurvated, small, tapering, and depressed at the base; the hairs at the mouth, which it opens very wide, are placed in a row. There are two species, viz. the Europasus, with the tubes of the nostrils hardly visible. It is a native of Europe, and feeds upon moths and nocturnal insects. This bird is said to suck goats in the night. See Pl. 63. 2. The Americanus, has the tubes of the nostrils very conspicuous. This is a night-bird, and is found in America.

CAPROLES, in the menage, leaps that a horse makes in the same place, without advancing, in such a manner, that when he is at the height of the leap, he jerks out with his hinder legs even and near. It is the most difficult of all the high menage. It differs from a croupade in this, that in a croupade the horse does not shew his heels; and from a seashare, because in this he does not jerk out. To make a horse work well at caprioles, he must be put between two pillars, and taught to raise first his fore-quarters, and then his hind quarters, while his fore are yet in the air, for which end you must give the whip and the poinson.

CAPRICORN, in zoology. See Mordella.
CAPTAIN, the commanding officer of a ship, galley, fire-ship, or the like. This officer ranks with a colonel in the land-service.

CAPTAIN of a merchant-ship, he who has the direction of the ship, her crew, and lading, &c. In small ships and short voyages, he is more ordinarily called the master. In the mediterranean, he is called the patron.

The proprietor of the vessel appoints the captain or master, and he is to form the crew, and chuse and hire the pilots, mates, and seamen; though, when the proprietor and master refide on the same spot, they generally act in concert together.

CAPTAIN BASHAW, or CAPONDAN BASHAW, in the polity of the Turks, signifies the Turkish high admiral. He poffeéés the third office of the empire, and is invested with the same power at sea that the vizir has on shore. Soliman II. instituted this office in favour of the famous Barbaroffa, with absolute authority over the officers of the marine and arsenal, whom he may punish, calk, or put to death, as soon as he is without the Dardanelles. He commands in chief in all the maritime countries, cities, castles, &c. and, at Contstantinople, is the first magistrate of police in the villages on the side of the Porte, and the canal of the Black-sea. The mark of his authority is a large Indian cane, which he carries in his hand, both in the arsenal and with the army.

The captain-bashaw enjoys two sorts of revenues; the one fixed, the other casual. The first arise from a capitaination of the islands in the Archipelago, and certain governments in Natalia and Galipoli. The latter consists in the pay of the men who die during a campaign; in a fifth of all prizes made by the flaves; in the profits accruing from the labour of the slaves, whom he hires as rowers to the grand sigror; and in the contributions he exacts in all places where he passes.

CAPTION, in Scots law, a writ issuing under his majesty's signet, in his majesty's name, obtained at the instance of a creditor in a civil debt, commanding messengers at arms and other officers of the law to apprehend and imprison the person of the debtor until he pay the debt. See Scots Law, title, Sentence and their execution.

CAPTIVITY, a punishment which God inflicted upon his people for their vices and invidities. The first of these captivities is that of Egypt, from which Moses delivered them; after which, are reckoned six during the government of the judges; but the greatest and most remarkable, were those of Judah and Israel, which happened under the kings of each of these kingdoms. It is generally believed, that the ten tribes of Israel never came back again after their dispersion; and Josephus and St Jerom are of this opinion: nevertheless, when we examine the writings of the prophets, we find the return of Israel from captivity pointed out in a manner almost as clear as that of the tribes of Benjamin and Judah. See Hosea i. 10. xi. 12. Amos ix. 14. Isaiah xi. 13, 14. Ezekiel xxxvii. 16, &c.

The
The captivities of Judah are generally reckoned four; the fourth and half of which fell in the year of the world 3416, under Zedekiah; and from this period begins the seventy years captivity, foretold by Jeremiah.

Since the destruction of the temple by the Romans, the Hebrews boast, that they have always had their heads, or particular princes, whom they call princes of the captivity, in the east and west. The princes of the captivity in the eft governed the Jews who dwelt at Babylon, in Chaldea, Assyria, and Phœnicia; and the prince of the captivity in the west governed those who dwelt in Judea, Egypt, Italy, and in other parts of the Roman empire. He who resided in Judea, took up his abode commonly at Tiberias, and assumed the title of Roshabbeth, head of the fathers or patriarchs. He presided in assemblies, decided in cases of conscience, levied taxes for the execution of his orders. As to the princes of the captivity of Babylon, or the caft, we know neither the original nor succession of them; it appears only, that they were not in being before the end of the second century.

CAPTURE signifies, particularly, prizes taken by privateers in time of war.

CAPE, a city of the province of Lavoro, in the kingdom of Naples, situated on the river Volturno, about fifteen miles north-west of the city of Naples: E. long. 15°, and N. lat. 41° 20'.

It is the see of an archbishop.

CAPUCHINS, in the church of Rome. See Franciscans.

CAPUT mortuum, in chemistry, that thick dry matter which remains after distillation of any thing, but of minerals especially.

CAPY-BARA, in zoology. See Surs.

CARABINE, a fire-arm, shorter than a musket, carrying a ball of twenty-four in the pound, borne by the light-horfe, hanging at a belt over the left shoulder.

The barrel is two feet and a half long, and is sometimes furrowed spirally within, which is said to add to the range of the piece.

CARABINEERS, or Carabiniers, regiments of light horfe, carrying longer carabines than the reft, and used sometimes on foot.

CARABUS, in zoology, a genus of insects belonging to the order of insecta coleoptera. The feelers are bristley; the breast is shaped like a heart, and margined; and the elytra are likewise margined. There are 43 species of this genus, mostly distinguished by their colour.

CARACATY, a large country in the north of Asia, extending from the wall of China to the ancient Mogolistan.

CARACOL, in menage, the half turn which a horsemann makes, either to the right or left.

In the army, the horse always makes a caracol after each discharge, in order to pass to the rear of the squadron.

CARACOL, in architecture, denotes a stair-case in a helix or spiral form.

CARACOLI, a kind of metal, of which the Caribbees, or natives of the Lesser Antilles, make a sort of ornament in the form of a crescent, which they also call caracoli.

This metal comes from the main land; and the common opinion is, that it is a compound of silver, copper, and gold, something like the Corinthian brass among the ancients. These metals are so perfectly mixed and incorporated together, that the compound which results from them, it is said, has a colour that never alters, how long soever it remains in the sea, or under ground. It is something brittle, and they who work at it, are obliged to mix a large proportion of gold with it, to make the compound more tough and malleable.

CARACT, Carat, or Carrat, the name of that weight which expresses the degree of fineness that gold is of.

The mint-maister, or custom, have fixed the purity of gold at 24 carats; though it is not possible so to purify and refine that metal, but it will want still about one fourth part of a carat in absolute purity and perfection. The carat is divided into 8, 7, 6, and 5. These degrees serve to distinguish the greater or less quantity of alloy therein contained; for instance, gold of 22 carats, is that which has two parts of silver, or of any other metal, and 22 of fine gold.

CARAT is also a certain weight which goldsmiths and jewelers use wherewith to weigh precious stones and pearls.

This carat weights four grains, but something lighter than the grains of other weights. Each of these grains is subdivided into 4, 3, 2, 1, &c.

CARAGROUTH, in commerce, a silver-coin of the empire, weighing nine drachms. It goes at Conftan-

This metal comes from the main land; and the common opinion is, that it is a compound of silver, copper, and gold, something like the Corinthian brass among the ancients. These metals are so perfectly mixed and incorporated together, that the compound which results from them, it is said, has a colour that never alters, how long soever it remains in the sea, or under ground. It is something brittle, and they who work at it, are obliged to mix a large proportion of gold with it, to make the compound more tough and malleable.

CARACT, Carat, or Carrat, the name of that weight which expresses the degree of fineness that gold is of.

The mint-maister, or custom, have fixed the purity of gold at 24 carats; though it is not possible so to purify and refine that metal, but it will want still about one fourth part of a carat in absolute purity and perfection. The carat is divided into 8, 7, 6, and 5. These degrees serve to distinguish the greater or less quantity of alloy therein contained; for instance, gold of 22 carats, is that which has two parts of silver, or of any other metal, and 22 of fine gold.

CARAT is also a certain weight which goldsmiths and jewelers use wherewith to weigh precious stones and pearls.

This carat weights four grains, but something lighter than the grains of other weights. Each of these grains is subdivided into 4, 3, 2, 1, &c.

CARAGROUTH, in commerce, a silver-coin of the empire, weighing nine drachms. It goes at Constan-

This metal comes from the main land; and the common opinion is, that it is a compound of silver, copper, and gold, something like the Corinthian brass among the ancients. These metals are so perfectly mixed and incorporated together, that the compound which results from them, it is said, has a colour that never alters, how long soever it remains in the sea, or under ground. It is something brittle, and they who work at it, are obliged to mix a large proportion of gold with it, to make the compound more tough and malleable.

CARACT, Carat, or Carrat, the name of that weight which expresses the degree of fineness that gold is of.

The mint-maister, or custom, have fixed the purity of gold at 24 carats; though it is not possible so to purify and refine that metal, but it will want still about one fourth part of a carat in absolute purity and perfection. CARAT is also a certain weight which goldsmiths and jewelers use wherewith to weigh precious stones and pearls.

This carat weights four grains, but something lighter than the grains of other weights. Each of these grains is subdivided into 4, 3, 2, 1, &c.
Caramanta is the name of the capital of that province, situated in 6° 18' N. lat.

Carapoa, in ichthyology, the trivial name of a species of gymnotus. See Gymnotus.

Caravan, or Caravanne in the east, signifies a company or assembly of travellers and pilgrims, and more particularly of merchants, who, for their greater security, and in order to aid each other, march in a body through the deserts, and other dangerous places, which are infested with Arabs or robbers.

There is a chief, or aga, who commands the caravan, and is attended by a certain number of janizaries, or other militia, according to the countries from whence the caravans set out; which number of soldiers must be sufficient to defend them and conduct them with safety to the places for which they are designed, and on a day appointed. The caravan encamps every evening near such wells or brooks, as their guides are acquainted with; and there is a strict discipline observed upon this occasion, as in armies in time of war. Their beasts of burden are partly horses, but most commonly camels, who are capable of undergoing a very great fatigue.

Caravansera, or Karavansera, a place appointed for receiving and loading the caravans.

It is commonly a large square building, in the middle of which there is a very spacious court; and under the arches or piazzas that surround it there runs a bank, raised some feet above the ground, where the merchants, and those who travel with them in any capacity, take up their lodgings as well as they can; the beasts of burden being tied to the foot of the bank.

Over the gates, that lead into the court, there are sometimes little rooms, which the keepers of the caravansers let out at a very high price to such as have a mind to be private.

The caravansers in the east are something in the nature of the inns in Europe, only that you meet with little accommodation either for man or beast, but are obliged to carry almost everything with you; there is never a caravansera without a well, or spring of water. These buildings are chiefly owing to the charity of the Mahometans; they are esteemed sacred dwellings, where it is not permitted to infitulate any person, or to pillage any of the effects that are deposited there. They even carry their precautions so far, as not to suffer any man who is not married to lodge there; because they are of opinion, that a man who has no wife is more dangerous than another.

Caravanseraskier, the steward, or keeper of a caravansera.

He keeps an account of all the merchandises that are sold upon trust, and demands the payments of the sums due to the merchants for what has been sold in the caravansera, on the seller's paying two per cent.

Caraway, in botany. See Carum.

Carbuncle, in natural history, a very elegant gem, whose colour is deep red, with an admixture of scarlet.

This gem was known among the ancients by the name of anthrax. It is usually found pure and faultless, and is of the same degree of hardness with the sapphire: it is naturally of an angular figure, and is found adhering, by its base, to a heavy and ferruginous stone of the emery kind: its usual size is near a quarter of an inch in length, and two thirds of that in diameter in its thickest parts: when held up against the sun, its loses its deep tinge, and becomes exactly of the colour of a burning charcoal, whence the propriety of the name which the ancients gave it. It bears the fire unaltered, not parting with its colour, nor becoming at all the paler by it. It is only found in the East Indies, so far as is yet known, and there but very rarely.

Carbuncle, or Anthrax, in surgery, an inflammation which arises, in time of the plague, with a vehicle or blister almost like those produced by burning.

Carbuncle, in heraldry, a charge or bearing, consisting of eight radii, four whereof make a common cross, and the other four a saltier.

Some call these radii buttons, or flaves, because round, and enriched with buttons, or pearled like pilgrims' slaves, and frequently tipped or terminated with flower-de-luces; others blazon them, royal sceptres, placed in saltier, pale and fesse.

Carochias, in ichthyology. See Squalus.

Carcasse, or Carcuss, in the art of war, an iron-cage, or hollow capacity, about the bigness of a bomb, of an oval figure, made of ribs of iron, filled with combustible matters, as meal-powder, saltpetre, sulphur, broken glass, shavings of horns, turpentine, tallow, &c.; the design of it is to be thrown out of a mortar to set houses on fire, and do other execution. It has two or three apertures through which the fire is to blaze.

Carcassonne, a town of Languedoc in France, situated on the river Aude, about twenty five miles west of Narbonne: E. long. 2°, and N. lat. 43° 20'. It is a bishop's see.

Carceres, in the ancient Circenian games, were inclosures, in the circus, wherein the horses were restrained till the signal was given for starting, when, by an admirable contrivance, they all at once flew open.

Carcinoma. See Canker.

Card, among artificers, an instrument consisting of a block of wood, beset with sharp teeth, serving to arrange the hairs of wool, flax, hemp, and the like: there are different kinds of them, as hand-cards, flock-cards, &c.

Cards, among gamesters, little pieces of thin pasteboard of an oblong figure, of several sizes, but most commonly in England three inches and an half long, and two and an half broad, on which are painted several points and figures.
CARDINAL, in a general sense, an appellation given to things on account of their preeminence: thus we say, cardinal virtues, &c.

CARDINAL SIGNS in the zodiac, are Aries, Libra, Cancer, and Capricorn.

CARDINAL, more particularly signifies an ecclesiastical prince in the Roman church, being one who has a voice in the conclave at the election of a pope. The cardinals were originally nothing more than deacons, to whom was intrusted the care of distributing the alms to the poor of the several quarters of Rome; and as they held assemblies of the poor in certain churches of their several dioceses, they took the title of these churches. They began to be called cardinals in the year 300, during the pontificate of St Sylvester, by which appellation was meant the chief priests of a parish, and next in dignity to a bishop. This office grew more considerable afterwards, and by small degrees arrived at its present height, in which it is the reward of such as have served his holiness well, even princes thinking it no diminution of their honour to become members of the college of cardinals.

The cardinals compose the pope's council, and till the time of Urban VIII. were styled nosti illustrius: but by a decree of that pope in 1630, they had the title of summum confero conferred upon them.

At the creation of a new cardinal, the pope performs the ceremony of shutting and opening his mouth, which is done in a private oratory. The shutting his mouth, implies the depriving him of the liberty of giving his opinion in congregations; and the opening his mouth, which is performed fifteen days after, signifies the taking off this restraint. However, if the pope happens to die during the time a cardinal's mouth is shut, he can neither give his voice in the election of a new pope, nor be himself advanced to that dignity.

The cardinals are divided into six classes or orders, confiding of six bishops, fifty priests, and fourteen deacons, making in all seventy, which constitute the sacred college. The number of cardinal-bishops has very seldom been changed, but that of priests and deacons have varied at different times.

The privileges of the cardinals are very great: They have an absolute power in the church during the vacancy of the holy see: They have a right to elect the new pope, and are the only persons on whom the choice can fall: Most of the grand offices in the court of Rome are filled by cardinals. The dress of a cardinal is a red soutane, a rochet, a short purple mantle, and the red hat. When they are lent to the courts of princes, it is in quality of legates: and when they are appointed governors of towns, their government is called by the name of legation.

CARDINAL is also a title given to some bishops, as those of Mentz and Milan, to the archbishop of Bourges; and the abbot of Vendome calls himself cardinalis natus.

CARDINAL'S FLOWER. See RAPUNTUM.

CARDIOID, in the higher geometry, an algebraical curve, so called from its resemblance to a heart.
CARIDIOSPERMUM, in botany, a genus of the octandria trigynia class. The calix has four leaves; there are four petals; an unequal four-leaved nectarium; and there are three inflated capsules. There are two species, both natives of the Indies.

CARDIUM, in zoology, a genus of infects belonging to the order of vermes tetraeces. The shell consists of two equal valves, and the sides are equal. There are 21 species of this genus.

CARDONA, a city of Catalonia, in Spain, situated on a river of the same name, about forty miles north-west of Barcelona: E. long. 1° 20', N. lat. 41° 35'.

CARDUEL, a province of Georgia, in Asia, lying between the Caspian and Euxine seas, the capital whereof is Tifis. It belongs partly to the Turks, and partly to the Persians.

CARDUELIS, in ornithology, a synonyme of a species of fringilla. See FRINGILLA.

CARDUUS, in botany, a genus of the fringenea polygamia equalis class. The calix is ovated, and imbricated with spinous scales; and the receptacle is hairy. There are 26 species, ten of which are natives of Britain, viz. the lanceolatus, or spear-thistle; the nutans, or milk-thistle; the acanthoides, or welted-thistle; the crispus, or thistle upon thistle; the palustris, or marsh-thistle; the disetteus, or English soft thistle; the helenioides, or melancholy thistle; the marianus, or milk-thistle; and the acaulos, or dwarf carline-thistle.

CAREEII, in the sea-language, the bringing a ship to lie down on one side, in order to trim and caulk the other side.

A ship is said to be brought to the careen, when the moff of her lading being taken out, she is halled down on one side by a small vessel as low as necessary; and there kept by the weight of the ballast, ordnance, &c. as well as by ropes, left her masts should be strained too much; in order that her sides and bottom may be trimmed, seams caulked, or any thing that is faulty under water mended. Hence when a ship lies on one side when she fails, she is said to fail on the careen.

CARELTA, in geography, a province of Finland, bounded by the province of Savolaxia on the north, and by the gulf of Finland on the south. It is subject to Russia.

CARELSCROON, a port-town of the province of Gothland, in Sweden, situated on the coast of the Baltic: E. long. 15°, and N. lat. 56° 20'.

It is an excellent harbour, where the Swedes lay up their royal navy.

CARENTAN, a town of Normandy, in France, situated at the mouth of a river of the same name: W. long. 3° 25', and N. lat. 44° 30'.

CARET, among grammarians, a character marked thus 3, signifying that something is added on the margin, or interlined, which ought to have come in where the caret stands.

CARETTA, in zoology, the trivial name of a species of testudo. See TESTUDO.

CAREX, in botany, a genus of the moncecia triandria class. The amentum of the male is imbricated; it has no corolla; and the calyx consists of one leaf. The amentum of the female is likewise imbricated; the corolla is wanting; and the calyx consists of one leaf; the nectarium is inflated and three-toothed; there are three stigmata; and the seeds are triangular and contained within the nectarium. There are 37 species, 26 of which are natives of Britain.

CARGA-BOL, or KARGAPOL, the capital of a territory of the same name, in the province of Dwina, in Muscovy: E. long. 36°, and N. lat. 63°.

CARGO denotes all the merchandises and effects which are laden on board a ship.

Super-Cargo, a person employed by merchants to go a voyage, and oversee the cargo, and dispose of it to the best advantage.

CARIAMA, in ornithology, a synonyme of the palamedea. See PALAMEDEA.

CARIBISLANDS, a cluster of islands, situated in the Atlantic ocean, between 59° and 63°, W. long., and between 15° and 18° N. lat. They belong partly to the British, and partly to the French, Dutch, &c.

CARIBBIA, or CARIBIANA, the north-east coast of Terra-firma, in South America, otherwise called New-Andalusia. See ANDALUSIA.

CARICA, in botany, a genus of the dioecia decandria class. The male has hardly any calix; the corolla is bell-shaped, and divided into five segments; the filaments are inferted into the tube of the corolla, and are alternately shorter. The calyx of the female has five teeth; the corolla consists of five petals; there are five stigmata; and the berry is unilocular, and contains many seeds.

CARICATURA, in painting, denotes the concealment of real beauties, and the exaggeration of blemishes, but still to as to preserve a resemblance of the object.

CARICOUS, an epithet given to such tumours as resemble the figure of a fig. They are frequently found in the piles.

CARIACITURA, in surgery, the corruption or mortification of a bone. See SURGERY.

CARIGNAN, a fortified town of Piedmont, situated on the river Po, about seven miles south of Turin: E. long. 7° 25', and N. lat. 44° 30'.

CARIGUE, or CARIGUEYA, in zoology, a synonyme of a species of didelphis. See Didelphis.

CARINTHIA, a duchy in the circle of Austria, in Germany, bounded by the archbishopric of Salzburg on the north, and by Carniola and the dominions of Venice on the south. It is subject to the house of Austria.

CARIONOLA, a city of the province of Lavoro, in
CARLOCK, in commerce, a sort of fine-glass made
the kingdom of Naples, about twenty miles north of
the city of Naples: E. long. 15°, and N. lat. 41° 20'.
It is a bishop's fee.

CARPI, a kind of cavalry in the Turkish army.
The carpi, to the number of about one thousand,
are not slaves, nor bred up in the feraglio, like the
reft, but are generally Moors, or renegade Christians,
who, having followed adventures, and being poor,
and having their fortune to seek by their dexterity and
courage, have arrived to the rank of horse-guards to
the grand signor.

CARISBROOK-Castle, a castle situated in the
middle of the isle of Wight, where king Charles I. was
imprisoned: W. long. 1° 30', and N. lat. 50° 40'.

CARKE denotes the thirtieth part of a farlar of wool.

CARLINGS, or Carlines, in a ship, two pieces of
the keel, and serve as a foundation for the whole bo-

CARLING FORD, a port-town of Ireland, in the

CARLINA, or Carline thistle, in botany, a genus
radiated, with long coloured scales. There are feven
species, only one of which, viz. the vulgaris, is a na-
tive of Britain. The roots are said to be diaphoretic
and alexipharmic.

CARLINE, or Caroline, a silver coin, current in the
Neapolitan dominions, and worth about four-pence of
our money.

CARLINGFORD, a port-town of Ireland, in the
county of Louth, and province of Leinster, about twenty-two miles north of Drogheda: W. long. 6° 22', and N. lat. 54° 5'.

CARLING, or Carlines, in a ship, two pieces of
timber, lying fore and aft, along from beam to beam,
whereon the leeds rest on which the planks of the
ship are fastened. All the carlings have their ends let
into the beams culvertail-wise: They are directed over
the keel, and serve as a foundation for the whole bo-
dy of the ship.

CARLISLE, the capital city of Cumberland, situate
near the mouth of the river Eden, and the Solway
frith: W. long. 2° 30', and N. lat. 54° 45'.

It is a bishop's see.

CARLOCK, in commerce, a sort of fine-glass made
with the flurgen's bladder, imported from Archan-
gel. The chief ufe of it is for clarifying wine; but it is also ufed by dyers. The belt carlock comes from
Altracan, where a great quantity of flurgen is caught.

CARLOWITZ, a town of Sclavonia, situated on the
weft fide of the Danube, about thirty-five miles north-
west of Belgrade: E. long. 20° 45', and N. lat. 45° 25'.

CARLSTADT, the capital of Croatia, a frontier pro-
vince of Chriftendom againft the Turks: E. long. 16°, and N. lat. 45° 5'. It is fejfected to the houfe of
Austria.

CARLSTADT is also the name of a town in the bifiopric
of Wurtzburg, in the circle of Franconia in Germany,
situated on the river Maine, about fourteen miles north
of Wurtzburg: E. long. 9° 50', and N. lat. 50°.

CARMAGNOIL, a fortified town of Piedmont, situa-
ted on the river Po, about ten miles south of Turin:
E. long. 7° 30', and N. lat. 44° 45'.

CARMELITES, or White Frizers, are an order of
our lady of Mount Carmel, making one of the four
orders of mendicants. They pretend to derive their
original from the prophets Elijah and Elifba. Their
original rules contained sixteen articles, one of which
confined them to their cells, and enjoined them to
employ themselves day and night in prayer; an-
other prohibited the brethren having any property;
another enjoined fasting, from the fast of the exalt-
ation of the holy crofs till Easter, excepting on Sundays;
abstinence at all times from flesh, was enjoined by an-
other article; one obliged them to manual labour;
another imposcd a strict silence on them, from vefpers
till the tierce the next day: However, these constitutions
have been in some repects altered.

This order is fo much increafed, that it has at pre-
fent thirty-eight provinces, besides the congregation
of Mantua (in which there are fifty-four monafteries,
under a vicar-general) and the congregation of bare-foot-
ed Carmelites in Italy and Spain, which have their pe-
culiar generals.

If a monk of this order lie with a woman, he is
prohibited faying mass for three or four years, is decla-
red infamous, and obliged to discipline himself publicly
once a week: If he is again guilty of the fame of-
ence, his penance is doubled: And if a third time,
he is expelled to order.

CARMENTALIA, fefts celebrated by the Romans,
in honour of the prophetefs Carmenta, the mother of
Evander.

They were solemnized twice in the month of Ja-
nuary, viz. on the nth and 15th.

CARMINATIVES, in pharmacy, medicines ufed in
colics, or other flatulent disorders, to difpel the wind.
The four carminative flores are thofe of camomile,
melilot, motherwort, and dill; besides, angelica, fen
nel, lovage, anife, caraway, coriander, cummin, &c.
all agree in their carminative qualities, and are there-
fore ufed in compositions of that intention.

CARMINE, a powder of a very beautiful red colour,
bordering upon purple, and ufed by painters in mini-
ture; though but rarely, because of its great price.

It is extracted from cochineal, by means of water,
wherein chouan and antour have been infufed; fome
add rocut, but this gives it too much of the oval ca-
ft. Others make carmine with brafl-wood, fernnbouc,
and leaf-gold, beat in a mortar, and steeped in white-
wine vinegar; the fcum ariling from this mixture, up-
on boiling, when dried, makes carmine; but this kind
is vafly inferior to the former: There is another car-
mine, made of brafl-wood and fernnbouc, by a dif-
ferent preparation.

CARMONA, a town of Andalusia in Spain, about fe-
venteen miles eft of Sevil: W. long. 5° 35', N. lat.
37° 20'.

CARNARVON, a borough-town of Carnarvonfhire, in
north Wales, about five miles south-west of Bangor:
W. long. 4° 25', and N. lat. 53° 20'. It gives the
title of earl to the noble family of Bridges; and fends
one member to parliament.
CARNATION, in botany. See Caryophyllus.

Carnation-colour, among painters, is underlain of all the parts of a picture, in general, which represent flesh, or which are naked and without drapery.

In colouring for flesh, there is so great a variety, that it is hard to lay down any general rules for instruction therein; neither are there any respected by those who have acquired a skill this way: The various colouring for carnations, may be easily produced, by taking more or less of red, blue, yellow, or buff, whether for the first colouring, or for the finishing: The colour for women should be bluish, for children a little red, both fresh and gay; and for the men it should incline to yellow, especially if they are old.

CARNELIAN, in natural history, a precious stone, of ray.

CARNIOLA, a territory of Austria, in Germany, bounded by Carinthia and Styria on the north, and by the dominions of Venice on the south.

CARNIVAL, or Carnaval, a time of rejoicing, a season of mirth, observed with great solemnity by the Italians, particularly at Venice, holding from twelfth-day till lent.

Feasts, balls, operas, concerts of music, intrigues, marriages, &c. are chiefly held in carnival-time. The carnival begins at Venice the second holiday in Christmas: Then it is they begin to wear masks, and open their play-houses and gaming-houses; the Place of St Mark is filled with mountebanks, jack-puddings, pedlars, whores, and such like mob, who flock thither from all parts: There have been no less than seven sovereign princes, and thirty thousand foreigners here, to partake of these diversions.

CAROB-tree. See Ceratonia.

CAROLINA, a province of N. America, belonging to Great Britain: It is situated, comprehending Georgia, between 75° and 86° W. long. and between 31° and 36° N. lat. and bounded by Virginia on the north, by the Atlantic ocean on the east, by Spanish Florida on the south, and by the Appalachian mountains on the west; or rather extends westward, without any limits. It is divided into three distinct governments, viz. North and South Carolina, and Georgia.

CAROLINE-books, the name of four books, composed by order of Charlemagne, to refute the second council of Nice. These books are couched in very harsh and severe terms, containing one hundred and twenty heads of accusation against the council of Nice, and condemning the worship of images.

CAROLSTAT, a town of Gothland in Sweden, situated at the north end of the Wener-lake, about one hundred and forty miles west of Stockholm: E. long. 13° 50', and N. lat. 59° 40'.

CAROLUS, an ancient English broad piece of gold, struck under Charles I. its value has of late been at twenty-three shillings sterling, though at the time it was coined, it is said to have been rated at twenty shillings.

CAROLUS, a small copper coin, with a little silver mixed with it, struck under Charles VIII. of France.

The carolus was worth twelve deniers, when it ceased to be current.

Those which are still current in trade, in Lorraine, or in some neighbouring provinces, go under the name of French sous.

CAROTIDS, in anatomy. See p. 226.

CARP, in ichthyology, the English name of a species of cyprinus. See Cyprinus.

CARPENTRY, the art of cutting, framing, and joining large pieces of wood, for the uses of building. It is one of the arts subordinated to architecture, and is divided into house-carpentry and ship-carpentry: The shell is employed in raising roofing, flooring of houses; &c. and the second in the building of ships, barges, &c.

The rules in carpentry are much the same as those of joinery: the only difference is, that carpentry is used in the larger coarser work, and joinery in the smaller and curious: See JOINERY.

CARPET, a sort of covering of stuff, or other materials, wrought with the needle or on a loom, which is part of the furniture of a house, and commonly spread over tables, or laid upon the floor.
PERESIAN and Turkey carpets are those most esteemed; though at Paris there is a manufactury after the manner of Persia, where they make them little inferior, not to say finer, than the true Peresian carpets. They are velvet, and perfectly imitate the carpets which come from the Levant. There are also carpets of Germany, some of which are made of woollen stuffs, as surges, &c. and called square carpets: Others are made of wool also, but wrought with the needle, and pretty often embellished with silk; and lastly, there are carpets made of dog's hair. We have likewise carpets made in England, which are used either for floor-carpets, or to make chairs and other household furniture: It is true, we are not arrived at the like perfection in this manufacture with our neighbours the French; but may not this be owing to the want of the like public encouragement?

**CARR, a land-carriage with two wheels, drawn commonly with horses, to carry heavy goods, &c. from one place to another.**

For the construction and mechanical principles of wheel-carriages, see Mechanics.

**CARRIAGE, a vehicle serving to convey persons, goods, merchandizes, and other things from one place to another.**

For the construction and mechanical principles of wheel-carriages, see Mechanics.

**CARRIAGE of a cannon, the frame or timber-work on which it is mounted, serving to point it for shooting, or to carry it from one place to another.** It is made of two planks of wood, commonly one half the length of the gun, called the cheeks, and joined by three wooden transoms, strengthened with three bolts of iron. It is mounted on two wheels; but on a march has two fore-wheels, with limbers added. The principal parts of a carriage are the cheeks, transoms, bolts, plates, train, bands, bridge, bed, hooks, truncheon-holes, and capguard.

**Block-CARriage, a cart made on purpose for carrying mortars and their beds from place to place.**

**Truck-CARriage, two short planks of wood supported on two axle-trees, having four trucks of solid wood for carrying mortars or guns upon battery, where their own carriages cannot go. They are drawn by men.**

**CARRICK, the most southerly division of the shire of Ayr in Scotland.**

**CARRICK on the (Are, a town of Ireland, in the county of Tipperary, and province of Munster, about fourteen miles north-west of Waterford: W. long. 7° 24', and N. lat. 52° 16'.**

**CARRICK-FERGUS, a town in the county of Antrim, and province of Ulster, in Ireland, about eighty-five miles north of Dublin: W. long. 6° 15', and N. lat. 54° 45'.**

**CARROT, in botany. See Daucus.**

**Garden-CARROT. See Myrrhis.**

**Deadly-CARROT. See Thapsia.**

**Mountain CARROT. See Foeniculum.**

**CARRUSAL, a course of horses and chariots, or a magnificent entertainment exhibited by princes on some public rejoicing. It consists in a cavalcade of several gentlemen richly dressed and equipped, after the manner of ancient cavaliers divided into squadrons, meeting in some public place, and pursuing juits: tournaments, &c. The last carroufals were in the reign of Lewis XIV.**

**CARS, or KARS, a city of Turcomania, or the greater Armenia, situated on a river of the same name: E. long. 44°, and N. lat. 41° 30'. It is subject to the Turks.**

**CARSE, or CASE of Gowry, the name of a district of Perthshire in Scotland, lying eastward of Perth, on the northern bank of the Tay.**

**CART, a land-carriage with two wheels, drawn commonly with horses, to carry heavy goods, &c. from one place to another. See Mechanics.**

**CARTAMA, a town of Granada, in Spain, about ten miles north-west of Malaga: W. long. 4° 30', and N. lat. 36° 40'.**

**CARET, an agreement made between two states for the exchange of their prisoners of war.**

**CARTERET, a county of South Carolina, in North America.**

**CARTESIANS, a sect of philosophers, who adhere to the system of Des Cartes, and founded on the two following principles: the one metaphysical, the other physical: the metaphysical one is, I think, therefore I am: the physical principal is, That nothing exists but substance. Substance he makes of two kinds; the one a substance that thinks, the other a substance extended; whence actual thought and actual extension are the essence of substance.**

**The essence of matter being thus fixed in extension, the Cartesians conclude, that there is no vacuum, nor any possibility thereof in nature, but that the world is absolutely full: there space is precluded by this principle.**
principle, in regard, extension being implied in the idea of space, matter is so too.

Upon these principles, the Cartesians explain mechanically, and according to the laws of motion, how the world was formed, and whence the present appearances of nature do arise. They suppose, that matter was created of an indefinite extension, and divided into little square masses, full of angles; that the Creator impressed two motions on this matter; one whereby each part revolved round its centre, another whereby an effembliage, or system, turned round a common centre; whence arose as many different vortexes as there were different masses of matter, thus moving round common centres.

The consequences of this hypothesis, according to the Cartesians, will be, that the parts of matter in each vortex could not revolve among each other, without having their angles gradually broken, and that this continual friction of parts and angles produced three elements; the first, an infinitely fine dust, formed of the angles broken off; the second, the spheres remaining, after all the angular irregularities are thus removed: these two make the matter of Des Cartes's first and second element; and those particles not yet rendered smooth and spherical, and which still retain some of their angles, make the third element.

Now, according to the laws of motion, the subtilest element must take up the centre of each system, being that which constitutes the sun, the fixed stars above, and the fire below; the second element, composed of spheres, makes the atmosphere, and all the matter between the earth and the fixed stars, in such a manner as that the largest spheres are always next the circumference of the vortex or system, and the smallest next its centre: the third element, or the hooked particles, is the matter that composes the earth, all terrestrial bodies, comets, spots in the sun, &c. Though both philosophers and divines have a just plea against this romantic system, yet it must be owned, that Des Cartes, by introducing geometry into physics, and accounting for natural phenomena by the laws of mechanics, did infinite service to philosophy.

CARTHAGE, or New CARTHAGE, the capital of Coftarica, a province of Mexico, in North America: W. long. 86°, and N. lat. 9° 44'.

CARTHAGENA, a large city, with one of the best harbours in Spain, situated in the province of Murcia, about twenty miles south of that city: W. long. 1° 5', and N. lat. 37° 40'. It is a bishop's see.

New CARTHAGENA, the capital of a province of the same name, in South America, situated on a kind of peninsula: W. long. 77°, and N. lat. 11°. It is one of the largest and best fortified towns in South America.

CARTHAMUS, or BASTARD-SAFFRON, in botany, a genus of the syngenesia polygamina æqualis clas. The calix is ovated, and imbricated with foliaceous scales of an oval shape. There are nine species, none of them natives of Britain. The seeds are purgative; but operate slowly, and disorder the bowels.

CARTHUSIANS, a religious order, founded in the year 1080, by one Bruno. Their rules are very severe. They are not to go out of their cells, except to church, without leave of their superior; nor speak to any person without leave. They must not keep any portion of their meat or drink till next day; their beds are of straw, covered with a felt; their clothing two hair-cloths, two cowls, two pair of hose, and a cloak, all coarse. In the refectory, they are to keep their eyes on the dish, their hands on the table, their attention on the reader, and their hearts fixed on God. Women are not allowed to come into their churches.

CARTHUSIAN-Powder, the same with kermes mineral. See KERMES.

CARTILAGE, in anatomy, a body approaching much to the nature of bones; but lubricious, flexible, and elastic.

CARTMEL, a market-town of Lancashire, about ten miles north-west of Lancaster: W. long. 2° 40', and N. lat. 5° 15'.

CARTON, or Cartoon, in painting, a design drawn on strong paper, to be afterwards calked through, and transferred on the fresh plaster of a wall to be painted in fresco.

Carton is also used for a design coloured, for working in mosaic, tapestry, &c. The cartons at Hampton-court are designs of Raphael Urbin, intended for tapestry.

CARTOUCHE, in architecture and sculpture, an ornament representing a scroll of paper. It is usually a flat member, with wavings, to represent some inscription, device, cypher, or ornament of armoury. They are, in architecture, much the same as modillions; only these are set under the cornice in wainscotting, and those under the cornice at the eaves of a house.

CARTOUCHE, in the military art, a case of wood, about three inches thick at the bottom, girt with marlin, holding about four hundred musket-balls, besides six or eight balls of iron, of a pound weight, to be fired out of a habit, for the defence of a pass, &c.

A cartouche is sometimes made of a globular form, and filled with a ball of a pound weight; and sometimes it is made for the guns, being of ball of half or quarter pound weight, according to the nature of the gun, tied in form of a bunch of grapes, on a topmion of wood, and coated over. These were made in the room of partridge-flot.

CARTRIDGE, in the military art, a case of palleboard or parchment, holding the exact charge of a fire-arm. Thores for muskets, carabines, and pilpols, hold both the powder and ball for the charge; and those of cannon and mortars are usually in cafes of palleboard or tin, sometimes of wood, half a foot long, adapted to the calibre of the piece.

CARTRIDGE-BOX, a case of wood or turned iron, covered with leather, holding a dozen musquet-cartidges. It is worn upon a belt, and hangs a little lower than the right pocket-hole.

CARVA, in botany. See LAURUS.

CARUI or Carvi, in botany. See Carum.

CARUI or Carvi, in botany. See Carum.

CARVING. See Sculpature.

CARUM, CARAVAY, in botany, a genus of the pentandra...
CARUNCULAE MYRTIFORMES. See p. 276.

CARUS, in medicine, a sudden deprivation of sense and motion, affecting the whole body.

CARVAR, a town on the coast of Malabar, in the Higher India, sixty miles south of Goa: E. long. 73°, and N. lat. 15°. Here our East-India company have a factory, from whence they import pepper.

CARYATIDES, or CARYATIS, in architecture. See

CARYOCATACTES, in ornithology, the trivial name of a species of corvus. See Corvus.

CARYOCOSTINUM, or FCELERATOR ET SCAMMONIA, in pharmacy, is composed of the following ingredients: An ounce and a half of scammony; of cloves and ginger, each half a dram; half a pound of honey; half a dram of essential oil of caraway-seeds; the species must be ground together and mixed with the honey; then add the powdered scammony, and afterwards the oil. This electuary is a warm brisk purgative.

CARYOPHYLLATA, in botany. See Geum.

CARYOPHYLLUS, the Pink, in botany. See Diasanthus.

CARYOPHYLLUS, the Clove-tree, in botany, a genus of the polyandria monogynia class. The corolla has four petals; the calyx consists of four duplicated leaves; and the berry contains one seed. There is but one species, viz. the aromaticus, a native of the Molucca islands. The cloves are the flower-cups, have a strong agreeable aromatic smell, and a bitterish pungent tafte. The essential oil of cloves is an ingredient in many of our officinal compositions.

CARYOTA, in botany, a genus of plants ranged under the palmæ bipinnatifolias. The calix of the male is common; the corolla is divided into three parts; and the staminal are numerous. The calix and corolla of the male are the same with those of the female; there is but one ptilillum; and the berry contains two seeds. There is but one species, viz. the urens, a native of India.

CASAL, the capital of the duchy of Montferrat, in Italy, situated on the river Po, forty-five miles east of Turin: E. long. 8° 35', and N. lat. 45°.

CASAN, or KASAN, a province of Russia, lying between the province of Moscow on the west, and Siberia on the east.

CASCADE, a steep fall of water from a higher into a lower place.

They are either natural, as that at Tivoli, &c. or artificial, as those of Versailles, &c. and either falling Vol. II. Numb. 31.
in the circle of the Upper Rhine, in Germany, situated on the river Fulde: E. long. 2° 20', and N. lat. 51° 20'.

CASTEL is also the name of a town in French Flanders, about fifteen miles south of Dunkirk: E. long. 2° 30', and N. lat. 50° 5'.

CASSIA, in botany, a genus of the decandria monogyni class. The calyx consists of five leaves; the petals are five; and the anthers are rosy red and barren; the pod is a legume. There are 30 species, all natives of warm climates. The cassia fistula is a native of Egypt, and the East Indies. The fruit is a cylindrical pod, the pulp of which is a gentle laxative medicine.

CASSIDA, in zoology. See Scutellaria.

CASTANEA, in botany. See Fagus.

CASTANOVITZ, a town of Croatia, situated on the river Unna, which divides Chriftendom from Turkey: E. long. 17° 20', and N. lat. 45° 40'. It is subject to the house of Austria.

CASTEL-ARAGON, a fortres of Sardinia, situated on the north-west coast of that island: E. long. 8° 45', and N. lat. 41°.

CASTELBAR, a town of Ireland, in the county of Mayo, and province of Connought, about thirty-eight miles north of Galway: W. long. 9° 24', N. lat. 53° 25'.

CASTELLAN, or Castillane, a gold-coin, current in Spain, about twelve miles east of Portalegre, and thirty-five west of Alcantara: W. long. 7° 40', N. lat. 39°.

CASTELLARE, a town of the Mantuan, in Italy, about fifteen miles east of the town of Mantua: E. long. 11° 15', N. lat. 45° 30'.

CASTELLAN, the name of a dignity or charge in Poland: The castellans are senators of the kingdom, but senators only of the lower class, who, in diets, fit on low seats, behind the palatines, or great senators. They are a kind of lieutenants of provinces, and command a part of the palatinate under the palatine.

CASTELLANY, the territory belonging to any city or town, chiefly used in France and Flanders: Thus we say, the castellany of Liége, Ypres, &c.

CASTIGLIONE, a fortified town in the duchy of Mantua, about twenty miles north-west of the city of Mantua: E. long. 11°, N. lat. 45° 15'.

CASTILE, the name of two inland provinces of Spain, situated almost in the middle of that kingdom: The most southerly one is called New Castile, and the other, forwards to the north, Old Castile; Madrid being the capital of the former, and Burgos of the latter.

CASTILLAN, or Castillane, a gold-coin, current in Spain, and worth fourteen reis and sixteen deniers.

CASTILLAN is also a weight used in Spain for weighing gold. It is the hundredth part of a pound Spanish weight.

What they commonly call a weight of gold in Spain, is always underfoot of the castillan.

CASTILLAR, a town of the Mantuan, in Italy, situated six miles north-east of the city of Mantua: E. long. 11° 25', N. lat. 45° 20'.

CASTILLO, a town of Perigort, in the province of Guienne, in France, situated on the river Dordonne, sixteen miles east of Bourdeaux: W. long. 2° 40', N. lat. 44° 50'.

CASTLE, a fortres or place rendered defenceable, either by nature or art. A castle is a fort, or little citadel. See Citadel. It frequently signifies with us the principal manuf of noblemen.

In the time of Henry II., there were no less than 1115 castles in England, each of which contained a manor.

CASTLE, in the sea-language, is a part of the ship, of which there are two, the fore-castle, being the elevation.
CASTLE-CARY, a market-town of Somersetshire, situated ten miles south-east of Wells: W. long. 2° 40', N. lat. 51° 15'.

CASTLE-RISING, a borough-town of Norfolk, situated near the sea coast, about thirty miles west of Norwich, and seven north of Lynn: E. long. 4° 30', N. lat. 52° 40'. It sends two members to parliament.

CASTLE-WORK, service or labour done by inferior tenants, for the building and upholding of castles of defence, towards which some gave their personal assistance, and others paid their contributions. This was one of the three necessary charges to which all lands among our Saxon ancestors were expressly subject.

CASTON, a market-town of Norfolk, about eight miles north-west of Norwich: E. long. 1° 30', N. lat. 52° 45'.

CASTOR, or Beaver, in zoology, a genus of quadrupeds belonging to the order of glires. The front-teeth of the upper jaw are truncated, and hollowed in a transverse angular direction. The tops of the front-teeth of the lower jaw lie in a transverse direction; and the tail is depressed. There are three species of castor, viz. 1. The fiber, with a plane ovated tail, is found on the banks of rivers in Europe, Asia, and America. It is from the inguinal glands of this animal that the castor is obtained; it is contained in pods or pouches which resemble a dog's testicles.

Several writers have taken notice of the ingenuity of American beavers in making their houses, of which we shall here give some account. The first thing they do when they are about to build, is to assemble in companies, sometimes of two or three hundred together; then they choose a place where plenty of provisions are to be had, and where all necessaries are to be found proper for their use. Their houses are always in the water, and when they can find neither lake nor pond, they endeavour to supply that defect by stopping the current of a brook or small river, by means of a dam. To this end they first cut down trees in the following manner: Three or four beavers will go to work about a large tree, and by continually gnawing of it with their teeth, they at last throw it down, and so contrive that the water, where they intend to place it. This description of one of their houses, which was examined and measured, will perhaps give the reader more satisfaction than an account in general. It was about three parts surrounded with water, and the other part was joined to the land. It was round, with an oval dome at the top, and the height above the surface of the water was eight feet. It was about forty feet in diameter, and about one hundred and twenty in circumference, which perhaps may seem strange, because the proportion is geometrical; this however is fast, for it was measured several times. The part that joined to the bank was not made out of it, but was of the same materials with the rest.

The bottom of the house was of earth, or soil, with pieces of wood laid in it, above three inches in circumference; then a parcel of poplar sticks laid with one end in the house, and another planting a long way under water; then a layer of earth again, and then poplar sticks, which were repeated to the height of eighteen inches. From thence to the top of the house there was a mixture of earth, stones, and sticks, curiously put together; and the whole was covered with sods, that had long grass growing thereon. The largest pieces of wood made use of near the top were about three inches in diameter, and all the rest was small stuff, not above two or three fingers thick.

The outermost part of this house did not stand farther out in the creek than the edge of the shore; but that which brought the water almost round the house were the trenches, which were made by taking out the earth; these were nine feet in the broadest part, and eighteen feet in length. The creek at the front of the house was six and thirty feet broad, and seemed to be pretty deep. The house was so contrived as to be very solid, for there was no breaking into it without an ax; and in the frosty season it was quite imperceptible. From this house there were several paths into the wood, through which they drew the sticks and trees, which they made use of for food or building.

The wall of the house was two feet thick; and it was covered with smooth clay on the inside in such a manner that it would not admit the least breath of air. Two thirds of the structure was out of the water; and in the upper part, each beaver had his particular
In the summer-time they live upon fruits, and the barks of trees, though sometimes they have held thirty; but this is very uncommon.

Thee creatures are never surprised by the frost and snow; for they finish their work towards the end of September; and then they lay in provisions for the winter. In the summer-time they live upon fruits, and the barks and leaves of trees; and they likewise catch small fish, and particularly crabs or craw-fish. However, their winter-provision is the tender branches of trees, particularly poplar, of which they seem to be very fond. It is usually said, and upon pretty good authority, that these bears make the walls of their houses of a thickness in proportion to the severity of the succeeding winter; which if true, these animals must be furnished with uncommon foresight.

When there are great floods caused by the melting of the snow, which damage the houses of the beavers, they then leave them, and shift for themselves as well as they can; however, the females return as soon as the waters are abated; but the males keep the field till July, when they assemble again to repair the damage that has been done by the flood, either to their houses or dams. When any of their houses are demolished by the hunters, they never repair them again, but build others quite new. Some authors have said, that the beavers make several rooms in their houses; but this upon examination has been found to be false.

In hunting the beavers, the savages sometimes shoot them, always getting on the contrary side of the wind; for they are very shy, quick in hearing, and of a very keen scent. This is generally done when the beavers are at work, or on shore feeding on poplar bark. If they hear any noise when at work, they immediately jump into the water, and continue there some time; and when they rise, it is at a distance from the place where they went in.

They sometimes are taken with traps: these are nothing but poplar sticks laid in a path near the water; which when the beaver begins to feed upon, they cause a large log of wood to fall upon their necks, which is put in motion by their moving of the sticks, and consequently requires an ingenious contrivance. The savages generally prefer this way of taking them, because it does not damage their skins.

In the winter time they break the ice in two places at a distance from the house, the one behind the other. They then take away the broken ice with a kind of a racket, the better to see where to place their flakes. They suffer their nets to these, which have large meshes, and sometimes are eighteen or twenty yards in length. When these are fixed, they proceed to demolish the house, and turn a dog therein; which terrifying the beaver, he immediately leaves it, and takes to the water; after which, he is soon entangled by the net.

Mr. Lawton who was general surveyor of North Carolina, affirms, that beavers are very plenty in that country. He confirms what has been said about their ingenuity in building of their dams and houses, and observes, that their food is chiefly the bark of trees and shrubs; such as that of the salicifras, ash, sweet gum, and several others. He adds, that if they are taken young, they will become very tame; but then they will do a great deal of mischief in the orchards, by breaking the trees. They will likewise block up the doors of the houses in the night, with the sticks and wood which they bring thither. He farther informs us, that it is certain death for them to eat any thing that is salt. The flesh is looked upon as very delicate food.

2. The mofchatus, with a long, compressed, lanceolated tail, and palmated feet. It is the exotic water-rat of Clusius, and is a native of Russia.

3. The zibethicus, or musk-rat, with a long, compressed, and lanceolated tail, and the toes of the feet separate from each other. The follicles of the tail are said to banish moths and other insects from cloaths, &c. For this reason the inhabitants of Russia and Canada favour them into the folds of their cloaths, to keep off vermin and contagious diseases.

CASTOR is also the name of a market-town of Lincolnshire, twenty miles north-east of Lincoln: W. long. 12°. and N. lat. 53° 30'.

CASTOREUM, in the materia medica, a substance obtained from the inguinal glands of the caffer. See CASTOR.

CASTRATION, in surgery, the operation of gelding. It was prohibited by a decree of the senate of Rome under Hadrian; and the Cornelian law subjected the person who performed the operation, to the same penalties as the person on whom it was performed, although it was done with his consent.

Castration is much in use in Asia and Turkey, where it is practiced upon the slaves, to prevent any commerce with their women. In Italy, castration is frequent from another motive, namely, to preserve the voice for singing. It is sometimes found necessary in chirurgical cases, as in a farceole and cancer of the testicles. For the method of performing this operation, see SURGERY.

CASTRES, a city of Languedoc, in France, about thirty-five miles east of Toulouse: E. long. 2°, and N. lat. 43° 40'. It is a bishop's see.

CASTRO, the capital of the island of Chloe, on the coast of Chili, in south America: W. long. 82°, S. lat. 43° 20'.

CASTRO is also the capital of a duchy of the same name in the pope's territories, in Italy, situated on the confines of Tuscany: E. long. 12° 35', N. lat. 42° 30'.

CASTRO is likewise a town in the territory of Otranto, in the kingdom of Naples, about seven miles south of Otranto: E. long. 19° 25', N. lat. 40° 8'.

CASTRO marino, a town in the province of Algarva, in Portugal, situated near the mouth of the river Guadiana, on the confines of Andaluva: W. long. 8° 15', N. lat. 37°.
CATAEUSIS, in rhetoric, a trope which borrows.

CASUS ammonis, in Scots law. In actions of proving the tenor of obligations extinguishable by the debtor's retiring or cancelling them, it is necessary for the pursuer, before he is allowed a proof of the tenor, to condescend upon such a casus ammonis, or accident, by which the writing was destroyed, as shews it was lost while in the creditor's possession. See Scots

CATACOMB, a grotto or subterraneous place for the burial of the dead. The term is particularly used in Italy, for a vast assemblage of subterraneous sepulchres, three leagues from Rome, in the via Appia, supposed to be the sepulchres of the ancients: Others imagine these catacombs to be the cells wherein the primitive Christians hid themselves. Each catacomb is three feet broad, and eight or ten high, running in form of an alley or gallery, and communicating with one another.

CATACRACTA, in antiquity, a kind of coat of mail, which covered the soldier from head to foot. Hence, cataphraucti were horsemen armed with the cataphracta, whose horses, as Sallust says, were covered with linen full of iron plates disguised like feathers.

CATAPLASM, an external topical medicine, prepared of ingredients of different virtues, according to the intention of the physician. Hence there are different sorts of cataplasm with respect to the matter of which they consist, as emollient, resolvent, diffusent, purgative, corroborative, and antieptic cataplasm. They are commonly applied hot, or lukewarm, rolled up in linen cloths, which by means of the oils which are added preserve heat for a considerable time; for which end also fome, upon these, apply a swine's or ox's bladder, and sometimes on the top of all apply an earthen tile.

CATAPULTA, in antiquity, a military engine contrived for the throwing of arrows, darts, and stones, upon the enemy. Some of these engines were of such force, that they would throw stones of an hundred weight. Josephus takes notice of the surprizing effects of these engines, and says, that the stones thrown out of them beat down the battlements, knocked off the angles of the towers, and would level a whole file of men, from one end to the other, were the phalanx never so deep.

CATARACTA, in hydrography, a precipice in the channel of a river, caufed by rocks, or other obftacles, stopping the course of the stream, from whence the water falls with a greater noise and impetuosity: Such are the cataracts of the Nile, the Danube, Rhine, and the famous one of Niagara in America.

CATARACTES, in ornithology, the trivial name of a species of larus. See LARUS.

CATAPHALM, among ancient physicians, signifies any dry medicine reduced to powder, in order to be used by way of inspiration in the whole body, or any part of it.

CATAPHONICS, the science which considers the properties of reflected sounds.

CATAPHORA, in medicine, the same as coma. See COMA.

CATAPUSIS, in medicine, a disorder of the humours in the eye, by which the pupilla, that ought to appear transparent and black, looks opaque, grey, blue, brown, &c. by which vision is varioufly impeded, or totally destroyed. See MEDICINE, and SURGERY.

CATARO, the capital of a territory of the same name, in the Venetian Dalmatia, about twenty five miles south-east of Ragusa: E. long. 19° 20', N. lat. 42° 25'.

CATARACTES, in ornithology, the trivial name of a species of larus. See LARUS.

CATARRH, in medicine, a diffillation or defluxion from the head upon the mouth and aspera arteria, and...
and through them upon the lungs. See Medicine.

CATASTASIS, in poetry, the third part of the ancient drama, being that wherein the intrigue, or action, is supported and carried on, and heightened, till it be ripe for the unravelling in the catastrophe. Scaliger defines it, the full growth of the fable, while things are at a stand in that confusion to which the poet has brought them.

CATASTROPHE, in dramatic poetry, the fourth and last part of the ancient drama, or that immediately succeeding the catastrophe: or, according to others, the third only; the whole drama being divided into prologue, epilogue, and catastrophe; or, in the terms of Aristotle, prologue, epilogue, and exode. See Epic and Dramatic compositions.

CATCH-fly, in botany. See Lychnis.

CATCH-word, among printers, that placed at the bottom of each page, being always the first word of the following page.

CATECHETIC. The catechetical schools were buildings appointed for the office of the catechist, adjoining to the church, and called catechumenæ: Such was that in which Origen, and many other famous men, read catechetical lectures at Alexandria. See Catechumen.

CATECHISM, the name of a small book, designed for instructing children in the principles of religion. The church of Rome, the church of England, the presbyterian church, &c. have all catechisms containing and enforcing their peculiar opinions.

CATECHU, in the materia medica, the name of a roach consiting of Japan earth and gum arabic, each two ounces, and of sugar of roses sixteen ounces, beat together, with a little water. It is recommended as a mild restringent, &c.

CATECHUMEN, a candidate for baptism, or one who prepares himself for the receiving thereof.

The catechumens, in church history, were the lowest order of Christians in the primitive church. They had some title to the common name of Christian, being a degree above pagans and heretics, though not constituted by baptism. They were admitted to the flate of catechumens, by the imposition of hands, and the sign of the cross. The children of believing parents were admitted catechumens; as soon as ever they were capable of instruction: But at what age those of heathen parents might be admitted, is not so clear. As to the time of their continuance in this state, there were no general rules fixed about it; but the practice varied according to the difference of times and places, and the readiness and proficiency of the catechumens themselves.

There were four orders or degrees of catechumens; the first were those instructed privately without the church, and kept at a distance, for some time, from the privilege of entering the church, to make them the more eager and desirous of it. The next degree were the audients, so called from their being admitted to hear sermons and the scriptures read in the church, but were not allowed to partake of the prayers. The third sort of catechumens were the gloria, fo called, because they received imposition of hands kneeling. The fourth order was the competentes et elegiti, denoting the immediate candidates for baptism, or such as were appointed to be baptized the next approach of festival, before which, strict examination was made into their proficiency under the several stages of catechetical exercises.

After examination, they were exercised for twenty days together, and were obliged to fasting and confession: Some days before baptism they went veiled; and it was customary to touch their ears, saying, Ephesians, i.e. be opened; as also, to anoint their eyes with clay; both ceremonies being in imitation of our Saviour's practice, and intended to shadow out to the catechumens their condition both before and after their admission into the Christian church.

CATEGORY, in logic, a series or order of all the predicates or attributes contained under any genus. The school-philosophers distribute all the objects of our thoughts and ideas into certain genera or classes, not so much, say they, to learn what they do not know, as to communicate a distinct notion of what they do know; and these classes the Greeks called categories, and the Latins predicaments.

Aristotle made ten categories, viz. quantity, quality, relation, action, passion, time, place, situation, and habit, which are usually expressed by the following technical terms:

 Arbor, sex, servos, ardore, refirgerat, ujios, Ruri oras flava, nec tunicatus ero.

CATENARIA, in the higher geometry, the name of a curve line formed by a rope hanging freely from two points of suspension, whether the points be horizontal or not. See Fluxions.

CATERGI, the name of the public carriers in the grand Signiour's dominions. In Europe, the merchant or traveller gives earnest to the carrier; but the catergi in Turkey give earnest to the merchant and others, as a security that they will certainly carry their goods, or not fet out with them.

CATERPILLAR, in zoology, the name of all winged insects when in their reptile or worm-state. See Natural History, Of insects.

CATESBAE, in botany, a genus of the tetrandria monogynia class. The corolla is long, monopetalous, and shaped like a tunnel; the stamina are within the fæs; and the berry contains but one seed. There is but one species, viz. the spinosa, a native of Providence.

CATHÆRITICS, in pharmacy, medicines of a caustic nature, serving to cut off proud flesh.

CATHARTICS, in medicine, remedies which promote evacuation by stool.

CATHEDRAL, a church wherein is a bishop's see or seat.

CATHETER, in surgery, a slender instrument, usually made of silver, to be introduced into the bladder, in order to search for the stone, or discharge the urine when suppressed. See Surgery.

CATHETUS, in geometry, a line or radius falling perpendicularly...
pendicularly on another line or surface: thus the catheti of a right-angled triangle are the two sides that include the right angle.

**Catetus of incidence**, in catoptrics, a right line drawn from a point of the object, perpendicular to the reflecting line.

**Catetus of reflection**, or of the eye, a right line drawn from the eye, perpendicular to the reflecting line.

**Catetus of obliquation**, a right line drawn perpendicular to the speculum, in the point of incidence or reflection.

**Catetus**, in architecture, a perpendicular line, supposed to pass through the middle of a cylindrical body, as a baluster, column, &c.

**Cathness**, the most northerly county of Scotland, having the Caledonian ocean on the north, east, and south-east, and the shire of Sutherland on the south and west. Its capital is Wick.

**Catholic**, in a general sense, denotes any thing that is universal or general.

**Catholic church.** The rise of heresies induced the primitive Christian church to assume to itself the appellation of catholic, being a characteristic to distinguish it from all sects, which, though they had party-names, sometimes sheltered themselves under the name of Christians.

The Roman church distinguishes itself now by the name of catholic, in opposition to all those who have separated from her communion, and whom the confessors as only heretics and schismatics, and herself only as the true and Christian church. In the strict sense of the word, there is no catholic church in being, that is, no universal Christian communion.

**Catholic king**, a title which hath been hereditary to the kings of Spain, ever since Alphonus, who, having gained several victories over the Saracens, and re-established the Christian faith in Spain, was honoured with the title of Catholic. Some say it was in the time of Ferdinand and Isabella.

**Catholic medicine**, in pharmacy, a kind of soft purgative, electuary, so called, as being supposed an universal purger of all humours.

**Catholic church**, in medicine, a disease, by which the patient is rendered, in an instant, as immovable as a statue, without either sense or motion, and continues in the same posture he was in at the moment he was seized. See Medicine.

**Catodon**, in ichthyology, the trivial name of a species of physeter. See Physeter.

**Catodon**, in medicine. See Myopias.

**Catoptrics**, that part of optics that treats of reflexion, and explains the laws and properties of reflection. See Optics.

**Catulus**, in ichthyology. See Squalus.

**Catulus-pardus**, in zoology. See Felis.

**Catulus bipedicus.** See Castor.

**Catzenelliibogen**, a city of Hesse, situated upon the Upper Rhine, in Germany, about sixteen miles north of Mentz: E. long. 7° 40', N. lat. 50° 20'. It is the capital of a county of the same name.

**Cavalier**, in fortification, an elevation of earth of different shapes, situated ordinarily in the gorge of a bastion, bordered with a parapet, and cut into more or less embrares, according to the capacity of the cavalier.

Cavaliers are a double defence for the faces of the opposite bastion: they defend the ditch, break the besiegers galleries, command the traverses in dry moats, scour the faillant angle of the counter-scarpe where the besiegers have their counter-batteries, and infide the enemies trenches, or oblige them to multiply their parallels: they are likewise very serviceable in defending the breach, and the retrenchments of the besieged, and can very much incommode the entrenchments which the enemy make, being lodged in the bastion.

**Cavalry**, a body of soldiers that charge on horseback. They are divided into squadrons, and encamp on the wings of the army.

**Cavan**, the capital of a county of the same name, in the province of Ulster, in Ireland, situated about sixty miles north-west of Dublin: W. long. 7° 35', and N. lat. 54°.

**Caulinis**, in botany, a genus of the pentandria gynia class. The corolla is radiated; the fruit is hairy, and the involucra are entire. There are six species, three of which are natives of Britain, viz. the arvensis, or small corn-parley; the anthricus, or hedge-parley; and the leptophylla, or fine-leaved battard parley.

**Caucasus**, a vaff ridge of mountains, running from the Leffèr Afa through the north of Persia to the East Indies; these acquire different names in the several countries through which they pass.

**Caudiverbera**, in zoology, the trivial name of a species of lacerta. See Lacerta.

**Cavear, Caveer, or Cavary**, the spaw, or hard roes of sturgeon, made into small cakes, an inch thick, and of an hand's breadth, salted, and dried in the sun. This sort of food is in great repute throughout Muscovy, because of their three lents, which they keep with a superflitious exactness: wherefore the Italianians settled at Moscow, drive a very great trade in this commodity throughout that empire, because there is a prodigious quantity of sturgeon taken at the mouth of the Wolga and of the other rivers which fall into the Caspian sea. There is a pretty large quantity of this commodity comsumed in Italy, and they are very well acquainted with it in France and England, where it is reckoned no despicable dish.

The French and Italians get the cavear from Archangel, but they seldom get it at the first hand, for they commonly buy it of the English and Dutch.

**Caveat**, in law, a kind of process in the spiritual courts, to stop the proving of a will, the granting letters of administration, &c. to the prejudice of another. It is also used to stop the institution of a clerk to a benefice.

**Caveating**, in fencing, is the shifting the sword from one side of that of your adversary to the other.
CAVEDO, in commerce, a Portuguese long measure, equal to 27 English inches.

CAVETTO, in architecture, a hollow member, or round concave moulding, containing a quadrant of a circle, and having a quite contrary effect to that of a quarter round: it is used as an ornament in cornices.

CAVEZON, in the menage, a sort of nose-band, either of iron, leather, or wood, sometimes flat, and at other times hollow or twisted, clapt upon the nose of a horse, to wring it, and so forward the suppling and breaking of the horse.

CAVIA-COBAYA, a synonyme of the mus porcellinus, or Guinea-pig. See Mus.

CAVILLON, a town of Provence in France, situated on the river Durance, about fifteen miles south of Avignon: E. long. 5°, and N. lat. 43° 50'. It is a bishop's see, and subject to the pope.

CAULKING, or Caulking of a ship, is driving oakum, or the like, into all the seams of the planks of a ship, to prevent leaking, and keep out the water.

Caulking-irons, are iron chisels for that purpose. Some of these irons are broad, some round, and others grooved. After the seams are stopped with oakum, it is done over with a mixture of tallow, pitch, and tar, as low as the ship draws water.

CAUL, in anatomy. See p. 266. col. 2.

Cauliflowers, in gardening, a much esteemed species of cabbage.

Cauliflowers have of late years been so much improved in Britain, as to exceed in goodness and magnitude any produced in most parts of Europe; and, by the skill of the gardeners, are continued for several months together, but the most common season for them is in May, June, and July.

CAULIS, in botany. See p. 641. col. 2. and Plate LVII. fig. 148.

CAULIFLOWERS, in botany. See p. 641. col. 2. and Plate LVII. fig. 148.

CAUSALTY, among miners, denotes the lighter, sulphurous, earthy parts of ores, carried off in the operation of washing.

This, in the mines, they throw in heaps upon banks, which, in six or seven years, they find it worth their while to work over again.

CAUSE, that from whence any thing proceeds, or by virtue of which any thing is done: it stands opposed to effect. We get the ideas of cause and effect from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings.

Causality, among metaphysicians, the action or power of a cause in producing its effect.

Causality, among miners, denotes the lighter, sulphurous, earthy parts of ores, carried off in the operation of washing.

This, in the mines, they throw in heaps upon banks, which, in six or seven years, they find it worth their while to work over again.

CAUSE, that from whence any thing proceeds, or by virtue of which any thing is done: it stands opposed to effect. We get the ideas of cause and effect from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings.

The method of preparing the lunar caustic is as follows: Dissolve pure silver by a sand-heat, in about four times its weight of aqua-fortis; then dry away the hus of the retort be exposed to the air, that it may run into a liquor.

CAUSALTY, among civilians, the same with action. See Action.

CAUSTICS, in phisic, an appellation given to medicines of so hot and fiery a nature, that, being applied, consume, and, as it were, burn the texture of the parts, like hot iron.

Cautious are generally divided into four sorts, the common stronger caustic, the common milder caustic, the antimonial caustic, and the lunar caustic.

The stronger caustic is prepared by boiling to a fourth part any quantity of the lees of almond-soap, adding lime that has been kept in a vessel pretty close flopped for several months; the lime is to be added till all the liquor is absorbed, and the whole reduced to a paste, which is to be kept in a vessel well flopped.

The common milder caustic is prepared by taking equal parts of soft soap and fresh quick-lime, and mixing them at the time of using.

The antimonial caustic is prepared thus: Take of antimony one pound, of corrosive sublimate two pounds; and being reduced separately into powder, mix them well, and distill them in a retort with a wide neck, in a gentle heat of sand; let what ascends into the neck of the retort be exposed to the air, that it may run into a liquor.

The method of preparing the lunar caustic is as follows: Dissolve pure silver by a sand-heat, in about five times its weight of aqua-fortis; then dry away the humidity with a gentle fire, afterwards melt it in a crucible, that it may be poured into proper moulds, carefully avoiding over-much heat, lest the matter should grow too thick.

CAUSTIC CURVE, in the higher geometry, a curve formed by the concourse or coincidence of the rays of light reflected from some other curve.

CAUSTIC GLASSES. See Burning-glasses.

CAUSTICUM ANTIMONIALE, in the London Dispensatory, the same with the oil of antimony.

CAUSUS, or Burning-fever, a species of continual fever, accompanied with a remarkable inflammation of the blood.

CAUTERIZATION, the application of cauteries to any part of the body.

CAUTERY,
CAUTERY, in surgery, a medicine for burning, eating, or corroding any solid part of the body.

Cauteries are distinguished into two classes, actual and potential: by actual cauteries, are meant red hot instruments, usually of iron, and by potential cauteries are understood certain kinds of corroding medicines. See Medicine, and Surgery.

CAUTION, in the civil and Scots law, denotes much the same with what, in the law of England, is called bail. See Bail.

CAUTIONER, in Scots law, that person who becomes bound for another to the performance of any deed or obligation. As to the different kinds and effects of cautionry, see Scots Law, title, Obligations arising from consent.

CAYA, a little coin made of lead, mixed with some tincture of copper, struck in China, but current chiefly at Bantam in the island of Java, and some of the neighbouring islands.

The cayas are of two kinds, great and small. Of the small, 300,000 are equal to fifty-six livres five sols French money; and of the great, 6000 are equal to four thillings and sixpence sterling.

CAZAMALCA, the name of a town and district of Peru, in South America, where there was a most magnificent palace belonging to the Incas, and a magnificent temple dedicated to the sun. It was at Caxamalca that Pizarro put to death Atahualpa, their last king.

CAZEROM, or Cazeron, a city of Persia, the capital of the province of Kurch Schabour, situated in 70° N. lat.

CAZIMIR, a town of Poland, in the palatinate of Lublin.

CAZIMIR, a town of Poland, in the palatinate of Lublin.

CEANS, in botany, a genus of the dicotyledonous family, they were more at liberty to adhere to the church of Rome, the clergy are obliged.

That celibacy has no pretence of divine or apodictical institution, seems no difficult point to prove: whence it is, at first, hard to conceive from what motive the court of Rome persisted so very obstinately to impose this institution on the clergy. But we are to observe, that this was a leading step to the execution of the project formed of making the clergy independent of princes, and rendering them a separate body, to be governed by their own laws. In effect, while priests had children, it was very difficult to prevent their dependence upon princes, whose favours have such an influence on private men; but having no family, they were more at liberty to adhere to the pope.

CELASTRUS, in botany, a genus of the pentandria monogynia class. The corolla consists of five open petals; the capsule is triangular, and has three cells; and the seeds have a calyptra. There are five species, none of them natives of Britain.

CELEBACY, the date of unmarried persons, to which, according to the doctrine, or at least the discipline, of the church of Rome, the clergy are obliged.

CELESTINS, in church-history, a religious order of Christians, reformed from the Bernardins by pope Celestin V. Their rules are divided into three parts; the first, of the provincial chapters, and the elections of superiors; the second contains the regular observances; and the third, the visitation and correction of the monks.

The Celestins rise two hours after midnight to say matins: they eat no flesh at any time, except when they are sick: they fast every Wednesday and Friday to the feast of the exaltation of the holy cross; and from that feast to Easter, every day.

CELIBACY, in mechanics, the swiftness of any body in motion.

It is also defined to be an affection of motion, by which any moveable body runs through a given space in a given time. See Mechanics.

CELESTINS, in church-history, a religious order of Christians, reformed from the Bernardins by pope Celestin V. Their rules are divided into three parts; the first, of the provincial chapters, and the elections of superiors; the second contains the regular observances; and the third, the visitation and correction of the monks.

The Celestins rise two hours after midnight to say matins: they eat no flesh at any time, except when they are sick: they fast every Wednesday and Friday to the feast of the exaltation of the holy cross; and from that feast to Easter, every day.

That celibacy has no pretence of divine or apodictical institution, seems no difficult point to prove: whence it is, at first, hard to conceive from what motive the court of Rome persisted so very obstinately to impose this institution on the clergy. But we are to observe, that this was a leading step to the execution of the project formed of making the clergy independent of princes, and rendering them a separate body, to be governed by their own laws. In effect, while priests had children, it was very difficult to prevent their dependence upon princes, whose favours have such an influence on private men; but having no family, they were more at liberty to adhere to the pope.

CELOSIA, in botany, a genus of the pentandria monogynia class. The calyx is divided into five segments; the corolla is wanting. The germina of the female monogynia class. The corolla consists of five open petals; the capsule is triangular, and has three cells; and the seeds have a calyptra. There are five species, none of them natives of Britain.

CELESCIA, in botany, a genus of the dicotyledonous family, they were more at liberty to adhere to the church of Rome, the clergy are obliged.

That celibacy has no pretence of divine or apodictical institution, seems no difficult point to prove: whence it is, at first, hard to conceive from what motive the court of Rome persisted so very obstinately to impose this institution on the clergy. But we are to observe, that this was a leading step to the execution of the project formed of making the clergy independent of princes, and rendering them a separate body, to be governed by their own laws. In effect, while priests had children, it was very difficult to prevent their dependence upon princes, whose favours have such an influence on private men; but having no family, they were more at liberty to adhere to the pope.

CELOSIA, in botany, a genus of the pentandria monogynia class. The calyx is divided into five segments; the corolla is wanting. The germina of the female monogynia class. The corolla consists of five open petals; the capsule is triangular, and has three cells; and the seeds have a calyptra. There are five species, none of them natives of Britain.
flamina, and two styli; the drupa contains but one seed. The calyx of the male is divided into six segments; it has no corolla; and the flamina are six. The species are three, none of them natives of Britain.

CEMENT, or CEMENT. See CEMENT.

CEMENTATION. See CEMENTATION.

CEMETERY. See Cemetery.

CENADA, a town of the Venetian territories in Italy, situated about thirty-two miles north of Padua: E. long. 12° 40', and N. lat. 46° 5'.

CENACHRUS,' in botany, a genus of the polygamia monosperma class. The involucrum is laciniate, and in- inviolate. The species are three, none of them natives of Britain.

CENCHRUS, in antiquity, a monument erected in honor of the deceased, was commonly the wreck of a ship, to denote the decease of the person in some foreign country.

CENSOR, in Roman antiquity, a magistrate, whose business it was to reform the manners, and to value the estates of the people.

CENSER, in antiquity, a vessel of incense to be used in sacrificing to the gods. Censors of books, are a body of doctors or others established in divers countries, to examine all books before they go to the press, and to see they contain nothing contrary to faith and good manners.

CENSORS, or Li- censors, or Confrators. See Licensor.

CENSUS, in Roman antiquity, an authentic declaration of the number of citizens capable of bearing arms, and the money they could afford for the expense of a war. It went through all ranks of people, though under different names: that of the common people was called cenos; that of the knights, censis. recensio; that of the senators, licentia, relection.

CENSURE, a judgment which condemns some book, person, or action, or more particularly a reproof from a superior. Ecclesiastical cenfures, are penalties by which, for some remarkable misbehaviour. Christians are deprived of the communion of the church, or prohibited to execute the sacra- sell office.

CENSUS, in Roman antiquity, an authentic declaration made before the censors, by the several subjects of the empire, of their respective names and places of abode. This declaration was registered by the censors, and contained an enumeration, in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, wife, children, domestics, tenants, slaves.

The census was instituted by Servius Tullius, and was held every five years. It was of great service to the republic, because, by means of it, they discovered the number of citizens capable of bearing arms, and the money they could afford for the expense of war. It went through all ranks of people, though under different names, that of the common people was called census; that of the knights, censis. recensio, recognitio; that of the senators, licentia, relection.

The census which entitled one to the dignity of a knight, was 400,000 sesterces; that of a senator, was double that sum.

In the Voconian law, census is used for a man, whose estate in the censor's books is valued at 100,000 sesterces.

CENTAUR, in ancient poetry, denotes a fabulous kind of animal, half man, half horse. The Thessalians who first taught the art of breaking horses, appearing on horseback to make only one body with the animal on which they rode, gave rise to the fiction of the hippocentaur.

CENTAUREA, in botany, a genus of the syngenesia polygymnia fruticans class. The receptacle is bris- bly-surfaced; the rays of the corolla are tunnel-shaped, long, and irregular. There are 61 species, five of which are natives of Britain, viz. the cyparissus, or blue-bottle; the scabiosa, or great knapweed; the Jaca, or common knapweed; the calcitrata, or star-thistle; and the festivitia, St Barnaby's thistle.
CENTAURY. See Chelidonium.

Center of gravity, in mechanics, that point about which all the parts of a body do, in any situation, exactly balance each other. See Mechanics.

Center of motion, that point which remains at rest, while all the other parts of a body move about it. See Mechanics.

CENTIMETATION, a milder kind of military punishment, in cases of desertion, mutiny, and the like, when only every hundredth man is executed.

CENTIPES, in zoology. See Scolopendra.

CENTONARII, in antiquity, certain officers of the Roman army, who provided tents and other stuff, called centones, made use of to quench the fire which the enemy's engines threw into the camp. These centonarii kept with the carpenters and other officers of the artillery.

CENTRAL FORCES, the powers which cause a moving body to tend towards, or recede from the centre of motion. See Mechanics.

CENTRAL RULE, a rule discovered by Mr Thomas Baker, whereby to find the centre of a circle defined to cut the parabola in as many points, as an equation to be constructed hath real roots. Its principal use is in the construction of equations, and he has applied it with good success as far as biquadratics.

The central rule is chiefly founded on this property of the parabola, that if a line be inscribed in that curve perpendicular to any diameter, a rectangle formed of the segments of the inscript, is equal to the rectangle of the intercepted diameter and parameter of the axis.

The central rule has the advantage over Cartes and De Lattr's methods of constructing equations, in that both these are subject to the trouble of preparing the equation, by taking away the second term.

CENTRIFUGAL FORCE, that force by which all bodies that move round any other body in a curve, endeavour to fly off from the axis of their motion in a tangent to the periphery of the curve, and that in every point of it. See Mechanics.

CENTRINA, in ichthyology, the trivial name of a species of Squalus. See Squalus.

CENTRIPETAL FORCE, that force by which a body is every where impelled, or any how tends towards some point as a centre. See Mechanics.

CENTRISCUS, in ichthyology, a genus belonging to the order of amphibia nates. The head gradually ends in a narrow snout; the aperture is broad and flat; the belly is carinated; and the belly-fins are united. There are two species, viz. 1. The C. latranus has its back covered with a smooth bony shell, which ends in a sharp spine, under which is the tail; but the back-fins are between the tail and the spine. It is a native of the East Indies. 2. The C. scolopax has a rough scabrous body, and a straight extended tail. It has two belly-fins, with four rays in each, and has no teeth. It is found in the Mediterranean.

CENTUMVIRI, in Roman antiquity, judges appointed to decide common causes among the people: they were chosen three out of each tribe; and though five more than an hundred, were nevertheless called centumviri, from the round number centum, an hundred.

CENTUNCULUS, in botany, a genus of the tetrandria monogyenia class. The calix consists of four segments; the corolla has four divisions, and open; the flamina are short; and the capsule has but one cell. There is only one species, viz. the minimus, or ballard pimpernel, a native of Britain.

CENTURION, among the Romans, an officer in the infantry, who commanded a century, or an hundred men.

The centurions held the first rank in the first cohort of a legion, and two of them the place of the two first hastati or pike-men: the first among the principes was also a centurion.

The centurion primipilus was the chief of the centurions: he was not under the command of any tribune, as all the rest were; he had four centuries under his direction, and guarded the standard and the eagle of the legion.

CENTURY, in a general sense, anything divided into or consisting of an hundred parts.

The Roman people, when they were assembled for the election of magistrates, enacting of laws, or deliberating upon any public affair, were always divided into centuries, and voted by centuries, in order that their suffrages might be the more easily collected; whence these assemблies were called centuria centuriantis. The Roman cohorts were also divided into centuries. See Centurion and Cohort.

CENTURY, in chronology, the space of one hundred years.

This method of computing by centuries is generally observed in church history, commencing from the time of our Saviour's incarnation; in which sense we say, the first century, the second century, &c.

CENTURIES OF MAGDEBURG, a famous ecclesiastical history, ranged into thirteen centuries, carried down to the year 1298, compiled by several hundred Prot- estants of Magdeburg, the chief of whom was Matthias Flacius Illyricus.

CENTUSSIS in Roman antiquity, a coin containing an hundred asses.

CEPAEA, in botany. See Sedum.

CEPA, in botany, the trivial name of a species of Allium. See Allium.

CEPEA in botany. See Sedum.

CEPHALANTHUS, in botany, a genus of the tetrandria monogyenia class. It has no common calix; the proper calix is tunnel-shaped; the receptacle is globular, and naked; and the seeds are downy. There is but one species, viz. the occidentalis, a native of America.

CEPHALIC, in a general meaning, signifies any thing belonging to the head.

CEPHALIE medicines are remedies for disorders of the head.

CEPHALIC veins, in anatomy. See p. 241.

CEPHALONIA, the capital of an island of the same name, situated in the Mediterranean, near the coast of.
CEPHUS, in astronomy, a constellation of the northern hemisphere.

CEPHALOPHARYNGEUS, in ichthyology, the trivial name of a species of Mugil. See Mugil.

CEPHALUS, in ichthyology, the trivial name of a species of Epirus. See Epirus.

CEPIALOPHARYNGEUS, in anatomy. See p. 302.

CEPHILUS, in ichthyology, the trivial name of a species of Mugil. See Mugil.

CEPIALOPHARYNGEUS, in anatomy. See p. 302.

CEPHUS, in ornithology, a synonime of a species of Moussow. See Moussow.

CEPHUS, in ornithology, a synonime of a species of Sitta. See Sitta.

CEPHUS, in ornithology, a synonime of a species of Phalacrocorax. See Phalacrocorax.

CEPHUS, in ornithology, a synonime of a species of Alcedo. See Alcedo.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Pica. See Pica.

CEPHUS, in ornithology, a synonime of a species of Sterna. See Sterna.

CEPHUS, in ornithology, a synonime of a species of Harpactes. See Harpactes.

CEPHUS, in ornithology, a synonime of a species of Alauda. See Alauda.

CEPHUS, in ornithology, a synonime of a species of Cypselus. See Cypselus.

CEPHUS, in ornithology, a synonime of a species of Sousa. See Sousa.

CEPHUS, in ornithology, a synonime of a species of Stercorarius. See Stercorarius.

CEPHUS, in ornithology, a synonime of a species of Tringa. See Tringa.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Sitta. See Sitta.

CEPHUS, in ornithology, a synonime of a species of Alcedo. See Alcedo.

CEPHUS, in ornithology, a synonime of a species of Phalacrocorax. See Phalacrocorax.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Pica. See Pica.

CEPHUS, in ornithology, a synonime of a species of Alauda. See Alauda.

CEPHUS, in ornithology, a synonime of a species of Cypselus. See Cypselus.

CEPHUS, in ornithology, a synonime of a species of Sousa. See Sousa.

CEPHUS, in ornithology, a synonime of a species of Stercorarius. See Stercorarius.

CEPHUS, in ornithology, a synonime of a species of Tringa. See Tringa.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Sitta. See Sitta.

CEPHUS, in ornithology, a synonime of a species of Alcedo. See Alcedo.

CEPHUS, in ornithology, a synonime of a species of Phalacrocorax. See Phalacrocorax.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Pica. See Pica.

CEPHUS, in ornithology, a synonime of a species of Alauda. See Alauda.

CEPHUS, in ornithology, a synonime of a species of Cypselus. See Cypselus.

CEPHUS, in ornithology, a synonime of a species of Sousa. See Sousa.

CEPHUS, in ornithology, a synonime of a species of Stercorarius. See Stercorarius.

CEPHUS, in ornithology, a synonime of a species of Tringa. See Tringa.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Sitta. See Sitta.

CEPHUS, in ornithology, a synonime of a species of Alcedo. See Alcedo.

CEPHUS, in ornithology, a synonime of a species of Phalacrocorax. See Phalacrocorax.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Pica. See Pica.

CEPHUS, in ornithology, a synonime of a species of Alauda. See Alauda.

CEPHUS, in ornithology, a synonime of a species of Cypselus. See Cypselus.

CEPHUS, in ornithology, a synonime of a species of Sousa. See Sousa.

CEPHUS, in ornithology, a synonime of a species of Stercorarius. See Stercorarius.

CEPHUS, in ornithology, a synonime of a species of Tringa. See Tringa.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Sitta. See Sitta.

CEPHUS, in ornithology, a synonime of a species of Alcedo. See Alcedo.

CEPHUS, in ornithology, a synonime of a species of Phalacrocorax. See Phalacrocorax.

CEPHUS, in ornithology, a synonime of a species of Anas. See Anas.

CEPHUS, in ornithology, a synonime of a species of Pica. See Pica.

CEPHUS, in ornithology, a synonime of a species of Alauda. See Alauda.

CEPHUS, in ornithology, a synonime of a species of Cypselus. See Cypselus.

CEPHUS, in ornithology, a synonime of a species of Sousa. See Sousa.

CEPHUS, in ornithology, a synonime of a species of Stercorarius. See Stercorarius.

CEPHUS, in ornithology, a synonime of a species of Tringa. See Tringa.
the ceremonies is absent. His salary is one hundred
and forty-one pounds thirteen shillings and four-
pence per annum.

Marshal of the Ceremonies is their officer, being sub-
ordinate to them both. His salary is one hundred
pounds per annum.

CERIUS, in botany. See CACTUS.

CERIGO, or CYTHEREA, in geography, an island of
the Archipelago, on the eastern coast of the Morea,
and fifty miles north of the island of Candia. It is
a mountainous country, between forty and fifty miles
in circumference, and situated in E. long. 23° 40',
and N. lat. 36°.

CERINTHE, in botany, a genus of the pentandria
monogynia class. The limbus of the corolla is tubu-
lar and ventricose, opening at the base. The seeds
are of two species, none of them natives of Britain.

CERINTHIANS, in church-history, Christian heretics,
followers of Cerinthus, who lived and published his
heresies in the time of the apostles themselves. They
did not allow that God was the author of the creatures,
but said that the world was created by an inferior
power; they attributed to this creator an only son,
but born in time, and different from the world: they
admitted several angels and inferior powers; they
maintained that the law and the prophets came not
from God, but from the angels; and that the God
of the Jews was only an angel: they distinguished be-
tween Jesus and Christ; and said, that Jesus was a
mere man, born, like other men, of Joseph and Ma-
ry; but that he excelled all other men in prudence
and wisdom; that Jesus being baptized, the Christ of
the suprême God, that is, the Holy Ghost, descend-
ed upon him; and that by the assistance of this Christ,
Jesus performed his miracles. It was partly to refute
this sect that St John wrote his gospel.

CERINTHOIDES, in botany. See Cerinthe.

CEROPEGIA, in botany, a genus of the pentandria
monogynia class. The limb of the corolla is conni-
vent; and the seeds are plumose. There are two
species, both natives of India.

CERRUS, in botany. See AEGILOPS.

CERTHA, in ornithology, a genus belonging to the
order of passer. The beak of this genus is arched,
slender, sharp, and triangular; the tongue is sharp at
the point; and the feet are of the walking kind, i.e.
having the toes open and unconnected. There are
23 species, viz. 1. The familiaris, or creeper, is grey
above and white underneath, with brown wings,
and ten white spots on the ten prime feathers. It is
a native of Europe, creeps up trees, lays about 20 eggs,
and feeds upon caterpillars and the eggs of insects.
2. The muraria, or wall-creeper, is ash-coloured,
with yellow spots on the wings. It frequents towers
and old walls, in the holes of which it builds its nest.
3. The pufilla, is grey above, and white below; the
eye-brows are white; the prime feathers of the wings
are brown, and white on the outer edge. It is a na-
tive of India. 4. The capenfis, is grey, with black-
ith wings, the outermost prime feathers of which are
edged with white. It is a native of the Cape of Good-
Hope. 5. The olivacea, is olive-coloured above, and
grey below, with the orbits of the eyes white. It is
found in Madagascar. 6. The currucaria is likewise
olive above, but yellowish below; and the prime wing-
feathers are equal. It is a native of Ceylon. 7. The
jugularis is greyish above, and yellowish below; the
throat is of a violet colour; and the two outermost
prime feathers of the wings are yellow at the points.
It is found in the Philippine Isles. 8. The carula
has a blue belt round the eyes; and the throat, and
prime wing and tail feathers are black. The bill is
very long. It is a native of Surinam. 9. The caya-
na is of a green shining colour above, and streaked
with white below. It is a native of Cayenne. 10.
The chalybeata is green and shining above; the breast
is red, and on the fore part of it there is an iron-
cooured belt. 11. The atra is green above; the breast
is red; the belly is white; and it has a short blue
tail. The above two species are found at the Cape
of Good Hope. 12. The spiza is green, with the
head and prime wing-feathers black. It is a native
of Brafil. 13. The sperata is purple above, and red
below; the head, throat, and tail, are violet. It is
found in the Philippine Isles. 14. The fenegelepis
is of a blackish violet colour; the top of the head and
throat are greenish, and the breast is red. It is a na-
tive of Senegal. 15. The gutturalis is greenish; the
throat is a shining green, and the breast is purple.
It is a native of Brafil. 16. The pinus is yellow be-
low, and olive above; the wings are blue, with two
white belts. It is a native of North America. 17.
The cruenta is blackish above, and white below; the
top of the head, the neck, and tail, are red. It is a
native of Bengal. 18. The flavola is black above,
and yellow below; the eye-brows, and the tops of the
outermost prime wing-feathers, are white. It is a na-
tive of America. 19. The pulchella has a green
shining body, and a red breast; the two intermediate
prime wing-feathers are very long. It is a native of
Senegal. 20. The famosa has the two intermediate
prime wing-feathers very long; the body is of a shin-
ing green; and the axillae of the wings are yellow.
It is found at the Cape of Good Hope. 21. The phil-
ippina has the two intermediate wing-feathers very
long, a greenish grey body, and yellowish underneath.
It is a native of the Philippine Isles. 22. The vio-
lacea has the two intermediate prime wing-feathers
very long, a shining violet-coloured body, and the
breast and belly are yellow. 23. The zeylonica has
a green head, an iron-coloured back, a yellow belly,
and the throat and tail are azure. It is a native of
Ceylon. 24. The cyna is blue, with a black belt
round the eyes; the shoulders, wings, and tail are
black, and the feet are red. It is a native of Brafil
and Cayenne. 25. The lenes is blue, with a red
belt over the breast. It is a native of Ceylon.
ceres, or Ceruss, white lead, a sort of calx of lead, made by expelling plates of that metal to the vapour of vinegar.

The best way of preparing it is the following: A glas-cucurbit is to be cut off in such a manner as to leave it a very long mouth; an alembic head of glas is to be fitted to this; some vinegar is to be put into the body, and a number of thin plates of lead are to be placed in the head in such a manner that they may stand somewhat erect: when the head is fitted on, the body is to be set in a gentle sand-heat for twelve hours; then unsetting the vessels, the receiver, which had been fitted to the nose of the head, will contain a sweet and Smyth liquor, nauseous and turbid, called the vinegar of lead, or the solution of lead; and the plates of lead, taken out of the head, will be found covered with a white dusty matter; this is cerufs; and if the operation be repeated, the whole lead will be in fine reduced to this state of cerufs.

Cerufs is used externally either mixed in ointments, or by sprinkling it on old gleetings and watery ulcers, and in many diseases of the skin. If, when it is reduced into a fine powder, it is received in with the breath in inspiration, and carried down into the lungs, it causes terrible athemes, that are almost incurable, and at last generally prove fatal: sad instances of the very pernicious effects of this metal are too often seen among those persons who work lead in any form, but particularly among the workers in white-lead.

The painters use it in great quantities, and, that it may be afforded cheap to them, it is generally adulterated with common whiting: the English and Dutch cerufs are very bad in this respect: the Venetian ought always to be used by apothecaries.

Ceruss of antimony, a medicine prepared by distilling powdered regulus of antimony with spirit of nitre, till no more fumes arise; what remains in the retort being pulverized and washed, makes the cerufs of antimony, which is esteemed a powerful diuretic.

Cervus, or Deer, in zoology, a genus of quadrupeds belonging to the order of pectora. The horns are solid, brittle, covered with a hairy skin, and growing from the top; they likewise fall off, and are renewed annually. There are eight fore-teeth in the under jaw, and they have no dog-teeth. The species of this genus are seven, viz. 1. The camelopardalis, with simple or unbranched horns, and the fore-feet remarkably longer than the hind feet. This is an un common animal, few of them having ever been seen in Europe. It is a native of Ethiopia, and is very mild and gentle: The head is like that of a fflag; its horns are blunt and about fix inches long. The neck resembles that of a camel, but much longer, being sometimes seven feet in length. The body is small, covered with white hair, and spotted with red. He is eighteen feet in length from the tail to the top of the head; and when he holds up his head, it is sixteen feet from the ground. He feeds principally on the leaves of trees.

2. The alices, or elk, has palmated horns, without any proper flem, and a flebby protruberance on the throat. This is the largest animal of the deer kind. At the fair of St Germain, at Paris, in the year 1752, a female elk was exhibited as a show. It was caught in the year 1749, in a foreft of Red Russia, belonging to a Khan of Tartary. The height was fix feet seven inches, the length ten feet, and the thickness eight. The hair was long, like that of a wild boer. The skin is said to refill the force of a gun bullet. The elk is a very swift animal; and he feeds upon leaves of alder, birch, willow, &c. When tamed, he devours large quantities of hay or bread. This animal is found in the northern woods of Europe, Asia, and America.
3. The elaphus, is a kind of elk, with cylindrical ramified horns, bent backwards. It is a native of the northern parts of Europe and Asia.

4. The tarandus, or rein-deer, is a native of Lapland, and the northern parts of Europe, Asia, and America. The horns are large, cylindrical, branched, and palmated at the tops. Two of the branches hang over the face. He is about the size of a buck, of a dirty whitish colour; the hairs of his skin are thick and strong. These animals are of great use to the Laplanders; they feed upon their flesh; they employ their finer in sewing the boards of sledges together, and their milk affords them good cheefe: They likewise make garments of their skins. The rein-deer are always employed in drawing sledges along the snowy mountains, where horses cannot travel. In a beaten track, they will drag a sledge twenty-five miles a day. When the animal is tired, his matter is in high repute with the luxurious. See Plate LXII.

5. The dama, or buck and doe, a well known animal, kept tame in parks; the horns are branched, compressed, and palmated at the top. It is a native of Europe. Their flesh, which goes by the name of venifon, is in high repute with the luxurious. See Plate LXII.

6. The capreolus, has ereft, cylindrical, branched horns, and forked at the top. It is called by some authors the Brazilian goat, and is a native of Europe and Asia.

7. The Guineenfs, is of a greyish colour, and black underneath. It is a native of Guinea; and the size and figure of its horns have not been hitherto described with any prccision.

Cervus volans, in zoology, a synonyme of a species of Lucaneus. See Lucaneus.

Cesaré, among logicians, one of the modes of the second figure of syllogisms; the minor propofition of which is an universal affirmative, and the other two universal negatives: Thus.

Ce No immoral books ought to be read.
SA But every obscene book is immoral.
RE Therefore no obscene book ought to be read.

Cessio bonorum, in Scots law. The name of that action by which an infolvent debtor may apply for liberation from prison, upon making over his whole real and personal estate to his creditors. See Scots Law, title, Sentences and their execution.

Cestrum, in botany, a genus of the pentandria digymia class. The involucre is tunnel-shaped; and the berry is unilocular. There are two species, both natives of America.

Cestus, among ancient poets, a fine embroidered girdle said to be worn by Venus, to which Homer ascribes the faculty of charming and conciliating love.

Cetaceous, an appellation given to fishes of the whale kind.

Cete, the name of Linnæus’s seventh order of mammalia, comprehending the Monodon, Baleña, Physeter, and Delphinus; see these articles.

Ceterach, in botany, the trivial name of a species of alpinium. See Alpinium.

Cette, a port-town of Languedoc, in France, situated on a bay of the Mediterranean, in E. long. 3° 16', and N. lat. 43° 25'.

Cetus, in astronomy, a constellation of the southern hemisphere, comprehending twenty-two stars in Ptolemy’s catalogue, twenty-one in Tycho’s, and in the British catalogue seventy-eight.

Ceyta, a city of the kingdom of Fez, in Africa, situated on the south side of the straits of Gibraltar, almost opposite to it: W. long. 6° 30', and N. lat. 25° 50'. It is a strong fortress, in the possession of the Spaniards.

Ceylon, an island in the Indian ocean, situated between 28° and 82° E. long. and between 6° and 10° N. lat. It is about two hundred and fifty miles long, and two hundred broad. The Dutch, who are in possession of all the sea-coast, monopolize all the cinnamon produced in the island, the king being obliged to keep in the centre of the island, in his capital of Candy.

Chablais, a country of Savoy, with the title of duchy.

Chaco, a large county of South America, situated between 18° and 25° S. lat.

Chærophyllum, or Chervil, in botany, a genus of the pentandria digynia class. The involucre is concave and reflected; the petals are cordated; and the fruit is smooth and oblong. The species are seven, only two of which are natives of Britain, viz. the fylvestre, or wild cicely, or cow-weed; and the rumulum, or wild chervil. The leaves of the chervil are gently aperient and diuretic, and at the same time grateful to the palate and stomach.

Chætodon, in ichthyology, a genus of fishes belonging to the order of thoraci. The teeth are very numerous, thick, setaceous, and flexile; The rays of the gills are six. The back-fins and the fin at the anus are fleshly and squamous. There are twenty-three species, distinguished from each other principally by the figure of the tail, and the number of spines in the back-fins.

Chaff-finch, in ornithology, the English name of a species of fringilla. See Fringilla.

Chagre, a fort at the mouth of a river of the same name, a little south of Porto Bello: W. long. 82°, and N. lat. 9° 50'.

Chain, a long piece of metal composed of several links or rings, engaged the one in the other. They are made of divers metals, some round, some flat, others square; some single, some double; and serve to so many uses, that it would be tedious to give a particular account of them all.

Chain is also a kind of measure in France, in the trade of wood for fuel: There are chains for wood by tale, for wood by the rope, for faggeots, for cleat wood, and for round ficks. There are also chains measuring the sheaves of all sorts of corn, particularly with regard to the payment of tythes; for measuring pottles of hay.
Chalk, and for measuring horses. All these are divided into feet, inches, hands, &c. according to the use they are designed for.

*Chain-shot*, two bullets with a chain between them. They are used at sea to shoot down yards or masts, and to cut the shrouds or rigging of a ship.

*Chain*, in surveying, a measure of length, made of a certain number of links of iron-wire, serving to take the distance between two or more places.

*Gunter’s chain* of 100 such links, each measuring 7½ inches, and consequently equal to 66 feet, or four poles. See Surveying.

*Chaise*, a sort of light, open chariot, or caless. See Chariot.

*Chalaza*, among naturalists, a white knotty fort of string at each end of an egg, formed of a plexus of the fibres of the membranes, whereby the yolk and white are connected together. See Egg.

*Chalcedony*, in natural history, a genus of semi-pellucid gems, of an even and regular tabulated texture, of a semi-opaque crystaline basis, and variegated with different colours, dispersed in form of mils and clouds, and, if nicely examined, found to be owing to an admixture of various kinds of earths, but imperfectly blended in the mass, and often visible in distinct molecules.

Of this genus there are a great many species, as the bluish-white chalcedony; the brownish-black chalcedony, or smokey jasper or capnitis of the ancients; and the yellow and red chalcedony.

All the chalcedonies give fire readily with steel, and make no effervescence with aqua-fortis.

*Chalices*, in zoology, the trivial name of a species lacerta. See Lacerta.

*Chaldea*, or *Chaldaic language*, that spoken by the Chaldeans, or people of Chaldea: It is a dialect of the Hebrew. See Hebrew.

*Chaldras*, or *Chalderon*, a dry English measure, consisting of thirty-six bushels, heaped up according to the sealed bushel kept at Guild-hall, London: but on shipboard, twenty-one chaldras of coals are allowed to the score.

The chaldras should weigh two thousand pounds.

*Chalk*, in natural history, the English name of the white, dry marle, with a dusty surface, found in hard masses, and called by authors creta, and terra creta.

Chalk thrown into water, raises a great number of bubbles, with a hissing noise, and slowly diffuses itself into an impalpable powder. It ferments more strongly with acids than any other earth, and burns to lime.

As a medicine, chalk deferves, perhaps, the highest estimate among the alkaline absorbents; nor is it less useful in many of the ordinary affairs of life. Its use in cleaning various utensils is well known; and it is in no small repute as a manure, especially for cold four lands; in which intention the soft unctuous chalk is most proper, as the dry, hard, and strong chalk is for lime. It is a great improver of lands, and will even change the very nature of them. However, it is most advivable to mix one load of chalk, with two or three of dung, mud, or fresh mould, whereby it will become a lasting advantage to the ground: The common allowance is fourteen loads of chalk to every acre.

*Black Chalk*, among painters, denotes a kind of ochreous earth, of a close structure, and fine black colour, used in drawing upon blue paper.

*Red Chalk*, an indurated clayey ochre, common in the colour-shops, and much used by painters and artists.

*Challons*, or *Challons on the Marne*, the capital of the Chal-lonoi, in the province of Champaign in France, situated eighty-two miles east of Paris, and thirty south-east of Reims: E. long. 4° 35', N. lat. 48° 55'. It is a bishop’s see.

*Challons on the Seine*, a city of Burgundy in France, thirty-two miles south of Dijon: E. long. 5°, N. lat. 46° 46’. It is the see of a bishop.

*Chalybeat*, in medicine, an appellation given to any liquid, as wine or water, impregnated with particles of iron or steel.

Dr Monro, professor of anatomy at Edinburgh, by pouring a tincture of galls into common water, and dissolving therein a small quantity of sal maris, adding some filings of iron, and oil of vitriol, procured a water exactly like the natural chalybeat water; and he is of opinion, that where these are not to be had, the artificial water may be made to answer all their intentions, according to its being more or less closely kept, or exposed in the air or heat, &c.

*Cham*, or *Khan*, a word of much the same import with king in English: It is the title of the sovereign princes of Tartary, and is likewise applied to the principal noblemen in Persia.

*Cham*, in geography, a town of the Bavarian palatinate, situated on a river of the same name, about twenty-five miles north-east of Ratibon; E. long. 13°, N. lat. 49° 15'.

*Chama*, in zoology, a genus of shell-fish belonging to the order of Vermes testacea. The shell is thick, and has two valves; it is an animal of the oyster kind. Linnaeus enumerates 14 species, principally distinguished by the figure of their shells.

*Chamaebatos*, or *Chamaebuxus*, in botany. See Rubus.

*Chamaecerasus*, in botany. See Lonicera.

*Chamaeclema*, in botany. See Hedera.

*Chamaecrista*, in botany. See Cassia.

*Chamaedaphne*, in botany. See Kalmia.

*Chamaedrys*, in botany. See Veronica.

*Chamaeleon*, in zoology, the trivial name of a species lacerta. See Lacerta.

*Chamaeleon*, in zoology, the trivial name of a species lacerta. See Lacerta.

*Chamaelimum*, or *Chamaelimum*, in botany, See Linum.

*Chamaemilum*, or *Chamaemilum*, in botany. See Matricaria.

*Chamaenerion*, in botany. See Epilobium.

*Chamaepitys*, or *Chamaepitys*, in botany. See Teucrium.

*Chamerhododendros*, or *Chamerhododendros*, in botany. See Azalea.

*Chamerops*, or *Humble Palm*, in botany, a genus ranged under the palmæ flabellifolis of Linnaeus. It is a native of Spain.
Capra Hircus,
or Common Goat.

Cervus Dama,
or Buck.

Caprimulgus,
or Goat Sucker.
Priev-Chamber. Gentlemen of the privy-chamber, are servants of the king, who are to wait and attend on him and the queen at court, in their diversions, &c. Their number is forty-eight under the lord-chamberlain, twelve of whom are in quarterly waiting, and two of these lie in the privy-chamber.

In the absence of the lord-chamberlain, or vice-chamberlain, they execute the king's orders: at coronations, two of them perfume the dukes of Aquitain and Normandy: and six of them, appointed by the lord-chamberlain, attend ambassadors from crowned heads to their audiences, and in public entries. The gentlemen of the privy-chamber were instituted by Henry VII.

Chamber, in policy, the place where certain assemblies are rendered of all the king's revenues, inventories, and two of these lie in the privy-chamber. Because the roof was painted with stars; the author of this was Henry VII.

Chamberlaine, an officer charged with the management and direction of a chamber. See Chamber, in policy.

There are almost as many kinds of chamberlains as chambers, the principal whereof are as follows.

Lord Chamberlain of Great Britain, the sixth great officer of the crown; to whom belongs livery and lodging in the king's court; and there are certain fees due to him from each archbishop or bishop, when they perform their homage to the king; and from all peers at their creation, or doing their homage. At the coronation of every king, he is to have forty ells of crimson velvet for his own robes. This officer, on the coronating-day, is to bring the king his shirt, coif, and wearing clothes; and after the king is dressed, he claims his bed, and all the furniture of his chamber, and the robes-royal and other suits, to be offered by the king, and the robes-royal and crown: he dresses and undresses the king on that day, waits on him before and after dinner, &c.

To this officer belongs the care of providing all things in the house of lords, in the time of parliament; to him also belongs the government of the palace of Westminster: he dispenses like wise of the sword of state, to be carried before the king, to what lord he pleases.
Lord Chamberlain of the household, an officer who has the oversight and direction of all officers belonging to the king's chambers, except the precinct of the king's bed-chamber.

He has the oversight of the officers of the wardrobe at all his majesty's houses, and of the removing wardrobes, or of beds, tents, reveals, music, comedians, hunting, meffengers, &c. retained in the king's service. He moreover has the oversight and direction of the serjeants at arms, of all physicians, apothecaries, surgeons, barbers, the king's chaplain, &c. and administers the oath to all officers above above. 

Other chamberlains are those of the king's court of exchequer, of North Wales, of Chester, of the city of London, &c. in which cases this officer is generally the receiver of all rents and revenues belonging to the place whereof he is chamberlain.

In the exchequer there are two chamberlains, who keep a controulment of the polls of receipts and exixus, and have certain keys of the treasury, records, &c.

Chamberlain of London keeps the city-money, which is laid up in the chamber of London: he also presides over the affairs of masters and apprentices, and makes free of the city, &c.

His office lasts only a year, but the custom usually obtains to re-chuse the same person, unless charged with any misdemeanor in his office.

Chamberry, the capital of the duchy of Savoy, in Italy, situated ninety miles north-west of Turin, and forty-five south of Geneva: E. long. 5° 45', N. lat. 45° 40'.

Chamois, or Chamois-goat, in zoology. See Capra.

Champaign, a province of France, bounded by Picardy on the north, by Lorrain on the east, by Burgundy on the south, and by the isle of France on the west. Its capital is Troyes.

Champain, or point Champain, in heraldry, a mark of dishonour in the coat of arms of him who kills a prisoner of war after he has cried quarter.

Champion, a person who undertakes a combat in the place or quarrel of another; and sometimes the word is used for him who fights in his own cause.

It appears that champions, in the just sense of the word, were persons who fought instead of those that, by custom, were obliged to accept the duel, but had a just excuse for disfrenching it, as being too old, infirm, or being ecclesiastics, and the like. Such causes as could not be decided by the course of common law, were often tried by single combat; and he who had the good fortune to conquer, was always reputed to have justice on his side. Champions who fought for interest only, were held infamous; these hired themselves to the nobility, to fight for them in cause of need, and did homage for their pension.

Champion of the king, a person whose office it is, at the coronation of our kings, to ride armed into Westminster-hall, while the king is at dinner there, and, by the proclamation of a herald, make challenge to this effect, viz. "That if any man shall deny the king's title to the crown, he is there ready to defend it in single combat, &c." Which done, the king drinks to him, and sends him a gilt cup, with a cover, full of wine, which the champion drinks, and has the cup for his see.

Chance, in a general sense, a term applied to events not necessarily produced as the natural effects of any proper foreknown cause. For the doctrine of chance and its application to games, &c. see Gaming.

Chance-meded, in law, is the accidental killing of a man, not altogether without the killer's fault, though without any evil intention; and is where one is doing a lawful act, and a person is killed thereby: For, if the act be unlawful, it is felony.

Chancel, a particular part of the fabric of a Christian church; or that part of the choir between the altar and the balustrade that incloses it, where the minister is placed at the celebration of the communion.

Chancellor, an officer supposed originally to have been a notary or scrivene under the emperors, and named cancellarius, because he sat behind a lattice, called in Latin cancellus, to avoid being crowded by the people.

According to a late treatise, the chancellor originally presided over a political college of secretaries, for the writing of treaties, and other public business; and the court of equity, under the old constitution, was held before the king and his council, in the palace, where one supreme court for business of every kind was kept. At first the chancellor became a judge, to hear and determine petitions to the king, which were preferred to him; and in the end, as business increased, the people addressed their suit to the chancellor, and not to the king; and thus the chancellor's equitable power, by degrees, commenced by prescription.

Lord high Chancellor of Great Britain, or Lord Keeper of the great seal, is the highest honour of the long robe, being made so per traditionem magni jihill, per dominum regem, and by taking the oaths: He is the first person of the realm next after the king, and princes of the blood, in all civil affairs; and is the chief administrator of justice, next the sovereign, being the judge of the court of chancery.

All other justices are tied to the strict rules of the law in their judgment: But the chancellor is invested with the king's absolute power, to moderate the written law, governing his judgment purely by the law of nature and conscience, and ordering all things according to equity and justice. In this respect, Staudford says, the chancellor has two powers, one absolute, the other ordinary: Meaning, that although by his ordinary power, in some cases, he must observe the forms of proceedings, as other inferior judges; yet in his absolute power, he is not limited by the law, but by conscience and equity.

The lord chancellor not only keeps the king's great seal; but also all patents, commissions, warrants, &c. from the king, are, before they are signed, perused by him: He has the disposition of all ecclesiastical benefices.
nefices in the gift of the crown under 20l. a year, in the king's books; and he is speaker of the house of lords. See Parliament.

Chancellor of a cathedral, an officer that hears lectures and lectures read in the church, either by himself or his vicar; to correct and let right the reader when he reads amiss; to inspect schools; to hear causes; apply the seal; write and dispatch the letters of the chapter; keep the books; take care that there be frequent preachings, both in the church and out of it; and all the office of preaching to whom he pleases.

Chancellor of the duchy of Lancaster, an officer appointed chiefly to determine controversies between the king and his tenants of the duchy-land, and otherwise to direct all the king's affairs belonging to that court. See Dutchy-court.

Chancellor of the exchequer, an officer who seals the comminations, and other matters in the gift of the crown under 20l. a year, in the king's books; and he is speaker of the house of lords. See Parliament.

He is always in commissary with the lord-treasurer, for the letting of crown-lands, &c. and has power, with others, to compound for forfeitures of lands, upon penal statutes: He has also great authority in managing the royal revenues, and in matters relating to the first-fruits.

Chancellor of the order of the garter, and other military orders, is an officer who seals the comminations and mandates of the chapter and assembly of the knights, keeps the register of their proceedings, and delivers acts thereof under the seal of their order.

Chancellor of an university, is he who seals the diplomas, or letters of degrees, provision, &c. given in the university.

The chancellor of Oxford is usually one of the prime nobility, chosen by the students themselves in convocation. He is their chief magistrate; his office is, during vita, to govern the university, preserve and defend its rights and privileges, convolve assemblies, and do justice among the members under his jurisdiction.

Under the chancellor is the vice-chancellor, who is chosen annually, being nominated by the chancellor, and elected by the university in convocation: He is always the head of some college, and in holy orders. His proper office is to execute the chancellor's power, to govern the university according to her statutes, to see that officers and students do their duty, that courts be duly called, &c. When he enters upon his office, he chooses four pro-chancellors out of the heads of the colleges, to execute his power in his absence.

The chancellor of Cambridge is also usually one of the prime nobility, and in most respects the same as that in Oxford; only he does not hold his office during vita, but may be elected every three years. Under the chancellor there is a commissary, who holds a court of record for all privileged persons and scholars under the degree of master of arts, where all causes are tried and determined by the civil and statute law, and by the customs of the university.

The vice-chancellor of Cambridge is chosen annually, by the senate, out of two persons nominated by the heads of the several colleges and hall.

Chancery, the grand court of equity and conscience, instituted to moderate the rigour of the other courts that are bound to the strict letter of the law.

The jurisdiction of this court is of two kinds, ordinary or legal, and extraordinary or absolute. The ordinary jurisdiction is that wherein the lord-chancellor, who is judge of this court, in his proceeding and judgment, is bound to observe the order and method of the common law; in such cases the proceedings, which were formerly in Latin, but now in English, are filed or enrolled in the petty-bag-office; and the extraordinary, or unlimited power, is that jurisdiction which the court exercises in causes of equity, wherein relief is to be had by bill and answer.

The ordinary court holds plea of recognizances acknowledged in the chancery, writs of fieri facias for repeal of the king's letters-patent, &c. also of all personal actions by or against any officer of the court, and of several offences and causes by act of parliament; all original writs, comminations of bankrupts, of charitable uses, of idiots, lunacy, &c. are issued hence.

The extraordinary court gives relief for and against infants, notwithstanding their minority; for and against married women, notwithstanding their overture. All frauds and deceit, for which there is no redress at common law; all breaches of trust, confidences and accidents, as to relieve obligors, mortgagors, &c. against penalties and forfeitures, where the intention was to pay the debt, are here remedied. But in all cases where the plaintiff can have his remedy at law, he ought not to be relieved in chancery; and a thing which may be tried by a jury, is not triable in this court.

The court of chancery will not retain a suit for anything under ten pounds value, except in causes of charity, nor for lands, &c. under forty shillings per annum. In this court all patents, mort-fores of commissions, deeds between parties touching lands and estates, treaties with foreign princes, &c. are sealed and enrolled. Out of it are issued writs to convene the parliament and convocation, proclamations and charters, &c. For the several officers belonging to the court of chancery, see the articles Master of the rolls, Masters in chancery, Clerk, &c.

Chandeliers in fortification, a kind of moveable parapet, consisting of a wooden frame, made of two upright flakes, about six feet high, with cross planks between them; serving to support fascines to cover the pioneers.

Channel, in geography, an arm of the sea, or a narrow sea between two continents, or between a continent and an island. Such are the Britifh channel, St George's channel, the channel of Constantinople, &c.

Chantilly, a village in France, about seven leagues from Paris, where there is a magnificent palace and fine forest belonging to the duke of Bourbon.

Chantor, a finger in the choir of a cathedral. The word is almost grown obsolete, chorister or singing-man being commonly used instead of it. All great chapters...
Chant or is used by way of excellence for the preceding.

CHANTRY, or Chauntary, a church or chapel, endowed with lands, for the maintenance of one or more priests to say masses for the souls of the donors. Hence, Chantry-rents, are rents still paid to the crown by the purchasers of those lands.

CHAOS, that confusion in which matter lay when newly produced out of nothing at the beginning of the world, before God, by his almighty word, had put it into the order and condition wherein it was after the six days creation.

CHAOS, in zoology, a genus of insects belonging to the order of vermes zoophyta. The body has no shell or covering, and is capable of reviving after being dead to appearance for a long time: It has no joints or external organs of sensation. There are five species, mostly obtained by infusions of different vegetables in water, and only discoverable by the microscope.

CHAPEAU, in heraldry, an ancient cap of dignity worn by dukes, being scarlet-coloured velvet on the outside, and lined with a fur. It is frequently borne above an helmet instead of a wreath, under gentlemen's crests.

CHAPEL, or CHAPEL, a place of divine worship, served by an incumbent under the denomination of a chaplain.

CHAPEL is also a name given to a printer's work-house; in which fene they lay, the laws of the chapel, the secrets of the chapel.

Knights of the Chapel, called also poor knights of Windsor, were instituted by Henry VIII. in his testament. Their number was at first thirteen, but has been since augmented to twenty-six. They assist in the funeral services of the kings of England: They are subject to the office of the canons of Windsor, and live on pensions assigned them by the order of the garter. They bear a blue or red cloak, with the arms of St George on the left shoulder.

CHAPELET, in the menage, a couple of stirrup leathers, mounted each of them with a stirrup, and joined at top in a sort of leather buckle, called the head of the chaplet, by which they are made fast to the pummel of the saddle, after being adjusted to the rider's length and bore. They are used both to avoid the trouble of taking up or letting down the stirrups, every time that the gentleman mounts on a different horse and saddle, and to supply the place of the academy faddles, which have no stirrups to them.

CHAPTERS, in architecture, the same with capitals.

Chapters, at this time, denote such articles as are delivered by the mouth of the justice in his charge to the inquest.

CHAPLAIN, an ecclesiastic who officiates in a chapel. See Chapel.

The king of Great Britain hath forty-eight chaplains in ordinary, usually eminent doctors in divinity, who wait four each month, preach in the chapel, read the service to the family, and to the king in his private oratory, and say grace in the absence of the clerk of the closet. Besides, there are twenty-four chaplains at Whitehall, fellows of Oxford or Cambridge, who preach in their turns, and are allowed 301. per annum each. According to a statute of Henry VIII. the persons vested with a power of retaining chaplains, together with the number each is allowed to qualify, is as follows: An archbishop, eight; a duke or bishop, five; marquess or earl, five; viscount, four; baron, knight of the garter, or lord-chancellor, three; a dutchess, marchioness, countess, baroness, the treasurer and comptroller of the king's house, clerk of the closet, the king's secretary, dean of the chapel, almoner, and master of the rolls, each of them two; chief justice of the king's bench, and warden of the cinque-ports, each one. All these chaplains maypurchase a licence or dispensation, and take two benefices with cure of souls. A chaplain must be retained by letters testimonial under hand and seal; for it is not sufficient that he serve as chaplain in the family.

CHAPLAIN of the order of Malta, otherwise called diaco, and clerk conventual, the second class of the order of Malta. The knights make the first rank.

CHAPLET, a string of beads used by the Roman Catholics, to count the number of their prayers. The invention of it is ascribed to Peter the hermit, who probably learned it of the Turks, as they owe it to the East-Indians.

Chaplets are sometimes called pater-noisters, and are made of coral, of diamonds, of wood, &c. The common chaplet contains fifty ave-marias, and five pater-noisters. There is also a chaplet of our Saviour, confisting of thirty-three beads, in honour of his thirty-three years living on earth, instituted by father Michael the Camaldulian.

CHAPPE', in heraldry, the dividing an escutcheon by lines drawn from the centre of the upper edge to the angles below, into three parts, the sections on the sides being of a different metal or colour from the rest.
CHAPTER, in ecclesiastical polity, a society or community of clergymen belonging to the cathedrals and collegiate-churches.

It was in the eighth century that the body of canons began to be called a chapter. The chapter of the canons of a cathedral were a flandering council to the bishop, and, during the vacancy of the see, had the jurisdiction of the diocese. In the earlier ages, the bishop was head of the chapter; afterwards abbots and other dignitaries, as deans, provosts, treasurers, &c., were preferred to this distinction. The deans and chapters had the privilege of chusing the bishops from the cathedrals, and placed secular canons in their room, tho' he thus regulated were called deans and chapters of the new foundation; such are Canterbury, Winchester, Ely, Carlisle, &c.

Chapter, in matters of literature, a division in a book-chapters had the privilege of chusing the bishops in the crown: and as the fame prince expelled the monks from the cathedrals, and placed secular canons in their room, tho' he thus regulated were called deans and chapters of the new foundation; such are Canterbury, Winchester, Ely, Carlisle, &c.

CHAPTER, in grammar, rhetoric, poetry, &c. Characters in geometry and trigonometry.

Characters in algebra, see p. 79, 80.

Characters used in astronony, viz.

\[ \text{Of the planets. See plate XXXIX.} \]

\[ \text{Of the signs. See plate XXXIX.} \]

\[ \text{Of the aspects.} \]

\[ \text{A. M. ante meridiem, before the sun comes upon the meridian.} \]

\[ \text{O. or N. noon.} \]

\[ \text{P. M. post meridiem, when the sun is past the meridian.} \]

Characters in commerce.

\[ \text{Do } \] ditto, the same

\[ \text{No } \] numero, or number

\[ \text{F} \] folio, or page

\[ \text{C or } \] hundred weight, of 112 pounds

\[ \text{q\textsuperscript{t}} \] quarters

\[ \text{S or } \] shillings

\[ \text{lb pound weight.} \]

Characters in chemistry. See Chemistry.

Characters in geometry and trigonometry.

\[ \text{1} \] the charaçon of $\equiv$ equiangular, or similar

\[ \triangle \] triangle $\perp$ equilateral

\[ \square \] square $\angle$ an angle

\[ \square \] rectangle $L$ right angle

\[ \bigcirc \] circle $\perp$ perpendicular

\[ \circ \] denotes a degree; thus $45^\circ$ implies 45 degrees.

\[ \text{a minute; thus, } 50^\circ, \text{ is 50 minutes. } \]

\[ \text{"\, \" denotes seconds, thirds, and seconds; and the same characters are used where the progressions are by tens, as is here by sixties.} \]

Characters in grammar, rhetoric, poetry, &c.

( ) parenthesis SS. T. D. doctor in divinity

[ ] crochets V. D. M. minister of the word of God

\[ \text{- hyphen} \]

\[ \text{` apostrophe} \]

\[ \text{\\textquotesingle emphasis or accent} \]

\[ \text{^ brief} \]

\[ \text{\textdaggerfis} \]

\[ \text{\textc{aret} and circumflex} \]

\[ \text{\textperiodcentered quotation} \]
Characters among the ancient lawyers, and in ancient inscriptions.

The Romans also expressed any number of thousands: so likewise $\overline{M}$ is one million, $\overline{MM}$ is two millions, &c.

Some modern writers have admitted variations in this method of notation; thus we find IIX expressing eight, IICIX eighty-nine, $\overline{A}$ or $\overline{V}$ denoting $1\overline{C}O$, and $\overline{X}$ or $\overline{A}$ standing for $\overline{C}O$; whence $\overline{X}$ ten thousand, $\overline{Y}$ twenty thousand.

The Greeks had three ways of expressing numbers: first, every letter, according to its place in the alphabet, denoted a number, from α one, to ω twenty-four. 2. The alphabet was divided into eight units, α one, β two, γ three, &c. into eight tens, ι ten, κ twenty, λ thirty, &c. and eight hundreds, σ one hundred, τ two hundred, ρ three hundred, &c. 3. I stood for one, Π five, Δ ten, Η a hundred, Χ a thousand, Μ ten thousand; and when the letter Π enclosed any of these, except I, it showed the enclosed letter to be five times its value; as Μ is fifty, ΜΜ is five hundred, ΜΜΜ is fifty thousand.

French Characters, used in the chamber of accounts, and by persons concerned in the management of the revenue, is, properly speaking, nothing else than the Roman numerals, in letters that are not majuscule: thus, instead of expressing fifty-six by LXVI, they denote it by smaller characters LVII.

Characters upon tomb-stones.

S. V. Silex viator, i.e. Stop traveller.

M. S. Memoriae sacrum, i.e. Sacred to the memory.

D. M. Dies manibus.

I H S. Jesus.

X. P. a character found in the catacombs, about the meaning of which authors are not agreed.

Character, in epic and dramatic poetry, that which distinguishes him from all others. See Epic, and dramatic compositions.

CHARADRIUS, in ornithology, a genus belonging to the order of grañæ. The beak is cylindrical and blunt; the nostrils are linear, and the feet have three toes. There are 12 species, viz. 1. The hiaçula, or sea-lark of Ray, has a black breast, a white breast along the front; the top of the head is brown; and the legs and beak are reddish. It is found on the shores of Europe and America. -2. The alexandrinus, or oriental dotterell, is of a brownish colour, with the fore-head, collar, and belly white; the prime tail-feathers on both sides are white; and the legs are black. It is a native of Egypt, and is much valued for its singing. It is about the size of a crow, and feeds on insects. 5. The moriæ, which inhabits the plains of Egypt, and feeds on infects. 4. The agygptius, has a black breast on the breast, white eye-brows, the prime tail-feathers streaked with black at the points, and bluish legs. It is found in the plains of Egypt, and feeds on infects. 5. The moriæ, has an iron coloured breast, a small white streak on the breast and eye-brows, and black legs. It is the dotterell of Ray, and a native of Europe. 6. The apricarius has a black belly; the body is brown.
brown, and variegated with white and yellow spots; and the legs are ash coloured. It is the spotted plover of Edwards, and a native of Canada. 7. The pluvialis, is black above, with green spots, white underneath, and the feet are ash-coloured. It is the green plover of Ray, and is a native of Europe. 8. The turdus, has a black breast, and a white front; the top of the head and the collar is black; and the neck and feet are bluish. It is a native of St Domingo. 9. The calidris, has black feet and a black bill; the rump is greyish; and the body is pure white below. It frequents the shores of Europe. 10. The cinclodesmus, or stone curlew of Ray, is of a grey colour, with two of the prime wing-feathers black, but white in the middle; it has a sharp bill, and ash-coloured feet. It is a native of Britain. 11. The luitantopus, is white below, with a black back, and a long black bill; the feet are red and very long. It is the autumnal dotterell of English authors, and frequents the sea-shores of Europe. 12. Spinifus, or the dotterell, or lapwing, has a black breast, legs, and wings; it has a crest on the hinder part of the head. It is of the size of a pigeon; the French call it dominicus, from the resemblance it has to the dres of a dominican monk: It is a native of Egypt.

CHARANTIA, in botany SeeMomordica.

CHARAX, in ichthyology. See Salmo.

CHARBON, in the menage, that little black spot on the head and the collar is black; and the body is pure white below. It frequents the shores of Europe. 10. The cinclodesmus, or stone curlew of Ray, is of a grey colour, with two of the prime wing-feathers black, but white in the middle; it has a sharp bill, and ash-coloured feet. It is a native of Britain. 11. The luitantopus, is white below, with a black back, and a long black bill; the feet are red and very long. It is the autumnal dotterell of English authors, and frequents the sea-shores of Europe. 12. Spinifus, or the dotterell, or lapwing, has a black breast, legs, and wings; it has a crest on the hinder part of the head. It is of the size of a pigeon; the French call it dominicus, from the resemblance it has to the dres of a dominican monk: It is a native of Egypt.

CHARCAS, the southern division of Peru, in South America, remarkable for the silver-mines of Potosi.

CHARCOAL, a kind of fuel, consisting of half burnt wood, much used by artificers of different professions; and that not only as fuel, but for polishing brasses or copper plates, &c.

The belt charcoal for common uses is that made of oak; but in the manufacture of gunpowder they commonly use charcoal made of alder.

CHARENTE, a river of France, which arising in the Limousin, runs westward by Angoulême and Saintes, falling into the bay of Biscay, opposite to the isle of Oleron.

CHARENTON, the name of two towns in France, the one upon the Marmaude, in the Bourbonois; the other in the Isle of France, near the confluence of the Marne with the Seine, about three miles south-east of Paris; E. long. 2° 30', and N. lat. 45° 45'.

CHARGE, in heraldry, is applied to the figures represented on the escutcheon, by which the bearers are distinguished from one another; and it is to be observed, that too many charges are not so honourable as fewer.

CHARGE of lead denotes a quantity of thirty-six pigs. See Pig.

CHARGE to enter heir, in Scots law, a writing passing under the signet, obtained at the instance of a creditor, either against the heir of his debtor, for fixing upon him the debt as representing the debtor, which is called a general charge; or, against the debtor himself, or his heir, for the purpose of vesting him in the right of any heritable subject to which he has made up no title, in order the creditor may attach that subject for payment of his debt, in the same manner as if his debtor or his heir were legally vested in it by service or otherwise. This last kind is called a special charge. See Scots Law, title, Appraisings and adjudications.

CHARGED, in heraldry, a shield carrying some impresa or figure, is said to be charged therewith; so also when one bearing, or charge, has another figure added upon it, it is properly said to be charged.

CHARIOT, a half coach, having only a seat behind, with a floor, at mott, before. See Coach.

The chariots of the ancients, chiefly used in war, were called by the several names bigae, trige, &c. according to the number of horses applied to draw them. Every chariot carried two men, who were probably the warrior and the charioteer; and we read of several men of note and valour employed in driving the chariot. When the warriors came to encounter in close fight, they alighted out of the chariot, and fought on foot; but when they were weary, which often happened, by reason of their armour, they retired into their chariot, and thence annoyed their enemies with darts and missive weapons. These chariots were made so strong, that they lasted for several generations.

Besides this fort, we find frequent mention of the currus falcati, or those chariots armed with hooks, or fcythes, with which whole ranks of soldiers were cut off together, if they had not the art of avoiding the danger; these were not only used by the Persians, Syrians, Egyptians, &c. but we find them among our British ancestors.

Triumphal Chariot was one of the principal ornaments of the Roman celebration of a victory.

The Roman triumphal chariot was generally made of ivory, round like a tower, or rather of a cylindrical figure; it was sometimes gilt at the top, and ornamented with crowns; and, to represent a victory more naturally, they used to stain it with blood. It was usually drawn by four white horses, but oftentimes by lions, elephants, tygers, bears, leopards, dogs, &c.

CHRISTIA, a festival of the ancient Romans, celebrated in the month of February, wherein the relations by blood and marriage met, in order to preserve a good correspondence; and that, if there happened to be any difference among them, it might be the more easily accommodated, by the good humour and mirth of the entertainment.

CHRISTITY, among divines, one of the three grand theological virtues, confinng in the love of God and of our neighbour, or the habit and disposition of loving God with all our heart, and our neighbour as ourselves.

Charity of St Hippolitus, a religious congregation founded, about the end of the XIVth century, by one Bernardin Alvarez, a Mexican, in honour of St. Hippolitus.
CHARTER, in Scots law, that writing which contains
the grant of a feudal subject to the vassal. See Scots
Law, tit. Of the constitution of heritable rights.

CHARLETON, an island at the bottom of Hudson's-
bay, in North America, subject to Great Britain:
W. long. 60° 50', and N. lat. 50° 16'.

CHARLETV, a strong town in the province of Na-
mur, in the Austrian Netherlands, situated on the ri-
ver Sambre, about nineteen miles west of Namur: E.
long. 4° 20', and N. lat. 50° 30'.

CHARLES's CAPE, a promontory of Virginia, in
North America, forming the northern head-land of
the sound that enters the bay of Chesapeake.

CHARLES's-CAVE, a promontory in the county of Cork, and
province of Munster in Ireland, situated at the mouth
of Kinsale harbour: W. long. 8° 20', and N. lat.
51° 31'.

CHARLES's-TOWN, the capital of South Carolina, in
North America, situated on a peninsula formed by
Ashley and Cooper rivers, the former of which is na-
vigable for ships twenty miles above the town: W.
long. 79° 30', and N. lat. 32° 30'.

CHARLES's-WAIN, in astronomy, seven stars in the con-
tellation called ura minor, or the great bear.

CHARLETON, an island at the bottom of Hudson's-
bay, in North America, subject to Great Britain:
W. long. 80°, and N. lat. 52° 30'.

CHARLEROY, a strong town in the province of Na-
mur, in the Austrian Netherlands, situated on the ri-
er Sambre, about eighteen miles west of Namur: E.
long. 4° 20', and N. lat. 50° 30'.

CHARLETON, a town of the province of Namur, in the
Austrian Netherlands, about eighteen miles south
of Namur: E. long. 4° 40', and N. lat. 50° 10'.

CHARLEMONT, also the name of a town in Ireland, situ-
tuated on the river Blackwater, in the county of Arm-
agh, and province of Ulster, about six miles south-
east of Dungannon: W. long. 6° 50', and N. lat.
50° 10'.

CHARTER, in law, a written instrument or evidence
of the grant of a feudal subject to the vassal. See Scots
Law, tit. Of the constitution of heritable rights.

CHARTOPHYLAX, the name of an officer of the
church of Constantinople, who attends at the door of
the rails when the sacrament is administered, and gives
notice to the priests to come to the holy table. He
represents the patriarch upon the bench, tries all eccle-
siastical causes, keeps all the marriage registers,
alights at the consecration of bishops, and presents the
bishop elect at the solemnity, and likewise all other
subordinate clergy. This office resembles in some
shape that of the bibliotecarius at Rome.

CHARTRES, a large city of France, in the province of Orleanois, situated on the river Eure, about forty-
two miles south-west of Paris: E. long. 1° 32', N. lat.
48° 27'. It is a bishop's see.

CHARTREUSE, or CHARTREUSE-GRAND, a cele-
brated monastery, the capital of all the convents of
the Carthusian monks, situated on a steep rock in the
middle of a large forest of fir-trees, about seven miles
north-east of Grenoble, in the province of Dauphine
in France: E. long. 5° 5', N. lat. 45° 20'. See CAR-
THUSIANS.

From this mother-convent, all the others of the same
order take their name; among which was the Chartreuse
of London, corruptly called the charter-houfe, now
converted into an hospital, endowed with a revenue of
600 l. per annum.

Here are maintained eighty decayed gentlemen, not
under fifty years of age: Alto forty boys are educated
and fitted either for the university or trades. Those
sent to the university, have an exhibition of 20 l. a
year for eight years; and have an immediate title to
nine church-livings in the gift of the governors of the
hospital, who are sixteen in number, all persons of the
first distinction, and take their turns in the nomination
of pensioners and scholars.

CHARYBDIS, a rock in the strait of Messina, between
Italy and Sicily, much celebrated in the writings of
ancient poets.

CHARYBDIS is also an appellation given by Dr Plot to
certain openings in the bottoms of the sea, whereby the
water is conveyed to the origin or sources of springs,
rivers, &c. such is Maelstrom, on the coast of Nor-
way, supposed to be. See MAELSTROM.

CHASING of gold, silver, &c. See Engraving.

CHASTE-LEIF. See Vitex.

CHATELET, the name of certain courts of justice es-
tablised in several cities in France. The grand cha-
telet at Paris, is the place where the prefidial or ordi-
nary court of justice of the provost of Paris is kept;
confisting of a prefidial, a civil chamber, a criminal
chamber, and a chamber of policy. The little chate-
telet is an old fort, now serving as a prifon.

CHATHAM, a port-town of Kent, adjoining to Ro-
chefer, situated on the river Medway, thirty miles
south-east of London: E. long. 40', N. lat. 51° 20'.

It is the principal station of the royal navy, furnished
with timber, rope-yards, and all manner of naval
stores, sufficient for the building and fitting out the
largest fleet.

CHATEAU-CAMBRESIS, a town of the Cambre-
sis, in the French Netherlands, situated on the river
Selle,
Selle, thirteen miles south-east of Cambray, E. long. 3° 25', N. lat. 50° 6'.

CHATTEAU DAUPHINE, a fortress situated on the frontier of Piedmont, in the province of Dauphine, but yielded to the king of Sardinia: E. long. 6° 40', N. lat. 43° 30'.

CHATTLES, in law, all sorts of goods moveable and immovable, except such as are in the nature of freehold.

CHATTIGAN, a port-town of India, in the province of Bengal.

CHATTELS, in law, all sorts of goods moveable and immovable.

CHECKY, in heraldry, is when the shield, or a part thereof, is divided or quartered, as a bordure, see.

CHECK, or Check-roll, a roll or book, wherein is contained the names of such persons as are attendants and in pay to the king, or other great personages, as clerks, &c.

Checks are of the first sort in any office.

CHECK, in anatomy, that part of the face situated below the eyes, on each side. See p. 305.

CHEESE, in anatomy, that part of the face situated below the eyes, on each side. See p. 305.

CHEESE, a fort of food, prepared of curdled milk, purged from the ferment or whey, and afterwards dried for use.

Physicians condemn the too free use of cheese, by reason it loads the stomach when new, and heats and inflames when old.

Every country has its places noted for this commodity: Thus Chester and Gloucester-cheese are famous in England; and the Parmesan cheese is in no less repute abroad, especially in France. This sort of cheese is entirely made of sweet cow's milk: But at Rochfort in Languedoc, they make cheese of ewe's milk; and in other places, it is usual to add goat or ewe's milk, in a certain proportion, to that of cow's.

There is likewise a kind of medicated cheese, made by intimately mixing the expressed juice of certain herbs, as sage, baum, mint, &c. with the curd, before it is fashioned into a cheese. The 100 weight of cheese pays on importation, 1 s. 3 1/2 d. and draws back, on exportation, 1 s. 1 1/4 d. at the rate of 6s. 8 d. The cheese of Ireland is prohibited to be imported.

CHEESE-RUNNET, in botany. See Gallium.

CHEGFORD, a market-town of Devonshire, about thirteen miles west of Exeter: W. long. 4° 9', N. lat. 56° 40'.

CHEIRANTHUS, in botany, a genus of the tetradynamia filiquea class. The germen has teeth-like glands on each side; the calix is close, and consists of two small leaves, gibus at the base; and the seeds are plain. There are thirteen species, only two of which are natives of Britain, viz. the chiuri, wall-flower, or wild chire, and the tricufpidatus, or sea stock-gillyflower. The leaves of the wall-flower are said to be cordial, anodyne, aperient, and emmenagogue, but are wholly neglected in practice.

CHEKAO, a kind of paste prepared by calcination and trituration from a hard stony substance, and afterwards wasting the powder in large quantities of fair water. The Chinese use the chekao in drawing the elegant figures we see in the wholly white china-ware, which they afterwards varnish in the common way. See China-ware.

CHEKAIM, a province of China, bounded by that of Nan-kin on the north, and by the ocean on the east.

CHELÆANCORORUM, in the materia medica. See Crab's Claws.

CHELIDONIUM, in botany, a genus of the polyandria monogynia class. The corolla has four petals;
the calyx consists of two leaves; and the pod is linear and unilocular. There are four species, three of which are natives of Britain, viz. the majus, or celandine; the glaucium, or yellow horned poppy; and the hybridum, or violet-coloured horned poppy. The leaves and root of the majus, or celandine, are stimulating, aperient, diuretic, and sudorific: It is peculiarly recommended in the flow kind of jaundice, where there are no symptoms of inflammation, and in dropsies.

Chelidonium lapidis, in natural-history, a stone said by the ancients to be found in the stomachs of young swallows, and greatly cried up for its virtues in the falling-sickness; but from their description, it appears to be only a species of lycodontes, or bufonitae. See Lycodontes, and Bufonitae.

CHELSE, a fine village situated on the northern bank of the river Thames, a mile westward of Westminister, remarkable for a magnificent hospital of invalids and old decrepit soldiers; and a pleasure-house, called Ranelagh, to which a great deal of fine company resort in summer.

CHELTENHAM, or Chiltenham, a market-town of Gloucester, seven miles north-east of Gloucester: W. long. 2° 10', N. lat. 51° 50'. It is chiefly remarkable for its mineral waters, of the same kind with those of Scarborough. See Scarborough.

CHEMISE, in fortification, the wall with which a bastion, or any other bulwark of earth, is lined for its greater support and strength: Or it is the solidity of the wall from the talus to the stone-row.

Fire-Che mise, a piece of linen cloth, steeped in a composition of oil of petrol, camphor, and other combustible matters, used at sea, to set fire to an enemy's vessel.
agrees in proportion to the degree of heat applied to it; the, consequence whereof is, that the same space now contains fewer particles of air than it did before. Cold again produces the contrary effect.

On this property which air has of being condensed and dilated by heat, its elasticity chiefly depends. For if air were forced by condensation into a less compass than it took up before, and then exposed to a very considerable degree of cold, it would remain quite inactive, without exerting such an effort as it usually makes against the depressing body. On the other hand, the elasticity of heated air arises only from hence, that being rarefied by the action of fire, it requires much more room than it occupied before.

Air enters into the composition of many substances, especially vegetable and animal bodies: For by analysing most of them such a considerable quantity thereof is extracted, that some naturalists have suspected it to be altogether delitute of elasticity when thus combined with the other principles in the composition of bodies. According to them, the efficacy of the elastic power of the air is so prodigious, and its force when compressed so excessive, that it is not possible the other component parts of bodies should be able to confine so much of it in that state of compulsion which it must needs undergo, if retaining its elasticity when pent up among them.

However that be, this elastic property of the air produces the most singular and important phenomena observable in the resolution and composition of bodies.

Of Water.

Water is a thing so well known, that it is almost needless to attempt giving a general idea of it here. Every one knows that it is a transparent, insipid substance, and usually fluid. We say it is usually so; for being exposed to a certain degree of cold, it becomes solid: Solidity therefore seems to be its most natural state.

Water exposed to the fire grows hot; but only to a limited degree, beyond which its heat never rises, be the force of fire applied to it ever so violent: It is known to have acquired this degree of heat by its boiling up with great tumult. Water cannot be made hotter, because it is volatile, and incapable of enduring the heat without being evaporated and entirely distilled.

If such a violent and sudden heat be applied to water as will not allow it time to exhale gently in vapours, as when, for instance, a small quantity thereof is thrown upon a metal in fusion, it is distilled at once with vast impetuosity, producing a most terrible and dangerous explosion. This surprising effect may be deduced from the instantaneous dilatation of the parts of the water itself, or rather of the air contained in it. Moreover, water enters into the texture of many bodies, both compound and secondary principles; but, like air, it seems to be excluded from the composition of all metals, and most minerals. For although an immense quantity of water exists in the bowels of the earth, moistening all its contents, it does not therefore follow, that it is one of the principles of minerals. It is only interposed between their parts; for they may be entirely robbed of it, without any fort of decomposition: Indeed it is not capable of an intimate connection with them.

Of Earth.

We observed, that the two principles above treated of are volatile; that is, the action of fire separates them from the bodies they help to compose. But earth is fixed, and, when absolutely pure, resists the utmost force of fire. So that, whatever remains of a body, after it hath been exposed to the power of the fiercest fire, must be considered as containing nearly all its earthly principle, and confiding chiefly thereof.

Earth therefore is a fixed principle which is permanent in the fire. There is reason to think it very difficult, if not impossible, to obtain the terrestrial principle wholly free from every other substance: For after our utmost endeavours to purify them, the earths we obtain from different compounds are found to have different properties, according to the different bodies from which they are procured; or else, if those earths be pure, we must allow them to be essentially different, seeing they have different properties.

Earth, in general, with regard to its properties, may be distributed into fusible and unfusible; that is, into earth that is capable of melting or becoming fluid in the fire, and earth that constantly remains in a solid form, never melting in the strongest degree of heat to which we can expose it.

The former is also called virtifiable, and the latter invirtifiable earth; because, when earth is melted by the force of fire, it becomes what we call glass, which is nothing but the parts of earth brought into nearer contact, and more closely united by the means of fusion. Perhaps the earth, which we look upon as incapable of vitrification, might be fused if we could apply to it a sufficient degree of heat. It is at least certain, that some earths, or stones, which separately resist the force of fire, so that they cannot be melted, become fusible when mixed together. Experience convinced Mr du Hamel, that lime-stone, that lime-stone and slate are of this kind. It is however undoubtedly true, that one earth differs from another in its degree of fusibility: And this gives ground to believe, that there may be a species of earth absolutely unvitrifiable in its nature, which, being mixed in different proportions with fusible earths, renders them difficult to melt.

Whatever may be in this, as there are earths which we are absolutely unable to vitrify, that is a sufficient reason of our division of them. Unvitrifiable earths seem to be porous, for they imbibe water; whence they have also got the name of absorbent earths.

Of Fire.

The matter of the sun, or of light, the phlogiston, fire, the sulphureous principle, the inflammable matter, are all of them names by which the element of fire is usually denoted. But it should seem, that an accurate distinction hath not yet been made between the different states in which it exists; that is, between the phenomena
of fire actually existing as a principle in the composition of bodies, and those which it exhibits when existing separately and in its natural state; nor have proper distinct apppellations been designed to it in those different circumstances. In the latter state we may properly give it the names of fire, matter of the sun, of light, and of heat; and may consider it as a substance composed of infinitely small particles, continually agitated by a most rapid motion, and of consequence effentially fluid.

This substance, of which the sun may be called the general reservoir, seems to flow incessantly from that source, diffusing itself over the world, and through all the bodies we know; but not as a principle, or essential part of them, since they may be deprived thereof, at least in a great measure, without suffering any decomposition. The greatest change produced on them, by its presence or its absence, is the rendering them fluid or solid; so that all other bodies may be deemed naturally solid; fire alone effentially fluid, and the principle of fluidity in others. This being presupposed, air itself might become solid, if it could be entirely deprived of the fire it contains; as bodies of most difficult fusation become fluid, when penetrated by a sufficient quantity of the particles of fire.

One of the chief properties of this pure fire is to penetrate easily into all bodies, and to diffuse itself among them with a sort of uniformity and equality: for if a heated body be contiguous to a cold one, the former communicates to the latter all its excess of heat, cooling in exact proportion as the other warms, till both come to have the very same degree of heat. Heat, however, is naturally communicable fonett to the upper parts of a body, and consequently, when a body cools, the under parts become fonett cold. It hath been observed, for instance, that the lower extremity of a heated body, freely suspended in the air, grows cold sooner than the upper; and that when a bar of iron is red-hot at one end, and cold at the other, the cold end is much sooner heated by placing the bar so that the hot end may be undermoft, than when that end is turned upward. The levity of the matter of fire, and the vicinity of the earth, may possibly be the causes of this phenomenon.

Another property of fire is to dilate all bodies into which it penetrates. This hath already been shewn with regard to air and water; and it produces the same effect on earth.

Fire is the most powerful agent we can employ to decompose bodies; and the greatest degree of heat producible by man, is that excited by the rays of the sun collected in the focus of a large burning-glares.

Of the Phlogiston.

From what hath been said concerning the nature of fire, it is evidently impossible for us to fix and confine it in any body. Yet the phenomena attending the combustion of inflammable bodies shew that they really contain the matter of fire as a constituent principle. By what mechanism then is this fluid, so subtile, so active, so difficult to confine, so capable of penetrating into every other substance in nature, so fixed as to make a component part of the most solid bodies? It is no easy matter to give a satisfactory answer to this question. But without pretending to guess the cause of the phenomenon, let us rest contended with the certainty of the fact, the knowledge of which will undoubtedly procure us considerable advantages. Let us therefore examine the properties of fire thus fixed and become a principle of bodies. To this substance, in order to distinguish it from pure and unfixed fire, the chemists have alligned the peculiar title of the Phlogiston, which is indeed no other than a Greek word for the inflammable matter; by which latter name, as well as by that of the sulphureous principle, it is also sometimes called. It differs from elementary fire in the following particulars. 1. When united to a body, it communicates to it neither heat nor light. 2. It produces no change in its state, whether of solidity or fluidity; so that a solid body does not become fluid by the accession of the phlogiston, and vice versa; the solid bodies to which it is joined being only rendered thereby more apt to be fus'd by the force of the culinary fire. 3. We can convey it from the body with which it is joined into another body, so that it shall enter into the composition thereof, and remain fixed in it.

On this occasion both these bodies, that which is deprived of the phlogiston and that which receives it, undergo very considerable alterations; and it is this last circumstance in particular that obliges us to distinguish the phlogiston from pure fire, and to consider it as the element of fire combined with some other substance, which serves it as a basis for constituting a kind of secondary principle. For if there were no difference between them, we should be able to introduce and fix pure fire itself where-ever we can introduce and fix the phlogiston: yet this is what we can by no means do, as will appear from experiments to be afterwards produced.

Hitherto chemists have never been able to obtain the phlogiston quite pure, and free from every other substance: for there are but two ways of separating it from a body of which it makes a part; to wit, either by applying some other body with which it may unite the moment it quits the former; or else by calcining and burning the compound from which you desire to sever it. In the former case, it is evident that we do not get the phlogiston by itself, because it only passes from one combination into another; and in the latter, it is entirely dissipated in the decomposition, so that no part of it can possibly be secured.

The inflammability of a body is an infallible sign that it contains a phlogiston; but from a body's not being inflammable, it cannot be inferred that it contains none; for experiments have demonstrated, that certain metals abound with it, which yet are by no means inflammable.

We have now delivered what is most necessary to be known concerning the principles of bodies in general. They have many other properties besides those above-mentioned; but we cannot properly take notice of them here, because they presuppose an acquaintance with some other things relating to bodies, of which we have hitherto said nothing, intending to treat of them in the sequel as occasion shall offer. We shall only observe in this place, that
that when animal and vegetable matters are burnt in such a manner as to hinder them from flaming, some part of the phlogiston contained in them unites intimately with their moist fixed earthy parts, and with them forms a compound that can be consumed only by making it red-hot in the open air, where it sparkles and wastes away, without emitting any flame. This compound is called a coal. We shall inquire into the properties of this coal under the head of oils; at present it suffices that we know in general what it is, and that it readily communicates to other bodies the phlogiston it contains.

A general View of the Affinities or elective Attractions that subsist between Bodies.

Before we can reduce compound bodies to the first principles above pointed out, we obtain, by analysing them, certain substances which are indeed more simple than the bodies they helped to compose, yet are themselves composed of our primary principles. They are therefore at one and the same time both principles and compounds; for which reason we shall call them by the name of secondary principles. Saline and oily matters chiefly constitute this class. But before we enter upon an examination of their properties, it is fit we lay before the reader a general view of what chemists understand by the relations or affinities of bodies; because it is necessary to know these, in order to a distinct conception of the different combinations we are to treat of.

All the experiments hitherto made concur in proving, that different bodies, whether principles or compounds, have such a mutual conformity, relation, affinity, or attraction, as disposes some of them to join and unite together, while they are incapable of contracting any union with others. This effect, whatever be its cause, will enable us to account for, and connect together, all the phenomena that chemistry produces. The nature of this universal affection of matter is laid down in the following propositions.

First, If one substance has any affinity or conformity with another, the two will unite together, and form one compound.

Secondly, All similar substances have an affinity with each other, and are consequently disposed to unite; as water with water, earth with earth, &c.

Thirdly, Substances that unite together lose some of their separate properties; and the compounds resulting from their union partake of the properties of those substances which serve as their principles.

Fourthly, The simper any substances are, the more perceptible and considerable are their affinities; whence it follows, that the less bodies are compounded, the more difficult it is to analyse them; that is, to separate from each other the principles of which they consist.

Fifthly, If a body confiff of two substances, and to this compound be presented a third substance that has no affinity at all with one of the two primary substances aforesaid, but has a greater affinity with the other than those two substances have with each other, there will ensue a decomposition, and a new union; that is, the third substance will separate the two compounding substances from each other, coalesce with that which has an affinity with it, form therewith a new combination, and disengage the other, which will then be left at liberty, and such as it was before it had contracted any union.

Sixthly, It happens sometimes that when a third substance is presented to a body consisting of two substances, no decomposition follows; but the two compounding substances, without quitting each other, unite with the substance presented to them, and form a combination of three principles; and this happens when that third substance has an equal, or nearly equal, affinity with each of the compounding substances. The same thing may also happen when the third substance hath no affinity with one of the compounding substances only. To produce such an effect, it is sufficient that one of the two compounding substances have to the third body a relation equal, or nearly equal, to that which it has to the other compounding substance with which it is already combined. Hence it follows, that two substances, which, when apart from all others, are incapable of contracting any union, may be rendered capable of incorporating together in some measure, and becoming parts of the same compound, by combining with a third substance with which each of them has an equal affinity.

Seventhly, A body, which of itself cannot decompose a compound consisting of two substances, because they have a greater affinity with each other than it has with either of them, becomes nevertheless capable of separating the two by uniting with one of them, when it is itself combined with another body having a degree of affinity with that one sufficient to compensate its own want thereof. In that case there are two affinities, and thence ensues a double decomposition, and a double combination.

These fundamental truths, from which we shall deduce an explanation of all the phenomena in chemistry, will be confirmed and illustrated by applying them to the several cases, of which our design in this treatise obliges us to give a circumstantial account.

Of Saline Substances in general.

If a particle of water be intimately united with a particle of earth, the result will be a new compound, which, according to our third proposition of affinities, will partake of the properties of earth and of water; and this combination principally forms what is called a saline substance. Consequentially every saline substance must have an affinity with earth and with water, and be capable of uniting with both or either of them, whether they be separate or mixed together; and accordingly this property characterizes all salts or saline substances in general.

Water being volatile, and earth fixed, salts in general are less volatile than the former, and less fixed than the latter; that is, fire, which cannot volatilize and carry off pure earth, is capable of rarefying and volatilizing a saline substance; but then this requires a greater degree of heat than is necessary for producing the same effects on pure water.

There are several sorts of salts, differing from one another in respect either of the quantity or the quality of the
Acids in general have a great affinity with earths: that with which they most readily unite is the unvitri- 
able earth to which we gave the name of absorbent earth. 
They seem not to act at all upon vitriable earths, such 
as sand; nor yet upon some other kinds of earths, at 
least while they are in their natural state. Yet the na-
ture of these earths may be in some measure changed, by 
making them red hot in the fire, and then quenching 
them suddenly in cold water: for by repeating this often 
they are brought nearer to the nature of absorbent earths, 
and rendered capable of uniting with acids.

When an acid liquor is mixed with an absorbent earth, 
for instance with chalk, these two substances instantly 
rush into union with so much impetuosity, that a great 
bullition is immediately produced, attended with con-
derable hissing, heat, and vapours, which rise the very 
instant of their conjunction.

From the combination of an acid with an absorbent 
earth there arises a new compound, which some chemists 
have called sal fulsum; because the acid by uniting with 
the earth loses its four tafts, and acquires another not 
unlike that of the common sea-salt used in our kitchens; 
yet varying according to the different sorts of acids and 
earths combined together. The acid at the same time 
loses its property of turning blue or violet vegetables red.

If we inquire what is become of its propensity to unite 
with water, we shall find that the earth, which of itself 
is not soluble in water, hath by its union with the acid 
acquired a facility of dissolving therein; so that our sal 
falsum is soluble in water. But, on the other hand, the 
acid hath, by its union with the earth, lost part of the 
affinity it had with water; so that if a sal salsum be 
dried, and freed of all superfluous humidity, it will re-
main in that dry solid form, instead of attracting the 
moisture of the air and running per deliquium, as the acid 
would do if it were pure and unmixed with earth.

Acids have likewise a great affinity with the phlogiston.

When we come to treat of each acid in particular, we 
shall examine the combinations of each with the phlo-
giston: they differ so widely from one another, and ma-
ny of them are so little known, that we cannot at present 
give any general idea of them.

Of Acids.

The simplest saline substance is that called an acid, on 
account of its taffe, which is like that of verjuice, forrel, 
vinegar, and other four things, which for the same rea-
on are also called acids. By this peculiar taffe are acids 
chiefly known. They have moreover the property of 
turning all the blue and violet colours of vegetables red, 
which distinguishes them from all other salts.

The form under which acids most commonly appear, 
is that of a transparent liquor; though solidity is rather 
their natural state. This is owing to their affinity with 
water; which is so great, that, when they contain but 
just as much of it as is necessary to constiute them salts, 
and consequently have a solid form, they rapidly unite 
therewith the moment they come into contact with it: 
and as the air is always loaded with moisture and aqueous 
vapours, its contact alone is sufficient to liquify them; 
beacause they unite with its humidity, imbibe it greedily, 
and by that means become fluid. We therefore say, they 
attract the moisture of the air. This change of a salt 
from a solid to a fluid state, by the sole contact of the 
air, is also called deliquium; so that when a salt changes 
in this manner from a solid into a fluid form, it is said to 
run per deliquium. Acids being the simplest species of 
SALINES bodies, their affinity with different substances are 
stronger than those of any other sort of salt with the same 
substances; which is agreeable to our fourth proposition 
concerning affinities.

Of Alkalis.

Alkalis are saline combinations in which there is a 
greater proportion of earth than in acids. The principal 
arguments that may be adduced to prove this fat are 
these: First, if they be treated in the manner propoed 
above for analysing saline substances, we obtain from them 
a much greater quantity of earth than we do from acids. 
Secondly; by combining certain acids with certain earths 
we can produce alkalis; or at least such saline compounds 
as greatly ressemble ahem. Our third and last argument 
is drawn from the properties of those alkalis which, when 
used and pure and undiluted with any other principle, have 
less affinity with water than acids have, and are also 
more fixed, reti-ing the utmost force of fire. On this 
account it is that they have obtained the title of fixed, 

Though
Though fixed alkalies, when dry, sustain the utmost violence of fire without being driven off in vapours, it is remarkable, that, being boiled with water in an open vessel, considerable quantities of them rise with the steam; an effect which must be attributed to the great affinity between these two substances, by means whereof water communicates some part of its volatility to the fixed salt.

Alkalies freed of their superfluous humidity by calcination attract the moisture of the air, but not so strongly as acids: so that it is easier to procure and preserve them in a solid form.

They flow in the fire, and are then capable of uniting with vitrifiable earths, and of forming therewith true glasses; which, however, will partake of their properties, if they be used in sufficient quantity.

As they melt more readily than vitrifiable earths, they facilitate its fusion: so that a weaker fire will reduce it to glass when a fixed alkali is joined with it, than will melt it without that addition.

Such an alkali, which is acid and fiery, and by the properties they possess of turning blue or violet vegetables green; particularly the eyes of violets.

Their affinity with acids is greater than that of absorbent earths; hence, if a fixed alkali be presented to a combination of an acid with an absorbent earth, the earth will be separated from the acid by the alkali, and a new union between the acid and the alkali will take place. This is both an instance and a proof of our fifth proposition concerning affinities.

If a pure alkali be presented to a pure acid, they rush together with violence, and produce the same phenomena as were observed in the union of an absorbent earth with an acid, but in a greater and more remarkable degree.

Fixed alkalies may in general be divided into two sorts: one of these hath all the above recited properties; but the other possesseth some that are peculiar to itself. We shall consider this latter sort more particularly under the head of sea-falt.

**Of Neutral Salts.**

The acid and the alkali thus uniting, mutually rob each other of their characteristic properties; so that the compound resulting from their union produces no change in the blue colours of vegetables, and has a tincture which is neither purple nor acrid, but saltish. A saline combination of this kind is for that reason named salutans, sal medium, or a neutral salt.

It must be observed, that in order to make these salts perfectly neutral, it is necessary that neither of the two saline principles of which they are compounded be predominant over the other; for in that case they will have the properties of the prevailing principle. The reason is this: neither of these saline substances can unite with the other but in a limited proportion beyond which there can be no further coalition between them. The action by which this perfect union is accomplished is termed saturation; and the instant when such proportions of the two saline substances are mixed together, that the one is incorporated with as much of the other as it can possibly take up, is called the point of saturation.

The point of saturation is known to be obtained, when, after repeated affusions of an acid in small quantities to an alkali, or an absorbent earth, we find those phenomena cease, which in such cases constantly attend the combination of union, namely, effulution, hissing, &c. and we may be assured the saturation is complete when the new compound hath neither an acid nor an acrid tincture, nor in the least changes the blue colours of vegetables.

Neutral salts have not so great an affinity with water as either acids or alkalies have, because they are more compounded; for we observed before, that the affinities of the most compound bodies are generally weaker than those of the most simple. In consequence hereof few natural salts, when dried, attract the moisture of the air; and those that do, attract it more slowly and in less quantity than either acids or alkalies do.

All neutral salts are soluble in water; but more or less readily, and in a greater or smaller quantity, according to the nature of their component principles.

Water made boiling hot dissolves a greater quantity of those salts which do not attract the moisture of the air, than when it is cold; and indeed it must be boiling hot to take up as much of them as it is capable of dissolving: but as for those which run in the air, the difference is imperceptible.

Some neutral salts have the property of shooting into crystals, and others have it not.

The nature of crystallization is this: Water cannot dissolve, nor keep in solution, more than a determinate quantity of any particular salt; when therefore such a quantity of water is evaporated from the solution of a salt capable of crystallization, that the remainder contains just as much salt as it can dissolve, then by continuing the evaporation the salt gradually recovers its solid form, and concretes into several little transparent masses called crystals. These crystals have regular figures, all differing from one another according to the species of salt of which they are formed. Different methods of evaporating saline solutions have different effects on the figure and regularity of the crystals; and each particular sort of salt requires a peculiar method of evaporation to make its crystals perfectly regular.

A solution of salt designed for crystallization is usually evaporated by means of fire to a pellicle; that is, till the salt begin to concrete; which is perceived by a kind of thin dark film that gathers on the surface of the liquor, and is formed of the crystallized particles of salt. When this pellicle appears, the solution is suffered to cool, and the crystals form therein smaller or larger according to the fort of salt in hand. If the evaporation be carried on briskly to perfect dryness, no crystals will be formed, and only an irregular mass of salt will be obtained.

The reasons why no crystals appear when the evaporation is hastily performed, and carried on to dryness, are, first, that the particles of salt, being always in motion while the solution is hot, have not time to exert their mutual affinities, and to unite together as crystallization requires: secondly, that a certain quantity of water enters into the very composition of crystals; which is therefore absolutely necessary to their formation, and in a greater
greater or smaller proportion according to the nature of the salt.

If these crystallized salts be exposed to the fire, they
first part with that moisture which is not necessary to a
fossilization, and which they retained only by means of
their crystallization; afterwards they begin to flow,
but with different degrees of fusibility.

It must be observed, that certain salts melt as soon as
they are exposed to the fire; namely, those which retain
a great deal of water in crystallizing. But this fluid
which they so readily acquire must be carefully distin-
guished from actual fusion; for it is owing only to their
superfluous humidity, which heat renders capable of dis-
folving and liquifying them; so that when it is evapo-
rated, the salt ceases to be fluid, and requires a much
greater degree of fire to bring it into real fusion.

The neutral salts that do not crystallize may indeed be
dried by evaporating the water which keeps them fluid;
but by becoming solid they acquire no regular form;
they again attract the moisture of the air, and are there-
by melted into a liquor. These may be called liques-
cent salts.

Most of the neutral salts, that consist of an acid joined
with a fixed alkali, or with an absorbent earth, are
themselves fixed and resist the force of fire; yet several
of them, if they be dissolved in water, and the solution
bulled and evaporated, will fly off along with the leams.

Of the several Sorts of Saline Substances.

1. Of the Universal, or Vitriolic Acid.

The universal acid is so called, because it is in fact
the acid which is most universally diffused through all
natures, in waters, in the atmosphere, and in the bowels
of the earth; but it is seldom pure; being almost always
combined with some other substance. That from
which we obtain it, with most ease, and in the greatest
quantity, is vitriol; and this is the reason why it is called
the vitriolic acid; the name by which it is best
known.

When the vitriolic acid contains but little phlegm, yet
even to give it a fluid form, it is called oil of vitriol;
on account of a certain unctuous belonging to it.

If the vitriolic acid contain much water, it is then
called spirit of vitriol. When it does not contain en-
ough to render it liquid, and so is in a solid form, it is
named the icy oil of vitriol.

When oil of vitriol, highly concentrated, is mixed
with water, they rush into union with such an impetu-
sity, that, the moment they touch each other, there arifes
a hissing noise, like that of red-hot iron plunged in cold
water, together with a very considerable degree of heat
proportioned to the degree in which the acid was con-
centrated.

If instead of mixing this concentrated acid with water,
you only leave it exposed to the air for some time, it
attracts the moisture thereof, and imbibles it most gree-
dly. Both its bulk and its weight are increased by this
accision; and if it be under an icy form, that is, if it
be concreted, the phlegm thus acquired will soon resolve
it into fluid.

The addition of water renders the vitriolic acid, and
indeed all other acids, weaker in one sense; which is,
that when they are very aqueous, they leave on the
tongue a much fainter taste of acidity, and are less ac-
tive in the solution of some particular bodies. But that
occasions no change in the strength of their affinities, but
in some cases rather enables them to dissolve several sub-
stances which, when well dephlegmated, they are not
capable of attacking.

The vitriolic acid combined to the point of saturation
with a particular absorbent earth, well known, forms a
neutral salt that crystallizes. This salt is called alum,
and the figure of its crystals is that of an octahedron or
solid of eight sides. These octahedra are triangular py-
ramids, the angles of which are so cut off that four of
the surfaces are hexagons, and the other four triangles.

There are several sorts of alum, which differ accord-
ing to the earths combined with the vitriolic acid. Alum
dissolves easily in water, and in crystallization retains a
considerable quantity of it; which is the reason that
being exposed to the fire it readily melts, swelling and
puffing up as its superfluous moisture exhales. When
that is quite evaporated, the remainder is called burnt
alum, and is very difficult to fuse. The acid of the alum
is partly digested by this calcination. Its taste is salty,
with a degree of roughness and alkonicity.

The vitriolic acid combined with certain earths forms a
kind of neutral salt called felenites, which crystallizes
in different forms according to the nature of its earth.
There are numberless springs of water infected with dis-
folved felenites; but when this salt is once crystallized,
it is exceedingly difficult to dissolve it, in water a second
time. For that purpose a very great quantity of water is
necessary, and moreover it must boil; for, as it cools,
much of the dissolved felenites takes a solid form, and
falls in a powder to the bottom of the vessel.

If an alkali be presented to the felenites, or to alum,
these salts will be thereby decomposed; that is, the
acid will quit the earths, and join the alkali, with
which it hath a greater affinity. And from this con-
junction of the vitriolic acid with a fixed alkali there re-
results another sort of neutral salt, which is called arca-
num duplicatum, sal de duobus, and vitriolated tartar,
because one of the fixed alcalis most in use is called salt
of tartar.

Vitriolated tartar is almost as hard to dissolve in wa-
ter as the felenites. It shoots into eight-sided crystals,
having the apices of the pyramids pretty obtuse. Its
taste is saltish, inclining to bitter; and it decrepitates
on burning coals. It requires a very great degree of
fire to make it flow.

The vitriolic acid is capable of uniting with the phlo-
giton, or rather it has a greater affinity with it than with
any other body; whence it follows, that all compounds
of which it makes a part may be decomposed by means
of the phlogiston.

From the conjunction of the vitriolic acid with the
phlogiston arises a compound called mineral sulphur, be-
cause it is found perfectly formed in the bowels of the
earth. It is also called sulphur vivum, or simply sul-
phur.
Sulphur is absolutely insoluble in water, and incapable of contracting any sort of union with it. It melts with a very moderate degree of heat, and sublimes in fine light downy tufts called flowers of sulphur. By being thus sublimed it suffers no decomposition; let the operation be repeated ever so often; so that sublimed sulphur, or flower of sulphur, hath exactly the same properties as sulphur that has never been sublimed.

If sulphur be exposed to a brisk heat in the open air, in takes fire, burns, and is wholly consumed. This deflagration of sulphur is the only means we have of decomposing it, in order to obtain its acid in purity. The phosphogen is destroyed by the flame, and the acid exhalés in vapours; these vapours collected have all the properties of the vitriolic acid, and differ from it only as they still retain some portion of the phosphogen; which, however, soon quits them of its own accord, if the free access of the common air be not precluded.

The portion of phosphogen retained by the acid of sulphur is much more considerable when that mineral is burnt gradually and slowly: in that case the vapours which rise from it have such a penetrating odour, that they instantaneous suffocate any person who draws in a certain quantity of them with his breath. These vapours constitute what is called the volatile spirit of sulphur. There is reason to think this portion of phosphogen which the acid retains is combined therewith in a manner different from that in which these two are united in the sulphur itself; for nothing but actual burning is capable of separating the vitriolic acid and the phosphogen, which by their union form sulphur; whereas in the volatile spirit of sulphur they separate spontaneously when exposed to the open air; that is, the phosphogen flies off and leaves the acid, which then becomes in every respect similar to the vitriolic acid.

That the volatile spirit of sulphur is a compound, appears evidently from hence, that whenever the vitriolic acid touches any substance containing the phosphogen, provided that phosphogen be disengaged or opened to the air when it is fuscd by the action of fire.

If sulphur be exposed to a brisk heat in the open air, in takes fire, burns, and is wholly consumed. This deflagration of sulphur is the only means we have of decomposing it, in order to obtain its acid in purity. The phosphogen is destroyed by the flame, and the acid exhalés in vapours; these vapours collected have all the properties of the vitriolic acid, and differ from it only as they still retain some portion of the phosphogen; which, however, soon quits them of its own accord, if the free access of the common air be not precluded.

The portion of phosphogen retained by the acid of sulphur is much more considerable when that mineral is burnt gradually and slowly: in that case the vapours which rise from it have such a penetrating odour, that they instantaneous suffocate any person who draws in a certain quantity of them with his breath. These vapours constitute what is called the volatile spirit of sulphur. There is reason to think this portion of phosphogen which the acid retains is combined therewith in a manner different from that in which these two are united in the sulphur itself; for nothing but actual burning is capable of separating the vitriolic acid and the phosphogen, which by their union form sulphur; whereas in the volatile spirit of sulphur they separate spontaneously when exposed to the open air; that is, the phosphogen flies off and leaves the acid, which then becomes in every respect similar to the vitriolic acid.

That the volatile spirit of sulphur is a compound, appears evidently from hence, that whenever the vitriolic acid touches any substance containing the phosphogen, provided that phosphogen be disengaged or opened to the air when it is fuscd by the action of fire.

Vol. II. No. 33.

Sulphur has less affinity than any acid with the fixed alkalis; and therefore liver of sulphur may be decomposed by any acid whatever; which will unite with the fixed alkali, form therewith a neutral salt, and separate the sulphur.

If liver of sulphur be dissolved in water, and an acid poured thereon, the liquor, which was transparent before, infantly turns to an opaque white; because the sulphur, being forced to quit its union with the alkali, lores at the same time the property of dissolving in water, and appears again in its own opaque form. The liquor thus made white by the sulphur is called milk of sulphur.

If this liquor be suffered to stand still for some time, the particles of sulphur, now most minutely divided, gradually approach each other, unite, and fall insensibly to the bottom of the vessel; and then the liquor recovers its transparency. The sulphur thus deposited on the bottom of the vessel is called the magistery or precipitate sulphur. The names of magistery and precipitate are also given to all substances whatever that are separated from another by this method; which is the reason that we use the expression of precipitating one substance by another, to signify the separating one of them by means of the other.

3. Of the Nitrous Acid.

The nitrous acid combined with certain absorbent earths, such as chalk, marle, boles, forms neutral salts which do not crystallize; and which, after being dried, run in the air per deliquium.

All those neutral salts which consist of the nitrous acid joined to an earth, may be decomposed by a fixed alkali, with which the acid unites, and forms the earth; and from this union of the nitrous acid with a fixed alkali results a new neutral salt, which is called nitre, or salt-petre. This latter name signifies the salt of stones; and in fact, nitre is extracted from the stones and platers, in which it forms, by boiling them in water saturated with a fixed alkali.

Nitre shoots in long crystals adhering sideways to each other; it has a faintish taste, which produces a sensation of cold on the tongue.

This salt easily dissolves in water; which, when it boils, takes up still a greater quantity thereof.

It flows with a pretty moderate degree of heat, and continues fixed therein: but being urged by a brisk fire, and in the open air, it lets go some part of its acid, and indeed flies off itself in part.

The most remarkable property of nitre, and that which characterizes it, is its fulmination or explosion; the nature of which is as follows:

When nitre touches any substance containing a phosphogen, and actually ignited, that is, red hot, it bursts out into a flame, burns, and is decomposed with much noise.

In this deflagration the acid is dissipated, and totally separated from the alkali, which now remains by itself.

Indeed the acid, at least the greatest part of it, is by this means quite destroyed. The alkali which is left when nitre is decomposed by deflagration, is called in general...
general fixed nitre, and, more particularly, nitre fixed by such and such a substance as was used in the operation. But if nitre be dephlegmated with an inflammable substance containing the vitriolic acid, as sulphur, for instance, the fixed salt produced by the dephlegmation is not a pure alkali, but retains a good deal of the vitriolic acid, and, by combining therewith, hath now formed a neutral salt.

The reason why nitre flames, and is decomposed in the manner above mentioned, when it comes in contact with a phlogiston properly circumstanced, is, that the nitrous acid, having a greater affinity with the phlogiston than with the fixed alkali, naturally quits the latter to join with the former, and so produces a kind of sulphur, differing probably from the common sulphur, formed by the vitriolic acid, in that it is combustible to such a degree, as to take fire and be consumed in the very moment of its production; so that it is impossible to prevent its being thus destroyed, and consequently impossible to save it. In support of this opinion let it be considered, that the concurrence of the phlogiston is absolutely necessary to produce this dephlegmation, and that the matter of pure fire is altogether incapable of effecting it: for though nitre be exposed to the most violent degree of fire, even that in the focus of the most powerful burning-glass, it will not flame; nor will that effect ever happen till the nitre be brought into contact with a phlogiston properly so called, that is, the matter of fire existing as a principle of some body; and it is moreover necessary that this phlogiston be actually on fire, and agitated with the igneous motion, or else, that the nitre itself be red-hot, and so penetrated with fire as to kindle any inflammable matter that touches it.

This experiment, among others, helps to shew the distinction that ought to be made between pure elementary fire, and fire become a principle of bodies to which we have given the name of phlogiston.

Before we leave this subject, we shall observe, that nitre dephlegmated only with such substances as contain the phlogiston in its simplest and purest form, such as charcoal, sulphur, and the metallic substances; and that, though it will not dephlegmate without the addition of some combustible matter, it is nevertheless the only known body that will burn, and make other combustibles burn with it, in cloce vessels, without the admission of fresh air.

The nitrous acid hath not so great an affinity with earths and alkalis as the vitriolic acid hath; whence it follows, that the vitriolic acid decomposes all neutral salts arising from a combination of the nitrous acid with an earth or an alkali. The vitriolic acid expells the nitrous acid, unites with the substance which served it for a basis, and therewith forms a neutral salt, which is an alum, a felenites, or a vitriolated tartar, according to the nature of that basis.

The nitrous acid, when thus separated from its basis by the vitriolic acid, is named spirit of nitre, or aqua fortis. If it be dephlegmated, or contain but little subtileous water, it exhales in reddish vapours; these vapours being condensed and collected, form a liquor of a brownish yellow, that incessantly emits vapours of the same colour, and of a pungent disagreeable smell. These characters have procured it the names of smoking spirit of nitre, and yellow aqua fortis. This property in the nitrous acid of exhaling in vapours, shews it to be less fixed than the vitriolic acid; for the latter, though ever so thoroughly dephlegmated, never yields any vapours, nor has it any smell.

3. Of the Acid of Sea-salt.

The acid of sea-salt is so called, because it is in fact obtained from such sea-salt as is used in our kitchens. It is not certainly known in what this acid differs from the vitriolic and the nitrous, with regard to its constituent parts.

When it is combined with absorbent earths, such as lime and chalk, it forms a neutral salt that does not crystallize; and, when dried, attracts the moisture of the air. If the absorbent earth be not fully saturated with the marine acid, the salt thereby formed has the properties of a fixed alkali: And this is what made us say, when we were on the subject of those salts, that they might be imitated by combining an earth with an acid. The marine acids, like the reft, hath not so great an affinity with earths as with fixed alkalis.

When it is combined with the latter, it forms a neutral salt which shoots into cubic crystals. This salt is inclined to grow moist in the air, and is consequently one of those which water dissolves in equal quantities, at least as to fent, whether it be boiling hot or quite cold.

The affinity of this acid with alkalis and absorbent earths is not so great as that of the vitriolic and nitrous acids: Whence it follows, that, when combined therewith, it may be separated from them by either of those acids.

The acid of sea-salt, thus difengaged from the substance which served it for a basis, is called spirit of salt. When it contains but little phlegm, it is of a lemon colour, and continually emits many white, very dense, and very elastic vapours; on which account it is named the smoking or volatile spirit of salt. Its smell is not disagreeable, nor much unlike that of saffron; but extremely quick and suffocating when it smokes.

The acid of sea-salt, like the other two, seems to have a greater affinity with the phlogiston, than with fixed alkalis. We are led to this opinion by a very curious operation, which gives ground to think, that sea-salt may be decomposed by the proper application of a substance containing the phlogiston.

From the marine acid, combined with a phlogiston, results a kind of sulphur, differing from the common sort in many respects; but particularly in this property, that it takes fire of itself upon being exposed to the open air. This combination is called English phosphorus, phosphorus of urine, because it is generally prepared from urine, or only phosphorus.

This combination of the marine acid with a phlogiston is not easily effected; because it requires a difficult operation in appropriated vessels. For these reasons it does not always succeed; and phosphorus is so scarce and dear, that hitherto chemists have not been able to make on it the experiments necessary to discover all its properties. If phosphorus be suffered to burn away in the air,
a small quantity of an acid liquor may be obtained from it, which seems to be spirit of salt, but either altered, or combined with some adventitious matter; for it has several properties that are not to be found in the pure marine acid; such as, leaving a fixed fusible substance behind it when exposed to a strong fire, and being easily combined with the phlogiston so as to reproduce a phlogorphorus.

Phosphorus resembles sulphur in several of its properties: it is soluble in oils; it melts with a gentle heat; it is very combustible; it burns without producing smoke; and its flame is vivid and bluish.

From what has been said of the union of the acid of sea-salt with a fixed alkali, and of the neutral salt resulting therefrom, it may be concluded, that this neutral salt is no other than the common kitchen-salt. But it must be observed, that the fixed alkali, which is the natural basis of the common salt obtained from sea-water, is of a sort somewhat differing from fixed alkalis in general, and hath certain properties peculiar to itself. For,

1. The basis of sea-salt differs from other fixed alkalis in this, that it crystallizes like a neutral salt.

2. It does not grow moist in the air: On the contrary, when exposed to the air, it loses part of the water that united with it in crystallization, by which means its crystals lose their transparency, become as it were mealy, and fall into a fine flour.

3. When combined with the vitriolic acid to the point of saturation, it forms a neutral salt differing from vitriolated tartar, first, in the figure of its crystals, which are oblong fixed solids; secondly, in its quantity of water, which in crystallization unites therewith in a much greater proportion than with vitriolated tartar; whence it follows, that this salt diffolves in water more readily than vitriolated tartar; thirdly, in that it flows with a very moderate degree of heat, whereas vitriolated tartar requires a very fierce one.

If the acid of sea-salt be separated from its basis by means of the vitriolic acid, it is easy to see, that, when the operation is finished, the salt we have been speaking of must be the reful. A famous chemist, named Glauber, was the first who extracted the spirit of salt in this manner, examined the neutral salt resulting from his processes, and finding it to have some singular properties, called it his sal mirabilis, or wonderful salt: On this account it is still called Glauber's sal mirabilis, or Glauber's salt.

4. When the basis of the sea-salt is combined with the nitrous acid to the point of saturation, there results a neutral salt, or a sort of nitre, differing from the common nitre, first, in that it attracts the moisture of the air pretty strongly; and this makes it difficult to crystallize: secondly, in the figure of its crystals, which are parallelopedps; and this has procured it the name of quadrangular nitre.

Common salt, or the neutral salt formed by combining the marine acid with this particular sort of fixed alkali, has a taste well known to everybody. The figure of its crystals is exactly cubical. It grows moist in the air, and, when exposed to the fire, it bursts, before it melts, into many little fragments, with a crackling noise; which is called the despiration of sea-salt.

That neutral salt mentioned above, which is formed by combining the marine acid with a common fixed alkali, and called sal febrifngum sylvii, hath also this property.

India furnishes us with a saline substance, known by the name of borax, which flows very easily, and then takes the form of glass. It is of great use in facilitating the fusion of metallic substances. It possesses some of the properties of fixed alkalis, which has induced certain chemists to represent it, through mistake, as a pure fixed alkali.

By mixing borax with the vitriolic acid, Mr Homberg obtained from it a salt, which sublimes in a certain degree of heat, whenever such a mixture is made. This salt has very singular properties; but its nature is not yet thoroughly understood. It diffolves in water with great difficulty; it is not volatile, though it rises by sublimation from the borax. According to Mr Rouelle's observation, it rises then only by means of the water which carries it up; for when once made, it abides the fiercest fire, flows and vitrifies just as borax does, provided care be taken to free it previously from moisture by drying it properly. Mr Homberg called it sedative salt, on account of its medical effects. The sedative salt hath the appearance, and some of the properties, of a neutral salt; for it shews into crystals, and does not change the colour of violets; but it acts the part of an acid with regard to alkalis, uniting with them to the point of saturation, and thereby forming a true neutral salt. It also acts, like the acid of vitriol, on all neutral salts; that is, it discharges the acid of such as have not the vitriolic acid in their composition.

Since Mr. Homberg's time it hath been discovered, that a sedative salt may be made either with the nitrous or with the marine acid; and that sublimation is not necessary to extract it from the borax, but that it may be obtained by crystallization only. For this latter discovery we are indebted to Mr Geoffroy, as we are to Mr Lemery for the former.

Since that time M. Baron d'Henouville, an able chemist, hath shewn that a sedative salt may be obtained by the means of vegetable acids; and linst lately demonstrated, that the sedative salt exists actually and perfectly in the borax, and that it is not produced by mixing acids with that saline substance, as it seems all the chemists before him imagined. This he proves convincingly from his analysis of borax, (which thereby appears to be nothing else but the sedative salt united with that fixed alkali which is the basis of sea-salt) and from his regenerating the same borax by uniting together that alkali and the sedative salt: a proof the more complete that can possibly be produced in natural philosophy, and equivalent to demonstration itself.

In order to finish what remains to be said upon the several sorts of saline substances, we should now speak of the acids obtained from vegetables and animals, and also of the volatile alkalis; but, seeing these saline substances differ from those of which we have already treated, only as...
as they are variously altered by the unions they have con-
tracted with certain principles of vegetables and animals,
of which nothing has been yet said, it is proper to defer
being particular concerning them, till we have explained
those principles.

Of Lime.

Any substance whatever, that has been roasted a con-
considerable time in a strong fire without melting, is com-
monly called a cals. Stones and metals are the prin-
cipal subjects that have the property of being converted in-
to cals. We shall treat of metallic cals in a subfe-
quent chapter, and in this confine ourselves to the cals of
stone, known by the name of lime.

In treating of earths in general, we observed that they
may be divided into two principal kinds; one of which
actually and properly flows when exposed to the action of
fire, and turns to glass; whence it is called a fusible or
vitrifiable earth; the other resists the utmost force of
fire, and is therefore said to be an unfusible or unvitrifi-
able earth. The latter is also not uncommonly called
calcinable earth; though many sorts of unfusible earths
are incapable of acquiring by the action of fire all the
qualities of calcined earth, or lime properly so called:
such earths are particularly distinguished by the denomina-
tion of refractory earths.

As the different sorts of stones are nothing more than
compounds of different earths, they have the same prop-
erties with the earths of which they are composed, and
may, like them, be divided into fusible or vitrifiable, and
unfusible or calcinable. The fusible stones are generally
denoted by the name of flints; the calcinable stones, on
the contrary, are the several sorts of marbles, cretaceous stones,
those commonly called free-stones, &c. some of which,
as they make the best lime, are, by way of eminence,
called lime-stones. Sea-shells also, and stones that a-
bound with fusible shells, are capable of being burnt to
lime.

All these substances being exposed for a longer or
shorter time to the violent action of fire, are said to be
calcined. By calcination they lose a considerable part of
their weight, acquire a white colour, and become friable,
though ever so solid before; as, for instance, the very
hardest marbles. These substances, when thus calcined,
take the name of quick-lime.

Water penetrates quick-lime, and ruffles it into an
attracting liquid. If a lump of newly calcined lime be thrown
into water, it instantly excites almost as great a noise, eb-
bullition, and smoke, as would be produced by a piece of
red-hot iron; with such a degree of heat too, that, if the
lime be in due proportion to the water, it will set fire
to combustible bodies; as hath unfortunately happened
to vessels laden with quick lime, on their springing a
small leak.

As soon as quick-lime is put into water, it swells, and
falls asunder into an infinite number of minute particles:
in a word, it is in a manner dissolved by the water,
which forms therewith a sort of white paste called flack-
ed lime.

If the quantity of water be considerable enough for
the lime to form with it a white liquor, this liquor is
called lac calcis; which, being left some time to settle,
grows clear and transparent, the lime which was suspend-
ed therein and occasioned its opacity subsiding to the
bottom of the vessel. Then there forms on the surface
of the liquor a crystalline pellicle, somewhat opaque and
dark coloured, which being skimmed off is reproduced
from time to time. This matter is called cremar calcis.

Slacked lime gradually grows dry, and takes the form
of a solid body, but full of cracks and disseiute of firm-
ness. The event is different when you mix it up, while
yet a paste, with a certain quantity of uncalcined flozy
matter, such as sand for example: then it takes the name
of mortar, and gradually acquires, as it grows drier and
older, a hardness equal to that of the best stones. This
is a very singular property of lime, nor is it easy to ac-
count for; but it is a beneficial one, for every body
knows the use of mortar in building.

Quick-lime attracts the moisture of the air in the fame
manner as concentrated acids and dry fixed alkalis, but
not in such quantities as to render it fluid: it only falls
into extremely small particles, takes the form of a fine
powder, and the title of lime flacked in the air.

Lime once flacked, however dry it may afterwards ap-
pear, always retains a large portion of the water it had
imbibed; which cannot be separated from it again but by
means of a violent calcination. Being so recalced it re-
turns to be quick-lime, recovering all its properties.

Besides this great affinity of quick-lime with water,
which discovets a saline character, it has several other
saline properties, to be afterwards examined, much re-
themising theofe of fixed alkalis. In chemistry it acts very
nearly as those salts do, and may be considered as hold-
ing the middle rank between a pure absorbent earth and
a fixed alkali; and this hath induced many chemists to
think that lime contains a true salt, to which all the pro-
erties it possiiblies in common with salts may be attri-
buted.

But as the chemical examination of this subject hath
long been neglected, the existence of a saline substance in
lime hath been long doubtful. Mr du Fay was one of
the first who obtained a salt from lime, by lixiviating it
with a great deal of water, which he afterwards evapo-
rated. But the quantity of salt he obtained by that
means was very small; nor was it of an alkaline nature,
as one would think it should have been, considering the
properties of lime. Mr du Fay did not carry his expe-
riments on this subject any further, probably for want
of time; nor did he determine of what nature the salt
was.

Mr Malouin had the curiosity to examine this salt of
lime, and soon found that it was nothing else but what
was above called cremar calcis. He found, moreover,
that, by mixing a fixed alkali with lime-water, a vitriol-
ated tartar was formed; that, by mixing therewith an
alkali like the basis of sea-salt, a Glauber's salt was pro-
duced; and lastly, by combining lime with a substance
abounding in phlogiston, he obtained a true sulphur. These
very ingenious experiments prove to a demonstration, that
the vitriolic acid conunittes the salt of lime; for, as hath
been shewn, no other acid is capable of forming such
combi-
combinations. On the other hand, Mr Malouin, having forced the vitriolic acid of this salt to combine with a phlogiston, found its bases to be earthy, and analogous to that of the felenites: whence he concluded, that the salt of lime is a true neutral salt, of the same kind as the selenites. Mr Malouin tells us he found several other salts in lime. But as none of them was a fixed alkali, and as all the saline properties of lime have an affinity with those of that kind of salt, there is great reason to think that all those salts are foreign to lime, and that their union with it is merely accidental.

Lime unites with all acids, and in conjunction with them exhibits various phenomena.

The vitriolic acid poured upon lime dissolves it with effervescence and heat. From this mixture there exhales a great quantity of vapours, in smell and colour perfectly like those of sea-salt; from which however they are found to be very different when collected into a liquor. From this combination of the vitriolic acid with lime arises a neutral salt, which shews into crystals, and is of the same kind with the selenitic salt obtained from lime by Mr Malouin.

The nitrous acid poured upon lime dissolves it in like manner with effervescence and heat; but the solution is transparent, and therein differs from the former, which is opaque. From this mixture there arises a neutral salt, which does not crystallize, and has within the very singular property of being volatile, and rising wholly by distillation in a liquid form. This phenomenon is so much the more remarkable, as lime, the basis of this salt, is one of the most fixed bodies known in chemistry.

With the acid of sea-salt lime forms also a singular sort of salt, which greedily imbibes the moisture of the air. We shall have occasion to take further notice of it in another place.

Lime applied to fixed alkalis adds considerably to their caustic quality, and makes them more penetrating and active. An alkaline lixivium in which lime hath been boiled, being evaporated to driness, forms a very caustic substance, which flows in the fire much more easily, attracts and retains moisture much more strongly, than fixed alkalis that have not been so treated. An alkali thus acted upon by lime is called the caustic stone, or potential cautery, because it is employed by surgeons to produce effusions on the skin and cauterize it.

Of Metallic Substances in general.

Metallic substances are heavy, glittering, opaque, fusible bodies. They consist chiefly of a vitrifiable earth united with the phlogiston.

Several chemists insist on a third principle in these bodies, and have given it the name of mercurial earth; which, according to Becher and Stahl, is the very same that being combined with the vitriolic acid forms and characterizes the acid of sea-salt. The existence of this principle hath not yet been demonstrated by any decisive experiment; but we shall believe that there are pretty strong reasons for admitting it.

We shall begin with mentioning the experiments which prove metallic substances to consist of a vitrifiable earth united with the phlogiston. The first is this: if they be calcined in such a manner as to have no communication with any inflammable matter, they will be spoiled of all their properties, and reduced to an earth or calx, that has neither the splendour nor the ductility of a metal, and in a strong fire turns to an actual glass, instead of flowing like a metal.

The second is, that the calx or the glass resulting from a metal thus decomposed, recovers all its metallic properties by being fused in immediate contact with an inflammable substance, capable of restoring the phlogiston of which calcination had deprived it.

On this occasion we must observe, that chemists have not yet been able, by adding the phlogiston, to give the properties of metals to all sorts of vitrifiable earths indiscriminately, but to each only as originally made a part of some metallic body. For example, a compound cannot be made with the phlogiston and sand that shall have the least resemblance of a metal; and this is what seems to point out the reality of a third principle as necessary to form the metallic combination. This principle may probably remain united with the vitrifiable earth of a metallic substance, when reduced to a glass; whence it follows, that such vitrified metals require only the addition of a phlogiston to enable them to appear again in their pristine form.

It may be inferred from another experiment, that the calx and the glass of a metal are not its pure vitrifiable earth, properly so called; for by repeated or long continued calcinations, such a calx or glass may be rendered incapable of ever returning the metallic form, in whatever manner the phlogiston be afterwards applied to it; so that by this means it is brought into the condition of a pure vitrifiable earth, absolutely free from any mixture.

When by adding the phlogiston to a metallic glass, we restore it to the form of a metal, we are said to reduce, refolute, or revivify that metal.

Metals are divided into metals and semi-metals.

Those are called metals, which besides their metallic splendour and appearance, are also malleable; that is, have the property of stretching under the hammer.

Those which have only the metallic splendor and appearance, without malleability, are called semi-metals.

Metals also are further subdivided into two sorts; viz. perfect and imperfect metals.

The perfect metals are those which suffer no damage or change whatever by the most violent and most lasting action of fire.

The imperfect metals are those which by the force of fire may be deprived of their phlogiston, and consequently of their metallic form.

When a moderate degree of fire only is employed to deprive a metal of its phlogiston, the metal is said to be calcined; and then it appears in the form of a powdered earth, which is called a calx; and this metallic calx being exposed to a more violent degree of fire, melts and turns to glass.

Metallic
Metallic substances have an affinity with acids, but not equally with all; that is, every metallic substance is not capable of uniting and joining with every acid.

When an acid unites with a metallic substance, there commonly arises an ebullition, attended with a kind of hissing noise and fuming exhalations. By degrees, as the union becomes more perfect, the particles of the metal combining with the acid become invisible: this is termed **dissolution**; and when a metallic mass thus disappears in an acid, the metal is said to be **dissolved** by that acid. It is proper to observe, that acids act upon metallic substances, in one respect, just as they do upon alkalics and absorbent earths: for an acid cannot take up above a certain proportion thereof as is sufficient to saturate it, to destroy several of its properties, and weaken others. For example, when an acid is combined with a metal to the point of saturation, it loses its taste, does not turn the blue colour of a vegetable red, and its affinity with water is considerably impaired. On the other hand, metallic substances, which, when pure, are incapable of uniting with water, by being joined with an acid, acquire the property of dissolving in water. These combinations of metallic substances with acids form different sorts of neutral salts; some of which have the property of shoot- ing into crystals, while others have it not: most of them, when thoroughly dried, attract the moisture of the air.

The affinity which metallic substances have with acids is less than that which absorbent earths and fixed alkalics have with the same acids; so that all metallic salts may be decomposed by one of these substances, which will unite with the acid, and precipitate the metal. Metallic substances thus separated from an acid solvent are called **magnifiers**, and **precipitates of metals**. None of these precipitates, except those of the perfect metals, retain the metallic form; most of their phlogiston has been destroyed by the solution and precipitation, and must be reflored before they can recover their properties. In short, they are nearly in the same state as the original metallic substance, retaining their phlogiston, deprived of their phlogiston by calcination; and accordingly such a precipitate is called a **calx**.

A metallic calx prepared in this manner loses a greater or a less portion of its phlogiston, the more or less effectually and thoroughly the metallic substance of which it made a part was dissolved by the acid.

Metallic substances have affinities with each other which differ according to their different kinds; but this is not universal, for some of them are incapable of any sort of union with some others.

It must be observed, that metallic substances will not unite, except they be both in a similar state; that is, both in a metallic form, or both in the form of a glass; for a metallic substance, retaining its phlogiston, cannot contract an union with any metallic glass, even its own.

**Of Metals.**

There are six metals, of which two are perfect, and four imperfect. The perfect metals are gold and silver; the others are copper, tin, lead, and iron. Some chemists admit a seventh metal, viz. quick-silver; but, as it is not malleable, it has been generally considered as a metallic body of a particular kind.

The ancient chemists, or rather the alchemists, who fancied a certain relation or analogy between metals and the heavenly bodies, bellowed on the seven metals, reckoning quick silver one of them, the names of the seven planets of the ancients, according to the affinity which they imagined they observed between those several bodies. Thus gold was called **Sol**, silver **Luna**, copper **Venus**, tin **Jupiter**, lead **Saturn**, iron **Mars**, and quick-silver **Mercury**. Though these names were assigned for reasons merely chimerical, yet they still keep their ground; so that it is not uncommon to find the metals called by the names, and denoted by the characters, of the planets, in the writings even of the best chemists. Metals are the heaviest bodies known in nature.

**Of Gold.**

Gold is the heaviest of all metals. The arts of wire-drawing and gold-beating shew its wonderful ductility. The greatest violence of fire is not able to produce any alteration in it.

Gold cannot be dissolved by any pure acid; but if the acid of nitre be mixed with the acid of sea-salt, there results a compound acid liquor, with which it has so great an affinity, that it is capable of being perfectly dissolved thereby. The chemists have called this solvent **aqua regis**, on account of its being the only acid that can dissolve gold, which they consider as the king of metals. The solution of gold is of a beautiful orange colour.

If gold dissolved in **aqua regis** be precipitated by an alkali or an absorbent earth, the precipitate gently dried, and then exposed to a certain degree of heat, is instantly dispersed into the air, with a most violent explosion and noise: gold thus precipitated is therefore called **aurum fulminans**. But if the precipitated gold be carefully walked in plenty of water, so as to clear it of all adhering saline particles, it will not fulminate; but may be melted in a crucible without any addition, and will then appear in its usual form. The acid of vitriol being poured on **aurum fulminans** likewise deprives it of its fulminating quality.

Gold does not begin to flow till it be red-hot like a live coal. Though it be the most malleable and most ductile of all metals, it has the singular property of losing its ductility more easily than any of them: even the fumes of charcoal are sufficient to deprive it thereof, if they come to contact with it while it is in fusion.

The malleability of this metal, and indeed of all the rest, is also considerably diminished by exposing it suddenly to cold when it is red-hot; for example, by quenching it in water, or even barely exposing it to the cold air. The way to restore ductility to gold, when lost by its coming in contact with the vapour of coals, and in general to every other metal rendered less malleable by being suddenly cooled, is to heat it again, to keep them red hot a considerable time, and then to let them cool very slowly and gradually: this operation frequently repeated will by degrees much increase the malleability of a metal.

Pure sulphur hath no effect on gold; but being combined
of Silver.

Next to gold, silver is the most perfect metal. Like gold, it resists the utmost violence of fire, even that in the focus of a burning-glass. However, it holds only the second place among metals; because it is lighter than gold by almost one half; is also somewhat less ductile; and lastly, because it is acted upon by a greater number of solvents.

Yet silver hath one advantage over gold, namely that of being a little harder; which makes it also more honorable.

This metal, like gold, begins to flow when it is so thoroughly penetrated by the fire as to appear ignited like a live coal.

While this metal is in fusion, the immediate contact of the vapour of burning coals deprives it almost entirely of its malleability, in the same manner as we observed happens to gold: but both these metals easily recover that property by being melted with nitre.

The nitrous acid is the true solvent of silver, and being somewhat dephlegmated will very readily and easily take up a quantity of silver equal in weight to itself.

Silver thus combined with the nitrous acid forms a metallic salt which shoots into crystals, called by the name of lunar crystals, or crystals of silver.

These crystals are more violently caustic: applied to the skin, they quickly affect it much as a live coal would; they produce a blackish eflar, corroding and entirely destroying the parts they touch. Surgeons use them to eat away the proud fungous flesh of ulcers. As silver united with the nitrous acid hath the property of blackening all animal substances, a solution of this metallic salt is employed to die hair, or other animal matters, of a beautiful and durable black.

These crystals flow with a very moderate heat, and even before they grow red. Being thus melted, they form a blackish mass; and in this form they are used by surgeons, under the title of lapis infernalis, infernal stone, or silver caustic.

Silver is also dissolved by the vitriolic acid; but then the acid must be concentrated, and in quantity double the weight of the silver; nor will the solution succeed without a considerable degree of heat.

Spirit of salt and aqua regis, as well as the other acids, are incapable of dissolving this metal, at least in the ordinary way.

Though silver be not soluble in the acid of sea-salt, nor easily in the acid of vitriol, as hath just been observed, it doth not follow, that it hath but a weak affinity with the latter, and none at all with the former; on the contrary, it appears from experiment, that it hath with these two acids a much greater affinity than with the acid of nitre: which is singular enough, considering the facility with which this last acid dissolves it.

The experiment which proves the fact is this. To a solution of silver in the nitrous acid add the acid either of vitriol or of sea-salt, and the silver will instantly quit its nitrous solvent to join with the superadded acid.

Silver thus united with the vitriolic or the marine acid is left soluble in water than when combined with the nitrous acid: and for this reason it is, that when either of these two acids is added to a solution of silver, the liquor immediately becomes white, and a precipitate is formed, which is no other than the silver united with the precipitating acid. If the precipitation be effected by the vitriolic acid, the precipitate will disappear upon adding a sufficient quantity of water, because there will then be water enough to dissolve it. But the case is not the same when the precipitation is made by the marine acid: for silver combined therewith is scarce soluble in water.

This precipitate of silver procured by means of the marine acid is very easily fusible, and when fusd changes to a substantive mixture transparent and flexible; which hath occasioned it to be called by the name of luna cornea. If it be proposed to decompose this luna cornea, that is, to separate the marine acid from the silver with which it is united, the luna cornea must be melted along with fatty and absorbent matters, with which the acid will unite, and leave the metal exceeding pure.

It must be observed, that if, instead of the marine acid, sea-salt in substance be added to a solution of silver in the nitrous acid, a precipitate is also produced, which by fusion appears to be a true luna cornea. The reason is, that the sea-salt is decomposed by the nitrous acid, which fixes its basis, as having a greater affinity therewith than its own acid hath; and this acid being consequently difengaged and set at liberty unites with the silver, which, as has been shewn, has greater affinity with it than with the nitrous acid. This is an infallible of decomposition effected by means of one of those double affinities mentioned in the seventh proposition concerning affinities.

From what hath been already said it is clear, that all these combinations of silver with acids may be compounded by absorbent earths and by fixed alkalies; it being a general law with regard to all metallic substances.

Silver, when separated by these means from the acids in which it was dissolved, requires nothing but simple fusion to reduce it to its usual form; because it does nor, any more than gold, lose its phlogiston by those solutions and precipitations.

Silver unites with sulphur in fusion. If this metal be only made red-hot in a crucible, and sulphur be then added,
ded, it immediately flows; the sulphur acting as a flux to it. Silver thus united with sulphur forms a mass that may be cut, is half malleable, and hath nearly the colour and consistence of lead. If this sulphurated silver be kept a long time in fusion, and in a great degree of heat, the sulphur flies off and leaves the silver pure. But if the sulphur be evaporated by a violent heat, it carries off with it part of the silver.

Silver unites and mixes perfectly with gold in fusion. The two metals thus mixed form a compound with properties partaking of both.

Metallurgists have hitherto sought in vain for a perfectly good and easy method of separating these two metals by the dry way only; (This term is used to signify all operations performed by fusion;) but they are conveniently enough parted by the moist way, that is, by acid solvents. This method is founded on the above-mentioned properties of gold and silver with respect to acids.

It hath been shewn, that aqua regis only will dissolve gold; that silver, on the contrary, is not soluble by aqua regis, and that its proper solvent is the acid of nitre: Consequently, when gold and silver are mixed together, if the compound mass be put into aqua fortis, this acid will take up all the silver, without dissolving a particle of the gold, which will therefore remain pure; and by this means the desired separation is effected. This method, which is commonly made use of by goldsmiths and in mines, is called the parting assay.

It is plain, that if aqua regis were employed instead of aqua fortis, the separation would be equally effected; and that the only difference between this process and the former would consist in this, that now the gold would be dissolved, and the silver remain pure. But the operation by aqua fortis is preferable; because aqua regis does take up a little silver, whereas aqua fortis hath not the least effect on gold.

It must be observed, that when gold and silver are mixed together in equal parts, they cannot be parted by the means of aqua fortis. To enable the aqua fortis to act duly on the silver, this metal must be, at least, in a triple proportion to the gold. If it be in a less proportion, you must either employ aqua regis to make the separation, or, if you prefer the use of aqua fortis, melt the metalline masses, and add as much silver as is necessary to make up the proportion above-mentioned: And hence this process is called quartation.

This effect, which is pretty singular, probably arises from hence, that when the gold exceeds, or even equals the silver in quantity, the parts of both being intimately united, the former are capable of coating over the latter, and covering them so as to defend them from the action of the aqua fortis; which is not the case when there is thrice as much silver as gold.

There is one thing more to be taken notice of with regard to this process; which is, that perfectly pure aqua fortis is rarely to be met with, for two reasons: First, it is difficult in making it wholly to prevent the rising of the medium employed to difeignage the nitrous acid; that is, a little of the vitriolic acid will mix with the vapours of the aqua fortis: Secondly, unless the saltpetre be very well purified, it will always hold some small portion of sea-salt, the acid of which, we know, is very readily set loose by the vitriolic acid, and consequently rises together with the vapours of the aqua fortis. It is easy to see, that aqua fortis, mixed either with the one or the other, is not proper for the parting process; because, as has just been said, the vitriolic and the saline acid equally precipitate silver dissolved in the nitrous acid; by which means, when they are united with that acid, they weaken its action upon the silver, and hinder the dissolusion. Add, that aqua fortis adulterated with a mixture of spirit of salt becomes an aqua regis, and consequently is rendered capable of dissolving gold, in proportion as its action upon silver is diminished.

In order to remedy this inconvenience, and free aqua fortis from the vitriolic or marine acid with which it is tainted, silver must be dissolved therein: By degrees, as the metal dissolves, those heterogeneous acids lay hold of it, and precipitate with it in the form of a white powder, as we observed before. This precipitate being wholly fallen, the liquor grows clear; after which, if it be found capable of dissolving more silver, without turning milky, it may be depended on as a perfectly pure aqua fortis. Then filter it, dissolve more silver in it, as long as it will take up any, and you will have a solution of silver in a very pure aqua fortis. By means of this solution may other aqua fortis be purified: For, pour a few drops thereof into a very impure aqua fortis, and immediately the vitriolic or marine acid, with which that aqua fortis is contaminated, will join the silver and fall therewith to the bottom. When the solution of silver prepared as above does not in the least affect the transparency of the aqua fortis, it is then very pure, and fit for the purposes of quartation.

This operation of purifying aqua fortis by a solution of silver is called the precipitation of aqua fortis; and aqua fortis thus purified is called precipitated aqua fortis.

When silver is dissolved in aqua fortis it may be separated therefrom, as has been shewn, by absorbent earths and fixed alkalis.

Of Copper.

Of all the imperfect metals, copper comes the nearest to gold and silver. Its natural colour is a deep-red yellow. It refists a very violent degree of fire for a considerable time; but losing its phlogiston at last, it changes its metalline form for that of a calx, or a pure reddish earth. This calx is hardly, if at all, reducible to glass, without the addition of something to promote its fusion; all that the fiercest heat can do being only to render it fott. Copper, even while it retains its metalline form, and is very pure, requires a considerable degree of fire to melt it, and does not begin to flow till long after it is red-hot. When in fusion, it communicates a greenish colour to the flame of the coals.

This metal is inferior to silver in point of gravity; nor is its ductility so great, though it be pretty considerable: But, on the other hand, it exceeds that metal in hardnesh. It unites readily with gold and silver; nor does it greatly leffen their beauty when added to them in a small quantity: Nay, it even procures them some advantages;
vant; such as making them harder, and less subject to lose their ductility. This may probably arise from hence, that the ductility of copper has the peculiarity of resisting most of those causes which rob the perfect metals of theirs.

The property which other metallic substances have in common with copper, of losing the phlogiston by calcining and then vitrifying, furnishes us with a method of separating them from gold and silver, when they are combined therewith. Nothing more is required than to expose the mass, compounded of the perfect metals and other metallic substances, to a degree of heat sufficient to calcine whatever is not either gold or silver. It is evident that by this means these two metals will be obtained as pure as is possible; for, as hath already been said, no metallic calx or glass is capable of uniting with metals possessed of their phlogiston. On this principle is formed the whole business of refining gold and silver.

When the perfect metals have no other alloy but copper, as this metal is not to be calcined or vitrified without great difficulty, which is increased by its union with the unvitriifiable metals, it is easy to see that it is almost impossible to separate them without adding something to facilitate the vitrification of the copper. Such metals as have the property of turning easily into glass are very fit for this purpose; and it is necessary to add a certain quantity thereof, when gold or silver is to be purified from the alloy of copper. We shall have occasion to be more particular on this subject when we come to treat of lead.

Copper is soluble in all the acids, to which it communicates a green colour, and sometimes a blue. Even the neutral salts, and water itself, act upon this metal. With regard to water indeed, as the procuring it absolutely pure and free from any saline mixture is next to an impossibility, it remains a question, whether the effect it produces on copper be not owing to certain saline particles contained in it. It is this great facility of being dissolved that renders copper so subject to rust; which is the soul of water in crystallizing, on which account it is easily rendered fluid by fire.

The rust of copper is always green or blue, or of a colour between these two. Internally used it is very noxious, being a real poison, as are all the solutions of this metal made by any acid whatever. The blue colour, which copper constantly assumes, when corroded by any saline substance, is a sure sign by which it may be discovered where-ever it exists, even in a very small quantity.

Copper dissolved in the vitriolic acid forms a kind of metallic salt, which shews into rhomboidal crystals of a most beautiful blue colour. These crystals are called blue vitriol, or vitriol of copper. They are sometimes found ready formed in the bowels of the earth; and may be artificially made by dissolving copper in the vitriolic acid; but the solution will not succeed unless the acid be well dephlegmated. The tafte of this vitriol is acrid and astringent. It retains a considerable quantity of water in crystallizing, on which account it is easily rendered fluid by fire.

It must be observed, that when it is exposed to a certain degree of heat in order to free it of its humidity, a great part of its acid flies off at the same time: And hence it is that, after calcination, there remains only a kind of earth, or metallic calx, of a red colour, which contains but very little acid. This earth cannot be brought to flow but with the greatest difficulty.

A solution of copper in the nitrous acid forms a salt which does not crystallize, but, when dried, powerfully attracts the moisture of the air. The same thing happens when it is dissolved in the spirit of salt, or in aqua regis.

If the copper, thus dissolved by any of these acids, be precipitated by an earth or an alkali, it retains nearly the colour it had in the solution: But these precipitates are scarce any thing more than the earth of copper, or copper deprived of most of its phlogiston; so that if they were exposed to a violent fire, without any addition, a great part of them would be converted into an earth that could never be reduced to a metallic form. Therefore, when we intend to reduce these precipitates to copper, it is necessary to add a certain quantity of a substance capable of restoring to them the phlogiston they have lost.

The substance which hath been found fittest for such reductions is charcoal dust; because charcoal is nothing but a phlogiston closely combined with an earth, which renders it exceedingly fixed, and capable of resisting a violent force of fire. But as charcoal will not melt, and consequently is capable of preventing rather than forwarding the flux of a metallic calx or glass, which nevertheless is essentially necessary to complete the reduction, it hath been contriv'd to mix it, or any other substance containing the phlogiston, with such fixed alkalis as easily flow, and are fit to promote the flux of other bodies. These mixtures are called reducing fluxes; because the general name of fluxes is given to all salts, or mixtures of salts, which facilitate fusion.

If sulphur be applied to copper made perfectly red-hot, the metal immediately runs; and these two substances uniting, form a new compound much more fusible than pure copper.

This compound is destroyed by the sole force of fire, for two reasons: The first is, that, sulphur being volatile, the fire is capable of subliming a great part of it, especially when it is in a great proportion to the copper with which it is joined; the second is, that the portion of sulphur which remains, being more intimately united with the copper, though it be rendered less combustible by that union, is nevertheless burnt and consumed in time. Copper being combined with sulphur, and together with it exposed to the force of fire, is found to be partly changed into a blue vitriol; because the vitriolic acid, being diffus'd by burning the sulphur, is by that means qualified to dissolve the copper. The affinity of copper with sulphur is greater than that of silver.

This metal, as well as the other imperfect metals and the semi-metals, being mingled with nitre and exposed to the fire, is decomposed and calcined much sooner than by itself; because the phlogiston which it contains occasions the desagregation of the nitre, and consequently the two substances mutually decompose each other. There are certain metallic substances whose phlogiston is so abun-
dant, and so weakly connected with their earth, that, when they are thus treated with nitre, there arises immediately a detonation, accompanied with flame, and as violent as if sulphur or charcoal duft had been employed; so that in a moment the metalline substance loses its phlogiston, and is calcined. The nitre, after these detonations, always assumes an alkaline character.

Of Iron.

Iron is lighter and less ductile than copper; but it is much harder, and of more difficult fusion.

It is the only body that has the property of being attracted by the magnet, which therefore serves to discover it where-ever it is. But it must be observed, that it hath this property only when in its metalline state, and loses it when converted to an earth or calx. Hence very few iron-ores are attracted by the loadstone; because, for the most part, they are only forts of earths, which require a phlogiston to be added before they can be brought to the form of true iron.

When iron hath undergone no other preparation but the fusion which is necessary to smelt it from its ore, it is usually quite brittle, and flies to pieces under the hammer: Which arises in some measure from its containing a certain portion of unmetallic earth interposed between its parts. This we call pig-iron.

By melting this a second time it is rendered purer, and more free from heterogeneous matters: But still, as its proper parts are probably not brought sufficiently near, or closely enough united, till the iron hath undergone some further preparation besides that of fusion, it seldom hath any degree of malleability.

The way to give it this property is to make it just red-hot, and then hammer it for some time in all directions; to the end that its parts may be properly united, incorporated, and welded together, and that the heterogeneous matters which keep them asunder may be separated. Iron made by this means as malleable as possible, we call bar-iron, or forged iron.

Bar iron is still harder to fuse than pig-iron: To make it flow requires the utmost force of fire.

Iron has the property of imbibing a greater quantity of phlogiston than is necessary to give it the metalline form. It may be made to take in this superabundant phlogiston two ways: The first is by fusing it again with matters that contain the phlogiston; the second is, by encompassing it with a quantity of such matters, charcoal-duft, for instance, and then exposing it so encompassed, for a certain time, to a degree of fire barely sufficient to keep it red-hot. This second method, whereby one substance is incorporated with another by means of fire, but without fusing either of them, is in general called cementation.

Iron thus impregnated with an additional quantity of phlogiston is called steel. The hardness of steel may be considerably augmented by tempering it; that is, by making it red-hot, and suddenly quenching it in some cold liquor. The hotter the metal, and the colder the liquor in which it is quenched, the harder will the steel be. By this means tools are made, such as files and shears, capable of cutting and dividing the hardest bodies, as glass, pebbles, and iron itself. The colour of steel is darker than that of iron, and the facets which appear on breaking it are smaller. It is also less ductile and more brittle, especially when tempered.

As iron may be impregnated with an additional quantity of phlogiston, and thereby converted into steel, so may steel be again deprived of that superabundant phlogiston, and brought back to the condition of iron. This is effected by cementing it with poor earths, such as calcined bones and chalk. By the same operation steel may be untempered: nay, it will lose the hardnes it had acquired by tempering, if it be but made red-hot, and left to cool gradually. As iron and steel differ only in the respects we have here taken notice of, their properties being in all other respects the same, what follows is equally applicable to both.

Iron being exposed to the action of fire for some time, especially when divided into small particles, such as filings, is calcined, and loses its phlogiston. By this means it turns to a kind of reddish yellow earth, which on account of its colour is called crocus Martis, or jafron of Mars.

This calx of iron has the singular property of flowing in the fire with somewhat less difficulty than iron itself; whereas every other metalline calx flows with less ease than the metal that produced it. It has moreover the remarkable property of uniting with the phlogiston, and of being reduced to iron without fusion; requiring for that purpose only to be made red-hot.

Iron may be incorporated with silver, and even with gold, by means of certain operations. Under the article of lead, we shall see how it may be separated from these metals.

The acids produce on it much the same effects as on copper: every one of them acts upon it. Certain neutral salts, alkalis, and even water itself, are capable of dissolving it; and hence it is also very susceptible to rust. The vitriolic acid dissolves it with the greatest ease: but the circumstances which attend the dissolution thereof are different from those with which the same acid dissolves copper. For, 1. Whereas the vitriolic acid must be concentrated to dissolve copper, it must on the contrary be diluted with water to dissolve iron, which it will not touch when well dephtitamated. 2. The vapours which rise in this dissolution are inflammable; so that if it be made in a small-necked bottle, and the flame of a candle be applied to the mouth thereof, the vapours in the bottle take fire with such rapidity as to produce a considerable explosion.

This solution is of a beautiful green colour; and from this union of the vitriolic acid with iron, there results a neutral metallic salt, which has the property of shooting into cryftals of a rhomboidal figure, and a green colour. These crystals are called green vitriol, and vitriol of Mars.

Green vitriol hath a saltish and astringent taste. As it retains a great deal of water in crystallizing it quickly flows by the action of fire: but this fluidity is owing to its water only, and is not a real fusion; for as soon as its moisture is evaporated, it refumes a solid form. Its green transparent colour is now changed into an opaque white.
white; and, if the calcination be continued, its acid also exhales, and is diffipated in vapours; and as it loses that, it turns gradually to a yellow colour, which comes so much the nearer to a red the longer the calcination is continued, or the higher the force of the fire is raised; which being driven to the utmost, what remains is of a very deep red. This remainder is nothing but the body of the iron, which, having lost its phlogiston, is now no more than an earth, nearly of the same nature with that which is left after calcining the metal itself.

Green vitriol dissolved in water spontaneously lets fall a yellowish earthy sediment. If this solution be defecated by filtration, it still continues to deposite some of the same substance, till the vitriol be wholly decomposed. This sediment is nothing but the earth of iron, which is then called ochre.

The nitrous acid dissolves iron with great ease. This solution is of a yellow colour, inclining more or less to a rufset, or dark-brown, as it is more or less saturated with iron. Iron dissolved by this acid also falls spontaneously into a kind of calx, which is incapable of being dissolved a second time; for the nitrous acid will not act upon iron that has lost its phlogiston. This solution does not crystallize, and if evaporated to dryness attracts the moisture of the air.

Spirits of salt likewise dissolves iron, and this solution is green. The vapours which rise during the dissolution are inflammable, like those which ascend when this metal is attacked by the vitriolic acid. Aqua regis makes a solution of iron, which is of a yellow colour.

Iron hath a greater affinity than either silver or copper with the nitrous and vitriolic acids; so that if iron be presented to a solution of either, in one of these two acids, the dissolved metal will be precipitated; because the acid quits it for the iron, with which it has a greater affinity.

On this occasion it must be observed, that if a solution of copper in the vitriolic acid be precipitated by means of iron, the precipitate has the form and splendour of a metallic substance with fulphur; on which account, it is always produced of a large burning-glass.

Chimstry.

Tin is the lightest of all metals. Though it yields easily to the impression of hard bodies, it has but little ductility. Being bent backwards and forwards it makes a small crackling noise. It flows with a very moderate degree of fire, and long before it comes to be red-hot. When it is in fusion, its surface soon grows dully, and there forms upon it a thin dark-coloured dusty pellicle, which is no other than a part of the tin that has lost its phlogiston, or a calx of tin. The metal thus calcined easily recovers its metallic form, on the addition of a phlogiston. If the calx of tin be urged by a strong fire it grows white, but the greatest violence of heat will not fuse it; which makes some chemists consider it as a calcinable or absorbent earth, rather than a vitrifiable one. Yet it turns to glass in some sort, when mixed with any other substance that vitrifies easily. However, it always produces a imperfect glass only, which is not at all transparent, but of an opaque white. The calx of tin thus vitrified is called enamel. Enamels are made of several colours by the addition of this or that metallic calx.

Tin unites easily with all the metals; but it destroys the ductility and malleability of every one of them, lead excepted. Nay, it poisons this property of making metals brittle, in such an eminent degree, that the very vapour of it, when in fusion, is capable of producing this effect. Moreover, which is very singular, the most ductile metals, even gold and silver, are thence on which it works this change with the most ease, and in the greatest degree. It has also the property of making silver, mixed with it, flow over a very small fire.

It adheres to, and in some measure incorporates with, the surface of copper and of iron; whence arose the practice of coating over those metals with tin. Tin plates are no other than thin plates of iron tinned over.

If to twenty parts of tin one part of copper be added, this
this alloy renders it much more solid, and the mixed mafs continues tolerably ductile.

If, on the contrary, to one part of tin ten parts of copper be added, together with a little zinc, a semi-metal to be considered hereafter, from this combination there results a metalline compound, which is hard, brittle, and very porous; so that it is used for calling bells: This composition is called bronze and bell-metal.

Tin hath an affinity with the vitriolic, nitrous, and marine acids. All of them attack and corrode it; yet none of them is able to difsolve it without great difficulty: So that if a clear solution thereof be desired, particular methods must be employed for that purpose; for the acids do but in a manner calcine it, and convert it to a kind of white calx or precipitate. The solvent which has the greatest power over it is aqua regis, which has even a greater affinity therewith than with gold itself; whence it follows, that gold difsolved in aqua regis may be precipitated by means of tin; but then the aqua regis must be weakened. Gold thus precipitated by tin is of a most beautiful colour, and is used for a red in enamelling and painting on porcelain, as also to give a red colour to artificial gems. If the aqua regis be not lowered, the precipitate will not have the purple colour.

Tin hath the property of giving a great lustre to all red colours in general; on which account it is used by the dyers for striking a beautiful scarlet, and tin-veffels are employed in making fine sirup of violets. Water does not act upon this metal, as it does upon iron and copper; for which reason it is not subject to rust: nevertheless, when it is exposed to the air, its surface soon lofes its polish and splendor.

Tin mixed with nitre, and exposed to the fire, deflagrates with it, makes it detonate, and is immediately converted to a refractory calx; for so all substances are called which are incapable of fusition.

Tin readily unites with sulphur, and with it becomes a brittle and friable mafs.

O F L E A D.

Next to gold and mercury, lead is the heaviest of all metalline substances, but in hardnefs is exceeded by every one of them. Of all metals also it melts the easieft, except tin. While it is in fusion there gathers incessantly on its surface, as on that of tin, a blackish, dully pellicle, which is nothing but a calx of lead.

This calx further calcined by a moderate fire, the flame being reverberated on it, soon grows white. If the calcination be continued it becomes yellow, and at last of a beautiful red. In this state it is called minium. Minium is not easily made, and the operation succeeds well in large manufactures only.

To convert lead into litharge, which is the metal in a manner half vitriified, you need only keep it melted by a pretty strong fire; for then, as its surface gradually calcines, it tends more and more to fusition and vitriification.

All these preparations of lead are greatly difposed to perfect fusion and vitriification, and for that purpose require but a moderate degree of fire; the calx or earth of lead being of all metalline earths that which vitrifies the most easily.

Lead hath not only the property of turning into glass with the greatest facility, but it hath also that of promoting greatly the vitriification of all the other imperfect metals; and, when it is actually vitriified, procures the ready fusion of all earths and stones in general, even those which are refractory, that is, which could not be fusited without its help.

Glafs of lead, besides its great fusibility, hath also the singular property of being so subtile and active as to corrode and penetrate the crucibles in which it is melted, unless they be of an earth that is exceeding hard, compact, and withal very refractory: for glafs of lead being one of the most powerful fluxes that we know, if the earth of the crucible in which it is melted be in the smallest degree fusible, it will be immediately vitriified; especially if there be any metallic matter in its composition.

The great activity of glafs of lead may be weakened by joining it with other vitriifiable matters; but unless these be added in a very great proportion, it will still remain powerful enough to penetrate common earths, and carry off the matters combined with it.

On these properties of lead, and of the glafs of lead, depends the whole business of refining gold and silver. It hath been shewn, that as these two metals are indifferible by fire, and the only ones which have that advantage, they may be separated from the imperfect metals, when mixed therewith, by exposing the compound to a degree of fire sufficiently strong to vitriify the latter; which when once converted into glass can no longer remain united with any metal that has its metalline form. But it is very difficult to procure this vitriification of the imperfect metals, when united with gold and silver; nay, it is in a manner impossible to vitriify them entirely, for two reasons: first, because most of them are naturally very difficult to vitriify; secondly, because the union they have contracted with the perfect metals defends them, in a manner, from the action of the fire, and that so much the more effectually as the proportion of the perfect metals is greater, which being indifferrible, and in some fort covering over those with which they are alloyed, serve them as a prefervative and impenetrable shield against the utmost violence of fire.

It is therefore clear, that a great deal of labour may be saved, and that gold and silver may be refined to a much greater degree of purity than can otherwise be obtained, if to a mixture of these metals with copper, for instance, or any other imperfect metal, be added a certain quantity of lead. For the lead, by its known property, will infallibly produce the desired vitriification; and as it likewise increases the proportion of the imperfect metals, and so leffens that of the perfect metals, in the mafs, it evidently deprives the former of a part of their guard, and so effects a more complete vitriification. As the glafs of lead hath the property of running through the crucible, and carrying with it the matters which it has vitriified, it follows, that when the vitriification of the imperfect metals is effected by its means, all those vitriified matters together penetrate the vefsel containing the fusited metalline mafs, disappear, and leave only the gold and silver perfectly
perfectly pure, and freed, as far as is possible, from all admixture of heterogeneous parts.

The better to promote the separation of such parts, it is usual to employ in this process a particular sort of small crucibles, made of the ashes of calcined bones, which are exceedingly porous and easily pervaded. They are called cupels, on account of their figure, which is that of a wide-mouthed cup: and from hence the operation takes its name; for when we refine gold and silver in this manner, we are said to cupel those metals. It is easy to perceive, that the more lead is added, the more accurately will the gold and silver be refined; and that so much the more lead ought to be added as the perfect metals are alloyed with a greater proportion of the imperfect. This is the most severe trial to which a perfect metal can be put, and consequently any metal that stands it may be fairly considered as such.

In order to denote the fineness of gold, it is supposed to be divided into twenty-four parts called carats; and gold, which is quite pure and free from all alloy, is said to be twenty-four carats fine. That which contains \( \frac{1}{2} \) part of alloy is called gold of twenty-three carats; that which contains \( \frac{1}{4} \) of alloy is but twenty-two carats fine; and so on. Silver again is supposed to be divided into twelve parts only, which are called penny-weights: so that when absolutely pure it is said to be twelve penny-weights fine; when it contains \( \frac{1}{2} \) of alloy, it is then called eleven penny-weights fine; when it contains \( \frac{1}{4} \) of alloy, it is called ten penny-weights fine; and so on.

In treating of copper, we promised to shew under the article of lead how to separate it from iron. The process is founded on that property of lead which renders it incapable of mixing and uniting with iron, though it readily dissolves all other metallic substances. Therefore if you have a mass compounded of copper and iron, it must be fused with a certain quantity of lead, and then the copper, having a greater affinity with lead than with iron, will deft the latter and join the former, which being incapable of any union with iron, as was said, will wholly exclude it from the new compound. The next point is to separate the lead from the copper; which is done by expelling the mass compounded of these two metals to a degree of fire strong enough to deprive the lead of its metallic form, but too weak to have the same effect on the copper: and this may be done, since all of the imperfect metals lead is, next to tin, the easiest to be calcined, and copper, on the contrary, refists the greatest force of fire longest, without losing its metallic form. Now what we gain by this exchange, viz. by separating copper from iron, and uniting it with lead, consists in this, that as lead is calcined with less fire than iron, the copper is less exposed to be destroyed: for it must be observed, that, however moderate the fire be, it is hardly possible to prevent a certain quantity thereof from being calcined in the operation.

Lead melted with a third part of tin forms a compound, which being exposed to a fire capable of making it thoroughly red hot, swells up, puffs up, seems in some sort to take fire, and is presently calcined. These two metals mixed together are much sooner calcined than either of them separately.

Vol. II. No. 33.
will not allow us to confound it with the semi-metals. The reason why quick-silver, by the chemists commonly called mercury, is not reputed a metal, is, that it wants one of the essential properties thereof, viz. malleability. When it is pure and unadulterated with any mixture, it is always fluid, and of course unmalleable. But as, on the other hand, it eminent in possessing the opacity, the splendor, and above all the gravity of a metal, being next to gold, the heaviest of all bodies, it may be considered as a true metal, differing from the rest no other way than by being constantly in fusion; which we may suppose arises from its aptness to flow with such a small degree of heat, that be there ever so little warmth on earth, there is still more than enough to keep mercury in fusion; which would become solid and malleable if it were possible to apply to it a degree of cold considerable enough for that purpose. These properties will not allow us to confound it with the semi-metals. Add, that we are not yet assured by any undoubted experiment that it can be wholly deprived of its phlogiston, as the imperfect metals may. Indeed we cannot apply the force of fire to it as could be wished: for it is so volatile, that it flies off and exhales in vapours with a much less degree of fire than is necessary to make it red-hot. The vapours of mercury thus raised by the action of fire, being collected and united in a certain quantity, appear to be no other than true mercury retaining every one of its properties; and no experiment has ever been able to shew the least change thus produced in its nature.

If mercury be exposed to the greatest heat that it can bear without sublimation, and continued in it for several months, or even a whole year together, it turns to a red powder, which the chemists call mercurius precipitatus per se. But to succeed in this operation, it is absolutely necessary that the heat be such as is above specified; for this metallic sub stance may remain exposed to a weaker heat for a considerable number of years, without undergoing any sensible alteration.

Some chemists fancied that by this operation they had fixed mercury, and changed its nature; but without any reason; for if the mercury thus seemingly transmuted be exposed to a somewhat stronger degree of fire, it sublimes and exhales in vapours as usual; and those vapours collected are nothing else but running mercury, which has recovered all its properties without the help of any addition.

Mercury has the property of dissolving all the metals, iron only excepted. But it is a condition absolutely necessary to the success of such dissolution, that the metallic substances be polleft of their phlogiston; for if they be calcined, mercury cannot touch them: and hence it follows, that mercury does not unite with substances that are purely earthly. Such a combination of a metal with mercury is called an amalgam. Trituration alone is sufficient to effect it; however, a proper degree of heat also is of use.

Mercury amalgamated with a metal gives it a consistence more or less soft, and even fluid, according to the greater or smaller proportion of mercury employed. All amalgams are softened by heat, and hardened by cold.

Mercury is very volatile; violently more so than the most unfixed metals: moreover, the union it contracts with any metal is not sufficiently intimate to entitle the new compound resulting from that union to all the properties of the two substances united; at least with regard to their degree of fixity and volatility. From all which it follows, that the belch and freeth method of separating it from metals dissolved by it, is to expel the amalgam to a degree of heat sufficient to make all the quick-silver rise and evaporate; after which the metal remains in the form of a powder, and being fuited recovers its malleability. If it be thought proper to save the quick-silver, the operation must be performed in close vessels, which will confine and collect the mercurial vapours. This operation is most frequently employed to separate gold and silver from the several sorts of earths and sands with which they are mixed in the ore; because these two metals, gold especially, are of sufficient value to compensate the loss of mercury, which is inevitable in this process: besides, as they very readily amalgamate with it, this way of separating them from every thing unmetallic is very commodious.

Mercury is dissolved by acids; but with circumstances peculiar to each particular acid.

The vitriolic acid concentrated and made boiling hot seizes on it, and presently reduces it to a kind of white powder, which turns yellow by the affusion of water, but does not dissolve in it: it is called turbith mineral. However, the vitriolic acid on this occasion unites with a great part of the mercury in such a manner that the compound is soluble in water. For if to the water which was used to wash the turbith a fixed alkali be added, there falls instantly a rust-coloured precipitate, which is no other than mercury separated from the vitriolic acid by the intervention of the alkali.

This dissolution of mercury by the vitriolic acid is accompanied with a very remarkable phenomenon; which is, that the acid contracts a strong smell of volatile spirit of sulphur: a notable proof that part of the phlogiston of the mercury hath united therewith. And yet, if the mercury be separated by means of a fixed alkali, it does not appear to have suffered any alteration. Turbith mineral is not so volatile as pure mercury.

The nitrous acid dissolves mercury with ease. The solution is limpid and transparent, and as it grows cold shoots into crystals, which are a nitrous mercurial salt.

If this solution be evaporated to drines, the mercury remains impregnated with a little of the acid, under the form of a red powder, which hath obtained the names of red precipitate, and arcanum corallinum. This precipitate, as well as turbith, is less volatile than pure mercury.

If this solution of mercury be mixed with a solution of copper made like water in the nitrous acid, and the mixture evaporated to drines, there will remain a green powder called green precipitate. These precipitates are caustic and corrosive; and are used as such in surgery.

Though mercury be dissolved more easily and completely by the nitrous acid than by the vitriolic, yet it has a greater affinity with the latter than with the former; for if a vitriolic acid be poured into a solution of mercury in spirit of nitre, the mercury will quit the latter
Cinabar is obtained by sublimation, and is called cinabar. It is fired, and is called cinabar. In this form chiefly is mercuric sulphur, as hath been said, yet it hath less affinity with mercure. Regulus of antimony is a metallic sub stance of a pretty bright white colour. It has the splendor, opacity, and gravity of a metal; but it is quite unamalleable, and crumbles to dust, instead of yielding or stretching under the hammer; on which account it is clasped with the semi-metals.

Mercury unites easily and intimately with sulphur. If the two substances be only rubbed together in a gentle heat, or even without any heat, they will contract an union, though but an incomplete one. This combination takes the form of a black powder, which has procured it the name of \textit{Elaeips mineral}.

If a more intimate and perfect union be desired, this compound must be exposed to a stronger heat; and then a red ponderous substance will be sublimed, appearing like a mass of shining needles: this is the combination described, and is called \textit{cinabar}. In this form chiefly is mercury found in the bowels of the earth. Cinabar finely levigated acquires a much brighter red colour, and is known to painters by the name of \textit{vermilion}. Cinabar rises wholly by sublimation, without suffering any decomposition; because the two substances of which it consists, viz. mercury and sulphur, are both volatile.

Though mercury unites and combines very well with sulphur, as hath been said, yet it hath less affinity with that mineral than any other metal, gold only excepted: whence it follows, that any of the other metals will decompose cinabar, by uniting with its sulphur, and so setting the mercury at liberty to appear in its usual form. Mercury thus separated from sulphur, is esteemed the purest, and bears the name of \textit{mercury revivis} from cinabar.

Iron is generally used in this operation preferably to the other metals, because among them all it has the greatest affinity with sulphur, and is the only one that has none with mercury.

Cinabar may also be decomposed by means of fixed alkalis; the affinity of these safts with sulphur being generally greater than that of any metallic sub stance whatever.

\textbf{Of the Semi-Metals.}

\textbf{Of Regulus of Antimony.}

\textit{Regulus} of antimony is a metallic sub stance of a pretty bright white colour. It has the splendor, opacity, and gravity of a metal; but it is quite unamalleable, and crumbles to dust, instead of yielding or stretching under the hammer; on which account it is clasped with the semi-metals.

It begins to flow as soon as it is moderately red; but, like the other semi-metals it cannot stand a violent degree of fire; being thereby dissipated into smoke and white vapours, which adhere to such cold bodies as they meet with, and are collected into a kind of \textit{farina} called \textit{flowers of antimony}.

If regulus of antimony, instead of being exposed to a strong fire, be only heated so moderately that it shall not even melt, it will calcine, lose its phlogiston, and take the form of a greyish powder deficient of all splendor: this powder is called \textit{calx of antimony}.

This calx is not volatile like the regulus, but will endure a very violent fire; and being exposed thereto will flow, and turn to a glafs of the yellowish colour of a hyacinth.

It is to be observed, that the more the regulus is deprived of its phlogiston by continued calcination, the more refractory is the calx obtained from it. The glafs thereof has also so much the less colour, and comes the nearer to common glafs.

The calx and the glafts of antimony will recover their metalline form, like every other calx and glaft of a metal, if reduced by roasting to them their loit phlogiston. Yet, if the calcination be carried too far, their reduction will become much more difficult, and a much smaller quantity of regulus will be refilublitated.

Regulus of antimony is capable of dissolving the metals; but its affinities with them are various, and differ according to the following order. It affects iron the most powerfully, next copper, then tin, lead, and silver. It promotes the fusion of metals, but makes them all brittle and unamalleable.

It will not amalgamate with mercury; and though, by certain processes, particularly the addition of water and continued triturations, a sort of union between these two sub-
sultances may be produced, yet it is but apparent and
momentary; for being left to themselves, and undisturb-
ed, they quickly difunite and separate.

The vitriolic acid, affifled by heat, and even by di-
stillation, dissolves regulus of antimony. The nitrous
acid likewise attacks it; but the solution can by no art
be made clear and limpid; fo that the regulus is only
calciued, in a manner, by this acid.

The marine acid difsolves it well enough; but then it
must be exceedingly concentrated, and applied in a pecu-
liar manner, and especially by distillation. One of the
bell methods of procuring a perfect union between the
acid of sea-falt and regulus of antimony, is to pulverize
the latter, mix it with corrosive sublimate, and distil the
whole. There rifes in the operation a white matter,
thick, and fcarce fluid, which is no other than the regulus
of antimony united and combined with the acid of sea-
falt. This compound is extremely corrosive, and is call-
ed butter of antimony.

It is plain, that the corrosive sublimate is here decomp-
ounded; that the mercury is revivified; and that the
acid which was combined therewith hath quitted it to join
the regulus of antimony, with which its affinity is greater.
This butter of antimony, by repeated distillations,
aquires a considerable degree of fluidity and limpidness.

If the acid of nitre be mixed with butter of antimony,
and the whole diftilled, there rifes an acid liquor, or a
sort of aqua regis, which still retains some of the dis-
folved regulus, and is called bezoardic spirit of nitre.
After the distillation there remains a white matter, from
which fresh spirit of nitre is again abtracted, and which
being then wafted with water, is called bezoar mineral.
This bezoar mineral is neither fo volatile, nor fo caufic,
as butter of antimony; beeause the nitrous acid hath not
the property of volatilizing metallic substances, as the
marine acid does, and becaufe it remains much more in-
timately combined with the reguline part.

If butter of antimony be mixed with water, the liquor
immediately becomes turbid and milky, and a precipitate
falls, which is nothing but the metallic matter partly se-
parated from its acid, which is too much weakened by the
addition of water to keep it difolved. Yet this precipi-
tate still retains a good deal of acid; for which reafon it
continues to be a violent emetic, and in fome degree cor-
rufive. It hath therefore been very improperly called
mercurius viva.

The proper solvent of regulus of antimony is aqua re-
gis; by means whereof a clear and limpid folution of this
femi-metal may be obtained.

Regulus of antimony mixed with nitre, and projected
into a red-hot crucible, fets the nitre in a flame, and
makes it detonate. As it produces this effect by means
of its phlogifton, it muft needs, at the fame time, be cal-
cined, and fave its metallic properties, which accordingly
happens: and when the nitre is in a triple proportion to
the regulus, the latter is fo perfectly calcined as to leave
only a white powder, which is faded with great difficulty,
and then turns to a faintly coloured glafs, not very dif-
ferent from common glafs, and which is not reducible to
a regulus by the addition of inflammable matter; at leaft
it yields but a very small quantity thereof. If lefs nitre
be used, the calx is not fo white; the glafs it produces
is more like a mettalline glafs, and is more easily reduced.
The calx of the regulus thus prepared by nitre is called,
on account of the medicinal virtue acribed to it, diapho-
retic antimony, or diaphoretic mineral.

Nitre always becomes an alkali by deflagration, and in
the prefent cafe retains part of the calx, which it even
renders fublime in water. This calx may be separated
from the alkali, if an acid be employed to precipitate it;
and then it is called materia perlata. This pearly mat-
ter is a calx of antimony, fo completely deprived of its
phlogifton as to be altogether incapable of reduction to a
regulus.

Regulus of antimony readily joins and unites with sul-
phur, forming therewith a compound which has a very
faint metallic splendor. This compound appears like a
mafs of long needles adhering together falamel; and
under this form it is usually found in the ore, or at leaft
when only difperfed from the ftones and earthy matters
with which the ore is mixed. It is called crude
antimony.

Antimony flows with a moderate heat, and becomes
even more fluid than other metallic substances. The
action of fire diffipates or consumes the sulphur it con-
tains, and its phlogifton alfo, fo as to convert it into a
calx and a glafs, as it does the regulus.

Aqua regis, which we obferved to be the proper sol-
vent of the regulus, being poured on antimony, attacks
and difsolves the reguline part, but touches not the sul-
phur; in confequence whereof it decomposes the antimo-
ny, and feparates its sulphur from its regulus.

There are feveral other ways of effecting this decom-
position, and obtaining the reguline part of antimony by
itfelf: They confit either in deftruying the sulphureus
part of the antimony by fubmifion, or in melting the
antimony with fome fubfance which has a greater affini-
ity than its reguline part with sulphur. Moft metals are
very fit for this latter purpofe: For though the regulus
has a confiderable affinity with sulphur, yet all the me-
tals, except gold and mercury, have a greater.

If therefore iron, copper, lead, silver, or tin, be
melted with antimony, the metal employed will unite
with the sulphur, and feparate it from the regulus.

It muft be obferved, that, as these metals have some
affinity with the regulus of antimony, the regulus will
be joined in the operation by fome of the metal employ-
ed as a precipitant, (fo thofe fubfances are called which
serve as the means of feparating two bodies from each
other;) and therefore the regulus procured in this man-
ner will not be abfolutely pure: On this account care is
taken to diftinguifh each by adding the name of the me-
tal employed in its precipitation; and thence come thes
titles, martial regulus of antimony, or only martial re-
gulus, regulus vemeris; and fo of the reft.

Antimony is employed with advantage to feparate
gold from all other metals with which it may be alloyed.
It has been fhewn, that all the metals have a greater affini-
ity, than the reguline part of antimony, with sulphur,
gold only excepted; which is incapable of contradicting
any union therewith: And therefore, if a mafs com-
pounded of gold and feveral other metals be melted with
anti-
antimony, every thing in that mass which is not gold will unite with the sulphur of the antimony. This union occasions two separations, to wit, that of the sulphur of the antimony from its reguline part, and that of the gold from the metals with which it was adulterated; and from the whole two new compounds arise; namely, a combination of the metals with the sulphur, which being lightest rises to the surface in fusion; and a metal-aline mass formed of the gold and the reguline part of the antimony united together, which being much the heaviest sinks to the bottom. There is no difficulty in parting the gold from the regulus of antimony with which it is alloyed: For the metal-aline mass need only be exposed to a degree of fire capable of dissipating into vapours all the semi-metal it contains; which being very volatile, the operation is much easier, and more expeditiously finished, than if the metals with which the gold was debased were to be vitrified on the cupel; without taking into the account that if silver were one of them, recourse must needs be had to the process of quartation after that of the cupel.

If equal parts of nitre and antimony be mixed together, and the mixture exposed to the action of fire, a violent detonation ensues; the nitre deflagrating consumes the sulphur of the antimony, and even a part of its phlogiston. After the detonation there remains a greyish matter which contains fixed nitre, vitriolated tartar, and the reguline part of the antimony in some measure deprived of its phlogiston, and half vitrified by the action of the fire, which is considerably increased by the deflagration. This matter is called liver of antimony.

If instead of equal parts of nitre and antimony, two parts of the former be used to one of the latter, then the reguline part lofs much more of its phlogiston, and remains in the form of a yellowish powder.

Again, if three parts of nitre be taken to one of antimony, the regulus is thereby entirely robbed of its phlogiston, and converted to a white calx which bears the name of diaphoretic antimony, or diaphoretic mineral. The pearly matter may be precipitated by pouring an acid on the saline substances which here remain after the detonation, in the same manner as we shewed above was to be done with regard to the regulus.

In the last two operations, where the nitre is in a double or triple proportion to the antimony, the reguline part is found after the detonation to be converted into a calx, and not into a half vitrified matter, which we have seen is the effect when equal parts only of nitre and antimony are used. The reason of this difference is, that in these two cases the reguline part, being wholly, or almost wholly, deprived of its phlogiston, becomes, as was observed, more difficult to fuse, and consequently cannot begin to vitrify in the same degree of heat as that which hath not lost so much of its phlogiston. If, instead of performing the operation with equal parts of nitre and antimony alone, a portion of some substance which abounds with phlogiston be added, in that case the sulphur only of the antimony will be confumed, and the regulus will remain united with its phlogiston, and separated from its sulphur.

The regulus prepared in this manner is absolutely pure, because no metallic substance being employed, none can mix with it and adulterate it. It is called regulus of antimony per se, or only regulus of antimony.

It is true indeed, that in this operation, much of the reguline part unavoidably loes its phlogiston and is calcined, and consequently a much smaller quantity of regulus is obtained than when metallic precipitants are employed: But this loss is easily repaired, if it be thought proper, by restoring to the calcined part its lost phlogiston.

Antimony melted with two parts of fixed alkali yields no regulus, but is entirely dissolved by the salt, and forms with it a mass of a reddish yellow colour.

The reason why no precipitate is produced on this occasion, is, that the alkali uniting with the sulphur of the antimony forms therewith the combination called liver of sulphur, which by its nature is qualified to keep the reguline part dissolved. This mass, formed by the union of the antimony with the alkali, is soluble in water. If any acid whatever be dropped into this solution, there falls a precipitate of a reddish yellow colour; because the acid unites with the alkali, and forces it to quit the matters with which it is combined. This precipitate is called golden sulphur of antimony.

As in the operation for preparing regulus of antimony per se, some of the nitre is, by the inflammable matters added thereto, turned to an alkali; this alkali feizes on part of the antimony, and therewith forms a compound like that just described. Hence it comes, that if the scoria formed in this process be dissolved in water, and an acid dropped into the solution, a true golden sulphur of antimony is thereby separated.

This union of antimony with an alkali may also be brought about by the humid way; that is, by making use of an alkali resolved into a liquor, and boiling the mineral in it. The alkaline liquor, in proportion as it acts upon the antimony, gradually becomes reddish and turbid. If left to settle and cool, when well saturated therewith, it gradually deposits the antimony it had taken up, which precipitates in the form of a red powder; and this precipitate is the celebrated remedy known by the name of kermes mineral. It is plain, that the kermes is nearly the same thing with the golden sulphur; Yet it differs from it in some respects; and especially in this, that being taken inwardly it operates much more gently than the golden sulphur, which is a violent emetic. Nitre, fixed by charcoal, and resolved into a liquor, is the only alkali employed in preparing the kermes.

It was shown above, that regulus of antimony, mixed and distilled with corrosive sublimate, decomposes it, diverges the mercury, and joining itself to the marine acid forms therewith a new combination, called butter of antimony. If the same operation be performed with crude antimony instead of its regulus, the same effects are produced; but the antimony itself is also decomposed; that is, the reguline part is separated from the sulphur, which being set free unites with the mercury, now also at liberty, and these two together form a true cinabar, called cinabar of antimony.
Of Bismuth.

Bismuth, known also by the name tin-glass, is a semi-metal, having almost the same appearance as regulus of antimony, yet it has a more dulky cast, inclining somewhat to red, and even presents some changeable flecks, especially after lying long in the air.

When exposed to the fire it melts long before it is red, and consequently with less heat than regulus of antimony, which does not flow, as was shewn above, till it begin to be red hot. It becomes volatile, like all the other semi-metals, when acted on by a violent fire: Being kept in fusion by a proper degree of heat it loses its phlogiston with its metallic form, and turns to powder or a calx; and that again is converted into glass by the continued action of fire. The calx and glass of bismuth may be reduced, like any other metallic calxes, by restoring their phlogiston.

Bismuth mixes with all the metals in fusion, and even facilitates the fusion of such as do not otherwise flow readily. It whitens them by its union, and destroys their malleability.

It amalgamates with mercury, if they be rubbed together with the addition of water. Yet after some time these two metallic substanfces detach each other, and the bismuth appears again in the form of a powder. Hence it is plain that the union it contracts with mercury is not perfect; and yet it has the singular property of attenuating lead, and altering it in such a manner that it afterwards amalgamates with mercury much more perfectly, so as even to pass with it through shawoy leather without any separation. The bismuth employed in making this amalgama afterwards separates from it spontaneously, as usual; but the lead still continues united with the mercury, and always retains the property thus acquired.

The vitriolic acid does not dissolve bismuth: Its proper solvent is the nitrous acid, which dissolves it with violence, and abundance of fumes.

Bismuth dissolved in the nitrous acid is precipitated not only by alkalis, but even by the bare addition of water. This precipitate is extremely white, and known by the name of magisterly of bismuth.

The acid of sea-felt and aqua regia likewise acts upon bismuth, but with less violence.

This semi-metal does not sensibly deaggregate with nitre: yet it is quickly deprived of its phlogiston, and turned into a vitrifiable calx, when exposed with it to the action of fire.

It readily unites with sulphur in fusion, and forms therewith a compound which appears to consist of needles adhering laterally to each other.

It may be separated from the sulphur with which it is combined, by only expositing it to the fire, without any addition; for the sulphur is either confumed or sublimed, and leaves the bismuth behind.

Of Zinc.

Zinc to appearance differs but little from bismuth, and has even been confounded with it by several authors. Nevertheless, besides that it has something of a bluish cast, and is harder than bismuth, it differs from it essentially in its properties, as will presently be shewn. These two metallic substanfces scarce resemble each other in any thing, but the qualities common to all semi-metals.

Zinc melts the moment it grows red in the fire, and then also begins to turn to a calx, which, like any other metallic calx, may be reduced by means of the phlogiston: But if the fire be considerably increased, it sublimes, flames, and burns like an oily matter; which is a proof of the great quantity of phlogiston in its composition. At the same time abundance of flowers rise from it in the form of white flakes, flying about in the air like very light bodies; and into this form may the whole substanfce of the zinc be converted. Several names have been given to these flowers, such as pomphelus, philosophic wool. They are supposed to be no other than the zinc itself deprived of its phlogiston; yet no body has hitherto been able to refuscitate them in the form of zinc, by restoring their phlogiston according to the methods used in the reduction of metals. Though they rise in the air with very great ease while the zinc is calcining, yet when once formed they are very fixed; for they withstand the utmost violence of fire, and are capable of being vitrified, especially if joined with a fixed alkali. They are soluble in acids.

Zinc unites with all metallic substanfces, except bismuth. It has this singular property, that being mixed with copper, even in a considerable quantity, such as a fourth part, it does not greatly lessen the ductility thereof, and at the same time communicates to it a very beautiful colour not unlike that of gold: On which account the composition is frequently made, and produces what is called brass. This metal melts much more easily than copper alone, because of the zinc with which it is alloyed.

If it be exposed to a great degree of heat, the zinc which it contains takes fire, and sublimes in white flowers, just as when it is pure.

It is to be observed, that brass is ductile only while it is cold, and not then unless the zinc used in making it was very pure; otherwise the composition will prove but tombac, or prince's metal, having very little malleability.

Zinc is very volatile, and carries off with it any metallic substanfce with which it is fused, making a kind of sublimate thereof. In the furnaces where they smelt ores containing zinc, the matter thus sublimed is called cadmia fornacum, to distinguish it from the native cadmia called also calamine, or lapis calaminaris; which, properly speaking, is an ore of zinc, containing a greater deal of that semi-metal, together with some iron, and a stony substanfce. The name of cadmia fornacum is not appropriated solely to the metallic sublumates procured by means of zinc, but is given in general to all the metallic sublumates found in smelting-houses.

If a violent and sudden heat be applied to zinc, it sublimes in its metallic form; there being time for it to burn and be resolved into flowers.

This semi-metal is soluble in all the acids, but especially in spirit of nitre, which attacks and difsolve it with very great violence.

Zinc has a greater affinity than iron or copper with the vitriolic acid; and therefore it decomposes the green and blue vitriols, precipitating those two metals by
by uniting with the vitriolic acid, with which it forms a metallic salt or vitriol called white vitriol, or vitriol of zinc.

Nitre mixed with zinc, and projected into a red hot crucible, detonates with violence; and during the detonation there arifes a great quantity of white flowers, like those which appear when it is calcined by itself. Sulphur has no power over zinc. Even liver of sulphur, which disolves all other metallic substances, contracts no union with this semi-metal.

Of Regulus of Arsenic.

Regulus of arsenic is the most volatile of all the semi-metals. A very moderate heat makes it wholly evaporate, and fly off in fumes; on which account it cannot be brought to fusion, nor can any considerable masses thereof be obtained. It has a metallic colour, somewhat resembling lead; but soon loses its splendor when exposed to the air.

It unites readily enough with metallic substances, having the same affinities with them as regulus of antimony hath. It makes them brittle, and unmanageable. It hath also the property of rendering them volatile, and greatly facilitates their scorification.

It very easily parts with its phlogiston and metallic form. When exposed to the fire it flies in a kind of shining crystalline calx, which on that account looks more like a saline matter than a metallic calx. To this calx or these flowers are given the names of white arsenic, crystalline arsenic, and most commonly plain arsenic.

Arsenic differs from every other metallic calx, first, in being volatile; whereas the calxes of all other metallic substances, not excepting those of the most volatile semi-metals, such as regulus of antimony and zinc, are exceedingly fixed; and secondly, in having a saline character, which is not found in any other metallic calx. The saline character of arsenic appears, first, from its being soluble in water; secondly, from its corrosive quality, which makes it none of the most violent poisons: a quality from which the other metallic substances are free, when they are not combined with some saline matter. Regulus of antimony must however be excepted: but then the best chemists agree, that this semi-metal is either nearly of the same nature with arsenic, or contains a portion thereof in its composition: besides, its noxious qualities never discover themselves so plainly as when it is combined with some acid. Lastly, arsenic acts just like the vitriolic acid upon nitre: that is, it decompounds that neutral salt, by expelling its acid from its alkaline basis, of which it takes possession, and therewith forms a new saline compound.

This combination is a species of salt that is perfectly neutral. When the operation is performed in a close vessei, the salt shoots into crystals in the form of right-angled quadrangular prisms, terminated at each extremity by pyramids that are also quadrangular and right-angled; some of which, however, instead of ending in a point, are obtuse as if truncated. The consequence is different when the operation is performed in an open vessel; for then nothing is obtained but an alkaline salt impregnated with arsenic, which cannot be crystallized.

The cause of this different effect is this: When the arsenic is once engaged in the alkaline basis of the nitre, it can never be separated from it by the utmost force of fire, so long as it is kept in a close vessel; whereas, if you expose it to the fire without that precaution, it readily separates from it.

This salt poffesses many singular properties, the chief of which are these: First, it cannot be decompounded by the intervention of any acid, even the strongest acid of vitriol: and this, joined to its property of expelling the nitrous acid from its basis, shews that it has a very great affinity with fixed alkalies.

Secondly, this very salt, on which pure acids have no effect, is decompounded with the greatest ease by acids united with metallic substances. The reason of this phenomenon is curious, and furnishes us with an instance of what we advanced concerning double affinities.

If to a solution of any metallic substance whatever, made by any acid whatever, (except that of mercury by the marine acid, and that of gold by aqua regis,) a certain quantity of this salt dissolved in water be added, the metallic substance is instantaneously separated from the acid in which it was dissolved, and falls to the bottom of the liquor.

All metallic precipitates obtained in this manner are found to be a combination of the metal with arsenic; whence it necessarily follows that the neutral salt is by this means decompounded, its arsenical part uniting with the metallic substance, and its alkaline basis with the acid in which that substance was dissolved.

The affinities of these several bodies must be considered as operating on this occasion in the following manner: The acids which tend to decompound the neutral salt of arsenic, by virtue of their affinity with its alkaline basis, are not able to accomplish it, because this affinity is powerfully counteracted by that which the arsenic has with the same alkaline basis, and which is equal or even superior to theirs. But if these acids happen to be united with a substance which naturally has a very great affinity with the arsenical part of the neutral salt, then, the two parts of which this salt consists, being drawn different ways by two several affinities, tending to separate them from each other, the salt will undergo a decomposition, which could not have been effected without the help of this second affinity. Now, as metallic substances have a great affinity with arsenic, it is not surprising that the neutral salt of arsenic, which cannot be decompounded by a pure acid, should nevertheless yield to an acid combined with a metal. The decomposition of this salt, therefore, and the precipitation which of course it produces in metallic solutions, are brought about by the means of a double affinity; namely, that of the acid with the alkaline basis of the neutral salt, and that of the metal with the arsenical part of that salt.

Arsenic has not the same effect on sea-salt as on nitre, and cannot expel its acid; a very singular phenomenon, for which it is hard to assign a reason; for the nitrous acid:
Acid is known to have a greater affinity than the marine acid with alkalis, and even with the basis of sea-salt itself.

Yet arsenic may be combined with the basis of sea-salt, and a neutral salt thereby obtained, like which results from the decomposition of nitre by arsenic: but for that purpose a quadrangular nitre must be first prepared, and arsenic applied thereto as to common nitre.

The salt produced by uniting arsenic with the basis of sea-salt very much resembles the neutral salt of arsenic above treated of, as well in the figure of its crystals as in its several properties.

Arsenic presents another singular phenomenon, both with the alkali of nitre and with that of sea-salt; which is, that if it be combined with these salts in a fluid state, it forms with them a saline compound, quite different from the neutral salts of arsenic which results from the decomposition of nitrous salts.

This saline compound, called liver of arsenic, takes up a much greater quantity of arsenic than is necessary for the perfect saturation of the alkali. It has the appearance of a glue, which is so much the thicker the more arsenic it contains. Its smell is disagreeable; it attracts the moisture of the air, and does not crystallize; it is easily decomposed by any acid whatever, which precipitates the arsenic and unites with the alkali. Lastly, the effects it produces on metallic solutions are different from those of our neutral arsenical salts.

Arsenic, is easily reduced to a regulus. It need only be mixed with any matter containing the phlogiston, and by the help of a moderate heat a true regulus will subside. This regulus is very volatile, and calcines with the greatest ease; which is the reason why it cannot be obtained but in small quantities; and also why, in order to obtain masses of it, some have thought of adding thereto some metal with which it has a great affinity, such as copper or iron; because, by joining with the metal, it is partly fixed and restrained from flying off. But it is plain the regulus obtained by this means is not pure, as it must partake considerably of the metal employed.

Arsenic readily unites with sulphur, and rises with it in a yellow compound called orpiment.

Sulphur cannot be separated from arsenic but by the intervention of two bodies only; to wit, a fixed alkali and mercury.

The property which mercury possesses of separating sulphur from arsenic is founded on this, that these two metallic substances are incapable of contracting any union; whereas, though most of the other metals and semimetals have a greater affinity with sulphur than mercury hath, nevertheless they are all unable to decompose orpiment; because some of them have as great an affinity with arsenic as with sulphur; others have no affinity with either; and lastly, sulphur hath as great an affinity with arsenic as with any of them.

It must be observed, that, if fixed alkalis be employed to purify arsenic in this manner, no more must be used than is necessary to absorb the sulphur or the phlogiston, of which also it is their nature to deprive arsenic; for otherwise, as it has been shown that arsenic readily unites with alkalis, they would absorb a considerable quantity thereof.

**Chemistry.**

**Oil in general.**

Oil is an unctuous body, which burns and consumes with flame and smoke, and is not soluble in water. It conflict of the phlogiston united with water by means of an acid. There is, moreover, in its composition a certain proportion of earth, more or less according to each several sort of oil.

The inflammability of oil evidently proves that it contains the phlogiston. That an acid is one of its constituent principles many experiments demonstrate, of which there are the chief: If certain oils be long triturated with an alkaline salt, and the alkali afterwards dissolved in water, crystals of a true neutral salt will be produced: some metals, and particularly copper, are corroded and rafied by oils, just as they are by acids: again, acid crystals are found in some oils that have been long kept. This acid in oil serves undoubtedly to unite its phlogiston with its water; because these two substances having no affinity with each other cannot be united without the intervention of such a medium as an acid, which has an affinity with both. As to the existence of water in oils, it appears plainly when they are decomposed by repeated distillations, especially after mixing them with absorbent earths. Lastly, when an oil is destroyed by burning, a certain quantity of earth is constantly left behind.

Oils exposed to the fire in close vessels pass over almost wholly from the containing vessel into any other applied to receive them. There remains, however, a small quantity of black matter, which is extremely fixed, and continues unalterable as long as it has no communication with the external air, be the force of the fire ever so violent. This matter is no other than part of the phlogiston of the oil united with its moist fixed and grosser earth; and this is what we called charcoal, or plainly a coal.

**Charcoal.**

When oil happens to be united to much earth, as it is in vegetable and animal bodies, it leaves a considerable quantity of coal or charred matter.

This coal, exposed to the fire in the open air, burns and waistes, but without blazing like other combustible matters: there appears only a small bluish flame, but not the least smoke. Most commonly it only glows and sparkles, and so gradually falls into ashes, which are nothing but the earth of the body combined with an alkaline salt in burning. This alkaline salt may be separated from the earth, by lixiviating the ashes with water, which dissolves all the salt, and leaves the earth quite pure.

Charcoal is unalterable and indestructible by any other body but fire; whence it follows, that when it is not actually kindled and ignited, the most powerful agents, such as the acids, though ever so strong and concentrated, have not the least effect on it.

The coal is otherwise when it is lighted, that is, when its phlogiston begins to separate from its earth; for then the pure acid of vitriol being joined therewith contracts an...
an instantaneous union with its phlogiston, and evaporates in a volatile sulphureous spirit. If the vitriolic acid, instead of being applied quite pure, be first clogged with some basis, especially an alkaline one, it quits that basis, enters into a more intimate union with the phlogiston of the burning coal, and so forms an actual sulphur, with which the alkali now unites and forms a phos- phorus.

The pure acid sea-salt hath not been observed to act in the leaf upon charcoal, especially when it is not on fire. But when this acid is incorporated with an alkaline or metallic basis, and combined according to a peculiar process with burning charcoal, it in like manner quits its basis, unites with the phlogiston, and therewith forms a phosphorus.

Nor has the pure nitrous acid any effect on a charred coal, even when ignited; and so far is it from being able to kindle a cold one, that when poured on a live one, it extinguishes it like water. But when this acid is united with a basis, it quits it, rapidly as soon as it touches a burning coal, and rushes violently into an union with the phlogiston thereof. From this union there follows the inflammability of the oils combined with them. Thus, while they serve to constitute soap, they do not, as is commonly supposed, lose the properties that belong to them; they mutually communicate the properties belonging to them. The acids of nitre and vitriol act upon oils; but very differently, according to the quantity of phlegm they contain. If they be awakened with much water, they have no effect at all upon oils: if they contain little water, or be dephlegmated to a certain degree, they dissolve them with heat, and with them form compounds of a thick consistence. Acids thus combined in a considerable proportion with oils render them soluble in water.

Of Soap.

Alkalis also have the same property. When an oil is combined with an acid, or an alkali, in such a manner that the compound resulting from their union is soluble in water; such a compound may in general be called soap. Soap itself hath the property of rendering fat bodies in some measure soluble in water; on which account it is very useful for scouring or cleansing any thing greasy.

Oily and saline substances, combined together, observe the same general rules as all other combinations; that is, they mutually communicate the properties belonging to each: thus oils, which naturally are not soluble in water, acquire by their union with saline matters the property of dissolving therein; and fats lose by their conjunction with oils part of their natural tendency to incorporate with water; so that while they serve to constitute soap, they do not, as before, attract the moisture of the air, &c. and in like manner, as they are not inflammable, they considerably lessen the inflammability of the oils combined with them.

Acid soaps are decomposed by alkalis, as alkaline soaps are by acids, according to the general rules of affinities.

The acids of nitre and vitriol, when highly concentrated, dissolve oils with such violence as to heat them, make them black, burn them, and even set them on fire. How sea-salt affects oils is not yet sufficiently ascertained. All oils have the property of dissolving sulphur; which is not at all surprising, seeing each of its component principles hath an affinity with oil.

It is also a property common to all oils to become more fluid, subtile, light, and limpid, the oftener they are distilled. On the contrary, by being incorporated with saline substances, they acquire a greater consistence, and sometimes form compounds that are almost solid.

Of the several sorts of Oils.

Oils are distinguished by the substances from which they are drawn: and as oils are extracted from minerals, from vegetables, and from animals, there are of course mineral, vegetable, and animal oils.

Of Mineral Oils.

In the bowels of the earth we find but one sort of oil, called petroleum: Its smell is strong, and not disagreeable, and its colour sometimes more, sometimes less yellow. There are certain mineral substances which yield by distillation a great deal of oil very like petroleum. This sort of substance is called a bitumen, and is, indeed, nothing but an oil rendered consistient and solid by being combined with an acid; as appears from hence, that, by uniting petroleum with the acid of vitriol, we can produce an artificial bitumen very like the native.

Of Vegetable Oils.

Vegetable substances yield a very great quantity and variety of oils; for there is not a plant, or part of a plant, that does not contain one or more sorts thereof, generally peculiar to itself, and different from all others. By expression only, that is, by bruising and squeezing vegetable substances, particularly certain fruits and seeds, a fort of oil is obtained which has scarce any smell or taste. Oils of this sort are very mild and unctuous; and, because in this respect they resemble animal fat more than the rest do, they are called fat oils.

These oils, being exposed to the air for some time, sooner or later grow thick, acquire an acid taste, and a strong disagreeable smell. Some of them congeal with the smallest degree of cold. This sort of oil is well adapted to dissolve those preparations of lead called litharge and minium, with which they form a thick tenacious substance, that is used for the basis of almost all plasters. They also dissolve lead in its metallic form, but not so easily as the sorts of calx above-mentioned; probably because its body is not so much opened, nor its parts so divided.

By expression alone we also procure from certain vegetable substances another sort of oil, which is thin, limpid, volatile, of a pungent taste, and retains the smell of the vegetable that yielded it; on which account it is called an essential oil. Of this there are several sorts, differing from one another, like the fat oils, according to the subjects from which they are obtained.

We must observe, that it is very difficult, or rather in most cases impossible, to force from the greatest part of vegetables, by expression only, all the essential oil they contain.
contain. For this purpose, therefore, recourse must be had to fire: a gentle heat, not exceeding that of boiling water, will extract all the essential oils of a vegetable; and this is the most usual and most convenient way of procuring them.

The fat oils cannot be obtained by the same method: these being much less volatile than the essential oils, require a much greater degree of heat to raise them; which, nevertheless, they cannot bear without being much spoiled and entirely changed in their nature, as shall presently be shewn. All oils, therefore, which rise with the heat of boiling water, and such alone, should be called essential oils.

Essential oils, in a longer or shorter time, according to the nature of each, lose the fragrant smell they had when newly distilled, and acquire another which is strong, rancid, and much less agreeable: they also lose their tenacity, becoming thick and viscid; and in this state they greatly resemble those substances abounding in oil which flow from certain trees, and which are called balsams or resins, according as they are less or more confinuous.

Balsams and resins are not soluble in water. But there are other oily compounds which likewise run from trees; and, though not unlike resins, are however soluble in water. These are called gums; and their property of dissolving in water arises from their containing more water and more salt than resins have; or at least their saline parts are less clogged and more dispersely. Balsams and resins distilled with the heat of boiling water yield great quantities of a limpid, subtle, odoriferous, and, in one word, essential oil. In the still there remains a substance thicker and more confinuous than the balsam or resin before distillation. The same thing happens to essential oils which by length of time have acquired a confinuous, and are grown resinous. If they be redistilled, they recover their former tenacity, leaving behind them a remainder thicker and more resinous than they themselves were. This second distillation is called the rectification of an oil.

It must be observed, that an essential oil, combined with an acid strong enough to dissolve it, immediately becomes as thick and resinous, in consequence of this union, as if it had been long exposed to the air; which proves the tenacity an oil acquires by long keeping to be owing to this, that its lightest and least acid parts being evaporated, the proportion of its acid to the remainder is so increased, that it produces therein the same change as an additional acid mixed with the oil would have wrought before the evaporation.

This also shews us, that balsams and resins are only essential oils combined with a great proportion of acid, and thereby thickened.

If vegetable substances, from which no more essential oil can be drawn by the heat of boiling water, be exposed to a stronger heat, they yield an additional quantity of oil; but it is thinner and heavier than the essential oil. These oils are black, and have a very disagreeable burnt smell, which hath made them be called fetid, or empyreumatic oils. They are moreover very acrid.

It must be observed, that if a vegetable substance be exposed to a degree of heat greater than that of boiling water, before the fat or the essential oil is extracted from it, an empyreumatic oil only will then be obtained; because both the fat and essential oils, when exposed to the force of fire, are thereby burnt, rendered acrid, acquire a smell of the fire, and, in a word, become truly empyreumatic. There is ground to think, that an empyreumatic oil is nothing else but an essential or fat oil burnt and spoilt by the fire, and that no other oil besides these two exists naturally in vegetables.

Empyreumatic oils, distilled and rectified several times by a gentle heat, acquire by every distillation a greater degree of tenacity, lightness, and limpidity. By this means also they lose something of their disagreeable odour; so that they gradually come nearer and nearer to the nature of essential oils: and if the rectifications be often enough repeated, ten or twelve times for instance, they become perfectly like those oils; except that their smell will never be so agreeable, nor like that of the substances from which they were obtained.

Fat oils may also be brought by the same means to resemble essential oils: but neither essential nor empyreumatic oils are capable of acquiring the properties of fat oils.

Of Animal Oils.

Distillation procures us considerable quantities of oil from all the parts of animal bodies, and especially from their fat. This oil at first is not very fluid, and is extremely fetid; but by many rectifications it gradually acquires a great degree of clearness and tenacity, and at the same time loses much of its disagreeable odour.

Of Fermentation in general.

By fermentation is meant an intestine motion, which, arising spontaneously among the insensible parts of a body, produces a new disposition and a different combination of those parts.

To excite a fermentation in a mixt body, it is necessary, first, that there be in the composition of that mixt a certain proportion of water, fatty, oily, and earthy parts; but this proportion is not yet sufficiently ascertained. Secondly, it is requisite that the body to be fermented be placed in a certain degree of temperate heat; for much cold obstructs fermentation, and too much heat decomposes bodies. Lastly, the concurrence of the air is also necessary to fermentation.

All vegetable and animal substances are susceptible of fermentation, because all of them contain in a due proportion the principles above specified. However, many of them want the proper quantity of water, and cannot ferment while they remain in such a state of dryness. But it is easy to supply that defect.

With respect to minerals properly so called, they are not subject to any fermentation, at least that our senses can perceive.

There are three sorts of fermentation, distinguished from one another by their several productions. The first produces wines and spirituous liquors; for which reason it is called the vinous or spirituous fermentation: the result of the second is an acid liquor; and therefore it is called
called the acetic fermentation: and the third generates an alkaline salt; which, however, differs from the alkaline salts hitherto treated of, in this respect chiefly, that, instead of being fixed, it is extremely volatile: This last fort takes the name of the putrid or putrefactive fermentation. We shall now consider these three forts of fermentation and their effects a little more particularly.

These three sorts of fermentation may take place successively in the same subject; which proves them to be only three different degrees of fermentation, all proceeding from one and the same cause. These degrees of fermentation always follow the order in which we have here placed them.

Of the Spirituous, or Vinous Fermentation.

The juices of almost all fruits, all saccharine vegetable matters, all farinaceous seeds and grains of every kind, being diluted with a sufficient quantity of water, are proper subjects of spirituous fermentation. If such liquors be exposed, in vessels slightly slopped, to a moderate degree of heat, they begin in some time to grow turbid; there arises infensibly a small commotion among their parts, attended with a hissing noise; this little and little increases, till the grosser parts appear, like little seeds or grains, moving to and fro, agitated among themselves, and thrown up to the surface. At the same time some air-bubbles rise, and the liquor acquires a pungent, penetrating smell, occasioned by the very subtle vapours which exhale from it.

These vapours have never yet been collected, in order to examine their nature; and they are known only by their noxious effects. They are so actively pernicious, that if a man comes rashly into a close place, where large quantities of liquors are fermenting, he suddenly drops down and expires, as if he were knocked on the head.

When these several phenomena begin to go off, it is proper to stop the fermentation, if a very spirituous liquor be required: for if it be suffered to continue longer, the liquor will become acid, and from thence proceed to its last stage, that is, to putrefaction. This is done by slopping the containing vessels very close, and removing them from the air and frost, agitated among themselves, and thrown up to the surface. At the same time some air-bubbles rise, and the liquor acquires a pungent, penetrating smell, occasioned by the very subtle vapours which exhale from it.

Liquors thus fermented are in general called wines:

For though in common life that word properly signifies the fermented juice of grapes only, and particular names are given to the fermented juices of other vegetable substances, as that obtained from apples, is called cyder; that made from malt is called beer; yet in chemistry it is of use to have one general term denoting every liquor that has undergone this first degree of fermentation.

By distillation we draw from wine an inflammable liquor, which, comes off in the first distillation is commonly loaded with much phlegm and some oily parts, from which it may be afterwards freed. In this state it goes by the name of brandy; but, when freed from these heterogeneous matters by repeated distillations, it becomes still clearer, lighter, more fragrant, and much more inflammable, and then is called spirit of wine, or ardent spirits, if considerably purified. The properties which distinguish an ardent spirit from all other substances are, its being inflammable; its burning and consuming entirely, without the least appearance of smoke or taint or ignitiveness; its containing no particles reducible to a coal; and its being perfectly miscible with water. Ardent spirits are lighter and more volatile than any of the principles of the mixts from which they were produced, and consequently more so than the phlegm, the acid, and the oil of which they themselves consist. This arises from a particular disposition of these principles, which are in a singular manner attenuated by fermentation, and thereby rendered more susceptible of expansion and rarefaction.

Ardent spirits are supposed to be the natural solvents of oils and oily matters. But it is very remarkable, that they dissolve essential oils only, without touching the fat of animals, or the fat oils obtained from vegetables by expression; yet when these oils have once undergone the action of fire, they become soluble in spirit of wine, and even acquire a new degree of solubility every time they are distilled. It is not so with essential oils, which can never be rendered more soluble in ardent spirits than they are at first; and are so far from acquiring a new degree of solubility every time they are distilled, that on the contrary they even in some measure lose that property by repeated rectifications.

Spirit of wine doth not dissolve fixed alkalis; or at least it takes up but a very small quantity thereof; and hence ardent spirits may be freed from much of their phlegm by means of these fats thoroughly dried: For as they strongly imbibe moisture, and have even a greater affinity than ardent spirits with water, if a fixed alkali well estracted be mixed with spirit of wine that is not perfectly dephlegmated, the alkali immediately attracts its superfusuous moisture, and is thereby resolved into a liquor, which on account of its gravity descends to the bottom of the vessel. The spirit of wine, which swims at top, is by this means as much dephlegmated, and as dry, as if it had been rectified by several distillations. As it takes up some alkaline particles in this operation, it is thereby qualified to dissolve oily matters with the greater facility. When rectified in this manner, it is called rawer or spirit of wine.

Yet spirit of wine, even when rectified to an alcohol, is not capable of dissolving all oily matters. Those named gums will by no means enter into any sort of union therewith; but it readily dissolves most of those which are known by the appellation of resins. When it has dissolved a certain proportion of resinous particles, it acquires a greater confidence, and forms what is called a spirit varnish, or a drying varnish, because it soon dries. This varnish is subject to be damaged by water. Many sorts thereof are prepared, different from each other according to the different resins employed, or the proportions
Such bitumens or resins as spirit of wine will not touch are dissolved in oils by means of fire, and then form another kind of varnish which water does not hurt. These varnishes are usually coloured, and require much longer time to dry than the spirit-varnishes: They are called oil-varnishes.

Spirit of wine hath a much greater affinity with water than with oily matters; and therefore if a solution of any oil or resin in spirit of wine be mixed with water, the liquor immediately grows turbid, and acquires a whitish milky colour, owing entirely to the oily parts being separated from the spirituous menstruum by the accession of water, and too finely divided to appear in their natural form. But if the liquor stands some time quiet, several of these particles unite together, and gradually acquire a bulk sufficient to render them very perceptible to the eye.

Acids have an affinity with spirit of wine, and may be combined with it. By this union they lose most of their acidity, and on that account are said to be dulced.

One part of highly concentrated oil of vitriol being mixed with four parts of well dephlegmated spirit of wine, there arises immediately a considerable ebullition and effervescence, attended with great heat, and abundance of vapours, which smell pleasantly, but are hurtful to the lungs. At the same time is heard a hissing like that produced by a piece of red-hot iron plunged in water. Indeed it is proper to mix the liquors very gradually; for otherwise the vessels in which the operation is performed will be in great danger of breaking.

If two liquors thus mixed be distilled with a very gentle heat, there rises first a spirit of wine of a most penetrating and grateful odour: When about half thereof is come over, what follows has a quicker and more sulphureous smell, and is also more loaded with phlegm. When the liquor begins to boil a little, there comes off a phlegm which smells very strong of sulphur, and grows gradually more acid. On this phlegm floats a small quantity of a very light and very limpid oil. In the still there remains a thick, blackish substance, somewhat like a resin or bitumen. From this substance may be separated a good deal of a vitriolic but sulphureous acid. When that is extracted, there remains a black mass like a charred coal, which, being put into a crucible, and exposed to a violent heat, leaves a small portion of earth, very fixed, and even vitrifiable.

By rectifying the ardent spirit, which came over in distilling the above-mentioned mixture, a very singular liquor is obtained, which differs essentially both from oils and from ardent spirits, though in certain respects it resembles them both. This liquor is known in chemistry by the name of æther, and its chief properties are as follows.

Æther is lighter, more volatile, and more inflammable, than the most highly rectified spirit of wine. It quickly flies off when exposed to the air, and suddenly catches fire when any flame approaches it. It burns like spirit of wine without the least smoke, and consumes entirely without leaving the smallest appearance of a coal or ashes. It dissolves oils and oily matters with great ease and rapidity. These properties it has in common with an ardent spirit. But it resembles an oil, in that it is not miscible with water; and this makes it essentially different from spirit of wine, the nature of which is to be miscible with all aqueous liquors.

Another very singular property of æther is its great affinity with gold, exceeding even that of aqua regis. It does not indeed dissolve gold when in a mass, and in its metallic form; But if a small quantity of æther be added to a solution of gold in aqua regis, and the whole shaken together, the gold separates from the aqua regis, joins the æther, and remains dissolved therein.

The reason of all the phenomena above-mentioned, resulting from the mixture of spirit of wine with oil of vitriol, is founded on the great affinity between this acid and water. For if the vitriolic acid be weak, and as it were over-dosed with watery parts, neither oil nor æther can be obtained by means thereof: But when highly concentrated, it attracts the aqueous parts very powerfully; and therefore being mixed with spirit of wine, lays hold of most of the water contained in it, and even robs it of some portion of that which is essential to its nature, and necessary to constitute it spirit of wine: Whence it comes to pass, that a certain quantity of the oily particles in its composition being separated from the watery particles, and so brought nearer to each other, they unite and assume their natural form; and thus the oil that swims at top of the sulphurous phlegm is produced.

The vitriolic acid moreover thickens and even burns some of this oil; and hence comes the bituminous residuum left at the bottom of the still, which looks like the result of a vitriolic acid combined with common oil. Lastly, the vitriolic acid becomes sulphurous, as it always doth when united with oily matters, and also very aqueous, on account of the quantity of phlegm which it attracts from the spirit of wine.

Æther may be considered as a spirit of wine exceedingly dephlegmated, even to such a degree that its nature is thereby changed; so that the few aqueous particles left in it are not sufficient to dissolve the oily particles and keep them asunder; which therefore being now much nearer to one another than in common spirit of wine, the liquor hath lost its property of being miscible with water.

Spirit of nitre, well dephlegmated, and combined with spirit of wine, presents likewise some very singular appearances.

First, in the very instant of its mixture with spirit of wine, it produces a greater and more evident effervescence than the vitriolic acid occasions.

Secondly, this mixture, without the help of distillation, and only by stopping the bottle in which the liquors are contained, affords a sort of æther, produced probably by the vapours which ascend from, and swim at the top of the mixture.

Thirdly, some authors pretend, that by distilling the mixture under consideration an oil is obtained greatly resembling that which rises from spirit of wine combined with vitriolic acid.

Fourthly, the two liquors we are speaking of, being intimately
intermediately mixed by distillation, form a liquor slightly acid, used in medicine, and known by the name of *fustet or distilled spirit of nitre*: a very proper name, seeing the nitrous acid, by uniting with the spirit of wine, actually loses almost all its acidity and corrosive quality.

Fifthly, when the distillation is finished, there remains in the bottom of the vessel a thick, blackish substance, nearly resembling that which is found after distilling oil of vitriol and spirit of wine.

Spirit of salt hath likewise been combined with spirit of wine; but it does not unite therewith so easily or so intimately as the two acids above mentioned. To mix them thoroughly, the spirit of salt must be highly concentrated, and smoked; and moreover the assistance of the still must be called in. Some authors pretend, that from this mixture also a small quantity of oil may be obtained; which probably happens when the liquors have the qualities above specified. The marine acid likewise, by uniting with spirit of wine, loses most of its acidity; on which account it is in like manner called *suest or distilled spirit of salt*. A thick residue is also found here after distillation.

Of the Acidous Fermentation.

Besides an ardent spirit, wine affords a great deal of water, oil, earth, and a sort of acid which shall be considered presently. When the spirituous part is separated from these other matters, they undergo no further change. But if all the constituent parts of wine remain combined together, then, after some time, shorter or longer as the degree of heat in which the wine stands is greater or less, the fermentation begins afresh, or rather arrives at its second stage. The liquor once more grows turbid, a new interlaced motion arises, and after some days it is found changed into an acid; which, however, is very different from those hitherto treated of. The liquor then takes the name of *vinaer*. The acetous fermentation differs from the spirituous, not only in its effect, but also in several of its concomitant circumstances. Moderate motion is of service to this, whereas it obstructs the spirituous; and it is attended with much more warmth than the spirituous. The vapours it produces are not noxious, like those of fermenting wine. Lastly, vinegar deposits no tartar, even when the wine employed in this operation is quite new, and had not had time to discharge its tartar: instead of tartar, vinegar deposits a viscid matter which is very apt to putrify.

Of Vinegar.

If wine, which has gone through this second stage of fermentation, be distilled, instead of an ardent spirit, only an acid liquor is obtained, which is called *distilled vinegar*.

This acid has the same properties as the mineral acids; that is, it unites with alkaline salts, absorbent earths, and metallic substances, and therewith forms neutral saline combinations.

Its affinity with these substances observes the same order as that observed by the mineral acids with regard to the same substances; but in general it is weaker; that is, any mineral acid is capable of expelling the acid of vinegar out of all matters with which it is united.

Vinegar hath likewise a greater affinity than sulphur with alcalis: whence it follows, that it is capable of decomposing that combination of sulphur with an alkali called liver of sulphur, and of precipitating the sulphur it contains.

The acid of vinegar is always clogged with a certain proportion of oily parts, which greatly weaken it, and deprive it of much of its activity; and for this reason it is not near so strong as the mineral acids, which are not tangled with any oil. By distillation, indeed, it may be freed from this oil, and at the same time from the great quantity of water which in a manner suffocates it, and by that means may be brought much nearer to the nature of the mineral acids: but this attempt hath not yet been prosecuted with the affiduity it deserves. Besides distillation, there is another way of freeing vinegar from a good deal of its phlegm; and that is, by exposing it to a hard frost, which readily congeals the watery part into ice, while the acid retains its fluidity.

Vinegar, saturated with a fixed alkali, forms a neutral oily salt, of a dark colour, which is semi-volatile, melts with a very gentle heat, flames when thrown upon burning coals, and dissolves in spirit of wine, of which, however, it requires fix parts to complete the solution. This solution being evaporated to driness leaves a matter in the form of leaves lying on each other; on which account it hath obtained the name of *terra foliata*. The same foliated matter will be obtained, though the salt be not previously dissolved in spirit of wine; but not so readily. This salt is also called *regenerated tartar*. Under the head of tartar we shall see the reason of these different appellations. Regenerated tartar is also in some degree capable of crystallizing: for this purpose a resolution thereof in water must be slowly evaporated to the constancy of a syrup, and then suffered to stand quiet in a cool place; by which means it will shoot into clusters of crystals, lying one upon another, not unlike the feathers on a quill.

With vinegar and several absorbent earths, such as calcined pearls, coral, shells of fish, &c. are also formed neutral saline compounds, each of which take the name of the particular earth employed in its composition.

Vinegar perfectly dissolves lead, and converts it to a neutral metallic salt, which shoots into crystals, and has a sweet saccharine taste. This compound is called sugar of lead, or *sal Saturni*.

If lead be exposed to the bare vapour of vinegar, it will be thereby corroded, calcined, and converted into a white matter much used in painting, and known by the name of *ceruse*, or, when it is finer than ordinary, *white-lead*.

Vinegar corrodes copper likewise, and converts it into a beautiful green ruff, which also is used in painting, and distinguished by the name of *verdigris*. However, vinegar is not commonly employed to make verdigris: for this purpose they use wine, or the rape of wine, from which fire extricates an acid analogous to that of vinegar.
CHEMISTRY.

OF TARTAR.

This substance is a saline compound, consisting of earthy, oily, and especially acid parts. It is found in the form of crusts, adhering to the inner sides of vessels in which wines have stood for some time, particularly acid wines, such as those of Germany.

Tartar derives its origin from the superabundant quantity of the acid contained in the juice of the grape. This superfluous acid, being more than is requisite to constitute the ardent spirit, unites with some of the oil and earth contained in the fermented liquor, and forms a kind of salt; which for some time continues suspended in that liquor, but, when the wine stands undisturbed in a cool place, is deposited, as hath been said, on the sides of the casks.

When it is purified, there appears on the surface of the liquor a sort of white crystalline pellicle, which is skimmed off as it forms. This matter is called cream of tartar. The same liquor which produces this cream, and in which the purified tartar is dissolved, being kept to cool, yields a great number of white semi-transparent crystals, which are called crystals of tartar. The cream and the crystals of tartar are therefore no other than purified tartar, and differ from each other in their form only.

Though the crystals of tartar have every appearance of a neutral salt, yet they are far from being such; for they have all the properties of a true acid, which scarce differs from that of vinegar, except that it contains less water, and more earth and oil; to which it owes its solid form, as well as its property of not being soluble in water without much difficulty: for a very great quantity of water is requisite to keep the crystals of tartar in solution; and it must moreover be boiling hot; otherwise as soon as it cools most of the tartar dissolved in it separates from the liquor, and falls to the bottom in the form of a white powder.

Tartar is decomposed by calcination in the open fire. All its oily parts are consumed or diffipated in smoke, together with most of its acid. The other parts of its acid, uniting intimately with its earth, forms a very strong and very pure fixed alkali, called salt of tartar.

It will be shewn in its proper place, that almost every vegetable matter, as well as tartar, leaves a fixed alkali in its ashes: yet tartar has these peculiar properties; first, it assumes an alkaline character even when burnt or calcined in close vessels, whereas other substances acquire it only by being burnt in the open air: secondly, the alkali of tartar is stronger and more saline than almost any that is obtained from other matters.

This alkali, when thoroughly calcined, powerfully attracteth the moisture of the air, and melts into an unctuous alkaline liquor, improperly called oil of tartar per deliquium. This is the alkali generally used in making the terra foliata, mentioned under the head of vinegar; for which reason this combination is called terra foliata tartari.

Crystals of tartar combined with alkali of tartar produce a great effervescence while they are mixing, as all acids usually do; and if the combination be brought exactly up to the point of saturation, a perfectly neutral salt is formed, which shoots into crystals, and easily dissolves in water; and this hath procured it the name of soluble tartar. It is also called the vegetable salt, as being obtained from vegetables only; and again tartarised tartar, because it consists of the acid and the alkali of tartar combined together.

Crystals of tartar combined with alkali procured from the ashes of sea-weeds, such as soda, which alkalis resemble the basis of sea-salt, form likewise a neutral salt, which crystallizes well, and dissolves easily in water. This salt is another sort of soluble tartar. It is called Saignette's salt, from the inventor's name.

Tartar likewise dissolves the absorbent earths, as lime, chalk, &c. and with them forms neutral salts which are soluble in water. It even attacks metallic bodies, and when combined with them becomes soluble. A soluble tartar for medical use is prepared with crystals of tartar and iron: the metallic salt thereby produced hath the name of chalybeated soluble tartar. This salt attracts the moisture of the air, and is one of those which do not crystallize.

Crystallized tartar acts also upon several other metallic substances: for instance, it dissolves the regulus, liver, and glafs of antimony, and thence acquires an emetic quality: it is then called fobiculated, or medicinal tartar. It likewise dissolves lead, and therewith forms a salt which, in the figure of its crystals, resembles tartarised tartar.

It is very extraordinary, that tartar, which of itself is not soluble in water, should be soluble therein when become a neutral salt by uniting either with alkalis or with absorbent earths, or even with metals. All the soluble tartars are easily decomposed by expelling them to a certain degree of heat. In distillation they yield the same principles which are obtained from tartar; and what remains fixed in the fire, after they are thoroughly burnt, is a compound of the alkali which tartar naturally produces, and of the alkaline or metallic substance with which it was converted into a neutral salt.

As crystal of tartar is the weakest of all acids, on account of the oily and earthy matters with which it is combined, soluble tartars are decomposed by all the acids; and by any of which crystal of tartar may be separated from the substance that serves it for a basis and renders it a neutral salt.

Of the Putrid Fermentation, or Putrefaction.

Every body which hath gone through the two stages of fermentation above described, that is, the spiritsuous and the acceous fermentation, being left to itself in a due degree of warmth, which varies according to the subject, advances to the last stage of fermentation; that is, to putrefaction.

When a body is in a putrefying state, it is easy to discover, by the vapours which rise from it, by the opacity which invades it, if a pellucid liquor, and frequently even by a greater degree of heat than is found in the two other forts of fermentation, that an intellel motion is begun among its constituent parts, which lasts till the whole be entirely putrefied.

The effect of this intellel motion is to break the union,
union, and change the disposition, of the particles constituting the body in which it is excited, and to produce a new combination.

If we examine a substance that has undergone putrefaction, we shall soon perceive that it contains a principle which did not exist in it before. If this substance be distilled, there rises first, by means of a very gentle heat, a saline matter which is exceedingly volatile, and affects the organ of smelling briskly and disagreeably. Nor is the aid of distillation necessary to discover the presence of this product of putrefaction: it readily manifests itself in most substances where it exists, as any one may soon be convinced by observing the different smell of fresh and of putrefied urine; for the latter not only affects the nose, but even makes the eyes smart, and irritates them so as to draw tears from them in abundance.

This saline principle, which is the product of putrefaction, when separated from the other principles of the body which affords it, and collected by itself, appears either in the form of a liquor, or in that of a concrete salt, according to the different methods used to obtain it. In the former state it is called a volatile urinous spirit; and in the latter a volatile urinous salt. The qualification of urinous is given it, because a great deal thereof is generated in putrefied urine, to which it communicates its smell. It goes also by the general name of a volatile alkali, whether in a concrete or in a liquid form. The enumeration of its properties will shew why it is called an alkali.

Volatile alkalis, from whatever substance obtained, are all alike, and have all the same properties; differing only according to their degrees of purity. The volatile alkali, as well as the fixed, consists of a certain quantity of acid combined with, and entangled by a portion of the earth of the mixt body from which it was obtained; and on that account it has many properties like those of a fixed alkali. But there is moreover in its composition a considerable quantity of a fat or oily matter, of which there is none in a fixed alkali; and on this account again there is a great difference between them. Thus the volatility of the alkali produced by putrefaction, which is the principal difference between it and the other kind of alkali, whose nature is to be fixed, must be attributed to the portion of oil which it contains: for there is a certain method of volatilizing fixed alkalis by means of a fatty substance.

Volatile alkalis have a great affinity with acids, unite therewith rapidly, and with ebullition, and form with them neutral salts, which shoot into crystals, but differ from one another according to the kind of acid employed in the combination.

The neutral salts which have a volatile alkali for their basis are in general called ammoniacal salts. That whose acid is the acid of sea-salt is called sal ammoniac. As this was the first known, it gave name to all the rest. Great quantities of this salt are made in Egypt, and hence brought to us. They sublime it from the foot of cow's dung, which is the fuel of that country, and contains sea-salt, together with a volatile alkali, or at least the materials proper for forming it; and consequently all the ingredients that enter into the composition of sal ammoniac.

The neutral salts formed by combining the acids of nitre and of vitriol with a volatile alkali, are called, after their acids, nitrous sal ammoniac, and vitriolic sal ammoniac: The latter, from the name of its inventor, is also called Glauber's secret sal ammoniac.

A volatile alkali, then, has the same property as a fixed alkali with regard to acids; yet they differ in this, that the affinity of the former with acids is weaker than that of the latter: and hence it follows, that any sal ammoniac may be decomposed by a fixed alkali, which will lay hold of the acid, and discharge the volatile alkali.

A volatile alkali will decompose any neutral salt which has not a fixed alkali for its basis; that is, all such as consist of an acid combined with an absorbent earth or a metallic substance. By joining with the acids in which they are dissolved, it enganges the earths or metallic substances, takes their place, and, in conjunction with their acids, forms ammoniacal salts.

Hence it might be concluded, that, of all substances, next to the phlogiston and the fixed alkalis, volatile alkalis have the greatest affinity with acids in general. Yet there is some difficulty in this matter: for absorbent earths and several metallic substances are also capable of decomposing ammoniacal salts, discharging their volatile alkali, and forming new compounds by uniting with their acids. This might induce us to think that these substances have nearly the same affinity with acids.

But it is proper to observe, that a volatile alkali decomposes such neutral salts as have for their basis either an absorbent earth or a metallic substance, without the aid of fire; whereas absorbent earths or metallic substances will not decompose an ammoniacal salt, unless they be affiled by a certain degree of heat.

Now, as all these matters are extremely fixed, at least in comparison with a volatile alkali, they have the advantage of being able to resist the force of fire, and so of acting in conjunction therewith; and fire greatly promotes the natural action of substances upon one another: whereas the volatile alkali in the ammoniacal salt, being unable to abide the force of fire, is compelled to defeat its acid; and that so much the more quickly, as its affinity therewith is considerably weakened by the presence of an earthy or metallic substance, both of which have a great affinity with acids.

These considerations oblige us to conclude, that volatile alkalis have a somewhat greater affinity, than absorbent earths and metallic substances, with acids.

Ammoniacal salts projected upon nitre in fusion make it detonate; and the nitrous sal ammoniac detonates by itself, without the addition of any inflammable matter. This singular effect evidently demonstrates the existence of an oily matter in volatile alkalis; for it is certain that nitre will never deglaze without the concurrence and even the immediate contact of some combustible matter.

This oily substance is often found combined with volatile alkalis in such a large proportion as to disguise it in some measure, and render it exceeding foul. The salt may be freed from its superfluous oil by repeated sublimations.
A General View of Chemical Decomposition.

Though we have considered all the substances which enter into the composition of vegetables, animals, and minerals, whether as primary or as secondary principles, it will not be improper to shew in what order we obtain these principles from the several mixts; and especially from vegetables and animals, because they are much more complicated than minerals. This is called analyzing a compound.

The method most commonly taken to decompose bodies is by applying to them successive degrees of heat, from the gentlest to the most violent, in appropriated vessels, so contrived as to collect what exhales from them. By this means the principles are gradually separated from each other; the most volatile rise first, and the rest follow in order, as they come to be acted on by the proper degree of heat: And this is called distillation.

But it being observed that fire, applied to the decomposition of bodies, most commonly alters their secondary principles very sensibly, by combining them in a different manner with each other, or even partly decomposing them, and reducing them to their primitive principles; other means have been used to separate those principles without the help of fire.

With this view the mixts to be decomposed are forcibly compressed, in order to squeeze out of them all such parts of their substance as they will by this means part with; or else those mixts are for a long time triturated, either alone with water, which carries off all their fatty and saponaceous contents; or with solvents, such as ardent spirits, capable of taking up everything in them that is of an oily or resinous nature.

We shall here give a succinct account of the effects of these different methods, as applied to the principal substances among vegetables and animals, and likewise to some minerals.

The Analysis of Vegetable Substances.

A vast many vegetable substances, such as kernels and seeds, yield by strong compulsion great quantities of mild, fat, unctuous oils, which are not soluble in ardent spirits; these are what we called expressed oils. They are also sometimes called fat oils, on account of their unctuousness, in which they exceed all other sorts of oil. As these oils are obtained without the aid of fire, it is certain that they existed in the mixt just as we see them, and that they are not in the least altered; which could not have been the case had they been obtained by distillation: For that never produces any oils but such as are acid and soluble in spirit of wine.

Some vegetable matters, such as the rind of citrons, lemons, oranges, &c. also yield, only by being squeezed between the fingers, a great deal of oil. This spirits out in fine small jets, which being received upon any polished surface, such as a looking-glass, run together, and form a liquor that is a real oil.
But it must be carefully noted, that this sort of oil, though obtained by expression only, is nevertheless very different from the oils mentioned before to which the title of *expressed oils* particularly belongs: For this is far lighter and thinner; moreover, it retains the perfect odor of the fruit which yields it, and is soluble in spirit of wine; in a word, it is a true essential oil, but abounds so in the fruits which produce it, and is lodged therein in such a manner, occupying a vast number of little cells provided in the peel for its reception, that a very slight pressure discharges it; which is not the case with many vegetables that contain an essential oil.

 Succulent and green plants yield by compression a great deal of liquor or juice, which consists of molt of the phlegm or gummy substances in the plant, and a small portion of the oil and earth of the plant. These juices, being set in a cool place for some time, deposit saline crystals, which are a combination of the acid of the plant with part of its oil and earth, wherein the acid is always predominant. These salts, as is evident from the description here given, bear a great resemblance to the tartar of wine treated of above. They are called *essential salts*; so that tartar might likewise be called the *essential salt of wine*.

Dried plants, and such as are of a ligneous, or acid nature, require to be long triturated with water, before they will yield their essential salts. Trituration with water is an excellent way to get out of them all their saline and faponaceous contents.

A vegetable matter that is very oily yields its essential salt with much difficulty, if at all; because the excessive quantity of oil entangles the salt so that it cannot extricate itself or shoot into crystals. Mr Gerke, in his *Principles of Chemistry*, says, That if part of the oil of a plant be extracted by spirit of wine, its essential salt may be afterwards obtained with more ease and in greater quantity.

Essential salts are among those substances which cannot be extracted from mixts by distillation; for the first impression of fire decomposes them.

Though the acid which predominates in the essential salts of plants be most commonly analogous to the vegetable acid, properly so called, that is, to the acid of vinegar and tartar, which is probably no other than the vitriolic acid disguised; yet it sometimes differs therefrom, and somewhat resembles the nitrous or the marine acid. This depends on the places where the plants grow which produce these salts: If they be submarginal plants, their acid is a-kin to the acid of sea-falts; if, on the contrary, they grow upon walls, or in nitrous grounds, their acid is like that of nitre. Sometimes one and the same plant contains salts analogous to all the three mineral acids; which shews that the vegetable acids are no other than the mineral acids variously changed by circulating through plants.

Liquors containing the essential salts of plants being evaporated by a gentle heat to the confection of honey, or even further, are called *extracts*. Hence it is plain, that an extract is nothing but the essential salt of a plant, combined with some particles of its oil and earth, that remain suspended in the liquor, and are now incorporated by evaporation.

Extracts of plants are also prepared by boiling them long in water, and then evaporating some part of it. But these extracts are of inferior virtue; because the fire dissipates many of the oily and saline parts.

**Emulsions.**

Substances which abound much in oil, being bruised and triturated with water for some time, afford a liquor of an opaque dead-white colour like milk. This liquor consists of such juices as the water is capable of dissolving, together with a portion of the oil, which being naturally indissoluble in water, is only divided and dispersed in the liquor, the limpidity whereof is by that means destroyed. This fort of oily liquor, in which the oil is only divided, not dissolved, is called an *emulsion*. The oily particles in emulsions spontaneously separate from the water, when left at rest, and, uniting into greater masses, rise, on account of their lightness, to the surface of the liquor, which by that means recovers a degree of transparency.

If vegetables, abounding in essential oils and resins, be digested in spirit of wine, the menstruum takes up these oily matters, as being capable of dissolving them; and they may afterwards be easily separated from it by the affusion of water. The water, with which spirit of wine has a greater affinity than with oily matters, separates them by this means from their solvent, agreeable to the common laws of affinities.

Without the help of fire fears not any thing, besides the substances already mentioned, can be obtained from a plant: But by the means of distillation we are enabled to analyse them more completely. In prosecuting this method of extracting from a plant the several principles of which it consists, the following order is to be observed.

A plant being exposed to a very gentle heat, in a distilling vessel set in the *balneum maria*, yields a water which retains the perfect smell thereof. Some chemists, and particularly the illustrious Boerhaave, have called this liquor the spiritus *vulgaris*. The nature of this odoriferous part of plants is not yet thoroughly known; because it is so very volatile, that it is difficult to subject it to the experiments necessary for discovering all its properties.

If instead of distilling the plant in the *balneum maria*, it be distilled over a naked fire, with the precaution of putting a certain quantity of water into the distilling vessel along with it, to prevent its suffering a greater heat than that of boiling water, all the essential oil contained in that plant will rise together with that water, and with the same degree of heat.

On this occasion it must be observed, that no essential oil can be obtained from a plant after the spiritus *vulgaris* hath been drawn off; which gives ground to think that the volatility of these oils is owing to that spirit.

The heat of boiling water is also sufficient to separate from vegetable matters the fat oils which they contain: That, however, is to be done by the way of decoction (2) only.
only, and not by distillation; because, though these oils will swim on water, yet they will not rise in vapours without a greater degree of heat.

When the essential oil is come over, if the plant be exposed to a naked fire, without the addition of water, and the heat be increased a little, a phlegm will rise that gradually grows acid; after which, if the heat be increased as occasion requires, there will come over a thicker and heavier oil; from some a volatile alkali; and last of all, a very thick, black, empyreumatic oil.

When nothing more rises with the strongest degree of heat, there remains of the plant a mere coal only, called the caput mortuum, or terra damnata. This coal when burnt falls into ashes, which being lixiviated with water give a fixed alkali.

It is observarble, that in the distillation of plants which yield an acid and a volatile alkali, these two salts are often found quite distinct and separate in the same receiver; which seems very extraordinary, considering that they are naturally dippofed to unite, and have a great affinity with one another. The reason of this phenomenon is, that they are both combined with much oil, which embarrassment them so that they cannot unite to form a neutral salt, as they would not fail to do were it not for that impediment.

All vegetables, except such as yield a great deal of volatile alkali, being burnt in an open fire, and so as to flame, leave in their ashes a large quantity of an acid, caustic, fixed alkali. But if care be taken to smother them, so as to prevent their flaming while they burn, by covering them with something that may continually beat down again what exhales, the salt obtained from their ashes will be much less acid and caustic; the cause whereof is, that some part of the acid and oil of the plant being detained in the burning, and stopped from being dissipated by the fire, combines with its alkali. These salts crystallize, and being much milder than the common fixed alkalis, may be used in medicine, and taken internally. They are called Tachetius’s salts, because invented by that chemist.

Marine plants yield a fixed alkali analogous to that of sea-salt. As for all other plants or vegetable substances, the fixed alkalis obtained from them, if rightly prepared and thoroughly calcined, are all perfectly alike, and of the same nature.

The last observation we have to make on the production of a fixed alkali is, that if the plant you intend to work upon be steeped or boiled in water before you burn it, a much smaller quantity of salt will be obtained from it; nay, it will yield none at all, if repeated boilings have robbed it entirely of those saline particles which must necessarily concur with its earth to form a fixed alkali.

The Analysis of Animal Substances.

Succulent animal substances, such as new-killed flesh, yield by expression a juice or liquid, which is no other than the phlegm, replete with all the principles of the animal body, except the earth, of which it contains but little. The hard or dry parts, such as the horns, bones, &c. yield a similar juice, by boiling them in water. These juices become thick, like a glue or jelly, when their watery parts are evaporated; and in this state they are true extracts of animal matters. These juices afford no crystals of effentual salt, like those obtained from vegetables, and shew no sign either of an acid or an alkali.

Great part of the oil which is in the flesh of animals may be easily separated without the help of fire; for it lies in a manner by itself: It is commonly in a concrete form, and is called fat. This oil somewhat resembles the fat oils of vegetables; for like them it is mild, unctuous, indiffoluble in spirit of wine, and is subtilized and attenuated by the action of fire. But there is not in animals, as in vegetables, any light essential oil, which rises with the heat of boiling water; so that, properly speaking, animals contain but one sort of oil.

Few animal substances yield a perceptible acid. Ants and bees are almost the only ones from which any can be obtained; and indeed the quantity which they yield is very small, as the acid itself is extremely weak.

The reason thereof is, that as animals do not draw their nourishment immediately from the earth, but feed wholly either on vegetables or on the flesh of other animals, the mineral acids, which have already undergone a great change by the union contracted between them and the oily matters of the vegetable kingdom, enter into a closer union and combination with these oily parts while they are passing through the organs and strainiers of animals; whereby their properties are destroyed, or at least so impaired that they are no longer sensible.

Animal matters yield in distillation, first, a phlegm, and then, on increasing the fire, a pretty clear oil, which gradually becomes thicker, blacker, more fetid, and empyreumatic. It is accompanied with a great deal of volatile alkali; and if the fire be raised and kept up till nothing more comes over, there will remain in the distilling vessel a coal like that of vegetables; except that when it is reduced to ashes, no fixed alkali, or at least very little, can be obtained from them, as from the ashes of vegetables. This arises from hence, that, as we said before, the saline principle in animals being more intimately united with the oil than it is in plants, and being consequently more attenuated and subtilized, is too volatile to enter into the combination of a fixed alkali; on the contrary, it is more diffipated to join in forming a volatile alkali, which on this occasion does not rise till after the oil, and therefore must certainly be the production of the fire.

The chyle, and the milk of animals which feed on plants, still retain some likenesses to vegetables; because the principles of which these liquors are composed have not gone through all the changes which they must suffer before they enter into the animal combination.

Urine and sweat are excrementitious aqueous liquors, loaded chiefly with the saline particles which are of no service towards the nourishment of the animal, but pass through its strainiers without receiving any alteration; such as the neutral fats which have a fixed alkali for their basis, and particularly the sea-salt which happens to be in the food of animals, whether it exit within naturally, as it does in some plants, or whether the animals eat it to please their palate.
The saliva, the pancreatic juice, and especially the bile, are faponaceous liquors; that is, they consist of saline and oily particles combined together; so that being themselves dissolved in an aqueous liquor, they are capable of dissolving likewise the oily parts, and of rendering them miscible with water.

Lastly, the blood being the receptacle of all these liquors, partakes of the nature of each, more or less, in proportion to the quantity thereof which it contains.

The Analysis of Mineral Substances.

Minerals differ greatly from vegetables, and from animals; they are not near so complex as those organized bodies, and their principles are much more simple; whence it follows, that these principles are much more closely connected, and that they cannot be separated without the help of fire; which not having on their parts the same action and the same power as on organized bodies, hath not the same ill effect on them; we mean the effect of changing their principles, or even destroying them entirely.

We do not here speak of pure, vitriifiable, or refractory earths, of mere metals and semi-metals, of pure acids; or even of their simplest combinations, such as sulphur, vitriol, alum, sea salt: Of all these we have said enough.

We are now to treat of bodies that are more complex, and therefore more susceptible of decomposition. These bodies are compound masses or combinations of those above-mentioned; that is, metallic substances as they are found in the bowels of the earth, united with several sorts of sand, stones, earths, semi-metals, sulphur, &c. When the metallic matter is combined with other matters in such a proportion to the rest that it may be separated from them with advantage and profit, these compounds are called ores; when the same is otherwise, they are called pyrites, and marcasites; especially if sulphur or arsenic be predominant therein, which often happens.

In order to analyze an ore, and get out of it the metal it contains, the first step is to free it from a great deal of earth and stones which commonly adhere to it very light and superficially. This is effected by pounding the ore, and then washing it in water: to the bottom of which the metallic parts presently sink, as being the heaviest, while the small particles of earth and stone remain suspended some time longer.

Thus the metallic part is left combined with such matters only as are most intimately compounded with it. These substances are most commonly sulphur and arsenic. Now, as they are much more volatile than other mineral matters, they may be distilled in vapours, or the sulphur may be confumed, by exposing the ore which contains them to a proper degree of heat. If the sulphur and arsenic be defined by themselves, the fumes thereof may be caught and collected in proper vessels and places. This operation is called roasting in ore.

The metal thus deposited is now fit to be exposed to a greater force of fire, capable of melting it.

On this occasion the semi-metals and the imperfect metals require the addition of some matter abounding in phlogiston, particularly charcoal-dust; because these metallic substances lose their phlogiston by the action of the fire, or of the fluxes joined with them, and therefore without this precaution would never acquire either the splendor or the ductility of a metal. By this means the metallic substance is more accurately separated from the earthy and stony parts, of which some portion always remains, combined therewith till it is brought to fusion. For, as we observed before, a metallic glass or calx only will contract an union with such matters; a metal possessed of its phlogiston and metallic form being utterly incapable thereof.

We took notice of the cause of this separation above, where we shewed that a metal possessed of its phlogiston and metallic form will not remain intimately united with any calcined or vitrified matter, not even with its own calx or glas.

The metal therefore on this occasion gathers into a mass, and lies at the bottom of the vessel, as being most ponderous; while the heterogeneous matters float upon it in the form of a glass, or a semi-vitrification. These floating matters take the name of scorix, and the metallic substance at bottom is called the regulus.

It frequently happens, that the metallic regulus thus precipitated, is itself a compound of several metals mixed together, which are afterwards to be separated.

It is proper to observe, before we quit this subject, that the rules here laid down for analyzing ores are not absolutely general: For example, it is often advisable to roast the ore before you wash it; for by that means some ores are opened, attended, and made very friable, which would cost much trouble and expense, on account of their excessive hardneas, if you should attempt to pound them without a previous torrefaction.

It is also frequently necessary to separate the ore from part only of its stone; sometimes to leave the whole; and sometimes to add more to it, before you smelt it. This depends on the quality of the stone, which always helps to promote fusion when it is in its own nature fusible and vitrifiable: It is then called the floor of the ore.

We shall now give a succinct account of the principal ores and mineral bodies, contenting ourselves with just pointing out the particulars of which they respectively consist.

Of the Pyrites.

The Yellow Pyrites.

The yellow pyrites is a mineral consisting of sulphur, iron, an unmetallic earth, and frequently a little copper: The sulphur, which is the only one of these principles that is volatile, may be separated from the rest by sublimation: It usually makes a fourth, and sometimes a third, of the whole weight of these pyrites. The other principles are separated from one another by fusion and reduction with the phlogiston, which, by metallizing the ferruginous and cupreous earths, parts them from the unmetallic earth: For this earth vitrifies, and cannot afterwards continue united with metallic matters possessed of their metallic form.

There is yet another way of decomposing the yellow pyrites, which is to let it lie till it effolves, or begins
to shoot into flowers; which is nothing but a sort of slow
accretion of the sulphur it contains. The sulphur being
by this means decomposed, its acid unites with the ferrur-
ginous and cuprous parts of the pyrites, and therewith
forms green and blue vitriols; which may be extracted
by steeping in water the pyrites which has effuoresced or
been burnt, and then evaporating the luxivium to a pelli-
cle; or by this means the vitriol will shoot into crystals.
Sometimes the pyrites contains also an earth of the same
nature with that of alum: A pyrites of this sort, after
flowering, yields alum as well as vitriol.

The White Pyrites.

The white pyrites contains much arsenic, a ferrur-
ginous earth, and an unmetallic earth. The arsenic being
a volatile principle, may be separated by sublimation or
distillation from the rest, which are fixed; and these a-

The Copper Pyrites.

The copper pyrites contains sulphur, copper, and an
unmetallic earth. A great deal thereof likewise holds
arsenic, and its colour approaches more or less to orange,

Of Ores.

Of Gold Ores.

Gold being constantly found in its metallic form,
and never combined with sulphur and arsenic, its ores are
not, properly speaking, ores; because the metal con-
tained in them is not mineralized. The gold is only
lodged between particles of stone, earth, or sand, from
which it is easily separated by leaching, and by amalgama-
tion with quick silver. The gold thus found is seldom
pure, but is frequently alloyed with more or less silver,
from which it is to be separated by quaquation.

It is also very common to find gold in most ores of oth-
er metals or semi-metals, and even in the pyrites; but
the quantity contained therein is generally so small, that
it would not pay the cost of extracting it. However, if
any should incline to attempt it, merely out of curiosity,
it would be necessary to begin with treating these ores in
the manner proper for separating their metallic part;
then to cupel the metallic regulus so obtained; and lat-
tly, to refine it by quaquation.

Of Silver Ores.

It is no rare thing to find silver, as well as gold, in
its metallic form, only lodged in sandy earths and stony
matters, from which it may be separated in the same man-
er as gold. But the greatest quantities of this metal are
usually dug out of the bowels of the earth in a truly mi-
neral state; that is, combined with different substances,
and particularly with sulphur and arsenic.

Several silver ores are distinguished by peculiar cha-

teristics, and are accordingly denoted by particular

names. That which is called the vitreous silver ore, is
scarce any thing else but a combination of silver and sul-
phur. Another is known by the name of the borns silver
ore, because when in thin plates it is semi-transparent:
In this ore the silver is mineralized by sulphur and a little
arsenic. The red silver ore is of the colour which its
name imports, sometimes more, sometimes less vivid;
and is chiefly composed of silver, arsenic, and sulphur:
It also contains a little iron.

These three ores are very rich in silver; the first con-
tains nearly three fourths of its weight, and the others
about two-thirds of theirs.

There is a fourth, called the white silver ore, which
though it be heavier, is not so rich in silver, because it
contains much copper. Many other ores contain silver,
yet are not, properly speaking, silver ores; because a
much greater quantity of other metals than of silver is
found in them.

When a silver ore is to be decomposed, in order to
have the silver pure, or when silver is to be extracted out
of any ore that contains it, the first thing to be done is
to roast the ore in order to clear it of the volatile min-
erals: and as silver cannot be had pure without the ope-
ration of the cupel, which requires more or less lead to
be joined with it, it is usual to mix with the torrifled
silver ore a quantity of lead proportioned to that of
the heterogeneous matters combined with the silver,
and to melt the whole together. Part of the added
lead vitrifies during the fusion, and at the same time
converts some of the heterogeneous matter also into glas,
with which it forms a scoria that rises to the surface of
the matter. The other part of the lead, with which the
silver is mixed, falls to the bottom in the form of a re-
gulus, which must be cupelled in order to have the silver
pure.

Of Copper Ores.

Copper is much reldomer found in a metallic form,
than gold or silver; it is commonly in a mineral state:
it is mineralized by sulphur and arsenic: almost all its
ores contain more or less iron; sometimes a little sil-
ver or even gold, together with unmetallic earths and
stones, as all ores do.

Most copper ores are of a beautiful green or blue,
or else in shades blended of these two colours. The min-
erals called mountain green, and mountain blue, are true
copper ores; not in the form of hard stones, like other
ores, but crumbly and friable like earth.

Nevertheless there are several copper ores of different
colours, as ash-coloured, whitish, and shaded with yel-
low or orange: which colours arise from the different
proportions of arsenic, sulphur, and iron, which these
ores contain.

In order to decompose a copper ore, and to extract
the copper it contains, it is first of all to be freed from
as many of its earthy, stony, sulphureous, and arsineal
parts, as is possible, by roasting and washing; then what
remains is to be mixed with a flux composed of a fixed
alkali and some inflammable matter; a little sea-salt
is to be put over all, and the whole melted by a strong
fire. The salts facilitate the fusion and scorification of
the
the unmetallic matters, and therewith form a flag, which
being the lighted rifes to the furfaepe. The metallic
matters are collected below in the form of a shining regu-
lus of copper; which however, is not usually fine copper,
but requires to be purified.

In order to separate the copper from the unmetallic
matters, it is absolutely necessary to melt its ore along
with the inflammable substances abounding in phlogiton.
For, as this metal is not possessed of its metalline form
while it is in a mineral state, as it is definite of the true
quantity of phlogiton, and, though it were not, would
lofe it by the action of the fire, it would come to pass,
that, if its ore were melted without the addition of any
inflammable matter, the cupreous earth, or calx, would
be scorified and confounded with the unmetallic matters;
and as all metallic matters, except gold and silver, are
subject to this inconvenience as well as copper, the addi-
tion of an inflammable substance, in fluxing all ores
that contain them, is a general rule that ought conftantly
to be observed.

Of Iron Ores.

Iron is seldom found pure and malleable in the earth;
yet it is much feldomer found in the mineral state, pro-
perly so called, than any of the other metals: for moft
iron ores are scarce any thing more than a ferruginous
earth mixed in different proportions with unmetallic
earths and stones. Some of them, however, contain al-
so volatile minerals, fuch, as sulphur and arfenic; and
therefore it is necessary to roast the iron ores, like all o-
thers, before you attempt to extract the metal out of
them. That being done, they are to be smelted with a
flux consisting of fusible and inflammable matters, as the
general rule directs.

Iron is the commonest of all metals; nay, it is fo u-
universally diffused through the earth, that it is difficult
to find any flone, earth, or sand, that does not contain
some of it; and therefore none of these are usually con-
fidered and treated as iron ores, except fuch as contain
a great deal of that metal, and melt eafily. The hema-
tites, emery, yellow pyrites, calamine, all contain a
pretty considerably quantity of iron; but nobody at-
ttempts to extract it from them, because they are very
hard to melt.

Ferruginous earth being naturally of an orange-colour,
a flone or earth may be judged to contain iron, if either
naturally or after roasting it appears to have any shade of
yellow or red.

The singular property which iron has of being attracted
by the magnet, and of being the only body, exclusive of
all others, that is fo, likewise affords us an eafe method
discovering the preence of this metal among other
matters, where it often e.xists in fuch a small quantity
that it could not otherwife be found out. For this pur-
pofe the body in which iron is suspected to lurk, must be
pulverized and torrefied with fome inflammable matter;
and then the powder thus roasted being touched with a
magnet, or a magnetic bar, if it contains any particles
of iron they will infallibly adhere to the magnet or bar.

Of Tin Ores.

Tin is never found in the earth pure and malleable,
Vol. II: No. 34.
posed, the first thing to be done, is to expose it to a degree of heat too weak to melt its earthy and stony parts, but strong enough to separate its reguline together with its sulphurous parts, which by this means are separated from the earth, and united into one mass, known by the name of Antimony.

It is plain, that this first operation, which is founded on the great fusibility of antimony, produces, with regard to the ore of regulus of antimony, the same effect that washing hath on other ores: so that after this first fusion nothing more is requisite to the obtaining of a pure regulus of antimony, but to separate it from its sulphur by roasting, and to melt it with some matter abounding in phlogiston, in the same manner as other metallic matters are treated. The term calcination is generally used to express this torrefaction of antimony, by means whereof the metallic earth of the regulus of antimony is separated from its sulphur.

As regulus of antimony hath, like mercury, much less affinity with sulphur than the other metals have, it follows that antimony may be decomposed by the same means as cinnabar; but the regulus so obtained is adulterated with a portion of the additament made use of, which combines therewith.

Of the Ores of Bismuth.

The ore of bismuth consists of the semi-metal mineralized by the arsenic, and of an unmetallic earth. It is very easy to decompose this ore, and to extract the bismuth it contains: for this purpose it need only be exposed to a moderate heat, whereby the arsenic will be dissipated in vapours, and the bismuth melted, which will then separate from the unmetallic earth. This earth, at least in several ores of bismuth, possesses the property of tinging all vitrifiable matters with which it is melted of a beautiful blue colour.

To decompose the ore of bismuth no flux or inflammable matter is used; because this semi metal is possessed, even in its mineral state, of all the phlogiston requisite to maintain its metallic properties; and its great fusibility makes it unnecessary to melt the metallic earth contained in its ore.

Of the Ores of Zinc.

Zinc is not generally obtained from a particular ore of its own; but sublimes during the fusion of a mineral, or rather a confused mass of minerals, that contains this semi-metal together with iron, copper, lead, sulphur, arsenic, and, like all other ores, an unmetallic earth.

Nevertheless there is a substance which may be considered as the proper ore of zinc, because it contains a pretty large quantity of that semi-metal, a little iron, and an unmetallic earth. It is called calamine, or lapis calaminaris; but hitherto the art of procuring zinc directly from this mineral hath no where been practiced. Calamine is commonly employed only to convert copper into brass or a yellow metal, by cementing it therewith. Indeed till lately no easy or practicable method of obtaining pure zinc from calamine was publicly known; for that semi-metal being volatile and very inflammable, its ore cannot be fused like others. Mr Margraaf was the first who, by mixing powdered charcoal with calamine in close vesicles, obtained a perfect zinc from it, by the means of distillation or sublimation.

Of Arsenical Minerals.

Arsenic, as well as sulphur, is naturally combined with almost all ores, or minerals containing metallic substances. As it is very volatile, while the matters with which it is united are fixed, at least in comparison therewith, it is easily separated by sublimation.

The minerals that contain most arsenic are the white pyrites, orpiment, and cobalt. We have already considered the white pyrites as to orpiment, it consists of sulphur and arsenic. Both these substances being very volatile, it is difficult to separate them by sublimation; yet, with proper management, and a due regulation of the fire, this separation may be effected; because sulphur sublimes a little more easily than arsenic. But it is more convenient, as well as more expeditious, to make use of some additament that hath a greater affinity with one of those substances than with the other. Fixed alcalis and mercury, both of which have more affinity with sulphur than with arsenic, may be very properly employed on this occasion. Cobalt is a mineral decomposed of arsenic, an unmetallic earth, and frequently bismuth; and as none of these are very volatile, except the arsenic, this may be easily separated from the rest by sublimation. The unmetallic earth which remains has, like that of the ore of bismuth, the property of giving a blue colour to any vitrifiable matters melted with it; whence it is conjectured, that cobalt and the ore of bismuth have a great resemblance, or are often blended with each other.

Besides the minerals already recited, there is found in the bowels of the earth another species of compound body, of which we have already taken notice; but which is supposed, with some degree of probability, to belong as much to the vegetable as to the mineral kingdom: we mean the bitumens; which the best observations have shewn are united with the mineral acids, and by that means acquired the thickness, confidence, and other properties observable in them.

By distillation they yield an oil, and an acid not unlike a mineral acid. Mr Bourdelin has even demonstrated, by a very artful and ingenious process, that amber contains a manifest acid of sea-salt.

Explanation of the Table of Affinities or elective Attractions.

We have already explained what is meant by affinities, and have laid down the principal laws to which the relations of different bodies are subject. The late Mr Geoffroy, being convinced of the advantages which all who cultivate chemistry would receive from having constantly before their eyes a table of the several affinities, undertook to reduce them into order, and unite them all in one point of view, by means of a table. This table will be of considerable use to such as are beginning to study
The reason thereof is, that this acid alone is not capable of dissolving gold and combining therewith, necessarily requiring for that purpose the aid of the nitrous acid, or at least of the phlogiston.

The third column exhibits the affinities of the nitrous acid, the character whereof stands at its head. Immediately below it is the sign of iron, as the metal which has the greatest affinity with this acid; and then follow other metals, each according to the degree of its relation, viz. copper, lead, mercury, and silver. In this column, as in the preceding one, we must suppose the substances, which in the first column stand above metallic substances, to be placed in their proper order before iron.

The fourth column is intended to represent the affinities of the vitriolic acid. The phlogiston stands uppermost. Below it the fixed alkalis, volatile alkalis, and absorbent earths, to shew that this is an exception to the first column. As to metallic substances, Mr Geoffrey has set down but three, being those with which the vitriolic acid has the most perceptible affinity: these metals, placed in the order of their affinities, are iron, copper, and silver.

The fifth column shews the affinities of absorbent earths. As these earths have no sensible affinity but with acids, this column contains only the characters of the acids ranked according to the degree of their strength, or affinity with the earths, viz. the vitriolic, the nitrous, and the marine acids. Underneath this last might be placed the acid of vinegar, or the vegetable acid.

The sixth column expresses the affinities of fixed alkalis with acids, which are the same with those of absorbent earths. Moreover, we find sulphur placed here below all the acids; because liver of sulphur, which is a combination of sulphur with a fixed alkali, is actually decomposed by any acid: for any acid precipitates the sulphur and unites with the alkali.

Immediately over the sulphur, or in the same square with it, might be set a mark denoting the volatile phlegmatic spirit; because, like sulphur, it has less affinity than any other acid with fixed alkalis. Oils might also be ranked with sulphur, because they unite with fixed alkalis, and therewith form soaps which are decomposed by any acid whatever.

The seventh column points out the affinities of volatile alkalies, which are likewise the same as those of absorbent earths; and the vegetable acid might be placed here also under the marine acid.

The eighth column specifies the affinities of metallic substances with acids. The affinities of the acids, which with respect to fixed alkalis, volatile alkalis, and absorbent earths, succeed each other uniformly, do not appear in the same order here. The marine acid, instead of being placed below the vitriolic and nitrous acids, stands, on the contrary, at their head: because, in fact, this acid separates metallic substances from all the other acids with which they happen to be united, and, forcing these acids to quit paffion, intrudes into their place. Nevertheless, this is not a general rule; for several metallic substances must be excepted, particularly iron and copper.

The ninth column declares the affinities of sulphur. Fixed alkalis, iron, copper, lead, silver, regulus of antimony, mercury, and gold stand below it in the order of their affinities. With regard to gold, it must be observed, that it will not unite with pure sulphur; it suf-
fers itself to be dissolved only by the liver of sulphur, which is known to be a composition of sulphur and fixed alkali.

At the head of the tenth column appears mercury, and beneath it several metalline substances, in the order of their affinities with it. Those metalline substances are gold, silver, lead, copper, zinc, and regulus of antimony.

The eleventh column shews that lead has a greater affinity with silver than with copper.

The twelfth, that copper has a greater affinity with mercury than with calamine.

The thirteenth, that silver has a greater affinity with lead than with copper.

The fourteenth contains the affinities of iron. Regulus of antimony stands immediately underneath it, as being the metallic substance which has the greatest affinity with it. Silver, copper, and lead, are placed together in the next square below, because the degrees of affinity which those metals have with iron are not exactly determined.

The same is to be said of the fifteenth column: Regulus of antimony stands at its head; iron is immediately below it; and below the iron the same three metals occupy one square as before.

Lastly, The sixteenth column indicates that water has a greater affinity with spirit of wine than with salts. By this general expression must not be understood any saline substance whatever; but only the neutral salts, which spirit of wine frees from the water that kept them in solution. Fixed alkalis, on the contrary, as well as the mineral acids, have a greater affinity than spirit of wine with water; so that these saline substances, being well dephlegmated and mixed with spirit of wine, imbibe the water it contains and rectify it.

The Theory of Constructing the Vessels most commonly used in Chemistry.

Chemists cannot perform the operations of their art without the help of a considerable number of vessels, instruments, and furnaces, adapted to contain the bodies on which they intend to work, and to apply to them the several degrees of heat required by different processes.

Vessels intended for chemical operations should be able to bear, without breaking, the sudden application of great heat and great cold; be impenetrable to every thing, and unalterable by any solvent; unvitrifiable, and capable of enduring the most violent fire without melting; but hitherto no vessels have been found with all these qualities united.

They are made of sundry materials, namely, of metal, of glass, and of earth. Metalline vessels, especially those made of iron or copper, are apt to be corroded by almost every saline, oily, or even aqueous substance. For this reason, in order to render the use of them a little more extensive, they are tinned on the inside. But, notwithstanding this precaution, they are on many occasions not to be trusted; and should never be employed in any nice operations which require great accuracy; they are, moreover, incapable of resisting the force of fire.

Earthen vessels are of several sorts. Some, that are made of a refractory earth, are capable of being suddenly exposed to a strong fire without breaking, and even of sustaining a great degree of heat for a considerable time: But they generally suffer the vapours of the matters which they contain, as well as vitriled metals, to pass through them; especially the glafs of lead, which easily penetrates them, and runs through their pores, as through a sieve. There are others made of an earth, that, when well baked, looks as if it were half vitrified: These being much less porous are capable of retaining the vapours of the matters which they contain, and even glases of lead in fusion; which is one of the fewest trials a vessel can be put to: But then they are more brittle than the other fort.

Good glas-vessels should constantly be employed in preference to all others, whenever they can possibly be used: And that not only because they are no way injured by the most active solvents, nor suffer any part of what they contain to pass through, but also because their transparencies allows the chemist to observe what paffes within them; which is always both curious and useful. But it is pity, that vessels of this fort should not be able to endure a fierce fire without melting.

Distillation, as hath been already said, is an operation by which we separate from a body, by the help of a gradual heat, the several principles of which it consists.

There are three methods of distilling. The first is performed by applying the heat over the body whose principles are to be extracted. In this case, as the liquors when heated and converted into vapours, constantly endeavour to fly from the centre of heat, they are forced to re-unite in the lower part of the vessel that contains the matter in distillation, and to passing through the pores or holes of that vessel, they fall into another cold vessel applied underneath to receive them. This way of distilling is, on this account, called distilling per ascensum. It requires no other apparatus than two vessels figured like segments of hollow spheres, whereof that which is pierced with little holes, and intended to contain the matter to be distilled, ought to be much less than the other which is to contain the fire, and clofe its aperture exactly; the whole together being supported vertically upon a third vessel, which is to serve the purpose of a recipient, admitting into its mouth the convex bottom of the vessel containing the matter to be distilled, which must accurately fill it. This method of distilling is but little used.

The second method of distilling is performed by applying the heat underneath the matter to be decomposed. On this occasion the liquors being heated, rared and converted into vapours, rise, and are condensed in a vessel contrived for that purpose, which we shall presently describe. This way of distilling is called distilling per ascensum, and is much used.

The vessel in which the distillation per ascensum is performed, we call an alembic. Plate LXIV, fig. 1.

There are several sorts thereof differing from one another both in the matter of which, and the manner in which, they are made.
Those employed to draw the odoriferous waters and essential oils of plants are generally made of copper, and consist of several pieces. The first, which is designed to contain the plant, is formed nearly like a hollow cone, the vertex whereof is drawn out in the shape of a hollow cylinder or tube: This part is named the cucurbit, Plate LXIV. fig. 1. A; and its tube the neck of the alembic. B. To the upper end of this tube another vessel is affixed: This is called the head C, and commonly has likewise the form of a cone, joined to the neck of the alembic by its base, round which on the inside is hollowed a small groove communicating with an orifice that opens at its most depending part. To this orifice is affixed a small pipe in a direction sloping downwards, which is called the nofe, fpout, or beak D of the alembic.

As soon as the matters contained in the alembic grow hot, vapours begin to arise from them, and ascending through the neck of the alembic into the head, are by the fides thereof flotted and condensed: From thence they trickle down in little streams to the groove, which conveys them to the fpout; and by that they pass out of the alembic into a glass vessel or receiver G with a long neck, the end of the fpout being introduced into that neck and luted thereto.

To facilitate the refrigeration and condensation of the vapours circulating in the head, all alembics of metal are moreover provided with another piece, which is a kind of large pan of the same metal, fitted and folded round the head. This piece serves to keep cold water in, which incessantly cools the head, and therefore it is called the refrigeratory E. The water in the refrigeratory itself grows hot after some time, and must therefore be changed occasionally; the heated water being first drawn off by means of a cock fixed near the bottom of the refrigeratory. All copper alembics should be tinned on the inside for the reasons already given.

When saline spirits are to be distilled, alembics of metal must not be used; because the saline vapours would corrode them. In this case recourse must be had to alembics of glass. These consist of pieces only; namely, a cucurbit, whose superior orifice is admitted into, and exactly luted with its head, which is the second piece.

In general, as alembics require that the vapours of the matter to be distilled should rise to a considerable height, they ought to be used only when the most volatile principles are to be drawn from bodies: And the lighter and more volatile the substances to be separated by distillation are, the taller must the alembic be; because the most ponderous parts, being unable to rise above a certain heighth, fall back again into the cucurbit as soon as they arrive there, leaving the lighter to mount alone, whole volatility qualifies them to ascend into the head.

When a matter is to be distilled that requires a very tall alembic, and yet does not admit of a metallic vessel, the end will be best answered by a glass vessel of a round or oval shape, having a very long neck, with a small head fitted to its extremity. Such a vessel serves many purposes: It is sometimes employed as a receiver, and at other times as a digesting vessel; on which last occasion it goes under the name of a matras, fig. 3. When one of these provided with a head, (fig. 3. C), is applied to the purpose of distilling, it forms a sort of alembic.

There are some alembics of glass, blown in such a manner by the workmen, that the body and head form but one continued piece. As these alembics do not stand in need of having their several pieces luted together, they are very useful on some occasions, when such exceeding subtile vapours rise as are capable of transpiring through lutes. The head must be open at the top, and provided with a short tube, through which by means of a funnel with a long pipe, the matter to be distilled may be introduced into the cucurbit. This is to be exactly closed with a glass stopple, the surface whereof must be made to fit the inside of the tube in every point, by rubbing those two pieces well together with emery.

Another sort of alembic hath also been invented, which may be used with advantage when cohabitation is required; that is, when the liquor obtained by distillation is to be returned upon the matter in the cucurbit; and especially when it is intended that this cohabitation shall be repeated a great number of times. The vessel we are speaking of is constructed exactly in the same manner as that last described; except that its beak, instead of being in a straight line as in the other alembics, forms a circular arch, and re-enters the cavity of the cucurbit, in order to convey back again the liquor collected in the head. This instrument hath commonly two beaks opposite to each other, both turned in this manner, and is called a pelican: It saves the artificer the trouble of frequently unluting and reluting his vessels, as well as the loss of a great many vapours.

There are certain substances which in distillation afford matters in a concrete form, or rise wholly in the form of a very light powder, called flowers. When such substances are to be distilled, the cucurbit which contains them is covered with a head without a nose, which is named a blind head.

When the flowers rise in great quantities and very high, a number of heads is employed to collect them; or rather a number of a kind of pots, consisting of a body only without any bottom, which fitting one into the other form a canal, that may be lengthened or shortened at pleasure, according to the flowers to be sublimed are more or less volatile. The last of the heads, which terminates the canal, is quite close at one end, and makes a true blind-head. These vessels are called aludels: they are usually of earthen or stone ware.

All the vessels above mentioned are fit only for distilling such light volatile matters as can be easily raised and brought over; such as phlegm, essificant oils, fragrant waters, acid oily spirits, volatile alkalis, &c. But when the point is to procure, by distillation, principles that are much less volatile, and incapable of rising high, such as the thick fetid oils, the vitriolic, the nitrous, and the marine acids, &c. we are under a necessity of having recourse to other vessels, and another manner of distilling.

It is easy to imagine, that such a vessel must be much lower than the alembic. It is indeed no more than a hollow globe, whose upper part degenerates into a neck
or tube, that is bent into a horizontal position; for which reason this instrument is called a retort: It is always of one single piece.

The matter to be distilled is introduced into the body of the retort by means of a ladle with a long tubular shank. Then it is set in a furnace built purposely for this use, and so that the neck of the retort coming out of the furnace may, like the nose of the alembic, stand in a sloping position, to facilitate the egress of the liquors, which by its means are conveyed to a receiver, into which it is introduced, and with which it is luted. This way of distilling, in which the vapours seem rather to be driven out of the vessel horizontally and laterally, than raised up and sublimed, is for that reason called distillation per latus.

Retorts are, of all the instruments of distillation, those that must sustain the greatest heat, and resist the strongest solvents; and therefore they must not be made of metal. Some, however, which are made of iron may do well enough on certain occasions: The rest are either of glafs or earth. Those of glafs, for the reasons above given, are preferable to the other fort, in all cases where they are not to be exposed to such a force of fire as may melt them. The best glafs, that which stands both heat and solvents best, is that in which there are fewest alkaline salts: Of this fort is the green German glafs: The beautiful white crytal glafs is far from being equally serviceable.

Retorts, as well as alembics, may be of different forms. For example, some matters are apt to swell and rise over the neck of the retort in subfiance without suffering any decomposition; when such matters are to be distilled in a retort, it is proper that the body of the vessel, instead of being globular, be drawn out into the form of a pear, so as nearly to resemble that of a cucurbit. In a retort of this kind, the distance between the bottom and the neck being much greater than in those whose bodies are spherical, the matters contained have much more room for expansion; so that the inconvenience here mentioned is thereby prevented. Retorts of this form are called English retorts: as they hold the middle place between alembics and common retorts, they may be used to distil such matters as have a mean degree of volatility between the greatest and the least.

It is moreover proper to have in a laboratory sundry retorts with necks of different diameters. Wide necks will be found the fittest for conveying thick matters, and such as readily become fixed; for instance, some very thick telluride oils, butter of antimony, &c. for as these matters acquire a confluence as soon as they are out of the reach of a certain degree of heat, they would soon choke up a narrow neck, and by stopping the vapours, which rise at the same time from the retort, might occasion the bursting of the vessels.

Some retorts are also made with an opening on their upper side, like that of tubulated glafs alembics, which is to be closed in the same manner with a glafs stopple. These retorts are also called tubulated retorts, and ought always to be used whenever it is necessary to introduce fresh matter into the retort during the operation; seeing it may be done by means of this invention, without un-
Those intermediate substances in which they plunge their vessels are called baths. They are either fluid or solid: The fluid baths are water, or its vapours. When the distilling vessel is set in water, the bath is called balneum mariae, or the water-bath; and the greatest degree of heat of which it is susceptible is that of boiling water. When the vessel is exposed only to the vapours which exhale from water, this forms the vapour-bath: the heat of which is nearly the same with that of the balneum mariae. These baths are useful for distilling essential oils, ardent spirits, sweet-scented waters; in a word, all such substances as cannot bear a greater heat without prejudice either to their odour, or to some of their other qualities.

Baths may also be made of any other fluids, such as oils, mercury, &c. which are capable of receiving and communicating much more heat; but they are very seldom used. When a more considerable degree of heat is required, a bath is prepared of any solid matter reduced to a fine powder, such as sand, ashes, filings of iron, &c. The heat of these baths may be pushed so far as to make the bottom of the vessel become faintly red. By plunging a thermometer into the bath, by the side of the vessel, it is easy to observe the precise degree of heat applied to the substance on which you are working. It is necessary that the thermometers employed on this occasion be constructed on good principles, and so contrived as to be easily compared with those of the most celebrated natural philosophers.

Furnaces have moreover several apertures: one of these is at the ash-hole, which gives passage to the air, and through which the ashes that fall through the grate are raked out; this aperture is called the ash-hole door: another is at the fire-place, through which the fire is supplied with fuel, as occasion requires; this is called the mouth or door of the fire-place, or the flue-hole: there is a third in the upper story, through which the neck of the vessel passes; and a fourth in the dome, for carrying off the fuliginosities of combustible matters, which is called the chimney.

To conclude, there are several other openings in the several parts of the furnace. The use whereof is to admit the air into those places, and also, as they can be easily shut, to incite or slacken the activity of the fire, and so to regulate it; which has procured them the title of registers. All the other openings of the furnace should be made to shut very close, the better to assist in governing the fire; by which means they likewise do the office of registers. In order to our forming a just and general idea of the construction of furnaces, and of the disposition of the several apertures in them, with a view to increase or diminish the activity of the fire, it will be proper to lay down, as our ground-work, certain principles of natural philosophy, the truth of which is demonstrated by experience.

And first, every body knows that combustible matters will not burn or consume unless they have a free communication with the air; insomuch that if they be deprived thereof, even when burning most rapidly, they will be extinguished at once: that conseqently combustion is greatly promoted by the frequent accession of fresh air; and that a stream of air, directed so as to pass with impetuosity through burning fuel, excites the fire to the greatest possible activity.

Secondly, it is certain that the air which touches or comes near ignited bodies is heated, rarefied, and rendered lighter than the air about it; that is, further di-Elm from the centre of heat; and conseqently that this air so heated and become lighter is necessarily determined thereby to ascend and mount aloft, in order to make room for that which is less heated and not so light, which by its weight and elasticity tends to occupy the place quitted by the other. Another consequence hereof is, that if fire be kindled in a place inclosed every where but above and below, a current of air will be formed in that place, running in a direction from the bottom to the top; so that if any light bodies be applied to the opening below, they will be carried up towards the fire; but, on the contrary, if they be held at the opening above, they will be impelled by a force which will drive them up and carry them away from the fire.
Thirdly, and lastly, it is a truth demonstrated in hydraulics, that the velocity of a given quantity of any fluid, determined to flow in any direction whatever, is so much the greater, the narrower the channel is to which that fluid is confined; and consequently that the velocity of a fluid will be increased by making it run from a wider through a narrower passage.

These principles being established, it is easy to apply them to the construction of furnaces. First, if a fire be kindled in the fire-place of a furnace, which is open on all sides, it burns nearly as if it were in the open air. It has with the surrounding air a free communication; so that fresh air is continually admitted to facilitate the entire combustion of the inflammable matters employed as fuel. But there being nothing to determine that air to pass with rapidity through the fire in this case, it does not at all augment the activity thereof, but suffers it to waffle away quietly.

Secondly, If the affi-hole or dome of a furnace in which a fire is burning be shut quite close, then there is no longer any free communication between the air and the fire; if the affi-hole be shut, the air is debarr'd from having free access to the fire; if the dome be flopt, the egress of the air rarefied by the fire is prevented; and consequently the fire must in either case burn very faintly and slowly; gradually die away, and at last go quite out.

Thirdly, If all the openings of the furnace be wholly closed, it is evident that the fire will be very quickly extinguished.

Fourthly, If only the lateral openings of the fire-place be shut, leaving the affi-hole and upper part of the furnace open; it is plain that the air entering by the affi-hole will necessarily be determined to go out at top, and that consequently a current of air will be formed, which will pass through the fire, and make it burn briskly and vigorously.

Fifthly, If both the affi-hole and the upper story of the furnace be of some length and form canals either cylindric or prismatic, then the air being kept in the same direction through a longer space, the course of its stream will be both stronger and better determined, and consequently the fire will be more animated by it.

Sixthly, and lastly, if the affi-hole and the upper part of the furnace, instead of being cylindric or prismatic canals, have the form of truncated cones or pyramids, standing on their bases, and so ordered that the upper opening of the affi-hole adjoining to the fire-place may be wider than the base of the superior cone or pyramid; then the stream of air, being forced to pass incessantly from a larger channel through a smaller, must be considerably accelerated, and procure to the fire the greatest activity which it can receive from the make of a furnace.

The materials fitted for building furnaces are, 1. Bricks, joined together with potters clay mixed with sand, and moistened with water. 2. Potters clay mingled with potholders, moistened with water, and baked in a violent fire. 3. Iron; of which all furnaces may be made; with this precaution, that the inside be provided with a great many prominent points, as fastenings for a coat of earth, with which the internal parts of the furnace must necessarily be covered to defend it from the action of the fire.

The reverberating furnace is one of those that are most employed in chemistry; it is proper for distillations and should be constructed in the following manner.

First, The use of the affi-hole being, as was said, to give passage to the air, and to receive the ashes, no bad consequence can attend its being made pretty high: It may have from twelve to twenty or twenty-four inches in height. Its aperture should be wide enough to admit billets of wood when a great fire is to be made.

Secondly, The affi-hole must be terminated at its upper part by an iron grate, the bars of which should be very substantial, that they may resist the action of the fire: this grate is the bottom of the fire-place, and defined to support the coals. In the lateral part of the fire-place, and nearly about the fame height with the grate, there should be a hole of such a size that it may easily admit charcoal, as well as little tongs and thongs for managing the fire. This aperture or mouth of the fire-place should be perpendicularly over the mouth of the affi-hole.

Thirdly, from six to eight or ten inches high above the grate, over the affi-hole, little apertures must be made in the walls of the furnace, of eight or ten lines in diameter, an inch from one another, and those in one side must be diametrically opposite to those in the other. The use of these holes is to receive bars of iron for the retort to rest on; which should be, as was said, at different heights, in order to accommodate retorts of different sizes. At the upper extremity of this part of the furnace, which reaches from the iron bars to the top, the height wherein should be somewhere less than the width of the furnace, must be cut a semi-circular aperture for the neck of the retort to come through. This hole must by no means be over the doors of the fire-place and affi-hole; for then, as it gives passage to the neck of the retort, it must of course be opposite to the receiver, and in that case the receiver itself must stand over against those two apertures; which would be attended with this double inconvenience, that the receiver would not only grow very hot, but greatly embarrass the operator, whose free access to the fire-place and affi-hole would be thereby obstructed. It is proper therefore, that the semi-circular cut we are speaking of be placed, that, when the greatest ballons are luted to the retort, they may leave an open passage to the fire-place or affi-hole.

Fourthly, in order cover in the laboratory of the reverberating furnace, there must be a roof made for it in the form of a cupola, or concave hemisphere, having the same diameter as the furnace. This dome should have a semi-circular cut in its rim answering to that above-directed to be made in the upper extremity of the furnace, so that, when adjusted to each other, the two together may form a circular hole for the neck of the retort to pass through. At the top of this dome there must also be a circular hole of three or four inches diameter, carrying a short tapering funnel of the same diameter, and three inches high, which will serve for a chimney
holes open in the fire-place, but the lateral ones; of
in order to promote the condensation of the vapours.

Sixthly and lastly, a conical canal must be provided of
about three foot long, and sufficiently wide at its lower
end to admit the funnel of the aperture at the top of the
dome. This conical tube is to be applied to the dome
when the fire is required to be extremely active: it tu-
pers gradually from its base upwards, and breaks off as
if truncated at top, where it should be about two inches
wide.

Besides the apertures already mentioned as necessary
to a reverberating furnace, there must also be many o-
other smaller holes made in its ash-hole, fire-place, labo-
atory, and dome, which must all be so contrived as to
be easily opened and shut with flloppies of earth: these
holes are the registers of the furnace, and serve to regu-
late the activity of the fire according to the principles
before laid down.

When the action of the fire is required to be exactly
uniform and very brisk, it is necessary to flop carefully
with moist earth all the little chinks in the juncture of the
dome with the furnace, between the neck of the retort
and the circular hole through which it passes, and which
it never fills exactly, and fairly the holes which receive
the iron bars that sustain the retort.

It is proper to have in a laboratory several reverbera-
ting furnaces of different magnitudes; because they must
be proportioned to the size of the retorts employed. The
retort ought to fill the furnace, so as to leave only
the distance of an inch between it and the inside of the
furnace.

Yet when the retort is to be exposed to a most violent
fire, and especially when it is required that the heat shall
act with equal force on all parts of the furnace, and as
strongly on its vault as on its bottom, a greater distance
must be left between the retort and the inside of the
furnace; for then the furnace may be filled with coals,
even to the upper part of the dome. If moreover some
pieces of wood be put into the ash-hole, the conical ca-
nal fitted on to the tunnel of the dome, and all the ap-
portures of the furnace exactly closed, except the ash-
hole and the chimney, the greatest heat will then be
excited that this furnace can produce.

The furnace now described may also be employed in
many other chemical operations. If the dome be laid a-
side, an alembic may very well be placed therein; but
then the space, which will be left between the body of the
alembic and the top of the upper part of the furnace,
must be carefully filled up with Wrinfor-loam moistened;
for without that precaution the heat would soon reach
the very head, which ought to be kept as cool as possible,
in order to promote the condensation of the vapours.

On this occasion therefore it will be proper to leave no
holes open in the fire-place, but the lateral ones; of
which also those over against the receiver must be flop-
ped.

A pot or broad-brimmed earthen pan may be placed
over this furnace, and being so fitted to it as to close the
upper-part thereof accurately, and filled with sand, may
serve for a sand-heat to distill with.

The bars designed to support distilling vessels being ta-
ken out, a crucible may stand therein, and many opera-
tions be performed that do not require the utmost violence
of fire. In a word, this furnace is one of the most com-
modious that can be, and more extensively useful than
any other.

The melting furnace is designed for applying the greatest
force of heat to the most fixed bodies, such as metals
and earths. It is never employed in distilling: it is of
no use but for calcination and fusion; and consequently
need not admit any vessels but crucibles.

The ash-hole of this furnace differs from that of the
reverberating furnace only in this, that it must be high-
er, in order to raise the fire-place to a level with the
artisan's hand; because in that all the operations of this
furnace are performed. The ash-hole therefore must be
about three foot high; and this height procures it more-
over the advantage of a good draught of air. For the
same reason, and in consequence of the principles we
laid down, it should be so built that its width lessening
indefinitely from the bottom to the top, it may be nar-
rower where it opens into the fire-place than any where
below.

The ash-hole is terminated at its upper end, like that
of the reverberating furnace, by a grate which serves for
the bottom of the fire-place, and ought to be very sub-
stantial that it may resist the violence of the fire. The
inside of this furnace is commonly an elliptic curve;
because it is demonstrated by mathematicians, that sur-
faces having that curvature reflect the rays of the sun, or
of fire, in such a manner, that, meeting in a point or a
line, they produce there a violent heat. But to answer
this purpose, those surfaces must be finely polished; an
advantage hardly procurable to the internal surface of
this furnace, which can be made of nothing but earth:
besides, if it were possible to give it a polish, the violent
action of the fire that must be employed in this furnace
would presently destroy it. Yet the elliptical figure must
not be entirely disregarded: for, if care be taken to keep
the internal surface of the furnace as smooth as possible,
it will certainly reflect the heat pretty strongly, and col-
lect it about the center.

The fire-place of this furnace ought to have but four
apertures.

First, that of the lower grate, which communicates
with the ash-hole.

Secondly, a door in its fore-side, through which may
be introduced coals, crucibles, and tongs for managing
them: this aperture should be made to shut exactly with
a plate of iron, having its inside coated with earth, and
turning on two hinges fixed to the furnace.

Thirdly, over this door a hole flanting downwards to-
wards the place where the crucible is to stand. The use
of this hole is to give the operator an opportunity of ex-
Nol. II. No. 34.
ameining the condition of the matters contained in his crucible, without opening the door of the fire-place: this hole should be made to open and shut easily, by means of a flop of earth.

Fourthly, a circular aperture of about three inches wide in the upper part or vault of the furnace, which should gradually lenen and terminate, like that of the dome of the reverberating furnace, in a short conical funnel of about three inches long, and fitted to enter the conical pipe before described, which is applied when the activity of the fire is to be increased.

When this furnace is to be used, and a crucible to be placed in it, care must be taken to set on the grate a cake of baked earth somewhat broader than the foot of the crucible. The use of this fland is to support the crucible, and raise it above the grate, for which purpose it should be two inches thick. Were it not for this precaution, the bottom of the crucible, which would stand immediately on the grate, could never be thoroughly heated, because it would be always exposed to the stream of cold air which enters by the ash-hole. Care should also be taken to heat this earthen bottom red-hot before it is placed in the furnace, in order to free it from any humidity, which might otherwise happen to be driven against the crucible during the operation, and occasion its breaking.

We omitted to take notice, in speaking of the ash hole, that, besides its door, it should have about the middle of its height a small hole, capable of receiving the nozzle of a good perpetual bellows, which is to be introduced into it and worked, after the door is exactly shut, when it is thought proper to excite the activity of the fire to the utmost violence.

The forge is only a mass of bricks of about three feet high, along whose upper surface is directed the nozzle or pipe of a pair of large perpetual bellows, so placed that the operator may easily blow the fire with one hand. The coals are laid on the hearth of the forge near the nozzle of the bellows; they are confined, if necessary, to prevent their being carried away by the wind of the bellows, within a space inclosed by bricks; and thus by pulling the bellows the fire is continually kept up in its greatest activity. The forge is of use when there is occasion to apply a great degree of heat suddenly to any substance, or when it is necessary that the-operator be at liberty to handle frequently the matters which he proposes to fuse or calcine.

The cupelling furnace is that in which gold and silver are purified, by the means of lead, from all alloy of other metallic substances. This furnace must give a heat strong enough to vitrify lead, and therewith all the alloy which the perfect metals may contain. This furnace is to be built in the following manner.

First, of thick iron plates, or of some such composition of earth as we recommended for the construction of furnaces, must be formed a hollow quadrangular prism, whose sides may be about a foot broad, and from ten to eleven inches high; and extending from thence upwards may converge towards the top, so as to form a pyramid truncated at the height of seven or eight inches, and terminated by an aperture of the width of seven or eight inches every way. The lower part of the prism is terminated and closed by a plate of the same materials of which the furnace is constructed.

Secondly, in the fore-side or front of this prism there is an opening of three or four inches in height by five or six inches in breadth: this opening, which should be very near the bottom, is the door of the ash-hole. Immediately over this opening is placed an iron grate, the bars of which are quadrangular prisms of half an inch square, laid parallel to each other, and about eight or nine inches asunder, and disposed that two of their angles are laterally opposite, the two others looking one directly upwards, and the other downwards. As in this situation the bars of the grate prevent to the fire place very oblique surfaces, the ashes and very small coals do not accumulate between them, or hinder the free entrance of the air from the ash-hole. This grate terminates the ash-hole at its upper part, and serves for the bottom of the fire-place.

Thirdly, three inches, or three and a half, above the grate, there is in the fore-side of the furnace another opening terminated by an arch for its upper part, which consequently has the figure of a semi-circle: it ought to be four inches wide at bottom, and three inches and an half high at its middle. This opening is the door of the fire-place; yet it is not intended for the same uses as the door of the fire-place in other furnaces: the purpose for which it is actually defined shall be explained when we come to shew how the furnace is to be used. An inch above the door of the fire-place, still in the foreside of the furnace, are two holes of about an inch diameter, and at the distance of three inches and a half from each other, to which answer two other holes of the same size, made in the hinder part, directly opposite to these. There is, moreover, a fifth hole of the same width about an inch above the door of the fire-place. The design of all these holes shall be explained when we describe the manner in which these furnaces are to be used.

Fourthly, the fore-part of the furnace is bounded by three iron braces, one of which is fixed just below the door of the ash-hole; the second occupies the whole space between the ash-hole door and the door of the fire-place, and has two holes in it, answering to those which we directed to be made in the furnace itself about this place; and the third is placed immediately over the door of the fire-place. These braces must extend from a corner of the front of the furnace to the other, and be fastened thereto with iron pins, in such a manner that their sides next to the doors may not lie quite close to the body of the furnace, but form a kind of grooves for the iron plates to slide in, that are designed to shut the two doors of the furnace when it is necessary. Each of these iron plates should have a handle, by which it may be conveniently moved; and to each door there should be two plates, which meeting each other, and joining exactly in the middle of the door-place, may shut it very close. Each of the two places belonging to the door of the fire-place ought to have a hole in its upper part; one of these holes should be a slit of about two lines wide, and half an inch long; the other may be a semi-circular opening of one inch in height and two in breadth.
breadth. These holes should be placed so that neither of them may open into the fire-place when the two plates are joined together in the middle of the door to shut it close.

Fifthly, to terminate the furnace above, there must be a pyramid, formed of the same materials with the furnace, hollow, quadrangular, three inches high, on a base of seven inches, which base must exactly fit the upper opening of the furnace: the top of this pyramidal cover must end in a tube of three inches in diameter and two in height, which must be almost cylindrical, and yet a little inclining to the conical form. This tube serves, as in the furnaces already described, to carry the conical funnel, which is fitted to the upper part when a fire of extraordinary activity is wanted.

The furnace thus constructed is fit to serve all the purposes for which it is designed; yea, before it can be used, another piece must be provided, which, though it does not properly belong to the furnace, is nevertheless necessary in all the operations performed by it; and that is a piece contrived to contain the cupels, or other vessels which are to be exposed to the fire in this furnace. It is called a muffle, and is made in the following manner.

On an oblong square, of four inches in breadth, and six or seven inches in length, a concave semi-cylinder is erected, in the form of a vault, which makes a semi-circular canal open at both ends. One of these is almost entirely closed, except that near the bottom two small semi-circular holes are left. In each of its sides likewise two such holes are made, and the other end is left quite open.

The muffle is intended to bear and communicate the fiercest heat; and therefore it must be made thin, and of an earth that will resist the violence of fire, such as that which crucibles are made of. The muffle being thus constructed, and then well baked, is fit for use.

When it is to be used, it must be put into the furnace by the upper opening, and let upon two iron bars, introduced through the holes made for that purpose below the door of the fire-place. The muffle must be placed on these bars in the fire-place, in such a manner that its open end shall stand next to and directly against the door of the fire-place, and may be joined to it with lute. Then the cupels are ranged in it, and the furnace is filled up, to the height of two or three inches above the muffle, with small coals not bigger than a walnut, to the end that they may lie close round the muffle, and procure it an equal heat on every side. The chief use of the muffle is to prevent the coals and ashes from falling into the cupels, which would be very prejudicial to the operations carrying on in them: for the lead would not vitrify as it ought, because the immediate contact of the coals would continually restore its phlogiston; or else the glafs of lead, which ought to penetrate and pass through the cupels, would be rendered incapable of so doing; because the ashes mixing therewith would give it such a tenacity and tenacity as would destroy that property, or at least considerably lessen it. The openings, therefore, which are left in the lower part of the muffle, should not be so high as to admit coals or ashes to get into the cupels; the use of them is to procure an easier passage for the heat and the air to those vessels. The muffle is left quite open in its fore-part, that the operator may be at liberty to examine what passes in the cupels, to stir their contents, to remove them from one place to another, to convey new matters into them, &c. and also to promote the free access of the air, which must concur with the fire towards the evaporation necessary to the vitrification of lead; which air, if fresh were not often enough admitted, would be incapable of producing that effect; because it would soon be loaded with such a quantity of vapours that it could not take up any more.

The government of the fire in this furnace is founded on the general principles above laid down for all furnaces. Yet as there are some little differences, and as it is very essential to the success of the operations for which this furnace is intended, that the artist should be absolutely master of his degree of heat, we shall in few words shew how that may be raised or lowered.

When the furnace is filled with coals and kindled, if the door of the ash-hole be set wide open, and that of the fire-place shut very close, the force of the fire is increased; and if, moreover, the pyramidal cover be put on the top, and the conical funnel added to it, the fire will become still more fierce.

Seeing the matters contained in this furnace are encompassed with fire on all sides, except in the fore part opposite to the door of the fire-place, and as there are occasions which require that the force of the fire should be applied to this part also, an iron box, of the shape and size of the door, hath been contrived to answer that purpose. This box is filled with lighted coals, and applied immediately to the door-place, by which means the heat there is considerably augmented. This help may be made use of at the beginning of the operation, in order to accelerate it, and bring the heat sooner to the desired degree; or in case a very fierce heat be required; or at a time when the air being hot and moist will not make the fire burn with the necessary vigour.

The heat may be heightened, by removing the iron box, and shutting the door of the fire-place quite close. It may be still further and gradually diminished, by taking off the conical funnel from the top; by shutting the door of the fire-place with one of its plates only, that which has the least, or that which has the greatest aperture in it; by taking off the pyramidal cover; by shutting the ash-hole wholly or in part; and lastly, by setting the door of the fire-place wide open: but, in this last case, the cold air penetrates into the cavity of the muffle, and refrigerates the cupels more than is almost ever necessary. If it be observed, during the operation, that the muffle grows cold in any particular part, it is a sign there is a vacuity left by the coals in that place: in this case, an iron wire must be thrust into the furnace, through the hole which is over the door of the fire-place, and the coal stirred therewith, so as to make them fall into their places and fill up the vacant interstices.

It is proper to observe, that, besides what has been said concerning the ways of increasing the activity of the fire in the cupelling furnace, several other causes also may concur to procure to the matters contained in the muffle a greater degree of heat: for example, the smaller the muffle is, the wider and more numerous the holes in it are;
as hath been said, that the neck of the distilling vessel be exactly joined with that of the receiver into which it is introduced, in order to prevent the vapours from escaping into the air and so being lost: And this junction is effected by means of a lute.

A few slips of paper, applied round the neck of the vessels with common size, will be sufficient to keep in such vapours as are aqueous, or not very spirituous.

If the vapours are more acid and more spirituous, recourse may be had to slips of bladder long steeped in water, which, containing a sort of natural glue, close the junctures of the vessels very well.

If it be required to confine vapours of a still more penetrating nature, it will be proper to employ a lute that quickly grows very hard; particularly a paste made with quick-lime and any sort of jelly, whether vegetable or animal; such as the white of an egg, fluff size, &c. This is an excellent lute, and not easily penetrated. It is also used to stop any cracks or fractures that happen to glass vessels. But it is not capable of resisting the vapours of mineral acid spirits, especially when they are strong and smoking: For that purpose it is necessary to incorporate the other ingredients thoroughly with fat earth softened with water; and even then it frequently happens that this lute is penetrated by acid vapours, especially those of the spirit of salt, which of all others are confined with the greatest difficulty.

In such cases its place may be supplied with another, which is called fat lute, because it is actually worked up with fat liquors. This lute is composed of a very fine cretaceous earth, called tobacco-pipe clay, moistened with equal parts of the drying oil of lint-feed, and a varnish made of amber and gum copal. It must have the consistence of a stiff paste. When the joints of the vessels are closed up with this lute, they may, for greater security, be covered over with slips of linen smeared with the lute made of quick-lime and the white of an egg.

Chemical vessels are liable to be broken in an operation by other causes besides the sudden application of heat or cold. It frequently happens that the vapours of the matters, exposed to the action of fire, rush out with such impetuosity, and are so elastic, that finding no passage through the lute with which the joints of the vessels are closed, they burst the vessels themselves, sometimes with explosion and danger to the operator.

To prevent this inconvenience, it is necessary, that in every receiver there be a small hole, which being stopped only with a little lute may easily be opened and shut again as occasion requires. It serves for a vent-hole to let out the vapours, when the receiver begins to be too much crowded with them. Nothing but practice can teach the artist when it is requisite to open this vent. If he hits the proper time, the vapours commonly rush out with rapidity, and a considerable hissing noise; and the vent should be stopped again as soon as the hissing begins to grow faint. The lute employed to stop this small hole ought always to be kept so ductile, that by taking the figure of the hole exactly it may entirely stop it. Besides, if it should harden upon the glass, it would stick so fast, that it would be very difficult to remove it without breaking...

ing the vessel. This danger is easily avoided by making use of the fat lute, which continues pliant for a long time, when it is not exposed to an excessive heat.

This way of stopping the vent-hole of the receiver has yet another advantage: For if the hole be of a proper width, as a line and half, or two lines, in diameter, then when the vapours are accumulated in too great a quantity, and begin to make a great effort against the sides of the receiver, they push up the top, force it out, and make their way through the vent hole: So that by this means the breaking of the vessels may always be certainly prevented. But great care must be taken that the vapours be not suffered to escape in this manner, except when absolute necessity requires it; for it is generally the very strongest and most subtle part of a liquor which is thus dissipated and lost.

Heat being the chief cause that puts the elasticity of the vapours in action, and prevents their condensing into a liquor, it is of great consequence in distillation that the receiver be kept as cool as possible. With this view a thick plank should be placed between the receiver and the body of the furnace, to intercept the heat of the latter, and prevent its reaching the former. As the vapours themselves rise very hot from the distilling vessel, they soon communicate their heat to the receiver, and especially to its upper part, against which they strike first. For this reason it is proper, that linen cloths dip in very cold water be laid over the receiver, and frequently shifted. By this means the vapours will be considerably cooled, their elasticity weakened, and their condensation promoted.

By what hath been said in this first part, concerning the properties of the principal agents in chemistry, the construction of the most necessary vessels and furnaces, and the manner of using them, we are sufficiently prepared for proceeding directly to the operations, without being obliged to make frequent and long stops, in order to give the necessary explanations on those heads.

Nevertheless, we shall take every proper occasion to extend the theory here laid down, and to improve it by the addition of several particulars, which will find their places in our treatise of chemical operations.

PART II. PRACTICE OF CHEMISTRY.

Of the Vitriolic Acid.

To extract Vitriol from the Pyrites.

Take any quantity you please of iron pyrites; leave them for some time exposed to the air: They will crack, split, lose their brightness, and fall into powder. Put this powder into a glass cucurbit, and pour upon it twice its weight of hot water; stir the whole with a stick, and the liquor will grow turbid. Pour it while it is yet warm into a glass funnel lined with brown filtering paper; and having placed your funnel over another glass cucurbit, let the liquor drain into it. Pour more hot water on the powdered pyrites, filter as before, and so go on, every time lessening the quantity of water, till that which comes off the pyrites appears to have no astringent vitriolic taste.
Put all these waters together into a glass vessel that widens upwards; let it on a sand bath, and heat the liquor till a considerable smoke arises; but take care not to make it boil. Continue the same degree of fire till the surface of the liquor begins to look dim, as if some dust had fallen into it; then cease evaporating, and remove the vessel into a cool place: In the space of four and twenty hours there will be formed therein a quantity of crystals, of a green colour and a rhomboidal figure: These are vitriol of Mars, or copperas. Decant the remaining liquor; add thereto twice its weight of water; filter, evaporate, and crystallize as before: repeat these operations till the liquor will yield no more crystals, and keep by themselves the crystals obtained at each crystallization.

In large works for extracting vitriol from the pyrites, they proceed thus. They collect a great quantity of pyrites on a piece of ground exposed to the air, and pile them up in heaps of about three foot high. There they leave them exposed to the action of the air, sun, and rain, for three years together: taking care to turn them every six months, in order to facilitate the efflorescence of those which at first lay undermoist. The rain-water which has washed those pyrites is conveyed by proper channels into a cistern; and when a sufficient quantity thereof is gathered, they evaporate it to a pellicle in large leaden boilers, having first put into it a quantity of iron, some part of which is dissolved by the liquor, because it contains a vitriolic acid that is not fully saturated therewith. When it is sufficiently evaporated, they draw it off into large leached wooden coolers, and there leave it to shoot into crystals. In these last vessels several sticks are placed, crossing each other in all manner of directions, in order to multiply the surfaces on which the crystals may fall.

To extract Sulphur from the Pyrites, and other sulphurous Minerals.

Reduce to a coarse powder any quantity of yellow pyrites, or other mineral containing sulphur. Put this powder into an earthen or glass retort, having a long wide neck, and so large a body that the matter may fill but two thirds of it. Set the retort in a sand-bath fixed over a reverberating furnace: Fit to it a receiver half full of water, and so placed that the nose of the retort may be about an inch under the water; Give a gradual fire, taking care you do not make it so strong as to melt the matter. Keep the retort moderately red for one hour, or an hour and half, and then let the vessels cool.

Almost all the sulphur, separated by this operation from its matrix, will be found at the extremity of the neck of the retort, being fixed there by the water. You may get it out either by melting it with such a gentle heat as will not set it on fire, or by breaking the neck of the retort.

To extract Alum from aluminous Minerals.

Take such minerals as are known or suspected to contain alum. Expose them to the air, that they may effloresce. If they remain there a year without any sensible change, calcine them, and then leave them exposed to the air, till a bit thereof being put onto the tongue imparts an astringent aluminous taste.

When your matters are thus prepared, put them into a leaden or glass vessel; pour upon them twice their weight of hot water; boil the liquor; filter it; and repeat these operations till the earth be so deliquescent that the water which comes off it hath no taste. Mix all these solutions together, and let them stand four and twenty hours, that the gels and earthy parts may settle to the bottom; or else filter the liquor; then evaporate till it will bear a new-laid egg. Now let it cool, and stand quiet four and twenty hours: in that time some crystals will shoot, which are most commonly vitriolic; for alum is rarely obtained by the first crystallization. Remove these vitriolic crystals: if any crystals of alum be found amongst them, these must be dissolved anew, and set to crystallise a second time in order to their purification; because they partake of the nature as well as of the colour of vitriol. By this method extract all the alum that the liquor will yield.

If you get no crystals of alum by this means, boil your liquor again, and add to it a twentieth part of its weight of a strong alkaline lixivium, or a third part of its weight of purged urine, or a small quantity of quick-lime. Experience and repeated trials must teach you which of these three substances is to be preferred, according to the particular nature of the mineral on which you are to operate. Keep your liquor boiling, and in four or five days other places, it effloresces naturally on the surface of the earth. There it is swept together with brooms, and thrown into pits full of water. This water is impregnated therewith till it can dissolve no more. Then it is filtered, and set to evaporate in large leaden vessels; and when it is sufficiently evaporated, and ready to shoot into crystals, it is drawn off into wooden coolers, and there left for the salt to crystallise.

Alum is obtained from several sorts of minerals. In some parts of Italy, and in sundry other places, it effloresces naturally on the surface of the earth. There it is swept together with brooms, and thrown into pits full of water. This water is impregnated therewith till it can dissolve no more. Then it is filtered, and set to evaporate in large leaden vessels; and when it is sufficiently evaporated, and ready to shoot into crystals, it is drawn off into wooden coolers, and there left for the salt to crystallise.

In aluminous soils there are often found springs strongly impregnated with alum; so that to obtain it the water need only be evaporated.

In the country about Rome there is a very hard stone, which is hewn out of the quarry, just like other stones for building; this stone yields a great deal of alum. In order to extract it, the stones are calcined for twelve or fourteen hours; after which they are exposed to the air in heaps, and carefully watered three or four times a day for forty days together. In that time they begin to effloresce, and to throw out a reddish matter on their surface. Then they are boiled in water, which dissolves all the alum they contain, and being duly evaporated gives it back in crystals. This is the alum called Roman alum.

Several sorts of pyrites also yield a great deal of alum. The English have a stone of this kind, which in colour is very like a flate. This stone contains much sulphur, which
which they get rid of by roasting it. After this they steep the calcined stone in water, which dissolves the alum it contains, and to this solution they add a certain quantity of a lye made of the ashes of sea-weeds.

To extract the Vitriolic Acid from Green Vitriol.

Take any quantity of green vitriol: put it in an unglazed earthen vessel, and heat it gradually. Vapours will soon begin to rise. Increase the fire a little, and it will liquify by means of the water contained in it, and acquire what we called an aqueous floor. Continue the calcination, and it will becomeless and less fluid, grow thick, and turn of a greyish colour. Now raise your fire, and keep it up till the salt recover its solidity, acquire an orange colour, and begin to grow red where it immediately touches the sides of the vessel. Then take it out and reduce it to powder.

Put the vitriol thus calcined and pulverized into a good earthen retort, of which one half at least must remain empty. Set the retort in a reverberatory furnace: Fit thereto a large glass receiver, and, having led the joint well, give fire by degrees. You will soon see white clouds rise into the receiver, which will render it opaque and heat it. Continue the same degree of fire till these clouds disappear: They will be succeeded by a liquor which will trickle down the sides of the receiver in veins. Still keep up the fire to the same degree as long as these veins appear. When they begin to abate, encrease the fire, and push it to the utmost extremity: Upon this there will come over a black, thick liquor: It will even be found congealed, and prove the icy oil of vitriol, if care hath been taken to change the receiver, keep the vessels perfectly close, and give a sufficient degree of heat. Proceed thus till nothing more comes over, or at least very little. Let the vessels cool, unlace them, pour the contents of the receiver into a bottle, and seal it hermetically.

To decompose Sulphur, and extract its Acid, by burning it.

Take any quantity of the purest sulphur; fill therewith a crucible or other earthen dish; heat it till it melts; then set it on fire, and when its whole surface is lighted, place it under a large glass head, so that the flame of the sulphur do not touch either its sides or bottom; that the air have free access, in order to make the sulphur burn clear; that the head incline a little toward the side on which its beat is, that as the vapours condense therein the liquor may run off with ease. To the beak of this vessel fit a receiver: The flames of the lighted sulphur will be condensed, and gather into drops in the head, out of which they will run into the receiver. There, when the sulphur has done burning, you will find an acid liquor, which is the spirit of sulphur.

To concentrate the Vitriolic Acid.

Take the vitriolic acid you intend to concentrate, that is, to dephlegmate and make stronger: Pour it into a good glass retort of such a size that your quantity of acid may but half fill it: Set this retort in the sand-bath of a reverberating furnace; fit it to a receiver; late it on, and give a gradual fire. There will come over into the receiver, a clear liquor, the first drops of which will be but faintly acid: This is the most aqueous part.

When the drops begin to follow one another much more slowly, raise your fire, till the liquor begin to bubble a little in the middle. Keep it thus gently boiling, till one half or two thirds thereof be come over into the receiver. Then let your vessels cool; unlace them; what remains in the retort pour into a crystal bottle, and stop it exactly with a glass stopple rubbed with emery.

To decompose vitriolated Tartar by means of the Phlogiston; or to compose Sulphur by combining the Vitriolic Acid with the Phlogiston.

Take equal parts of vitriolated tartar, and very dry salt of tartar, separately reduced to powder; add an eighth part of their weight of charcoal dust; and mix the whole together very accurately. Throw this mixture into a red hot crucible, placed in a furnace filled with burning coals. Cover it very close, and keep it very hot, till the mixture melt, which may be known by uncovering the crucible from time to time. There will then appear a bluish flame, accompanied with a pungent smell of sulphur.

Take the crucible out of the fire; disolve its contents in hot water; filter the solution through brown paper supported by a glass funnelly drop into the filtered liquor by little and little any acid whatever. As you add the acid, the liquor will grow more and more turbid, and let fall a grey precipitate. Continue dropping in acid till the liquor will yield no more precipitate. Filter it a second time to separate it from the precipitate: What remains on the filter is a true inflammable sulphur, which you may either melt or sublime into flowers.

Of the Nitrous Acid.

To extract nitre out of nitrous earths and flowers. The purification of salt petre. Mother of nitre. Magnesia.

Take any quantity of nitrous earths or flowers; reduce them to powder; and therewith mix a third part of the ashes of green wood and quicklime. Put this mixture into a barrel or vat, and pour on it hot water to about twice the weight of the whole mass. Let it stand thus for twenty four hours, stirring it from time to time with a stick. Then filter the liquor through brown paper, or pass it through a flannel bag, till it come clear; it will then have a yellowish colour. Boil this liquor, and evaporate till you perceive that a drop of it let fall on any cold body coagulates. Then stop the evaporation, and let your liquor in a cool place. In the space of four and twenty hours crystals will be formed in it, the figure of which is that of an hexagonal prism, having its opposite planes generally equal, and terminated at each extremity by a pyramid of the same number of faces. These crystals will be of a brownish colour, and delagrate on a live coal.

Decant the liquor from these crystals; mix it with twice
twice its weight of hot water; evaporate and crystallize as before. Repeat the same operation till the liquor will yield no more crystals: it will then be very thick, and goes by the name of mother of nitre.

Earth and stones that have been impregnated with animal or vegetable juices susceptible of putrefaction, and have been long exposed to the air, but sheltered from the sun and rain, are those which yield the greatest quantity of nitre. But all sorts of earths and stones are not equally fit to produce it. None is ever found in clints or sands of a crystalline nature.

Some earths and stones abound so with nitre, that it effervesces spontaneously on their surface, in the form of a crystalline down. This nitre may be collected with brooms, and accordingly has the name of salt-petre. Some of this sort is brought from India.

The process by which our salt-petre makers extract nitre in quantities, out of rubbish and nitrous earths, is very nearly the same with that here set down: so that we shall not enter into a particular account of it. We shall only take notice of one thing, which it is of some consequence to know; namely, that there is no nitrous earth which does not contain sea salt also. The greatest quantities of this salt are to be found in those earths which have been drenched with urine or other animal excrements. Now, as the rubbish of old houes in great cities is in this clafs, it comes to pafs, that when the salt-petre workers evaporate a nitrous lixivium drawn from that rubbish, as soon as the evaporation is brought to a certain pitch, a great many little crystals of sea-salt form in the liquor, and fall to the bottom of the vessel.

The salt-petre workers in France call these saline particles the grain, and take great care to separate them from the liquor, (which as long as it continues hot keeps the salt-petre dissolved) before they set it to crystallize. This fact seems a little singular considering that sea-salt dissolves in water more easily than salt-petre, and crystallizes with more difficulty.

In order to discover the cause of this phenomenon, we must recollect, first, that water can keep but a determinate quantity of any salt in solution, and that if water fully saturated with a salt be evaporated, a quantity of salt will crystallize in proportion to the quantity of water evaporated. Secondly, that those salts which are the most soluble in water, particularly those which run in the air, will dissolve in cold and in boiling water equally; whereas much greater quantities of the other salts will dissolve in hot and boiling water than in cold water. These things being admitted, when we know that sea-salt is one of the first sorts and salt-petre of the second, the reason why sea-salt precipitates in the preparation of salt-petre appears at once. For,

When the solution of salt-petre and sea-salt comes to be evaporated to such a degree that it contains as much sea-salt as it possibly can, this salt must begin to crystallize, and continue to do so gradually as the evaporation advances. But because at the same time it does not contain as much salt-petre as it can hold, being it is capable of dissolving a much greater quantity thereof when it is boiling hot than when it is cold, this last named salt will not crystallize so soon. If the evaporation were continued till the case of the salt-petre came to be the same with that of the sea-salt, then the salt-petre also would begin to crystallize gradually in proportion to the water evaporated, and the two sorts would continue crystallizing promiscuously together; but it is never carried so far; nor is it ever necessary; for as the water cools, it becomes more and more incapable of holding in solution the same quantity of salt-petre as when it was boiling hot.

And then comes the very reverse, with regard to the crystallizing of the two sorts; for then the salt-petre shews, and not the sea-salt. The reason of this fact also is founded on what has just been said. The sea-salt, of which cold water will dissolve as much as boiling water, and which owes its crystallizing before only to the evaporation, now ceases to crystallize as soon as the evaporation ceases; while the salt-petre, which the water kept dissolved only because it was boiling hot, is forced to crystallize merely by the cooling of the water.

When the solution of salt-petre has yielded as many crystals of that salt as it can yield by cooling, it is again evaporated, and being then suffered to cool yields more crystals. And thus they continue evaporating and crystallizing till the liquor will afford no more crystals.

It is plain, that as the salt-petre crystallizes, the proportion of sea-salt to the dissolving liquor increases; and as a certain quantity of water evaporates also during the time employed in crystallizing the salt-petre, a quantity of sea-salt, proportioned to the water so evaporating, must crystallize in that time; and this is the reason why salt-petre is adulterated with a mixture of sea-salt. It likewise follows, that the last crystals of nitre, obtained from a solution of salt-petre and sea-salt, contain much more sea-salt than the first.

From all that has been said concerning the crystallization of salt-petre and sea-salt, it is easy to deduce the proper way of purifying the former of these two sorts from a mixture of the latter. For this purpose the salt-petre to be refined need only be dissolved in fair water. The proportion between the two sorts in this second solution is very different from what it was in the former; for it contains no more sea-salt than what had crystallized along with the salt-petre under favour of the evaporation, the rest having been left dissolved in the liquor that refused to yield any more nitrous crystals.

As there is therefore a much greater quantity of salt-petre than of sea-salt in this second solution, it is easy to evaporate it to such a degree that a great deal of salt-petre shall crystallize, while much more of the water must necessarily be evaporated before any of the sea-salt will crystallize.

However, the salt-petre is not yet entirely freed from all mixture of sea-salt by this first purification; for the crystals obtained from this liquor, in which sea-salt is dissolved, are still incrusted, and, as it were, infected therewith: hence it comes, that, to refine the salt-petre thoroughly, these crystallizations must be repeated four or five times.

The salt-petre men commonly content themselves with crystallizing it thrice, and call the produce salt-petre of the first, second, or third shoot, according to the number of crystallizations it has undergone. But their best refined
The nitrous acid is not pure in the earths and stones from which it is extracted. It is combined partly with the vegetable or animal matters that concurred to its generation. A fixed alkali and quick-lime are added to the divinum of a nitrous earth, in order to decompose the nitrous salts formed in that earth, and to separate the acid from the volatile alkali and the absorbent earth with which it is united: thence comes that copious sediment which appears in the lye at the beginning of the evaporation. These matters form with that acid a true nitre, much more capable than the original nitrous salts of crystallisation, detonation, and the other properties which are essential thereto. The basis of nitre is therefore a fixed alkali mixed with a little lime.

The mother of nitre, which will yield no more crystals, is brown and thick; by evaporation over a fire it is further impregnated, and becomes a dry, solid body, which however being left to itself soon gives, and runs into a liquor. This water still contains a good deal of nitre, sea-salt, and the acids of these salts united with an absorbent earth. It contains moreover a great deal of a fat, viscid matter, which prevents its crystallising.

All saline solutions in general, after having yielded a certain quantity of crystals, grow thick, and refuse to part with any more, though they still contain much salt. They are all called mother-waters, as well as that which hath yielded nitre. The mother-waters of different salts may prove the subjects of curious and useful enquiries.

If a fixed alkali be mixed with the mother of nitre, a copious white precipitate immediately falls, which being collected and dried is called magnesia. This precipitate is nothing but the absorbent earth that was united with the nitrous acid, together with a good deal of the lime that was added, and was also united with that acid, from which they are now separated by the fixed alkali, according to the usual laws of affinities or elective attractions.

The vitriolic acid poured upon mother of nitre causes many acid vapours to rise, which are a compound of the nitrous and marine acids, that is, an aqua regis. On this occasion also there falls a large quantity of a white powder, which is still called magnesia; yet it differs from the former in that it is not, like it, a pure absorbent earth, but combined with the vitriolic acid.

An aqua regis may also be drawn from nitrous earths by the force of fire only, without the help of any addition.

Take the purest salt petre in powder; put it into a large crucible, which it may half fill; set the crucible in a common furnace, and surround it with coals. When it is red-hot the nitre will melt, and become as fluid as water. Then throw into the crucible a small quantity of charcoal dust: the nitre and the charcoal will immediately deflagrate with violence; and a great commotion will be raised, accompanied with a considerable hissing, and abundance of black smoke. As the charcoal vanishes, the detonation will abate, and cease entirely as soon as the coal is quite consumed.

Then throw into the crucible the same quantity of charcoal-dust as before, and the same phenomena will be repeated. Let this coal also be consumed; then add more, and go on in the same manner till you can excite no further deflagration, always observing to let the burning coal be entirely consumed before you add any fresh. When no deflagration ensues, the matter contained in the crucible will have lost much of its fluidity.

Nitre will not take fire, unless the inflammable matter added to it be actually burning; or the nitre itself red hot, and so thoroughly ignited as immediately to kindle it. Therefore, if you would procure the detonation of nitre with charcoal, and make use of cold charcoal, as in the process, the nitre in the crucible must be red hot, and in perfect fusion: but you may also use live coals, and then the nitre need not be red-hot.

The matter remaining in the crucible after the operation, is a very strong fixed alkali. Being exposed to the air, it quickly extracts the moisture thereof, and runs into a liquor. It is called alkalized nitre; or to distinguish it from nitre alkalized by other inflammable matters, nitre fixed by charcoal.

The nitrous acid is not only dissipated during the deflagration of the nitre, but is even destroyed, and perfectly decomposed. The smoke that rises during the operation has not the least odour of an acid.

In order to collect the vapours discharged by the deflagration of nitre, fit to a subilated earthen retort two or three large adopters: set the retort in a furnace; and under it make a fire sufficient to keep its bottom moderately red. Then take a small quantity, two or three pinches for example, of a mixture of three parts of nitre with one of charcoal-dust, and drop it into the retort through its tube, which must be uppermost, and immediately stopped close. A detonation instantly ensues; and the vapours that rise from the inflamed mixture of nitre and charcoal, passing out through the neck of the retort into the adopters, circulate therein a while, and at last condense into a liquor.

When the detonation is over, and the vapours condensed, or nearly so, drop into the retort another equal quantity of the mixture; and repeat this till you find there is liquor enough in the recipients to be examined with care and accuracy. This liquor is almost impid, and shews no tokens of acidity; or at most but very slight ones. It is called clyssus of nitre.

Nitre is also decomposed and takes fire by the means of sulphur; but the circumstances and the result differ widely from those produced therewith by charcoal or any other inflammable body.

Nitre deflagrates with sulphur on account of the phlogiston which the latter contains. If one part of sulphur be mixed with two or three parts of nitre, and the mixture thrown by little and little into a red-hot crucible,
upon every projection there arises a detonation accompa-
nied with a vivid flame.

The vapours discharged on this occasion have the
mingled smell of a sulphureous spirit and spirit of nitre;
and if they be collected by means of a tubulated retort,
and such an apparatus of vessels as was used in the pre-
ceding experiment, the liquor contained in the recipients
is found to be an actual mixture of the acid of sulphur,
the sulphureous spirit, and the acid of nitre; the first
being of greater quantity than the other two, and the sec-
ond greater than the first.

Nor is the remainder after detonation a fixed alkali,
as in the former experiments; but a neutral salt, consist-
ing of the acid of sulphur combined with the alkali of
nitre; a sort of vitriolated tartar, known in medicine by
the name of sal polychrescum.

To decompofe Nitre by means of the Vitriolic Acid.

The Smoking Spirit of Nitre. Sal de duobus.

Take equal parts of well purified nitre and green vi-
trio1: dry the nitre thoroughly, and bruife it to a fine
powder. Calcine the vitriol to redness: reduce it like-
wise to a very fine powder; and mingle these two sub-
stances well together. Put the mixture into an earthen
long neck, or a good glass retort coated, of such a fize
that it may be both half full.

Set this vessel in a reverberating furnace covered with
its dome; apply a large glass receiver, having a small
hole in its body, flopped with a little lute. Let this re-
cipient be accurately luted to the retort with the fat lute,
and the joint covered with a flip of canvas smeared with
lute made of quick-lime and the white of an egg. Heat
the vessels very gradually. The receiver will soon be
filled with very dense red vapours, and drops will begin
to distill from the nofe of the retort.

Continue the distillation, increafing the fire a little
when you observe the drops to follow each other but
slowly, fo that above two thirds of a minute paffes be-
tween them; and, in order to let out the redundant va-
pours, open the small hole in the receiver from time to
time. Towards the end of the operation raise the fire
fo as to make the retort red. When you find that, even
when the retort is red-hot, nothing more comes over,
unlace the receiver, and without delay pour the liquor
it contains into cryftal bottle, and clofe it with a cry-
ftal flopple rubbed in its neck with emery. This liquor
will be of a reddish yellow colour, smoking exceedingly,
and the bottle containing it will be constantly filled with
red fumes like thofe obferved in the receiver.

By the procefs here delivered, a very strong, perfectly
dephlegmated, and very fmoaking spirit of nitre is ob-
tained.

When the operation is over, you will find a red mafs
at the bottom of the retort, cafte as it were in a mould.
This is a neutral falt of the nature of vitriolated tartar,
resulting from the union of the acid of the vitriol with
the alkaline bases of the nitre.

The ferruginous bases of the vitriol, which is mixed
with this falt, gives it the red colour. To separate it
therefrom, you must pulverife it, difsolve it in boiling
water, and filter the folution feveral times through brown
paper; because the ferruginous earth of the vitriol is so
fine, that some of it will pass through the firft time.
When the folution is very clear, and deposites no fedi-
ment, let it be set to shoot, and it will yield cryftals of
vitriolated tartar; to which chemifts have given the pe-
culiar title of fal duobus.

Nitre may alfo be decompofed, and its acid obtained,
by the interpoftion of any of the other vitriols, alums,
gypsums, boles, clays; in fhort, by means of any com-
 pound in which the vitriolic acid is found, provided it
have not a fixed alkali for its basis.

The confumers of aqua fortis, who make large quan-
tities at a time, and who ufe the leaft chargeable methods,
do their bufinefs by the means of earths imregnated with
the vitriolic acid; fuch as clays and boles. With these
earth they accurately mix the nitre from which they in-
tend to draw their spirit; this mixture they put into large
oblong earthen pots, having a very fhort curved neck,
which enters a recipent of the fame matter and form.
These vessels they place in two rows oppofite to each o-
er in long furnaces, and cover them over with bricks
cemented with Windfor-loam, which ferves for a rever-
beratory: then they light the fire in the furnace, making
it at firft very small, only to warm the vessels; after
which they throw in wood, and raise the fire till the pots
grow quite red-hot, in which degree they keep it up till
the distillation is entirely finifhed.

Moft experiments require the spirit of nitre to be ab-
olutely pure; and if it be intended for such, it muft be
perfectly cleaned from the vitriolic taint.

This is eafily effected by mixing your spirit with very
pure nitre, and distilling it a second time. The vitriolic
acid, with which this spirit of nitre is adulterated,
coming in contact with a great quantity of undecomposed
nitre, unites with its alkaline bases, and expels a propor-
tionable quantity of the nitrous acid.

Of the Marine Acid.

To extract Sea-falt from Sea-water, and from Brine-
springs. Epfom Salt.

Filter the falt-water from which you intend to ex-
tract the falt; evaporate it by boiling, till you fee on its
surface a dark pellicle: this confists wholly of little cry-
ftals of falt juft beginning to shoot: now, facken the fire,
that the brine may evaporate more slowly, and without
any agitation. The cryftals, which at firft were very
small, will become larger, and form hollow truncated
pyramids, the apices whereof will point downwards, and
their bases be even with the surface of the liquor.

These pyramidal cryftals are only collections of small
cubical cryftals concreted into this form. When they
have acquired a certain magnitude they fall to the bottom
of the liquor. When they come to be in fuch heaps as
almost to reach the surface of the liquor, decant it from
them, and continue the evaporation till no more cryftals
of sea-falt will shoot.

The acid of sea-falt isScarce ever found either in sea-
water or in the earth, otherwife than united with a fixed
alkali.
alkali of a particular kind, which is its natural basis; and consequently it is in the form of a neutral salt. This salt is plentifully dissolved in the waters of the ocean, and when obtained therefrom bears the name of sea-salt. It is also found in the earth in salt crystalline masses, and is then called salt-gem; so that sea-salt and salt-gem are but one and the same sort of salt, differing very little from each other, except as to the places where they are found.

In the earth are also found springs and fountains, whose waters are strong brines, a great deal of sea-salt being dissolved in them. These springs either rise directly from the sea, or run through some mines of salt-gem, of which they take up a quantity in their passage.

As the name, or at least nearly the same quantity of sea-salt will continue dissolved in cold water as boiling water will take up, it cannot shoot, as nitre does, by the mere cooling of the water in which it is dissolved; it crystallizes only by the means of evaporation, which continually lessens the proportion of the water to the salt; so that it is always capable of containing just so much of the lefs sea-salt the more there is crystallized.

The brine should not boil after you perceive the pel-licle of little crystals beginning to form on its surface; for the caldrons of the liquor allows them to form more regularly, and become larger. Nor after this should the evaporation be hurried on too fast; for a saline crust would form on the liquor, which, by preventing the vapours from being carried off, would obstruct the crystallization.

If the evaporation be continued after the liquor ceases to yield any crystals of sea-salt, other crystals will be obtained of an oblong four-sided form, which have a bitter taste, and are almost always moist. This sort of salt is known by the name of Epsom salt, which it owes to a certain sort of a congeries of Glauber’s salt and sea-salt, in a manner confounded together, and mixed with some of the mother of sea-salt, in which it is contained a kind of bituminous matter. These two neutral salts, which constitute the Epsom salt, may be easily separated from each other, by means of crystallization only. Epsom salt is purgative and bitter; and therefore named salt catharticum amarum, or bitter purging salts.

There are different methods used in great works for obtaining sea-salt out of water in which it is dissolved. The simplest and easiest is that practiced in France, and in all those countries which are not colder. On the sea-shore they lay out a fort of broad shallow pits, pans, or rather pools, which the sea fills with the tide of flood. When the ponds are thus filled, they stop their communication with the sea, and leave the water to evaporate by the heat of the sun; by which means all the salt contained in it necessarily crystallizes. These pits are called salt ponds. Salt can be made in this way in the summer-time only, at least in France, and other countries of the same temperature; for during the winter, when the sun has lost power, and rains are frequent, this method is not practicable.

For this reason, as it often rains in the province of Normandy, the inhabitants take another way to extract salt from sea-water. The labourers employed for this purpose raise heaps of sand on the shore, so that the tide waters and drenches them when it flows, and leaves the sand dry when it ebbs. During the interval between two tides of flood the sun and the air easily carry off the moisure that was left, and so the sand remains impregnated with all the salt that was contained in the evaporated water. Thus they let it acquire as much salt as it can by several returns of flood, and then wash it out with fresh water, which they evaporate over a fire in leaden boilers.

To obtain the salt from brine-springs, the water need only be evaporated: but as several of these springs contain too little salt to pay the charges that would be incurred, if the evaporation were effected by the force of fire only, the manufacturers have fallen upon a less expensive method of getting rid of the greatest part of the water, and preparing the brine for crystallization, in much less time, and with much less fire, than would otherwise have been necessary.

The method consists in making the water fall from a certain height on a great many small spars of wood, which divide it into particles like rain. This is performed under shades open to all the winds, which pass freely through this artificial shower. By this means the water prevents to the air a great extent of surface, being indeed reduced almost entirely to surface, and the evaporation is carried on with great ease and expedition. The water is raised by pumps to the height from which it is intended to fall.

Experiments concerning the decomposition of Sea-salt, by means of the phlogiston. Kunckel’s Phosphorus.

“Of pure urine that has fermented five or six days, take a quantity in proportion to the quantity of phosphorus you intend to make: it requires about one third part of a hogstall to make a dram of phosphorus. Evaporate it in iron pans, till it becomes clotted, hard, black, and nearly like chimney soot; at which time it will be reduced to about a sixtieth part of its original weight before evaporation.

“When the urine is brought to this condition, put it in several portions into so many iron pots, under which you must keep a pretty brisk fire so as to make their bottoms red, and stir it incessantly till the volatile salt and the fetid oil be almost wholly diffipated, till the matter cease to emit any smoke, and till it smell like peacock blossoms. Then put out the fire, and pour on the matter, which will now be reduced to a powder, somewhat more than twice its weight of warm water. Stir it about in this water, and leave it to look therein for twenty-four hours. Pour off the water by inclination; dry the drenched matter, and pulverize it. The previous calculation carries off from the matter a third of its weight, and the lixiviation washes out half the remainder.

“With what remains thus calcined, washed, and dried, mix half its weight of gravel, or yellow freestone rasped, having lifted out and thrown away all the fine salt particles. River-land is not proper on this occasion, because it flies in a hot fire. Then add to this mixture...
mixtures a sixteenth part of its weight of charcoal, made of beech, or of any other wood except oak, because that also dies. Melt the whole with as much water as will bring it to a slurry paste, by working and kneading it with your hands. Now introduce it into your retort, taking care not to daub its neck. The retort must be of the bough earth, and of such a size, that when your matter is in it, a full third thereof shall still be empty.

"Place your retort, thus charged, in a reverberating furnace, so proportioned, that there may be an interval of two inches all round between the sides of the furnace and the bowl of the retort, where it contracts to form the neck, which should stand inclined at an angle of sixty degrees. Stop all the apertures of the furnace, except the doors of the fire-place and ash-hole.

"Put on to the retort a large glass balloon two thirds full of water, and lute them together, as in diffilling the smoking spirit of nitre. In the hinder part of this balloon, a little above the surface of the water, a small hole must be bored. This hole is to be stopped with a small peg of birch-wood, which must slip in and out very easily, and have a small knob to prevent its falling into the bowl. This peg is to be pulled out from time to time, that by applying the hand to the hole it may be known whether the air rarefied by the heat of the retort, issues out with too much or too little force.

"If the air rushes out with too much rapidity, and with a hissing noise, the door of the ash-hole must be entirely shut, in order to slacken the heat. If it do not strike pretty smartly against the hand, that door must be opened wider; and large coals thrown into the fire-place to quicken the fire immediately.

"The operation usually lasts four and twenty hours; and the following signs show that it will succeed, provided the retort rekindle the fire.

"You must begin the operation with putting some unlighted charcoal in the ash-hole, and a little lighted charcoal at the door thereof, in order to warm the retort very slowly. When the whole is kindled, pull it into the ash-hole, and close the door thereof with a tile. This moderate heat brings over the phlegm of the mixture. The same degree of heat must be kept up four hours, after which some coals may be laid on the grate of the fire-place, when the fire underneath will kindle by degrees. With this second heat brought nearer the retort, the balloon grows warm, and is filled with white vapours which have the smell of heated oil. In four hours after, this vessel will grow cool and clear; and then you must open the door of the ash-hole one inch, and row fresh coals into the fire-place every three minutes, and every time shut the door of it, lest the cold air from without should strike against the bottom of the retort and crack it.

"When the fire has been kept up to this degree for about two hours, the inside of the balloon begins to be netted over with a volatile salt of a singular nature, which cannot be driven up but by a very violent fire, and which smells pretty strong of peach-kernels. Care must be taken that this concrete salt do not push the little hole in the balloon; for in that case it would burst, the retort being then red-hot, and the air exceedingly rarefied. The water in the balloon, being heated by the vicinity of the furnace, exhalates vapours which dissolve this sprigged salt, and the balloon clears up in half an hour after it has ceased rising.

"In about three hours from the first appearance of this salt, the balloon is again filled with new vapours, which smell like sal ammoniac thrown upon burning coals. They condense on the sides of the receiver into a salt which is not branched like the former, but appears in long perpendicular streaks, which the vapours of the water do not dissolve. These white vapours are the fore-runners of the phosphenous; and a little before they cease to rise they lose their first smell of sal ammoniac, and acquire the odoar of garlic.

"As they ascend with great rapidity, the little hole must be frequently opened, to observe whether the hissing be not too strong; for in that case it would be necessary to shut the door of the ash-hole quite close. These white vapours continue two hours. When you find they cease rising, make a small passage through the dome, by opening some of its registers, that the flame may just begin to draw. Keep up the fire in this mean time till the first volatile phosphenous begin to appear.

"This appears in about three hours after the white vapours first begin to rise. In order to discover it, pull out the little birchen peg once every minute, and rub it against some hot part of the furnace, where it will leave a trail of light, if there be any phosphenous upon it.

"Soon after you observe this sign, there will issue out through the little hole of the balloon a stream of blue light, which continues of a greater or shorter extent to the end of the operation. This stream or spout of light does not burn. If you hold your finger against it for twenty or thirty seconds, the light will adhere to it; and if you rub that finger over your hand, the light will befmeer it, and render it luminous.

"But from time to time this streamer darts out to the length of seven or eight inches, snipping and emitting sparks of fire; and then it burns all combustible bodies that come in its way. When you observe this, you must manage the fire very warily, and shut the door of the ash-hole quite close, yet without ceasing to throw coals into the fire-place every two minutes.

"The volatile phosphenous continues two hours; after which the little spout of light contracts to the length of a line or two: And now is the time for pulling your fire to the utmost. Immediately set the door of the ash-hole wide open, throw billets of wood into it, unstop all the registers of the reverberatory, supply the fire-place with large coals every minute: In short, for six or seven hours all the inside of the furnace must be kept of a white heat, so that the retort shall not be diffingible.

"In this fierc extremity of heat the true phosphenous distills like an oil, or like melted wax: One part thereof floats on the water in the recipient, the other falls to the bottom. At last the operation is known to be quite over when the upper part of the balloon, in which the volatile phosphenous appears condensed in a blackish film, begins to grow red: For this shews that the phosphenous is burnt where the red spot appears. You must now stop all the registers, and shut all the doors of the furnace, in order to smother the fire; and then close up the little hole in
in the ballon with fat lute or bees-wax. In this condition the whole must be left for two days; because the vefsets must not be parted till they are perfectly cold, left the phosphorus should take fire.

"As soon as the fire is out, the ballon, which is then in the dark, prefents a molt agreeable object: All the empty part thereof above the water feems filled with a beautiful blue light; which continues for feven or eight hours, or as long as the ballon keeps warm, never dif-appearing till it is cooled.

"When the furnace is quite cold, take out the vefsets, and separate them from each other as neatly as poftible. With a linen cloth wipe away all the black ftuff appearing till it is cooled. When this water in which you have melted the phosphorus is cool enough, take out the phosphorus, throw it into cold water, and therein break it into little bits in order to mould it.

"Then take a matras, having a long neck somewhat wider next the body than at its mouth: Cut off half the body, fo as to make a funnel of the neck-part, the smaller end of which must be flopped with a cork. The firft mould being thus prepared, plunge it endwise, with its mouth uppermoft, in a vefsel full of boiling water, and fill it with that water. Into this funnel throw the little bits of your flate-like mafs, which will melt again in this hot water, and fall fo melted to the bottom of the tube. Stir this melted matter with an iron wire, to promote the separation of the phosphorus from the fuliginous matter with which it is fouled, and which, being les ponderous than the phosphorus, will gradually rife above it towards the upper part of the cylinder.

"Keep the water in the vefsel as hot as at firft, till on taking out the tube you fee the phosphorus clean and tranfparent. Let the clear tube cool a little, and then set it in cold water, where the phosphorus will congeal as it cools. When it is perfectly congealed, pull out the cork, and with a small rod near as big as the tube, pull the cylinder of phosphorus towards the mouth of the funnel, where the feculency lies. Cut off the black part of the cylinder, and keep it apart: For when you have got a quantity thereof, you may melt it over again in the fame manner, and separate the clean phosphorus which it still contains. As to the rest of the cylinder which is clean and tranfparent, if you intend to mould it into smaller cylinders, you may cut it in flices, and melt it again by the help of boiling water in glafs tubes of smaller dimensions."

It is proper to observe, in the firft place, that one of the molt ufual caufes of misfcarriage in this operation is a defect of the requisite qualities in the retort employed. It is absolutely necessary to have that vefsel made of the beft earth, and fo well made that it fhall be capable of refifting the utmost violence of fire, continued for a very long time.

We shall, in the second place, obferve with M. Hellot, that, before you set your retort in the furnace, it is proper to make an effay of your matter, to fee if there be reafon to hope for fuccefs. For this purpofe put about an ounce thereof into a small crucible, and heat it till the veffel be red. The mixture, after having smoked, ought to chop and crack without puffing up, or even rising in the leaf. From these cracks will iffue undulated flames, white and bluish, darting upwards with rapidity. This is the firft volatile phosphorus, which occasions all the danger of the operation. When these firft flashes are over, increafe the heat of your matter by laying a large live coal upon the crucible. You will then fee the second phosphorus, like a luminous, steady vapour, of a colour inclining to violet, covering the whole surface of the matter: It continues for a very long time, and diffuses a smell of garlick, which is the diftinguifhing odour of the phosphorus you are feeking.

"When this luminous vapour is entirely gone, pour the red-hot matter out of the crucible upon an iron plate. If you do not find one drop of falt in fufion, but that, on the contrary, the whole falls readily into powder, it is a proof that your matter was fufficiently lixiviated, and that it contains no more fixed falt, or fea-falt, if you will, than is requifite. If you find on the plate a drop of falt coagulated, it fhews that there is too much left in it, and that there is danger of your misfcarrying in the operation; because the redundant falt would corrode and eat through the retort. In this cafe your matter muft be washed again, and then sufficiently dried."

The furnace muft be fo conftrufted, that within a narrow compafs it may give a heat at leaft equal to that of a glafs-houfe furnace, or rather greater, efpecially during the laft feven or eight hours of the operation. M. Hellot, in his Memoir, gives an exact defcription of fuch a furnace.

"As certain accidents may happen in the course of the operation, fome precautions are to be taken againft them. For inftance, if the ballon fhould break while the phosphorus is diftilling, and any of it fhould fall on combufible bodies, it would set them on fire, and probably burn the laboratory, because it is not to be diftinguifhed without the greatest difficulty. The furnace muft therefore be erected under fome vault, or upon a bed of brick-work, raised under fome chimney that draws well: Nor muft any furniture or utenfils of wood be left near it. If a little flaming phosphorus fhould fall on a man's legs or hands, in lefs than three minutes it would burn its way to the very bone. In fuch a cafe nothing but urine will stop its progres."

"If the retort crack while the phosphorus is diftilling,
there is an unsuccessful end of your operation. It is easy
to perceive this by the flink of garlic which you will
smell about the furnace; and moreover, the flame that
issues through the apertures of the reverberatory will
be of a beautiful violet colour. The acid of sea-falt
always gives this colour to the flame of such matters
as are burnt along with it. But if the retort break be-
fore the phosphorus hath made its appearance, its con-
tents may be saved by throwing a number of cold bricks
into the fire-place, and upon them a little water to quench
the fire at once. All these useful observations we owe
also to M. Hellot.

The phosphorus here described was first discovered by
a citizen of Hamburg named Brandt, who worked upon
urine in search of the philosopher's stone. Afterwards
two other skilful chemists, who knew nothing more of
the process than that phosphorus was obtained from urine,
or in general from the human body, likewise endeavoured
to discover it; and each of them separately did actu-
ally make the discovery. These two chemists were
Kunckel and Boyle.

The former perfected the discovery, and found out a
method of making it in considerable quantities at a time;
which occasioned it to be called Kunckel's phosphorus.
The other, who was an English gentleman, had not time
to bring his discovery to perfection, and contented him-
self with lodging a voucher of his having discovered it in
the hands of the secretary of the Royal Society of
London, who gave him a certificate thereof.

"Though Brandt, who had before this fold his fecret
to a chemist named Krafft, sold it afterwards to sever-
al other persons, and even at a very low rate: and though
Mr Boyle published the proces for making it; yet it is
extremely probable that both of them kept in their own
hands the master-key; I mean, the particular manage-
ment necessary to make the operation succeed: For all
Kunckel found it out, no other chemist ever made any
considerable quantity thereof, except Mr Godfrey Han-
worth, an English chemist, to whom Mr Boyle revealed
the whole mystery.

"And thus it came to pass, that, after Kunckel and
Boyle died, M. Godfrey Hankwitz was the only chemi-
that could supply Europe therewith; on which account
it is likewise very well known by the name of English
phosphorus."

Almost all the chemists consider phosphorus as a sub-
fance consisting of the acid of sea-falt combined with
the phlogiston, in the same manner as sulphur consists of
the vitriolic acid combined with the phlogiston. This
opinion is founded on the following principles.

First, urine abounds with sea-falt, and contains also
a great deal of phlogiston: now these are the ingredients
of which they conjecture phosphorus to be composed.

Secondly, phosphorus has many of the properties of
sulphur; such as being soluble in oils; melting with a
gentle heat; being very combustible; burning without
any foot; giving a vivid and bluish flame; and lastly,
leaving an acid liquor when burnt: sensible proofs that
it differs from sulphur in nothing but the nature of its
acid.

Thirdly, this acid of phosphorus, being mixed with a
solution of silver in spirit of nitre, precipitates the silver;
and this precipitate is a true luna cornua, which appears
to be more volatile even than the common form. This
fact proves more incontestably that the acid of phospho-
rus is of the same nature with that of sea-falt.

Fourthly, M. Stahl observes, that if sea-falt be caff
on live coals, they instantly burn with great activity;
that they emit a vivid flame, and are much sooner con-
fumed than if none of this salt had touched them;
that sea-falt in substance, which will bear the violence of
fire a considerable time when fused in a crucible, without
suffering any sensible diminution, yet evaporates very
quickly, and is reduced to white flowers, by the im-
mediate contact of burning coals; and lastly, that the
flame which rises on this occasion is of a blue colour in-
clining to violet, especially if it be not thrown directly
on the coals themselves, but kept in fusion amidst burn-
ing coals, in a crucible so placed that the vapour of
the salt may join with the inflamed phlogiston as it rises from
the coals.

These experiments of Mr Stahl's prove, that the phlo-
giston acts upon the acid of sea-falt, even while it is com-
bined with its alkaline basis. The flame that appears on
this occasion may be considered as an imperfect phospho-
rus: and indeed its colour is exactly like that of phos-
phorus.

All the facts above related evince, that the acid of
phosphorus is akin to that of sea-falt; or rather, that it is
the very fame. But there are other facts which prove,
that this acid undergoes some change at leaft, some pecu-
lar preparation, before it enters into the composition
of a true phosphorus; and that, when extricated there-
from by burning, it is not a pure acid of sea-falt, but is
still adulterated with a mixture of some other sub stance,
which makes it considerably different from that acid.
For these observations we are obliged to M. Marggraf.

M. Marggraf hath also published a proces for mak-
ing phosphorus, and affures us, that by means thereof
we may obtain in less time, with less heat, less trouble,
and less expense, a greater quantity of phosphorus than
by any other method. His operation is this:

He takes two pounds of sal ammoniac in powder,
which he mixes accurately with four pounds of minium.
This mixture he puts into a glafs retort, and with a gra-
duated fire draws off a very sharp, volatile, urinous spirit.

We observed in Part I. that some metallic sub stance
have the property of decomposing sal ammoniac, and se-
parating its volatile alkali. Minium, which is a calx of
lead, is one of those metallic sub stances. In this expe-
riment it decomposes the sal ammoniac, and separates its
volatile alkali: what remains in the retort is a combi-
nation of the minium with the acid of sal ammoniac,
which is well known to be the fame with the marine acid;
and consequently the residue of this operation is a fort of
plumbum cornu m.

The quantity thereof is four pounds eight ounces.
Of this he mixes three pounds with nine or ten pounds of
urine, that has stood putrefying for two months, evapo-
rated to the consistence of honey. These he mixes
by
by little and little in an iron pan over the fire, stirring the mixture from time to time. Then he adds half a pound of charcoal dust, and evaporates the matter, kept continually stirring, till the whole be brought to a black powder. He next diffills the mixture in a glass retort with degrees of fire, which he raises towards the end so as to make the retort red-hot, in order to expel all the urinous spirit, superfluous oil, and ammoniacal falt. The distillation being finished, there remains nothing in the retort but a very friable caput mortuum.

This remainder he pulverizes again, and throws a pinch of it on live coals to discover whether or no the matter be rightly prepared for yielding phosphorus. If it be so, it presently emits an arfencal odour, and a blue undulating flame, which passes over the surface of the coals like a wave.

Being thus affured of the success of his operation, he puts one half of his matter, in three equal parts, into three small earthen German retorts, capable of holding about eighteen ounces of water a-piece. These three retorts, none of which is above three quarters full, he places together in one reverberatory furnace, built much like those we have described, except that it is so constructed as to hold the three retorts disposed in one line. To each retort he lutes a recipient something more than half full of water, ordering the whole in such a manner, that the nozes of his retorts almost touch the surface of the water.

He begins the distillation with warming the retorts slowly, for about an hour, by a gentle heat. When that time is elapsed he raises the fire gradually, so that in half an hour more the coals begin to touch the bottoms of the retorts. He continues throwing coals into the furnace by little and little, till they rise half way the height of the retorts; and in this he employs another half hour. Lastly, in the next half hour, he raises the coals above the bowels of the retorts.

Then the phosphorus begins to ascend in clouds: on this he instantly increases the heat of the fire as much as possible, filling the surface quite up with coals, and making the retorts very red. In this degree of fire causes the phosphorus to diffill in drops which fall to the bottom of the water. He keeps up this intense heat for an hour and half, at the end of which the operation is finished; so that it lasts but four hours and a half in all: In the same manner he distills the second moiety of his mixture in three other such retorts.

He purifies and moulds his phosphorus much in the same manner as M. Hellot does. From the quantity of ingredients above-mentioned, he obtains two ounces and a half fine cryftalline moulded phosphorus.

The acid of phosphorus seems to be more fixed than any other: and therefore if you would separate it by burning from the phlogiston with which it is united, there is no occasion for such an apparatus of vessels as is employed for obtaining the spirit of sulphur. For this acid will remain at the bottom of the vessel in which you burn your phosphorus; indeed, if it be urged by the force of fire, its most subtile part evaporates, and the remainder appears in the form of a vitrified matter.

This acid effervesces with fixed and volatile alkalies, and therewith forms neutral falt; but very different from sea-falt, and from falt ammoniac. That which has a fixed alkali for its basis does not crackle when thrown on burning coals; but swells and vitrifies like borax. That which has a volatile alkali for its basis shoots into long pointed cryftals; and, being urged by fire in a retort, lets go its volatile alkali, a vitrified matter remaining behind.

We shall conclude this article with an account of certain properties of phosphorus which have not yet been mentioned.

Phosphorus diffolves by lying exposed to the air. What water cannot effect, says M. Hellot, or at least requires eight or ten years to bring about, the moiure of the air conquers in ten or twelve days; whether it be that the phosphorus takes fire in the air, and the inflammable part evaporating, almost entirely, leaves the acid of the phosphorus naked, which like all other acids, when exceedingly concentrated, is very greedy of moisture; or else that the moisture of the air, being water divided into infinitely fine particles, is so subtile as to find its way through the pores of the phosphorus, into which the greater particles of common water can by no means infinuate themselves.

Phosphorus heated by the vicinity of fire, or by being in any way rubbed, soon takes fire and burns fiercely. It is fusible in all oils, and in ether, giving to those liquors the property of appearing luminous, when the bottle containing the solution is opened. Being boiled in water, it likewise communicates thereto this luminous quality.

The late Mr Groffe observed, that phosphorus being dissolved in effential oils cryftallizes therein. Thes cryfitals take fire in the air, either when thrown into a dry vefsel, or wartp up in a piece of paper. If they be dipped in spirit of wine, and taken out immediately, they do not afterwards take fire in the air; they smoke a little, and for a very short time, but hardly waite at all. Though some of them were left in a fpoon for a fortnight, they did not seem to have lost any thing of their bulk: but when the fpoon was warmed a little they took fire, just like common phosphorus that had never been dissolved and cryftallized in an effential oil.

M. Marggraff, having put a dram of phosphorus with an ounce of highly concentrated spirit of nitre into a glass retort, obferved, that, without the help of fire, the acid dissolved the phosphorus; that part of the acid came over into the recipient which was luted to the retort; that at the fame time the phosphorus took fire, burnt furiously, and burst the vefsels with explosion. Nothing of this kind happens when any of the other acids, though concentrated, are applied to phosphorus.

To decompose Sea falt by means of the Vitriolic Acid.

Glauber's Salt. The Purification and Concentration of Spirit of Salt.

Put the sea-falt from which you mean to extract the acid into an unglazed earthen pipkin, and let it amidt live coals. The falt will decrepitate, grow dry, and fall into a powder. Put this decrepitated falt into a tubulated glass retort, leaving two thirds thereof empty. Set the retort in a reverberating furnace; apply a receiver
cever like that used in distilling the smoking spirit of nitre, and lute it on in the same manner, or rather more exactly if possible. Then through the hole in the upper convexity of the retort pour a quantity of highly concentrated oil of vitriol, equal in weight to about a third part of your salt, and immediately shut the hole very close with a glass stopple, first rubbed therein with emery so as to fit it exactly.

As soon as the oil of vitriol touches the salt, the retort and receiver will be filled with abundance of white vapours; and soon after, without lighting any fire in the furnace, drops of a yellow liquor will diffill from the nose of the retort. Let the distillation proceed in this manner without fire, as long as you perceive any drops come; afterwards kindle a very small fire under the retort, and continue distilling and raising the fire by very slow degrees, and with great caution, to the end of the distillation; which will be finisht before you have occasion to make the retort red-hot. Unlute the vessels, and without delay pour the liquor, which is a very smoking spirit of salt, out of the receiver into a crystall bottle, like that directed for the smoking spirit of nitre.

When the operation is finished, we find a white, saline mass at the bottom of the retort as in a mould. If this mass be dissolved in water, and the solution crystallized, it yields a considerable quantity of sea-salt that hath not been decomposed, and a neutral salt consisting of the vitriolic acid united with the alkaline basis of that part which hath been decomposed. This neutral salt, which bears the name of Glauber its inventor, differs from the same, the differences that appear between them must be attributed to the peculiar nature of the basis of sea-salt.

The nitrous acid hath a greater affinity than the marine acid with fixed alkalis. When therefore spirit of nitre and sea-salt are mixed together, the same consequences will follow as when the vitriolic acid is mixed with that salt; that is, the nitrous acid will, like the vitriolic, decompose it, by dissolving its acid from its alkaline basis, and affuming its place. But as the nitrous acid is considerably weaker, and much lighter, than the vitriolic acid, a good deal of it rises along with the acid of sea-salt during the operation. The liquor found in the receiver is therefore a true aqua regis.

If decrepitated salt, and a right smoking spirit of nitre, be employed in this process, the aqua regis obtained will be very strong.

The operation being finished, there is left in the retort a saline mass, containing sea-salt not decomposed, and a new species of nitre, which having for its basis the alkal of sea-salt, that is, an alkali of a peculiar nature, differs from the common nitre. 1. In the figure of its crystals; which are solids of four sides, formed like lozenges; 2. In that it crystallizes with more difficulty, retains more water in its crystals, attracts the moisture of the air, and diffolves in water with the same circumstances as sea-salt.

Of Borax.

To decompose Borax by the means of Acids, and to separate from it the Sedative Salt by Sublimation and by Crystalization.

Reduce to a fine powder the borax from which you intend to extract the sedative salt. Put this powder into a wide-necked glass retort. Pour upon it an eighth part of its weight of common water, to moisten the powder; and then add concentrated oil of vitriol, to the weight of somewhat more than a fourth part of the weight of the borax. Set the retort in a reverberatory, make a moderate fire at first, and augment it gradually till the retort become red-hot.

A little phlegm will first come over, and then, with the least moisture that the heat expels, the sedative salt will rife; by which means some of it will be dissolved in this first phlegm, and passes therewith into the receiver; but most of it will adhere in the form of saline flowers to the fore-part of the neck of the retort, just where it is clear of the groove of the furnace. There they collect into a heap, which the succeeding flowers push insensibly forward till they slightly stop the passage. Those which rise after the neck is thus stopped flick to the after part of it which is hot, vitrify in some measure, and form a circle of fuscd salt. In this case the flowers of the sedative salt seem to issue out of the circle, as from their bases: They appear like very thin, light, shining scales, and must be brushed off with a feather.

At the bottom of the retort will be left a saline mass: Dissolve this in a sufficiency quantity of hot water; filter the solution, in order to free it from a brown earth which it deposits; let the liquor to evaporate, and crystals of sedative salt will form in it.

Though borax is of great use in many chemical operations, especially in the fussion of metals, as we shall have
have occasion to see, yet, till of late years, chemists were quite ignorant of its nature, as they still are of its origin; concerning which we know nothing with certainty, but that it comes rough from the East Indies, and is purified by the Dutch.

Of Operations on Metals.

Of Gold.

To separate Gold, by Amalgamation with Mercury, from the Earths and Stones with which it is found mixed.

Pulverize the earths and stones containing gold. Put the powder into a little wooden tray; dip this tray in water, gently shaking it and its contents. The water will grow muddy, by taking up the earthy parts of the ore. Continue washing it in this manner till the water cease to appear turbid. Upon the ore thus washed pour strong vinegar, having first dissolved therein, by the help of heat, about a tenth part of its weight of alum. The powder must be quite drenched and covered with this liquor, and so left to stand for twice twenty-four hours.

Decant the vinegar, and wash your powder with warm water, till the last that comes off hath no taste; then dry it, and put it into an iron mortar, with four times its weight of quick-silver; triturate the whole with a heavy wooden pestle, till all the powder be of a blackish colour: then pour in a little water, and continue rubbing for some time longer. More earthy and heterogeneous particles will be separated from the metallic parts by means of this water, which will look dirty; it must then be decanted, and more fair water added. Repeat this several times; then dry what remains in the mortar with a sponge, and by the help of a gentle heat; you will find it an amalgam of the mercury with the gold.

Put this amalgam into a chamoy bag: tie a knot on its neck, and squeeze it hard between your fingers, over some wide-mouthed vessel; there will issue through the pores of the leather numberless little jets of mercury, forming a sort of shower, that will collect into large globules in the vessel placed underneath. When you can force out no more mercury by this means, open the bag, and in it you will find the amalgam freed from the superfluous mercury; the gold retaining only about as much thereof as nearly equals itself in weight.

Put this amalgam into a glass retort; set this retort in the sand-bath of a reverberating furnace; cover it quite over with sand; apply a glass receiver half full of water, so that the nofe of the retort may be under the water. The receiver need not be fixed to the retort. Give a gradual heat, and raise the fire till drops of the sublimed mercury appear in the neck of the retort, and fall into the water with a hissing noise. If you hear any noise in the retort, slacken your fire a little. Lastly, when you observe, that, though you raise the fire still higher than before, nothing more will come over, take out your retort, break it, and there you will find the gold, which must be melted in a crucible with borax.

To dissolve Gold in Aqua regis, and by that means to separate it from Silver.

Take gold that is perfectly pure, or alloyed with silver only. Reduce it to little thin plates, by hammering it on an anvil. If it be not sufficiently tough, neal it till it be red in a moderate, close fire, quite free from smoking coals, and then let it cool gradually, which will restore its ductility.

When the plates are thin enough, make them red-hot once more, and cut them into small bits with a pair of sheers. Put these bits into a tall, narrow-mouthed cucurbit, and pour on them twice their weight of good aqua regis, made of one part sal-ammoniac, or spirit of salt, and four parts spirit of nitre. Set the cucurbit in a sand-bath moderately heated, slopping its orifice slightly with a paper coffin, to prevent any dirt from falling in. The aqua regis will presently begin to smoke. Round the little bits of gold will be formed an infinite number of small bubbles, which will rise to the surface of the liquor. The gold will totally dissolve, if it be pure, and the solution will be of a beautiful yellow colour: if the gold be alloyed with a small quantity of silver, the latter will remain at the bottom of the vessel in the form of a white powder. If the gold be alloyed with much silver, when the gold is dissolved the silver will retain the form of the little metalline plates put into the vessel.

When the dissolution is completed, gently pour off the liquor into another low, wide-mouthed, glass cucurbit, taking care that none of the silver, which lies at the bottom in the form of a powder escape with the liquor. On this powder of silver pour as much fresh aqua regis as will cover it entirely; and repeat this till you are sure that nothing more can be taken up by it. Lastly, having decanted the aqua regis from the silver, wash the silver with a little spirit of salt weakened with water, and add this spirit of salt to the aqua regis in which your gold is dissolved. Then to the body containing these liquors fit a head and a receiver, and distill with a gentle heat, till the matter contained in the cucurbit becomes dry.

Mix together equal parts of common brimstone, and a very strong fixed alkali; for instance, nitre fixed by charcoal. Put them in a crucible, and melt the mixture, stirring it from time to time with a small rod. There is no occasion to make the fire very brisk, because the sulphur facilitates the fusion of the fixed alkali. Some sulphureous vapours will rise from the crucible: these two substances will mix intimately together, and form a reddish compound. Then throw into the crucible some little pieces of gold beaten into thin plates, so that the whole do not exceed in weight one third part of the liver of sulphur: raise the fire a little. As soon as the liver of sulphur is perfectly melted, it begins to dissolve the gold with ebullition; and will even emit some flashes of fire. In the space of a few minutes the gold will be entirely dissolved, especially if it was cut and flattened into small thin leaves.

The process here delivered is taken from M. Stahl. The design of his inquiries was to discover how Moses could burn the golden calf, which the Israelites had set up and worshipped while he was on the mount; how he could afterwards reduce that calf to powder, throw it into the water which the people used, and make all who had apostatized drink thereof, as related in the book of Exodus.
Exodus; and he concludes, that Moses must have performed this operation by means of liver of sulphur.

To separate Gold from all other metallic Substances by means of Antimony.

Having put the gold you intend to purify into a crucible, set it in a melting furnace, cover it, and make the gold flow. When the metal is in fusion, cast upon it, by a little at a time, twice its weight of pure crude antimony in powder, and after each projection cover the crucible again immediately; this done keep the matter in fusion for a few minutes. When you perceive that the metallic mixture is perfectly melted, and that its surface begins to sparkle, pour it out into a hollow iron cone, previously heated, and smeared on the inside with tallow. Immediately strike with a hammer the floor on which the cone stands; and when all is cold, or at least sufficiently fixed, invert the cone and strike it; the whole metallic mass will fall out, and the under part thereof, which was at the point of the cone, will be a regulus more or less yellow as the gold was more or less pure. On striking the metallic masts, the regulus will freely part from the sulphureous crust at top.

Return this regulus into the crucible, and melt it. Less fire will do now than was required before. Add the same quantity of antimony, and proceed as at first. Repeat the same operation a third time, if your gold be very impure.

Then put your regulus into a good crucible, much larger than is necessary to hold it. Set your crucible in a melting furnace, and heat the matter but just enough to make it flow, with a smooth, brilliant surface. When you find it thus conditioned, point towards it the nose of a long-nosed pair of bellows, and therewith keep gently and constantly blowing. There will arise from the crucible a considerable smoke, which will abate greatly when you cease to blow, and increase as soon as you begin again. You must raise the fire gradually as you approach towards the end of the operation. If the surface of the metal lose its brilliant polish, and seem covered with a hard crust, it is a sign the fire is too weak; in which case it must be increased, till the surface recover its shining appearance. At last, when no more smoke rises, and the surface of the gold looks neat and greenish, cast on it, by little and little, some pulverized nitre, or a mixture of nitre and borax. The matter will swell up. Continue thus adding more nitre gradually, till no commotion is thereby produced in the crucible; and then let the whole cool. If you find, when the gold is cold, that it is not tough enough, melt it over again; when it begins to melt cast it in the same salt as before; and repeat this till it be perfectly ductile.

To separate Silver from its Ore, by means of Scoriification with Lead.

Beat to powder in an iron mortar the ore from which you mean to separate the silver, having first roasted it well in order to free it from all the sulphur and arsenic that it may contain. Weigh it exactly; then weigh out by itself eight times as much granulated lead. Put one half of this lead into a tafli, and spread it equally thereon; upon this lead lay your ore, and cover it quite over with the remaining half of the lead.

Place the tafli thus loaded under the further end of the muffle in a cupelling furnace. Light your fire, and increase it by degrees. If you look through one of the apertures in the door of the furnace, you will perceive the ore, covered with calcined lead, swim upon the melted lead. Presently afterwards it will grow soft, melt, and be thrown towards the sides of the vessel, the surface of the lead appearing in the middle thereof bright and shining like a luminous disc; the lead will then begin to boil, and emit fumes. As soon as this happens, the fire must be a little checked, so that the ebullition of the lead may almost entirely cease for about a quarter of an hour. After this it must be excited to the degree it was at before, so that the lead may begin again to boil and smoke. Its shining surface will gradually lessen, and be covered with scoria. Stir the whole with an iron hook, and draw in towards the middle what you observe towards the sides of the vessel; to the end that, if any part of the ore should still remain undissolved by the lead, it may be mixed therewith.

When you perceive that the matter is in perfect fusion, that the greatest part of what sticks to the iron hook, when you dip it in the melted matter, separates from it again, and drops back into the vessel; and that the extremity of this instrument, when grown cold, appears varnished over with a thin, smooth, shining crust; you may look on these as marks that the business is done; and the more uniform and evenly the colour of the crust is, the more perfect may you judge the scoriification to be.

Matters being brought to this pass, take the tafli with a pair of tongs from under the muffle, and pour its whole contents into an iron cone, first heated and greased with tallow. This whole operation lasts about three quarters of an hour. When all is cold, the blow of a hammer will part the regulus from the scoria; and as it is not possible, how perfect soever the scoriification be, to avoid leaving a little lead containing silver in the scoria, it is proper to pulverize this scoria, and separate therefrom whatever extends under the hammer, in order to add it to the regulus.

The refining of Silver by the Cupel.

Take a cupel capable of containing one third more matter than you have to put into it: set it under the muffle of a furnace like that described in our theoretical elements, as peculiarly appropriated to this sort of operation. Fill the furnace with charcoal; light it; make the cupel red-hot, and keep it so till all its moisture be evaporated; that is, for about a good quarter of an hour. If the cupel be made wholly of the ashes of burnt bones; and for a whole hour, if there be any wafheh wood-ash in its composition.

Reduce the regulus which remained after the preceding operation to little thin plates, flitting them with a small hammer, and separating them carefully from all the adherent scoria. Wrap these in a bit of paper, and with a small pair of tongs put them gently into the cupel.

When the paper is consumed, the regulus will soon melt, and
and the scoria, which will be gradually produced by the lead as it turns to litharge, will be driven to the sides of the cupel, and immediately absorbed thereby. At the same time the cupel will assume a yellow, brown, or blackish colour, according to the quantity and nature of the scoria imbibed by it.

When you see the matter in the cupel in a violent ebullition, and emitting much smoke, lower the fire by the methods formerly preferred. Keep up such a degree of heat only that the smoke which ascends from the matter may not rise very high, and that you may be able to distinguish the colour which the cupel acquires from the scoria.

Increase the fire by degrees, as more and more litharge is formed and absorbed. If the regulus examined by this assay contain no silver, you will see it turn wholly into scoria, and at last disappear. When it contains silver, and the quantity of lead is much diminished, you will perceive little vivid irises, or beautiful rain-bow colours, shooting swiftly along its surface, and crossing each other in many different directions. At last, when all the lead is destroyed, the thin dark skin, that is continually protruded by the lead while it is turning into litharge, and which hitherto covered the silver, suddenly disappears; and, if at this moment the fire happen not to be strong enough to keep the silver in fusion, the surface of that metal will at once dart out a dazzling splendor; but, if the fire be strong enough to keep the silver in fusion, though freed from all mixture of lead, this change of colour, which is called its fulguration, will not be so perceptible, and the silver will appear like a bead of fire.

These phenomena show that the operation is finished. But the cupel must still be left a minute or two under the muffle, and then drawn slowly out with the iron hook towards the door of the furnace. When the silver is so cooled as to be but moderately red, you may take the cupel from under the muffle with your little tongs, and in the middle of its cavity you will find an exceeding white bead of silver, the lower part whereof will be unequal, and full of little pits.

To purify Silver by Nitre.

Granulate the silver you intend to purify, or reduce it to thin plates; put it into a good crucible; add thereto a fourth part in weight of very dry pulverized nitre, mixed with half the weight of the nitre of calcined wine-les, and about a sixth part of the same weight of common glass in powder. Cover this crucible with another crucible inverted; which must be of such a size that its mouth may enter a little way into that of the lower one, and have its bottom pierced with a hole of about two lines in diameter. Lute the two crucibles together with clay and Windfor-loam. When the lute is dry, place the crucibles in a melting furnace. Fill the furnace with charcoal, taking care however that they do not rise above the upper crucible.

Kindle the fire, and make your vessels of a middling red heat. When they are so, take up with the tongs a live coal, and hold it over the hole of the upper crucible. If you immediately perceive a vivid splendor round the coal, and at the same time hear a gentle hissing noise, it is a sign that the fire is of a proper strength; and it must be kept up at the same degree till this phenomenon cease.

Then increase the fire to the degree requisite to keep pure silver in fusion; and immediately take your vessels out of the furnace. You will find the silver at the bottom of the lower crucible covered with a mass of alkaline scoria of a greenish colour. If the metal be not rendered perfectly pure and ductile by this operation, it must be repeated a second time.

To dissolve Silver in Aqua Fortis, and thereby separate it from every other metallic Substance.

The silver you intend to dissolve being beaten into thin plates, put it into a glass cucurbit; pour on it twice its weight of good precipitated aqua fortis; cover the cucurbit with a paper, and set it on a sand-bath moderately heated. The aqua fortis will begin to dissolve the silver as soon as it comes to be a little warm. Red vapours will rise; and from the upper surfaces of the silver there will seem to issue streams of little bubbles, ascending to the top of the liquor, between which and the silver they will form, as it were, a number of fine chains: This is a sign that the dissolution proceeds duly, and that the degree of heat is such as it ought to be. If the liquor appear to boil and be agitated, a great many red vapours rising at the same time, it is a sign that the heat is too great, and should be lessened till it be reduced to the proper degree indicated above: having obtained that, keep it equally up till no more bubbles or red vapours appear.

If your silver be alloyed with gold, the gold will be found, when the dissolution is finished, at the bottom of the vessel in the form of a powder. The solution must now be decanted while it is yet warm: on the powder pour half as much fresh aqua fortis as before, and make it boil; again decant this second aqua fortis, and repeat the same a third time; then with fair water wash the remaining powder well: It will be of a brown colour inclining to red.

To separate Silver from the Nitrous Acid by Distillation. Crystals of Silver. The Infernal Stone.

Into a large, low, glass body, put the solution of silver from which you intended to separate the silver by distillation. To this body fit a tubulated head provided with its stopple. Set this alembic in a sand bath, so that the body may be almost covered with sand: apply a receiver, and distill with a moderate heat, so that the drops may succeed each other at the distance of some seconds. If the receiver grow very hot, check the fire. When red vapours begin to appear, pour into the alembic, through the hole in its head, a fresh quantity of your solution of silver, first made very hot. Continue distilling in this manner, and repeating the addition of fresh liquor, till all your solution be put into the alembic. When you have no more fresh solution to put in, and when, the phlegm being all come over, red vapours begin again to appear, convey into the alembic half a dram or a dram of tallow, and distill to drink it; which being.
being done, increase your fire so as to make the velliel containing the sand-bath red-hot. In the alembic you will find a cake of silver, which must be melted in a crucible with some soap and calcined wine-lees.

If the distillation be stopped when part of the phlegm is drawn off, and the liquor be then suffered to cool, many crystals will shoot therein, which are a neutral salt constituted of the nitrous acid and silver. If the distillation be carried further, and stopped when near its conclusion, the liquor being then suffered to cool will wholly coagulate into a blackish mass called the infernal stone.

To separate Silver from the nitrous Acid by Precipitation. Luna Cornea. Luna Cornea reduced.

Into your solution of silver pour about a fourth part in weight of spirit of salt, solution of sea-salt, or solution of sulphur amoniacal. The liquor will instantly become turbid and milky. Add twice or thrice its weight of fair water, and let it stand some hours to settle. It will deposit a white powder. Decant the clear liquor, and on the precipitate pour fresh aqua fortis, or spirit of salt, and warm the whole on a sand bath with a gentle heat for some time. Pour off this second liquor, and boil your precipitate in pure water, shifting it several times, till the precipitate and the water be both quite insipid. Filter the whole, and dry the precipitate, which will be a luna cornea, and must be reduced in the following manner.

Smear the inside of a good crucible well with soap. Put your luna cornea into it; cover it with half its weight of white of tartar, thoroughly dried and pulverized; press the whole hard down; pour thereon as much oil, or melted tallow, as the powder is capable of imbibing; set the crucible when it is cold, and separate the cement from your plates of gold. Boil the gold repeatedly till the face of the copper become bright and shining, from which you may separate the regulus, of a bright yellow colour, and semi-malleable; and over it a scoria of a yellowish brown colour, hard, and shining, from which you may separate the regulus with a hammer.

To dissolve Silver, and separate it from Gold, by Cementation.

Mix thoroughly together fine brick-dust four parts, vitriol calcined to redness one part, and sea-salt or nitre one part. Moisten this powder with a little water. With this cement cover the bottom of a crucible half an inch thick; on this first bed lay a thin plate of the mafs of gold and silver you intend to cement, and which you must previously take care to beat into such thin plates. Cover this plate with a second layer of cement, of the same thickness as the former; on this second bed lay another plate of your metal; cover it in like manner with cement; and so proceed till the crucible be filled to within half an inch of its brim. Fill up the remaining space with cement, and close the crucible with a cover, luted with a paste made of Windsor-loam and water: Set your crucible thus charged in a furnace, whose fire-place is deep enough to let it be entirely surrounded with coals, quite up to its mouth. Light some coals in the furnace, taking care not to make the fire very brisk at first; increase it by degrees, but only so far as to make the crucible moderately red; keep up the fire in this degree for eighteen or twenty hours: Then let the fire go out; open the crucible when it is cold, and separate the cement from your plates of gold. Boil the gold repeatedly in fair water, till the water come off quite insipid.

Of Copper.

To separate Copper from its Ore.

Beat your copper ore to a fine powder, having first freed it as accurately as possible, by washing and roasting, from all stony, earthy, sulphureous, and arfencial parts. Mix your ore thus pulverized with thrice its weight of the black flux; put the mixture into a crucible; cover it with common salt to the thickness of half an inch, and press the whole down with your finger. With all this the crucible must be but half full. Set it in a melting furnace; kindle the fire by degrees, and raise it insensibly till you hear the sea-salt crackle. When the decrption is over, make the crucible red-hot for half a quarter of an hour. Then give a considerable degree of heat, exciting the fire with a pair of good perpetual bellows, so that the crucible may become very red-hot, and be perfectly ignited. Keep the fire up to this degree for about a quarter of an hour; then take out the crucible, and with a hammer strike a few blows on the floor on which you set it. Break it when cold. If the operation hath been rightly and successfully performed, you will find at the bottom of the velliel a hard regulus, of a bright yellow colour, and semi-malleable; and over it a scoria of a yellowish brown colour, hard, and shining, from which you may separate the regulus with a hammer.

To purify black Copper, and render it malleable.

Break into small bits the black copper you intend to purify; mix therewith a third part in weight of granulated lead, and put the whole into a cupel fet under the muffle in a cupelling furnace, and previously heated quite red. As soon as the metals are in the cupel raise the fire considerably, making use, if it be needful, of a pair of perpetual bellows, to melt the copper speedily. When it is thoroughly melted, lower the fire a little, and continue it just high enough to keep the metalline mafs in perfect fusion. The melted matter will then boil, and throw up some scoria, which will be absorbed by the cupel.

When most of the lead is consumed, raise the fire again till the face of the copper become bright and shining, thereby shewing that all its alloy is separated. As soon as your copper comes to this state, cover it with charcoal dust conveyed into the cupel with an iron laddle: Then take the cupel out of the furnace, and let it cool.

To deprive Copper of its Phlogiston by Calcination.

Put your copper in filings into a test, and set it under the muffle of a cupelling furnace; light the fire, and keep up such a degree of heat as may make the whole quite
To refusitate the Cals of Copper, and reduce it to Copper, by restoring its Phlogiston.

Mix the calx of copper with thrice as much of the black flux; put the mixture into a good crucible, so as to fill two thirds thereof, and over it put a layer of sea-felt a finger thick. Cover the crucible, and set it in a melting furnace; heat it gradually, and keep it moderately red till the decrepitation of the sea-falt be over. Then raise the fire considerably by means of a good pair of perpetual bellows; satisfy yourself that the matter is in perfect fusion, by dipping into the crucible an iron wire; continue the fire in this degree for half a quarter of an hour. When the crucible is cold, you will find at its bottom a button of very fine copper, which will easily separate from the saline scoria at top.

To dissolve Copper in the Mineral Acids.

On a sand-bath, in a very gentle heat, set a matras containing some copper filings; pour on them twice their weight of oil of vitriol. That acid will presently attack the copper. Vapours will rise, and issue out of the neck of the matras. A vast number of bubbles will ascend from the surface of the metal to the top of the liquor, and the liquor will acquire a beautiful blue colour. When the copper is dissolved, put in a little and a little more, till you perceive the acid no longer acts upon it. Then decant the liquor, and let it stand quiet in a cool place. In a short time great numbers of beautiful blue crystals will float in it. These crystals are called vitriol of copper, or blue vitriol. They dissolve easily in water.

Of Iron.

To separate Iron from its Ore.

Pound into a coarse powder the martial stones or earths out of which you design to extract the iron: Roast this powder in a tell under the muffle for some minutes, and let your fire be brisk. Then let it cool, beat it very fine, and roast it a second time, keeping it under the muffle till it emit no more smell.

Then mix with this powder a flux composed of three parts of nitre fixed with tartar, one part of fulphur glafs, and half a part of borax and charcoal-duft. The dose of this reducing flux must be thrice the weight of the ore.

Put this mixture into a good crucible; cover it with about half a finger thick of sea-falt; over the crucible put its cover, and lute it on with Windsor-loam made into a paste with water. Having thus prepared your crucible, set it in a melting furnace, which you must fill up with charcoal. Light the fire, and let it kindle by gentle degrees, till the crucible become red-hot. When the decrepitation of the sea-falt is over, raise your fire to the highest by the blast of a pair of perpetual bellows, or rather several. Keep up this intense degree of heat for three quarters of an hour, or a whole hour, taking care that during all this time the furnace be kept constantly filling up with fresh coals as the former consume. Then take your crucible out of the furnace; strike the pavement on which you set it several times with a hammer, and let it stand to cool: Break it, and you will find therein a regulus of iron covered with flag.

In smelting-houses iron ore is suffed amidst charcoal, the phlogiston of which combines with the martial earth, and gives it the metallic form. The iron thus melted runs down to the bottom of the furnace, from whence it is let out into large moulds, in which it takes the shape of oblong blocks, called pigs of iron. This iron is still very impure, and quite unmalleable. Its want of ductility after the first melting arises partly from hence, that notwithstanding the previous roasting which the ore underwent, there still remains, after this first fusion, a considerable quantity of sulphur or arsenic combined with the metal.

A certain quantity of quick-lime, or of stones that will burn to lime, is frequently mixed with iron ore on putting it into the smelting furnace. The lime being an absorbent earth, very apt to unite with sulphur and arsenic, is of use to separate those minerals from the iron.

It is also of use to mix some such matters with the ore, when the stones or earths which naturally accompany it are very fusible; for, as the iron is of difficult fusion, it may happen that the earthy matters mixed with the iron shall melt as easily as the metal, or perhaps more easily. In such a case there is no separation of the earthy from the metallic part, both of which melt and precipitate together promiscuously: Now quick-lime, being extremely refractory, serves on this occasion to check the melting of those matters which are too fusible.

Yet quick-lime, notwithstanding its refractory quality, may sometimes be of use as a flux for iron: This is the case when the ore happens to be combined with substrances which, being united with lime, render it fusible: Such are all arseneal matters, and even some earthy matters, which, being combined with quick-lime, make a fusible compound.

When the ore of an iron mine is found difficult to reduce, it is usually neglected even though it be rich; because iron being very common, people choose to work those mines only whose ores are smelted with the most ease, and require the least consumption of wood.

Yet refractory ores are not to be altogether rejected, when another iron ore of a different quality is found near them. For it often happens, that two several iron ores, which being worked separately are very difficult to manage, and yield at last but bad iron, become very tractable, and yield excellent iron, when smelted together: And accordingly such mixtures are often made at iron-works.

The iron obtained from ores by the first fusion may be divided into two sorts. The one, when cold, refists the hammer, doth not easily break, and is in some measure extensible on the anvil; but if struck with a hammer, when red-hot, flies into many pieces: This sort of iron hath
always a mixture of sulphur in it. The other sort, on the contrary, is brittle when cold, but somewhat ductile when red-hot. This iron is not sulphurated, is naturally of a good quality, and its brittleness arises from its metallic parts not being sufficiently compacted together.

Iron abounds so much, and is so universally diffused through the earth, that it is difficult to find a body in which there is none at all: And this hath led several chemists into the error of thinking, that they had transmuted iron several sorts of earths in which they suspected no iron, by combining them with an inflammable matter; whereas, in fact, all they did was to give the metallic form to a true martial earth which happened to be mixed with other earths.

To render Pig-iron and brittle Iron malleable.

Into an earthen vessel widening upwards, put some charcoal-dust, and thereon lay the pig-iron which you propose to render ductile; cover it all over with a quantity of charcoal; excite the fire violently with a pair, or more, of perpetual bellows till the iron melt. If it do not readily flow and form a great deal of flag on its surface, add some flux, such as a very fusible sand.

When the matter is in fusion, keep stirring it from time to time, that all the parts thereof may be equally acted on by the air and the fire. On the surface of the melted iron foam will be formed, which must be taken off as they appear. At the same time you will see a great many sparks darted up from the surface of the metal, which will form a fort of fiery flower. By degrees, as the iron grows purer, the number of these sparks diminishes, though they never vanish entirely. When but few sparks appear, remove the coals which cover the iron, and let the flag run out of the vessel; whereupon the metal will grow solid in a moment. Take it out while it is still red hot, and give it a few strokes with a hammer, to try if it be ductile. If it be not yet malleable, repeat the operation a second time, in the same manner as before. Lastly, when it is thus sufficiently purified by the fire, work it for a long time on the anvil, extending it different ways, and making it red hot as often as there is occasion. Iron thus brought to the necessary degree of ductility, so as to yield to the hammer, and suffer itself to be extended every way, either hot or cold, without breaking to bits, or even cracking in the least, is very good and very pure. If it cannot be brought to this degree by the method here prescribed, it is a proof, that the ore from which this iron was extracted, ought to be mixed with other ores; but it frequent: requires a great number of trials to obtain an exact knowledge of the quality and proportion of those other ores with which it is to be mixed.

To convert Iron into Steel.

Take small bars of the best iron; that is, of such as is malleable both hot and cold; set them on their ends in a cylindrical earthen vessel, whose depth is equal to the length of the bars, and in such a manner that they may be an inch distant from each other, and from the sides of the crucible. Fill the vessel with a cement compounded of two parts of charcoal, on part of bones burnt in a close vessel till they become very black, and one half part of the ashes of green wood; having first pulverised and thoroughly mixed the whole together. Take care to lift up the iron bars a little, to the end that the cement may cover the bottom of the vessel, and so that there be about the depth of half an inch thereof under every bar: Cover the crucible and lute on the cover.

Set the crucible thus prepared in a furnace, so contrived, that the crucible may be surrounded with coals from top to bottom: For eight or ten hours keep up such a degree of fire that the vessel may be moderately red; after this take it out of the furnace; plunge your little iron bars into cold water, and you will find them converted into steel.

The principal difference between iron and steel consists in this, that the latter is combined with a greater quantity of phlogiston than the former.

It appears by this experiment, that, to make iron unite with an inflammable matter, it is necessary it should be in fusion; it is sufficient that it be red hot as to be opened and softened by the fire.

Every kind of charcoal is fit to be an ingredient in the composition of the cement employed to make steel, provided it contain no vitriolic acid. However, it hath been observed, that animal coals produce a speedier effect than others: for which reason it is proper to mix something of that kind with charcoal-dust, as above directed.

The following signs shew that the operation hath succeeded, and that the iron is changed into good steel.

This metal being quenched in cold water as proposed above, acquires such an extraordinary degree of hardness, that it will by no means yield to any impression of the file or hammer, and will sooner break in pieces than stretch upon the anvil. And here it is proper to observe, that the hardness of steel varies with the manner in which it is quenched. The general rule is, that the hotter the steel is when quenched, and the colder the water in which you quench it, the harder it becomes. It may be deprived of the temper thus acquired, by making it red-hot, and letting it cool slowly; for it is thereby softened, rendered malleable, and the file will bite upon it. For this reason the artificers who work in steel begin with tempering it, that they may with more ease shape it into the tool they intend to make. They afterwards new-temper the tool when finished, and by this second temper the steel recovers the same degree of hardness it had acquired by the first temper.

The colour of steel is not so white as that of iron, but darker, and the grains, facets, or fibres, which appear on breaking it, are finer than those observed in iron.

If the bars of iron thus cemented, in order to convert them into steel, be too thick, or not kept long enough in cementation, they will not be turned into steel throughout their whole thickness: their surfaces only will be steel to a certain depth, and the centre will be mere iron; because the phlogiston will not have thoroughly penetrated them. On breaking a bar of this sort, the difference in colour and grain between the steel and the iron is very visible.

It is easy to deprive steel of the superabundant quantity of
CHEMISTRY

Of Tin.

To extract Tin from its Ore.

Break your tin ore into a coarse powder, and by washing carefully, separate from it all the heterogeneous matters and ores of a different kind that may be mixed therewith. Then dry it, and roast it in a strong degree of fire, till no more arsenical vapour rise from it. When the ore is roasted, reduce it to a fine powder, and mix it thoroughly with twice its weight of the black flux well-dried, a fourth part of its weight of clean iron filings, together with as much borax and pitch: put the mixture into a crucible; over all put sea-salt to the thickness of four fingers, and cover the crucible close.

Set the crucible thus prepared in a melting furnace: apply at first a moderate and slow degree of fire, till the flame of the pitch, which will escape through the joints of the cover, disappear entirely. Then suddenly raise your fire, and urge it with rapidity to the degree necessary for melting the whole mixture. As soon as the whole is in fusion, take the crucible out of the furnace, and separate the regulus from the scoria.

All tin ores contain a considerable quantity of arsenic, and no sulphur at all, or at most very little. Hence, though tin be the lightest of all metals, its ore is nevertheless much heavier than any other; arsenic being much heavier than sulphur, of which the ores of every other kind always contain a pretty large proportion. This ore is moreover very hard, and is not brought to a fine powder with so much ease as the red.

These properties of tin ore furnish us with the means of separating it easily by lotion, not only from earthy and flinty parts, but even from the other ores which may be mixed with it. And this is of the greater advantage on two accounts, viz. because tin cannot endure, without the destruction of a great part thereof, the degree of fire necessary to scoriify the refractory matters which accompany its ore; and again, because this metal unites so easily with iron and copper, the ores of which are pretty commonly blended with tin ore, that after the reduction it would be found adulterated with a mixture of these two metals, if they were not separated from it before the fusion.

Into an unvarnished earthen dish put the quantity of tin you intend to calcine; melt it, and keep furring it from time to time. Its surface will be covered with a greyish white powder. Continue the calcination till all your tin be converted into such a powder, which is the calx of tin.

The dissolution of Tin by Acids.

Put into a glass vessel what quantity you please of tin cut into little bits. Pour on it thrice as much aqua regis, compounded of two parts aqua fortis weakened with an equal quantity of very pure water, and one part spirit of salt. An expedition will arise, and the tin will be very rapidly dissolved, especially if the quantities of metal and of aqua regis be considerable.
To extract Lead from its Ore.

Having roasted your lead-ore, reduce it to a fine powder; mix it with twice its weight of the black flux, and one fourth of its weight of clean iron filings and borax; put the whole into a crucible capable of containing at least thrice as much; over all put sea-felt four fingers thick; cover the crucible; lute the juncture; dry the whole with a gentle heat, and set it in a melting furnace.

Make the crucible moderately red: you will hear the sea-felt decollect, and after the decrепitation a small hissing in the crucible. Keep up the same degree of fire till that be over.

Then throw in as many coals as are necessary to complete the operation entirely, and raise the fire suddenly, so as to bring the whole mixture into perfect fusion. Keep up this degree of fire for a quarter of an hour, which is time sufficient for the precipitation of the regulus.

When the operation is finished, which may be known by the quietness of the matter in the crucible, and by a bright vivid flame that will rise from it, take the crucible out of the furnace, and separate the regulus from the scoria.

To separate Lead from Copper.

With luting earth and charcoal dust make a flat vessel, widening upwards, and large enough to contain your mettalline masses. Set it shelving downwards from the back towards the fore-part; and in the fore-part, at the bottom, make a little gutter communicating with another vessel of the same nature, placed near the former and a little lower. Let the mouth of the gutter widen to the upper vessel be narrowed, by means of a small iron plate fixed across it, while the loam is yet soft; so as to leave a very small aperture in the lower part of this canal sufficient to discharge the lead as it melts. Dry the whole by placing lighted coals round it.

When this apparatus is dry, put your mixed masses of copper and lead into the upper vessel; both in that, and in the other vessel, light a very gentle fire of wood or charcoal, so as not to exceed the degree of heat necessary to melt lead. In such a degree of heat the lead contained in the mixed masses will melt, and you will see it run out of the upper vessel into the lower; at the bottom of which it will unite into a regulus. When in this degree of heat no more lead flows, increase the fire a little, so as to make the vessel moderately red.

When no more will run, collect the lead contained in the lower vessel. Melt it over again in an iron ladle, with a degree of fire sufficient to make the ladle red; throw into it a little tallow or pitch, and while it burns keep stirring the metal, in order to reduce any part of it that may be calcined. Remove the pellicle or thin crust which will form on the surface; squeeze out all the lead it contains, and then put it to the mass of copper left in the upper vessel. Check the fire, and in the same manner take off a second skin that will form on the surface of the lead. Lastly, when the metal is ready to fix, take off the skin that will then appear on it. The lead remaining after this will be very pure, and free from all alloy of copper.

With regard to the copper itself, you will find it in the upper vessel covered with a thin coat of lead, and if the lead mixed with it was in the proportion of a fourth or a fifth part only, and the fire applied was gentle and slow, it will retain nearly the same form after the operation that the mixed masses had before.

The Calcination of Lead.

Take what quantity of lead you please; melt it in one or more unglazed earthen pans: a dark grey powder will be found on its surface. Keep furring the metal incessantly till it be wholly converted into such a powder, which is the calx of lead.

In the calcination of all metals, and particularly in this of lead, there appears a singular phenomenon which is not easily accounted for. It is this: though these matters lose a great deal of their sublimate, either by the dissipation of their phlogiston, or because some of the metal perhaps exhales in vapours, yet, when the calcination is over, their calxes are found to be encreased in weight, and this increase is very considerable. An hundred pounds of lead, for example, converted into minium, which is nothing but a calx of lead brought to a red colour by continuing the calcination, are found to gain ten pounds weight; so that for an hundred pounds of lead we have one hundred and ten pounds of minium: a prodigious and almost incredible augmentation, if it be considered that, from adding any thing to the lead, we have on the contrary dissipated part of it.

To prepare Glass of Lead.

Take two parts of litharge, and one part of pure crystalline sand; mingle them together as exactly as possible, adding a little nitre and sea-salt: put this mixture into a crucible of the most solid and most compact earth. Shut the crucible with a cover that may perfectly close it.

Set the crucible thus prepared in a melting furnace; fill the furnace with coals; light the fire gradually, so that the whole may be slowly heated: Then raise the fire so as to make the crucible very red, and bring the matter it contains into fusion; keep it thus melted for a quarter of an hour.

Then take the crucible out of the furnace, and break it: In the bottom thereof you will most commonly find a small button of lead, and over it a transparent glafs of a yellow colour nearly resembling that of amber. Separate this glass from the little button of metal, and from the saline matters which you will find above it.

Lead dissolv'd by the Nitrous Acid.

Put into a matras some aqua fortis precipitated like that used to dissolve silver; weaken it by mixing there with an equal quantity of common water; set the matras in a hot sand-bath; throw into it, little by little, small bits of lead, till you see that no more will dissolve. Aqua fortis thus lowered will dissolve about a fourth of its weight of lead.

There is gradually formed upon the lead, as it dissolves, first a grey powder, and afterwards a white crust, which
which at last hinder the solvent from acting on the remaining part of the metal; and therefore the liquor should be made to boil, and the vessel should be shaken to remove those impediments, by which means all the lead will be dissolved.

Of Mercury.

To extract Mercury from its Ore, or to revivify it from Cinabar.

Pulverize the cinabar from which you would extract the mercury; with this powder mix an equal part of clean iron filings; put the mixture into a retort of glass or iron, leaving at least one third part thereof empty. Set the retort thus prepared in a sand-bath, so that its body may be quite buried in the sand, and its neck decline considerably downwards: fit on a receiver half filled with water, and let the nose of the retort enter about half an inch into the water.

Heat the vessel so as to make the retort moderately red. The mercury will rise in vapours, which will condense into little drops, and fall into the water in the receiver. When you see that nothing more comes over with this degree of heat, increase it, in order to raise what mercury may still be left. When all the mercury is thus brought over, take off the receiver, pour out the water contained in it, and collect the mercury.

Mercury is never mineralized in the bowels of the earth by any thing but sulphur; with which it forms a compound of a brownish red colour, known by the name of Cinabar.

The oldest and richest mine of mercury is that of Almaden in Spain. It is a singular property of that mine, that though the mercury found in it is combined with sulphur, and in the form of cinabar, yet no addition is required to procure the separation of these two; the earthy and stony matter, with which the particles of the ore are incorporated, being itself an excellent absorbent of sulphur.

In the quick-silver works carried on at this mine they make no use of retorts. They place lumps of the ore on an iron grate, which stands immediately over the furnace. The furnaces which serve for this operation are closed at the top by a port of dome, behind which stands the shaft of a chimney that communicates with the fireplace, and gives vent to the smoke. These furnaces have in their lower side sixteen apertures, to each of which is luted an aludel in a horizontal position, communicating with a long row of other aludels placed likewise in an horizontal direction; which aludels so connected together form one long pipe or canal, the further end whereof opens into a chamber defined to receive and condense all the mercurial vapours. These rows of aludels are supported from end to end by a terraf, which runs from the body of the building, wherein the furnaces are erected, to that where the chambers are built that perform the office of receivers.

This a very ingenious contrivance, and saves much labour, expense, and trouble, that would be unavoidable if retorts were employed.

Vol. II. No. 35.
common with the vegetable turbith, whose name it hath therefore taken.

**To combine Mercury with Sulphur. Ethioip Mineral.**

Mix a dram of sulphur with three drams of quicksilver, by triturating the whole in a glas mortar with a glas pestle. By degrees, as you triturate, the mercury will disappare, and the matter will acquire a black colour. Continue the trituration till you cannot perceive the least particle of running mercury. The black matter you will then have in the mortar is known in medicine by the name of *Ethioip mineral*. An ethioip may also be made by fire in the following manner.

In a shallow unglazed earthen pan melt one part of flowers of sulphur; add three parts of running mercury, making it fall into the pan in the form of small rain, by squeezing it through chamoy leather. Keep stirring the mixture with the shank of a tobacco-pipe all the while the mercury is falling: you will see the matter grow thick and acquire a black colour. When the whole is thoroughly mixed, set fire to it with a match, and let as much of the sulphur burn away as will flame.

**To sublimate the combination of Mercury and Sulphur into Cinabar.**

Grind to powder ethioip mineral prepared by fire. Put it into a cucurbit; fit thereto a head; place it in a sand-bath, and begin with applying such a degree of heat as is requisite to sublimate sulphur. A black matter will rise, and adhere to the sides of the vessel. When nothing more will rise with this degree of heat, raise the fire to make the sand and the bottom of the cucurbit red; and then the remaining matter will sublimate in the form of a brownish red mass, which is true cinabar.

**To dissolve Mercury in the Nitrous acid. Sundry Mercurial Precipitates.**

Put into a matras the quantity of mercury you intend to dissolve: pour on it an equal quantity of good spirit of nitre, and let the matras in a sand-bath moderately heated. The mercury will dissolve with the phenomena that usually attend the dissolutions of metals in this acid. When the dissolusion is completed, let the liquor cool. You will know that the acid is perfectly saturated, if there remain at the bottom of the vessel, notwithstanding the heat, a little globule of mercury that will not dissolve.

Mercury dissolves in the nitrous acid with much more facility, and in much greater quantity, than in the vitriolic; so that it is not necessary, on this occasion, to make the liquor boil. This solution when cold yields crystals, which are a nitrous mercurial salt. If you desire to have a clear limpid solution of mercury, you must employ an aqua fortis that is not tainted with vitriolic or marine acid: for, the affinity of these two acids with mercury being greater than that of the nitrous acid, they precipitate it in the form of a white powder, when they are mixed with the solvent.

Mercury thus precipitated in a white powder, out of a solution thereof in the spirit of nitre, is used in medi-
that no globule thereof can be perceived. The matter will then be grey. Put this powder into an apothecary’s phial, or into a matras, whole neck is not above four or five inches long, leaving two thirds thereof empty. Set the vefsel in a sand-bath, and put sand round it to one third of its height. Apply a moderate fire at first; and afterwards raise it gradually till you perceive that the mixture sublimes. Keep it up to this degree till nothing more will rife, and then break the vefsel. Reject, as useless, a small quantity of earth which you will find at the bottom; separate also what adheres to the neck of the vefsel, and carefully collect the matter in the middle, which will be white. Pulverize it; sublime it a second time, in the fame manner as before; and in the fame manner separate the earthy matter left at the bottom of the vefsel, and what you find sublimed into the neck. Pulverize, and sublime a third time, the white matter you last found in the middle. The white matter of this third sublimation is the sweet sublimate, called also aquila alba.

The Panacea of Mercury.

PULVERISE some sweet sublimate, and sublime it in the fame manner as you did thrice before. Repeat this nine times. After these sublimations it will make no impression on the tongue. Then pour on it aromatic spirit of wine, and set the whole in digestion for eight days. After that decent the spirit of wine, and dry what remains, which is the panacea of mercury.

O F A N T I M O N Y.

To separate Antimony from its Ore by Fusion.

Having drilled some small holes, of about two lines diameter, in the bottom of a crucible, put into it your antimonial ore broken into little bits, about the size of a hazel nut; lute on its cover; set the crucible thus prepared in the mouth of another crucible, and close the joints with lute. At the distance of half a foot from this compound vessel place bricks all round, so as to form a furnace; the sides of which must rise as high as the brim of the uppermost crucible. Let the bottom of this furnace be filled with ashes, up to the top of the lower crucible, and the rest of the furnace with lighted coals. Blow the fire, if it be necessary, with bellows, till the upper crucible become red. Keep it up in this degree for about a quarter of an hour. Then take your vessels out of the furnace, and you will find the antimony collected in the bottom of the lower crucible, and you will have run through the holes of the upper one. The common Regulus of Antimony.

REDUCE crude antimony to powder. Mix it with three fourths of its weight of white tartar, and half its weight of refined salt-petre, both pulverized. Into a large crucible, made red-hot in the fire, throw a spoonful of your mixture, and cover it. There will be a very considerable detonation. When it is over, throw in a second spoonful of your mixture, and cover the crucible as before: this will produce a second detonation. Go on thus, till you have thrown in all your mixture.

When the whole has thus fulminated, increase the fire so as to bring the matter into fusion; that being done, take the crucible out of the furnace, and immediately pour its contents into an iron cone heated and greased with tallow. Strike the floor and the cone some gentle blows with a hammer, to make the regulus precipitate; and when the matter is fixed and cold, invert the cone, and turn it out. You will see it consist of two distinct substances: the uppermost of which is a saline scoria, and the undermost the reguline part. Strike this mass a blow with a hammer, in the place where these substances join, and you will by this means separate the scoria from the regulus; the latter of which will have the form of a metallic cone, on whose base you will observe the signature of a bright star.

Regulus of Antimony precipitated by Metals.

Put one part of small iron nails into a crucible, and set it amid burning coals, in a melting furnace. When the iron is thoroughly red-hot, and begins to grow white, add thereto little by little, and at several times, two parts of crude antimony in powder. The antimony will immediately flow and unite with the iron. When the antimony is entirely melted, add thereto, at several times, the fourth of its weight of pulverized nitre: a detonation will ensue, and the whole mixture will be in fusion.

After you have kept the matter in this condition for some minutes, pour it into an iron cone, first heated and tallowed. Strike the sides of the cone with a hammer, that the regulus may fall to the bottom; and, when all is cold, separate it from the scoria by a blow with a hammer. Melt this first regulus again in another crucible, adding a fourth part of its weight of crude antimony. Keep the crucible close shut, and give no more heat than is necessary to melt the matter. When it is in perfect fusion, add to it at several times, as you did before, the fifth part of its weight of pulverized nitre; and, in half a quarter of an hour after this, pour the whole into a cone as you did the first time.

Lastly, Melt your regulus over again a third or even a fourth time, always adding a little nitre, which will detonate as before. If after all these fusions you pour the regulus into an iron cone, you will find it very beautiful, and the star well formed: it will be covered with a semi-transparent, lemon-coloured scoria. This scoria is extremely acrid and caustic.

The Calcination of Antimony.

TAKE an unglazed earthen vesseil, wider at top than at bottom; put into it two or three ounces of crude antimony finely pulverized. Set this vessel over a weak charcoal-fire, and increase the heat till you see the antimony begin to smoke a little. Continue the fire in this degree, and keep incessantly stirring the antimony with the flake of a tobacco-pipe all the while it is upon the fire.

The powder of antimony, which, before calcination, was of a brilliant colour inclining to black, will become dull,
this appearance, raise your fire till the vessel be red-hot, and keep it up in this degree till the matter cease entirely to smoke.

**Calx of Antimony reduced to a Regulus.**

Mix the calx of antimony, which you intend to reduce, with an equal quantity of black soap. This mixture will make a thin paste. Put it little by little into a crucible, previously made red-hot amidst live coals. Thus let the soap burn, till it cease to emit an oily smoke. When this noise is over, let the crucible cool, and then break it: you will find in it a beautiful scoria, marked with circles of several colours; and under that a button of regulus, which is not yet quite pure, and must be purified in the following manner.

Pour this regulus, and mix it with half its weight of an antimonial calx as perfectly depurphurated as possible. Put it into a crucible, and cover it: melt the whole, so that the surface of the melted matter may be smooth and uniform. Let the crucible cool, and then break it; you will find in it a beautiful button of very pure regulus, covered with a scoria, having the appearance of an opaque glass, or a kind of greyish enamel, moulded on the finely radiated surface of the regulus.

**Antimony calcined with Nitre. Liver of Antimony.**

Pulverise and mix perfectly together equal parts of nitre and antimony: put the mixture into an iron mortar, and cover it with a tile, which however must not shut it quite close. With a live coal set fire to the matter in the mortar, and immediately withdraw it. The mixture will flame, with great detonation; which being over, and the mortar cooled, invert it, and strike its bottom to make all the matter fall out. Then, by a blow with a hammer, separate the scoria from the shining part, which is the liver of antimony.

**Another Calcination of Antimony with Nitre. Diaphoretic Antimony.**

Mix one part of antimony with three parts of nitre; project this mixture by spoonfulls into a crucible kept red hot in a furnace. Each projection will be attended with a detonation. Continue doing this till you have used all your mixture: then raise the fire, and keep it up for two hours; after which throw your matter into a pan full of hot water. Let it lie steeping in water kept hot for a whole day. Then pour off the liquor: wash the white powder you find at bottom in warm water; and repeat the ablutions till the powder become infuspid. Dry it, and you have diaphoretic antimony.

**Calx of Antimony vitrified.**

Take any quantity you please of calx of antimony, made without addition; put it into a good crucible, which set in a melting furnace: kindle the fire gradually, and leave the crucible uncovered at the beginning.

A quarter of an hour after the matter is red-hot, cover the crucible, and excite the fire vigorously till the calx melt. You may know when it is thoroughly melted, by dipping into the crucible an iron wire, to the end of which a little knob of glass will adhere, if the matter be in perfect fusion. Keep it in fusion for a quarter of an hour, or rather longer if your crucible can bear it. Then take it out of the furnace, and immediately pour out the melted matter on a smooth stone, made very hot for the purpose: it will presently fix into a yellow glass.

**Kermes Mineral.**

Break any quantity you will of Hungarian antimony into little bits: put it into a good earthen coffee-pot: pour on it twice its weight of rain-water, and a fourth part of its weight of well filtered liquor of nitre fixed by charcoal. Boil the whole briskly for two hours, and then filter the liquor. As it cools it will acquire a red colour, grow turbid, and leave a red powder on the filter.

Return your antimony into the coffee-pot. Pour on it as much rain-water as before, and three fourths of the former quantity of the liquor of fixed nitre. Boil it again for two hours, and then filter the liquor. It will again depurate a red sediment. Return your antimony into the coffee pot: pour on it the same quantity of rain-water, and half the first quantity of the liquor of fixed nitre. Boil it again for two hours, and filter the liquor as formerly. Wash all these sediments with warm water, till they become insipid; then dry them, and you have the kermes mineral.

**Regulus of Antimony dissolved in the Mineral Acids.**

Compound an aqua regis by mixing together four measures of spirit of nitre, and one measure of spirit of salt: on a sand-bath moderately heated place a matras, into which pour sixteen times as much of this aqua regis as you have regulus to dissolve. Break your regulus in little bits; and throw them successively one after another into the matras, observing not to add a new one till that put in before is entirely dissolved: continue this till your regulus be all used. By degrees, as the dissolution advances, the liquor will acquire a beautiful golden colour; which however will insensibly disappear, as the white fumes that continually ascend from it evaporate.

**Regulus of Antimony combined with the Acid of Sea-salt. Butter of Antimony. Cinabar of Antimony.**

Pulverise and mix thoroughly six parts of regulus of antimony, and sixteen parts of corrosive sublimate. Put this mixture into a glafs retort that hath a wide short neck, and let one half of its body at least be left empty. Set it in a reverberatory furnace, and having fitted a recipient thereeto and luted the joint, make a very small fire at first, to heat it slowly. Increase it afterwards by degrees, till you see a liquor ascend from the retort that grows thick as it cools. Keep up the fire to this degree as long as you see any of this matter come over.

When no more arises with this degree of fire, unlute your vessels, take off the receiver, and in its place substitute another filled with water. Then increase your fire by degrees till the retort be red-hot, some running
nong mercury will fall into the water, which you may
dry and keep for use; it being very pure.

Soon after mixing the regulus with the corrosive sub-
limate, the matter sometimes grows considerably hot:
This is occasioned by the marine acid’s beginning to act
on the reguline part, and to defeat its mercury.

The butter of antimony rises with a very moderate
heat; because the acid of sea-falt hath the property of
volatilizing, and carrying up along with it, the metallic
substances with which it is combined: And for this rea-
on a very gentle heat only is required at the begin-
ing of the operation.

It is absolutely necessary that the neck of the retort
be wide and short: for otherwise, if the butter of antimo-
y should fix and be accumulated therein, it might stop
up the passage entirely, and occasion the burfting of the
vessels. By this operation we obtain eight parts and
three quarters of fine butter of antimony, and ten parts
of running mercury; there being left in the retort one
part and a half of a rarefied matter, black, white, and
red.

This is probably the most earthy and most impure
part of the regulus of antimony.

If crude antimony, instead of regulus of antimony,
be mixed with corrosive sublimate, a butter of antimony
will be obtained in the same manner; but, instead of
having a running mercury after the butter, you will find
a cinabar sublimed into the neck and upper concavity
of the retort.

The reason of this difference is easily conceived: for,
when the regulus is used, the mercury being deferred by
its acid, finds no other substance to unite with, and so rifes
in the form of quick-silver; but when crude antimony is
employed instead of its regulus, as the reguline part
thereof cannot combine with the acid without quitting
its sulphur, so this sulphur, being at liberty, unites with
the mercury, which is so likewife, and therewith forms
a cinabar; which from its origin is named cinabar of an-
timony.

Butter of Antimony decomposed by means of Water
only. The Pulvis Algaroth, or Mercurius Vite.

Melt with a gentle heat as much butter of antimony
as you please. When it is melted, pour it into a large
quantity of warm water. The water will immediately
grow turbid, but whitish, and let fall a great quantity
of white powder. When all the precipitate is settled,
decant the water: pour on fresh warm water; and hav-
ing thus edulcorated it by several ablutions, dry it, and
you have the pulvis Algaroth, or mercurius vite.

Bezoar Mineral.

Melt butter of antimony over warm ashes, and put
it into a phial or matras. Gradually pour on it good
spirit of nitre, till the matter be entirely dissoloved. This
usually requires as much spirit of nitre as there is butter
of antimony. During the dissolusion fumes will rife,
which must be carefully avoided. Pour your solution,
which will be clear and of a reddish colour, into a glas
cucurbit, or a pan of stone ware; set it in a sand-bath,
and evaporate to dryness with a moderate heat. There
will be left a white mass, weighing a fourth part less
than the whole quantity used, both of butter and the spirit
of nitre. Let it cool, and again pour on it as much
spirit of nitre as you used the first time. Place the ve-
sels again in the sand-bath, and evaporate the moisture
as before. You will have a white mass that hath neither
gained nor lost in weight. On this pour, for the third
time, the same quantity of spirit of nitre as you did the
first time. Again evaporate the moisture to perfect dry-
ness: then increase your fire, and calcine the matter for
half an hour. You will have left a dry, friable, light,
white mass, of an agreeable acid taste; which will fall
into a coarse powder, and must be kept in a phial care-
fully stopp’d. This is Bezoar mineral: it is neither caustic
nor emetic, and has only a sudorific virtue. It obtained
the name it bears, because, like the animal bezoar, it
was imagined to have the property of refuting poison.

Flowers of Antimony.

Take an unglazed earthen pot, having an aperture in
its side, with a stopple to shut it clofe. Set this pot in a
furnace, the cavity whereof it may fit as exactly as pos-
ible; and fill up with lute the space, if any, left between the
vessel and the furnace. Over this vessel fix three aludels
with a blind-head at the top; and light a fire in the fur-
nace under the pot.

When the bottom of the pot is thoroughly red, throw
into the lateral aperture a small spoonful of powdered an-
timony. Stir the matter immediately with an iron spatula
made a little bending, in order to spread it over the
bottom of the vessel, and then stop the hole. The
flowers will rife and adhere to the infides of the aludels.
Keep up the fire so that the bottom of the pot may al-
ways continue red; and, when nothing more sublimes,
put in a like quantity of antimony, and operate as be-
fore. In this manner go on subliming your antimony,
till you have as many flowers as you want. Then let the
fire go out; and when the vessels are cold, unloose them.
You will find flowers adhering all round the infides of
the aludels and the head, which you may collect with a
feather.

Regulus of Antimony converted into Flowers.

Pulverize your regulus of antimony: put the pow-
derer into an unglazed earthen pot: three or four fingers
breadth above the powder, fix into the pot a little cover,
made of the fame earth and having a small hole in its
middle, fo that it may with ease be placed in the pot
and taken out when there is occasion: cover the mouth
of the pot with a common lid; set it in a furnace, and
kindle a fire under it sufficient to make the bottom of the
pot red and to melt the regulus. When it hath been
thus kept in fufion for about an hour, let the fire go out and
the whole cool. Then remove the two covers. You will find adhering to the surface of the regulus,
which will be in a mass at the bottom of the pot, white
flowers resembling snow, intermixed with beautiful, bril-
liant, silver coloured needles. Take them out, and you
will find them make about one part in (ixty-two of the
whole quantity used, both of butter and the spirit
of nitre. Let it cool, and again pour on it as much
spirit of nitre as you used the first time. Place the ve-
sels again in the sand-bath, and evaporate the moisture
as before. You will have a white mass that hath neither
gained nor lost in weight. On this pour, for the third
time, the same quantity of spirit of nitre as you did the
first time. Again evaporate the moisture to perfect dry-
ness: then increase your fire, and calcine the matter for
half an hour. You will have left a dry, friable, light,
white mass, of an agreeable acid taste; which will fall
into a coarse powder, and must be kept in a phial care-
fully stopp’d. This is Bezoar mineral: it is neither caustic
nor emetic, and has only a sudorific virtue. It obtained
the name it bears, because, like the animal bezoar, it
was imagined to have the property of refuting poison.

nor emetic, and has only a sudorific virtue. It obtained
the name it bears, because, like the animal bezoar, it
was imagined to have the property of refuting poison.
cold, you will find half as many more flowers as you got the first time.

Proceed thus till you have converted all your regulus into flowers. This will require a considerable number of sublimations, which, as you advance, will always yield you a greater portion of flowers; respect, however, being had to the quantity of regulus remaining in the pot.

**Of Bismuth.**

**To extract Bismuth from its Ore.**

Break the ore of bismuth into small pieces, and therewith fill a crucible either of earth or iron. Set the crucible in a furnace, and light such a fire that the bits of ore may become moderately red. Stir the ore from time to time; and if you perceive it crackle and fly, keep the crucible covered. At the bottom you will find a button of bismuth.

Into a matras put bismuth broken into little bits: pour on it, by little and little, twice as much aqua fortis. This acid will attack the semi-metal briskly, and dissolve it entirely, with heat, effervescence, vapours, and puffing up. The solution will be clear and limpid.

If you would have a magistery of bismuth beautifully white, you must perform the dissolution with an aqua fortis that is not tainted with any mixture of the vitriolic acid; for this gives the precipitate a dirty white colour, inclining to grey.

Bismuth may also be precipitated by the means of fixed or volatile alkalis; but the precipitate is not of so fine a white as when procured by the means of pure water only.

A solution of bismuth prepared with the proper quantity of aqua fortis, that is, with two parts of the acid to one of the semi-metal, coalesces into little crystals almost as soon as made.

Aqua fortis not only acts on bismuth when separated from its ore, and reduced to a regulus, but attacks it even in its ore, and likewise dissolves at the same time some portion of the ore itself. With this solution of the ore of bismuth Mr Hellot makes a very curious sympathetic ink differing from all that were known before.

Mr Hellot prepares the liquor in the following manner: He bruises the ore of bismuth to a coarse powder. On two ounces of this powder he pours a mixture of five ounces of common water with five ounces of aqua fortis. He does not heat the vessel till the first ebullitions are over. He then sets it in a gentle sand-heat, and lets it digest there till he sees no more air-bubbles rise. When none appear in this heat, he increases it so as to make the solvent boil slightly for a full quarter of an hour. It takes up a tincture nearly of the colour of brown beer. The ore that gives the aqua fortis this colour is the best. He then lets the solution cool, laying the matras on its side, that he may decant the liquor more conveniently when all is precipitated that is not taken up by the solvent.

"The second vessel, into which the liquor is first decanted, he also lays declining, that a new precipitation of the undissolved matters may be obtained; after which he pours the liquor into a third vessel. This liquor must not be filtered, if you would have the rest of the process succeed perfectly; because the aqua fortis would dissolve some of the paper, and that would spoil the colour of your liquor.

"When this solution, which Mr Hellot calls the impregnation, is thoroughly clarified by being decanted three or four times, he puts it into a glafs bason with two ounces of very pure sea-salt. The fine white salt made by the sun succeedeth best with Mr Hellot. If that cannot be had, common bay-salt purified by solution, filtration, and crystallisation, may be used instead of it. But as it is rare to meet with any of the sort that is not a little tainted with iron, the white bay salt is to be preferred. The glafs bason he sets in a gentle sand-heat, and keeps it there till the mixture be reduced by evaporation to an almost dry saline mass.

"If you desire to save the aqua regis, the impregnation must be put into a retort, and distilled with the gentle heat of a sand-bath. But there is an inconvenience, as Mr Hellot observes, in employing a retort; which is, that, as the saline mass cannot be stirred while it coagulates in the retort, it is reduced to a compact cake of coloured salt, which presents but one single surface to the water in which it must be dissolved; so that the dissolution thereof takes up sometimes no less than five or six days. In the bason, on the contrary, the saline mass is easily brought to a granulated salt, by stirring it with a glafs rod; and, when thus granulated, it has a great deal more surface; it dissolves more easily, and yields its tincture to water in four hours time. Indeed one is more exposed to the vapours of the solvent, which would be dangerous, if the operation were to be often performed, without proper precautions.

"When the bason, or little vessel containing the mixture of the impregnation and sea-salt, is heated, the liquor, which was of an orange-coloured red, becomes a crimson red; and, when all the phlegm of the solvent is evaporated, it acquires a beautiful emerald colour. By degrees it thickens, and turns of the colour of a mass of verdigris. It must then be carefully stirred with the glafs rod, in order to granulate the salt, which must not be kept over the fire till it be perfectly dry: because you run a risk of losing irrecoverably the colour you are seeking. You may be sure you have lost it, if by too much heat the salt that was of a green colour turn to a dirty yellow. If it be once brought to this state, it will continue without changing when cold; but if care be taken to remove it from the fire while it is still green, you will see it gradually grow pale, and become of a beautiful rose-colour as it cools.

"Mr Hellot separates it from this vessel, and throws it into another containing distilled rain-water: and this second vessel he keeps in gentle digestion, till he observes that the powder which falls to the bottom is perfectly white. If, after three or four hours digesting, this powder still continues tinged with a rose colour, it is a proof that water enough was not added to dissolve all the salt.
falt impregnated with the tincture of the solution. In this case, the first tinged liquor must be poured off, and fresh water added in proportion to the quantity of tinged falt that is supposed to remain mixed with the precipitate.

"When the ore is pure, and doth not contain a great deal of fugible stone, commonly called flour, or quartz, an ounce of it generally yields tincture enough for eight or nine ounces of water, and the liquor is of a beautiful colour, like that of the lilach or pipe-tree blossom. In order to prove the effect of this tincture, you must write with this lilach coloured liquor on good well-gummed paper, that does not stick: or you may use it to shade the leaves of some tree or plant, having first drawn the outlines thereof lightly with China ink or with a black lead pencil. Let this coloured drawing, or writing, dry in a warm air. You will perceive no colour while it is cold; but, if it be gently warmed before the fire, you will see the writing, or the drawing, gradually acquire a blue or greenish blue colour, which is visible as long as the paper continues a little warm, and disappears entirely when it cools."

The singularity of this sympathetic ink consists in its property of disappearing entirely, and becoming invisible, though it be not touched with anything whatever; and this distinguishes it from all others; which, when once rendered visible by the application of proper means, do not again disappear, or at least not without touching the strokes on the paper with some other liquor.

Of Zinc.

To extract Zinc from its Ore, or from Calamine.

Take eight parts of calamine reduced to a powder; mix this powder accurately with one part of fine charcoal dust; previously calcined in a crucible to free it from all moisture: put this mixture into a stone retort coated with lute, leaving a third part of it empty: set your retort in a reverberatory furnace, capable of giving a very fierce heat. To the retort apply a receiver, with a little water in it. Kindle the fire, and raise it by degrees till the heat be strong enough to melt copper. With this degree of fire the zinc being metallified will separate from the mixture, and sublime into the neck of the retort, in the form of metallic drops. Break the retort when it is cold, and collect the zinc.

Most of the zinc we have comes from an ore of difficult fusion that is worked at Golgar, and yields, at one and the same time, lead, zinc, and another metallic matter called cadmia fornacum, which also contains much zinc.

The furnace used for melting this ore is closed on its fore-side with thin plates or tables of stone, not above an inch thick. This stone is greyish, and bears a violent fire.

In this furnace the ore is melted amidst charcoal, by the help of bellows. Each melting takes twelve hours, during which time the zinc flowing with the lead is resolved into flowers and vapours, great part of which adheres to the sides of the furnace in the form of a very hard crust of earth. The workmen take care to remove this crust from time to time; for it would otherwise grow so thick at last, as to lessen the cavity of the furnace very considerably.

There adheres moreover to the fore-part of the furnace, which is formed, as we said before, of thin plates of stone, a metallic matter, which is the zinc, and is carefully collected at the end of each melting, by removing from this part all the live coals. A quantity of small coal is laid unlighted at the bottom; and on this small-coal, by striking the stone-plates gently with a hammer, the zinc is made to fall out of the other matter, known by the Latin name of cadmia fornacum, among which it appears fixed in a radiated form. To this other matter we may properly enough give the name of furnace-calamine. The zinc falls in the form of a melted metal, all on fire, and in a bright flame. It would soon be entirely burnt and reduced to flowers, if it were not extinguished, and easily cooled and fixed, by being hid under the unlighted small-coal placed below on purpose to receive it.

The zinc adheres to the fore-part of the furnace preferably to any other, because that being the thinnest, is therefore the coolest: and, in order further to promote its fixing on this part, they take care to keep the thin stone-plates cool during the operation, by throwing water on them.

Hence it appears that zinc is not extracted from its ore by fusion and the precipitation of a regulus, like other metallic substances. This is owing to the great volatility of our semi-metal, which cannot, without subliming, bear the degree of fire necessary to melt its ore. It is at the same time so combustible, that a great part of it rises, in flowers which have not the metalline form.

To sublimate Zinc into Flowers.

Take a very deep, large crucible: place this crucible in a furnace, so that it may stand inclining in an angle of forty-five degrees nearly. Throw some zinc into it, and kindle a fire in the furnace somewhat stronger than would be necessary to keep lead in fusion. The zinc will melt. Stir it with an iron wire, and there will appear on its surface a very bright white flame: two inches above this flame a thick smoke will be formed, and with this smoke exceeding white flowers will rise, and remain some time adhering to the sides of the crucible, in the form of a very fine light down. When the flame flackens, stir your melted matter again with the iron wire: you will see the flame renewed, and the flowers begin again to appear in greater abundance. Go on thus till you observe that the matter will not flame, nor any more flowers rise.

To combine Zinc with Copper. Brass, Prince's Metal, &c.

Pound one part and an half of calamine, and an equal quantity of charcoal: mingle these two powders together, and moisten them with a little water. Put this mixture into a large crucible, or some other earthen vessel that will bear a melting heat. Amongst and over this mixture put one part of very pure copper in thin plates, and then put fresh charcoal-dust over all: close the.
the crucible; set it in a melting furnace; put coals all round it, and let them kindle gradually. Raise the fire so as to make the crucible very red-hot. When you observe that the flame hath acquired a purple or bluish-green colour, uncover the crucible, and dip it into an iron wire, to examine whether or no the copper be in fusion under the charcoal dust. If you find it is, moderate the force of the fire a little, and let your crucible remain in the furnace for a few minutes. Then take it out and let it cool: you will find your copper of a gold colour, increased in weight a fourth, or perhaps a third part, and yet very malleable.

The *lapis calaminaris* is not the only sub stance with which copper may be converted into brass: all other ores containing zinc, the furnace-calamine that sublimes where such ores are worked, tarry, zinc in substance, may be substituted for it, and, like it, will make very fine brasses; but, in order to succeed, sundry precautions are necessary.

This process is a sort of cementation; for the calamine doth not melt; only the zinc is converted into vapours, and then combines with the copper. On this the success of the operation partly depends, as it is the means of the copper’s preserving its purity and malleability; because the other metallic substances that may be united with the ore of zinc, or with the zinc itself, not having the same volatility, cannot be reduced to vapours. If you are apprised that the calamine, or other ore of zinc used on this occasion, is contaminated with a mixture of any other metallic matter, you must mingle luting earth with the charcoal-dust and the matter containing the zinc; make it into a stiff paste with water; of this make a bed at the bottom of your crucible, and ram it hard down; lay the copper-plates therein, cover them with charcoal-dust, and then proceed as before. By this means, when the copper melts, it cannot fall to the bottom of the crucible, nor mix with the ore; but is borne up by the mixture, and cannot combine with any thing but the zinc, that rises in vapours, and, passing through the lute, fixes in the copper.

*Lapis Calaminarius*, or other ore of zinc, may be also purified before it be used for making brass; especially if adulterated with lead ore, which is often the case. For this purpose the ore must be roasted in a fire strong enough to give a small degree of fusion to the leaden matter; which will thereby be reduced into larger, heavier, and tougher masses. The most fubtile particles are diffipated in the torrefaction, together with some of the calamine. The calamine, on the contrary, is by roasting made more tender, lighter, and much more friable. When it is in this condition, put it into a walking tray or pan; dip the tray in a vessel full of water, and bruise the matter it contains. The water will carry off the lightest powder, which is the calamine, and leave nothing at the bottom of the tray but the heaviest substance; that is, the leaden matter, which is to be rejected as useless. The powder of the calamine will settle at the bottom of the vessel, where, after pouring off the water, it may be found, and used as above directed.

In this operation the charcoal-dust serves to prevent both the copper and the zinc from being calcined: and for this reason, when you work on a great quantity of materials at once, it is not necessary to use so much charcoal dust, in proportion, as when you work but on a small quantity; because, the greater the mass of metal, the less easily will it calcine.

Though the copper melts in this operation, yet it is far from being necessary to apply such a strong fire as copper usually requires to melt it: for the accession of the zinc, on this occasion, communicates to it a great degree of fusibility. The increase of its weight is also owing to the quantity of zinc combined with it. Copper acquires still another advantage by its association with this semi-metal; for it remains longer in the fire without calcining.

Brass well prepared ought to be malleable when cold. But in whatever manner it be made, and whatever proportion of zinc there be in it, it is constantly found quite unmalleable when red-hot.

Brass melted in a crucible, with a fierce heat, takes fire almost like zinc, and from its surface many white flowers ascend, dancing about in flakes like the flowers of zinc. They are indeed the flowers of zinc, and the flame of brass urged by a strong fire is no other than the flame of the zinc that is united with the copper, and then burns. If brass be thus kept long in fusion, it will lose almost all the zinc it contains. It will also lose much of its weight, and its colour will be nearly that of copper. It is therefore necessary, towards performing this operation aright, to seize the moment when the copper is sufficiently impregnated with zinc, when it hath acquired the most weight and the finest colour, with the least detriment to its ductility, that is possible, and that instant to put out the fire; because, if the copper be left longer in fusion, it will only lose the zinc already united with it. Skill acquired by much practice, and an acquaintance with the particular calamine employed, are necessary to guide the artist surely through this operation; for there are very considerable differences between the sundry ores of zinc. Some of them contain lead, and in others there is iron. When these heterogeneous metals come to be mixed with the copper, they do indeed augment its weight, but they render it at the same time pale, and make it very harsh. Some calamines require to be roasted before they can be used for this purpose, and in the torrefaction emit vapours of a volatile alkali, succeeded by vapours of a sulphureous spirit: others exhale no vapours while roasting, and may be employed without any antecedent preparation. These different qualities must evidently produce great differences in the operation.

Brasses may also be made, as prince’s metal and other imitations of gold are actually made, by using zinc in substance, instead of the ores that contain it. But these compositions have not, when cold, the ductility of brasses prepared with *lapis calaminaris*, because zinc is seldom pure, or free from a mixture of lead. Perhaps also the different manner in which the zinc unites with the copper may contribute to this variation.

To obviate this inconvenience, the zinc must be refined from all alloy of lead. The property of being indissoluble by sulphur, which this semi-metal possesseth, points out
of all the same phenomena. Zinc is dissolved by the nitrous and marine acids, much out a very practicable method of doing it. The zinc must be melted in a crucible, and stirred briskly with a strong iron wire, while tallow and mineral sulphur are alternatingly projected upon it; but so that the quantity of sulphur may greatly exceed that of the tallow. If the sulphur do not burn entirely away, but form a kind of scoria on the surface of the zinc, it is a sign that your semi-metal contains lead. In this case you must continue throwing in more sulphur, and keep stirring the zinc incessantly, till you perceive that the sulphur ceases to unite any more with a metallic substance, but burns freely on the surface of the zinc. The semi-metal is then refined; because the sulphur, which cannot dissolve it, unites very readily with the lead, or other metallic substance, contained in it.

If zinc thus refined be mixed with pure copper, in the proportion of a fourth or a third part, and the mixture be kept in fusion and constantly stirring for some time, the brass produced will be as ductile, when cold, as that made by cementation with the lapis calaminaris.

With regard to prince's metal, and other imitations of gold, they are made either with copper or brass recombined with more zinc. As it is necessary, for giving them a fine golden colour, to mix with them other proportions of zinc than that required to make brass only, they are generally much less ductile.

**Zinc dissolved in the Mineral Acids.**

*Weaken* concentrated oil of vitriol by mixing with it an equal quantity of water. Into a matras put the zinc you intend to dissolve, first broken to small pieces. Pour on it six times its weight of the vitriolic acid, lowered as above directed, and set the matras in a sand-bath gently heated. The zinc will dissolve entirely, without any sediment. The neutral metallic salt resulting from this dissolution shoots into crystals, which go by the name of white vitriol, or vitriol of zinc.

Zinc is dissolved by the nitrous and marine acids, much in the same manner as by the vitriolic; except that the marine acid does not touch a black, spongy, rarefied matter, which it separates from the zinc. M. Hellot found upon trial that this matter is not mercury, and that it cannot be reduced to a metallic substance.

A solution of zinc in the marine acid, being distilled to dryness, yields a sublimate on applying a violent heat to it.

All the acids dissolve with ease; not only zinc, but its flowers also; and that nearly in the same quantity, and with almost all the same phenomena.

**Of Arsenic.**

To extract Arsenic from its Matrices. **Zaffre or Smalt.**

Powder some cobalt, white pyrites, or other arsenaclional matters. Put this powder into a retort with a short wide neck, leaving a full third thereof empty. Set your retort in a reverberating furnace; lute on a receiver; heat your vessel by degrees, and increase the fire till you see a powder sublimate into the neck of the retort. Keep up the fire in this degree as long as the sublimation continues; when this begins to slacken, raise your fire, and make it as strong as the vessels will bear. When nothing more ascends, let it go out. On unluting the vessels, you will find in the receiver a little arsenic in the form of a fine light *farina*. The neck of the retort will be full of white flowers, not quite so fine, some of which will appear like little crystals; and if a good deal of arsenic be sublimed, a ponderous matter, like a white, semi-transparent glafs, will be found adhering to that part of the neck of the retort which is next its body.

When all the arsenic the cobalt will yield is thus separated, the earthy fixed matter left behind is mixed with divers fusible matters and vitrified, and produces a glafs of beautiful blue colour. It is called *smalt*. This glafs is to be prepared in the following manner.

Take four parts of fine fusible sand, an equal quantity of any fixed alkali perfectly depurated, and one part of cobalt from which the arsenic hath been sublimed by sublimation. Pulverize these different substances very finely, and mix them thoroughly together; put the mixture into a good crucible, cover it, and set it in a melting furnace. Make a strong fire, and keep it up constantly in the same degree for some hours. Then dip an iron wire into the crucible; to the end of which a glasy matter will stick, in the form of threads, if the fusion and vitrification be perfect. In this case take the crucible out of the fire; cool it by throwing water on it, and then break it. You will find in it a glafs, which will be of an exceeding deep blue, and almost black, if the operation hath succeeded. This glafs, when reduced to a fine powder, acquires a much brighter and more lively blue colour.

If you find after the operation that the glasfs hath too little colour, the fusion must be repeated a second time, with twice or thrice the quantity of cobalt. If, on the contrary, the glafs be too dark, less cobalt must be used.

In order to make the essay of a particular cobalt, with a view to know what quantity of blue glafs it will yield, it is not necessary to perform the operation in the manner here set down; a great deal of time and trouble may be saved by melting one part of cobalt with two or three parts of borax. This salt is very fusible, and turns, when melted, into a substance which, for a time, possesses all the properties of glafs. In this trial the glafs of borax will be nearly of the same colour as the true glafs, or smalt, made with the same cobalt.

The ores of bismuth, as well as cobalt, yield a matter that colours glafs blue; nay, the smalt made with those ores is more beautiful than that procured from the ore of pure arsenic. Some coals yield both arsenic and bismuth. When such coals are used, it is common to find at the bottom of the crucible a little button of metallic matter, which is called regulus of cobalt. This regulus is a sort of bismuth, generally adulterated with a mixture of ferruginous and arsenaclinal parts.

The heaviest and most fixed flowers of arsenic, procured from cobalt, have likewise the property of giving a blue colour to glafs. But this colour is faint; it is owing to a portion of the colouring matter carried up along with the arsenic. These flowers may be made an ingredient in the composition of blue glafs, not only because of the colouring principle they contain, but also because...
they greatly promote fusion; arsenic being one of the most efficacious fluxes known.

In short, all those blue glasses, or smalts, contain a certain quantity of arsenic; for a portion of this fémimetal always remains united with the fixed matter of the cobalt, though roasted for a long time, and in a very hot fire. The portion of arsenic that is thus fixed vitrifies with the colouring matter, and enters into the composition of the smalt.

The blue glasses made with the fixed part of cobalt hath several names, according to the condition in which it is.

When it hath undergone the first imperfect degree of fusion only, it is called saffre. It takes the name of smalt when perfectly vitrified; and this again being pulverized is called powder blue; or, if finely levigated, blue enamel; because it is used in enamelling, as well as in painting earthen ware and porcelain.

To separate Arsenic from Sulphur.

Powder the yellow or red arsenic which you intend to separate from its sulphur. Moisten this powder with a fixed alkali resolved into a liquor. Dry the mixture gently; put it into a very tall glass cucurbit, and fit on a blind-head. Set this cucurbit in a sand-bath; warm the vessels gently, and increase the fire by degrees, till you perceive that no more arsenic sublimes. The arsenic, which before was yellow and red, rises into the head partly on white flowers, and partly in a compact, white, semi-transparent matter, which looks as if it were vitrified. The sulphur combined with the fixed alkali remains at the bottom of the cucurbit.

To give Arsenic the Metalline Form. Regulus of Arsenic.

Take two parts of white arsenic in fine powder, one part of the black flux, half a part of borax, and as much clean iron filings. Rub the whole together, in order to mix them thoroughly. Put this mixture into a good crucible, and over it put sea-salt three fingers thick. Set this crucible in a sand-bath; warm the vessels gently, and increase the fire by degrees, till you perceive that no more arsenic sublimes. The arsenic, which before was yellow and red, rises into the head partly on white flowers, and partly in a compact, white, semi-transparent matter, which looks as if it were vitrified. The sulphur combined with the fixed alkali remains at the bottom of the cucurbit.

To distil the Nitrous Acid by the Interposition of Arsenic. Blue Aqua Fortis.

Pulverize finely any quantity you please of refined salt-petre. Mix it accurately with an equal weight of white crystalline arsenic well pulverised, or else with very white and very fine flowers of arsenic. Put this mixture into a glass retort, leaving one half of it empty. Set your retort in a reverberating furnace; apply a receiver, having a small hole drilled in it, and containing a little filtered rain-water; lute the receiver to the retort with stiff lute. Begin with putting two or three small live coals in the ash-hole of the furnace, and replace them with others when they are ready to go out. Go on thus warming your vessels by insensible degrees, and put no coals in the fire-place till the retort begin to be very warm. You will soon see the receiver filled with vapours of a dark red, inclining to a rufset colour. With a bit of lute flop the little hole of the receiver. The vapours will be condensed in the water of this vessel, and give it a very fine blue colour, that will grow deeper and deeper as the distillation advances. If your salt-petre was not very dry, some drops of acid will also come over, and falling from the nozzle of the retort mix with the water in the receiver. Continue your distillation, increasing the fire little by little as it advances, but exceeding slowly, till you see that when the retort is red-hot nothing more comes off; and then let your vessels cool.

When the vessels are cold, unlute the receiver, and as expeditiously as you can pour the blue aqua fortis it contains into a crystal bottle; which you must seal hermetically, because this colour disappears in a short time when the liquor takes air. You will find in the retort a white saline mass moulded in its bottom, and some flowers of arsenic sublimed to its upper cavity, and into its neck.

Pulverize the saline mass, and dissolve it in warm water. Filter the solution, in order to separate some arsénical parts that will be left on the filter. Let the filtered liquor evaporate of itself in the open air; when it is sufficiently evaporated, crystals will shoot in it representing quadrangular prisms terminated at each extremity by pyramids that are also quadrangular. These crystals will be in confused heaps at the bottom of the vessel; over them will be other crystals in the form of needles; a saline vegetation creeping along the sides of the vessel; and the surface of the liquor will be obscured by a thin dusty pellicle.

To alkalize Nitre by Arsenic.

Melt in a crucible the nitre you intend to alkalize. When it is melted, and moderately red, project upon it two or three pinches of pulverised arsenic. A consider-able effervescence and ebullition will immediately be produced in the crucible, attended with a noise like that which nitre makes when it detonates with an inflammable matter. At the same time a thick smoke will rise, which at first will smell like garlic, the odour peculiar to arsenic; it will also smell afterwards like spirit of nitre. When the effervescence in the crucible is over, throw again upon the nitre as much pulverised arsenic as you did the first time; and all the same phenomena will be repeated. Continue thus throwing in arsenic in small parcels, till it produce no more effervescence; taking care to stir the matter at every projection with an iron wire, the better to mix the whole together. Then increase your fire, and melt what remains. Keep it thus in fusion for a quarter of an hour, and then take the crucible out of the fire. It will contain a nitre alkalized by arsenic.
Of Vegetables.

Of the Substances obtained from Vegetables by Expression only.

To express and separate the Juice of a Plant, containing its Essential Salt. The Crystalization of that Salt.

Before sun-rise, gather a good quantity of the plant, from which you design to express the juice, in order to obtain its salt. Wash it well in running water, to clear it of earth, insects, and other adventitious matters. Bruise it in a marble mortar; put it into a bag of new, strong, thick linen cloth; tie the bag tight, and commit it to a press. By pressing it strongly you will squeeze out a great quantity of green, thick juice, which will have the same tafte as the plant. Dilute this juice with six times as much pure rain water, and filter it repeatedly through a woolen bag, till it passes clear and limpid. Evaporate the filtered juice with a gentle heat, till it be almost as thick as before it was mixed with water. Put this infpiflated juice into a jar, or other vessel of earth or glass; on its surface pour olive oil to the depth of a line, and let it in a cellar. Seven or eight months after this pour off gently the liquor contained in the vessel, the infide of which you will find covered with a crystallized salt. Separate the crystals gently; wash them quickly with a little fair cold water, and dry them: this is the essential oil of the plant.

Every plant is not equally disposed to yield its essential salt by the method here proposed. Succulent vegetables only, whose juices are aqueous and not too viscid, are fit for this purpose. Such, for example, as forrel, brook-lime, fuccory, fumitory, water-cress, plantain, &c. An essential salt cannot be procured from those that yield thick, viscid, mucilaginous juices, such as the seeds of rice-wort, unless their juices be previously attenuated by fermentation, and that viscidity destroyed which obstructs the crystalization of this salt.

Nor can the essential salt be obtained in any quantity from vegetable matters abounding in oil. Most kernels and seeds are of this sort: they all contain a great quantity of fat oil, which so entangles and clogs this salt, that the particles thereof cannot shoot away from the tenacious juices into crystals.

The fame is to be said of dry aromatic plants; because they contain much essential oil, or refrinous matters that produce the same effect. It is true, the essential salt itself contains a certain portion of oil; for it is no other than the acid of the plant incorporated and crystallized with part of its oil and of its earth; but then the oil must not be in too great a quantity; because it thickens the acid, renders it clammy, as it were, and binds it from extricating itself so as to be able to exert its qualities, and appear in the form of salt.

The juice of plants obtained by expression is very thick; because it contains many particles of the bruised plant that are unavoidably squeezed out along with it. In order to clear it of these superfluous parts it is proper to filter it: but as that would be difficult, on account of the thicken of the juice, it must be thinned, by diluting it with a quantity of water, sufficient to give it the requisite degree of fluidity.

Instead of thus diluting the expressed juice, the plant may be ground with water before it is put into the press: it will by this means furnish a more fluid juice, that will easily pass through the filter. This method may be employed with success on dry plants, or such as are not very succulent. For this operation rain-water is to be preferred to any other; because it is the purest.

The juice of the plant, when diluted with the quantity of water sufficient to facilitate its filtration, is too aqueous to let the salt it contains unite into crystals: It must therefore be evaporated till it hath recovered a somewhat thicker consistence. The heat applied for that purpose must be gentle; left the acid and oily parts that are to form the salt, be spoiled or dissolved, as they are not very fixed.

The oil poured on the liquor prevents its fermenting, putrefying, or growing mouldy, during the long space of time required for the crystalization of the essential salt. These salts are excellent medicines, being endowed with the same virtues as the plants from which they were obtained.

To draw the Oils out of Kernels, Seeds, and Fruits, by Expression.

Pour in a marble mortar, or grind in a mill, the kernels, seeds, or fruits, out of which you intend to express the oil. If your matters be meagre, and grind to meal, suspend that meal in the steam of boiling water, in order to moisten it a little, and then dry it.

Tie up your matters thus prepared in a new, strong, thick canvass bag, and put it into a press, between two iron plates previously heated in boiling water: squeeze it strongly, and you will see the oil run in streams into the receiving vessel.

To draw the Essential Oil of certain Fruits by Expression.

Take the rind of a citron, lemon, orange, Bergamot-pear, or other fruit of that kind; cut it in slices, and doubling the slices squeeze them between your fingers over a polished glass set upright, with its lower end in a vessel of earth or porcelain. Every time you squeeze the peel in a new ply, there will squirt out of it several fine jets of liquor, which, meeting with the surface of the glass, will be condensed into drops, and trickle down in small streams into the recipient. This liquor is the essential oil of the fruit.

Of the Substances obtained from Vegetables by Trituration.

To make the Extracts of a Plant by Trituration.

Bruise the vegetable substance of which you intend to make the extracts; or, if it be hard and dry, grind it to a powder; put the matter thus prepared, together with seven or eight times as much rain-water, into an earthen vessel; and into this vessel fit a churning staff, so that
that it may be continually whirled round with a rotatory
motion, by means of a cord, a wheel, and a winch. 
Ply this machine for ten or twelve hours; and then filter
the liquor through two linen cloths spread on a hair-
sieve. Let your filtered liquor stand quiet for twelve
hours more: Then pour it off by inclination from the
sediment you will find at bottom; and filter it a second
five hours. Let your filtered liquor ftand quiet for twelve
hours more: Then pour it off by inclination from the
time through a flannel bag.

motion, by means of a cord, a wheel, and a winch.
that it may be continually whirled round with a rdtatory
motion, by means of a cord, a wheel, and a winch.

To extrall from Seeds and Kernels, by Trituration, the
Matter of Emulsions.
BLANCH the kernels of which you desire to make an
emulsion; put them into a marble mortar; add a ve-
ry little water; and pound them with a wooden pelle.
Continue pounding and triturating till the matter become
like a white pate. From time to time pour on it, by
little and little, more fair water warmed, still continuing
the trituration; by which means the pate will grow
thinner. Go on thus till every particle of your kernels
be crushed to pap. Then add, still rubbing the mix-
ture, enough of water to make the whole an actual fluid;
and you will have a liquor of a dead-white colour, re-
fembling milk. Strain it through a clean linen cloth :
it will leave on the filter some coarse parts, which must
be returned to those left in the mortar. Again triturate
and rub the remainder of the kernels, with the addition
of water as before. This second liquor will not be so
white nor so rich as the former: filter it in the same
manner, and again grind with water the solid parts re-
maining. In this manner proceed, repeatedly rubbing
and adding fresh water, till it appear no longer milky,
but come off clear. The white milky waters thus ob-
tained go by the name of an emulsion.

All the matters, from which a fat oil is obtainable
by expression, produce emulsions when triturated with
water.

An emulsion consists chiefly of two substances. One
of these is mucilaginous, and soluble in water. This
substance by itself would not give any milky appearance to
the emulsion, which, with it alone, would be limpid.
The other is a fat oil, which of itself is not soluble in
water; but being divided by the means of trituration in-
to very small globules, it is dispersed through the whole
liquor, and suspended therein by the aid of the mucila-
ginous part. It is this oily part that gives the emulsion
its dead-white milky colour; because it is not actually
dissolved in the water, but only diffused through it.

If oil be mixed with water in a phial, and the mixture
strongly shaken for some time, with a rapid and continued
motion, the oil will be divided into a vast number of lit-
tle globules, which intervening between the parts of
the water will destroy its transparency, and give it a dead-
white colour, like that of our emulsion. But, as the
oil is not so minutely divided by this means as by tritu-
rating the matters containing it; and again, there being
no mucilage in this liquor, as there is in emulsions, the
oil soon separates from the water when it is left at reft,
re-unites into round globules, and these joining together
rise to the surface of the liquor, which then recovers its
transparency.

The affair is not exactly the same with emulsions; but
something like it happens to them also. If they be left
to stand quiet in a long bottle, the liquor, which at first
appeared homogeneous, separates into two manifestly
different parts. The upper part retains itsdead-white
colour, but is thicker and more opaque; while the lower
part becomes perfectly transparent. This is the begin-
ning of an entire separation of the oil from the aqueous
parts. The former, being the lighter, ascends and gains
the upper part of the liquor; while the lower, being
freed from that which obstructed its transparency, re-
covers its proper limpidity: but the oily parts do not re-
unate into malles large enough to form one homogeneous
whole, with the appearance and limpidness of oil; their
being minutely divided and entangled in the mucilage im-
peding their natural tendency.

Emulsions first begin to spoil, as they grow old, not by
turning rancid and acrimonious like the fat oils drawn by
expression, but by turning four; which is owing to the
great quantity of mucilage they contain. As there is a
fat oil in their composition, they have the same virtues
with that sort of oil: but they are moreover increasat-
ing, cooling, and emollient; qualities which render them
extremely useful in acute and inflammatory disorders. They
grow four in a very short time, especially in the heat
of summer; nay, they sometimes do so in two hours:
and therefore they ought to be prepared from time to
time as they are to be used.

The matter that is left when all the substance of the
emulsion is extracted, and from which the water comes
off clear and limpid, is scarce anything but the earthly
part of the seed or kernel that was triturated; which,
however, still retains a portion of tenacious and gros
oil, adhering to it so firmly as not to be separable by
water.

The chyle and milk of animals resemble an emulsion
in several respects, and particularly in their dead-white
colour; which arises, in the same manner, from the very
minute particles of oil contained in them, and distributed
through an aqueous gelatinous fluid, but not dissolved
therein. In general, whenever any oil of any kind hap-
pens to be lodged in this manner between the parts of an
aqueous liquor, it always makes the whole of an opaque
white: for oil will not mix with water, so as to produce
a liquor that shall appear homogeneous and transparent,
unless it be intimately diffolved in the water; which
cannot be effected but by means of an union previously
contracted between it and some saline matter; as is the
case of mucilages, certain faponaceous matters, and some
other combinations of which we shall have occasion to
treat in the sequel.

The methods we have hitherto proposed, for extrac-
ting from vegetable substances all that they will yield
without
oil will be more and more attenuated, and, after being thus distilled twice or thrice with water, will be so limpid, so thin, and so clear, that you will scarce be able to distinguish it from water itself.

To combine Fat Oils with Acids.

Put any fat oil whatever into a glass basin, and set it in a sand-bath very moderately heated. Pour on this oil an equal quantity of concentrated oil of vitriol, which will immediately dissolve it with violence; a considerable ebullition and effervescence will arise, attended with great heat, and a prodigious quantity of black thick vapours, in which may be easily perceived the smell of burnt oil, together with that of a sulphureous acid. The mixture will become of a deep-red, black, and thick. Stir it with a small thistle, till you observe that all is quiet.

To combine Fat Oils with Fixed Alkalis. Hard and Soft Soap. The Decomposition of Soap.

Take a lixivium of Alicante kelp made more caustic by lime, as we shall shew when we come to speak of alkalis. Evaporate this lyce till it be capable of bearing a new-laid egg. Divide it into two parts; and to one of these put just water enough to weaken it so that a new laid egg will not swim in it, but fall to the bottom. With the lye thus weakened, mix an equal quantity of fresh-drawn olive oil. Stir and agitate the mixture well till it become very white. Set it over a gentle fire, and continue stirring it incessantly, that the two ingredients of which it is compounded may gradually combine together, as part of the water evaporates. When you perceive they begin to unite, pour into the mixture twice as much of the first strong lye as you took of olive oil. Continue the cocction with a gentle fire, always stirring the matter, till it become so thick that a drop of it fixes, as it cools, into the consistence that soap ought to have. By dissolving a little of this soap in water, you will discover whether or no it contains more oil than ought to be in the composition. If it dissolve therein wholly and perfectly, without the appearance of the least little drop of oil floating on the water, it is a sign that it doth not contain too much oil. If, on the contrary, you perceive any of these little globules, you must pour into the vessel containing your matter a little more of the strong lye, to absorb the redundant oil. If there be too much of the alkali, it may be discovered by the taffle. If the soap leave on your tongue the sensation of an alkaline salt, and produce an unrisurous savour, it is a sign that there is too much salt in proportion to the oil. In this case a little oil must be added to the mixture, to saturate the superabundant alkali. An excess in the quantity of alkali discovers itself likewise by the soap’s growing moist in the air, on being exposed to it for some time.

Fixed alkalis, even when resolved into a liquor, that is, when loaded with much water, unite easily with fat oils, as appears from the experiment just recited, and require but a moderate heat to perfect that union. This combination may even be completely effected without the aid of fire, and by the heat of the sun only, provided sufficient time be allowed for that purpose. It only requires the mixture of the oil and alkali to be kept five or

...
Soap may be decomposed either by distillation, or by mixing it with some substance that hath a greater affinity than oil with alkalis. We may decompose it by distillation, a phlegm, or transparent spirit, of a somewhat yellowish colour, first comes over. This liquor is the aqueous part of the soap, quickened by a little of its alkali, which gives it an acid taste. It is followed by a red oil, which at first is pretty thin and limpid, but thickens as the distillation advances, grows black, and has a very disagreeable empyreumatic smell. This oil is soluble in spirit of wine.

When the distillation is finisht, that is, when the retort being kept red hot for some time will discharge no more, there is left in it a saline mass; which is the alkali of the soap, crusted over with some of the most fixed parts of the oil, that are charred to a coal. This salt may be restored to the same degree of purity it had before its combination with the oil, by calcining it in a crucible with a naked fire, that may confume this burnt part of the oil, and reduce it to ashes.

It is plain, that the oil contained in soap is affected by distillation, much in the same manner as that which we mixed with lime and distilled.

Mr Geoffroy, by analysing soap with care, discovered that two ounces thereof contain ninety-six grains of salt of kelp, freed from all oil and moisture; or two drams and forty-eight grains of that salt, as it is used in manufacturing soap; that is, containing water enough to make it crystalline; one ounce three drams twenty grains of olive oil; and about two drams four grains of water.

As acids have a greater affinity than any other substance with alkalis, they may be very effectually employed to decompose soap.

If you propose to decompose soap by means thereof, you must first distil the oil into a sufficient quantity of water. Mr Geoffroy, who made this experiment likewise, distilled two ounces thereof in about three gallons of warm water, and to the solution added oil of vitriol, which he let fall into it drop by drop. Every time a drop of acid falls into it, a coagulum is formed in the liquor. The vessel in which the solution is contained must then be shaken, that the acid may equally attack all the alkali diffused in it. When no new coagulation is produced by a drop of the acid, it is a sign you have added enough. The liquor then begins to grow clear; and if another quart of water be added, in order to facilitate the separation of the oily particles, you will see them rise and unite together on the surface of the liquor.

This is a pure, clear, true olive oil, hath its taste, its smell, and, like it, is fluid in warm weather, and becomes fixed by cold. Yet it differs in some respects from that which never hath been united with an alkali in order to form a soap; for it burns more vividly and more rapidly, and is soluble in spirit of wine. We shall account for these differences when we come to treat of ardent spirits.

Not only the vitriolic acid, but all others, even those obtained from vegetables, are capable of decomposing soap, and separating the oil from the alkali. In the liquid wherein soap is thus decomposed, is found a neutral salt, confisting of the acid made use of, united with the alkali of the soap. If the vitriolic acid be used, you will have a Glauber's salt; a quadrangular nitre, if the nitrous acid be used; and so of the rest.

The facility with which acids decompose soap is the reason that no water, but what is very pure, will dissolve it, or is fit to be used in washing with it.

Water that doth not dissolve soap well is usually called hard water. Such waters contain a certain quantity of saline matters, washed out of the earths through which they pass. The hardness of water is generally occasioned by selenitic particles.

The hardness of most well-water is owing to a considerable quantity of selenitic gypsum with which the soil abounds. The selenites are neutral salts consisting of the vitriolic acid united with an earthy basis. If, therefore, soap be put into water in which a salt of this kind is dissolved,
solved, it is evident that the vitriolic acid in the felenites, having a greater affinity with the fixed alkali of the soap than with its own earthy basis, will quit the latter to unite with the former; and thus the soap will be decomposed instead of being dissolved. Accordingly we see, that, when we attempt to dissolve soap in our well-water, the surface of the liquor is in a short time covered with a fat oily pellicle. However, this decomposition of soap is not complete; at least but a small part of it is perfectly decocompounded; because the great quantity of felenites, with which the water is impregnated, hinders the soap from mixing so thoroughly with it, as is requisite to produce a total decomposition thereof.

All mineral waters are likewise hard, with regard to soap; for, as most of them owe their virtues to the effluencies they have washed off, from pyrites that have grown hot and begun to decompose, they are impregnated with the saline matters produced by pyrites in that state; that is, with aluminous, vitriolic, and fulphureous substan¬ces, which have the same effect on soap as the felenites hath.

Mineral waters containing neutral salts only, such as sea-salt, Epsom salt, Glauber's salt, are nevertheless hard with regard to soap, though the acids of those salts, being united with fixed alkalies, are incapable of decomposing it. The reason is, that those neutral salts are more soluble in water than soap is; so much indeed as even to exclude it: because each of the two principles that compose them hath a very great affinity with water; whereas only one of the principles of soap, namely, its alkali, hath that affinity; the other, viz. the oily principle, having none at all. Thus water impregnated with an acid, or with any neutral salt, is hard with regard to soap, and incapable of dissolving it; and hence it follows, that soap is a sort of touchstone for trying the purity of water.

Wine dissolves soap; but imperfectly, because it contains an acid or tarterous part. Spirit of wine also dissolves it; but neither is this dissolution perfect; because it contains too little water: for its spirituous part can dissolve nothing but the oil of the soap; and the alkali is not at all, or at least in a very small quantity, soluble in this menstruum. The true solvent of soap is therefore a liquor that is partly spirituous, partly aqueous, and not acid.

Brandy has these qualities: and accordingly it is the solvent that unites best with soap, dissolves the greatest quantity, and makes the most limpid solution thereof. Yet even this solution hath something of a milky cast, occasioned by its not being entirely free from an acid, or the tarterous principle. This fault may be easily corrected, by mixing with it a little alkali to absorb the acid. A dram of crystallised salt of kelp mixed with three ounces and a half of good brandy, renders it capable of dissolving an ounce and two drams of good hard soap into a perfectly limpid liquor. Some years ago it was discovered that soap might be used with great success in medicine, and that it possesses the property of dissolving the stony concretions that form in several parts of the body, particularly in the kidneys and bladder. Soap is the basis of the composition known by the name of Mrs Stephen's remedy; and in this one ingredient its whole virtue resides.

From what hath been said on the nature of this compound, as well as on the cause and phenomena of its dissolution, it plainly appears to be of the last consequence, in administering it to a patient, that his constitution be considered, and a proper regimen ordered. All acids should be absolutely forbid him; as we know they hinder the soap from dissolving, and decomposing it: and if the patient have any acridities in the first passages, matters capable of neutralizing them should be prescribed him; as prepared crabs eyes, and other absorbents known in medicine: in such cases those with which the soap is compounded in Mrs Stephen's remedy may be of use.

To combine Fat Oils with Sulphur.

Put any fat oil whatever into an earthen vessel; add to it about a fourth part of its weight of flower of sulphur, and set the vessel in a furnace, with lighted coals under it. When the oil hath acquired a certain degree of heat, the sulphur will melt, and you will see it fall immediately to the bottom of the oil, in the form of a very red fluid. The two substances will remain thus separated, without mixing together, while the heat is no greater than is necessary to keep the sulphur in fusion. Increase it therefore, but slowly, and with circumspection, lest the matter take fire. When the oil begins to smoke, the two liquors will begin to mix and look turbid: at last they will unite so as to appear one homogeneous whole. If you keep up the heat, so that the mixture shall always continue smoking and ready to boil, you may add more sulphur, which will perfectly incorporate with it; and thus may a pretty considerable quantity thereof be introduced into this composition.

To combine Fat Oils with Lead, and the Calxes of Lead.

The Basis of Plasters. The Decomposition of this Combination.

Into an earthen vessel put granulated lead, litharge, ceruse, or minium; and pour thereon twice its weight of any fat oil whatever. If you set the vessel over a brisk fire, the lead at bottom will melt before the oil begin to boil. When it boils, stir the matter with a flick: the lead, or the calx of lead, will gradually disappear, and at last be totally dissolved by the oil, to which it will give a very thick consistence.

Fat oils dissolve not only lead, but its calxes also: nay, they dissolve the latter more readily than lead in substance; probably because they are more divided. The result of a combination of these matters is a thick, tenacious mass, that grows in some degree hard in the cold, and soft by heat. This composition is known in pharmacy by the name of plaster. It is made up with several drugs into plasters, which partake of the virtues of those drugs; so that it is the basis of almost all plasters. Lead itself is seldom used to make plasters: ceruse, litharge, or minium, are preferred to it; because these matters unite more readily with oils.
Of the Substances obtained from Vegetables with a Degree of heat not exceeding that of boiling Water.

To obtain from Plants, by distilling them with the mean Degree of heat between freezing and boiling Water, a Liquor impregnated with their Principle of Odour.

In the morning, before sun-rise, gather the plant from which you design to extract its odoriferous water. Choose the plant in its full vigour, perfectly found, and free from all adventitious matters, except dew. Put this plant, without squeezing it, into the body of a tinned copper alembic, and set it in a water bath. Fix on its head, and to the nofe thereof lute a glass receiver with wet bladder.

Warm the bath to the mean degree between freezing and boiling water. You will see a liquor distil and fall drop by drop into the receiver. Continue the distillation with this degree of heat, till no more drops fall from the nose of the alembic. Then untie the vessels; and if you have not as much liquor as you want, take out of the cucumber the plant already distilled, and put a fresh one in its place. Distil as before, and go on thus till you have a sufficient quantity of odoriferous liquor. Put it into a bottle; stop it clofe; and let it in a cool place.

The liquor obtained from plants, with the degree of heat here prescribed, consists of the dew that was on the plant, and some of the phlegm of the plant itself, together with its odoriferous principle. Mr Boerhaave, who examined this odoriferous part of plants with great care, calls it the spiritus refior. The nature of this spirit is not yet thoroughly ascertained; because it is so very volatile, that it cannot easily be subjected to the experiments that are necessary to analyze it, and to discover all its properties. If the bottle containing the liquor, which may be considered as the vehicle of this spirit, be not exceeding carefully stopped, it flies quite off; so that in a few days nothing will be found but an insipid inodorous water.

Great part of the virtue of plants resides in this their principle of odour; and to it must be ascribed the most singular and the most wonderful effects we every day see produced by them. Every body knows that a great number of odoriferous plants affect, in a particular manner, by their scent only, the brain and the genus nervosum, of such especially whole nerves are very sensible, and susceptible of the slightest impression; such as hypochondriacal or melancholy men, and hysterical women. The smell of the tuberose, for instance, is capable of throwing such persons into fits, so as to make them drop down and swoon away. The smell of rue again, which is equally strong and penetrating, but of a different kind, is a specific remedy against the ill effects of the tuberose; and brings those persons to life again, with as quick and as surprizing an efficacy as that by which they were reduced to a state not unlike death. This is Mr Boerhaave's observation.
which matters are no other than fat oils in a fixed state. The cacao yields, by this means, a very mild butter; and in the same manner is a wax obtained from a certain shrub in America.

To extract the Essential Oils of Plants by distillation with the heat of boiling water. Distilled waters.

Put into a cucurbit the plant from which you design to extract the essential oil. Add as much water as will fill two thirds of your vessel, and dissolve therein half an ounce of sea-salt for every quart of water you use. To this body fit on an alembic-head, and to the nose thereof a receiver with fixed paper or wet bladder. Set it in a furnace, and let the whole digest together, in a very gentle warmth, for twenty-four hours.

This being done, light a wood-fire under your vessel, brisk enough to make the water in it boil immediately. Then flacken your fire, and leave it just strong enough to keep the water simmering. There will come over into the receiver a liquor of a whitish colour, somewhat milky; on the surface of which, or at the bottom, will be found an oil, which is the essential oil of the vegetable you put into the cucurbit. Continue your distillation with the same degree of heat, till you perceive the liquid come off clear, and unaccompanied with an oil.

When the distillation is finished, unlace the receiver; and, if the essential oil be of that sort that is lighter than water, fill the vessel up to the top with water. On this occasion a long-necked matras should be used for a receiver; that the oil which floats on the water may collect together, in a vessel, which, having little air, must be sealed up very tight. The distillation is then continued, till you perceive nothing more discharged.

To extract the Essential Oils of Plants by distillation per securum. Of a very tall cylindrical glass vessel, which is to do the office of a receiver in this distillation; and, by means of a piece of small pack-thread, fasten down the extremities of the cloth, by winding the thread several times over them and round the vessel; in such a manner, however, that the cloth be not tight, but may yield to a small weight, and sink about five or six lines deep into the vessel over which it is fastened. Set this recipient in a larger vessel, containing so much cold water as will reach half way up the cylindrical vessel, which, having little in it but air, must be ballasted with as much lead as will sink it to the bottom of the water.

On the cloth, containing the substance to be distilled, set a flat pan of iron or copper, about five or six lines deep, that may just fit the mouth of the glass vessel over which the cloth is fastened, so as to shut it quite close. Fill this pan with hot ashes, and on these lay some live coals. Soon after this you will see vapours descend from the cloth, which will fill the recipient, and drops of liquor will be formed on the under side of the cloth, whence they will fall into the vessel. Keep up an equal gentle heat, till you perceive nothing more discharged. Then uncover the recipient; you will find in it two distinct liquors; one of which is the phlegm, and the other the essential oil of the substance distilled.

Infusions, Decoctions, and Extracts of Plants.

Make some water boiling-hot, and then take it off the fire. When it ceases to boil, pour it on the plant of which you desire to have the infusion; taking care there be enough of it to cover the plant entirely. Cover the vessel, and let your plant lie in the hot water for the space of half an hour, or longer if it be of a firm clove texture. Then pour off the water by inclination: it will have partly acquired the colour, the smell, the taste, and the virtues of the plant. This liquor is called an infusion.

To make the decoction of a vegetable substance, put it into an earthen pan, or into a tinned copper vessel, with a quantity of water sufficient to bear being boiled for several hours without leaving any part of the plant dry. Boil your plant more or less according to its nature; and then pour off the water by inclination. This water is impregnated with several of the principles of the plant.

If the infusions and decoctions of plants be filtered, and evaporated in a gentle heat, they become extracts, that may be kept for whole years, especially if they be evaporated to a thick consistence; and better still if they be evaporated to dryness.

Of Operations on Essential Oils.

The Redistillation of Essential Oils.

Put into a cucurbit the essential oil you propose to rectify. Set the cucurbit in a balneum maris; fit to it a head of tin, or of copper tinned, together with its refrigeratory; and lute on a receiver. Make the water in the bath boil, and keep up this degree of heat till nothing more will come over. When the distillation is finished,
Sulphur, you will find in the receiver a rectified essential oil, which will be clearer, thinner, and better scented than before it was thus before re-distilled; and in the bottom of the cucurbit will be left a matter of a deeper colour, more tenacious, more refrinous, and of a less grateful smell.

Essential oils, even the purest, the best prepared, and the thinnest, suffer great changes, and are much impaired by growing old: they gradually turn thick and refrinous; their sweet, grateful scents is lost, and succeeded by a more disagreeable smell, somewhat like that of turpentine.

The cause of these changes is, that their finest and most volatile part, that which contains most of the odorous principle, is dissipated and separated from that which contains least of it, which therefore grows thicker, and comes so much the nearer to the nature of a resin, as the quantity of acid, that was distributed through the whole oil before the dissipation of the more volatile part, is, after such dissipation, united and concentrated in the heaviest part; the acid in oils being much less volatile than the odorous part, to which alone they owe their levity.

Hence it appears what precautions are to be used for preserving essential oils as long as possible without spoiling. * They must be kept in a bottle perfectly well stoppered, and always in a cool place, because heat quickly dissipates the volatile parts. Some authors direct the bottle to be kept under water.

To fire Oils by combining them with highly concentrated Acids: instanced in Oil of Turpentine.

Mix together in a glass equal parts of concentrated oil of vitriol, and highly smoking fresh-drawn spirit of nitre; pour this mixture at several times, but suddenly, on three parts of oil of turpentine, set for that purpose in a glass basin. By a part here must be understood a dram at least. A most violent commotion, accompanied with smoke, will immediately be raised in the liquors, and the whole will take fire in an instant, flame, and be consumed.

There is not in chemistry a phenomenon more extraordinary, and more surprising, than the firing of oils by mixing them with acids. It could never have been suspected, that a mixture of two cold liquors would produce a sudden, violent, bright, and lasting flame, like that we are at present considering.

To combine Essential Oils with fixed Alkalis. Starkey's Soap.

Take salt of tartar, or any other alkali, thoroughly calcined, heat it in a crucible till it be red, and in that condition throw it into a hot iron mortar: rub it quickly with a very hot iron pestle; and as soon as it is powdered, pour on it, little by little, nearly an equal quantity of oil of turpentine. The oil will enter into the salt, and unite intimately with it, so as to form a hard pale. Continue rubbing this composition with a pestle, in order to complete the union of the two substances; and, as your oil of turpentine disappears, add more, which will unite in the same manner, and give a foder consolence to the soapy mass. You may add still more oil, according to the confidence you intend to give your soap.

Starkey, the first chemist who found the means of making soap with an essential oil, and by whose name this kind of soap is therefore called, made use of a much more tedious method than that proposed in our process. He began with mixing a very small quantity of oil with his salt, and waited till all the oil united therewith of its own accord, so as to disappear entirely, before he added any more; and thus protracted his operation exceedingly, though in the main it was the same with ours. The method here proposed is more expeditious, and was invented by Dr. Geoffroy.

Starkey's soap dissolves in water much as common soap does, without any separation of the oil: and by this mark it is known to be well made. It may also be compounded, either by distillation, or by mixing it with an acid; and its decomposition, in either of these ways, is attended with nearly the same phenomena as the decomposition of common soap.

Of the Substances obtained from Vegetables by means of a graduated Heat, from that of boiling Water, to the strongest that can be applied to them in close Vessels.

To analyse Vegetable Substances that yield neither a Fat nor an Essential Oil. Infused in Guaiacum-wood.

Take thin shavings of Guaiacum-wood, and put them into a glass or stone retort, leaving one half thereof empty. Set your retort in a reverberating furnace, and lute on a large glass receiver having a small hole drilled in it, such as is used for distilling the mineral acids. Put a
live coal or two in the furnace, to warm the vessels gently and slowly.

With a degree of heat below that of boiling water, you will see drops of a clear infipid phlegm fall into the receiver. If you raise the fire a little, this water will come slightly acid, and begin to have a pungent smell.

With a degree of fire somewhat stronger, a water will continue to rise which will be full more acid, smell stronger, and become yellowish. When the heat comes to exceed that of boiling water, the phlegm that rises will be very acid, high coloured, have a strong pungent smell, like that of matters long smoked with wood in a chimney, and will be accompanied with a red, light oil, that will float on the liquor in the receiver.

And now it is necessary, that the operation be carried on very cautiously, and vent frequently given to the rarefied air by opening the small hole in the receiver; such an incredible quantity thereof rising out of the wood, with this degree of heat, as may burst the vessels to pieces, if not discharged from time to time.

When this red, light oil is come over, and the air ceases to rush out with impetuousity, raise your fire gradually, till the retort begin to redden. The receiver will be filled with denser vapours; and together with the watery liquor, which will then be extremely acid, there will rise a black, thick, ponderous oil, which will fall to the bottom of the receiver and lie under the liquor.

Then give the utmost degree of heat; that is, the greatest your furnace will allow, and your vessels bear. With this excessive heat a little more oil will rise, which will be very ponderous, as thick and black as pitch; and the vessels will continue full of vapours that will not condense.

At last, when you have kept the retort exceeding red for a long time in this extremity of heat, so that it begins to melt if it be of glass, and you perceive nothing more come over, let the fire go out and the vessels cool.

Then take off your receiver: from the black oil at bottom decant the acid liquor with the red oil floating on it, and pour them both into a glass funnel, lined with brown filtering paper, and placed over a bottle. The acid liquor will pass through the filter into the bottle, and the oil will be left behind, which must be kept by itself in a separate bottle. Lastly, into another funnel, prepared as the former, pour the thick oil remaining with a little of the acid liquor at the bottom of the receiver. This liquor will filter off in the same manner, and thus be separated from the heavy oil.

In the retort you will find your Guaiacum shavings not in the least altered as to their figure, but light, friable, very black, scentlefs and tasteless, easily taking fire, and consuming without flame or smoke: in short you will find them charred to a perfect coal.

Hitherto we have examined the substances that may be obtained from vegetables, either without the help of fire, or with a degree of heat not exceeding that of boiling water. The analysis of plants can be carried no further without a greater degree of heat: for, when the principle of odour and the essential oil of an aromatic plant are wholly extracted by the preceding processes, if the distillation be afterward continued without increasing the heat, nothing more will be obtained but a little acid; which will soon cease, as a small part only of the quantity contained in the plant will be elevated; the rest being either too ponderous, or too much entangled with the other principles of the body, to rise with so small a degree of heat.

In order therefore to carry on the decomposition of a plant, from which you have, by the methods before proposed, extracted all the principles it is capable of yielding when so treated; or, in order to analyze a vegetable matter, which affords neither an expressed nor an essential oil, it must be distilled in a retort with a naked fire, as directed in the processes, and be made to undergo all the degrees of heat successively, from that of boiling water to the highest that can be raised in a reverberating furnace.

A heat inferior to that of boiling water, with which we must begin in order to warm the vessels gradually, brings nothing over, but an infipid water, destitute of all acidity. By increasing it nearly to the degree of boiling water, the distilled water comes to be slightly acid.

When the heat is made a little stronger than that which is necessary for the elevation of an essential oil, the acidity of the water that comes off is much more considerable. It hath now both colour and smell, and there rises with it a red, light oil, that floats on the liquor in the receiver. This is not an essential oil; it hath none of the odour of the plant. Though so light as to float on water, yet it will not rise with the degree of heat that raises essential oils, even those that much surpass it in gravity, and will not swim on water as they do. This proves, that the ease or difficulty with which a particular degree of heat raises any substance in distillation doth not depend altogether on its gravity: its dilatability, or the volatile nature of the matters with which it is so closely united as not to be separated from them by distillation, may probably contribute greatly to produce this effect.

It is very surprising, that a substance so hard, so compact, so dry in appearance, as Guaiacum-wood, should yield such a large quantity of water by distillation; and it is equally so, that it should discharge so much air, and with so much impetuosity, as nothing but experience could render credible.

It hath been remarked, that the heaviest and most compact woods yield the most air in distillation; and accordingly Guaiacum-wood, as exceeding almost all others in hardness and weight, discharges a vast quantity of air when analyzed.

The thick, burnt, empyreumatic oil, that comes over last in this distillation, is heavier than water; on account, probably, of the great quantity of acid with which it is replete. The two kinds of oil obtained in this analysis may be rectified, by distilling them a second time, or rather several times; by which means they will become lighter and more fluid. In general, all thick, heavy oils confinently owe these qualities to an acid united with them; and it is by being freed from some of that acid in distillation, that they always acquire a greater
er degree of lightness and fluidity from that operation.

The analysis of a vegetable substance, shows what may be obtained from them when distilled in close vessels, with a graduated heat, from that of boiling water, to that which converts the mixt to a perfect coal; viz. phlegm, an acid, a light oil, much air, and a thick oil. But this analysis is far from being a complete one; it may be carried much farther, and made more perfect.

None of the principles obtained by this analysis are pure, simple, and thoroughly separated from the rest. They are still in some measure blended all together: their separation is but begun; and each requires a second and more accurate analysis, to reduce it to the greatest degree of purity of which it is capable. The oil and the acid chiefly merit so much pains.

A great deal of the acid of the plant remains, combined with the two sorts of oil here obtained; which we have reason to think differ no otherwise from one another, than as there is more or less acid united with each. The best way of freeing these oils from their redundant acid is to distill them frequently from alkalis and absorbents.

The acid is in the same circumstances nearly as the oil. The first that rises is mortified with much water, to which it owes a good deal of its volatility. That which comes over last is much more concentrated, and consequently heavier; yet it is still very aqueous. It might be freed in a great measure from this adventitious water, and so rendered much stronger; which would give us a better opportunity to discover its nature and properties, of which we know but very little.

Water is not the only heterogeneous substance that dilutes the vegetable acid; a pretty considerable quantity of the oil of the plant is also combined with it, and contaminates its purity. The proof of this is, that when these acids are kept, in the same condition in which they first come over, for any length of time, in a glass vessel, they gradually depoite, on the bottom and sides of the vessel, an oily incrustation, which grows thicker and thicker the longer it stands; and, as this oily matter separates from it, the acid liquor appears less unctuous and soponaceous.

A very good way to separate this oil more effectually from the acid is to combine the whole with absorbents, and abstract the oil again by distillation. By this means a very sensible quantity of oil may be separated that was not perceived before.

The fire, that is discharged with impetuosity in the operation, and must be let out, is loaded with many particles of acid and oil reduced to vapours, which it carries off; and by this means the quantity of the principles extracted from the mixt cannot be accurately determined: nor are the vapours, of which the vessels remain full after the operation, any other than particles of acid and oil, which the violence of the fire hath rarified exceedingly, and which do not easily condense.

If we distill in this manner a vegetable aromatic substance, which of course contains an essential oil, provided it hath not been previously extracted by the appropriated procets, this essential oil will rise first, as soon as the distilling vessel acquires the heat of boiling water; but its scent will not be so sweet or grateful, as if it were distilled in the manner before directed as properest for it. On the contrary, it will have an empyreumatic smell; because in this way it is impossible to avoid scorching, and half-burning some of the matter distilled; especially that part of it which touches the sides of the retort. Moreover, the very same equable degree of heat can hardly be kept up with a naked fire. The essential oil therefore, though it rises first, will not be pure, but contaminated with a mixture of the empyreumatic oil that first comes over, and will be confused therewith.

Molt vegetable substances, when distilled with a strong fire, yield the same principles with that which we have chosen for an instance. Entire plants of this kind, those from which the odorous principle, the essential oil, or the fat oil, hath been drawn, those of which extracts have been made by infusion or decoction, or the extracts themselves; all such matter being distilled yield a phlegm, an acid, a thin oil, air, and a thick oil; and the products of their several analyses differ from each other, only on account of the different quantity or proportion that each contains of the principles here enumerated.

But there are many other plants, which, besides these substances, yield also a considerable quantity of a volatile alkaline salt. This property is possessed chiefly by that tribe of plants which is distinguished by having cruciform flowers; among which there are some that, being analysed, greatly resemble animal-matters. We shall now analyse one of these; mustard-feed, for instance.

To analyse a Vegetable Substance which yields the same Principles as are obtained from Animal-matters: instanced in Mustard-feed.

With an apparatus like that of the preceding process, and with the same fire, distil mustard-feed. With a degree of heat, inferior to that of boiling water, there will come over a phlegm somewhat coloured, and impregnated with a volatile alkaline salt. This property is possessed chiefly by that tribe of plants which is distinguished by having cruciform flowers; among which there are some that, being analysed, greatly resemble animal-matters. We shall now analyse one of these; mustard-feed, for instance.

If the fire be gradually raised, there will come over a black thick oil, lighter however than water; and at the same time vapours will rise, and, condensing on the sides of the receiver, form into springs or ramifications. This is a volatile alkaline salt, in a concrete form, like that of animals, as we shall hereafter see. These vapours are much whiter than those of Guaiacum.

When you have thus drawn off, with a very strong fire, all the volatile alkaline and thick oil contained in the subject, there will be nothing left in the retort but a sort of coal, from which a small quantity of phosphorus may be obtained, provided the retort you employ for that purpose be good enough to stand a very violent heat.

Mustard-feed furnishes us with an instance of a vegetable, from which we obtain, by analysing it, the very same principles that animal-matters yield. Instead of
of getting an acid from it, we obtain only a volatile alkali.

We shall not here speak of the manner of separating and deputating the principles obtained by this process; but reserve it for the analysis of animals, which is absolutely the same. We shall content ourselves with observing, that the first volatile alkali, which rises at the beginning of the operation together with the phlegm, in a degree of heat below that of boiling water, differs from that which does not come over till towards the end of the distillation, when the last thick oil ascends. The different times, and different degrees of heat, in which these two alkaes rise, shew that the former exists actually and perfectly in the plant; but that the latter is generated during the distillation, and is the product of the fire, which combines together the materials whereof it is composed.

Vegetables, that thus yield a volatile alkali with a heat less than that of boiling water, irritate the organ of finelling, affecting it with a sensation of acrimony; and the effluvia, which rise from them when bruised, make the eyes smart so as to draw tears from them in abundance. Several of these matters, being only bruised, effervesce with acids: effects producible only by a very volatile, alkaline principle.

This is that alkali, the lightest of all the principles that can be extracted from bodies, which rises first in our distillation along with the phlegm, and with a degree of heat much inferior to that of boiling water. As the phlegm with which it rises is very copious, it is diffolved thereby; which is the reason it does not appear in a concrete form. To this water it gives a yellowish tinge, because it is impure and oily. The saline alkaline properties of this liquor have procured it the title of a volatile spirit. This volatile alkali, which exists naturally and perfectly formed in mustard-seed, onions, garlic, cresses, and other such vegetables, constitutes a difference between them and animal substances, which contain only the materials requisite to form a volatile alkali, but none really formed, unless they have undergone the putrid fermentation.

The second volatile alkali, which rises in our distillation, but not without a very strong degree of fire, and at the same time with the last thick oil, seems to be a production of the fire; for, if it were already formed in the mixt, as the other is, it would rise with the same heat, and at the same time, being equally volatile.

Of the Substances obtained from Vegetables by Combustion.

To procure a fixed Caustic Alkaline Salt from a Vegetable Substance, by burning it in the open Air.

Take any vegetable matter whatever; set it on fire, and let it burn in the open air till it be wholly reduced to ashes. On these ashes pour a quantity of boiling water sufficient to drench them thoroughly. Filter the liquor, in order to separate the earthy parts; and evaporate your lye to dryness, flirring it incessantly; and you will have a yellowish-white salt.

Put this salt in a crucible; set it in a melting furnace, and make a moderate fire, so as not to fuse the salt. It will turn first of a blue-grey colour, afterwards of a blue-green, and at last reddish. Put on the dome of the furnace; fill it with coals; make your fire strong enough to melt the salt, and keep it in fusion for an hour, or an hour and half. Then pour it into a heated metal mortar; pound it while it is red-hot; put it as soon as possible into a glass bottle, first made very hot and dry, and shut it up close with a glass stopple rubbed with cotton. By this means you will have the pure fixed alkali of the vegetable substance you burnt.

Burning a vegetable substance in the open air is a kind of violent and rapid analysis made by fire, which separates, resolves, and decomposes several of its principles.

When any wood or plant is laid on a quick fire, there ascends from it immediately an aqueous smoke, which consists of little more than phlegm; but this smoke soon becomes thicker and blacker; it is then pungent, draws tears from one's eyes, and excites a cough if drawn into the lungs with the breath. Those effects arise from its being replete with the acid, and some of the oil, of the vegetable converted into vapours. Soon after this the smoke grows exceeding black and thick; it is now full more acid, and the plant turns black. Its strongest acid and last thick oil are now discharged with impetuosity.

This rarefied oil being heated red-hot suddenly takes fire and flames. The vegetable burns and desagrates rapidly, till all its oil is consumed. Then the flame ceases; and nothing remains but a coal, like that found in a retort after all the principles of a plant have been extracted by the force of fire. But this coal having a free communication with the air, which is absolutely necessary to keep a combustible burning, continues to be red, sparkles, and waftes till all its phlogiston is dissipated and destroyed. After this nothing remains but the earth and fixed salt of the vegetable; which, mixed together, form what we call the ashes. Water, which is the natural solvent of salts, takes up everything of that kind that is contained in the ashes; so that by lixiviating them, as directed, all the salt is extracted, and nothing left but the pure earth of the mixt which is thus decomposed.

The phenomena observed in the burning of a vegetable substance, and the production thereby of a fixed alkali, seem to prove that this salt is the work of the fire; that it did not exist in the plant before it was burnt; that the plant only contained materials adapted to form this salt; and that this salt is no other than a combination of some of the acid, united with a portion of earth, by means of the igneous motion.

The alkali obtained from the ashes of burnt plants is not perfectly pure: it is contaminated with a small mixture of fatty matters, which were probably defended thereby against the action of the fire, and which render it somewhat saponaceous. In order to free it from this extraneous matter, and to render it very caustic, it must be calcined a long time in a crucible, but without melting it at first; because it is with this salt as with most metallic matters, which are sooner and more easily deprived of their phlogiston by being calcined without melting, provided they be comminuted into small particles, than when they are in fusion; all melted matters having but
a small surface exposed to the air, by the contact of which the evaporation of any thing whatever is exceedingly promoted.

To procure the fixed Salt of a Plant, by burning it after the manner of Tachenius.

Into an iron pot put the plant whose salt you desire to obtain in the manner of Tachenius, and set it over a fire, strong enough to make its bottom red-hot; at the same time cover your plant with a plate of iron, that may be immediately upon it in the pot. The plant will grow black, and smoke considerably; but will not flame, because it hath not a sufficient communication with the air. The black smoke only will escape through the interstice left between the side of the pot and the rim of the plate; which, for that purpose, should be made so as not to fit exactly into the pot. From time to time take up the iron plate, stir the plant, and cover it again immediately, to prevent its taking fire, or to smother it if it should happen to flame: go on thus till the black smoke ceases.

Then take off the iron plate: the upper part of the half-burnt plant will take fire as soon as the air is admitted, consume gradually, and be reduced to a white ash. Stir your matter with an iron wire, that the unburnt plant will take fire as soon as the air is admitted.

Your ashes being thus prepared, lixiviate them with seven times their quantity of water, made to simmer over the fire, and keep stirring it with an iron ladle. When all the humidity is evaporated, you will have a salt of a darkish colour and alkaline nature; which you may melt in a crucible, and mould into cakes.

To render Fixed Alkalis very caustic by means of Lime.

The Caustic Stone.

Take a lump of newly burnt quick-lime, that hath not yet begun to flake in the air: put it into a stone pan, and cover it with twice its weight of the unwashed ashes of some plant that are full of the salt you design to render caustic. Pour on them a great quantity of hot water; let them steep in it five or six hours, and then boil them gently. Filter the liquor, and evaporate it in an iron pot, stirring it incessantly towards the end, lest the matter, when it grows stiff, should adhere too closely to the vessel. When all the humidity is evaporated, you will have a salt of a darkish colour and alkaline nature; which you may melt in a crucible, and mould into cakes. This is the fixed salt of plants, prepared in the manner of Tachenius.

The Analysis of Soot.

Take wood-foot from a chimney under which no animal matter hath been dress'd or burnt; put it into a glass retort set in a reverberating furnace; let on a receiver, and begin to distil with a degree of heat somewhat less than that of boiling water. A considerable quantity of limpid phlegm will come over. Keep the fire in the same degree as long as any of this phlegm rises, but increase it when the drops begin to come flow; and then there will accend a good deal of a milky water. When this water ceases to run, change the receiver, and increase your fire a little: a yellow volatile salt will rise, and stick to the sides of the receiver. The fire ought now to be very fierce, and, if so, will force up at the same time a very thick black oil. Let the vessels cool: you will find a saline matter risen into the neck of the retort, which could not pass over into the receiver: in the bottom of the retort will be a caput mortuum, or black charred substance, the upper part of which will be crusted over with a saline matter, like that in the neck of the retort.

As we are at present inquiring into the nature of vegetables only, it is evidently necessary that we chuse a foot produced by burning vegetables alone. Soot, though dry in appearance, contains nevertheless much humidity, as appears from this analysis: seeing there comes over at first a considerable quantity of phlegm, that doth not seem to be impregnated with any principle, except perhaps an extremely subtle, saline, and oily matter, that communicates to it a disagreeable smell, from which it cannot by any means be entirely freed.

The volatile alkali obtained from foot is, in a double respect, the product of the fire. In the first place, though it derives its origin wholly from wood, or other vegetables, which, when distilled in close vessels, yield no volatile alkali at all, yet it produces such a salt when analysed in the present manner: whence it must be inferred, that the principles of those vegetables are metamorphosed into a volatile alkali, by being burnt in the open air, and sublimed in the form of foot. Secondly, though foot, when analysed, yields a great deal of this salt, yet this salt doth not formally pre-exist therein; for it doth not rise till after the phlegm, nor without a very considerable degree of heat: therefore foot contains only the materials necessary to form this salt; therefore the perfect combination of this salt requires that the force of fire be applied a second time; therefore it is, as was said, doubly the product of the fire.

The saline matter which we find sublimed into the neck of the retort, and that also forms the crust that covers the caput mortuum of the foot, appears by all chemical trials to be an ammoniacal salt; that is, a neutral salt, consisting of an acid and a volatile alkali. This ammoniacal salt rises only into the neck of the retort, and doth not come over into the receiver; because it is but semi-volatile. We shall treat more at large of the production
production of a volatile alkali, and of this ammoniacal
salt, when we come to the analysis of animals, and the
article of salt ammoniac.

The Analysis of some particular Substances be-
longing to the Vegetable Kingdom.

Analysis of the natural Balsams : instanced in Tur-
pentine.

Into a cucurbit put as much rain-water as will fill
about a fourth part of its cavity, and pour into it the
turpentine you intend to analyse. Cover the cucurbit
with its head, and lute it on with slips of sized paper
or wet bladder. Set your alembic in a sand-heat; lute
on a long-necked receiver; and give a gradual fire till
the water in the cucurbit boil. There will come over
into the receiver a good deal of phlegm, which, by little
and little, will become more and more acid; and at the
same time there will rise a great quantity of an aethereal
oil, extremely light, fluid, and as limpid and colourless
as water.

When you observe that no more oil comes off, unlute
your vessels; and in the receiver you will find an acidu-
lated water, and the aethereal oil floating on it. These
two liquors may be easily separated from each other, by
means of a glass funnel.

In the cucurbit will be left some of the water you put
in, together with the remainder of your turpentine;
which, when cold, instead of being fluid, as it was before
distillation, will be solid, and of the consistency of a resin,
and is then called rosin.

Put this residuum into a glass retort, and distill it in a
reverbatory with a naked fire, gradually increased ac-
cording to the general rule for all distillations. At first,
with a degree of heat a little greater than that of boiling
water, you will see two liquors come over into the recip-
ient; one of which will be aqueous and acid, the other
will be a transparent, limpid, yellowish oil, floating on
the acid liquor.

Continue your distillation, increasing your fire from
time to time, by slow degrees. These two liquors will
continue to come off together; and the nearer the op-
eration draws to its end, the more acid will the aqueous
liquor become, and the thicker and deeper coloured will
the oil grow. At last the oil will be very thick, and of
a deep reddish-yellow colour. When nothing more a-
cends, unlute your vessels; in the retort you will find
only a very small quantity of a charred, light, friable
substance.

All natural balsams, as well as turpentine, are oily,
aromatic matters, which flow in great quantities from
the trees containing them, either spontaneously, or thro'
incisions made on purpose. As these matters have a
strong scent, it is not surprizing that they should greatly
abound with effential oils. They may even be con-
idered as effential oils, that naturally, and of their own
accord, separate from the vegetables in which they exist.

Natural balsams, and effential oils grown thick with
age, are exactly one and the same thing. Accordingly
we see that fire and distillation produce the same effects
on both. The rectification of an effential oil, thicken-
ened by keeping, is nothing but a decomposition thereof,
by separating, with the heat of boiling water, all those
parts that are light enough to rise with that degree of
heat, from what is so loaded with acid as to remain fixed
therein.

The newer natural balsams are, the thinner they are,
and the more effential oil do they yield; and this effen-
tial oil, like all others, grows thick in time, and at last
turns again to an actual balsam.

These balsams, by being long exposed to the heat of
the sun, acquire such a consistence as to become solid.
They then take another name, and are called resins.
Resins yield much less effential oil when distilled, than
balsams do. Hence it follows, that resins are to balsams,
what balsams are to effential oils.

The Analysis of Resins : instanced in Benjamin. The
Flowers and Oil of Benjamin.

Into a pretty deep earthen pot, having a border or
rim round its mouth, put the benjamin you intend to a-
alyse. Cover the pot with a large conical cap of very
thick white paper, and tie it on under the rim. Set your
pot in a sand-bath, and warm it gently till the benjamin
melt. Conserve the heat in this degree for an hour and
half. Then untie the paper cap and take it off, shaking
it as little as possible. You will find all the inside of the
cap covered with a great quantity of beautiful, white,
shining flowers, in the form of little needles. Brush them
off gently with a feather, put them into a bottle, and
flop it close.

As soon as you take off the first cap, cover your pot
immediately with a second like the former. In this man-
ner go on till you perceive the flowers begin to grow
yellowish; and then it is proper to distil.

The matter left in the pot will be blackish and friable
when cold. Pulverize it; mix it with sand; and distill
it in a glass retort with a graduated heat. There will
come over a light oil, of a fragrant scent, but in very
small quantity; a little of an acid liquor, and a great
quantity of a red thick oil. There will be left in the
retort a charred, spungy substance.

Of the Nature and Properties of Camphor.

We do not propose to give an analysis of this singular
body; because hitherto there is no process known in
chemistry by which it can be decomposed. We shall
therefore content ourselves with reciting its principal
properties, and making a few reflections on its nature.

Camphor is an oily concrete substance; a kind of re-
sin, brought to us from the island of Borneo, but chiefly
from Japan. This substance resembles resins, in being
inflammable, and burning much as they do; it is not fo
soluble in water, but diffolves entirely and perfectly in spi-
rit of wine; it is easily separated again from this me-
strum, as all other oily matters are, by the addition of
water; it diffolves both in expressed and in distilled oils;
it hath a very strong aromatic smell. These are the
chief
chief properties which camphor possesses in common with resins: but in other respects it differs totally from them; especially in the following particulars.

Camphor takes fire and flames with vastly more ease than any other resin. It is so very volatile, that it vanishes entirely in the air, without any other heat than that of the atmosphere. In distillation it rises entire, without any decomposition, or even the least alteration. It dissolves in concentrated mineral acids; but with circumstances very different from those that attend other oily or resinous substances. The dissolution is accompanied with no effervescence, no sensible heat; and consequently can produce no inflammation. Acids do not turn black, or thicken it, as they do other oily matters: on the contrary, it becomes fluid, and runs with them into a liquor that looks like oil.

Camphor doth not, like other oily matters, acquire a disposition to dissolve in water by the union it contracts with acids; though its union with them seems to be more intimate than that of many oily matters with the same acids. On the contrary, if a combination of camphor and an acid be diluted with water, these two substances instantly separate from each other: the acid unites with the water, and the camphor, being entirely disengaged from it, swims on the surface of the liquor. Neither volatile alkaüs, nor the most caustic fixed alkalis, can be brought into union with it; for it always eludes their power.

Notwithstanding these wide differences between camphor and all other oily and resinous substances, the rule, that acids thicken oils, seems to be so universal, and so constantly observed by nature, that we cannot help thinking this substance, like all the rest, is an oil thickened by an acid. But what oil? what acid? and how are they united? This is a subject for very curious inquiries.

With a yellow oil drawn from wine, and an acid vinous spirit, Mr. Hellas made a kind of artificial camphor: a substance having the odour, favour, and inflammability of camphor; an imperfect camphor. True camphor hath the lability, the volatility, and the inflammability of ether. Can it be a substance of the same nature with ether, a kind of solid ether, an ether in a concrete form?

The Analysis of Bitumens insinuated in Amber. The Volatile Salt and Oil of Amber.

Into a glass retort put some small bits of amber, so as to fill but two thirds of the vessel. Set your retort in a furnace covered with its dome; fit on a large glass receiver; and beginning with a very gentle heat, distill with degrees of fire. Some phlegm will first come off, which will gradually grow more acid, and be succeeded by a volatile salt, figured like fine needles, that will stick to the sides of the receiver.

Keep the fire up to this degree, in order to drive over all the salt. When you perceive that little or none rises, change the receiver, and increase your fire a little. A light, clear, limpid oil will ascend. As the distillation advances, this oil will grow higher coloured, less limpid, and thicker; till at last it will be opaque, black, and have the consistence of turpentine.

When you perceive that, though the retort be red-hot, nothing more comes off, let the fire go out. You will have in the retort a black, light, spongy coal. If you have taken care to shift the receiver, from time to time, during the distillation of your oil, you will have sandy separate portions thereof, each of which will have a different degree of tenuity or thickness, according as it came over at the beginning, or towards the end of the distillation.

The substance of which we have here given the analysis, together with all others of the same, that is, of the bituminous kind, is, by most chemists and naturalists, classed with minerals: and so far they are right, that we actually get these mixts, like other minerals, out of the bowels of the earth, and never procure them immediately from any vegetable or animal compound. Yet we have our reasons for acting otherwise, and for thinking that we could not, in this work, place them better, than immediately after those vegetable substances which we call resins.

Several motives determine us to proceed in this manner. The analysis of bitumens demonstrates, that, with regard to the principles of which they consist, they are totally different from every other kind of mineral; and that, on the contrary, they greatly resemble vegetable resins in almost every respect. In short, though they are not immediately procured from vegetables, there is the greatest reason for believing that they were originally of the vegetable kingdom, and that they are no other than resins and oily parts of trees or plants, which, by lying long in the earth, and there contracting an union with the mineral acids, have acquired the qualities that distinguish them from resins.

Mineralogists know very well that we find, every where in the earth, many vegetable substances, that have lain very long buried under it, and frequently at a considerable depth. It is not uncommon to find, under ground, vast beds of fossil trees, which seem to be the remains of immense forests: and bitumens, particularly amber, are often found among this subterraneous wood.

These considerations, joined to proofs drawn from their analysis, make this opinion more than probable; nor are we singular in maintaining it, as it is adopted by many able modern chemists.

The analysis of amber, above described, may serve as a general specimen of the decomposition of other bitumens: with this single difference, that amber is the only one among them which yields the volatile salt aforesaid; and this determined us to examine it preferably to any other. As for the ret, they all yield a phlegm, an acid liquor, and an oil; which is thin at first, but grows thicker and thicker as the distillation draws towards an end. It must be understood, however, that these acids and thefe oils may differ, according to the nature of the bitumens from which they are drawn: just as the phlegm, the acid, and the oil, resulting from the decomposition of resins, differ in quantity and quality, according to the nature of the resins from which they are procured.

The
The principal differences observed between resins and bitumens are these: the latter are less soluble in spirit of wine; have a peculiar scent, which cannot be accurately described, and of which the feme of smelling only can judge; and their acid is stronger and more fixed. This last property is one of the motives which induce us to think, that besides the vegetable acid, originally combined with the resinous or oily matter now become a bitumen, a certain quantity of mineral acid hath, in a course of time; been superadded to constitute this mixt. We shall presently see that the fact is certainly fo, in the cafe of amber at least.

The Analysis of Bees-wax.

Melt the wax you intend to analyse, and mix with it as much fine sand as will make it into a stiff paste. Put this paste in little bits into a retort, and distil as usual, with a graduated fire, beginning with a very gentle heat. An acid phlegm will come over, and be followed by a liquor which at first will look like an oil, but will soon congeal in the receiver, and have the appearance of a butter or grease. Continue the distillation, increasing the fire by infensible degrees, till nothing more will come off. Then separate the butter from the acid phlegm in the receiver, mix it with fresh sand, and distil it again just as you did the wax before. Some acid phlegm will still come off, and an oil will ascend, which will not fix in the receiver, though it be still thick. Continue the distillation, with a fire so governed that the drops may succeed each other at the distance of six or seven seconds of time. Do not increase it, till you perceive the drops fall more slowly; and then increase it no more than is necessary to make the drops follow each other as above directed. When the distillation is finished, you will find in the receiver the oil come wholly over, and a little acid phlegm. Separate the oil from this liquor; and, if you desire to have it more fluid, redistil it a third time in the same manner.

The Saccharine Juices of Plants analysed: instanced in Honey.

Put into a stone cucurbit the honey you intend to distil; set it in a moderate sand-heat, and evaporate the greatest part of its humidity, till you perceive the phlegm to be acid. Then take out the matter remaining in the cucurbit, put it into a retort, leaving a full third thereof empty, and distil in a reverberatory with degrees of fire. An acid amber-coloured liquor will come over. As the operation advances, this liquor will continually become deeper coloured and more acid, and at the same time a little black oil will ascend. When the distillation is over, you will find in the retort a pretty large charred mass, which being burnt in the open air, and lixiviated, affords a fixed alkali.

Sugar, manna, and the saccharine juices of fruits and plants, are of the same nature as honey, yield the same principles, and in the same proportions. All these substances must be considered as native soaps; because they consist of an oil rendered miscible with water, by means of a fatty substance. They differ from the common artificial soaps in several respects; but chiefly in this, that their fatty part is an acid, whereas that of common soap is an alkali. The natural soaps are not for that reason the less perfect: on the contrary, they dissolve in water without destroying its transparency, and without giving it a milky colour; which proves, that acids are not less proper than alkalis, or rather that they are more proper additaments, for bringing oils into a sapid state.

Gummy Substances analysed: instanced in Gum Arabic.

Distil gum arabic in a retort with degrees of fire. A limpid, scentless, and tasteless phlegm will first come over; and then a rufset coloured acid liquor, a little volatile alkali, and an oil, which will first be thin and afterwards grow thick. In the retort will be left a good part of its humidity, till you perceive the phlegm at last; set it in a moderate sand-heat, and evaporate the gummy substance, which, being burnt and lixiviated, will give a fixed alkali.

Gums have at first light some resemblance of resins; which hath occasioned many resinous matters to be called gums, though very improperly: for they are two distinct sorts of substances, of natures absolutely different from each other. It hath been shewn, that resins have an aromatic odour; that they are indissoluble in water, and soluble in spirit of wine; that they are only an essential oil grown thick. Gums, on the contrary, have no odour, are soluble in water, indissoluble in spirit of wine, and, by being analysed as in the process, are converted almost wholly into a phlegm, and an acid. The small portion of oil contained in them is so thoroughly united with their acid, that it dissolves perfectly in water, and the solution is clear and limpid. In this respect gums resemble honey, and the other vegetable juices analogous to it. They are all fluid originally; that is, when they begin to ooze out of their trees. At that time they perfectly resemble mucilages, or rather they are actual mucilages, which grow thick and hard in time by the evaporation of a great part of their moisture: just as resins are true oils, which, losing their most fluid parts by evaporation, at last become solid. Infusions or light decoctions of mucilaginous plants, when evaporated to dryness, become actual gums.

Some trees abound both in oil and in mucilage: these two substances often mix and flow from the tree blended together. Thus they both grow dry and hard together in one mass, which of course is at the same time both gummy and resinous: and accordingly such mixts are named gum resins.

Of Operations on Fermented Vegetable Substances.

Of the Product of Spirituous Fermentation.

To make Wine of Vegetable Substances that are susceptible of Spirituous Fermentation.

Let a liquor susceptible of, and prepared for, the spirituous fermentation, be put into a cask. Set this cask in a temperately warm cellar, and cover the bung-hole with a bit of linen cloth only. In more or less time, according to the nature of the liquor to be fermented,
and to the degree of heat in the air, the liquor will begin to swell, and be rarefied. There will arise an intertine motion, attended with a small hissing and effervescence, throwing up bubbles to the surface, and discharging vapours; while the gros, viscous, and thick parts, being driven up by the fermenting motion, and rendered lighter by little bubbles of air adhering to them, will rise to the top, and there form a kind of foft spongy crust, which will cover the liquor all over. The fermenting motion still continuing, this crust will, from time to time, be lifted up and cracked by vapours making their escape through it; but those suffures will presently close again, till, the fermentation gradually going off, and at last entirely ceasing, the crust will fall in pieces to the bottom of the liquor, which will infensibly grow clear. Then stop the cask close with its bung, and set it in a cooler place.

Matters that are susceptible of the spirituous fermentation are seldom so perfectly prepared for it by nature as they require to be. If we except the juices that flow naturally from certain trees, but oftener from incisions made on purpose in them, all other substances require some previous preparation.

Boerhaave divides the substances that are fit for spirituous fermentation into five classes. In the first he places all the meally seeds, the legumes, and the kernels of almost all fruits. The second class includes the juices of all fruits that do not tend to putrefaction; and consequentlly those which yield much volatile alkali are to be excluded. The fourth class comprehends the juices or saps that spontaneouslydiffil from several trees and plants, or flow from them when wounded. He forms his fifth and last class of the faponaceous, saccharine, and concrete or thick juices of vegetables. Resinous or purely gummy matters are excluded, as not being fermentable.

Thefe five classes may be reduced into two; one comprehending all the juices, and another all the meally parts of vegetables that are susceptible of fermentation. The juices want nothing to fit them for fermentation, but to be expressed out of the substances containing them, and to be diluted with a sufficient quantity of water. If they be very thick, the best way is to add so much water as shall render the mixed liquor just capable of bearing a new-laid egg. With respect to farinaceous substances, as they are almost all either oily or mucilaginous, they require a little more management. The method of brewing malt liquors will furnish us with examples of such management. See Brewing.

Besides the preparations relating chiefly to malt liquors, there are many other things to be observed relating to spirituous fermentation in general, and to all matters susceptible of that fermentation. For example; all grains and fruits designed for that fermentation must be perfectly ripe; for otherwise they will not ferment without difficulty, and will produce little or no inflammable spirit. Such matters as are too aulac, too acid, or astrangent, are for the same reason unfit for spirituous fermentation; as well as those which abound too much in oil.

In order to make the fermentation succeed perfectly, so as to produce the best wine that the fermented liquor is capable of affording, it is necessary to let it stand quiet without stirring it, left the crust that forms on its surface should be broken to little fragments, and mix with the liquor. This crust is a kind of cover, which hinders the spirituous parts from exhaling as fast as they are formed. The free access of the air is another condition necessary to fermentation: and for this reason the vessel that contains the fermenting liquor must not be close stopped; the bung-hole is only to be covered with a linen clothe, to hinder dirt and insects from falling into it. Nor must the bung-hole be too large, lest too much of the spirituous parts should escape and be lost.

Lastly, a just degree of warmth is one of the conditions most necessary for fermentation: for in very cold weather there is no fermentation at all; and too much heat precipitates it in such a manner that the whole liquor becomes turbid, and many fermenting and fermented particles are dissolved.

If, notwithstanding the exact esteem of every particular requisite to excite a successful fermentation, the liquor cannot, without difficulty, be brought to effervece, which fearce ever happens but to malt-liquor, it may be accelerated by mixing therewith some matter that is very susceptible of fermentation, or actually fermenting. Such matters are called ferment. The crust that forms on the surface of fermenting liquors is a most efficacious ferment, and on that account very much used.

It sometimes happens, that there is occasion to check the fermentation excited in the liquor, before it ceases of itself. To effect this, such means must be used as are directly opposite to those mentioned above for promoting fermentation. The same end is obtained by mixing with the liquor a quantity of alkali, sufficient to absorb the acid contained therein; but this method is seldom made use of, because it spoils the liquor; which, after being thus treated, is incapable of any spirituous fermentation, but on the contrary will certainly putrefy.

Spirituous fermentation may also be stopped by mixing with the liquor a great quantity of some mineral acid. But this likewise alters its nature; because these acids, being fixed, always remain confounded therewith, and never separate from it.

The best method yet found out for checking this fermentation, without injury to the fermenting liquor, is to impregnate it with the fumes of burning sulphur. These fumes are known to be acid, and it is that quality in them which suspend the fermentation. But at the same time this acid is extremely volatile; so that it separates spontaneously from the liquor, after some time, and leaves it in a condition to continue its fermentation.

For this reason, when a wine is desired that shall be but half fermented, and shall partly retain the sweet taste it had in the state of must, (the proper name for the unfermented juice of the grape,) it is put into casks in which sulphur hath been previously burnt, and the vapours thereof confined by stopping the bung-hole. These are called matched wines. If the same operation be performed on muft, its fermentation will be absolutely prevented; it will retain all its saccharine taste, and is then called
CHEMISTRY. 163

Spirit of Wine combined with different Substances.

To combine Spirit of Wine with the Vitriolic Acid. This Combination decompounded. Æther.

Into an English glass retort put two pounds of spirit of wine perfectly dephlegmated, and pour on it at once two pounds of highly concentrated oil of vitriol: shake the retort gently several times, in order to mix the two liquors. This will produce an ebullition, and considerable heat; vapours will ascend, with a pretty loud hissing noise, which will diffuse a very aromatic smell, and the mixture will be of a deeper or lighter red colour, according as the spirit of wine was more or less oily. Set the retort on a sand-bath made nearly as hot as the liquor; lute on a tubulated ballon, and diffil the mixture with a fire strong enough to keep the liquor always boiling; a very aromatic spirit of wine will first come over into the ballon, after which the æther will rise. When about five or six ounces of it are come off, you will see in the upper concavity of the retort a vast number of little points in a veined form, which will appear fixed, and which are nevertheless so many little drops of æther, rolling over one another, and trickling down into the receiver. These little points continue to appear and succeed each other to the end of the operation. Keep up the same degree of fire, till upon opening the little hole in the ballon you perceive that the vapours, which instantly fill the receiver, have the suffocating smell of volatile spirit of sulphur.

Then unlute the ballon, pour the liquor it contains into a crystal bottle, and stop it close: there will be about eighteen ounces of it. Lute on your receiver again, and continue the distillation with a greater degree of fire. There will come over an aqueous, acid liquor, smelling strong of a sulphureous spirit, which is not inflammable. It will be accompanied with undulating vapours; which being condensed will form an oil, most commonly yellow, one part of which will float on the surface of the liquor, and another will sink to the bottom.

Towards the end of the distillation of this acid liquor, and of the yellow oil of which it is the vehicle, that part of the mixture, which is left in the retort and grown black, will begin to rise in froth. Then suppress your fire at once: flop the distillation, and change your receiver once more. When the vessels are grown pretty cool, finish your distillation with a lamp-heat kept up for twelve or fifteen days, which in all that time will raise but a very little sulphureous spirit. Then break your retort, in which you will find a black, solid mass, like a bitumen. It will have an acid taste, arising from a remainder of the acid imperfectly combined with oil.

This artificial bitumen may be freed from its redundant acid, by washing it in several waters. Then put it into a glass retort, and distil it with a strong reverberated fire. You will obtain a reddish oil that will swim on water, much like the oil obtained by distilling the natural bitumens.
bitumens. This oil also will be accompanied with an aqueous acid liquor. In the retort will be left a charred matter, which, being put into an ignited crucible in the fire, burns for some time, and, when well calcined, leaves a white earth.

The liquors that rise first in this distillation, and which we directed to be kept by themselves, are a mixture consisting, 1. of a highly dephlegmated spirit of wine, of a most fragrant smell; 2. of another, which the spirit of wine wherewith it is united renders miscible with water; 3. of a portion of oil, which commonly rises with the ether towards the end of the operation; 4. and sometimes of a little sulphureous acid, if the receiver be not changed soon enough.

In order to separate the ether from these other substances, put the whole into an English retort, with a little oil of tartar per deliquium to absorb the sulphureous acid, and distil very slowly in a sand-bath heated by a lamp, till near half the liquor be come over. Then cease distilling; put the liquor in the receiver into a phial with some water, and shake it; you will see it rise with rapidity to the upper part of the phial, and float on the surface of the water: this is the oil.

**Spirit of Wine combined with Spirit of Nitre.**

**Sweet Spirit of Nitre.**

Into an English retort of crystal glass put some highly rectified spirit of wine; and, by means of a glass funnel with a long pipe, let fall into your spirit of wine a few drops of the smoking spirit of nitre. There will arise in the retort an effervescence attended with heat, red vapours, and a hissing noise like that of a live coal quenched in water. Shake the vessel a little, that the liquors may mix thoroughly, and that the heat may be equally communicated to the whole. Then add more spirit of nitre, but in a very small quantity, and with the same precautions as before. Continue thus adding spirit of nitre, by little and little at a time, till you have put into the retort a quantity equal to a third part of your spirit of wine. Let this mixture stand quiet, in a cool place, for ten or twelve hours; then set it to digest in a very gentle warmth for eight or ten days, having first luted on a receiver to the retort.

During this time a small quantity of liquor will come over into the receiver, which must be poured back into the retort. Then distil with a somewhat stronger degree of heat, but still very gently, till nothing be left in the retort but a thick matter. In the receiver you will find a spirituous liquor, of a quick grateful smell, which will excite a very smart sensation on the tongue, but without any corrosive acrimony. This is the sweet spirit of nitre.

**Spirit of Wine combined with the Acid of Sea-salt.**

**Dulcified Spirit of Salt.**

Mix together, little by little, in a glass retort, two parts of spirit of wine with one part of spirit of salt. Set this mixture to digest for a month in a gentle heat, and distil it, till nothing remain in the retort but a thick matter.

The acid of sea-salt is much less disposed to unite with inflammable matters than the other two mineral acids; and therefore, though it be ever so highly concentrated when mixed with spirit of wine, it never produces effervescence comparable to that which is produced by the spirit of nitre. Neither the proportion nor strength of the spirit of salt, requisite to prepare the sweet spirit of salt, are unanimously agreed upon by authors. Some direct equal parts of the two liquors; while others prescribe from two to four or five parts of spirit of wine to one part of spirit of salt. Some use only common spirit of salt; others require the smoking spirit distilled by means of spirit of vitriol. Lastly, some order the mixture to be distilled, after some days digestion; and others content themselves with barely digesting it. The whole depends on the degree of strength which the sweet spirit of salt is intended to have. This composition, as well as the sweet spirit of nitre, is esteemed in medicine to be very aperitive and diuretic.

When the mixture of spirit of salt and spirit of wine is distilled, there comes over but one liquor, which appears homogeneous. This is the sweet spirit of salt. The nature of the marine acid is not changed in this combination: the acid is only weakened and rendered more mild; but in other respects it retains its characteristic properties.

**Oils, or Oily matters, that are soluble in Spirit of Wine, separated from Vegetables, and dissolved by means of that Menstruum.**

**Tinctures; Elixirs; Varnishes.**

Aromatic strong waters.

Put into a matras the substances from which you intend to extract a tincture, having first pounded them, or pulverized them if they are capable of it. Pour upon them spirit of wine to the depth of three fingers breadth. Cover the matras with a piece of wet bladder, and tie it on with packthread. Make a little hole in this bit of bladder with a pin, leaving it in the hole to keep it stopped. Set the matras in a sand-bath very gently heated. If the spirit of wine diffuse any part of the body, it will accordingly acquire a deeper or lighter colour. Continue the digestion till you perceive that the spirit of wine gains no more colour. From time to time pull out the pin, to give vent to the vapours, or rarefied air, which might otherwise burst the matras. Decant your spirit of wine, and keep it in a bottle well corked. Pour upon some fresh spirit in its stead: digest as before; and go on in this manner, pouring on and off fresh spirit of wine, till the last come off colourless.

**Spirit of wine impregnated with such parts of any vegetable substance as it is capable of dissolving, is commonly called a tincture.** Several tinctures mixed together, or a tincture drawn from sundry vegetable substances at the same time, and in the same vessel, take the name of an elixir. Tinctures of elixirs impregnated with refinorous matters only, are true varnishes. All these preparations are made in the same manner; to wit, as directed in our process. We shall only add here, that if the substances from which a tincture or elixir is to be made contain too much moiure, it is proper to free them from it by gentle decoction; especially if you design that the tincture should be well impregnated with the oily and refinorous
Of Tartar.

Tartar analysed by distillation. The Spirit, Oil, and Alkaline Salt of Tartar.

Into a stone retort, or a glass one coated with lute, put some white tartar broken into small bits; observing that one half, or at least a full third, of the vessel be left empty. Set your retort in a reverberating furnace. Fit on a large ballon, having a small hole drilled in it; lute it exactly with fat lute, and secure the joint with a linen cloth smeared with lute made of quick-lime and the white of an egg. Apply at first an exceeding gentle heat, which will raise a limpid, fpongy, pungent water, having but little smell, and a bitternith taste.

When this first phlegm ceases to come off, increase your fire a little, and make the degree of heat nearly equal to that of boiling water. A thin, limped oil will rise, accompanied with white vapours, and with a prodigious quantity of air, which will issue out with such impetuosity, that if you do not open the little hole in the receiver time enough to give it vent, it will burst the vessels with explosion. An acid liquor will rise at the same time. Continue the distillation, increasing the heat by insensible degrees, and frequently unitopping the little hole of the receiver, till the elastic vapours cease to issue, and the oil to diffil.

Then raise your fire more boldly. The acid spirit will continue to rife, and will be accompanied with a black, fetid, empyreumatic, ponderous, and very thick oil. Urge the fire to the utmost extremity, so that the retort may be of a perfect red heat. This violent fire will raise a little volatile alkali, besides a portion of oil as thick as pitch. When the distillation is finished, you will find in the retort a black, fetid, charred matter, which grows hot when wetted, attracts the moisture of the air, runs per deliquium, and hath all the properties of a fixed alkali.

Crystal of Tartar combined with several substances.

Crystal of Tartar combined with Absorbent Earths. Soluble Tar.tars.

Boil an absorbent earth, such as chalk, in a pan with water; and, when you perceive the earth thoroughly divided and equally distributed through the water, throw into the pan, from time to time, some powdered crys-tal of tartar, which will excite a considerable effervescence. Continue these projections, till you observe no effervescence excited thereby. All the absorbent earth, which obscured the transparency of the water, and gave it an opaque white colour, will gradually disperse as the crystal of tartar combines with it; and when the combination is perfected, the liquor will be clear and limpid. Then filter it, and there will be left on the filter a great quantity of a crystallised saline matter, which is crystal of tartar.

Crystal of Tartar combined with several substances.

Crystal of Tartar combined with Fixed Alkalies. The Vegetable Salt. Saignette’s Salt. The decomposition of Soluble Tartars.

In eight parts of water dissolve one part of a very pure alkaline salt, perfectly freed from the phlogiston by calcination. Heat this lixivium in a stone pan let on a sand-bath, and from time to time throw into it a little powdered cream or crystal of tartar. Each projection will excite a great effervescence, attended with many bubbles, which will rise to a considerable height, over the other. Stir the liquor when the effervescence ceases, and you will see it begin again.

The Depuration of Tartar. Cream and Crystals of Tartar.

Reduce to a fine powder the tartar you intend to purify, and boil it in twenty five or thirty times as much water. Filter the boiling liquor through a flannel bag, and then gently evaporate some part of it; there will soon form on its surface a saline crust, which is the cream of tartar. Let your liquor cool, and there will adhere to the sides of the vessel a great quantity of a crystallised saline matter, which is crystal of tartar.
When no effervescence appears upon stirring the liquor, add a little more cream of tartar, and the same phenomena will be renewed. Go on thus till you have obtained the point of perfect saturation.

Then filter your liquor. If the alkali you made use of was the salt of Soda, evaporate your liquor quickly to a pellicle, and there will shoot in it crysals of ninesides resembling a coffee; the bottom part thereof being concave, and streaked with a great many parallel lines; and this is Saignette's salt. If you have employed any other alkali but soda, or the bases of sea-salt, evaporate your liquor slowly to the consistence of a syrup; let it stand quiet, and there will form in it crysals having the figure of flattened parallelopipeds; and this is the vegetable salt, or tartarified tartar.

All soluble tarts are easily decomposed, by means of a certain degree of heat. They yield in distillation the same principles as tartar; and the alkali that remains, when they are perfectly calcined, consists of that which the tartar naturally affords, and of the alkaline matter with which it was converted into a neutral salt.

**Crystal of Tartar combined with Iron. Chalybeated Tartar. Tincture of Steel with Tartar. Soluble Chalybeated Tartar.**

Mix four ounces of iron in filings with one pound of white tartar finely pulverized. Boil the mixture in about twelve times as much water as you took of tartar. When the fatty part of the tartar is dissolved, filter the liquor boiling-hot through a flannel bag, and then set it in a cool place. In a very little time crystals of a ruflet colour will shoot therein. Decant the liquor from these crystals; evaporate it to a pellicle, and set it again to crystallize. Go on in this manner till it will shoot no more. Collect all the salt you have thus obtained, and keep it under the name of chalybeated tartar.

To make the tincture of steel with tartar, mix together six ounces of clean iron filings, and one pound of white tartar in powder. Put this mixture into a large iron kettle, and pour thereon as much rain-water as will moisten it. Make a paste of this matter, and leave it twelve hours at least, stirring the mixture frequently, and adding from time to time some hot water, to supply the place of what evaporates. When you have thus boiled the liquor, let it stand quiet for some time, and then pour it off from the sediment at bottom. Filter, and evaporate to the consistence of a syrup; and you have the tincture of Mars with tartar. The distillatories generally order an ounce of rectified spirit of wine to be poured on this tincture, in order to preserve it, and to keep it from growing mouldy, as it is very apt to do.

Soluble chalybeated tartar is prepared by mixing four ounces of tartarified tartar with one pound of the tincture of Mars with tartar, and evaporating them together in an iron vessel to drynesh; after which it is kept in a well stopped phial to prevent its growing moist in the air.

**Pulverize and mix together equal parts of the glas and of the liver of antimony. Put this mixture, with the same quantity of pulverified cream of tartar, into a vessel capable of containing as much water as will dissolve the cream of tartar. Boil the whole for twelve hours, from time to time adding warm water, to replace what is dissipated by evaporation. Having thus boiled your liquor, filter it while boiling hot; evaporate to dryness; and you will have a saline matter, which is emetic tartar.**

**Of the Product of Acetous Fermentation.**

**Substances susceptible of the Acetous Fermentation turned into Vinegar.**

The wine, the cyder, or the malt-liquor, you intend to convert into vinegar, being first thoroughly mixed with its lees, and with the tartar it may have deposited, put your liquor into a fat used before either for making or for holding vinegar. This vessel must not be quite full, and the external air must have access to the liquor contained in it. Set it where the air may have a degree of warmth answering nearly to the twentieth degree above o in Mr de Reaumur's thermometer. Stir the liquor from time to time. There will arise in it a new fermentative motion, accompanied with heat; its vinous odour will gradually change, and turn to a four smell, which will become stronger and stronger till the fermentation be finished and cease of itself. Then stop your vessel close; the liquor it contains will be found converted into vinegar.

All substances that have undergone the spirituous fermentation are capable of being changed into an acid by palling through this second fermentation, or this second stage of fermentation. Spirituous liquors, such as wine, cyder, beer, being exposed to a hot air, grow four in a very short time. Nay, these liquors, though kept with all possible care, in very close vessels, and in a cool place, degenerate at last, change their natures, and infensibly turn four. Thus the product of spirituous fermentation naturally and spontaneously degenerates to an acid.

For this reason it is of great importance, in making wine, or any other vinous liquor, to stop the fermentation entirely, if you desire the wine should contain as much spirit as possible. It is even more advantageous to check the fermentation a little before it come to the height than afterwards: because the fermentation, tho' slackened and in appearance totally ceased, still continues in the vessels; but in a manner so much the less perceptible as it proceeds more slowly. Thus those liquors, in which the fermentation is not quite finished, but check'd, continue for some time to gain more spirit; whereas, on the contrary, they degenerate and gradually turn four, if you let the spirituous fermentation go on till it be entirely finished.

The production of the second fermentation, which we are now to consider, is an acid of so much the greater strength,
strength, the stronger and more generous the spirituous
liquor in which it is excited originally was. The
strength of this acid, commonly called vinegar, depends
likewise in a great measure on the methods used in fer-
fmenting the vinous liquor, in order to convert it into vi-
negar: for if it be fermented in broad, flat vesseLs, and
left to grow four of itself; the spirituous parts will be
diffipated, and the liquor be four indeed, but rapid and
effeLce.

The vinegar-makers, to increase the strength of their
vinegar, use certain methods of which they make a my-
sfery, keeping them very secret. However, Mr. Boer-
haave give us, from some authors, the following descrip-
tion of a process for making vinegar:

"Take two large oaken vats or hogheads, and in
each of these place a wooden grate or hurdle, at the di-
fance of a foot from the bottom. Set the vessel upright,
and on the grates place a moderately close layer of green
twigs, or fresh cuttings of the vine. Then fill up the
vessel with the foot-stalks of grapes, commonly called
the rape, to within a foot of the top of the vessel, which
must be left quite open.

"Having thus prepared the two vessels, pour into
them the wine to be converted into vinegar, so as to fill
one of them quite up, and the other but half full. Leave
them thus for twenty-four hours, and then fill up the
half-filled vessel with liquor from that which is quite full,
and which will now in its turn be left only half full. Four
and twenty hours afterwards repeat the same operation,
and go on thus, keeping the vessels alternately full and
half full during every twenty-four hours, till the vine-
gar be made. On the second or third day there will a-
risé, in the half-filled vessel, a fermentative motion, ac-
companied with a sensible heat, which will gradually in-
crease from day to day. On the contrary, the fer-
mencing motion is almost imperceptible in the full vesseL; and
as the two vessels are alternately full and half full, the fer-
mencing is by that means, in some measure, inter-
rupLed, and is only renewed every other day, in each
vessel.

"When this motion appears to be entirely ceased,
even in the half-filled vessel, it is a sign that the fer-
mementation is finished; and therefore the vinegar is then
to be put into common calks closeStoped, and kept in
a cool place.

"A greater or less degree of warmth accelerates or
checks this, as well as the spirituous fermentation. In
France it is finished in about fifteen days, during the sum-
mer; but if the heat of the air be very great, and ex-
ceed the twenty-fifth degree of Mr de Réaumur's ther-
mometer, the half-filled vessel must be filled up every
twelve hours; because if the fermentation be not so
checked in that time, it will become so violent, and
the liquor will be so heated, that many of the spirituous
parts, on which the strength of the vinegar depends, will
be diffipated; so that nothing will remain, after the fer-
mementation, but a rapid wash. Four indeed, but effeLce.
The better to prevent the diffusion of the spirituous
parts, it is a proper and usual precaution to close the
mouth of the half-filled vessel, in which the liquor fer-
mements, with a cover made also of oak wood. As to the
full vessel, it is always left open, that the air may act
freely on the liquor it contains: for it is not liable to
the same inconveniences, because it ferments but very
slowly."

The vine-cuttings and grape-stalks, which the vinegar-
makers put into their vessels, serve to increase the strength
of the liquor. These matters contain a very manifest
and perceptible acid. They also serve as a ferment;
that is, they depurate the wine to become eager more exp-
peditiously and more vigorously. They are the better
and the more efficacious for having been once united,
because they are thereby thoroughly drenched with the
fermented acid: and therefore the vinegar-makers lay
them by for preparing other vinegar, after washing them
nimble in running water, in order to free them from a
vificid oily matter which settles on them during the fer-
mennentation. This matter must by all means be removed;
because it is disposed to grow mouldy and rot; so that
it cannot but be prejudicial to any liquor in which you
put it.

As the acetic fermentation differs from the spirituous
in its production, so doth in many circumstances at-
tending it. 1. Motion and agitation are not prejudicial
to the acetic fermentation, as they are to the spirituous;
on the contrary, moderate stirring, provided it be not
continual, is of service to it. 2. This fermentation is
accompanied with remarkable heat; whereas the warmth
of the spirituous fermentation is scarce sensible. 3. We
do not believe there ever was an instance of the vapour
that rises from a liquid in acetic fermentation proving
noxious, and producing either disorders or sudden death,
as the vapour of fermenting wine doth. 4. Vinegar de-
porates a vificid oily matter, as hath just been observed,
very different from the lees and tartar of wine. Vinegar
never deposits any tartar; even though new wine, that
hath not yet deposited its tartar, should be used in ma-
king it.

To concentrate Vinegar by Froth.

Exposure to the air, in frothy weather, the vinegar you
desire to concentrate. Icicles will form in it; but the
whole liquor will not freeze. Take out those icicles:
and if you desire a further concentration of your vinegar
by this method, the liquor which did not freeze the first
time must be exposed to a stronger froth. More icicles
will form therein, which must likewise be separated, and
kept by themselves. The liquor which doth not freeze
this second time will be a very strong concentrated
vinegar.

Vinegar analysed by Distillation.

Into a glass or stone cucurbit put the vinegar to be
distilled; fit to it a glass's head; place your alembic in the
sand-bath of a distilling furnace, and let on a receiver.
Apply a very gentle heat at first. A clear, limpid, light
liquor will rise, and fall in distinct drops, like water, from
the nofe of the alembic.

Continue distilling this first liquor, till the vinegar con-
tained in the cucurbit be diminished about a fourth part.
Then drift your receiver, and increase the fire a little. A
clear liquor will still come over, but heavier and more
acid.
acid than the former. Distill in this manner till you have drawn off into your second receiver two thirds of the li-
qur that was left in the cucurbit.
A thick matter will now remain at the bottom of the still: put it into a rerort; lute on a receiver; let your rerort in a reverberating furnace, and distil with degrees of fire. There will come over a limpid liquor, very acid and sharp, yet ponderous, and requiring a degree of fire to raise it; on which account it makes the receiver very hot. It hath a strong empyreumatic smell. When the distillation begins to slacken, increase your fire. There will rise an oil of a fetid, quick smell. At last nothing more will rise with the strongest fire, break the rerort, and in it you will find a black charred matter: burn it, and from the ashes lixiviated with water you will obtain a fixed alkali.

The Acid of Vinegar combined with different Substances.

The Acid of Vinegar combined with Alkaline Substances.
Foliated Salt of Tartar, or regenerated Tartar. Decomposition of that Salt.

Into a glass cucurbit put some very pure and well dried salt of tartar; and pour on it some good distilled vinegar, by little and little at a time. An effervescence will arise. Pour on more vinegar, till you attain the point of saturation. Then fit a head to the cucurbit; set it in a sand-bath; and, having luted on a receiver, distil with a gentle heat, and very slowly, till nothing remain but a dry matter. On this residuum drop a little of the fame vinegar; and if any effervescence appears, add more vinegar till you attain the point of saturation, and distil again as before. If you observe no effervescence, the operation was rightly performed.

It is not easy to hit the exact point of saturation in preparing this neutral salt; because the oily parts, with which the acid of vinegar is loaded, hinder it from acting so briskly and readily as it would do, if it were as pure as the mineral acids: and for this reason it often happens, that, when we have nearly attained the point of saturation, the addition of an acid makes no sensible effervescence, though the alkali be not yet entirely saturated; which deceives the operator, and makes him conclude erroneously that he hath attained the true point of saturation.

But he easily perceives his mistake, when, after having separated from this saline compound all its superfluous moisture by distillation, he drops fresh vinegar upon it: for then the salts being more concentrated, and consequently more active, produce an effervescence, which would not have been sensible if this last portion of acid, instead of coming into immediate contact with the dried alkali, could not have mixed therewith till diffused through, and in a manner suffocated by that phlegm from which the acid of the vinegar before neutralised was gradually separated by its combining with the alkali; that phlegm keeping in solution both the neutral salt already formed, and the alkali not yet saturated. And for this reason it is necessary to try, after the first distillation of the salt, which is called regenerated tartar, whether or no the just point of saturation hath been attained.

From what hath been said, concerning the deficcation of this neutral salt, it is plain, that the use of it is only to free the salt from the great quantity of superfluous moisture wherein it is dissolved: which proves, that the acid of vinegar, like all other acids diffolved in much water, is separated from most of this redundant phlegm by being combined with a fixed alkali. And hence we must conclude, that the acid of vinegar, contained in regenerated tartar deficcated, is vastly stronger and more concentrated than it was before.

Though the acid of vinegar is freed, by combining with a fixed alkali, from a great quantity of superfluous phlegm, yet the oily parts with which it is entangled still cleave to it; these parts are not separated from it by its conversion into a neutral salt, but, without quitting it, combine also with the fixed alkali; and this gives regenerated tartar a saponeaceous quality, and several other peculiar properties.

Regenerated tartar, when dried, is of a brown colour. It is semi-volatile; melts with a very gentle heat, and then resembles an unctuous liquor; which indicates its containing an oil: when cast upon live coals, it flames; and, when distilled with a strong heat, yields an actual oil; all which evidently proves the existence of that oil.

This salt is soluble in spirit of wine: a quality which it probably owes also to its oil. It requires about six parts of spirit of wine to dissolve it; and the dissolement succeeds very well in a matras, with the help of a gentle warmth. If the spirit of wine be abstracted from this solution, by distilling with a small fire, it remains at the bottom of the cucurbit, in the form of a dry saltnce, composed of leaves lying one upon another; which hath procured it the name of terra foliata tartari, or foliated salt of tartar.

It is not absolutely necessary that regenerated tartar be dissolved in spirit of wine to make the foliated salt; for it may be procured in this form only by evaporating the water in which it is dissolved. But the operation succeeds better with spirit of wine; probably because the success thereof depends on using an exceeding gentle warmth: now spirit of wine evaporates with much less heat than water.

Regenerated tartar may also be crystallised. If you desire to have it in this form, combine the acid with the alkali to the point of saturation; evaporate the liquor slowly to the confiquence of a syrup, and set it in a cool place; where it will shoot into clusters of crystals lying one upon another like feathers.

Vinegar perfectly dissolves absorbent matters also, and particularly those of the animal kingdom; such as corals, crabs eyes, pearls, &c. In order to a dissolement of such matters, you must pulverize them, put them into a matras, and pour on them spirit of vinegar to the depth of four fingers breadth: an effervescence will arise: when that is over, set the mixture to digest two or three days in a sand-bath; then decant the liquor, filter it, and evaporate it to dryness with a very gentle heat. The matter which remains is called salt of coral, of pearls,
of crabs'-eyes, &c. according to the substances dissolved. It,
if, instead of evaporating the liquor, a fixed alkali be mixed therewith, the absorbent matter, that was dissolved by the acid, will precipitate in the form of a white powder, which is called the magastery of coral, of pearls, &c.

The Acid of Vinegar combined with copper. Verdegris. Crystals of Copper. This Combination decomposed.

Spirit of Verdegris.

Into a large matras put verdegris in powder. Pour on it distilled vinegar to the depth of four fingers breadth. Set the matras in a moderate and heat, and leave the whole in digestion, shaking it from time to time. The vinegar will acquire a very deep blue-green colour. When the liquor is sufficiently coloured, pour it off by inclination. Put some fresh vinegar into the matras; digest as before; and decant the liquor again when it is sufficiently coloured. Proceed in this manner till the vinegar will extract no more colour. There will remain in the matras a considerable quantity of undissolved matter. The vinegar thus impregnated with verdegris is called tincture of copper.

Mix these several tinctures, and evaporate them with a gentle heat to a pellicle. Then let the liquor in a cool place: in the space of a few days a great many crystals of a most beautiful green colour will shoot therein, and stick to the sides of the vessel. Pour off the liquor from the crystals; evaporate it again to a pellicle, and let it dry by to crystalline. Continue these evaporations and crystallizations, till no more crystals will shoot in the liquor. These are called crystals of copper, and are used in painting. To this combination of the acid of vinegar with copper the painters and dealers have given them the title of distilled verdegris.

Verdegris is prepared at Montpellier. To make it they take very clean plates of copper, which they lay, one over another, with husks of grapes between, and after a certain time take them out. Their surfaces are then covered all over with a very beautiful greenstuff, which is verdigris. This verdigris is nothing but copper corroded by the action of tartar, analogous to the acid of vinegar, which abounds in the wines of Languedoc, and especially in the rape, husks, and stones of grapes that have a very sulfure taste. Verdegris is a form of rust of copper, or copper corroded and opened by the acid of wine, but not yet converted entirely into a neutral salt: for it is not soluble in water, nor does it crystallize. This arises from its not being united with a sufficient quantity of acid. The design of the operation here described is to furnish the verdigris with the quantity of acid requisite to make it a true metallic salt; for which purpose distilled vinegar is very fit.

Crystals of copper may be obtained, without employing verdigris, by making use of copper itself dissolved by the acid of vinegar, according to the method practiced with respect to lead: as shall be shewn hereafter. But verdigris is generally used, because it diffolves soonest; it being a copper already half dissolved by an acid correspondent to that of vinegar.

Crystals of copper are decomposed by the action of fire alone, without any adittament; because the acid of vinegar adheres but loosely to copper. In order to decompose this salt, and extract its acid, it must be put into a retort, and distilled in a reverberatory furnace with degrees of heat. An insipid phlegm rises first, which is the water retained by the salt in crystallizing. This phlegm is succeeded by an acid liquor, which rises in the form of white vapours that fill the receiver. Towards the end of the distillation the fire must be violently urged, in order to raise the strongest and most fixed acid. At last there remains in the retort a black matter, which is nothing but copper, that may be reduced by melting it in a crucible with one part of saltpetre and two parts of tartar. A similar acid, but more oily, and in a much smaller quantity, may be obtained from verdegris by distillation.

The acid, which in this distillation comes over after the first phlegm, is an exceeding strong and concentrated vinegar. It is known by the title of spirit of verdigris.

The Acid of Vinegar combined with Lead. Ceruse. Salt or Sugar of Lead. This Combination decomposed.

Into the glass head of a cucurbit put thin plates of lead, and secure them so that they may not fall out when the head is put upon the cucurbit. Fit on this head to a wide-mouthed cucurbit containing some vinegar. Set it in a sand-bath; let it on a receiver, and distil with a gentle heat for ten or twelve hours. Then take off the head: in it you will find the leaden plates covered, and, in a manner, crusted over with a white matter. This being brushed off with a hare's foot is what we call ceruse. The leaden plates thus cleaned may be employed again for the same purpose, till they be wholly converted into ceruse by repeated distillations. During the operation there will come over into the receiver a liquor somewhat turbid and whitish. This is a distilled vinegar in which some lead is dissolved.

Reduce a quantity of ceruse into powder; put it into a matras; pour on it twelve or fifteen times as much distilled vinegar; set the matras in a sand-bath; leave the matter in digestion for a day, shaking it from time to time: then decant your liquor, and keep it apart. Pour fresh vinegar on what is left in the matras, and digest as before. Proceed thus till you have dissolved one half, or two thirds, of the ceruse.

Evaporate to a pellicle the liquors you poured off from the ceruse, and let them in a cool place. Greyish crystals will shoot therein. Decant the liquor from the crystals; evaporate it again to a pellicle, and let it dry by to crystalline. Proceed thus evaporating and crystallizing, as long as any crystals will shoot. Dissolve your crystals in distilled vinegar, and evaporate the solution, which will then shoot into whiter and purer crystals. This is the salt, or sugar of lead.

Lead is easily dissolved by the acid of vinegar. If it be barely exposed to the vapour of that acid, its surface is corroded, and converted into a kind of calx or white rust, much used in painting, and known by the name of ceruse, or white lead. But this preparation of lead is not combined with a sufficient quantity of acid to convert 2
it into a salt: it is no more than lead divided and opened by the acid of vinegar; a matter which is to lead what verdigris is to copper. And therefore if you desire to combine ceruse with the quantity of acid necessary to convert it into a true neutral salt, you must treat it in the same manner as we did verdigris in order to procure crystalline copper; that is, you must dissolve it in distilled vinegar, as the process directs. The salt of lead is not very white when it first shoots; and for this reason it is dissolved again in distilled vinegar, and crystallized a second time. If salt of lead be repeatedly dissolved in distilled vinegar, and the liquor evaporated, it will grow thick; but still cannot be decocted without great difficulty. If the same operation be oftener repeated, this quality will be thereby more and more increased; till at last it will remain on the fire like an oil or melted wax: it coagulates as it cools, and then looks, at first sight, like a metallic mass, somewhat resembling silver. This matter runs with a very gentle heat, almost as easily as wax.

The salt of lead hath a saccharine taste, which hath prepared it the name also of sugar of lead. For this reason, when wine begins to turn sour, the sure way is to curdle it of that disagreeable taste, is to substitute a sweet one. It is not unpleasing. But, as lead is one of the most dangerous poisons we know, this method ought, never to be practised; and whoever uses such a pernicious drug deserves to be most severely punished. Yet some thing dangerous we know, this method ought, never to be practised; and whoever uses such a pernicious drug deserves to be most severely punished. Yet some thing very like this happens every day, and must needs have very bad consequences; while there is nobody to blame, and those to whom the thing may prove fatal can have no mistreatment of it. Salt of lead may be decompounded by distillation without addition. In order to perform this, you must put the salt of lead into a glass or iron retort, leaving a full third thereof empty, and distil in a reverberating furnace with degrees of fire. A spirit rises, which fills the retort with clouds. When nothing more will come over with a fire that makes the retort red-hot, let the vessels cool, and then unstop them. You will find in the receiver an aetheric liquor, which is inflammable; or, at least, an inflammable spirit may be obtained from it, if about one half thereof be drawn off by distillation in a glass alembic. The retort in which the salt of lead was decompounded contains, at the end of the operation, a blackish matter: this is lead, which will resume its metallic form on being melted in a crucible; because the acid by which it was dissolved, and from which it hath been separated, being of a very oily nature, hath left in it a sufficient quantity of phlogiston.

What is most remarkable in this decomposition of salt of lead, is the inflammable spirit which it yields, though the vinegar which entered into the composition of the salt seemed to contain none at all.

Of the Putrid Fermentation of Vegetable Substances.

The Putrefaction of Vegetables.

Fill a hog's head with green plants, and tread them down a little; or, if the vegetables be dry and hard substances, divide them into minute parts, and steep them a little in water to moisten them? then leave them, or the green plants, in the vessel, uncovered and exposed to the open air. By degrees a heat will arise in the center of the vessel, which will continue increasing daily, at last grow very strong, and be communicated to the whole mass. As long as the heat is moderate, the plants will retain their natural smell and taste. As the heat increases, both these will gradually alter, and at last become very disagreeable, much like those of putrid animal substances. The plants will then be tender as if they had been boiled; or even be reduced to a kind of pap, more or less liquid according to the quantity of moisture they contained before. Almost all vegetable matters aresusceptible of putrefaction; but some of them rot sooner, and others more slowly. As putrefaction is only a species of fermentation, the effect whereof is to change entirely the state of the acid, by combining it with a portion of the earth and oil of the mixt, which are so attirnuated that from this union there results a new saline substance in which no acid is discernible; which on the contrary hath the properties of an alkali, but rendered volatile; it is plain, that, the nearer the acid of a plant set to putrefy is to this state, the sooner will the putrefaction of that plant be completed. Accordingly all plants that contain a volatile alkali ready formed, or from which it can be obtained by distillation, are the most disposed to putrefaction. Those plants, in which the acid is very manifest and sensible, are the apt to putrefy; because all their acid must undergo the change above specified. But vegetable matters, whose acid is entangled and clogged by several of their other principles, must be still longer elaborated before they can be reduced to the condition into which complete putrefaction brings all vegetables. The earthy and oily parts, in which the acids of these substances are sheathed, must be attenuated and divided by a previous fermentation, which, of those parts subtilized and united with the acid, forms an ardent spirit, wherein the acid is more perceptible than in the almost infipid or saccharine juices out of which it is produced. The acid contained in the ardent spirit must be still further digested, before it can enter into the combination of a volatile alkali; consequently the ardent spirit must undergo a sort of decomposition; its acid must be rendered more senile, and be brought to the same condition as the acid of plants in which it manifests all its properties. Hence it appears that the spirituous and acetic fermentations are only preparatives which nature makes use of for bringing certain vegetable matters to putrefaction. These fermentations therefore must be considered as advances.
vances towards that putrefaction in which they terminate, or rather as the first stages of putrefaction itself.

Putrefied Vegetable Substances analysed.

Put the putrefied plants you mean to analyse into a glass cucurbit, and set it in a sand-bath. Put to it a head; lute on a receiver; distil with a gentle fire, and a limpid yellowish white; this is called cream. Gently skim off this cream with a spoon, letting the milk you take up with it run off. Put all this cream into another vessel, and keep it. The milk thus skimmed will not be quite so thick as before; nor will it be of such a dead white, but have a little blueish cast. If all the cream be not separated from it, more will gather on its surface after some time, which must be taken off as the former. In two or three days the skimmed milk will coagulate into a soft mass called curd, and then it taffles and smells four.

Cut this curd across in several places. It will immediately discharge a large quantity of serum. Put the whole into a clean linen cloth; hang it up, and underneath it set a vessel to receive the serum as it drops. When the aqueous part hath done dripping, there will remain in the filter a white substance somewhat harder than the curdled milk. This substance is called cheese, and the serum separated from it is known by the name of whey.

The milk of animals that feed only on vegetables is, of all animal matters, the leaf removed from the vegetable nature. The truth of this will be demonstrated by the experiments we shall produce by and by, for the further analysis of milk.

Most chemists justly consider milk as of the same nature with chyle. Indeed there is great reason to think, that, except some small differences to be afterwards taken notice of, these two matters are nearly the same. They are both of a dead white colour, like that of an emulsion; which proves that, like emulsions, they consist of an oily matter divided, diffused and suspended, but not perfectly dissolved, in an aqueous liquor.

It is not surprising that these liquors should resemble emulsions; for they are produced in the same manner, and may very justly be called animal emulsions. For how are vegetable substances converted into chyle and milk in an animal body? They are bruised, divided, and triturated by mastication and digestion, as perfectly, at least, as the matters pounded in a mortar to make an emulsion; and must thereby undergo the same changes as those matters; that is, their oily parts, being attenuated by those motions, must be mixed with and lodged between the aqueous parts, but not dissolved therein; because they do not, in the bodies of animals, meet with fatty matters, sufficiently disentangled and active, to unite intimately with them, and by that means render them soluble in water.

Nevertheless, chyle and milk, though produced in the same manner as emulsions, and very much resembling them, differ greatly from them in some respects; owing chiefly to the time they remain in the bodies of animals, their being heated while there, the elaborations they undergo therein, and the animal juices commixed with them.

New milk hath a mild agreeable taste, without any saline pungency; nor hath any chemical trial discovered in it, either an acid or an alkali. Yet it is certain, that the juices of plants, out of which milk is formed, contain many saline matters, and especially acids; accordingly milk also contains the same; but the acids are so sheathed and combined, that they are not perceptible. The cafe

Of Operations on Animal Substances.

Of Milk.

Milk separated into Butter, Curd, and Whey: insinuated in Cow's Milk.

Put new cow's milk into a flat earthen pan, and set it in a temperate heat. In ten or twelve hours time there will gather on its surface a thick matter, of a somewhat
is the same with all the other liquors intended to constitute part of an animal body: there is no perceptible acid in any of them.

Hence it may be inferred, that one of the principal changes which vegetables undergo, in order to their being converted into an animal substance, consists in this, that their acids are combined, entangled, and sheathed in such a manner, that they become imperceptible, and exert none of their properties.

Milk left to itself, without the help of distillation, or any addition whatever, undergoes a fort of decomposition. It runs into a kind of spontaneous analysis; which does not indeed reduce it to its first principles, yet separates it into three distinct substances, as the process shows; namely, into cream, or the buttery fat part, into curd or cheese, and into serum or whey: which shows that those three substances of which milk consists, are only mixed and blended together, but not intimately united.

The first parts, being the lightest, rise gradually to the surface of the liquor as they separate from the rest; and this forms the cream.

Cream, as skimmed from the surface of milk, is not however the pure buttery or fat part; it is still mixed with many particles of cheese and whey, which must be separated in order to reduce it into butter. The most simple, and at the same time the best method of effecting this, is daily practised by the country people. It consists in beating or churning the cream, in a vessel contrived for that purpose, with the flat side of a circular piece of wood, in the centre of which a staff is fixed. One would think that the motion, imparted on the cream by this instrument, would rather serve to blend more intimately the particles of butter, cheese, and whey, of which it consists, than to separate them from each other; as this motion seems perfectly adapted to divide and attenuate those particles. But, if we consider what passes on this occasion, we shall soon perceive that the motion by which butter is churned is nothing like trituration; for churning is no other, properly speaking, than a continually repeated compaction, the effect whereof is to squeeze out from amongst the butter particles those of cheese and whey mixed therewith; by which means the particles of butter are brought into contact with each other, unite, and adhere together.

Milk, whether skimmed or not, grows four of itself, and curdles in a few days. When it is newly curdled, the cheese and whey seem to be united, and to make but one mass: but these two matters separate spontaneously from each other, with the greatest ease, and in a very short time.

The acidity, which milk naturally contracts in the space of a few days, must be considered as the effect of a fermenting motion, which discovers in that liquor an acid that was not perceptible before. This, properly speaking, is an acetous fermentation, which milk passes through in its way to putrefaction; and it soon follows, especially if the milk be exposed to a hot air.

If, instead of leaving milk to grow four and curdle of itself, an acid be mixed therewith, while it is yet sweet and newly milked, it immediately coagulates; which gives reason to think, that its curdling naturally is the effect of the acid, which discovers itself therein as it grows stale.

The coagulation of milk may also be considerably accelerated, by setting it in a sand-bath gently heated; or by mixing therewith a little of what, in the language of the dairy, is called runnet; which is nothing but some curdled and half-digested milk taken from the stomach of a calf; or both these methods may be employed at once, which will produce the effect still more expeditiously.

It is not difficult to find out the cause of these effects. The runnet, which is milk already curdled and grown four is an actual ferment to sweet milk, dispersing it to turn four much more readily: for though milk, when thus hastily curdled by the runnet, hath not a manifestly acid taste, yet it is certain that this acid begins to exert itself. The proof thereof is, that, being exposed to the same degree of heat with milk equally new, that is not mixed with this ferment, it turns four much sooner. As to the effect of heat in coagulating milk, there is nothing extraordinary in it; we know how much it promotes and accelerates all fermentative motion. The whole of this perfectly agrees with what we said before concerning fermentation.

Fixed alkalies also coagulate milk; but at the same time they separate the whey from the cheese, which floats on the liquor in clots. They give the milk a rufset colour inclining to red; which may arise from their attacking the fat part.

The separation of milk into butter, cheese, and whey, is a kind of imperfect analysis thereof, or rather the beginning of one. In order to render it complete, we must examine each of these substances separately, and find the principles of which they consist. This we shall endeavour to do in the following process.

Butter analysed by Distillation.

Into a glass retort put the quantity of fresh butter you intend to distil. Set the retort in a reverberatory; apply a receiver; and let your fire be very gentle at first. The butter will melt, and there will come over some drops of clear water, which will have the peculiar smell of fresh butter, and shew some tokens of acidity. If the fire be increas'd a little, the butter will seem to boil; a froth will gather on its surface, and the phlegm, still continuing to run, will gradually come to smell but like butter clarified in order to be preferred. Its acidity will be stronger and more manifest than that of the first drops that came over.

Soon after this, by increasing the fire a little more, there will rise an oil, having nearly the same degree of fluidity as fat oils; but it will grow thicker as the distillation advances, and at last will fix in the receiver when it cools. It will be accompanied with some drops of liquor, the acidity whereof will always increase, while its quantity decreases, as the distillation advances.

While this thick oil is distilling, the butter contained in the retort, which at first seemed to boil, will be calm and smooth, without the least appearance of ebullition; though the heat be then much greater than when it boiled. Continue the distillation, constantly increasing the fire.
CHEMISTRY. 173

fire by degrees as you find it necessary for the elevation of the thick oil. This oil, or rather this kind of butter, will be at last of a rufset colour. There will rife along with it fume white vapours exceeding sharp and pungent.

When you observe that nothing more comes over, though the retort be quite red-hot, let the vessels cool, and unlute them. You will find in the receiver an aqueous acid liquor, a fluid oil, and a kind of fixed brown butter. Break the retort, and you will find therein a kind of charred matter; the surface of which, where it touched the glass, will be of a fliming black, and have a fine polish.

The analysis of butter proves, that this subftance, which is an oily matter in a concrete form, owes its conftance to the acid only, with which the oily part is combined: that is, it follows the general rule frequently mentioned above in treating of other oily compounds; the conftance whereof we believed to be fo much the firmer, the more acid they contain. The firft portions mentioned above in treating of other oily compounds: that is, it follows the general rule frequently

This oil, being freed from its acid, and by that means rendered fluid, rifes firft; becaufe it is by the fame means rendered lighter. The kind of butter that comes over afterwards, though it be fixed, is nevertheless far from having the fame conftance as it had before the operation; becaufe it loses much of its acid in the operation. This acid is what rifes in the form of white vapours. These vapours are at leaft as pungent and irritating as the fulphureous acid or volatile alkalis; but their smell is different: it hath a reemblance, or rather is the fame, with that which rifes from butter when it is burnt and browed in an open vefsel. But, when concentrated and collected in clofe vefsels, as in the diſtillation of butter, they are vaſtly stronger: they irritate the throat fo as to inflamme it; they are exceeding sharp and pungent to the smell, and are fo hurtful to the eyes that they quickly inflame them, as in an ophthaimy, and make them flow abundance of tears. The great volatility of this acid is entirely owing to a portion of the phlegm which come over at firft, and, in ftruggling to get free, lift up the buttery parts, or actually boil, which occafions the ebullition observafble at the beginning of the procfs. When they are once feparated, the melted butter remains calm and smooth, without boiling. If you want to make it boil, you muft apply a much greater degree of heat; which you cannot do in clofe

veffels, without spoiling the whole operation: becaufe the degree of heat neceffary for that purpafe would force up the butter in fubftance, which would rush over into the receiver, without any decomposition. Indeed if the veffels were luted, they would be in danger of burfting.

As to the cafeous parts, which are mixed with fresh butter, they allo separate at the beginning of the diſtillation when the butter is melted, and gather on its surface in a ficum. Thofe particles of cheefe and whey, which are heterogeneous to butter, help to make it foop the fooner. And for this reafon, thofe who want to keep butter a long time, without the ufe of falt, melt it, and thereby evaporate the aqueous parts. The lighteft portion of the particles of cheefe rifes to the surface, and is skimmed off: the reft remains at the bottom of the veffel, from which the butter is easily feparated, by decanting it while it is yet fluid.

Butter may also be diſtilled, by incorporating it with fome additament which will yield no principle itfelf, nor retain any of thofe of the butter. It may be diſtitled in this manner with the additament of fine fand: the operation succeeds very well, is sooner finished, and more eafily conducted.

If you defire to convert the butter wholly into oil, you must take the fixed matter you find in the receiver, and diftit it once more, or oftener, according to the degree of fluidity you want to give it. The cafe is the fame with this matter as with all other thick oils, which, the oftener they are diftitled, grow always the more fluid, becaufe in every diſtillation they are feparated from part of the acid, to which alone they owe their conftance.

The Curd of Milk analysed by Diſtillation.

Into a glafs retort put fome new curd, having firft drained it thoroughly of all its whey, and even squeezed it in a linen cloth to express all its moisture. Diſtit it as you did butter. There will come over at firft an acidulated phlegm, fmmelling like cheefe or whey. As the diſtillation advances, the acidity of this phlegm will increafe.

When it begins to run but very flowly, raise your fire. There will come over a yellow oil, somewhat empyreumatic. Continue the diſtillation, till increasing the fire by degrees as occasion requires. The oil and acid phlegm will continue to rife; the phlegm growing gradually more acid, and the oil deeper coloured and more empyreumatic. At laſt, when the retort is almoft red-hot, there comes off a fecond black oil, of the conftance of turpentine, very empyreumatic, and fo heavy as to fink in water. In the retort will be left a confiderable quantity of charred matter.

Cheefe curd barely drained, till no more whey will drip from it, is not entirely freed thereof; and for this reafon we directed it to be prefixed in a linen cloth, before it be put into the retort to be diſtitled. Without this precaution, the remaining whey would rife in a confiderable quantity on the firft application of heat; and, inftead of analysing the curd only, we fhould at the fame time analyfe the whey alfo. This is to be underftood of green curd and new-made cheefe: for, if it be fuffered to grow old,
old, it will at length dry of itself: but then we should not obtain from it the same principles by distillation, as it corrupts and begins to grow putrid after some time, especially if it be not mixed with some seafoning to preserve it.

The first phlegm that rises in this distillation, as in that of butter, is a portion of the whey that was left in the cheese, notwithstanding its being well pressed. This phlegm grows gradually more acid, being the vehicle of the acids of the cheese, which are forced up along with it by the fire.

The acid obtained from this matter is left in quantity, and weaker, than that of butter: and accordingly the oil distilled from cheese is not fixed like that of butter. Yet it is remarkable that the laft empyreumatic oil, and weaker, than that left by butter: which proves that the former contains a much greater quantity of earth.

The quantity of charred matter, which remains in the retort after the distillation of cheese, is much greater than that left by butter: which proves that the former

Whey analysed.

Evaporate two or three quarts of whey almost to dryness in a balneum maris; and distil the extract or residuum in a retort set in a reverberating furnace, with degrees of fire, according to the general rule. At first some phlegm will come over; then a lemon-coloured acid spirit; and afterwards a pretty thick-oil. There will remain in the retort a charred matter, which being exposed to the air grows moist. Lixiviate it with rain water, and evaporate the lixivium; it will yield you crystals of sea-salt.

It will appear, on examining the three analyses of the substances whereof milk consists, that none of them yields a volatile alkali: which is worthy of notice; as it is the only animal matter from which such a salt cannot be obtained. It is true, the milk of animals that feed on vegetables may be considered as an intermediate liquor between vegetable and animal substances; as an imperfect animal-juice, which still retains much of the vegetable nature: and we actually find, that milk almost always hath, at least in part, the properties of those plants with which the animals that yield it are fed. Yet, as it cannot be formed in the body of the animal, without mixing with several of its juices that are entirely perfected, and become purely animal, it must appear strange that the analysis thereof should not afford the least vestige of that principle, which all other animal-matters yield in the greatest plenty.

The reason of this may be found in the ufe to which milk is employed. It is intended for the nourishment of animals of the same species with those in whose bodies it is produced. Consequently it ought as much as possible to resemble the juices of the food which is proper for those animals. Now, as animals that live only on vegetables could not be properly nourished by animal matters, for which nature itself hath given them an aversion, it is not surprising that the milk of such animals should be free from any mixture of such things as are unfit for the young ones whom it is designed to nourish. There is reason therefore to think, that nature hath bestowed on the organs in which the secretion of milk is performed, so as to separate it entirely from all the animal juices first mixed with it: and this is the principal difference between milk and chyle; the latter being necessarily blended with the saliva, the gastric and pancreatic juices, the bile and lymph, of the animals in which it is formed. Hence it may be concluded, that, if a quantity of chyle could be collected sufficient to enable us to analyse it, the analysis thereof would differ from that of milk, in this chiefly, that it would yield a great deal of volatile alkali, of which milk, as hath been said, yields none at all.

The same thing probably takes place in carnivorous animals. It is certain, that those animals chuse to eat the flesh of such others only as feed upon vegetables; and that nothing but extreme hunger, and the absolute want of more agreeable food, will force them to eat the flesh of other carnivorous animals. Wolves, which greedily devour sheep, goats, &c. seldom eat foxes, cats, polecats, &c. though these animals are not strong enough to resist them. Foxes, cats, and birds of prey, that make such terrible havoc among wild-fowl, and other sorts of game, do not devour one another. This being laid down, there is reason to think, that the milk of carnivorous animals is something of the nature of the flesh of those animals that feed on vegetables, and which they chuse to eat, and not of the nature of their own flesh; as the milk of animals that feed on vegetables is analogous to the juices of vegetables, and when analysed yields no volatile alkali, though every other part of their body does.

But whatever be the nature of milk, and of whatever ingredients it be formed, it always contains the three several substances above mentioned; namely, the fat, or buttery part, properly so called, the cheesy, and the ferus part, the last of which we are now to examine. It is, properly speaking, the phlegm of the milk, and consists almost entirely of water. For this reason it is proper to lessen the quantity thereof considerably by evaporation, so that its other principles, being concentrated and brought nearer together, may become much more sensible. There is no danger of losing any essential part of the whey in the evaporation, if it be performed in the balneum maris with such a gentle heat as may carry off the aqueous parts only: this greatly shortens the analysis, which will be exceeding long and tedious if all the water be distilled off in close vesels.

As whey is chiefly the aqueous part of milk, as said above, it must contain all the principles thereof that are soluble in water; that is, its saline and faponaceous parts. And accordingly the analysis thereof shews that it contains an oil, rendered perfectly faponaceous by an acid; that is, made perfectly miscible with water. This quality of the oil contained in whey appears from the perfect transparency of that liquor; which we know is the
In a vessel, coagulates as it grows cold; and sometimes after-wards the coagulum discharges a yellowish fluid; which rendered it milky with water, comes over in its natural form, and doth not afterwards mix with the aqueous part.

Besides the saponaceous matter, which contains another saline substance; namely, sea-salt: this is obtained by precipitating the caput mortuum left in the retort, which, because of its fixedness, cannot rise with the other principles in distillation. To this fact it is owing that what remains in the retort after distillation grows moist in the air; for we know that sea-salt thoroughly dried hath this property.

The fixed alkaline salt, obtained from the caput mortuum burnt to ashes, proves that milk still retains something of the vegetable nature: for the following analysis will shew us that matters purely animal yield none at all.

**Of the Substances which compose an Animal Body.**

**Blood analysed. Infixed in Bullock's Blood.**

In a balneum mariae evaporate all the moisture of the blood that the heat of boiling water will carry off. There will remain an almost dry matter. Put this dried blood into a glass retort, and distil with degrees of heat, till nothing more will come over, even when the retort is quite red-hot, and ready to melt. A brownish phlegm will rise at first: this will soon be impregnated with a little volatile alkali, and then will come over a yellow oil, a very pungent volatile spirit, a volatile salt in a concrete form, which will adhere to the sides of the receiver; and, at last, a black oil, as thick as pitch. There will be left in the retort a charred matter, which being burnt yields no fixed alkali.

Blood, which is carried by the circulation into all the parts of the animal body, and furnishes the matter of all the secretions, must be considered as a liquor consisting of almost all the fluids necessary to the animal machine: so that the analysis thereof is a sort of general though imperfect analysis of an animal.

Blood drawn from the body of an animal, and set by in a vessel, coagulates as it grows cold; and sometimes afterwards the coagulum discharges a yellowish ferum or lymph; and in the midst thereof swims the red part, which continues curdled. These two substances, when analysed, yield nearly the same principles; and in that respect seem to differ little from each other. Though the ferum of blood be naturally in a fluid form, yet it hath also a great tendency to coagulate; and a certain degree of heat applied to it, either by water or by a naked fire, will curdle it. Spirit of wine mixed with this liquor produces on it the same effect as heat.

Blood, while circulating in the body of a healthy animal, and when newly taken from it, hath a mild taste, which discoveres nothing like either an acid or an alkali; nor doth it shew any sign of either the one or the other in chemical trials. When tasted with attention, it betrays something like a favour of sea-salt; because it actually contains a little thereof, which is found in the charred matter left in the retort after the distillation, when carefully examined.

We shewed that milk also contains a little of this salt. It enters the bodies of animals with the food they eat, which contains more or less thereof according to its nature. It plainly suffers no alteration by undergoing the digestions, and passing through the strainers, of the animal body. The case is the same with the other neutral salts which have a fixed alkali for their basis: we find them unchanged in the juices of animals into whose bodies they have been introduced. They are incapable of combining, as acids do, with the oily parts; and so are dissolved by the aqueous fluids, of which nature makes use to free herself from those salts, and discharging them out of the body.

Blood, like all other animal-matters, is, properly speaking, susceptible of no fermentation but that of putrefaction. Yet it turns somewhat sour before it putrefies. This small degree of acetic fermentation is most sensible in fish; and especially in the fish of young animals, such as calves, lambs, chickens, &c.

The quantity of pure water, which blood, in its natural state, contains, is very considerable, and makes almost seven eighths thereof. If it be distilled, without being first dried, the operation will be much longer; because it will be necessary to draw off all this insipid phlegm with a gentle fire. There is no reason to apprehend that, by drying blood in open vessels as directed, any of its other principles will be carried off with its phlegm: for it contains no other substance that is volatile enough to rise with the warmth of a balneum mariae. This may be proved by putting some undried blood into a glass cucurbit, fitting thereto a head and receiver, and distilling, in a balneum mariae, all that the heat of the bath, not exceeding the heat of boiling water, will raise: for, when nothing more will come over, you will find in the receiver an insipid phlegm only, scarce differing from pure water, except in having a faint smell like that of blood: wherein it resembles all the phlegms that rise first in distillation, which always retain something of the smell of the matters from which they were drawn. That part of the blood, which remains in the cucurbit after this first distillation, being put into a retort, and distilled with a stronger fire, yields exactly the same principles, and in the same proportion, as blood dried in open vessels in a balneum mariae: so that, if this phlegm of blood contains any principles, the quantity thereof is so small as to be scarce perceptible.

The volatile alkali that rises with the oil, when blood is distilled in a retort with a degree of heat greater than that of boiling water, is either the production of the fire, or ariseth from the decomposition of an ammoniacal salt of which it made a part. For we shall see, when we come to treat of this saline substance, that it is so extremely volatile as to exceed, in that respect, almost all other bodies that we know: and therefore if this volatile alkali pre-existed formerly in the blood, uncombined with any other matter capable, in some measure,
of fixing it; it would rise at first almost spontaneously, or at least on the first application of the gentlest heat. We have an instance of this in blood, or any other animal-matter, that is perfectly purified, which containing a volatile alkali, either formed or extricated by putrefaction, lets go this principle when distilled, even before the first phlegm: and, for this reason, when purified blood is to be analyzed, it must by no means be dried, like fresh blood, before distillation; for all the volatile alkali would by that means be diffipated and lost at once.

Though blood and other animal matters afford no fixed alkali, but, on the contrary, yield much volatile alkali, it doth not therefore follow that all the acid, which those substances contained before they were analyzed, is employed in the production of a volatile alkali.

**Flesh analyzed. Insinuated in Beef.**

Let us take an alembic or retort, placed in a sand-bath, put some lean beef, from which you have carefully separated all the fat. Distill till nothing more will rise. In this first distillation a phlegm will come over, weighing at least half the mass of the distilled flesh. In the retort you will find a matter almost dry, which you must afterwards distill with a naked fire in a reverberating furnace, taking the usual precautions. There will come over at first a little phlegm replete with volatile alkali; then a volatile alkali in a dry form, which will stick to the sides of the vessel; and also a thick oil. After the distillation there will be left in the retort a black, shining, light coal. Burn it to ashes in the open air, and lixiviate the vessel; and also a thick oil. After the distillation there will be left in the retort a charred matter, from which a little sea-salt, with a little more volatile salt. There will be left in the retort a charred matter.

The flesh of an animal, as appears from the process, yields much the same principles with its blood: and it cannot be otherwise, because it is formed altogether of materials furnished by the blood.

**Bone analyzed. Insinuated in Ox-Bones.**

Cut into pieces the bones of a leg of beef, carefully separating all the marrow. Put them into a retort, and distill them in a reverberating furnace as usual. A phlegm will come over first; then a volatile spirit, which will become stronger and stronger; afterwards a volatile salt in a dry form, with some oil; and, lastly, a black oil, with a little more volatile salt. There will be left in the retort a charred matter, from which a little sea-salt may be extracted. Reduce this charred matter to ashes, by burning it in the open air. These ashes will give some slight tokens of a fixed alkali.

The analysis of bones proves, that they confit of the same principles with flesh and blood; and the fame may be said in general of all matters that are truly animal, that actually constitute any part of an animal.

**Animal Fat Analyzed. Insinuated in Mutton-Suet.**

Put as much mutton-suet as you please into a glass retort, only taking care that the vessel be but half full; and distill with degrees of fire as usual. A phlegm smel-
If, instead of distilling the hard white of an egg, with a view to draw off the great quantity of water it contains, you leave it some time in an air that is not too dry, the greatest part of its moisture separates spontaneously, and becomes very sensible. In all probability, this is the effect of a beginning putrefaction, which attenuates this substance, and breaks its contexture. The liquor thus discharged by the white of an egg thoroughly dissolves the gum-refins, and particularly myrrh. If you desire to dissolve myrrh in this manner, cut a hard-boiled egg in halves; take out the yolk; put the powdered gum-refin into the cavity left by the yolk; join the two halves of the white; fallen them together with a thread, and hang them up in a cellar. In a few days time the myrrh will be dissolved by the moisture that issues from the white of the egg, and will drop into the vessel placed underneath to receive it. This liquor is improperly called oil of myrrh per deliquium.

All the properties of the whites of eggs, as well as the principles obtained by analyzing them, are the fame with those of the lymphatic part of the blood; so that there is a great resemblance between these two substances.

As to the yolk, it is plain from its analysis, that oil is the predominant principle thereof. If the yolk of an egg be mixed with water, the oil with which it is replete, and which is by nature very minutely divided, diffuses easily through the whole liquor, and remains suspend- ed therein by means of its viscositas. The liquor at the same time becomes milk-white like an emulsion, and is in fact a true animal emulsion.

In order to obtain the oil of eggs by expression with the more care, care must be taken to choose eggs that are seven or eight-days old; because they are then a little less viscositas. Nevertheless their viscositas is still so great, that they will not easily yield their oil by expression: and therefore, in order to attenuate and destroy entirely this viscositas, they must be torrefied before they are put to be pressed.

The oil of eggs, like all the other oily animal matters, seems analogous to the fat oils of vegetables. It hath all the properties that characterize those oils. Its colour is yellow, and it smells and tastes a little of the empyreuma, occasioned by torrefying the yolks. It is rendered somewhat disagreeable by being exposed to the dew for thirty or forty nights, if care be taken to stir it often in the mean time.

To conclude: all the principles both in the yolk and the white of an egg are the same as those found in bloods, and all other matters that are perfectly animal.

Of the Excrements of Animals:

Dung analyzed. Insinuated in human Excrements.

Mr. Homberg's Proothesis.

Take any quantity you please of human excrement, and distil it in a glass alembic set in the balneum marie. You will obtain an aqueous, clear, insipid liquor; which will nevertheless have a disagreeable odour. Having urged the distillation as far as is possible with the heat of this bath, unlace your vessels, and you will find at the bottom of the cucurbit a dry matter, making about an eighth part only of what you put into it. Put this ruddiment into a glass retort, and distil in a reverberating furnace, with degrees of heat. You will obtain a volatile spirit, and a volatile salt, with a fetid oil; and a charred matter will be left in the retort.

This substance, consisting of matters subject to putrefaction, hath constantly a fetid smell, like that of all putrid matters; having been for some time confined in a warm, moist place, which we know promotes putrefaction, and even quickly produces it. Yet the analysis thereof proves that it is not putrefied, or at least not entirely so; for all putrefied matters contain a volatile alkali perfectly formed and extricated; and, as this principle arises with less heat than that of boiling water, it always comes over first in distillation. Now we have seen that, with the heat of boiling water, it parts with nothing but an insipid phlegm, containing no volatile alkali: a sure proof that the local matter is not completely putrefied.

One of the methods by which Mr Homberg endeavoured to obtain from excrement a clear oil, without any bad smell, was to separate its earthy and gross parts, by filtering it before he distilled it. For this purpose he diluted excrement newly discharged with hot water, using a quart of water to an ounce of feces. Then he let the mixture stand to cool, and the gross parts falling to the bottom, he poured off the water by inclination. This liquor he filtered through brown paper, and evaporated to a pellicle over a gentle fire. There shot in it long crysotals of four, five, and six sides, which Mr Homberg thinks may be called the essential salt of excrement. They resemble salt-petre, in some measure, and delagrate in the fire much like it; with this difference, that their flame is red, and they burn slowly; whereas the flame of salt-petre is white and very vivid; probably, says Mr Homberg, because there is too much of an oily matter in the one, and less in the other.

Mr Homberg distilled this salt in a glass retort with degrees of fire, and at last with a very violent one. At first there came over an aqueous liquor, sharp and acid, which was followed by a brown fetid oil, smelling very strong of empyreuma. This distillation he attempted four several times; and each time the matter in the retort took fire, just when the oil began to come off.

The salt which Mr Homberg obtained from excrement is very remarkable. Its nitrous character is by no means ambiguous; its delagrating on live coals convinced Mr Homberg of its being a true nitre. But its conflagrantly taking fire in the retort, as oft as distilled, is a sure proof that it is a nitrous salt: for nitre only hath the property of thus taking fire in close vessels, and making other combustible matters burn along with it.

The process, by which Mr Homberg at last obtained from excrement a clear oil without any bad smell, is curious, and worthy of a place here, on account of the views and occasions of reflection which it may open.

Mr Homberg having tried in vain, by distilling excrement a great many different ways, to obtain from it such an oil as he wanted, resolved to employ fermentation,
tion, the effect whereof is to change the disposition of the principles of mixts. With this view he dried some excrement in the water-bath, and, having pulverized it, poured thereon six times its weight of phlegm that had been separated from it by distillation, and put the whole into a large glass cucurbit, covered with an inverted vessel that fitted exactly into it, and was closed luted. This vessel he set in a balneum marie for six weeks, keeping up such a gentle heat as would not burn one's hand; after which he uncovered the cucurbit, and having fitted thereto a head and a receiver, distilled off all the aqueous moilure in the balneum marie with a very gentle heat. It had now lost almost all its bad smell, which was changed into a faint one. It came over somewhat turbid, whereas it was very clear when put into the cucurbit. Mr. Homberg found this water to have a cosmetic virtue: he gave some of it to persons whose complexion, neck, and arms, were quite spoiled, being turned brown, dry, rough, and like a goose skin: they washed it with it once a day, and, by continuing the use of this water, their skin became very soft and white.

"The dry matter left in the cucurbit after the first distillation, had not the least smell of feces: on the contrary, it had an agreeable aromatic odour; and the vessel in which Mr. Homberg had digested it, being left open in a corner of his laboratory, acquired in time a strong smell of ambergris. It is surprising, as Mr. Homberg justly observes, that digestion alone should change the abominable smell of excrement into an odour as agreeable as that of ambergris.

"This dry matter he powdered coarsely, and put two ounces thereof at once into a glass retort that would hold about a pound or a pound and a half of water. This he distilled in a sand-bath with a very gentle heat. A small quantity of an aqueous liquor came over at first, and then an oil as colourless as spring-water. Mr. Homberg continued the same gentle degree of heat till the drops began to come off a little redish; and then he changed the receiver, emptying that which contained the clear oil very close with a cork. Having carried on the distillation with a fire gradually augmented, there came over a little smoke with a cork. Having carried on the distillation, had not the least smell of feces: on the contrary, it had an agreeable aromatic odour; and the vessel in which Mr. Homberg had digested it, being left open in a corner of his laboratory, acquired in time a strong smell of ambergris. It is surprising, as Mr. Homberg justly observes, that digestion alone should change the abominable smell of excrement into an odour as agreeable as that of ambergris.

"This dry matter he powdered coarsely, and put two ounces thereof at once into a glass retort that would hold about a pound or a pound and a half of water. This he distilled in a sand-bath with a very gentle heat. A small quantity of an aqueous liquor came over at first, and then an oil as colourless as spring-water. Mr. Homberg continued the same gentle degree of heat till the drops began to come off a little redish; and then he changed the receiver, emptying that which contained the clear oil very close with a cork. Having carried on the distillation with a fire gradually augmented, there came over a considerable quantity of red oil; and there remained in the retort a charred matter which burnt very readily.

"The clear oil, without any ill smell, which Mr. Homberg obtained from the fecal matter by this process, was the very thing he was in search of, and which he had been assured would convert mercury into fine fixed silver; yet he ingenuously owns, that, whatever way he applied it, he could never produce any change in that metallic substance. We shall now proceed to the other discoveries made by Mr. Homberg on this occasion.

"In his attempt to obtain a clear oil from excrement, he distilled it with different additaments, and amongst the red with vitriol and alum. He found that the matters left in the retort, when he made use of these salts, being exposed to the open air, took fire of themselves; that they kindled combustible matters; in a word, that they were a true phosporous, of a species different from all then known. Pursuing these first hints, he sought and found the means of preparing this phosporous by a way much more expeditious, certain, and easy. His process is this.

"Take four ounces of feces newly excreted: mix therewith an equal weight of roch-salum coarse powdered; put the whole into a little iron pan that will hold about a quart of water, and set it over a gentle fire under a chimney. The mixture will melt, and become as liquid as water. Let it boil with a gentle fire, constantly stirring it, breaking it into little crumbs, and scraping off with a spatula whatever sticks to the bottom or sides of the pan, till it be perfectly dry. The pan must from time to time be removed from the fire that it may not grow red hot; and the matter must be stirred, even while it is off the fire, to prevent too much of it from sticking to the pan. When the matter is perfectly dried, and in little clots, let it cool, and powder it in a metal mortar. Then put it again into the pan, set it over the fire, and stir it continually. It will again grow a little moist, and adhere together in clots, which must be continually roasted and bruised till they be perfectly dry; after which they must be suffer'd to cool, and then be pulverized. This powder must be returned a third time to the pan, set on the fire, roasted, and perfectly dried; after which it must be reduced to a fine powder, and kept in a paper in a dry place. This is the first or preparatory operation.

"Take two or three drams of this powder. Put it into a little matras, the belly of which will hold an ounce, or an ounce and a half of water, and having a neck about fix or seven inches long. Order it so that your powder shall take up no more than about a third part of the matras. Stop the neck of the matras finely with paper: then take a crucible four or five inches deep; in the bottom of the crucible put three or four spoonfuls of sand: set the matras on this sand, and in the middle of the crucible, so as not to touch its sides. Then fill up the crucible with sand, so that the belly of the matras may be quite buried therein. This done, place your crucible with the matras in the midst of a little earthen furnace, commonly called a flove, about eight or ten inches wide above, and six inches deep from the mouth to the grate. Round the crucible put lighted coals about half way up, and when it hath stood thus half an hour, fill up with coals to the very top of the crucible. Keep up this fire a full half hour longer, or till you see the inside of the crucible begin to be red. Then increase your fire, by raising your coals above the crucible. Continue this strong heat for a full hour, and then let the fire go out.

"At the beginning of this operation dense fumes will rise out of the matras, through the flippole of paper. These fumes issue sometimes in such abundance as to push out the flippole; which you must then replace, and slake the fire. The fumes cease when the inside of the matras begins to grow red; and then you may increase the fire without any fear of spoiling your operation.

"When the crucible is so cold that it may be safely taken out of the furnace with one's hand, you must gradually draw the matras out of the sand, that it may cool slowly, and then stop it close with a cork.

"If the matter at the bottom of the matras appear to
be in powder when shaken, it is a sign the operation hath
succeeded; but if it be in a cake, and doth not fall into
powder on shaking the matter, it shows that your matter
was not sufficiently roasted and dried in the iron pan
during the preparatory operation.”

Mr Lemeri hath shewn, that excrement is not the only
matter capable of producing this phosphorus with alum;
but that, on the contrary, almost all animal and even ve-
getable matters are fit for this combination; that though
Mr Homberg mixed alum in equal quantities only with
the fecal matter, it may be used in a much greater pro-
portion; and, in certain cafes, will succeed the better;
that, according to the nature of the substances to be
worked on, the quantity of that salt may be more or less
increased; and that whatever is added, more than the
dosage requisite for each matter, serves only to lessen the
virtue of the phosphorus, or even destroys it entirely;
that the degree of fire applied must be different according
to the nature of those matters; and, daily, that salts
containing exactly the same acid with that of alum, or
the acid of those salts separated from its basis and reduced
into spirit, do not answer in the present operation: which
shows, says Mr Lemeri, that many phosphureous matters
may be substituted for excrement in this operation; but
that there are not salts, or very few, if any, that will
succeed but if it be in a cake, and doth not fall into
powder on shaking the matter, it shows that your matter
was not sufficiently roasted and dried in the iron pan
during the preparatory operation.”

This phosphorus, made either by Mr Homberg’s or
by Mr Lemeri’s method, shines both by day and by
night. Besides emitting light, it takes fire soon after it
is exposed to the air, and kindles all combustible matters
with which it comes in contact; and this without being
rubbed or heated.

Meff. Homberg and Lemeri have given the most pro-
able and the most natural explanation of the cause of
the ascension and other phenomena of this phosphorus.
What they say amounts in short to what follows.

Alum is known to be a neutral salt, consisting of the
vitriolic acid and a calcareous earth. When this salt is
calcined with the fecal matter, or other substances a-
bounding in oil, the volatile principles of these substances,
such as their phlegm, their fats, and their oils, exhale
in the same manner as if they were distilled; and there
is nothing left in the matter, when those principles are
disengaged, but a charred matter, like that which is found
in retorts wherein such mixtures have been decomposed by
diffillation.

This remainder therefore is nothing but a mixture of
alum and charcoal. Now, as the acid of this salt, which
is the vitriolic, hath a greater affinity with the phlogiston
than with any other substance, it will quit its basis to
unite with the phlogiston of the coal, and be converted
by that union into a sulphur. And this is the very cafe,
of which we have certain proofs in the operation for pre-
paring this phosphorus; for when, after the volatile
principles of the oily matter are drawn off, the fire is
increased, in order to combine closely together the fixed
parts that remain in the matter, that is, the alum and
the charred matter, we perceive at the mouth of the ma-
tras a small blue phosphureous flame, and a pungent smell
of burning sulphur. Nay, when the operation is finis-
ed, we find a real sulphur flicking in the neck of the ma-
tras; and, while the phosphorus is burning, it hath
plainly a strong phosphureous smell. It is therefore cer-
tain, that this phosphorus contains an actual sulphur;
that is, a matter disposed to take fire with the greatest
eafe. But though sulphur be very inflammable, it never
takes fire of itself, without being either in contact with
some matter that is actually ignited, or else being exposed
to a considerable degree of heat. Let us see then what
may be the cause of its ascension, when it is a constituent
part of this phosphorus.

We mentioned just now, that the acid of the alum quits
its basis, in order to form a sulphur by combining with the
phlogiston of the coal. This basis we know to be an
earth capable of being converted into lime; and that it
is actually converted into quick-lime by the calculation
necessary to produce the phosphorus. We know that
new made lime hath the property of uniting with water
so readily, that it thereby contracts a very great degree
of heat. Now when this phosphorus, which is partly
constituted of the basis of the alum converted into quick-
lime, is exposed to the air, the lime instantly attracts
the moisture of which the air is always full, and by this
means, probably, grows so hot as to fire the sulphur
with which it is mixed. Perhaps also the acid of the
alum is not totally changed into sulphur: some part
thereof may be only half-disengaged from its basis, and
in that condition capable of attracting strongly the hu-
midity of the air, of growing very hot likewise by in-
bibing the moisture, and so of contributing to the ascen-
sion of the phosphorus.

There is also room to think that all the phlogiston of
the charred matter is not employed in the production of
sulphur in this phosphorus, but that some part of it re-
 mains in the state of a true coal. The black colour of
the unkindled phosphorus, and the red sparkles it emits
while burning, sufficiently prove this.

Human Urine analysed.

Put some human urine into a glass alerobic; set it in
a water bath, and distill till there remain only about a
fortieth part of what you put in; or else evaporate the
urine in a pan set in the balsamic marie till it be reduced
to the same quantity. With this heat nothing will ex-
hale but an insipid phlegm, smelling however like urine.
The residuum will, as the evaporation advances, become
of a darker and darker rufset, and at last acquire an al-
moft black colour. Mingle this residuum with twice its
weight of sand, and distill it in a retort set in a reverber-
rating furnace, with the usual precautions. At first there
will come over a little more insipid phlegm like urine.

Mix together the spirit, the volatile salt, the phlegm, and the oil, obtained from any substance whatever. Put the whole into a large wide-mouthed glass body, and thereto fit a head with a large beak. Set this alembic in a water-bath, lute on a receiver, and distil with a very gentle heat. There will ascend a spirit strongly impregnated with volatile alkali, and a volatile salt in a concrete form, which must be kept by itself. Then increase your heat to the degree of boiling water; whereupon there will rise a second volatile spirit, somewhat more ponderous than the former, with a light oil that will swim on its surface, and a little concrete volatile salt. Proceed till nothing more will rise with this degree of heat. Keep by itself what came over into the receiver. At the bottom of the cucurbit you will find a thick fetid oil.

Into such another distilling vessel put the spirit and salt that rose first in this distillation, and distil them in the bain-marie with a heat still gentler than before. A whiter, purer, volatile salt will sublimate. Continue the distillation till an aqueous moisture rise, which will begin to dissolve the salt. At the bottom of the vessel will be left a phlegm, with a little oil floating on it. Keep your salt in a bottle well stopp'd.

On a volatile spirit or salt pour gradually any acid whatever. An effervescence will arise, and be more or less violent according to the nature of the acid. Go on adding more acid in the same manner, till no effervescence be thereby excited, or at least till it be very small. The liquor will now contain a semi-volatile neutral salt, called an ammoniacal salt; which may be obtained in a dry form by crystallizing as usual, or by subliming it in close vessels, after the superfluous moisture hath been drawn off. Volatile alkalis have the same properties with fixed alkalis, fixity only excepted: so that a volatile alkali must produce an effervescence when mixed with acids, and form therewith neutral salts, differing from each other in nothing but the nature of the acid in their composition.

It must be observed, that the point of saturation is very difficult to hit on this occasion; owing probably to the volatility of the alkali, which, being much lighter than the acid, tends always to prefect the uppermost part of the mixture, while the acid sinks to the bottom: whence it comes to pass, that the lower part of the liquor is sometimes overcharged with acid, while the upper part is still very alkaline. But it is most eligible that the alkali should predominate in the mixture; because the excess of this principle cally flies off while the moisture is evaporating in order to the crystallization or sublimation of the ammoniacal salt; which being only semi-volatile, refiis the heat longer, and remains perfectly neutral.

If the vitriolic acid be combined with a volatile alkali, and the mixture distilled in a retort to draw off the superfluous moisture, a liquor comes over into the receiver which smells strong of a sulphureous acid. Now, as the acid of vitriol never becomes sulphureous, but when it is combined with an inflammable matter, this experiment is one of those which demonstrate that volatile alkalis contain a very sensible quantity of inflammable matter. This same liquor taints an ammoniacal salt; which proves that it carries up with it some of the neutral salt contained in the mixture. The rest of this salt, which is called Glauber's secret sal ammoniac, or vitriolic sal ammoniac, sublimes into the neck of the retort. It is very pungent on the tongue; it crackles a little when thrown on a red-hot shovel, and then flies off in vapours.

The ammoniacal salt formed by the acid of nitre exhibits much the same phenomena; but it requires greater care in drying and subliming it, because it hath the property of detonating all alone, without the addition of any other inflammable matter: and it will infallibly do so, if too strong a fire be applied towards the end of the operation, when it begins to be very dry. This property of detonating by itself it derives from the inflammable matter contained in the volatile alkali which serves for its basis: and this is another demonstrative proof of the existence of such an inflammable matter in the volatile alkali. This salt is called nitrous ammoniacal salt.

With the vegetable acids, that of vinegar for instance, is formed an ammoniacal salt of a singular nature, and which can scarce be brought to a dry form.

A volatile alkali, combined to the point of saturation with the acid of sea-falt, forms another neutral salt, which takes a concrete form either by sublimation or crystallization. The crystals of this salt are so very soft and fine, that a parcel of it looks like cotton or wool. This is the salt properly called sal ammoniac. It is of great use in chemistry and in manufactures; but that which is daily consumed in great quantities is not made in the manner above mentioned. It would come extremely dear, if we had no other way of procuring it, but by forming it thus with the acid of sea-falt and a volatile alkali. This salt, or at least the materials of which it is formed, may be found in the fuliginosities and foots of mast animal, and of some vegetable substanaces. The greatest part of what we use comes from Egypt, where vast quantities thereof are made.

The method of preparing sal ammoniac in Egypt was not known among us till Melle Lemaire and Granger. Their memoirs inform us, that chimney-foot alone, without any addition, is the matter from which they obtain their sal ammoniac; that those chimneys under which nothing is burnt but cow's-dung, furnish the best foot. Six and twenty pounds of that foot yield usually six pounds of sal ammoniac.

"The operation takes up about fifty, or two and fifty hours. The vessels in which they put the foot are barrels of very thin glafs, terminating in a neck of fifteen or sixteen lines long, and an inch in diameter: but they are not all of the same size. The least contain twelve pounds of foot, and the greatest fifty; but they fill them only three quarters full, in order to leave room for the sublimation of the salt."

"The furnace, in which they place these barrels, consists..."
consists of four walls built in a quadrangular form. The two front-walls are ten, and the sides nine foot long; but they are all five foot high, and ten inches thick. Within the quadrangle formed by these walls, three arches run lengthwise from end to end thereof, at the distance of ten inches a funder. The mouth of this furnace is in the middle of one of its fronts, and of an oval form; two foot four inches high, and sixteen inches wide. "The balls lie in the spaces between the arches of the furnace, which serve instead of a grate to support them. Four of them are usually placed in each interval; which makes sixteen for one furnace. They are set at the distance of about half a foot from each other, and secured in their places with brick and earth. But they leave about four inches on the upper part of the ball uncovered, with a view to promote the sublimation, as they also do six inches of the interior part, that the heat may the better act on the matters to be sublimed. Things being thus prepared, they first make a fire with straw, which they continue for an hour. Afterwards they throw in cow's dung made up in square cakes like bricks. (The want of wood in this country is the reason that they generally make use of this fuel.) These cakes of dung add to the violence of the fire, which they continue in this manner for nineteen hours; after which they increase it considerably for fifteen hours more; and then they slacken it by little and little.

"When the matter contained in the vessels begins to grow hot, that is, after six or seven hours baking, it emits a very thick and ill-scented smoke, which continues for fifteen hours. Four hours after that, the sal ammoniac is observed to rise in white flowers, which continue in this manner for nineteen hours; after which they increase it considerably for fifteen hours more; and then they slacken it by little and little.

"From this history of the preparation of sal ammoniac it appears, that foot, and particularly the foot of animal matters, either contains abundance of this salt perfectly formed, and waiting only for distillation to separate it from thereon, or at least that it contains the proper materials for forming it; and that during the operation, which is a kind of distillation of foot, these materials combine together and sublime.

We shewed, in our analysis of foot, that this substance yields by distillation a great deal of volatile, alkalii; and this is an ingredient which makes at least one half of sal ammoniac. As to the other principle of this salt, the saline acid, this also must needs exist in foot: but it is not so easy to conceive how it should come there. It is very true that vegetable and animal substances, the only ones that produce foot in burning, contain some portion of sea-salt: but then this salt is very fixed, and seems unfit to rise with the acid, the oil, and the fibrous earth, of which the volatile alkalii is formed. Therefore we must suppose either that its elevation is procured by the force of the fire, aided by the volatility of the matters that exhale in burning; or that, being decomposed by the violence of the combustion, its acid alone rises with the other principles above mentioned. The latter seems probable enough: for though in the common operations of chemistry the bare force of fire doth not seem sufficient to decompose sea-salt; yet the example of sea-plants, which, before burning, contain this salt in abundance, and whose ashes contain scarce any at all, but are reunited with its fixed part, that is, with its alkaline bases, seems to prove, that, when this salt is intimately mixed with inflammable matters, it may be destroyed by burning; so that its acid shall desert its bases, and fly off with the foot.

Before the exact method of procuring sal ammoniac was known, it was generally imagined that the manufacturers mixed sea-salt, and even urine, with the foot; because these two substances contain the principles of which this salt consists. But, besides that the contrary now certainly appears from the above mentioned memoirs, it has been shewn by Mr Duhamel, who hath published several memoirs and experiments concerning the composition and decomposition of sal ammoniac, from which we have partly taken what we have already laid on this subject; it hath been shewn, in the first of these memoirs, that the addition of sea-salt to the foot, from which sal ammoniac is to be extracted, contributes nothing to its production, and cannot increase its quantity. That alone, therefore, which was originally contained in the matters that produced the foot, enters as a principle into the composition of sal ammoniac.

Sal ammoniac is sometimes found perfectly formed in the neighbourhood of volcanos. This salt is probably produced from the fuliginosities of vegetable or animal matters consumed by the fire of the volcanos.

Sal ammoniac is often impure, because it carries up with it, in sublimation, some of the black charred matter which ought to be left at the bottom of the vessel; but it is easily purified. For this purpose you need only dissolve it in water, filter the solution, then evaporate and crystallize; by which means you will have a very white and very pure sal ammoniac. You may if you please, sublime it again in a cucurbit and blind head, with a fire not too brisk. Some of it will rise in the form of a light white powder, called flower of sal ammoniac. These flowers are no other than true sal ammoniac, which hath suffered no decomposition; because the bare action of fire is incapable of separating the acid and the volatile alkalii, of which this neutral salt consists. When you intend to decompose it, you must use the means to be mentioned hereafter.

Though sal ammoniac be only semi-volatile, and requires a considerable heat to sublime it, yet it hath the property of carrying up with it matters that are very fixed and ponderous; such as metallic substances, and some kinds of earths. For medicinal uses we sublime therein with iron, lapis specularis, the copper in blue vitriol, &c. and then it takes different names, as martial flowers of sal ammoniac, sal ammoniac, and other such denominations, which it borrows from the matters sublimed with it.
Sal Ammoniac decompounded by acids.

Into a large tubulated retort put a small quantity of sal ammoniac in powder; set your retort in a furnace, and lute on a large ballon, as in the distillation of the fuming acids of nitre and sea-salt. Through the hole in your retort pour a quantity of oil of vitriol or spirit of nitre equal in weight to your sal ammoniac. An effervescence will instantly follow. The mixture will swell, and discharge white vapours which will come over into the receiver. Stop the whole in the retort immediately, and let the first vapours pass over, together with some drops of liquor, which will distil without fire. Then put a few coals into the furnace, and continue the distillation with a very gentle heat; which however must be increased little by little till nothing more will come over. When the operation is finished, you will find in the receiver a spirit of salt if you made use of oil of vitriol: or an aqua regis, if the spirit of nitre was employed: and in the retort will be left a saline mass, which will be either a glauber's secret sal ammoniac, or a nitrous sal ammoniac, according to the nature of the acid used to decompound the sal ammoniac.

Sal ammoniac decompounded by fixed Alkalis. Volatile salt. The Febrifuge of Sylvius.

Into a glass alembic or retort put sal ammoniac and salt of tartar pulverized and mixed together in equal quantities. Set your vessel in a proper furnace, and immediately lute on a large receiver. A little volatile spirit will ascend; and a volatile alkali, in a concrete form, very white and beautiful, will sublime into the head, and come over into the receiver, in quantity near two thirds or three fourths of the sal ammoniac used. Continue the distillation, increasing the fire by degrees till nothing more will sublime. Then unlute your vessels. Put up your volatile salt immediately into a wide mouthed bottle, and stop it close with a crystall stopple. At the bottom of the retort or cucurbit you will find a saline mass, which, being dissolved and crystallized, will form a salt nearly cubical, having the taste and other properties of sea-salt. This is the sal febrifugum sylvii.

Let one part of sal ammoniac and three parts of lime flaked in the air be pulverized separately, and expeditiously mixed together. Put this mixture immediately into a glas retort, so large that half of it may remain empty. Apply thereto a capacious receiver, with a small hole in it to give vent to the vapours, if needful. Let your retort stand in the furnace about a quarter of an hour, without any fire under it. While it stands thus, a great quantity of invisible vapours will rise, condense into drops, and form liquor in the receiver. Then put two or three live coals in your furnace, and gradually increase the fire till no more liquor will rise. Now unlute your vessels, taking all possible care to avoid the vapours, and quickly pour the liquor out of the receiver into a bottle, which you must stop with a crystall stopple, rubbed with emery. There will remain, at the bottom of the retort, a white mass, consisting of the lime employed in the distillation, together with the acid of the sal ammoniac: this is called fixed sal ammoniac.

Volatile Alkalis combined with oily matters. A Volatile Oily Aromatic salt.

Pulverize and mix together equal parts of sal ammoniac and salt of tartar; put the mixture into a glas or stone cucurbit: pour on it good spirit of wine till it rise half an inch above the matter. Mix the whole with a wooden spatula; apply a head and a receiver, and distil in a sand-bath, gently heated, for two or three hours. A volatile salt will rise into the head; and then the spirit of wine will distil into the receiver, carrying with it a portion of the volatile salt.

When nothing more will come over, let your vessels cool; then unlute them, separate the volatile salt, and weigh it directly. Return it into a glas cucurbit, and for every ounce thereof add a dram and a half of essential oil, drawn from one or more sorts of aromatic plants. Stir the whole with a wooden spatula, that the essence may incorporate thoroughly with the volatile salt. Cover the cucurbit with a head, fit on a receiver, and, having luted it exactly, distil in a sand-bath, as before, with a very gentle heat. All the volatile salt will rise, and stick to the head. Let the fire go out; and when the vessels are cooled take your salt out of the head. It will have an odour compounded of its own proper smell, and the smell of the essence with which it is combined. This is an aromatic oily salt. Put it into a bottle stopped close with a crystall stopple.
CHEMOSIS, a disease of the eyes, proceeding from an inflammation, when the white of the eye swells above the black, and overtops it to such a degree, that there appears a sort of gap between them.

Others define it to be an elevation of the membrane which surrounds the eye, and is called the white; being an affection of the eye, like white itch.

CHENOPODIUM, in botany, a genus of the pentandria digynia class. The calyx consists of five leaves; it has no corolla; and there is but one lenticular seed. There are 18 species, 13 of which are natives of Britain, viz. the bonus herinus, common English mercury, or all-good; the urticum, or upright blite; the rubrum, or sharp leaved goose foot; the morule, common goose-foot, or bow-bane; the hydridum, or maple-leaved blite; the album, or common orache; thePolypemum, round-leaved blite, or all seed; the maritimum, sea blite, or white glass-wort; and the fruticosum, shrub flone-crop, or glass-wort. The leaves of the vulvaria, or flinking orache, are said to be an excellent anti hyteric.

CHESTER, a port-town in Lancashire, about nine miles south of Manchester: W. long. 2° 40', N. lat. 51° 45'.

CHESWICK, or Chester, the prince of Mecca, who is, as it were, high priest of the law, and sovereign pontiff of all the Mahometans, of whatever sect or country they be. See Caliph.

The grand signor, sultanes, moguls, khans of Tartary, &c. send him yearly presents, especially tapestry to cover Mahomet's tomb withal, together with a fumptuous tent for-himself, and vast sums of money to provide for all the pilgrims during the seventeen days of their devotion.

CHESY, in Jewish antiquity, the second and greater of excommunication among the Jews.

The cherem deprived the excommunicated person of almost all the advantages of civil society: he could have no commerce with any one, could neither buy nor sell, except such things as were absolutely necessary for life; nor resort to the schools, nor enter the synagogues; and no one was permitted to eat or drink with him.

The sentence of cherem was to be pronounced by ten persons, or at least in the presence of ten: but the excommunicated persons might be abolved by three judges, or even by one, provided he were a doctor of the law. The form of this excommunication was loaded with a multitude of curses and imprecations, taken from different parts of the scripture.

CHERRY TREE, in botany. See Prunus.

CHERRY-ISCLE, in geography, an island situated in the north or frozen ocean, between Norway and Greenland: E. long. 20°, N. lat. 75°.

CHERSO, the capital of the Chersonese, among geographers, the same with the gulf of Venice, and subject to the Venetians: E. long. 15°, N lat. 43° 25'.

CHERSOESUS, among geographers, the same with a peninsula. See Peninsula.

CHERTSEY, a market town of Surry, about seven miles west of Kingston: W. long. 3° 30', N. lat. 51° 25'.

CHERUB, or Cherubim, a celestial spirit, which in the hierarchy is placed next to the seraphim. See Hierarchy.

The several descriptions which the scripture gives us of cherubins, differ from one another; but all agree in representing a figure composed of various creatures, as a man, an ox, an eagle, and a lion.

Cherub, in botany. See Chermes.

Cherub-Tree, a market town of Surry, about seven miles west of Kingston: W. long. 3° 30', N. lat. 51° 25'.

Cherubim, or Cherubim, a celestial spirit, which in the hierarchy is placed next to the seraphim. See Hierarchy.

The several descriptions which the scripture gives us of cherubins, differ from one another; but all agree in representing a figure composed of various creatures, as a man, an ox, an eagle, and a lion.

CHERWEL, a river, which, arising in Northamptonshire, runs southwards by Banbury, and unites its waters with those of the Isis, near Oxford.

Chesham, a market-town of Buckinghamshire, about nine miles south-east of Aylesbury: W. long. 3° 5', N. lat. 51° 36'.

CHESHIRE, a maritime county of England, bounded by Staffordshire on the east, and by the Irish sea on the west: its chief commodities are salt and cheese, the laft of which is much esteemed all over Britain.

Chesnut-tree, in botany. See Fagus.

Chess, an ingenious game, performed with different pieces of wood, on a board divided into sixty-four squares or houses; in which chance has so small a share, that it may be doubted whether a person ever lost but by his own fault.

Each gamerster has eight dignified pieces, viz. a king, a queen, two bishops, two knights, and two rooks; also eight pawns: all which, for distinction fakes, are painted of two different colours, as white and black.
As to their disposition on the board, the white king is to be placed on the fourth black house from the corner of the board, in the first and lower rank; and the black king is to be placed on the fourth white house on the opposite or adversary’s end of the board. The queens are to be placed next to the kings, on houses of their own colour. Next to the king and queen, on each hand, place the two bishops; next to them, the two knights; and last of all, on the corners of the board, the two rooks. As to the pawns, they are placed without distinction, on the second rank of the house, one before each of the dignified pieces.

Having thus disposed the men, the onset is commonly begun by the pawns, which march straight forward in their own file, one house at a time, except the first move, when it can advance two houses, but never moves backwards; the manner of their taking the adversary’s men, is side-ways, in the next house forwards; where having captivated the enemy, they move forward as before. The rook goes forward or cross-ways through the whole file, and back again. The knight stops backward and forward to the next, or cross-ways, or guards his friends that may be exposed in his way, or guards his friends that may be exposed on that side. The bishop walks always in the same colour of the field that he is placed in at first, forward and backward, alope, or diagonally, as far as he lifts. The queen’s walk is more universal, as she takes all the steps of the before-mentioned pieces, excepting that of the knight; and as to the king’s motion, it is one house at a time, and that either forward, backward, alope, or side ways.

As to the value of the different pieces, next to the king is the queen, after her the rooks, then the bishops, and last of the dignified pieces comes the knight. The difference of the worth of pawns, is not so great as that of noblemen; only, it must be observed, that the king’s bishop’s pawn is the best in the field, and as to the king’s motion, it is one house at a time, and that either forward, backward, alope, or side ways.

Chevy chase.

CHESTER, the capital city of Cheshire, situated fifteen miles south of Liverpool: W. long. 3°, N. lat. 53° 15’. It is a bishop’s see, and gives the title of earl to the prince of Wales.

New-Chester, the capital of a county of the same name in Pennsylvania, in North America, situated on the river Delaware, south of Philadelphia: W. long. 74°, N. lat. 40° 15’. Its harbour is fine and capacious, admitting vessels of any burden.

CHESTERFIELD, a market-town of Derbyshire, fifteen miles north of Derby, W. long. 1° 25’, N. lat. 53° 20’. It gives the title of earl to a branch of the noble family of Stanhope.

CHEVALER, in the manage, is laid of a horse when in passing upon a walk or trot, his off fore-leg crosses or overlaps the near fore-leg every second motion.

CHEVALER, in a general sense, signifies a knight, or horsemann.

CHEVAUX DE PRISE, in fortification, a large joist, or piece of timber, about a foot in diameter, and ten or twelve in length, into the fides whereof are driven a great number of wooden pins. About fix foot long, armed with iron points, and crossing one another. See Fortification.

CHEVERON, in heraldry. See Chevrons.

CHEVIL. See Chevrons.

CHEVIOT, or TIVIOT-HILLS, run from north to south through Cumberland, and were formerly the borders or boundaries between England and Scotland, where many a bloody battle has been fought between the two nations, one of which is recorded in the ballad of Chevy chaise.

CHEVISANCE, in law, denotes an agreement or composition, as an end or order set down between a creditor and his debtor, &c.

In our figures, this word is most commonly used for an unlawful bargain, or contract.

CHEVRON, or Cheveron, in heraldry, one of the honourable ordinaries of a shield, representing two rafters of an house, joined together as they ought to stand; it was anciently the form of the prielefies head attire: some lay, it is a symbol of protection; others, of confancy; others, that it represents knights spears, &c. It contains the fifth part of the field, and is figured as in Plate LV. fig. 2.

A chevron is said to be abased, when its point does not approach the head of the chief, nor reach farther than the middle of the coat; mutilated, when it does not touch the extremities of the coat; cloven, when the upper pieces are taken off, and the lower only touch at one of the angles; broken, when one branch is lepated into two pieces; couched, when the point is turned towards one side of the escutcheon; divided, when the branches are of several metals, or when metal is opposed to colour; inverted, when the point is turned towards the point of the coat, and its branches towards the chief.

Per Chevron, in heraldry, is when the field is divided only by two single lines, rising from the two base points, and meeting in the point above, as the chevron does.

CHEVRONED,
CHEVRONED, is when the coat is filled with an equal number of chevrons, of colour and metal.

CHEVRONEL, a diminutive of chevron, and as such only containing half a chevron.

CHEVRONNE, or CHEVRONNY, signifies the dividing of the shield several times chevron-wise.

CHEWING-BALLS, a kind of balls made of afeetida, liver of antimony, bay-wood, juniper-wood, and pellitory of Spain; which being dried in the sun, and wrapped in a linen-cloth, are tied to the bit of the bridle for the horse to chew; they create an appetite and pellitory of Spain; which being dried in the sun, and it is said, that balls of Venice treacle may be used in the same manner with good success.

CHIAMPAY, the south division of Cochin-China, a country of the East-Indies.

CHIAROSCURO, among painters. See Claro-ob-scuro.

CHICK, or Chicken, in zoology, denotes the young of the gallinaceous order of birds, especially the common hen. See Phasianus.

CHICKLING, in medicine. See Pernio.

CHILD-bed. See Midwifery.

CHILD-birth. See Midwifery.

CHILDERS-day, or Innocent’s-day, an episcopal held by the church, on the 28th of December, commemoration of the children at Bethlehem, massacred by order of Herod.

CHILI, a province of South America, bounded by Peru on the north, by the province of La Plata on the east, Patagonia on the south, and by the Pacific ocean on the west; lying between 25° and 45° S. lat. and between 75° and 85° W. long. But some comprehend Patagonia in Chili, extending it to Cape Horn, in 57° 30' S. lat. It is to take up just the third part of the escutcheon, as all other honourable orders do, especially if they are alone on the shield; but if there be several of them, they must be lessen'd in proportion to their number, and the same holds when they are cantoned, attended and bordered upon by some other figures; then the painter or engraver may be allowed to bring them into a smaller compass, to the end that all that is represented about the ordinaris may appear with some proportion and symmetry. Chiefs are very much varied, for they may be couvert, supported, crenell'd, surmounted, abyssi, rempli, dentill'd, engrel'd, cassell'd, danc'd, nell'd, fleurdelis'd, flueronné, vair, echequet'd, lozange'd, burcelled, patt'd, fretted, gironné, chaperonné, chopp'd, mantel'd, emmanch'd, chausses, veulls or reffu. See COUVERT, SUPPORTED, &c.

CHIEF, or CHIEFTAIN, denotes the captain, or chief, of any class, family, or body of men; thus, the chieftains, or chiefs, of the highland clans, were the principal noblemen or gentlemen of their respective clans.

CHIEL, imports something borne in the chief part or top of the escutcheon.

CHIEF lord, the feudal lord, or lord of an honour on whom others depend.

CHIEF-justice of the king’s bench and common pleas. See JUSTICE.

CHIETI, or Innocent’s-day, an episcopal held by the church, on the 28th of December, commemoration of the children at Bethlehem, massacred by order of Herod.

CHILDERMAS-day, or Innocent’s-day, an episcopal held by the church, on the 28th of December, commemoration of the children at Bethlehem, massacred by order of Herod.

CHILI, a province of South America, bounded by Peru on the north, by the province of La Plata on the east, Patagonia on the south, and by the Pacific ocean on the west; lying between 25° and 45° S. lat. and between 75° and 85° W. long. But some comprehend Patagonia in Chili, extending it to Cape Horn, in 57° 30' S. lat. CHILIAD, denotes a thousand of any thing, ranged in several divisions, each whereof contains that number.

CHILBLAINS, in medicine. See Pernio.

CHILD-BIRTH. See Midwifery.

CHILDERMAN-s-day, or Innocent’s-day, an episcopal held by the church, on the 28th of December, commemoration of the children at Bethlehem, massacred by order of Herod.

CHILI, a province of South America, bounded by Peru on the north, by the province of La Plata on the east, Patagonia on the south, and by the Pacific ocean on the west; lying between 25° and 45° S. lat. and between 75° and 85° W. long. But some comprehend Patagonia in Chili, extending it to Cape Horn, in 57° 30' S. lat.

CHILDIAD, denotes a thousand of any things, ranged in several divisions, each whereof contains that number.

CHILDAR, or CHILLARCUS, in antiquity, a military officer, who had the command of a thousand men.

CHILLOTS, in church-history. See MILLENIARIANS.

CHILMINAR, Chelminar, or Tchelminar, the most beautiful piece of architecture remaining of all antiquity, being the ruins of the famous palace of Per- copolis, to which Alexander the Great, in a drunken fit, set fire, at the instigation of Thais the courtesan.
the word comes from the Persian techebele minor, that is to say, forty towers.

Don Garcias de Silva Figueroa, Pietro della Valle, Sir John Chardin, and Le Brun, have been very particular in describing these ruins.

There appear, say they, the remains of near four-score columns, the fragments of which are at least fix feet high; but there are only nineteen can be called entire, with another detached from the rest, about an hundred and fifty paces: a rock of hard black marble serves as a foundation to the edifice: the first plan of the house is ascended to by ninety-five steps, all cut in the rock; the gate of the palace is about twenty feet wide, with the figure of an elephant on one side, and that of a rhinoceros on the other, thirty feet high, and both of polished marble: near these animals there are fragments of magnificent columns in white marble, the smallest of which are fifteen cubits high, the largest eighteen, having forty flutings three full inches wide each; from whence we may judge of their thickness and other proportions. Near the gate is seen an inscription on a square piece of black marble, containing about twelve lines; the characters are of an extraordinary figure, resembling triangles, or pyramids: besides this, there are other inscriptions, the characters of which resemble the Hebrew, Chaldaic, or Syrian; others the Arabic or Persian; and others, in fine, the Greek characters. Dr Hyde, who hath explained the Greek inscription, by supplying some words that are effaced, observes, that the inscriptions are engraved very negligently, and perhaps by some soldiers; or, if they are the work of an engraver, he thinks that he was from Palmyra. From the Phoenician tongue: he adds, that as they are in praise of Alexander, they were probably done in the time of that conqueror.

CHILTERN, a chain of chalky hills, running from east to west through Buckinghamshire.

CHIMERA, in geography, a port-town of Turky in Europe, situated at the entrance of the gulf of Venice, in the province of Epirus, about thirty-two miles north of the city Corfu, near which are the mountains of Chimera, which divide Epirus from Thessaly: E. long. 20° 40’, and N. lat. 40° 20’.

CHIMAY, the name of a great lake, lying in the province of Acham, between the East-Indies and China.

CHIMERA, a fabulous monster, which the poets reign to have the head of a lion, the body of a goat, and the tail of a dragon; and add, that this odd beast was killed by Bellerophon. The foundation of the fable was, that in Lycia there was a burning mountain, or vulcano, of this name; that the top of this mountain was seldom without lions, nor the middle, which had very good grass, without goats; that ferpents bred at the bottom, which was marlhy; and that Bellerophon rendered the mountain habitable.

By a chimera, among the philosophers, is understood a mere creature of the imagination, composed of such contradictions and absurdities as cannot possibly any where exist but in thought.

CHIMES of a clock, a kind of a periodical music, produced at equal intervals of time, by means of a particular apparatus added to a clock.

CHIMNEY, in architecture, a particular part of a house, where the fire is made, having a tube or funnel to carry away the smoke. See ARCHITECTURE.

CHINA, including Chinese Tartary, a large empire, situated between 95° and 135° E. long. and between 21° and 55° N. lat. being accounted two thousand miles in length, and one thousand five hundred in breadth; it is bounded by Russian Tartary on the north, by the Pacific ocean on the east and south, and by Tonquin, Tibet, and the territories of Russia on the west. It is usually divided into sixteen provinces, which will be described in their alphabetical order. In these provinces there are computed to be one hundred and fifty-five capital cities, one thousand three hundred and twelve of the second rank, two thousand three hundred and fifty-seven fortified towns, and upwards of ten millions of families, which may amount to about fifty millions of people.

The principal commodities of this country are silk, tea, China ware, Japan-ware, and gold dust; of all which the maritime states of Europe import great quantities, sending them silver in return.

CHINA-root, in pharmacy, a medicinal root, brought both from the East and West-Indies, thence distinguished into oriental and occidental; it is the root of a species of smilax. See SMILAX.

CHINA-ware. See PORCELAIN.

CHINCA, a port-town of Peru, in South America, situated in an extensive valley, on a river of the same name, about sixty miles south of Lima: W. long. 76°, and S. lat. 13°.

CHIN COUGH, a convulsive kind of cough, which children are chiefly subject to. See MEDICINE.

CHINESE, in general, denotes any thing belonging to China. See CHINA.

It is observed by some, that the Chinese language has no analogy with any other language in the world: it only consists of three hundred and thirty words, which are all monosyllables, at least they are pronounced so short that there is no distinguishing above one syllable or found in them; but the same word, as pronounced with stronger or weaker tone, has different significations; accordingly, when the language is accurately spoke, it makes a sort of music, which has a real melody, that constitutes the efficacy and distinguishing character of the Chinese-tongue.

As to the Chinese characters, they are as singular as the language; the Chinese have not, like us, any alphabet, containing the elements, or, as it were, the principles of their words; instead of an alphabet they use a kind of hieroglyphics, whereof they have above eighty thousand.

As the Chinese pretend to an antiquity both with regard to their nation and arts, far beyond that of any other nation, it will not perhaps be unacceptable to give
give a short view of these pretensions, principally extracted from their own writers, but, when any thing is quoted from the Chinese history, it is absolutely necessary to attend, 1. To the times purely fabulous and mythical; 2. To the doubtful and uncertain times; and, 3. To the historical times, when the Chinese history, supported by indubitable monuments, begins to proceed on sure grounds.

I. Sóme ascribe to Tiene-hoang, a book in eight chapters, which contains the origin of letters. They add, that the characters used by the Sane hoang were natural, without any determinate form, that they were nothing but gold and precious stones.

Lieou-jou, author of Ouai-ki, says, that Tiene-hoang gave names to the ten KANE, and to the twelve TCHI, to determine the place of the year: this is meant of the cyclic characters.

Tiene-hoang signifies emperor of heaven. They call him also Tiene ling, the intelligent heaven; Tsee jirn, the son who nourishes and adorns all things; and finally Tchong-tiene-hoang-kune, the supreme king of the middle heaven, &c. This Tiene-hoang succeeded Pouane-chou.

The Ouai-ki says, that Ti-hoang (emperor of the earth), the successor of Tiene-hoang, divided the day and the night, and appointed thirty days to make one moon. The book Tong li, quoted in Lopi, adds further, that this emperor fixed the winter-solstice to the eleventh moon. A proof that the Chinese year was originally very incorrect, and that the course of it was regulated only by that of the seasons, is, that for a long time, to express a year, they said a change of the leaves.

This Ti-hoang, says, was father of Tiene-hoang, and of Gine-hoang who follows.

They give Gine-hoang (sovereign of men) nine brothers, and pretend, that they divided the government among them. They were nine brothers (says Yuene-leoa-fane) who divided the earth among them, and built cities, which they surrounded with walls. It was under this prince (says Lopi), that there first began to be a distinction between the sovereign and the subject; they drank, they eat, and the two sexes united.

After these three emperors which we have just now named, they place the period named Ou-long-(the five Long or dragons) composed of five different families. But they do not tell us their names, nor the duration of their reigns. In these times (says an author) men dwelt in the bottom of caves, or perched upon trees as it were in concert, made war against them.

They say nothing of the third Ki. Of the fourth, named Ho lo, and composed of three families, they say, that the Ho-lo taught men to retire into the hollows of rocks. This is all they say of it. Neither do they say anything of the fifth Ki, named Lienie-tong, and composed of six families; of the sixth Ki, named Su-niing, and composed of four families.

It is folly to dwell upon the epocha of these six Ki; nothing is more absurd. Lopi cites an author who generously gives them 1,100,750 years duration; Lopi says himself, that the five first Ki after Gine hoang make in all 99,000 years.

The seventh Ki is named Sune-fei, and comprehends twenty-two families. But they lay nothing under all these reigns that has any relation to the arts or sciences. Only under the twenty-second and last, named Tsee-che-chi, they say, that it was not till then men ceased to dwell in caves. Is it not a palpable absurdity, that after so many ages, and under kings of whom they relate so many wonders, they had not yet found out the art of building huts to shelter them from the winds and rains?

The eighth Ki, named Tsee-it, contains thirteen families or dynasties. Tchine-fang-chi, the first of this period, reigned after Tsee-che-chi, and founded the first family. They say, that at the beginning men covered their bodies with leaves and herbs; serpents and beasts were very numerous; the waters had overflowed, were not yet returned into their channels; and the misery of mankind was extreme. Tchine-fang taught men to prepare skins, to take off the hair with rollers of wood, and use them against the winds and frost which incommoded them very much. He taught them also to make a kind of web of their hair, to serve them as a covering to their heads against the rain. They obeyed him with joy; he called his subjects people clothed with skins; he reigned 350 years. To Tchine-fang-chi succeeded Chou-chane-chi, then Hai-koueichi, of whom they lay nothing which has any relation to our subject.

The fourth prince, who also succeeded Hai-kouei-chi, was named Hoene-tune; he founded the fourth dynasty, (for each of these princes which we have just now mentioned, was the founder of a family or dynasty.) In the history of this king, Lopi quotes Lao-chene-teee, who speaks thus:

"The ancient kings wore their hair dishevelled, without any ornament upon their heads. They had neither sceptre nor crown, and they governed their people in peace. Being of a beneficent disposition, they cherished all things, and put no person to death. Always giving, and never receiving any thing, their subjects, without dreading their power as tyrants, revered their virtue in their hearts. Then heaven and earth observed a most beautiful order, and every thing flourished in a surprising manner. The birds built their nests so low, that they might be reached-with the hand; all the animal creation tamely submitted to the will of man. Then the just medium was observed, and harmony reigned over all. They did not reckon the year by the days. There was no distinction between within and without, between mine, and thine. In this manner reigned Hoene-tune. But, when mankind had degenerated from this happy state, birds and beasts, insects and serpents, all together, as it were in concert, made war against them."

To this dynasty of Hoene-tune, succeeded that of Tong-hou-chi, containing seven kings which are not named. To this fifth dynasty succeeded the sixth, whose founder was Hoang-tane-chi.

The 7th, the dynasty of Ki-tong-chi.*

The 8th, the dynasty of Ki-y-chi*.
The 9th, the dynasty of Ki-ku-chi.
The 10th, the dynasty of Hi-ouei-chi.
The 11th, the dynasty of Yeou-t'ao-chi.
The 12th, the dynasty of Soui-gine.
The 13th and last, the dynasty of Yong-t'ching-chi.

Of these seven kings, or founders of dynasties, which remain to be considered, to complete the number of dynasties included in this eighth period, nothing is said of tho' marked * that has any relation to our subject.

As to Yeou-t'ao-chi, founder of the eleventh dynasty, whose reign, they say, lasted more than 300 years, and whose family, they add, continued more than 100 generations during the space of 12 or 18,000 years: here is what we find recorded.

Hane-t'ee says, that, in the first ages of the world, animals multiplied very fast; and that men being but few, they could not subdue the beasts and serpents.

Yene-t'ee says also, that the ancient, either perched on trees, or stretched in hollow caves, possessed the universe; (Tien-tsia, that is to say, China). These good kings (continues he) breathed nothing but charity without any shadow of hatred. They gave much, and took nothing. The people did not go to pay their court to them, but all the world submitted to their virtues.

Lopi and Ouai-ki say almost in the same words, that, in the most remote antiquity, men sheltered themselves in the hollows of rocks, that they dwelt in deserts, and lived in society with all the other creatures. They had no thought of doing any injury to the beasts, and the beasts did not think of hurting them. But in the succeeding ages they became too wise, which made the animals rebel; armed with claws, teeth, horns, and venom, they assaulted man, and man was not able to resist them. Yeou-t'ao reigned then. He was the first who built houset of wood, in the form of birds' nests; he persuaded men to retire into them to avoid the wild beasts. They did not know as yet how to cultivate the earth; they lived on herbs and fruits. They drank the blood of animals; and these names (say they) were so expressive, that the nature of every thing was known by its name.

The 9th, the dynasty of Ki-ku-chi.
The 10th, the dynasty of Hi-ouei-chi.
The 11th, the dynasty of Yeou-t'ao-chi.
The 12th, the dynasty of Soui-gine.
The 13th and last, the dynasty of Yong-t'ching-chi.

They say further, that, in the days of Soui-gine, there was much water upon the earth, and that this prince taught men the art of fishing. He must, of consequence, have invented nets or lines, which invention is after this ascribed to Fou-hi.

One Long-ma, or Dragon-horse, brought him a kind of table, and the tortoise letters. Soui-gine is the first to whom they apply this event, but the same thing will be said in the sequel of several others.

Soui-gine was the first who gave names to plants and animals; and these names (say they) were so expressive, that the nature of every thing was known by its name. He invented weights and measures for the regulation of commerce, which had been unknown before him.

Anciently (says an author) men married at fifty, and women at thirty years of age: Soui-gine shortened this period, and appointed that young men should marry at thirty, and girls at twenty.

Lastly, the Liki says, that it was Soui-gine who first taught men urbanity and politeness.

It now remains to speak of Yong-t'ching-chi, the founder of the thirteenth and last dynasty of this period.

In his time, they used slender cords on which they tied various knots, and this served them instead of writing. But, after the invention of letters, how could they return again to the use of these cords, which is so limited and imperfect? This evidently contradicts the period.

We come now to the ninth Ki or period, named Chene-t'ong. This ninth period will bring us down to the times of Fou-hi. It comprehends twenty-one kings, whose names are as follow:

1. Se-hoang, or Ts'an-hie,
2. Pe-hoang-chi,
3. Tchong hoang-chi,
4. Tai-ting-chi,
5. Kouene hie,
6. Yene-chi,
7. Tai chi,
8. Tching hoie-chi,
9. Li lou, or Hoei-chi,
10. Sohoang chi,
11. Nuei-touane chi,
12. Hien-yuene,
13. He fou,
14. Kai-tiene,
15. Tsene liu chi,
16. Tcho jong,
17. Hao-yung,
18. You-t'ao-chi,
19. Tchu-fiang-chi,
20. Yne-khang-chi,

Liu-pou-ouei says plainly, that Se-hoang made letters. This Se-hoang, is called also T'fang hie. Some historians place him under Hoang-ti, whose minister they make him; while others make him a sovereign prince, and much anterior to Hoang-ti.

The first inventor of letters was T'fang-hie, then the king Fou-hoai made them be engraved on the coin, and Fou-hi used them in the public acts for the government of the empire.

The first inventor of letters was T'fang-hie. Some historians place him under Hoang-ti, whose minister they make him; while others make him a sovereign prince, and much anterior to Hoang-ti.

To this criticism it may be answered, You have told us, that letters had been invented in the reign of Soui-gine, the 12th king of the eighth period; how then can you pretend to give the honour of this invention to T'fang-
T'ang-hie, who, according to your own testimony, did not flourish till the ninth period? However this may be, Ssee-hoa (say some romancers) knew to form letters the moment he was born. He was endowed with great wisdom, &c. After he had received the Ho-tou, he visited the south, went upon mount Yang-yu, and stalked on the bank of the river Lo. A divine tortoise carrying blue letters upon his shell, delivered them to him: then Ssee-hoa penetrated all the changes of heaven and earth; above he observed the various configurations of the stars; below he examined all the marks he had seen upon the tortoise; he viewed the plumage of birds, he took notice of the mountains, and of the rivers which flow from them, and of all this he composed letters. Some very learned Chinese think, that this was the ancient kind of writing named Ko-teou chu, which continued (say they) to the reign of the emperor Suene-oung, that is, to the year 827 before J. C.

But Cong-ying-ta very well observes, that though the external figures of the letters have changed several times in some things, the fix rules on which Tfang-hie formed his alphabet, have never suffered any change.

Then (continues Lopi) there was a difference between the sovereign and the subject, relation between the father and the son, distinction between the precious and the vile, laws appeared, rites and music reigned. Punishments were inflicted with vigour. Thus Ssee-hoa laid the foundations of good government, he appointed officers for each affair, the smallest did not escape him; and thus heaven and earth arrived at their full perfection.

They say nothing of the successor of Ssee-hoa which has any relation to our subject; but they say, that, under the reign of Tchong-hoang-chi, the third king of this period, they still used flender cords for writing.

From this prince we come at once to Hienie-yuene, the 12th in order of this period, because nothing is said of his predecessors.

We find a great many things under the reign of this prince, because he is the same with Hoang-ti, or at least he has confounded these two princes together.

They ascribe to Hienie-yuene the invention of cars. He joined two pieces of wood together, the one placed upright, and the other across, to the honour of the Most High. It is from this he is called Hienie-yuene. The piece of wood placed across is called hiene, and that which is placed upright is called yuene. Hienie-yuene struck copper money, and made use of the balance to determine the weight of things. By this means he ruled the world in peace. Ho signifies merchandise in general. Formerly they wrote simply ho, which signifies exchange. These merchandizes (say they) consisted in metal, kine, in precious stones, yu, in ivory, techi, in skins, pi, in coined money, t'suene, and in fluffs, pou, &c.

They then denominated money (as is done still) by the name of the reigning family. That of Hienie-yuene was one inch seven lines, and weighed twelve tebu, [the tebu is the 20th part of a yo, and a yo weighs 1200 little grains of millet]. They then ingraved letters on their money (as is still done at present.) It is for this reason that t'en tsee, letters, signifies also a piece of money, which is called likewise kini, and t'suene, and tao.
that we may judge of a reign by the dances which are used in it.

The 21st and last king of the 9th period is named Vou-hoeat-chi; but they relate nothing of this prince which is worthy of notice.

2. This is all that the fabulous times contain. If these times cannot enable us to fix the real epochs of various inventions, (as the Chinese are so full of contradictions about the time of these different discoveries), we see at least from them, that the origin of arts has been much the same among them as among other nations. We are now come down to Fou-hi, who is considered by the Chinese historians as the founder of their monarchy. What they say of this prince and his successors, has some more solidity in it than what we have hitherto seen.

**F O U - H I.**

The Ouai-ki, quoted in the Chinese annals, thus describes the manners of mankind in those days. “In the beginning, men differed nothing from other animals in their way of life. As they wandered up and down in the woods, and women were in common, it happened that children never knew their fathers, but only their mothers. They abandoned themselves to lust without shame, and had not the least idea of the laws of decency. They thought of nothing but sleeping and snoring, and then getting up and yawning. When hunger prevailed, they sought for something to eat; and when they were glutted, they threw the rest away. They eat the very feathers and hair of animals, and drank their blood. They clothed themselves with skins quite hairy. The emperor Fou-hi began by teaching them to make lines fitting clothes for garments. Lopi adds, that it is a mistake to imagine, that, in the times of Fou-hi, they still used cords tied and knotted, and that books were not introduced till under Hoang-ti.

Fou-hi taught men to rear the six domestic animals, not only for food, but also for victims, in the sacrifices which they offered to China, and to Ki. They pretend that Fou-hi regulated the rites Kia-chen.

Fou-hi also introduced marriage; before this the intercourse of the sexes was indiscriminate; he settled the ceremonies with which marriages were to be contracted, in order to render this great foundation of society respectable. He commanded the women to wear a different dress from that of the men, and prohibited a man’s marrying a woman of the same name, whether a relation or not, a law which is actually still in force. Fou-hi appointed several ministers and officers to assist him in the government of the empire.

One of these officers made the letters, another drew up the calendar, a third built the houses, a fourth practised medicine, a fifth cultivated the ground, a sixth was the master of the woods and waters.

They pretend that Fou-hi applied himself very much to astronomy. The Tcheou-pi fouane says, that he divided the heavens into degrees. Lopi takes notice, that properly the heavens have no degrees, but that this term is used with relation to the path of the sun in the course of a year.

The period of sixty years is reckoned due to Fou-hi. The Tiene-prene says plainly, that this prince made a calendar to fix the year, and that he is the author of Kia-tse. The Sanen-prene says the same thing; and the Hane-li-tchi says, that Fou-hi made the first calendar by the Kia-tse; but the Ci-prene ascribes this to Hoang-ti.

This is one of these contradictions so common in the Chinese historians.

The fame Fou-hi, they say, made arms, and ordained punishments. These arms were of wood, those of Chinnong were of stone, and Tchi-you made some of metal.

Fou-hi drained off the waters, and surrounded the cities with walls. In the mean time, as Chinnong is esteemed the first who made walls of stone, we must suppose that those raised by Fou-hi were only of earth or brick.

Fou-hi gave rules to music. Those who ascribe this fine art to Hoang-ti are deceived (or vice versa.) After Fou-hi had invented fishing, he made a long for the fishers. It was from his example that Chinnong made one for the labourers.

Fou-hi took the wood of Tong; he made it hollow; and of it made a kine (a lyre, or what you please to translate it) seven feet two inches long; the strings were of silk, to the number of 27; he commanded this instrument to be named Li. Others say it had but 25 strings. }
flings, others t0, and others only 5; (which of them shall we believe?) Besides, others make this instrument only three feet six inches six lines in length.

Fou-hi made this instrument, say some, to ward off incantations, and banish impurity of heart.

He took of the wood of *fang, and made also a guitar of 36, or rather of 50 strings. This instrument served to adorn the person with virtues, and to regulate the heart, &c. Lastly, he made a third instrument of baked earth; after which, say they, ceremonies and music were in high esteem.

The money which Fou-hi introduced, was of copper, round within to imitate heaven, and square without to resemble the earth.

He himself made trial of many medicinal plants. (This is most commonly said of Chin-nong: but it is pretended, that Chin-nong finished what Fou-hi had begun.)

This is all we read of Fou-hi. Several contradictions will be remarked in most of these traditions, especially when we come to see in the sequel, that almost all these inventions are ascribed to the successors of Fou-hi.

From hence may be judged what regard is due to the beginnings of the Chinese history.

We have still some reigns to examine, before we have done with the fabulous and uncertain times.

They say of Kung-king, that he employed iron in making hangers and hatchets.

They ascribe to Niu-oua (who is the Eve of the Chinese) several instruments of music. The instruments *feng and *hoang served her, say they, to communicate with the eight winds. By means of *kouene, or double flutes, they united all sounds into one, and made concord between the sun, moon, and stars. This is called perfect harmony. Niu-oua had a guitar (*fe) of five strings; she made another of 50 strings, whose sound was so affecting, that it could not be borne; wherefore she reduced these 50 strings to 25, to diminish its force.

The emperor Chin-nong is very famous among the Chinese, by the great discoveries which, they say, he made in medicine, agriculture, and even in the military art; since they believe, that, in the times of Han, they had a book of this prince on the military art.

A fondness for the marvellous has made some say, that, at three years of age, he knew every thing that concern education. The very name Chin-nong, in the Chinese language, signifies, the spirit of husbandry. Chin-nong took very hard wood, of which he made the handle of the plough, and softer wood of which he made the handle. He taught men to cultivate the earth.

They ascribe to him the invention of wine. He fowed the five kinds of grains on the south of Mount Ki, and taught the people to make them their food.

Chin-nong commanded that they should be diligent in gathering the fruits which the earth produced. He taught every thing relative to hemp, to the mulberry tree, and the art of making cloth and fluffs of silk. They owe also to Chin-nong the potters and the founders art; others, however, ascribe pottery to Hoang-ti, and the art of melting metals to Tchi-yeou.

Chin-nong invented fairs in the middle of the day. This was the origin of commerce and mutual exchange.
the Khi of the Yne and of Yang, he determined the change of the four seasons, and gave calculations for astronomy, geometry, and arithmetic.

Yong yuene, by order of Hoang-ti, made twelve bells of copper, which corresponded to the moons, and served to adjust the five tones, and fix the seasons, &c. fables.

Hoang ti invented a kind of diadem or tiara, called Miene. He ordered a blue and yellow robe to be made for himself, in imitation of the colours of heaven and earth. Having viewed the bird hoei, and considered the variety of its colours, as well as those of the flowers, he made garments be dyed of different colours, to make a dillinction between the great and small, the rich and poor.

Nin-fong and Tche-tfiang invented mortars for pounding rice; kettles or caldrons: they invented the art of building bridges, and of making shoes; they made coffins for the dead; and men reaped great advantages from all these inventions. Hoei invented the bow, Ymeou arrows; Khy-pe invented the drum, which made a noise like thunder, trumpets and horns, which imitated the voice of the dragon.

Kong kou and Hoa-hu, by order of the Emperor Hoang ti, hollowed a tree of which they made a ship; of the branches of the same tree they made oars; and by this means they were able to penetrate into places which seemed inaccessible, and where men had never been.

For the transportation of merchandise by land, they also invented chariots under this reign, and trained oxen and horses to draw them.

Hoang-ti also turned his thoughts to buildings, and gave models of them. He built a temple, called He-kong, in which he sacrificed to Chang-ti, or to the Supreme Being.

With a view to facilitate commerce, Hoang-ti struck money, called kine-tao, knife of metal, because it had the shape of the blade of a knife.

Hoang-ti having observed that men died before the time fixed by nature, of diseases which carried them off, he commanded Yu-fou, Ki-pe, and Lei-kong, three famous physicians of these times, to assist him to determine what remedies were proper for each disease.

Si-ling-chi, the chief confort of that emperor, contributed on her part to the good of the state, and taught the people the art of rearing silk-worms, of spinning their cocoons, and making fluffs of them.

Lei-tsi, who was the founder of the imperial dynasty of Hane. It has been adopted also by Hoang-fou-mi, and by most part of the best writers. The proofs of this opinion are taken partly from the book Tcheou-li, an ancient record, or state of the empire, which many afcribe to the famous Tcheou-coue, minifter and brother of Vou-vang, who was the founder of the imperial dynasty of Hane, eleven hundred and some odd years before the Christian era; partly from the commentaries of Tiou-kieou-mine on the Tchune-tcheou of Confucius's master. In these works, mention is made of the books, Sane-fene, and Ou-tiene, which, they say, are the histories of the three Hoang, and of the five Ti; now, the two first chapters of Chou-king, which contain an extract of the histories of Yao and of Chune, bore the title of Tiene-yao and Tiene-Chune; from whence it was concluded, that Yao and Chune were two of the five Ti; consequently Fou-hi, Ching-nong, and Hoang-ti, were what are called the three Hoang; and Chao-hao, Tcheouen-hio, Tico, Yao, and Chune, the five Ti. These may perhaps be thought but feeble proofs to support an historical fact of this kind; but those who are of a contrary opinion, bring nothing to induce us to believe them, rather than Confucian-coue and Hoang-fou mi.

Hou-chouang-hou, in a preface before the Tienepienne of Kine-gine-chane confesses, that we find in the Tcheou-li, the existence of the book of three Hoang, and that of five Ti; but he adds, that we do not find there the names of these eight monarchs; that, under the Thun, they spoke of Tiene hoang, of Ti hoang, and of Gine hoang; that Confucian-coue, in his preface to Chou-
Chou-king, gives Fou-hi, Chine nong, Hoang-ti, for the three Hoang, and that he takes Chao hao, Tchouene-hio, Tio, Yao, and Chune for the five Ti; but that we know not on what foundation he does this, since Confucius, in the Kiu-ku, distinguishes by the title of Ti, all the kings after Fou-hi. The same thing is proved by some passages of Tio-chi and of Liu-pou-ouei; from whence they conclude, that Fou-hi, Chine nong, and Hoang ti are not the three Hoang, and that there are no other Hoang but heaven, earth, and man.

Tchine-huene renounces Hoang-ti from the number of the Sane hoang, and puts in his place Niou-oua, whom he ranges between Fou-hi and Chine nong. Others strike out Niou-oua, and put Tcho-yong in the place of Hoang ti. Niou-oua was the father of Fou-hi, and Fou-hi, they say, reigned 115 years. At what age must this princes have mounted the throne, for they make her succeed her brother?

The famous Se ma-tièn, to whom the Chinefes, from their high esteem of him, have given the name of Tai fevong, or father of history, will have Hoang-ti, Tchouene-hio, Cao-fine, Yao, and Chune to be the five Ti; and he gave these princes for their predecessors Soui-gine chi, Fou-hi, and Chine nong, who, according to him, were the three Hoang. This opinion, since his time, has been embraced by several other writers, who depended upon his authority more than upon proofs which he could not produce.

Confucius says in his Kiu yu, that the princes who had governed the empire began at Fou-hi to take the name of Ti or Emperor. The fame philofophers says farther, in the treatife Hi-tsee, or commentary upon the Y-king, that anciently Fou-hi governed China, that Chine nong succeeded him, that after them Hoang-ti, Yao, and Chune were feated on the throne. From fo decisive a testimony, Hou-ou-fang, and several others with him, have not doubted, that these five princes named by Confucius were the Ou ti, or five emperors. As to the Sane hoang, they admitted Tienè hoang chi, Ti hoang chi, Gine-hoang chi, as three chiefs of the people who had governed the empire before Fou-hi.

As it is from Tcho-fe, that the severals authors we have now quoted, have borrowed their idea of this chi-riterical divifion of the eight firft Chinefe emperors, into three Hoang and five Ti, it is neceffary to relate what these religious think themfelves. They have opinions peculiar to themselves about these firft ages of the monarchy. They believe, that at the firft there were three Augusti, Sane-hoang; then five emperors, Ou ti; next three kings, Sane-vang; and lafly, five Pa, Ou-pa; that is to fay, five chiefs of Regulos.

This order fo regularly observed of three and then five, which is repeated twice, fews plainly, that all this has no foundation in truth, but that it is a fylllem invented at pleasure. Wherefore Tou-chong-chu, who lived under the Hane, explained this in an allegorical manner. The three Hoang were, according to him, the three powers, (heaven, earth, and man); The five Ti were the five duties (the duties of king and subjeft, of father and children, of husband and wife, of elder and younger brothers, of friends); the three Vang were the three lights, (sun, moon, and stars); finally, the five Pa were the five mountains, four of which are situated at the four cardinal points of the empire, and the fifth at the centre. Thus Tong-tchang chu allegorized this this pretended succession of kings. But Lopi, who relates this explanation, adds, it was not his own. This is a point of criticism of little importance to us; let them, if they please, ascribe it to fame other than Tong-tchang chu; we have fill ground to fay, that it came from fome writer who lived in an age not far from that of Tong-chang chu. This is enough for our present purpofe; since we fee from hence the little regard they then paid to this divifion, which they confidered as chimerical. It would be in vain to attempt to reconcile all these contradictions. All these imaginary reigns are in the manner of the Tao-fe, who have darkened the origin of the Chinefe monarchy by their fables and mythology. The ten Ki or periods are of their inventing; they gave them between two and three millions of years duration. But before these ten periods, they place three dynafties, viz. the dynasty of Thiene hoang-chi, that of Ti hoang-chi, and finally, that of Gine hoang-chi.

If we attend to the fignification of these names, they must be interpreted thus: the Sovereign of heaven, the Sovereign of earth, the Sovereign of men. We fee from hence, that the allegorical explanation of Tong-tchang chu, which made the three Hoang signify the three powers, that is, heaven, earth, and man, is not without probability.

These three Hoang succeeded to Pouane-cou, otherwife Hoene tune, the chaos, the origin of the world, which several of the Tao-fe take for the firft man, or the firft king who governed China.

The dynafty of Thiene hoang-chi had thirteen kings, who reigned, fay they, 18,000 years; then came the dynafty of Ti-hoang-chi, whose kings, to the number of eleven, make up a like duration of 18,000 years. Finally, to Ti-hoang-chi succeeded the Gine hoang-chi, whose dynafty, compofed of nine kings, furnifhes a fpace of 45,600 years. These three fums added, give us pre-cifely 81,600 years. But if we add to these three dynafties, thofe which are comprehended in each of the ten Ki, and which amount, according to fome calculations, to more than 230; we fhall find that the pretentions of the Chinefe very much exceed thofe of the Chaldeans and Egyptians. For if we believe the calculations of various authors, from Pouane-cou to the death of Confucius, which happened in the year 479 before J.C. there is elapsed 276,000 years, or 2,276,000, or 2,595,860, or even 3,275,000; or, finally, which is a great deal more, 96,961,740 years: for we find all these different calculations.

It is visible enough, that these extravagant numbers can be nothing else but astronomical periods, contrived to give the conjuncion of the planets in certain constellations, or calculations which have fome relation to the ideas of the Tao-fe, concerning the perpetual deftructions and reproductions of worlds. In fact, fome have endeavoured to make these numbers agree with the period of Tcha-cang-tfe, a famous philofophier in the days of Song, who had undertaken to determine the period of the duration of the world; for the fylllem of the de-
fution and reproduction of worlds was very current, not only in the sect of Ju or of the learned, but also among the Bonzes, Ho-chang or the religious of Fo, and among the Tao-fle or followers of Lao-Kiune; that is to say, among the three great sects, who have the most influence in the empire. Tchao-cang the established then a great period of 129,000 years, called Yuen, composed of twelve equal parts, called kow, or conjunctions, which were each of 10,800 years. In the first conjunction, said he, heaven was formed by little and little, not only in the left of Ju or of the learned, but also among the Tao-fle or followers of Lao-Kiune,-that is to say, all things shall be destroyed, and the world shall fall back again into its primitive chaos, from whence it shall not arise till after the twelfth conjunction is expired.

It is not difficult at present to conceive, that the Taoists had invented that prodigious number of reigns before Fou-hi, for no other reason, but to fill up that interval, which, according to them, had elapsed from the production of man, to the beginning of the Chinese monarchy, that is to say, to the reign of Fou-hi. The same calculator determined the half of Yuen, or of his great period of 129,000 years, at the reign of Yao.

These Taoists, as was said already, laid down these ten ages or ten Ki as an indubitable principle; each Ki comprehended several dynasties, whose duration they determined as they thought fit, and as their calculation required: but if they were at liberty to increase or diminish the duration of the ten Ki, it was not the same as to their number, which was in some sort a fundamental principle of their sect, from which they were not allowed to depart.

Some missionaries, to whom this doctrine of Tao-fle was not unknown, imagined, that they discerned in these ten Ki, six were before Fou-hi, and four after him; these ten Ki, six were before Fou-he, and four after him; these fame missionaries have imagined, that Fou-hi was Enoch. It must be owned, in the mean time, that Tchine-huene and several others do not observe the same order; that they place Chine-nong in the ninth Ki, Hoang-ti in the tenth, &c. By this computation Hoang-ti would be Noah, and Fou-hi Methufelah, which contradicts their hypothesis.

The opinion which considers the ten Ki of the Chinese as the ten generations which preceded Noah, is very ingenious, and not improbable. Towards the end of the reign of Tcheou, about 300 years before the Christian era, some Jews travelled into China, who might have made the writings of Moses known there; and, of consequence, the ten generations which preceded the deluge: besides, this knowledge was common to the Chaldeans, who might have penetrated into China before the Jews.

CHINEY, a city of the Austrian Netherlands, on the confines of the bishopric of Liege; E. long. 5°, N. lat. 50° 20'.

CHINON, a town in France in the province of the Orleans, about twenty-three miles south-west of Tours; E. long. 20', and N. lat. 47° 15'.

CHIO, or CHIO, or Scio, an Asiatic island, lying near the coast of Ionia, in Natoia or Leffer Asia, about one hundred miles west of Smyrna. It is called by the Turks Sakisaduci, and is about one hundred miles in circumference; being chiefly inhabited by Chaldaeans of the Greek church, who are said to have three hundred churches in the island.

CHIO is also the capital of the above island, situated on the east coast; E. long. 27°, and N. lat. 38°.

CHIONANTHUS, or snow-drop tree, in botany, a genus of the diandria-monogynia class. The calyx divided into four oval segments; and the drupa contains but one seed. There are two species, viz. the virginica and zeylonica, both natives of the Indies.

CHIOZZO, or CHIOGGIO, a town on an island of the same name, in the gulf of Venice, by which there is a passage into the Lagunes, situated about twelve miles south of the city of Venice.

CHIPPENHAM, a borough-town in Wiltshire, about twenty-two miles south-west of Salifbury; W. long. 42° 25', and N. lat. 51° 25'. It sends two members to parliament.

CHIPPING, or Much-Wiccumb, a borough-town of Buckinghamshire, about ten miles south of Ailefbury; W. long. 2° 12', and N. lat. 51° 35'. It sends two members to parliament.

CHIROGRAPHY, a writing under one's own hand.

CHIROGRAPHY, in antiquity, the art of representing any past transaction by the gestures of the body, more especially by the motions of the hands: this was a part of liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIRONIA, in botany, a genus of the pentandria-monogynia class. The corolla is rotated; the pistil is bilocular. There are eight species, none of them natives of Britain.

CHIRONOMY, in antiquity, the art of representing any past transaction by the gestures of the body, more especially by the motions of the hands: this was a part of liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIROTONY, among ecclesiastical writers, denotes the imposition of hands used in conferring priestly orders.

However, it is proper to remark, that chirotony originally was a method of selecting magistrates, by holding up the hands.

CHIRVAN, a province of Peria, lying on the western coast of the Caspian sea.

CHIRURGIC. See Surgery.

CHISLEY-LAND, in agriculture, a soil of a middle nature between sandy and clayey land, with a large admixture of pebbles.

CHISEL,
CHISSEL, an instrument much used in carpentry, masonry, joinery, sculpture, &c. and distinguished according to the breadth of the blade into half-inch chisels, quarter-inch chisels, &c. They have also different names according to the different uses to which they are applied: as 1. The former, used by carpenters, &c. just after the work is scribed: it is struck with a mallet. 2. The paring-chisel, which is used in paring off the irregularities made by the former: this is prefixed with the workman's shoulder. 3. The broad-chisel cleanses acute angles with the point of its narrow edge. 4. The mortice chisel, used in cutting deep square holes in wood, for mortices: it is narrow, but thick and strong, to endure hard blows. 5. Socket-chisels, having their Shank made with a hollow socket at top, to receive a strong wooden spike fitted into it with a shoulder. 6. Ripping chisel, having a blunt edge, with no bail, used in tearing two pieces of woof together. And, 7. the gouge. See Gouge.

CHITAU, in the materia medica, a kind of lignum-aloe, of reddish colour. See Lignum-aloe.

CHIVALRY, in law, is a tenure of service, whereby the tenant is bound to perform some noble or military office to his lord; and is either regular, held only of the king; or common, such as may be held by a common person as well as the king: the former is properly called serjeanty, and the latter escheate.

A statute of Charles II. abolishes all tenures by chivalry, in capite, &c. and ordains that all tenures shall be confirmed to be free and common foage.

CHIVES, in botany. See Anthers.

CHISEL, an instrument used in carpentry, masonry, joinery, sculpture, &c. and distinguished according to the breadth of the blade into half-inch chisels, quarter-inch chisels, &c. They have also different names according to the different uses to which they are applied: as 1. The former, used by carpenters, &c. just after the work is scribed: it is struck with a mallet. 2. The paring-chisel, which is used in paring off the irregularities made by the former: this is prefixed with the workman's shoulder. 3. The broad-chisel cleanses acute angles with the point of its narrow edge. 4. The mortice chisel, used in cutting deep square holes in wood, for mortices: it is narrow, but thick and strong, to endure hard blows. 5. Socket-chisels, having their Shank made with a hollow socket at top, to receive a strong wooden spike fitted into it with a shoulder. 6. Ripping chisel, having a blunt edge, with no bail, used in tearing two pieces of wood together. And, 7. the gouge. See Gouge.

The Spaniards improved this method: when the cacao was sufficiently ground, is put quite hot into tin moulds, in which it congeals in a very little time. The form of these moulds is arbitrary; the cylindrical ones, holding two or three pounds, are the most proper, because the bigger the cakes are, the longer they will keep. Observe, that these cakes are very liable to take any good or bad scent, and therefore must be carefully wrapt up in paper, and kept in a dry place. Complaints are made, that the Spaniards mix with the cacao nuts too great a quantity of cloves and cinnamon, besides other drugs without number, as musk, ambergris, &c. The grocers of Paris use few or none of these ingredients: they only use the best nuts, which are called Caracca, from the place from whence they are brought, and with these they mix a very small quantity of cinnamon, the freethiff vanilla, and the finest sugar, but very seldom any cloves. Among us in England, the chocolate is made of the simple cacao, excepting that sometimes sugar, and sometimes vanilla is added.

Chocolate ready made, and cacao paste, are prohibited to be imported from any part beyond the seas. If made and sold in Great Britain, it pays inland-duty 1s. 6d. per lb. avoidaposte: it must be inclosed in papers containing one pound each, and produced at the excife-office, to be flamed. Upon three days notice given to the officer of excife, private families may make chocolate for their own use, provided no lessthan half an hundred weight of nuts be made at one time.

CHOEUS, in botany, containing a forty-eighth part of a medimnus, or six bushels. Hence the celebrated proverb of Pythagoras, Super choenice ne fea.

CHOIR, that part of the church or cathedral where choicers sing divine service: it is separated from the nave of the church, where the people are placed: the patron is said to be obliged to repair the choir of the church.

CHOLEDOCHUS, in anatomy. See Vol. i. p. 265.

CHOLEDOCHUS, in anatomy. See Vol. i. p. 265.

CHOLEMAIUS, in botany, See Anthera.

CHOLIC, in medicine, See Licanthus.

CHORASSAN, a province of Persia, on the north-east, adjoining to Ufbe Tartary; this was the ancient Hachria, and the native country of the late Koubi Kan.

Chronology, in geometry, a right line drawn from one part of an arch to a circle to the other. Hence, Chord of an arch is a right line joining the extremities of that arch. See Trigonometry.
CHORDS, or CORDS, in music, are strings by the vibration of which the sensation of sound is excited, and by the divisions of which the several degrees of tune are determined.

Chord is also used in music for the note or tone to be touched or sounded: in this sense the fifth is said to consist of five chords or sounds.

CHORDAPSUS, in medicine, a disease of the intestines, where the effusion of which the sensation of sound is excited, is frequent and involuntary. See Medicine.

CHORDEE, in medicine and forgery, a symptom at the time with the latter passion.

CHORION, in anatomy, the exterior membrane which orbs, or Cords, in music, are firings, by the violin.

CHOREUS, in ancient poetry. See Trochee.

CHORGES, or Gorges, a town of Dauphiny, in France, about six miles east of Gap: E. long. 6°, 44' 36".

CHORIASTUS, in ancient poetry, a foot consisting of five syllables, whereof the first and last are long, and the two middle ones are short; or, which is the same thing, it is made up of a trochaeus and iambus: such is the word nobilis tus.

CHORION, in anatomy, the exterior membrane which involts the fuctus in the uterus.

CHOROBATA, or CHOROBATES, a kind of water-level among the ancients, of the figure of the letter T, according to Vitruvius's description.

CHOROGRAPHY, the art of making a map of some country or province.

CHORUS, in dramatic poetry, one or more persons present on the stage during the representation, and supposed to be by flanders without any share in the action. Tragedy in its origin was no more than a single chorus, who trod the stage alone, and without any actors, singing dithyrambs or hymns in honour of Bacchus. Thespis, to relieve the chorus, added an actor, who rehearsed the adventures of some of their heroes; and Æchylus, finding a single person too dry an entertainment, added a second, at the same time reducing the singing of the chorus, to make more room for the recitation. But when once tragedy began to be formed, the recitative, which at first was intended only as an accocy part to give the chorus a breathing time, became a principal part of the tragedy. At length, however, the chorus became invested and incorporated into the action: sometimes it was to speak, and then their chief, whom they called corryphæus, spoke in behalf of the rest: the singing was performed by the whole company; so that when the corryphæus struck into a song, the chorus immediately joined him.

The chorus sometimes also joined the actors in the course of the representnation, with their plaints and lamentations on account of any unhappy accidents that befel them: but the proper function, and that for which it seemed chiefly retained, was to swell the intervals of the acts: while the actors were behind the scenes, the chorus engaged the spectators; their songs usually turned on what was exhibited, and were not to contain any thing but what was suited to the subject, and had a natural connection with it: so that the chorus concurred with the actors for advancing the action. In the modern tragedies the chorus is laid aside, and the fiddles supply its place. Mr Dacier looks on this retrenchment as of ill consequence, and thinks it robs tragedy of a great part of its luftre; he therefore judges it necessary to re-establish it, not only on account of the regularity of the piece, but also to correct, by prudent and virtuous reflections, any extravagancies that might fall from the mouths of the actors, when under any violent passion.

Mr Dacier observed also, that there was a chorus, or gres, in the ancient comedy; but this is suppressed in the new comedy, because it was used to reprosecue by attacking particular persons; as the chorus of the tragedy was laid aside to give the greater probability to those kind of intrigues which require secrecy.

CHORUS, in music, is when, at certain periods of a song, the whole company are to join the singer in repeating certain couplets, or verses.

CHOTZIM, a frontier-town of Moldavia, on the confines of Poland, situated on the river Neiter, and subject to the Turks: E. long. 27°, and N. lat. 48° 36'.

CHOU, a town of Syria, upon the road from Aleppo to Sayde, called by some travellers Shogool.

CHOUCH, in ornithology. See Corvus.

CHOURS, in ancient poetry. See Trochee.

CHRIMP, in ichthyology. See Sparus.

CHRISM, oil consecrated by the bishop, and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction.

Order of CHRIST, a military order, founded by Dionysius I. king of Portugal, to animate his nobles against the Moors.

The arms of this order are gules, a patriarchal cross argent: they had their residence at first at Caftromarin, afterwards they removed to the city of Thomar, as being nearer to the Moors of Andalusia and Estremadura.

CHRIST is also the name of a military order in Livonia, instituted in 1205, by Albert bishop of Riga. The end of this institution was to defend the new Christianites, who were converted every day in Livonia, but were persecuted by the heathens. They wore on their cloaks a sword with a cross over it, whence they were also denominated brothers of the sword.

CHRIST-BURGH, a town of Poland, near the lake Drafen, and about three Polish miles from Marienburgh.

CHRIST-CHURCH, a borough town of Hampshire, thirty miles south-west of Winchester, near the sea-coast: W. long. 5°, N. lat. 50° 46'. It sends two members to parliament.

CHRIST thorn, in botany. See Rhamnus.
Christian religion, that instituted by Jesus Christ. See Religion.

Christians, those who profess to believe the Christian religion. See Religion.

Christians of St John, a sect of Christians very numerous in Baffara and the neighbouring towns: they formerly inhabited along the river Jordan, where St John baptized, and it was from thence they had their name. They hold an anniversary feast of five days, during which they all go to the bishop, who baptizes them with the baptism of St John. Their baptism is also performed on rivers, and that only on Sundays; they have no notion of the third person in the Trinity, nor have they any canonical book, but abundance full of charms, &c. Their bishoprics descend by inheritance, as our edates do, though they have the ceremony of ordination.

Christians of St Thomas, a sort of Christians in a peninsula of India, on this side of the gulf: they inhabit chiefly at Cranganor, and the neighbouring country: these admit of no images, and receive only the crosses, to which they pay a great veneration: they affirm, that the souls of the saints do not see God till after the day of judgment: they acknowledge but three sacraments, viz. baptism, orders, and the eucharist: they make no use of holy oils in the administration of baptism, but after the ceremony anoint the infant with an undulation composed of oil and walnuts, without any benediction. In the eucharist, they confecrate little cakes made of oil and salt, and instead of wine make use of water in which raisins have been infused.

Christiania, a town of Norway, in the province of Aggerhuys, situated on a bay of the sea, a hundred miles north of Gottenburgh: E. long. 10° 15', N. lat. 59° 30'.

Christianople, a port-town of Sweden, situated on the Baltic sea, in the territory of Bleking, and province South Gothland, about thirty miles north-east of Carleiscoon: E. long. 15° 40', and N. lat. 57°.

Christiansburgh, a Danish factory upon the gold-coast of Africa, near Agra.

Christianstad, a town of Sweden, situated on the river Helles, in the territory of Bleking, and province of South Gothland, forty-five miles west of Carleiscoon: E. long. 14° 40', N. lat. 56° 30'.

Christmas, a festival of the Christian church, observed on the 25th of December, in memory of the nativity of Jesus Christ.

Christopher-herb, in botany. See Christophriona.

Christophers, or St Christophers, one of the Caribbee islands, to which Columbus gave his Christian name: W. long. 69°, N. lat. 71° 30'.

It is about twenty miles long, and seven broad; and has a high mountain in the middle, from whence some rivulets run down. Its produce is chiefly sugarcotton, ginger, and indigo. It is a British colony, and lies about sixty miles west of Antego.

Christophoriana, in botany. See Actea.

Chroastaces, in natural history, a genus of pelliculcid gems, comprehending all those of variable colours, as viewed in different lights; of which kinds are the opal and the afteria, or oculus cati. See Opal, and Asteria.

Chroma, in music, a note or character of time, usually termed a quaver.

Chroma is also a graceful way of singing, or playing with quavers and trilloes.

Chromatic, in the ancient music, the second of the three kinds into which the consonant intervals were subdivided into their concinnous parts. The other two kinds are enharmonic and diatonic.

Chromatic, in painting, a term used to signify the colouring, which makes the third part in the art of painting.

Chromis, in ichthyology. See Sparus.

Chronic or Chronical, among physicians, an appellation given to diseases that continue a long time, in contradif finction to those that soon terminate, and are called acute. See Medicine.

Chronicle, in matters of literature, a species or kind of history, disposed according to the order of time, and agreeing in most respects with annals. See Annals.

Books of Chronicles, in the canon of scripture, two sacred books, called by the Greeks paralipomena, that is, remains, additions, or supplements, as containing many circumstances omitted in the other historical books.

Chronogram, a species of false wit, consisting in this, that a certain date or epocha is expressed by numeral letters of one or more verses: such is that which makes the motto of a medal struck by Gustavus Adolphus, in 1632.

Chronivs DvX, ergo trVMphVs.

Chronology, the science or doctrine of time, in so far as it regards history, whether civil or ecclesiastical.

The business of chronology, is to ascertain and adjudge the various epochas, aras, and other periods mentioned in history; so that the revolutions of empires and kingdoms, and other remarkable events, may be truly stated. For the principles of chronology, see Astronomy, Of the division of time.

Chronometer, in general, denotes any instrument or machine, used in measuring time; such are dials, clocks, watches, &c. See Clock, Dial, &c.

Chronoscope, denotes much the same with chronometer. See the preceding article.

Chrostasima, in natural history, a genus of pelliculcid gems, comprehending all those which appear of one simple and permanent colour in all lights: such are the diamond, carbuncle, ruby, garnet, amethyst, sapphire, beryl, emerald, and the topaz. See Diamond, Carbuncle, &c.
CHRYSANTHEMUM, in botany, a genus of plants belonging to the syngenesia polygama superficiae clafs. The receptacle is naked; it has no pappus; the calix is hemispherical and imbricated; and the scales on the margin are membranaceous. There are nineteen species, two of which are natives of Britain, viz. the fegetum, or corn mary-gold; and the leucanthemum, or ox-eye daily.

CHRYSOMALANUS, in botany, a genus of the icofandra monogynia clafs. The corolla consists of five petals; the calix has five teeth; and the drupa contains a nut with five furrows. There is but one species, viz. the icaco, a native of America.

CHRYSOPHYTUM, in botany, a genus of the pen- dandria monogynia clafs. The calix is divided into ten segments, which alternately spread wider; and the berry contains ten seeds. There are but two species, both natives of America.

CHRYSOPRASUS, or CHRYSOPRASUS, the tenth of the precious stones, mentioned in the Revelations, as forming the foundation of the heavenly Jerusalem. The chrysoptalmin is a species of pralis, of a pale but pure green colour, with an admixture of yellow.

CHRYSOSPLLENIIUM, in botany, a genus of the pendandria digynia clafs. The calix is divided into four or five coloured segments; it has no corolla; and the capsule has two beaks, and one cell containing many seeds. The species are two, viz. the alternifolium, or alternate leaved golden saxifrage; and the oppositifolium, or common golden-saxifrage; both natives of Britain.

CHRYSANTHEMOIDES, in botany. See OSTEOSPERMUM.

CHURCH, has different significations, according to the different subjects to which it is applied. 1. It is understood of the collective body of Christians, or all those over the face of the whole earth who profess to believe in Christ, and acknowledge him to be the Saviour of mankind. This is what the ancient writers call the catholic or universal church. Sometimes the word church is considered in a more extensive sense, and divided into several branches; as the church militant, that is, the assembly of the faithful on earth; the church triumphant, that of the faithful already in glory; to which the Papists add the church patient, that of the faithful still in purgatory.

2. Church is applied to any particular congregation of Christians, who associate together and concur in the participation of all the institutions of Jesus Christ, with their proper pastors and ministers. Thus we read of the church of Antioch, the church of Alexandria, the church of Thessalonica, and the like.

3. Church denotes a particular sect of Christians distinguished by particular doctrines and ceremonies. In this sense, we speak of the Romish church, the Greek church, the reformed church, the church of England, &c.

The Latin or western church, comprehends all the churches of Italy, France, Spain, Africa, the north, and all other countries whither the Romans carried their language. G. Britain, part of the Netherlands, of Germany, and of the North, have been separated from hence ever since the time of Henry VIII. and constitute what we call the reformed church, and what the Romanists call the western schism.

The Greek or eastern church, comprehends the churches of all the countries anciently subject to the Greek or eastern empire, and through which their language was carried; that is, all the space extended from Greece to Mesopotamia and Persia, and thence into Egypt. This church has been divided from the Roman, ever since the time of the emperor Phocas.

The Gallican church, denotes the church of France, under the government and direction of their respective bishops and pastors. This church has always enjoyed certain franchises and immunities, not as grants from popes, but as derived to her from her first original, and which she has taken care never to relinquish. These liberties depend upon two maxims; the first, that the pope
The church wardens are a corporation to sue, and be sued, for the goods of the church; they are to take care of the repairs of the church; and if they erect or add any thing new to the same, they must have the consent of the parishioners, or vestry; and if in the church, the license of the ordinary: they have, with consent of the minister, the placing of the parishioners in the seats of the body of the church, appointing gallery keepers, &c. referring to the ordinary a power to correct the same. In London, the church wardens have this authority in themselves: they are bound to fix first cocks, keep engines, &c. in their parishes, under the penalty of 10l.

Besides their ordinary power, the church wardens have the care of the benefice during its vacancy: they are to join with the overseers of the poor in making rates for their relief, setting up trades for employing them, placing out poor apprentices, setting poor persons, &c. It is their duty to collect the charity money upon briefs read in churches; they are to sign the certificates of those persons who receive the sacrament, to qualify them to bear offices, &c.

CHURCHING of women after child-birth, an office in the liturgy, containing a thanksgiving to be used by women after being delivered from the great pain and peril of child-birth.

CHURN-OWL, in ornithology. See CAPRIMULGUS.

CHURN-WORM, in zoology. See ONYX.

CHUSAN, or CHEUXAN, an island on the eastern coast of China, near the province of Chekiang: E. long. 124°, N. lat. 30° 40'.

CHUSTAN, a province in the south-west part of Persia, bounded by the gulf of Persia on the south, and by the province of Eyraca Agem on the north.

CHUTSON, CHUTTON, a market-town of Somersettshire, about seven miles north-east of Wells: W. long. 2° 36', N. lat. 51° 25'.

CHYLE, in the animal economy, a milky fluid, secreted from the aliment by means of digestion.

The principles of the chyle seem to be sulphurous, mucilaginous, saline, and aqueous. It is a kind of natural emulsion, both with regard to the colour, the ingredients, and the manner of preparation. There is this difference between the artificial and natural emulsion, that the latter is far more pure, and is prepared with much greater apparatus, not by the sudden expression of part of the liquid, but by a gentle and successive percolation. The chyle is made sooner or later, according to the difference of the temperaments, strength, aliments and customs: therefore how many hours chylification requires, cannot be certainly determined. When the chyle enters the villous ofcula of the gut, it is not a fluid extracted merely from the aliment and drink, but a mixture of fluids; that is, the saliva and thinner mucus of the mouth, and the two fluids of the oesophagus, one proceeding from the villous membrane of the tube itself, the other from its glands. To these may be added the glutinous fluid of the stomach, the pancreatic juice, the mucous fluid of peyer's glands, which are very numerous in the small intestines. Hence the reason appears, why men may live upon bread and water, why the oriental nations ate rice in the room of all kinds of pulse, and why acids, spirituous liquors, saline things, and many vegetable juices, herbs, roots, acrid and aromatic substances, are the least fit to generate chyle.

CHYLIFICATION, the formation of the chyle, or the act whereby the food is changed into chyle.

Chylification commences by comminuting the aliment in the mouth, mixing it with saliva, and chewing it with the teeth; by these means the food is reduced into a kind of pulp, which, being received into the stomach, mixes with the juices thereof; and thus diluted, begins to ferment or putrefy, and, assuming a very different form from what it had before, grows either acid or rancid. Here it meets with a juice separated from the blood by the glands of that part, whose excretory ducts open into the cavity of the stomach.
ChiYMOsis is also a distortion of the eye-lids, arising from an inflammation; also an inflammation of the cornea unica in the eye.

CIALIS, the name of the capital of a kingdom of that name in independent Tartary, situated on the road from Sama cand to China.

CIBDELOPLACIA, in natural history, a genus of spondal spondals deflab by a very large admixture of earth: they are opaque, formed of thin crufts, covering vegetables and other bodies, by way of incrustations.

Of this genus we have the following species: 1. A greyish-white one, with a rough surface. 2. A whitish-brown one: both these are friable. 3. A hard, pale-brown kind, which is the oft-colla of the chips. 4. The whitish-grey kind, with a smooth surface: this is the unicornu fistule and ceratites of authors. 5. The whitish-brown coralloide kind.

CIBDELOSTRACIA, in natural history, terrene spondals, deflab of all brightnefs and transparence, formed into thin plates, and usuallly found coating over the fides of fifiers, and other cavities of stone, with congeries of them of great exent, and of plain or botroyide surfaces.

Of these there are usuall reckoned seven kinds: the firft is the hard, brownifh-white cibdeloftracium, found in Germany; the second is the hard, whitifh cibdeloftracium, with thin crufts, and a smooth surface, found alfo in the Harts-foreft in Germany: the third is the hard, pale-brown cibdeloftracium, with numerous very thin crufts, found in subterranea caverns in many parts of England as well as Germany: the fourth is the white, light, and friable cibdeloftracium, found alfo in Germany, but very rafely in any part of England: the fifth is the light, hard, pale-brown cibdeloftracium, with a smooth surface, found in almoft all parts of the world: the fixth is the whitifh, friable, crustaceous cibdeloftracium, with a rougher surface, frequent in Germany and England; and the seventh is the brownifh-white, friable cibdeloftracium, with a dully surface, found in feveral parts of Ireland, as well as Germany.

CICADIA, in zoology, a genus of insects belonging to the order of hemiptera. The beak is infletfted; the antennae are feteaceous; the four wings are membranaceous and deflected; and the feet, in moft of the spondals, are of the jumping kind. The spondals are fifty-one. The larvae of feveral of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants, in the midft of which they conftantly refide.

CICATRICULA, among natural historians, denotes a small whitifh speck in the yolk of an egg, supposfed to be the firft rudiments of the future chick.

CICATRIX, in surgery, a little fcat or elevation of callous flth rising on the skin, and remaining there after the healing of a wound or ulcer. It is common ly called a fear. See Surgery.

CICATRIZANTS, in pharmacy, medicines which affift nature to form a cicatrix. Such are arminian bole, powder of tutton, difcartulatum rubrum, &c.

Cicatrizes are otherwise called echtarotics, eplastics, incarnatives, agglutinants, &c.

CICELY.

CILICIUM, in Hebrew antiquity, a sort of habit made of linen cloth.

CILICIUM, in botany, a fynonime of the aethufa, Cicuta is also a fynonime of the conium. See Conium.

CILICIA, a province of Mexico, in North America, lying on the Pacific Ocean, opposite to the south end of California.

CILIA, or SIMA, in architecture, the same with cymatium or ogee. See Ogee.

CILIA, in botany, a genus of the Syngenia polygama class. The receptacle is palaceous; the calix is calcified; and the pappus has five teeth on its margin. The species are three, only one of which, v.z., the virofa, or long-leaved water-hemlock, is a native of Britain. The leaves and root are detergent, aperient, and attenuating.

CICARIS, in antiquity, the mitre used by the Jewish high-priests. The Rabbins say, that the bonnet used by priests in general was made of a piece of linen cloth sixteen yards long, which covered their heads like a helmet or a turban; and they allow no other difference between the high-priest's bonnet, and that of other priests, than this, that one is flatter and more in the form of a turban; whereas that worn by ordinary priests, rose something more in a point.

CICONIA, or CINCHONA, in botany, a genus of the pentandria class. The corolla is bell-shaped; and the capsule is below the flower, and opens at the base. There is but one species, viz. the officinallia, a native of Peru. The Peruvian bark, which is the bark of this tree, is brought to us in pieces of different sizes, sometimes rolled up into short thick quills, and sometimes flat: the outside is brownish, and generally covered in part with a whitish moss; the inside is of a yellowish, reddish, or rusty iron colour. It has a lightly aromatic smell, somewhat musty, yet not disagreeable; a bitterish, astringent taste, which dwells long upon the tongue, accompanied with a degree of aromatic warmth. The small, thin, flat pieces are by some accounted the best; by others, the quill sort, with the roughest coat, especially if of a bright cinnamon colour on the inside; though the large flat pieces, whether rough or smooth, of a lighter or darker colour, are often of equal goodness. The best bark is that which is strongest in smell and taste: this likewise proves friable between the teeth, and does not separate into fibres; it breaks, not shivery, but close and smooth.

The virtues of this bark, as a febrifuge, were discovered by the Indians about the year 1500: Europe did not become acquainted with it till 1649: nor was it received into general practice till several years after this; some ill consequences ensuing from its imprudent use, having brought it for a time into disrepute. At present, it is looked upon as the most effectual remedy in intermittent fevers of almost every kind, and safe in all ages and constitutions; provided it be judiciously and feanoably administered, and due regard be had to the circumstances of the disease. The modern practice, previous to the use of this medicine, usually gives an emetic at the beginning of a paroxysm: in some cafes a cathartic, and in plethoric habits venesection, are premised: these render the bark not only more safe, but likewise more certain and speedy in its operation: where these evacuations are neglected, or not sufficiently plentiful, the disease, if of long

CILEY, the capital of a territory of the same name in Stiria, and the circle of Austria in Germany: E. lon. 15° 35', N. lat. 46° 35'.
flanding, scarce yields to the cortex; or if it appears
at length subdued, yet the patient does not recover his
strength, and soon suffers a relapse. The use of the
bark is begun at the end of a paroxysm, and repeated,
in the quantity of half a dram (more or less, according
to the circumstances of the patient) every third or
fourth hour during the intermission: where the fever
is of the bilious kind, and accompanied with great
heat, a little nitre is joined: in all cases, moderate
exercise generally promotes its effect. At first, it u-
ually loosens the belly, and sometimes operates as if
a cathartic had been taken; and by this means sup-
plies the omission of evacuations before its exhibition:
if the purging continues, the medicine does not an-
swer the purposes intended by it: in such case, a little op-
um is added, which effectually suppresses the flux; if
after this the patient continues too colitive, recourse is
had to glytters. The loofeners, however, ought not to
be slop too soon: on the contrary, where the bark
does not itself produce this effect, it is necessary, as
Dr Mead informs us, to join to it a little rhubarb, fo
as to occasion for a time two stools a day; by this
means the disease is more effectually cured, and lefts
subject to be followed by a dropsey, or ill habit of bo-
dy: after a dram or two of rhubarb have been taken,
it is to be discontinued, and the bark exhibited by it-
self. After the fever has been removed, the medicine
is continued for some time longer, to prevent a relapse;
and evacuations, unless absolutely necessary, abstained
from. The disease is nevertheless seldom completely
cured before some very considerable evacuation, either
by stool, urine, or perpiration, ensues: if this does
not succeed spontaneously, cathartics, diuretics, or
diaphoretics, are given in conjunction with the bark;
otherwise the patient continues weak, and without ap-
petite, till either the disease returns, or changes into
one of a different kind.

In symptomatic agues, hectic and purulent fevers,
cachexic habits, and where the hypochondres are
swelled and distended, this medicine is improper, and
for the most part prejudicial. Its manifest astringency
forbids its use in obstructions of the abdominal vis-
cera, or suppuration of any critical evacuation; until the
obstruction is first removed, or the evacuation had its due
course.

In acute, inflammatory, or malignant fevers, the
bark does not seem to have any good effect. Never-
thelass, in the decline of long nervous fevers, or after
a remission, when from bad habit, old age, fatigue, or
the like, the patient is extremely weak, and the pulse
low, the cortex proves a medicine of excellent ser-
vice; provided that there is no extravasation, that the
veisells remain entire, and pus is not already formed.

Peruvian bark has likewise been found eminently ser-
viceable in gangrenes and mortifications, proceeding
either from an internal or external cause. In all the
cases of this kind, where it proved successful, it oc-
casioned a kind of suppuration, which degenerated when
the use of the medicine was discontinued, and again
turned kindly upon resuming it. Some have been

hence induced to try the cortex in various cases,
where either the pustules did not rightly suppurate, or
petechias showed a disposition to a gangrene; and here
likewise it answered expectation: the empty vesicles
filled with matter, watery fumes changed into thick
white pus, the petechies became gradually of a pale
colour, and at length disappeared, and the pox began
to turn sooner than was expected.

The bark has been applied likewise, and not with-
out success, to the cure of periodic head-achs, hysterie-
and hypochondriac fits, and other disorders, which
have regular intermissions. By its astringency and a-
romatic quality, it strengthens the whole nervous sys-
tem, and proves useful in weaknesses of the stomac,
and fundry chronic troubles, proceeding from too
great laxity of the fibres. In obstinate uterine fluxes,
and old gleetts, bark joined with chalybeates has no-
table effects.

The virtues of Peruvian bark reside chiefly in a re-
finous substance, and hence are extracted in perfection
by rectified spirit. By strong cohesion in water, the re-
fine is melted out, and mingled with the water; which
whilst hot appears transparent, but in cooling grows
turbid, and deposits great part of the reffin to the
bottom. Water elevates in distillation the aromatic
part of the bark; pure spirit brings over nothing.
Hence an aqueous extract proves not only less in quan-
tity, but likewise inferior in quality to one made with
rectified spirit. Proof-spirit extracts the virtues of
this drug in tolerable perfection, in the cold; heat ena-
bles it to take up more than it can retain when
cold. Spirit of sal ammoniac, prepared with fixt al-
kaline salts, gains very little from the cortex, either
with or without heat; the spirit prepared with quick-
lime, and the dulcified spirit, in a few hours become
strongly impregnated with its sinell and taste.

The officinal preparations of bark are an extract re-
sine, spirituous tincture, tincture in volatile spirit, and
compound tincture. It is an ingredient also in the
flomachic tincture.

The sufficences usually joined with bark in pre-
scription seem calculated either to promote its efficacy,
or merely for reducing it into the intended form;
without much regard to its agreeabenefs, and the con-
venience of taking it: this is nevertheless a point of
great conquence, as its talette, and the quantity which
is necessary, make the patient too frequently loath it,
before enough has been taken to produce the desired
effect. If designed to be given in the solid form of a
bolus, electuary, &c. it should be made up, not, as is
customary, with syrups, but with mucilages: with the
former, it flock about the mouth and fauces, whence
its taste remains for a considerable time; with the lat-
ter, it passes freely, scarce leaving any taste in the
mouth. Aromatics do not prevent the taste of the
bark from discovering itself; extract of liquorece very
effectually conceals it. The extract of logwood also,
joined to that of bark, and a proper quantity of mu-
cilage, form a very elegant and agreeable composition.

CINCLUS, in ornithology. See Tringa.

CINCTURE,
CINNABAR, a mixture of mercury and sulphur, is either native or fictitious. The native cinnabar is an ore of quicksilver, moderately compact, very heavy, and of an elegant, striated red colour. In this ore the quicksilver is blended in different proportions with sulphur. It is so rich an ore, as to be no other than mercury impregnated with a small quantity of sulphur, just enough to reduce it to that state, being commonly more than six parts of mercury to one of sulphur; and even the poorest cinnabar yields one half mercury: it is of a very bright, glittering appearance, when fresh broken, and is usually found lodged in a bluish, indurated clay, though sometimes in a greenish talcstone.

For the method of separating mercury from cinnabar, see Mercury.

Fictitious Cinnabar, a mixture of mercury and sulphur sublimed, and thus reduced into a fine red glebe. The best is of a high colour, and full of fibres, like needles. The receipt for making it, according to the late college-dispensatory, is as follows. Take of purified quicksilver, twenty-five ounces; of sulphur, seven ounces; melt the sulphur, and stir the quicksilver into it while fluid; if it take fire, let it be immediately extinguished, by covering it with another vessel. When cold, let it be rubbed into a fine powder. Let this powder be put into a subliming vessel, and setting it over a gentle fire, raise it by degrees till the whole is sublimed into a red, striated, heavy mass, which perfectly resembles native cinnabar. This, as well as the native cinnabar, is excellent in epilepsies, and in all complaints of the head and nerves. But the fictitious is rather to be preferred, as it doth not excite nauscea, vomittings, and other disorders which arise from vitriolic and perhaps arsenical particles blended by nature among some of the masses of the native mineral.

Cinnabar is likewise used by painters as a colour, and is rendered more beautiful, by grinding it with gum-water and a little saffron.

CINNAMON-TREE, in botany. See Laurus.

Cinnamon-water is made by distilling the bark first infused in spirit of wine, brandy, or white-wine.

Clove-Cinnamon is the bark of a tree growing in Brazil, which is often substituted for real cloves.

White Cinnamon, called also Winter's bark, is the bark of a tree frequent in the islands of St Domingo, Guadaloupe, &c. of a sharp biting taste like pepper. Some use it instead of nutmeg; and in medicine it is esteemed a rhomastic and antiscorbutic.

CINOLA, or Cinaloa, the capital of the province of Cinaloa, in North America, about thirty miles east of the bay of California: W. long. 113°, and N. lat. 25°. See Cinaloa.

CINQUEFOIL, quinquefolium, in botany. See Potentilla.

CINQUE-PORTS, an appellation given to five ports, situated on the coast of Kent and Sussex, over against France, and famous in English history. The five ports are Hastings, Dover, Hithe, Romney, and Sandwich; which have had large privileges granted them, on account of their former great importance, being then not only the keys of the kingdom, but considerable for their maritime strength: thus, we are told, that they were obliged to provide eighty ships at their own charge for forty days, as often as the king should have occasion in his wars.

Cinque-port is also a particular kind of fishing-net much used in landing-fish, so called on account of the five entrances into it.

CINTRA, a cape and mountain of Portugal, in the province of Estremadura, usually called the rock of Lisbon, situated on the north side of the entrance of the river Tagus: W. long. 10° 15', N. lat. 39°.

CINTRA, or CINNOR, in Jewish antiquity, generally translated cithara, lyra, &c. a musical instrument used before the flood, and invented by Jubal the son of Lamech.

CION, or CYON, among gardeners, denotes a young sprig, or sprout of a tree.

CIPHER, or CYpher, one of the Arabic characters, or figures, used in computation, formed thus, o. See Arithmetic.

Cipher is also a kind of enigmatic character, composed of several letters interwoven, which are generally the initial letters of the persons names for whom the ciphers are intended.

Cipher denotes likewise certain secret characters disguised and varied, used in writing letters that contain some secret, not to be understood but by those between whom the cipher is agreed on.

CIPUS, in antiquity, a low column, with an inscrip. tion, erected on the high roads, or other places, to shew the way to travellers, to serve as a boundary, to mark the grave of a deceased person, &c.

CIRCAEA, or ENCHANTERS NIGHTSHADE, in botany, a genus of the diandria monogynia class. The corolla consists of two petals; the corolla has likewise two leaves; and the capsule contains but one seed. The species are three, two of which are natives of Britain, viz, the littiriana, or enchanters-nightshade; and the alpina, or mountain enchanters-nightshade.

CIRCASSIA, a country situated between 40° and 50° E. long, and between 45° and 50° N. lat.

It is bounded by Russia on the north, by Afrasia and the Caspian sea on the east, by Georgia and Daghestan on the south, and by the river Don and the Palus Meotis on the west.

The Circassian Tartars form a kind of republic, but sometimes put themselves under the protection of Persia, and sometimes of Russia, or the Turks. They live mostly in tents, removing from place to place for the benefit of pasturage; and are chiefly remarkable for the beauty of their children, the feraglios of Turky
and Persia being usually supplied with boys and young virgins from this and the neighbouring country of Georgia.

CIRCENSIAN GAMES, a general term under which was comprehended all combats exhibited in the Roman circus, in imitation of the Olympic games in Greece. Most of the feasts of the Romans were accompanied with Circensian games; and the magistrates, and other officers of the republic, frequently presented the people with them, in order to procure their favour. The grand games were held five days, commencing on the 15th of September. There were six kinds of games exhibited: the first was wrestling, and fighting with swords, with knives, and with pikes; the second was racing; the third, leaping; the fourth, quoits, arrows, and celtus; all which were on foot; the fifth was horse-courseing: the sixth courses of chariots.

CIRCIA, in ornithology, a species of anas, called in English the summer-teeal, and all over of a dulky yellowish brown, with black feet.

CIRCINALIS, in botany, a name used by some for adiantum, maiden-hair. See Adiantum.

CIRCLE, in geometry, a plane figure comprehended by right lines drawn from a point in the middle, called the centre, are equal to each other. To find the area of a circle, see Practical Geometry.

Circles of the sphere. See Geography and Astronomy.

Circles of latitude. See Geography.

Circles of longitude. See Geography.

Horary Circles, in dialling, are the lines which shew the hours on dials, though these be not drawn circular, but nearly straight. See Dialling.

Horary Circle, on the globe. See Geography.

Polar Circle. See Geography.

Circle, in logic, or logical Circle, is when the same terms are proved in orbem by the same terms, and the parts of the syllogism alternately by each other, both directly and indirectly.

Circles of the empire, such provinces and principalities of the German empire as have a right to be present at diets. Maximilian I. divided the empire into six, and some years after into ten circles. This last division was confirmed by Charles V. The circles, as they stand in the Imperial Matricola, are as follows, Austria, Burgundy, the Lower Rhine, Bavaria, Upper Saxony, Franconia, Swabia, Upper Rhine, Westphalia, and the Lower Saxony.

CIRCOLO MEZZO, in the Italian music, denotes a diminution of four quavers or semiquavers, which represent a femicircle, proceeding by conjoint degrees.

Circuit, in law, signifies a longer course of proceedings than is needful to recover the thing sued for.

Circuit, also signifies the journey, or progress, which the judgestake twice every year, through the several counties of England and Wales, to hold courts and administer justice, where recourse cannot be had to the king's courts at Westminster: hence England is divided into six circuits, viz. the Home circuit, Norfolk circuit, Midland circuit, Oxford circuit, Western circuit, and Northern circuit.

In Wales there are but two circuits, North and South Wales: two judges are assigned by the king's commission to every circuit.

CIRCUIT court, in Scots law, the judges of the supreme criminal court, or court of judicature, are divided into three separate courts, consisting of two judges each, and the kingdom into as many districts. In certain boroughs of every district, each of these courts by rotation are obliged to hold two courts in the year, in spring and autumn; which are called circuit courts. See Scots Law, Of the supreme judges and courts of Scotland.

CIRCULAR, in a general sense, any thing that is described or moved in a round, as the circumference of a circle, or surface of a globe.

CIRCULAR NUMBERS, called also spherical ones, according to some, are such whose powers terminate in the roots themselves.

Thus, for instance, 5 and 6, as the square of 5 is 25, the square of 6 is 36, &c.

CIRCULAR SAILING is the method of sailing by the arch of a great circle. See Navigation.

CIRCULATION, the act of moving round, or in a circle: thus we say, the circulation of the blood, &c.

CIRCULATION of the blood, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart into all parts of the body, by the arteries, from whence it is brought back to the heart again by the veins.

This motion is chiefly caused by the dilatation and contraction of this organ, and is the principle on which life depends; for when it ceases in any part, it dies; when it is diminished, the operations are weak; and, when it ceases totally, life is extinguished.

All the veins discharge themselves into the ventricles of the heart; from hence all the arteries arise: the blood expelled out of the right ventricle must be carried, through the pulmonary artery, into the lungs; from which it must be returned, by the pulmonary veins, to the left ventricle; from the left ventricle the blood, thus impelled, is, by the contraction of that part, again expelled into the aorta, and by it distributed all over the rest of the body, and thence is returned again to the right ventricle by the cava, which completes the circulation.

This circulation becomes actually visible, with the assistance of a microscope, especially in fish, frogs, &c. wherein the insufflation, or union of the extremities of the arteries with those of the veins, together with the globules of the blood flowing from the one into the other, may be plainly seen.

The auricles of the heart being large hollow muscles, furnished with a double series of strong fibres, proceeding with a contrary direction to the opposite tendons, the one adhering to the right ventricle, the other to the sinus venosus; as also with innumerable veins.
veins and arteries; by the contractile force of the arteries, the blood will be vigorously expressed and driven into the right ventricle, which, upon this contraction, is rendered flaccid, empty, and disposed to admit it.

Now, if the right ventricle, thus full of blood, by the contraction of its fibres, press the blood towards the aperture again, the venous blood at the same time pouring in, will drive it back again into the cavity, and mix it more intimately, till, rising up against the fibres, it raise the valves triicuspid, which are so connected to the seven columns extended on the opposite side, as that, when laid quite down, they cannot close the parietes of the right ventricle; these it thrusts towards the right auricle, till being there joined, they stop the passage very closely, and prevent any return.

By the same means, the same blood rises into the three semilunar valves, placed in the extremity of the other mouth, and lying open to the pulmonary artery; these it thrusts against the sides of the artery, and leaves a passage into the artery alone: the blood carried by this artery into the lungs, and distributed by its branches through the whole substance thereof, is first admitted into the extremities of the pulmonary vein, called arteria venosa; whence passing into four large vessels, which unite together, it is brought to the left sinus venosus, or trunk of the pulmonary vein, by the force of whose mucous structure it is driven into the left ventricle, which, on this occasion, is relaxed, and by that means prepared to receive it.

Hence, as before, it is driven into the left ventricle, which is relaxed by the same means; and by the valves mitrales opening, admit it into the left ventricle, and hinder its flux into the pulmonary vein: from hence it is forced into the aorta, at whose orifice there are three semilunar valves, which also prevent a reflux, by closing the same.

The motion of the blood in living animals is attended with the following phenomena: 1. Both the venous sinuses are filled, and grow turgid at the same time. 2. Both auricles grow flaccid at the same time, and both are filled at the same time with blood, impelled by the contractile force of its correspondent mucous venous sinus. 3. Each ventricle contracts and empties itself of blood at the same time; and the two great arteries are filled and dilated at the same time. 4. As soon as the blood, by this contraction, is expelled, both ventricles being empty, the heart grows larger and broader. 5. Upon which the mucous fibres of both venous sinuses contract, and express the blood contained in them into the ventricle of the heart. 6. In the mean time the venous sinuses are again filled as before, and the auricles, &c. return into their former habitude. 7. This alteration continues till the animal begins to languish under the approach of death, at which time the auricles and venous sinuses make several palpitations, for one contraction of the ventricle.

In a fetus, the apparatus for the circulation of the blood is somewhat different from that in adults. The septum, which separates the two auricles of the heart, is pierced through with an aperture, called the foramen ovale, and the trunk of the pulmonary artery, a little after it has left the heart, sends out a tube into the descending aorta, called the communicating canal. The fetus being born, the foramen ovale closes by degrees, and the canal of communication dries up, and becomes a simple ligament.

As to the velocity of the circulating blood, and the time wherein the circulation is completed, several computations have been made. By Dr. Keil's account, the blood is driven out of the heart into the aorta, with a velocity which would carry it twenty-five feet in a minute; but this velocity is continually abated in the progress of the blood, in the numerous sections or branches of the arteries, so that before it arrive at the extremities of the body, its motion is greatly diminished. The space of time wherein the whole mass of blood ordinarily circulates, is variously determined. Some state it thus: Supposing the heart to make two thousand pulses in an hour, and that at every pulse there is expelled an ounce of blood, as the whole mass of blood is not ordinarily computed to exceed twenty-four pounds, it must be circulated seven or eight times over in the space of an hour.

The circulation of the blood was first discovered in England, in the year 1728, by Dr. Harvey.
takes hold of the prepuce with one hand, and with the other cuts it off; a third person holds a porringier, with sand in it, to catch the blood; then the operator applies his mouth to the part, and having sucked the blood, spits it into a bowl of wine, and throws a hyptic powder upon the wound. This ceremony was usually accompanied with great rejoicings and feasting, and it was at this time that the child was named in presence of the company. The Jews invented several superstitious customs at this ceremony, such as placing three stools, one for the circumcisor, the second for the person who holds the child, and the third for Elijah, who, they say, assists invisibly at the ceremony, and removes the foreskin of the clitoris, which bears a near resemblance to the preputium of the male penis. The Jews distinguished their proselytes into two forts, according as they became circumcised, or not: those who submitted to this rite were looked upon as children of Abraham, and obliged to keep the laws of Moses; the uncircumcised were only bound to observe the precepts of Noah, and were called noachides. This ceremony, however, was not confined to the Jews: Herodotus and Philo Judæus observe, that it obtained also among the Egyptians and Ethiopians. Herodotus says, that the custom was very ancient among each people, so that there was no determining which of them borrowed it from the other. The same historian relates, that the inhabitants of Colchis also used circumcision; whence he concludes, that they were originally Egyptians.

The Turks never circumcise till the seventh or eighth year, as having no notion of its being necessary for salvation. The Persians circumcise their boys at thirteen, and their girls from nine to fifteen. Those of Madagascar cut the flesh at three several times; and the most zealous of the relations present, catches hold of the prepuce with one hand, and with the other cuts it off; a third person holds a porringier, and swallows it.

Circumcision is practised on women by cutting off the foreskin of the clitoris, which bears a near resemblance and analogy to the preputium of the male penis. We are told that the Egyptian captive women were circumcised; and also the subjects of Prester John.

Circumcision is also the name of a feast, celebrated on the first of January, in commemoration of the circumcision of our Saviour.

Circumduaction, in Scots law. When parties in a suit are allowed a proof of addicement after the time limited by the judge for taking that proof is elapsed, either party may apply for circumcision of the time of proving; the effect of which is, that no proof can afterwards be brought, and the course must be determined as it stood when circumcision was obtained. See Scots Law, title Pobation.

Circumference, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense, for the curve line which bounds a circle, and otherwise called a periphery; the boundary of a right-lined figure being expressed by the term perimeter.

Circumferentor, an instrument used by surveyors, for taking angles. See Practical Geometry.
CIRSOCELE, a species of hernia. See Medicine and Surgery.

CISALPINE, any thing on this side the Alps. Thus the Romans divided Gaul into cisalpine and transalpine.

CISLEU, in Hebrew chronology, the ninth month of their ecclesiastical, and the third of the civil year, answering nearly to our November.

CISMAR, a town of lower Saxony, in Germany, at a little distance from the Baltic sea.

CISSAMPELOS, in botany, a genus of the dioecia class. The calyx of the male has four leaves; the corolla is wanting; the nectarium is rosetted; and the stamina are four connected together. The calyx of the female consists of one ligulated roundish-leaf; it has no corolla; the stamens are three; and the fruit is a berry containing one seed. There are three species, all natives of America.

CISSOID, in geometry, a curve of the second order, first invented by Diocles, whence it is called the cissoid of Diocles. See Fluxions.

CISSUS, in botany, a genus of the tetrandria monogynia class. The berry contains but one seed, and is surrounded by the corolla and calyx, which are both divided into four segments. The species are five, all natives of the Indies.

CISTERCIANS, in church-histroy, a religious order founded in the eleventh century by St Robert, a beneficence. They became so powerful, that they governed almost all Europe, both in spirituals and temporals. Cardinal de Vitri describing their observances, says, they neither wore skins nor harts; nor ever eat flesh, except in sickness; and abstained from fish, eggs, milk, and cheese: they lay upon straw-beds, in their tunics and cowls: they rose at midnight to prayers: they spent the day in labour, reading and prayer: and in all their exercises observed a continual silence.

The habit of the Cistercian monks is a white robe, in the nature of a cassock, with a black scapulary and hood, and is girt with a wooden girdle. The habit of the Cistercian nuns wear a white tunic, and a black scapulary and girdle.

CISTERN, denotes a subterraneous reservoir of rainwater; or a vessel serving as a receptacle for rain or other water, for the necessary uses of a family.

There are likewise lead-cisterns, jar-cisterns, &c. See Plumbery and Jar.

Authors mention a cistern of Constantinople, the vaults of which are supported by two rows of pillars, 212 in each row, each pillar being two feet in diameter. They are planted circularly, and in radii tending to that of the center.

CITRUS, in botany, a genus of the polyadelphia icosahedra class. The calyx is divided into five segments; the petals are five, and oblong; and the fruit, is a berry, confiding of nine cells. The species are three, viz. the medica, or lemon-tree, a native of Asia; the aurantium, or orange-tree, a native of the Indies; and the trifoliata, a native of Japan.

CITTADELLAPIEVE, a town of Italy, in the territory of the pope, near the lake of Peruga.

CITTADELLA, the capital of the island of Minorca, about twenty-three miles west of Port-mahon. E. long. 3° 30', N. lat. 40°.

CITADELLA, the capital of the island of Minorca.

CITRON-TREE, in botany. See Citrus.

CITRULLUS, in botany. See Cucurbita.

CITRUS, in botany, a genus of the polyadphela icosahedra class. The calyx is divided into five segments; the petals are five, and oblong; and the fruit is a berry, confiding of nine cells. The species are three, viz. the medica, or lemon-tree, a native of Asia; the aurantium, or orange-tree, a native of the Indies; and the trifoliata, a native of Japan.

CITRON-TREE, in botany. See Citrus.

CITRULLUS, in botany. See Cucurbita.

CITRUS, in botany, a genus of the polyadphela icosahedra class. The calyx is divided into five segments; the petals are five, and oblong; and the fruit is a berry, confiding of nine cells. The species are three, viz. the medica, or lemon-tree, a native of Asia; the aurantium, or orange-tree, a native of the Indies; and the trifoliata, a native of Japan.

CITADELLA, the capital of the island of Minorca.

CIVET, a soft unctuous matter produced in the manner of frions, built on a convenient ground near a city, that it may command it in case of a rebellion.

CITATION, in ecclesiastical courts, is the same with summons in civil courts. See Summons.

CITATION is also a quotation of some law, authority, or passage of a book.

CITHARA, in antiquity, a musical instrument, the precise structure of which is not known; some think it resembled the Greek delta Δ; and others, the shape of a half moon. At first it had only three strings, but the number was at different times increased to eight, to nine, and lastly to twenty-four. It was used in entertainments and private houses, and played upon with a plectrum or quill, like the lyre.

CITHAREXYLON, in botany, a genus of the didymia angiofpermia class. The calyx is bell-shaped, and has five teeth; the corolla is tunnel shaped; and the berry contains two seeds. There are two species, both natives of America.

CITHARISTA, or Citharoedus, one who played on the cithara.

CITIZEN, a native or inhabitant of a city, veiled with the freedom and liberties of it.

A citizen of Rome was distinguished from a stranger, because he belonged to no certain commonwealth subject to the Romans. A citizen is either by birth or election; and sons may derive the right from their fathers. To make a good Roman citizen, it was necessary to be an inhabitant of Rome, to be enrolled in one of the tribes, and to be capable of dignities. Those to whom were granted the rights and privileges of Roman citizens, were only honorary citizens. It was not lawful to scourge a citizen of Rome.

CITRINELLA, in ornithology. See Emberiza.

CITRINUS, in natural history, a kind of sprig crystal, of a fine yellow colour, which being set in rings is often mistaken for a topaz.

CITRON-TREE, in botany. See Citrus.

CITRULLUS, in botany. See Cucurbita.

CITRUS, in botany, a genus of the polyadphela icosahedra class. The calyx is divided into five segments; the petals are five, and oblong; and the fruit is a berry, confiding of nine cells. The species are three, viz. the medica, or lemon-tree, a native of Asia; the aurantium, or orange-tree, a native of the Indies; and the trifoliata, a native of Japan.

CITADELLA, the capital of the island of Minorca, about twenty-three miles west of Port-mahon. E. long. 3° 30', N. lat. 40°.
of mark, in bags growing from the lower part of the belly of a civet-cat. See Castor.

Civet-cat, the English name of the animal which produces the civet. See Castor.

Civil death, any thing that cuts off a man from civil society, as a condemnation to the galleys, perpetual banishment, condemnation to death, outlawry, and execution.

Civil law, is properly the peculiar law of each state, country, or city: but what we usually mean by the civil law, is a body of laws composed out of the best Roman and Grecian laws, compiled from the laws of nature and nations, and, for the most part, received into the civil law; but more especially the doctors and professors thereof are called civilians.

Civita Vecchi, a port town and fortress of Italy.

Clack, among country-men. To clack wool, is to cut off the sheep's mark, which makes the weight less, and yields less custom to the king.

Clackmannan, the capital of Clackmannanshire, in Scotland, situated on the northern shore of the Forth, about twenty five miles north-west of Edinburgh: W. long. 3° 40', N. lat. 56° 15'.

The county of Clackmannan is joined with that of Kinnofs, which each in their turn chuse a member to reprent them in parliament.

Clagenfurt, or Clagenfort, the capital of Carinthia, in the circle of Aultria in Germany, 120 miles south-west of Vienna: E. long. 14°, N. lat. 47°.

Claim, in law, a challenge of interest in any thing that is in possession of another.

Clakis, in ornithology, a synonyme of the anas bernicle. See Anas.

Clamp in a ship, denotes a piece of timber applied to the beams of the first orlop, or second deck, and is the fame that the rising timbers are to the deck.

Clamp is likewise the term for a pile of unburnt bricks built up for burning. These clamps are built much after the same manner as arches are built in kilns, viz. with a vacuity betwixt each brick's breadth for the fire to ascend by; but with this difference, that instead of arching, they trusf over, or over-span; that is, the end of one brick is laid about half way over the end of another, and so till both sides meet within half a brick's length, and then a binding brick at the top finishes the arch.

Clamp-nails, such nails as are used to fasten on clamps in the building or repairing of ships.

Clamping, in joinery, is the fitting a piece of board with the grain, to another piece of board crossed the grain. Thus the ends of tables are commonly clamped, to prevent their warping.

ClanDESTINA, in botany. See Lathrea.

ClanDSTINE, any thing done without the knowledge of the parties concerned, or without the proper solemnities. Thus a marriage is said to be clandestine, when performed without the publication of bans, the consent of parents, &c.

Clangula, in ornithology. See Anas.

Clap, in medicine, the first stage of the venereal disease, more usually called a gonorrhoea. See Medicine.

Claramont-powder, a kind of earth, called Terra de Baira, from the place where it is found: it is famous at Venice, for its efficacy in stopping haemorrhages of all kinds, and in curing malignant fevers.

Precept of Claire Constat, in Scots law, the warrant of a superior for entering and infefting the heir of his former vassal, without the interposition of an inquest. See Scots Law, title, Succession in heritable Rights.

Clare, a market-town of Suffolk, thirteen miles south of Bury: E. long. 35', N. lat 52° 15'. It gives the title of earl to the duke of Newcastle.

Clare is also the capital of a county of the same name in the province of Connaught, in Ireland, situated about seventeen miles north-west of Limerick: W. long. 9°, N. lat. 52° 40'.

Clarencieux, the second king at arms, so called from the duke of Clare, to whom he first belonged; for Lionel third son to Edward III. having by his wife
wife the honour of Clare, in the county of Thomond, was afterwards declared duke of Clarence; which dukedom afterwards escheating to Edward IV. he made this earl a king at arms. His office is to marshal and dispose of the funerals of all the lower nobility, as baronets, knights, esquires, on the south side of the Trent; whence he is sometimes called Surroy, or South-roy, in contradistinction to Norroy.

CLARENDA. The constitutions of Clarendon are certain ecclesiastical laws drawn up at Clarendon, near Salisbury. They were sixteen in number, all tending to restrain the power of the clergy, and readily assented to by all the bishops and barons, the archbishop Becket excepted, who opposed them at first, but was afterwards prevailed upon to sign them. The pope Alexander III. declared against and annulled most of them.

CLARENZA, the capital of a duchy of the same name, is, that the chords are covered with pieces of cloth, which render the sound sweeter, and deaden it so, that it cannot be heard at any considerable distance: whence he is sometimes called Surrey, of the Trent; whence he is sometimes called Surrey,

The word is also applied to two prints of two colours, taken off at twice, whereof there are volumes in the cabinets of the curious in prints.

CLARY, in botany. See SALVIA.

Clary-water, a spirit drawn from an infusion of the herb clary in spirit of wine, being a very pleasant and excellent cordial.

CLASSIC, or Classical, an epithet chiefly applied to authors read in the classes at schools.

This term seems to owe its origin to Tullius Servius, who, in order to make an elimation of every person's estate, divided the Roman people into fix bands, which he called classes. The estate of the first classes was not to be under 200 l. and these by way of eminence were called classici, classes: hence authors of the first rank came to be called classici, all the rest being said to be infra class: thus Aristotle is a Classic author in philosophy; Aquinas, in school-divinity, &c.

CLASS, an appellation given to the most general subdivisions of any thing: thus, animal is subdivided into the classes quadrupeds, birds, fishes, &c., which are again subdivided into serices or orders; and these last into genera. See Natural History, and Botany.

CLASH, also used in schools, in a synonymous sense, with form, for a number of boys all learning the same thing.

CLARIFICATION, in chemistry, the act of clearing and fining any fluid from all heterogeneous matter or feculencies. See Chemistry.

CLARION, a kind of trumpet, whose tube is narrower, and its tone acuter and shriller than that of the common trumpet. It is said that the clarion, now used among the Moors and Portuguese, who borrowed it from the Moors, served anciently for a treble to several trumpets, which founded tener and bafes.

CLARION, in heraldry, a bearing as represented in Plate LXV. fig. 5. He bears ruby, three clarions topaz, being the arms of the earl of Bath, by the name of Granville: —Guillim is of opinion, that these three clarions are a kind of old-fashioned trumpets; but others say, that they rather resemble the rudder of a ship; others, a reft for a lance.

CLARO-OBSCURO, or CLAIR-OBSCURO, in painting, the art of distributing to advantage the lights and shadows of a piece, both with regard to the cathing of the eye, and the effect of the whole piece.

CLARO-OBSCURO, or CHIARO-SCURO, is also used to Vol. II. No. 38.
CLAUSE, in grammar, denotes a member of a period, or sentence.

Clause signifies also an article, or particular stipulation in a contract, a charge or condition in a testament, &c.

Clausesenburg, a large city of Transylvania, situated on the river Samos, about fifty-five miles northwest of Hermannstadt: E. long. 20° 50', N. lat. 47° 10'.

Clavus, in antiquity, an ornament upon the robes of the Roman senators and knights, which was more or less broad, according to the dignity of the person; hence the distinction of tunica augufii-clavia and lati-clavia.

Clavus, in medicine and surgery, is used in several significations: 1. Clavus hyleriicus, is a shooting pain in the head, between the pericranium and cranium, which affects such as have the green-sickness. 2. Clavus oculorum, according to Celsus, is a callous tuber on the white of the eye, taking its denomination from its figure. 3. Clavus importus indurated tubercles of the uterus. 4. Clavus importus a chirurgical instrument of gold, mentioned by Amatus Lusitanus, designed to be introduced into an exulcerated palate, for the better articulation of the voice. 5. Clavus is a callus or corn on the foot.

Claw, among zoologists, denotes the sharp-pointed nails with which the feet of certain quadrupeds and birds are furnished.

Crab's Claws, in pharmacy, See Crab's Claws.

Clay, in natural history, a genus of earths, the characters of which are these: they are firmly coherent, weighty, and compact; slaty, viscous, and ductile to a great degree, while moist; smooth to the touch, not easily breaking between the fingers, nor readily fusible in water, and when mixed not readily subsiding from it.

Claytonia, in botany, a genus of the pentandria monogynia class. The calyx consists of two valves; the corolla has five petals; the stigmas are trifid; and the capsule has three valves, and contains three seeds. The species are two, none of them natives of Britain.

Cape Clear, a promontory in a little island on the southwest coast of Ireland.

Cleavers, in botany. See Gallium.

Cleburne, a market-town of Shropshire, about 25 miles south-east of Shrewsbury: W. long. 2° 30', and N. lat. 52° 27'.

Cleche, in heraldry, a kind of cross, charged with another cross of the same figure, but of the colour of the field. See Plate LXV. fig. 6.

Cledge, among miners, denotes the upper stratum of fuller's earth.

Clef, or Cliff, in music, a mark set at the beginning of the lines of a song, which fires the tone or key in which the piece is to begin; or it is a letter marked on any line, which explains the right.

Clemà, in antiquity, a twig of the vine, which served as the badge of a centurion's office.

Clematis, in botany, a genus of the polyandria po-
Clerk of the crown, in chancery, an officer whose business it is constantly to attend the lord chancellor, in person or by deputy, to write and prepare for the great seal, special matters of state by commission, both ordinary and extraordinary, viz. commissions of lieutenant, of justices of assize, oyer and terminer, goal-delivery, and of the peace; all general pardons, granted either at the king's coronation, or in parliament: the writs of parliament, with the names of the knights, citizens, and burgesses, are also returned into his office. He also makes out special pardons, and writs of execution on bonds of statute-staple forfeited.

Clerk of the deliveries, an officer of the tower, whose function is to take indentures for all florses and ammunition issued from thence.

Clerk of the errors, in the court of common pleas, an officer who transcribes and certifies into the king's bench, the tenor of the record of the action on which the writ of error, made out by the curitor, is brought there to be determined. In the king's bench, the clerk of the errors transcribes and certifies the records of causes, by bill, in that court, into the exchequer. And the business of the clerk of the errors in the exchequer, is to transcribe the records certified thereto out of the king's bench, and to prepare them for judgment in the exchequer-chamber.

Clerk of the essoins, in the court of common pleas, keeps the essoin-roll, or enters essoins: he also provides parchment, cuts it into rolls, marks the number on them, delivers out all the rolls to every officer, and receives them again when written. See Essoin.

Clerk of the esquires, an officer in the exchequer, who every term receives the esquires out of the lord-treasurer's remembrancer's office, and writes them out, to be levied for the crown.

Clerk of the green cloth. See Green-cloth.

Clerk of the hanaper, or hanaper, an officer in chancery, whose business is to receive all money due to the king for the seals of charters, letters patent, commissions, and writs; also the fees due to the officers for enrolling and examining them.

Clerk-comptroller of the king's household, an officer of the king's court, authorized to allow or disallow the charges of pursuivants, messengers of the green cloth, &c. to inspect and control all defects of any of the inferior officers; and to fit in the counting-house with the lord-steward and other officers of the household, for regulating such matters.

Clerk of the king's fioler, an officer of the common pleas, to whom every fine is brought, after it has passed the office of the compotus brevium; and who enters the effect of writs of covenant, into a book kept for that purpose, according to which all the fines of that term are recorded in the rolls of the court.

Clerk of the market, an officer of the king's house, to whom is given the charge of the king's meafures and weights, the standards of those that ought to be used all over England.

Clerk of the nichils, or nihils, an officer of the exchequer, who makes a roll of all such sums as are nichiled by the sheriffs upon their esquires of green wax, and delivers them in to the remembrancer of the treasury, to have execution done upon them for the king. See Nihil.

Clerk of the outlawries, an officer of the common pleas, and deputy to the attorney-general, for making out all writs of capias utlagatum, after outlawry, to which there must be the king's attorney's name.

Clerk of the paper-office, an officer belonging to the king's bench, whose business is to make up the paper-books of special pleadings in that court.

Clerk of the peace, an officer belonging to the sessions of the peace, whose business is to read indictments, inroll the proceedings, and draw the proccls: he likewise certifies into the king's bench, transcripts of indictments, outlawries, attainders and convictions had before the justices of peace, within the time limited by statute, under a certain penalty. This office is in the gift of the culutos rotulorum, and may be executed by deputy.

Clerk of the pipes, an officer that belongs to the exchequer, whose business is to enter every teller's bill into a parchment roll called pelis receptorum, and to make another roll of payments called pelis eximia.

Clerk of the petty bags, an officer of the court of chancery, whereof there are three, the matter of the rolls being the chief: their business is to record the return of all inquisitions out of every shire, to make out patents of customers, gaugers, comptrollers, &c. liberates upon extents of statutes-staple, conge d'elites for bishops, summons of the nobility, clergy, and burgesses to parliament, and commissions directed to knights and others, of every shire, for assessing subsidies and taxes.

Clerk of the pipe, an officer of the exchequer, who having the accounts of all debts due to the king delivered out of the remembrancer's office, charges them in a great roll folded up like a pipe. He writes out warrants to sheriffs, to levy the said debts on the goods and chattels of the debtors: and if they have no good, then he draws them down, to the treasurer's remembrancer, to write esquires against their lands.

Clerk of the pleas, an officer of the exchequer, in whose office all the officers of the court, having special privilege, ought to be, or be fusd, in any action. In this office also actions at law may be prosecuted by other persons, but the plaintiff ought to be tenant or debtor to the king, or some way accountable to him. The under clerks are attorneys in all suits.

Clerks of the privy-seal, four officers that attend the lord privy-seal, for writing and making out all things that are sent by warrant from the privy-seal, and to be passed the great-seal; and likewise to make out priy-seals, upon special occasions of his majesty's affairs, as for loan of money, or the like.

Clerk of the rolls, an officer of the chancery, whose business is to make searches after, and copies of deeds, officers, &c.

Clerk of the signet, an officer continually attending upon his majesty's principal secretary, who has the custody of the privy-signet, as well for sealing the king's

CLIENT, among the Romans, a citizen who put him-
self under the protection of some great man, who, in

This patron assisted his client with his protection, in-
terest, and goods; and the client gave his vote for his

The right of patronage was appointed by Romulus,
to unite the rich and poor together in such a manner,
as that one might live without contempt, and the other
without envy; but the condition of a client, in course
of time, became little else but a moderate slavery.

CLIENT is now used for a party in a lawsuit, who has
turned over his cause into the hands of a counsellor or

CLIFFORTIA, in botany, a genus of the dioecia poly-
andria class. The calyx of the male consists of three
leaves; it has no corolla; and the stamina are about
three. The calyx of the female consists likewise of
three leaves; and the corolla is wanting; the stylus
are two; and the capsule is bilocular, and contains
one seed. The species are four, all natives of Ethiopia.

CLIMACTERIC, among physicians, a critical year in
a person's life, in which he is supposed to stand in
great danger of death.

According to some, every seventh year is a clima-
teric; but others allow only those years produced by
multiplying 7 by the odd number 3, 5, 7, and 9, to
be climacterial. These years, they say, bring with
them some remarkable change with respect to health,
life, or fortune; the grand climacteric is the sixty-
third year; but some, making two, add to this the
eighty-eighth: the other remarkable climacterics are the
seventh, twenty-first, thirty-fifth, forty-ninth, and
fifty-fifth.

CLIMATE, in geography, a space upon the surface of
the terrestial globe, contained between two parallels,
and so far distant from each other, that the longest
day in one differs half an hour from the longest day
in the other parallel. See Geography.

CLINCH, in the sea-language, a kind of flight
caulking used at sea, in a prospect of foul weather, a-
bout the polls: it consists in driving a little oakum in-
to their seams, to prevent the water's coming in at
them.

CLINIC,
CLINIC, a term applied by the ancient church-historians, to those who received baptism on their death-bed.

CLINIC MEDICINE, was particularly used for the method of visiting and treating sick persons in bed, for the more exact discovery of all the symptoms of their disease.

CLINOPODOID, in botany, a genus of the didynamia clafs. The involucrum is hoary. The species are three, only one of which is a native of Britain, viz. the vulgare, or great willow.

CLIO, in zoology, a genus of infedts belonging to the Gymnofpermia clafs. The involucrum is hoary. The species are five, all natives of the Indies.

CLIPERUS, in natural history, a name given to the flat deprefled centroniae, from their resembling a shield.

CLITORIA, in botany, a genus of the diadelphia descandria clafs. The vexillum is large, open, plaited, and covers the ale. The species are five, all natives of the Indies.

CLOSE, in heraldry. When any bird is drawn in a piece of paper, or nifties, so disposed, as that they may be eas'd, or at least retrieved in Germany, about 150 years ago; and the invention of pendulum clocks, so late as the last age, is disputed between Huygens and Galileo. For the principles of Clock and Watch Work, see Watch.

CLOGHER, a city and bishop's see of Ireland, in the county of Tyrone, and province of Ulter, situated twelve miles west of Armagh: W. long. 70 30', and N. lat. 54 16'.

CLOISTER, an habitation surrounded with walls, and inhabited by religious.

In a more general sense, it is used for a monastery of religious of either sex. In the first sense, it is the principal part of a regular monastery, being a square surrounded with walls or buildings. It is commonly placed between the church, the chapter-house, and refectory, underneath the dormitory.

CLOSE, in heraldry. When any bird is drawn in a coat of arms with its wings close down about it, (i.e. not displayed), and in a flanding posture, they blazon it by this word close; but if it be flying, they call it volant. See VOLANT.

CLOT-BIRD. See FRINGILLA.

CLOTH, in commerce, a manufacture made of wool, wove in the loom.

Vol. II. No. 39.

Cloths are of divers qualities, fine or coarse. The goodness of cloth, according to some, consists in the following particulars. 1. That the wool be of a good quality, and well drefsed. 2. It must be equally spun, carefully observing that the thread of the warp be finer and better twisted than that of the woof. 3. The cloth must be well wrought, and beaten on the loom, so as to be every where equally compact. 4. The wool must not be finer at one end of the piece than in the rest. 5. The lifts must be sufficiently strong, of the same length with the fluff, and must confit of good wool, hair, or of rich-feathers; or, what is still better, of Danish dog's hair. 6. The cloth must be free from knots, and other imperfections. 7. It must be well foured with fuller's earth, well filled with the best white soap, and afterwards washed in clear water. 8. The hair or nap must be well drawn out with the teasel, without being too much opened. 9. It must be thorn close without making it thread-bare. 10. It must be well dried. 11. It must not be tenter-stretched, to force it to its just dimensions. 12. It must be pressed cold, not hot preffed, the latter being very injurious to woollen cloth.

Manufacturing of white cloths which are intended for dyeing.

The best wool for the manufacturing of cloths are those of England and Spain, especially those of Lincolnshire and Segovia. To use those wools to the best advantage, they must be foured, by putting them into a liquor somewhat more than lukewarifl, composed of three parts fair water, and one of urine. After the wool has continued long enough in the liquor to soak, and diffuse the greafe, it is drained and well wash'd in running water. When it feels dry, and has no smell but the natural one of the sheep, it is said to be duly foured.

After this it is hung to dry in the shade, the heat of the sun making it harfi and inflexible: when dry, it is beat with rods upon hurdles of wood, or on cords, to cleanse it from dust, and the grofler filth; the more it is thus beat and clean'd, the softer it be- comes, and the better for spinning. After beating, it must be well picked, to free it from the rest of the filth that had escaped the rods.

It is now in a proper condition to be oiled, and carded on large iron cards, placed dopewise. Olive oil is esteemed the beft for this purpose: one fifth of which should be used for the wool intended for the woof, and a ninth for that defigned for the warp. After the wool has been well oiled, it is given to the spinners, who first card it on the knee with small fine cards, and then spin it on the wheel, obferving to make the thread of the warp smaller by one third than that of the woof, and much compacter twisted.

The thread thus spun, reeled, and made into itakens, that defigned for the woof is wound on little tubes, pieces of paper, or tubes, fo disposed, as that they may be easily put in the eye of the shuttle. That for the warp is wound on a kind of large wooden bobbins, to dipole it for warp'-ing. When warped, it is thicken'd with size, the belt of which is that made of threds
of parchment, and when dry, is given to the weavers, who mount it on the loom.

The warp thus mounted, the weavers, who are two to each loom, one on each side, tread alternately on the treddle, first on the right step, and then on the left, which raises and lowers the threads of the warp equally; between which they throw transversely the shuttle from the one to the other: and every time that the shuttle is thus thrown, and a thread of the wool inserted within the warp, they strike it conjunctly with the same frame, wherein is fastened the comb or reed, between whose teeth the threads of the warp are paffed, repeating the stroke as often as is necessary.

The weavers having continued their work till the whole warp is filled with the woof, the cloth is finished; it is then taken off the loom by unrolling it from the beam whereon it had been rolled in proportion as it was wove; and now given to be cleansed of the knots, ends of threads, straws, and other filth, which is done with iron nippers.

In this condition it is carried to the fullery, to be scoured with urine, or a kind of potter’s clay, well steeped in water, put along with the cloth in the trough wherein it is fulfilled. The cloth being again cleared from the earth or urine, is returned to the former hands to have the leffer filth, small straws, &c. taken off as before: then it is returned to the fuller to be beat and cleansed with hot water, wherein a suitable quantity of soap has been dissolved; after fuller, it is taken out to be smoothed, or pulled by the lifs lengthwise, to take out the wrinkles, crevices, &c.

The smoothing is repeated every two hours, till the fulling be finished, and the cloth brought to its proper breadth: after which it is washed in clear water, to purge it of the soap, and given wet to the carders to raise the hair or nap on the right side with the thistle or weed. After this preparation the cloth-worker takes the cloth, and gives it its first cut or shearing: then the carders refume it, and after wetting, give it as many more courses with the teasle, as the quality of the cloth requires, always observing to begin against the grain of the hair, and to end with it; as also to begin with a smoother thistle, proceeding still with one sharper and sharper, as far as the sixth degree.

After these operations, the cloth being dried, is returned to the cloth-worker, who sheers it a second time, and returns it to the carders, who repeat their operation as before, till the nap be well ranged on the surface of the cloth, from one end of the piece to the other.

The cloth thus wove, scoured, napped, and shorn, is sent to the dyer: when dyed, it is washed in fair water, and the worker takes it again wet as it is, lays the nap with a brush on the table, and hangs it on the tenters, where it is stretched both in length and breadth sufficiently to smooth it, set it square, and bring it to its proper dimensions, without straining it too much; observing to brush it afresh, the way of the nap, while a little moist, on the tenters.

When quite dry, the cloth is taken off the tenters, and brushed again on the table, to finish the laying of the nap; after which it is folded, and laid cold under a press, to make it perfectly smooth and even, and give it a gloss.

Lastly, the cloth being taken out of the press, and the papers, &c. for gulling it removed, it is in a condition for sale or use. With regard to the manufacture of mixt cloths, or those wherein the wools are first dyed, and then mixt, spun and wove of the colours intended, the process, except what relates to the colour, is mostly the same with that just represented.

CLOU, a collection of vapours suspended in the atmosphere. See PNEUMATICS.

CLOVE-TREE, in botany. See Caryophyllus.

CLOVE, a term used in weights of wool. Seven pounds make a clove.

In Essex, eight pounds of cheese and butter go to the clove.

CLOVE-JULY-FLOWER. See Caryophyllus.

CLOVER-GRASS, in botany. See trifolium.

CLOYNE, a city and bishop’s see of Ireland, in the county of Cork, and province of Munster, about fifteen miles east of Cork: W. long. 8°, and N. lat. 51° 40’.

CLUPEA, or herring, in ichthyology, a genus belonging to the order of abdominales. The upper jaw is furnished with a serrated mylilache; the branchiiole membrane has eight rays; a scaly serrated line runs along the belly from the head to the tail; and the belly-fins have frequently nine rays. There are 11 species, viz.

1. The harengus, or common herring, has no spots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water, whence the proverb arises, As dead as a herring.

The flesh is every where in great esteem, being fat, soft, and delicate, especially if it is dred as soon as caught; for then it is incomparably better than on the next day. There are vast quantities of these fish taken, salted, smoke-dried, and consumed all over Europe. They make a progress every year from the seas near the north of Scotland, into the British channel, coming in pursuit of worms and small fish, which at that time abound there. There is also plenty near Norway and Denmark, from whence they proceed annually as far as the coast of Normandy.

The herring-fisher is begun both by the English and Dutch towards the latter end of June; and the Dutch alone employ no less than one thousand ships therein, called buffils, from forty-five to sixty ton each. The best time for catching herrings is from the latter end of September, to the latter end of October; and the nets they make use of, are about twenty-five yards long, and five deep. They sometimes fall in many of these nets together, as will take in a mile in compass. They judge where the herrings lie by the hovering of birds of the sea-birds, which continually pursue them, in expectation of prey. The fishermen row very gently along, letting the nets fall into the sea,
fe, and taking their courses as near as they can against the tide; that so, when they draw their nets, they may have the assistance of the tide. As soon as any boat has got its load, it makes to the shore, and delivers its load to those that wan and gut them.

Herrings are put into a tub with salt or brine, where they lie for twenty-four hours, and are then taken out and put into wicker baskets and wafted. After this, they are spitted on sharp wooden spits, and hung up in a chimney, built for that purpose, at such distances, that the smoke may have free access to them all. These places will hold ten or twelve thousand at a time; and they kindle billets on the floor in order to dry them. This done, they fuit the doors, having before stopped up all the air-holes. This they repeat every quarter of an hour, infomuch that a single laft of herrings requires five hundred billets to dry them. A laft is ten barrels, and each barrel contains about one thousand herrings. When they are smoke-dried in this manner, they are called red herrings. Salt herrings, and pickled herrings, are cured after a different manner; the laft of which were formerly bent done by the Dutch; but now the Scotch and English are become their rivals in that trade. Herrings always swim in shoals, delighting to be near the shore. They spawn but once a year, that is about the beginning of November; a little before which, like most other fish, they are in highest season.

There are likewise herrings on the coasts of North America, but they are not so plenty as in Europe; and they never go farther south than the rivers of Carolina. There are none here Spain, Portugal, in the Mediterranean, nor on the coast of Africa.

2. The sprattus has 13 rays in the back-fin. It is a native of the European seas, and has a great resemblance to the herring, only it is of a less size.

3. The alofa, has a forked snout, and black spots on the fides. It is found in the Indian ocean.

4. The encrasicolus, or anchovy, has its upper jaw longer than the under one, and is found in the European seas. It is about three inches long, and is frequently used as a pickle.

5. The atherinoides has a shining line on each fide, and small belly-fins. It is a native of Surinam.

6. The thrifla has 28 rays in the fkin at the anus. It is found in the Indian ocean.

7. The fina has yellow fins, those of the belly being very small. The mouth is flat; the upper jaw is very short; the body is of a shining silver colour; and the fins are yellow. It is a native of Asia.

8. The ilencra has no belly-fins, and the body is broad. It is a native of Surinam.

9. The mylfs is shaped like a sword, and the fins at the anus are united. It is found in the Indian ocean.

10. The tropica has a wedge-like tail, and a white, broad, compressed body; and the tail is wedge-shaped. It is found at Ascension island.

11. The finifhis is very like the common herring, but broader. It has no teeth, and is a native of China.

CLUSIA, in botany, a genus of the polygamia monoeeria class. The calix of the male consists of six leaves; the corolla has five petals; and the stamens are numerous. The calix and corolla of the female are the same as those of the male; the nectarium includes the germs and united anthera; and the capsule has five cells, five valves, and a fluffed pulp. The species are four, all natives of America.

CLUTIA, in botany, a genus of the dioecia gymandra class. The calix and corolla, both of the male and female, consist of five leaves; the stamens are three; and the capsule has three cells and one seed.

CLYEDE, a river in Scotland, which, arising in Annandale, runs north-west by Lanark, Hamilton, and Glasgow, and falls into the Frith of Clyde, over-against the isle of Bute.

CLYMENU, in botany. See Lathytrum.

CLYPEOLA, in botany, a genus of the tetradynamia class. The pod is emarginated, roundish, entire, compressed, and deciduous. The species are two, none of them natives of Britain.

CLYPEUS, or Clypeum, a shield or buckler. See Shield.

CLYSUS, an extract prepared, not from one, but several bodies mixed together: and, among the moderns, the term is applied to several extracts procured from the same body, and then mixed together. Thus, if from wormwood we draw the water, spirit, oil, salt, and tincture, and according to the rules of art re-unite these into a mass composed of them all, and containing the joint virtues of all, we have a Clythus of wormwood.

CLYSTER, is a liquid remedy, to be injected chiefly at the anus into the larger intestines. It is usually administered by the bladder of a hog, sheep, or ox, perforated at each end, and having at one of the apertures an ivory pipe fastened with pack-thread. But the French, and sometimes the Dutch, use a pewter syringe, by which the liquor may be drawn in with more ease and expedition than in the bladder, and likewise more forcibly expelled into the large intestines. This remedy should never be administered either too hot or too cold, but tepid; for either of the former will be injurious to the bowels.

Clysters are prepared of different ingredients, according to the different intentions proposed.

Clysters are sometimes used to nourish and support a patient who can swallow little or no aliment, by reason of some impediment in the organs of deglutition. In which case they may be made of broth, milk, ale, and decoctions of barley and oats with wine. The English introduced a new kind of clyster, made of the smoke of tobacco, which has been used by several other nations, and appears to be of considerable efficacy when other clysters prove ineffectual; and particularly in the ileus passione, in the hernia incarcerata, and for the recovery of drowned persons.

CNEORUM, in botany, a genus of the triandria monoeeria class. The calix has three teeth; and the corolla has three equal petals. There is but one species, viz. the tricoccus, a native of Spain.
COB (214)

COB, in zoology, the trivial name of a species of coluber. See Coluber.

COBELLA, in zoology, the trivial name of a species of viverra and ursus. See Viverra and Ursus.

COBITIS, the loache, in ichthyology, a genus of fishes belonging to the order of bony fishes. See Theobroma.

COCOON, a port-town of the hither India, situated on the coast of Surinam. Twelve miles south of Fort St George: E. long. 80°, N. lat. 12° 50'.

COBWEB, in physiology, the fine net-work which spiders spin out of their own bowels, in order to catch their prey. See Aranea.

COCCEROS, or Saffron flower, in botany, a genus of the syngeneric polygama equalis clafs. The calyx is ovated, and imbricated with spinous branches; and the corolla is equal. The species are seven, none of them native of Britain.

COACH, in botany. See Hippocratea.

COACH, a commodious vehicle for travelling, so well known as to need no description. Their invention was owing to the French about the reign of Francis I.

COAGULATION, in a general sense, imports a certain change in the state of any liquor, by means of which, instead of retaining its fluidity, it becomes more or less colligent, according to the degree of coagulation.

COAGULUM, is the same with what in English we call curd, or rather the card formed thereby.

COAL, or Pit-coal, in natural history. See Lignite.

Cannel-Coal, a sort of charcoal prepared from the spray and brusht-wood, sometimes bound in bavins for that purpose, and sometimes charred without binding, and then it is called coming it together.

COALITION, the reunion of the parts of a body before separated.

COAT, or Coat of Arms, in heraldry, a habit worn by the ancient knights over their arms both in war and tournaments, and still borne by heralds at arms. It was a kind of fur-coat, reaching as low as the haunches, sometimesoccurringat the sides with short sleeves, sometimesfurred with ermine and hair, upon which were applied the armories of the knights embroidered in gold and silver, and enamelled with beaten tin-coloured black, green, red, and blue; whence the rule never to apply colour on colour, nor metal on metal. The coats of arms were frequently open, and diversified with bands and fillets of several colours, alternately placed, as we still see cloths scarlet, watered, &c. Hence they were called devises, as being divided and composed of several pieces sewed together; whence the words false, pale, chevron, bend, cross, faltier, lozenge, &c. which have since become honourable pieces, or ordinaries of the shield. See Cross, Bend, Chevron, &c.

Coats of arms and banners were never allowed to be worn by any but knights and ancient nobles.

COAT, in anatomy. See Part VI.

COAT, in zoology. See Mail.

COATI, in zoology, a species of viverra and ursus. See Viverra and Ursus.

COBALT, in chemistry, a genus of fishes, of the order of the spawrureata: it is a denfe, compact, and ponderous mineral, very bright and shining, and much resembling some of the antimonal ores. See Antimony, and Chemistry, p. 139, 140, 141.

It is sometimes found of a deep blueish-black, very heavy and hard, and of a granulated structure, looking like a piece of pure iron where fresh broken: at other times it is found more compact, not granulated, but resembling a mass of melted lead on the surface. These are the more ordinary appearances of cobalt, besides which there are other accidental varieties of it, being sometimes found of a florid red, or a red debased by mixtures of grey, black, or yellow; and in this state, it either forms an uniform mass, or a beautifully fliated and ridged one.

From this mineral are produced the several kinds of arsene, zaffre, and smalt. See Chemistry, p. 145.

COBELLIA, in zoology, the trivial name of a species of coluber. See Coluber.

COBITIS, the loache, in ichthyology, a genus of fishes belonging to the order of bony fishes. See Theobroma.

COCCIIFEROUS plants, the same with bacciferous. See Viverra and Ursus.
eminences; and instead of spines has a fine smooth membrane, of a permanent and lively green.

The method of planting the nopal is by making rows of holes about half a yard deep, and about two yards distant from one another. In each of these holes is placed one or two leaves of the nopal, in a flat position, and then covered with earth. This leaf soon after shoots up into a single stem, which during its growth divides into several branches, and these successively produce fresh leaves, the largest being nearest to the stem, which is full of knots, as are also the branches, and from these the leaves have their origin. The usual height of this plant is about three yards, which it seldom exceeds. The season when the nopal displays all its beauty and vigour, is like that of other plants, from the spring to the autumn, which at Oaxaca and other parts of North America is at the same time as in Spain. Its blossoms is small, of a bright red, and in the shape of a bud; from the centre of which proceeds the tuna, a name given to its fruit; and as this increases the blossoms fades, till at length it falls. When the tuna, or fig, is ripe, the outward skin becomes white; but the pulp is so fully impregnated with a deep red, that it tingles the urine of those who eat it of a blood colour, a circumstance attended with no small uneasiness to those who are unacquainted with this particular. Few fruits, however, are either more wholesome or pleasant.

The ground where the nopal is intended to be planted, must be carefully cleaned from all kinds of weeds, as they drain the soil of those juices which the nopal requires. Also after the cochineal is taken from the plant, which is their sole nourishment, becomes converted into their subsistence; when, instead of being thin and waterth, and, to all outward appearance, of little or no use, is rendered a most beautiful crimson colour. The plant is in May or June in its most vigorous state, and at this most favourable season the eggs are deposited; and in the short space of two months, from an animalcule, the insect grows up to the size above-mentioned; but its infant state is exposed to a variety of dangers; the violent blasts of the north wind sweep away the eggs from the foliage of the plant; and, what is equally fatal to their tender constitutions, showers, fogs, and frosts, often attack them, and destroy the leaves, leaving the careful cultivator this only recourse, namely, that of making fires at certain distances, and filling the air with smoke, which frequently prevents them from the fatal effects of the inclemency of the weather.

The breeding of cochineal is also greatly obstructed by birds of different kinds, which are very fond of these insects; and the same danger is to be apprehended from the worms, &c. which are found among the plantations of nopals: so that unless constant care be taken to fright the birds away from the plantation, and to clear the ground of those various kinds of vermin, which multiply so fast in it, the owner will be greatly disappointed in his expectations.

When the insects are at their full growth, they are gathered and put into pots of earthen ware; but great attention is requisite to prevent them from getting out, as, in that case, great numbers of them would be lost; though there is no danger of it, where they are at liberty on the nopal leaves, those being their natural habitations; and where they enjoy a plenty of delicious food; for, though they often remove from one leaf to another, they never quit the plant; nor is it uncommon to see the leaves entirely covered with them, especially when they are at maturity. When they have been confined some time in these pots, they are killed and put in bags. The Indians have three different methods of killing these insects, one by hot water, another by fire, and a third by the rays of the sun: and to these are owing the several gradations of the colour, which in some is dark, and in others bright; but all require a certain degree of heat. Tho' therefore, who use hot water are very careful to give it the requisite heat, and that the quantity of water be proportioned to the number of insects. The method of killing the creatures by fire is to put them on shovels into an oven moderately heated for that intention; the fine quality of the cochineal depending on its not being over dried at the time of killing the insects: and it must be owned, that among the several ways made use of to destroy this valuable creature, that of the rays of the sun seems to bid fairest for performing it in the most perfect manner.

Besides the precaution requisite in killing the cochineal, in order to preserve its quality, it is equally necessary to know when it is in a proper state for being removed from the leaves of the nopal; but as experience only can teach the cultivator this necessary criterion, no fixed rule can be laid down. Accordingly in those provinces where the cultivation of these insects is chiefly carried on, those gathered by Indians of one village differ from those gathered in another; and even those gathered by one person in the same village, are often different from those gathered by another; every individual adhering to his own method.
The cochineal insect may, in some circumstances, be compared to the silk worm, particularly in the manner of depositing its eggs. The insects destined for this particular are taken at a proper time of their growth, and put into a box well closed, and lined with a coarse cloth that none of them be lost: and in this confinement they lay their eggs and die. The box is kept close shut till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a sufficient indication that the animalcule has life, tho' the egg is so minute as hardly to be perceived; and this is the feed placed on the foliage of the nopal, and the quantity contained in the shell of a hen's egg is sufficient for covering a whole plant. It is remarkable that this insect does not, or at least in any visible manner, injure the plant, but extracts its nourishment from the most succulent juice, which it sucks by means of its probosces through the fine teguments of the leaves.

The principal countries where the cochineal insects are bred, are Oaxaca, Flacalca, Chulula, Nueva Galicia, and Chiapa, in the kingdom of New Spain; and Hambato, Loja, and Tucuman in Peru: but it is only in Oaxaca, that they are gathered in large quantities, and form a branch of commerce, the cultivation of these little creatures being there the chief employment of the Indians.

COCOTHRAUSTES, in ornithology, the trivial name of a species of loxia. See Loxia.

COCCULUS INDICUS, the name of a poisonous berry, too frequently used by brewers in order to render their malt liquors intoxicating. It is the fruit of the menispermum cocculus. See Menispermum.

COCCUS, in zoology, a genus belonging to the order Coccyc/gus musculus, in anatomy. See Vol. I.

COCCYX, or Coccygis os, in anatomy. See Vol. I.

COCHRINEAL. See coccinella.

COCHLEA, the snail-shell, in zoology. See Limax.

COCHLEARIUM, scurvy-grass, in botany, a genus of the tetradyamia siliculosa class. The pod is emarginated, turgid, and feaceous; and the valves are obtuse and gibbous. The species are eight, six of which are natives of Britain, viz. the officialis, or common scurvy-grass, the leaves of which are famous for curing the scurvy; the groenlandica, or Groenland scurvy-grass; the anglica, or common sea-scurvy-grass; the danica, or Danish scurvy-grass; the coronopus, or swine-crefles; and the armoracia, or horse-radish.

COCHLITES, in natural history, an appellation given to the petrified shells of the cochleae, or snails.

COCK, in zoology, the English name of the males of gallinaceous birds, but more especially used for the common dunhill-cock. See Phasianus.

COCK-PIT, a fort of theatre upon which game-cocks fight.

COCK-PIT, in a man of war, a place on the lower floor, or deck, abaft the main capftain, lying between the platform and the steward's room, where are partitions for the purfer, surgeon, and his mates.

COCK-SWAIN, or Coxon, an officer on board a man of war, who has the care of the barge and all things belonging to it, and must be also ready with his crew to man the boat on all occasions: he fits at the stern of the boat, and fleers.

COCKERMOUTH, a borough-town of Cumberland, situated on the river Derwent, near the Irish sea, about twenty-five miles south-west of Carlisle: W. lon. 2° 10', and N. lat. 54° 35'. It sends two members to parliament.

COCKET, or cocker, a certificate of discharge.

COCKET is a seal belonging to the king's custom-house, or rather a scroll of parchment sealed and delivered by the officers of the custom to merchants, as a warrant that their merchandises are customed.

It is also used for the office where goods transported were first entered, and paid their custom, and had a cocker or certificate of discharge.

COCOA, or Cacao, in botany. See Theobroma.

COCOI, in ornithology. See Arctea.

COCONATO, a town of Italy in the province of Piedmont, about twenty miles east of Turin; it is said to be the birth-place of the famous Columbus, who discovered America: E. lon. 8°, and N. lat. 44° 50'.

COCTION, a general term for all alterations made in bodies by the application of fire or heat.

COD, in ichthyology. See Gadus.

CODDY MODDY, the English name of a species of larus. See Larus.

COD, in anatomy. Cod is also a term used, in some parts of the kingdom, for a pod. See Pod.

CODE, in antiquity, denotes a book or tablet, on which the ancients wrote. It was of the bark of a tree, of ivory, of parchment, or of paper.

CODIA, among botanists, signifies the head of any plant, but more particularly a poppy-head, whence its syrup is called diacodium.

CODICIL,
CODICIL is a writing by way of supplement to a will, when any thing is omitted which the testator would have added, or wants to be explained, altered, or recalled.

CODLIN, an apple useful in the kitchen, being proper for baking.

CODLING, an appellation given to the cod-fish, when young. See Gadus.

COEFFICIENTS, in algebra. See Vol. I. p. 86.

COELESTIAL, in general, denotes any thing belonging to the heavens; thus we say, celestial observations, the celestial globe, &c.

COELIAC passage, in medicine, a kind of flux, or diarrhoea, wherein the aliment, either wholly changed, or only in part, passes off by stool. See Medicine.

COELOMA, among physicians, a hollow ulcer seated in the cornea tunica of the eye.

COENOBITE, in church-history, a fort of monks in the primitive Christian church. They were so called from living in common; in which they differed from the anachorites, who retired from society.

COENOBITE, in a modern sense, is a religious who lives in a convent or community, under certain rules.

COEUR, in heraldry, a fliort line of partition in pale.

COELESTIAL, in general, denotes any thing belonging to the heavens.

COELIAC PaSsion, in medicine, a kind of flux, or diarrhoea, wherein the aliment, either wholly changed, or only in part, passes off by stool. See Medicine.

CODLING, an appellation given to the cod-fish, when young. See Gadus.

COFFERER of the king's household, a principal officer in the court, next under the comptroller, who, in the counting-house, and elsewhere at other times, has a special charge and oversight of other officers of the house, for their good demeanor and charge in their offices, to all which he pays their wages.

CODDLE. See Cogs.

COGGSHALL's sliding rule. See Sliding rule.

COGITATION, a term used by some for the act of thinking.

COGNATE, in Scots law, any male relation through blood.

COGNIZANCE, in heraldry. See Crest.

COGNIZANCE, or Connusance, in law, has divers significations: sometimes it is an acknowledgment of a fine, or confession of something done; sometimes the hearing of a matter judicially, as to take cognizance of a cause; and sometimes a particular jurisdiction, as cognizance of pleas is an authority to call a cause or plea out of another court, which no person can do but the king, except he may demand cognizance of the plea, and that it be determined before them.

COGNIZANCE, or Connusance, in law, has divers significations: sometimes it is an acknowledgment of a fine, or confession of something done; sometimes the hearing of a matter judicially, as to take cognizance of a cause; and sometimes a particular jurisdiction, as cognizance of pleas is an authority to call a cause or plea out of another court, which no person can do but the king, except he may demand cognizance of the plea, and that it be determined before them.

COGNIZANCE, in heraldry. See Crest.

COGNIZATION, or Comprifings and adjudications.

COGNITIONIS CAUSA, in Scots law: When a creditor charges the heir of his debitor to enter, in order to constitute the debt against him, and the heir renounces the succession, the creditor can obtain no decreet of constitution of that debt against the heir; but only a decreet subjecting the hereditat jacens, or the estate which belonged to the debitor, to his diligence: and this is called a decreet cognitionis causa. See Scots Law, title, Comprifings and adjudications.

COGNIZE, in Scots law, any male relation through blood.

COGSHALL, a sliding rule. See Cogs.

COGENDE, a city of Tartary in Asia, situated in 74° E. long. and 41° N. lat. remarkable for its commerce in mulk.

COGGS, or Goggles, a kind of flat-bottomed boats used in rivers.

COHABITATION, denotes the state of a man and woman who live together like husband and wife, without being legally married.

CO-HEIR, one who succeeds to a share of an inheritance, to be divided among severall.

COHESION, in philosophy, that action by which the particles of the same body adhere together, as if they were but one. See Mechanics.

COHORT, in Roman antiquity, the name of part of the
COINAGE, or Coining, the art of making money, as coin is often used for a solid angle composed of two surfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, or in-terior, as the coin of a chamber or chimney. See Tonsure.

COIL. See Quoil.

COILON in the ancient Grecian theatres, the same with COILOPHYLUM, in botany. See Sarracena.

COIMBRA, a large city of Portugal, in the province of Beira, situated on the river Mondego, about nine-six miles north of Lisbon: W. long. 9°, and N. lat. 40° 20'.

COIN denotes all manner of the several stamps and species of money in any nation. See Money.

COIN, in architecture, a kind of dye cut diagonal-wise, after the manner of a flight of a stair-case, serving at bottom to support columns in a level, and at top to correct the inclination of an entablature supporting a vault.

COIN is also used for a solid angle composed of two surfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, &c. or interior, as the coin of a chamber or chimney. See Quoin.

COINAGE, or Coining, the art of making money, as performed either by the hammer or mill.

Formerly the fabric of coins was different from what it is at present. They cut a large plate of metal into several little squares, the corners of which were cut off with sheers. After having shaped these pieces, so as to render them perfectly conformable, in point of weight, to the standard piece, they took each piece in hand again, to make it exactly round, by a gentle hammering. This was called a planchet, and was fit for immediate coining. Then engravers prepared, as they still do, a couple of steel maffes in form of dyes, cut and terminated by a flat surface, rounded off at the edges. They engraved or stamped on it the hollow of a head, a crofs, a scutcheon, or any other figure, according to the custom of the times, with a short legend. As one of these dyes was to remain dormant, and the other moveable, the former ended in a square prism, that it might be introduced into the square hole of the block, which, being fixed very fast, kept the dye as steady as any vice could have done. The planchet of metal was horizontally laid upon this inferior maff, to receive the stamp of it on one side, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved surface resting upon the planchet, had at its opposite extremity a flat square, and larger surface, upon which they gave several heavy blows, with a hammer of an enormous fize, till the double stamp was sufficiently, in releeve, impressed on each side of the planchet. This being finished, was immediately succeeded by another, and they thus became a standard coin, which had the degree of fineness, the weight and mark, determined by the judgment of the inspectors, to make it good current money. The strong tempering which was and is still given to the two dyes, rendered them capable of bearing those repeated blows. Coining has been considerably improved and rendered expeditious, by several ingenious machines, and by a wise application of the surest physical experiments to the methods of fining, dyeing, and flamping the different metals.

The three finest instruments the mint-man uses, are the laminating engine, the machine for making the impressions on the edges of coins, and the mill.

After they have taken the laminate, or plates of metal, out of the mould into which they are cast, they do not beat them on the anvil, as was formerly done, but they make them pass and repass between the several rollers of the laminating engine, which being gradually brought cloer and cloer to each other, presently give the laminate its uniform and exact thickness. Instead of dividing the laminate into small squares, they at once cut clean out of it as many planchets as it can contain, by means of a sharp steel trepan, of a round-figured figure, hollow within, and of a proportionate diameter, to shape and cut off the piece at one and the same time. After these planchets have been prepared and weighed with standard pieces, filed or scraped to get off the superfluous part of the metal, and then boiled and made clean, they arrive, at last, at the machine, (Plate LXVI. fig. 1.), which marks them upon the edge; and finally, the mill, (fig. 2.) which, squeezing each of them singly between the two dyes, brought near each other with one blow, forces the two surfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which serves to laminate lead, gives a sufficient notion of that which serves to flatten gold and silver laminæ between rollers of a lesser size. See Laminating.

The principal pieces of the machine, (fig. 1.), to stamp coins on the edge, are two steel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thickness of one of the laminate, and the other half on the thickness of the other; and these two laminate are straight, although the planchet marked with them be circular.

When they stamp a planchet, they first put it between the laminate in such a manner, as that these being each of them laid flat upon a copper-plate, which is fastened upon a very thick wooden table, and the planchet being likewise laid flat upon the same plate, the edge of the planchet may touch the two laminate on each side, and in their thick part.

One of these laminate is immovable, and fastened with

11. Crowns of the British Nobility
with several screws; the other slides by means of a
dented wheel, which takes into the teeth that are on
the surface of the lamina. This sliding lamina makes
the planchet turn in such a manner, that it remains
stamped on the edge, when it has made one turn. On-
ly crown and half crown pieces can bear the impre-
sion of letters on the thickens of their edges.

The coining engine or mill is so handy (fig. 2.)
that a single man may stamp twenty thousand planchet
in one day: gold, silver, and copper planchets, are
all of them coined with a mill, to which the coining
squares, (fig. 3.), commonly called dyes, are fasten-
ed; that of the face under, in a square box garnishe
with male and female screws, to fix and keep it steady;
and the other above, in a little box garnished with the
same screws, to fasten the coining square. The plan-
chets are laid flat on the square of the effigy, which is
dormant; and they immediately pull the bar of the
mill by its cords, which caufes the screw set within it
to turn. This enters into the female screw, which is
in the body of the mill, and turns with so much
strength, that by putting the upper square upon that
of the effigy, the planchet, violently pressed between
both squares, receives the impression of both at one
pull, and in the twinkling of an eye.

The planchet thus stamped and coined, goes through
a final examination of the mint wardens, from whose
hands it goes into the world.

In the Coining of medals, the procefs is the fame, in
effect, with that of money; the principal difference
consisting in this, that money having but a small re-
lievo, receives its impression at a single stroke of the
engine; whereas for medals, the height of their re-
lievo makes it necessary that the stroke be repeated se-
veral times: to this end the piece is taken out from
between the dyes, heated, and returned again; which
procefs in medallions and large medals, is repeated
fifteen or twenty times before the full impression
be given, care must be taken, every time the plan-
chets removed, to take off the fuperfluous metal
stamped on the edge, When it has made one turn.

In Persia is feven and a half per cent, for all the mo-
cies coined, which are lately reduced to silver and cop-
per, there being no gold coin there, except a kind of
medals, at the accession of a new sophi.

Mufcovite Coinage. In Mufcovy there is no other
coin struck but silver, and that only in the cities of
Mufcow, Novogrod, Tvere, and Plefscow, to which
may be added Peterburgh. The coining of each of
these cities is let out to farm, and makes part of the
royal revenue.

Spanifh Coinage is esteemed one of the loft perfecf
in Europe. It is fettled at Seville and Segovia, the only
cities where gold and silver are struck.

COIATION. See Generation.

COIX, or Job’s tears, in botany, a genus of the
monoeica triandria class. The calix of the male is a
double-flowered glume, without any awn; the corolla
is like a glume without an awn: the calix of the
female is an open, oval, one-flowered glume; the sty-
lus is bifid; and the seed is cartilaginous. There is
but one species, viz. the latifolia, a native of Ja-
"mica.

COLCHICUM, or Meadow Saffron, in botany, a

| Vol. II. No. 39. | 3 K |
COLD, in general, denotes the privation or absence of heat; and, consequentely, those who suppose heat to consist in a brisk agitation of the component particles of the hot body, define cold to be such a faint motion of these parts, as is either altogether or nearly imperceptible to our organs of feeling: in which sense, cold is a mere term of relation between the cold body and the organs of sensation; and, in fact, the same body will be felt either hot or cold, according as the sensible organ is colder or hotter than it.

Cold, in medicine, is found to be productive of inflammatory disorders, as coughs, pleurisy, pneu monies, rheumatic pains, consumption, &c. See Medicine.

COLDENIA, in botany, a genus of the tetradaea trigyna class. The calyx has four leaves; the corolla is tulip-shaped; the fruit consists of four seeds. There is but one species, a native of India.

COLD-FINCH. See Motacilla.

COLE-IRON. See Mazarilla.

COLESHIRE-IRON, that which is brittle when cold.

COLEOPTERA, the name of Linnaeus's first order of insects. See Parus.

COLE-FISH. See Gaster.

COLE-SEED, the food of the napus fastuus, or long-rooted, narrow-leaved rape, called, in English, navew, and comprehended by Linneus among the brassicas, or cabbage-kind. See Brassica.

COLE-WORT. See Brassica.

This plant is cultivated to great advantage in many parts of England, on account of the rape-oil expressed from its seeds. It requires a rich and strong soil, especially in March or fenny lands, those newly recovered from the sea, or indeed any other land that is rank and fat, whether arable or pasture. The best feeds are brought from Holland, and should be sown about Midsummer, the very day that the land is plowed: a gallon will serve an acre.

Besides the oil already mentioned, it is likewise cultivated for winter-food to cattle, and is a very good preparative of land for barley or wheat.

COLISEUM, in ancient architecture, an oval amphitheatre at Rome, built by Vespasian, wherein were statues set up, representing all the provinces of the empire: in the middle whereof stood that of Rome, holding a golden apple in her hand.

This structure was so large, that it would hold near 100,000 spectators.

COLLAR, in Roman antiquity, a sort of chain put on the necks of slaves that had run away, after they were taken, with an inscription round it, intimating their being deferters, and requiring their being restored to their proper owners, &c.

COLLAR, in a more modern sense, an ornament consisting of a chain of gold, enamelled, frequently set with cyphers or other devices, with the badge of the order hanging at the bottom, wore by the knights of several military orders over their shoulders, on the mantle, and its figure drawn round their armories.

Thus, the collar of the order of the garter consists of S S, with roses enamelled red, within a garter enamelled blue, and the George at the bottom.

Lord Mayor's Collar is more usually called chain.

Knights of the Collar, a military order in the republic of Venice, called also the order of St Mark, or the medal.

It is the doge and the senate that confer this order; the knights bear no particular habit, only the collar, which the doge puts around their neck, with a medal, wherein is represented the winged lion of the republic.

Collar of a draught horse, a part of harness made of leather and canvas, and stuffed with straw or wool, to be put about the horse's neck.

Collarage, a tax or fine laid for the collars of wine-drawing horses.

COLLATERAL, any thing, place, country, &c. situated by the side of another.

Collateral, in genealogy, those relations which proceed from the same stock, but not in the same line of ascendants or descendants, but being, as it were, aside of each other.

Thus, uncles, aunts, nephews, nieces and cousins, are collaterals, or in the same collateral line: those in a higher degree, and nearer the common root, represent a kind of paternity with regard to those more remote.

Collateral succession, in Scots law: When a deceased, for want of heirs descended of himself, is succeeded in his estate by a brother or sister, or their descendants, the estate is said to have gone to collateral heirs. See Scots Law, title, Succession in bicollateral rights.

Collation, in the canon law, the giving or bequeathing of a benefice on a clergyman by a bishop, who has in his own gift or patronage.

Collation, in common law, the comparison or presentation of a copy to its original, to see whether or not it be conformable; or the report or act of the officer.
College of cities, is, in like manner, the body of deputys which the imperial cities send to the diet.

College of princes, the body of princes, or their deputies, assembled in the COLLEGATORY, in the civil law, a person who has hereafter and congregation.

Collector, in matters of civil polity, is a person appointed to collect the revenues of the state. See Adjunct.

Collectors, in an ecclesiastical sense, the short prayers appointed by the bishop alone, after the joint prayers of the deacons and congregation.

Collective, among grammarians, a term applied to a noun expressing a multitude, though itself be only singular; as an army, company, troop, &c. called collective nouns.

Collector, in general, denotes a person who gets together things formerly dispersed and separated. Hence, Collector, in matters of civil polity, is a person appointed by the commissioners of any duty, the inhabitants of a parish, &c. to raise or gather any kind of tax.

Collectors, among botanists, one who gets together as many plants as he can, without studying botany in a scientific manner.

COLLEGATORY, in the civil law, a person who has a legacy left him in common with one or more other persons. COLLEGE. An assemblage of several bodies or societies, or of several persons into one society.

College, among the Romans, served indifferently for the offices of religion, of government, the liberal, and even mechanical arts and trades; so that, with them, the word signified what we call a corporation or company.

Each of these colleges had distinct meeting-places or halls; and likewise, in imitation of the state, a treasury and common chief, a register, and one to represent them upon public occasions, and acts of government. These colleges had the privilege of manumitting slaves, of being legates, and making by-laws for their own body, provided they did not clash with those of the government.

There are various colleges on foot among the moderns, founded on the model of those of the ancients. Such are the three colleges of the empire, viz.,

College of electors, or their deputies, assembled in the diet of Ratisbon.

College of princes, the body of princes, or their deputies, at the diet of Ratisbon.

College of cities, is, in like manner, the body of deputys which the imperial cities send to the diet.

College of cardinals, or the SACRED COLLEGE, a body composed of the three orders of cardinals. See Cardinals.

College is also used for a public place endowed with certain revenues, where the several parts of learning are taught.

An assembly of several of these colleges constitute a university. The creation of colleges is part of the royal prerogative, and not to be done without the king's license. See University.

College of civilians, commonly called Doctors-commons, founded by Dr. Harvey, dean of the arches, for the professors of the civil law residing in the city of London. The judges of the arches, admiralty, and prerogative court, with several other eminent civilians, commonly reside here.

To this college belong thirty-four professors, who make themselves parties for their clients, manage their causes, give licences for marriages, &c.

In the common hall of Doctors-commons are held several courts, under the jurisdiction of the civil law, particularly the high court of admiralty, the court of delegates, the arches court of Canterbury, and the prerogative court of Canterbury, whose terms for sitting are much like those at Westminster, every one of them holding several court-days; most of them fixed and known by preceding holidays, and the rest appointed at the judge's pleasure.

College of physicians, a corporation of physicians in London, whole number, by charter, is not to exceed eighty. The chief of them are called fellows, and the next candidates, who fill up the places of fellows as they become vacant by death, or otherwise. Next to these are the honorary fellows; and lastly, the licentiates, that is, such as being found capable, upon examination, are allowed to practice physic.

This college has several great privileges granted by charter and acts of parliament. No man can practice physic in, or within seven miles of London, without license of the college, under the penalty of 5l. Also, persons practicing physic in other parts of England are to have letters testimonial from the president and three elects, unless they be graduate physicians of Oxford or Cambridge. Every member of the college is authorized to practice surgery in London or elsewhere; and that they may be able at all times to attend their patients, they are freed from all parish-offices.

The college is governed by a president, four censors, and twelve electors. The censors have, by charter, power to survey, govern, and arrest all physicians, or others, practicing physic in, or within seven miles of London; to fine, amerce, and imprison them at discretion; to search apothecaries shops, &c. in and about London; to see if their drugs, &c. be wholesome, and the compositions according to the form prescribed by the college in their dispensatories; and to burn, or otherwise destroy, those that are defective or decayed, and not fit for use.

In 1696, forty-two members of the college made a subscription, to set on foot a dispensary for the relief of the sick poor, who are advised gratis every day but Sunday,
Sunday, and medicines sold at the intrinsic value: since this they have erected two other dispensatories.

**College of justice**, in Scots law, the supreme civil court of Scotland; otherwise called Court of Session, or, of council and session. See Scots Law, title, Supreme judges and courts of Scotland.

**Sion College**, or the college of the London clergy, was formerly a religious house, next to a spital or hospital; and now it is a composition of both, viz. a college for the clergy of London, who were incorporated in 1631, at the request of Dr White, under the name of the president and fellows of Sion-college; and an hospital of ten poor men, the first within the gates of the house, and the latter without.

This college consists of a president, two deans, and four assistants, who are annually chosen from among the rectors and vicars in London, subject to the vibration of the bishop. They have one of the finest libraries in England, built and stocked by Mr Simpson, chiefly for the clergy of the city, without excluding other students or certain terms; they have also a hall with chambers for the students, generally filled with the ministers of the neighbouring parishes.

Gresham-College, or College of philosophy, a college founded by Sir Thomas Gresham, who built the Royal exchange; a moiety of the revenue whereof he gave in trust to the mayor and commonalty of London, and their successors for ever, and the other moiety to the company of mercers; the first to find four able men to read in the college divinity, astronomy, music, and geometry; and the last, three or more able men to read rhetoric, civil law, and physic; a lecture upon each subject is to be read in term-time, every day, except Sundays, in Latin, in the forenoon, and the same in English in the afternoon; only the music-lecture is to be read alone in English. The lecturers have each 50 l. per annum, and a lodging in the college.

In this college formerly met the royal society, that noble academy, celebrated throughout the world for their improvements in natural knowledge. See Society.

**College of heralds**, commonly called the heralds office, a corporation founded by charter of King Richard III. who granted them several privileges, as to be free from subsidies, tolls, offices, &c. They had a second charter from King Henry VI.; and a house built near Doctors commons, by the earl of Derby, in the reign of King Henry VII. was given them by the duke of Norfolk, in the reign of queen Mary, which house is now rebuilt.

This college is subordinate to the earl-marshals of England. They are assistants to him in his court of chivalry, usually held in the common hall of the college, where they fit in their rich coats of his majesty’s arms. See Herald.

**Collegiate churches**, those which though no bishop’s fee, yet have the retinue of the bishop, the canons and prebends. Such are, among us, Westminster, Windsor, Ripon, Wolverhampton, Southwell, Manchester, &c. governed by deans and chapters.

**Collet**, among jewelers, denotes the horizontal face or plane at the bottom of brilliants. See Brilliant.

**Collet**, in glaas-making, is that part of glaas vessels which sticks to the iron instrument wherewith the metal was taken out of the melting pot: these are afterwards used for making green glass.

**Colletics**, in pharmacy, denote much the same with agglutinants or vulneraries. See Vulnerary.

**Collinsonia**, in botany, a genus of the decandria monogynia class. The corolla is unequal, the inferior lip being multipartite and capillary. It has but one seed. There is only one species, a native of Canada.

**Collaquamentum**, in natural history, an extreme transparent fluid in an egg, observable after two or three days incubation, containing the first rudiments of the chick. It is included in one of its own proper membranes, distinct from the albumen. Harvey calls it the oculus.

**Colligation**, in chemistry, is applied to animal, vegetable, and mineral substances, tending towards fusion. See Fusion.

**Colligation**, in physic, a term applied to the blood, when it loses its crafts or balsamic texture; and to the solid parts, when they waste away, by means of the animal fluids flowing off through the several glands, and particularly those of the skin, fatter than they ought: which occasions fluxes of many kinds, but mostly profuse, greasy, and clammy sweats.

**Colliquative fever**, in physic, a fever attended with a diarrhoea, or profuse sweats.

**Collision**, the striking of one hard body against another; or the friction or percussion of bodies moving violently with different directions, and dashing against each other. See Mechanics.

**Collurio**, in ornithology. See Lanius.

**Collusion**, in law, a secret understanding between two parties, who plead or proceed fraudulently against each, to the prejudice of a third person. See Mechanics.

**Colum**, the same with neck. See Neck, and Cervix.

**Collyrium**, in pharmacy, a topical remedy for a disorder of the eyes; designed to cool and repel hot, sharp humours.

They are generally of two kinds, the one liquid, and the other dry: liquid collyrias are composed of ophthalmic powders in waters, as rofe-water, plantain-water, or that of fennel, eye-bright, &c. where-in titty, white vitriol, or some other proper powder, is dissolved.

The dry collyrium is troches of chafe, fugar-candy, ttytty prepared, &c. blown into the eye.

**Cocolasia**, in botany. See Arum.

**Cocolythis**, in botany. See Cucumis.

**Cologne**, the capital of the circle of the Lower Rhine, in Germany, situated on the Rhine, about forty-five miles east of Maystreich; E. long. 6° 40', N. lat. 50° 50'. It is one of the largest and most elegant cities of Germany, being the see of an archbishop, who is one of the electors of the empire, and has a yearly revenue of 130,000 l.
COLONNADE, in architecture, a peristyle of a circular figure; or a series of columns disposed in a circle, and insulated within side.

Colonel, in military matters, the commander in chief of a regiment, whether horse, foot, or dragoons. A colonel may lay any officer of his regiment in arrest, but must acquaint the general with it; he is not allowed a guard, only a centry from the quarter-guard.

Colonel-lieutenant, he who commands a regiment of guards, whereof the king, prince, or other person of the first eminence, is colonel. These colonel-lieutenants have always a colonel's commissiorn, and are usually general officers.

Lieutenant-colonel, the second officer in a regiment, who is at the head of the captains, and commands in the absence of the colonel.

COLONNA, a town of Italy, in the Campagna of Rome, eighteen miles eastward of that city: E. long. 13° 15', N. lat. 42°.

COLONNADE, in architecture, a peristyle of a circular figure; or a series of columns disposed in a circle, and insulated within side.

A polysyle colonnaide, is that whose number of columns is too great to be taken in by the eye at a single view. Such is the colonnaide of the palace of St Peter's at Rome, consisting of 284 columns of the Doric order, each above four foot and an half diameter, all in Tiburtine marble.

COLONY, a company of people transplanted into a remote province, in order to cultivate and inhabit it. Colonies are of three sorts: the first are those that serve to ease and discharge the inhabitants of a country, where the people are become too numerous; the second are those established by victorious princes in the middle of vanquished nations, to keep them in awe and obedience; and the third are those established for the promotion of trade, called colonies of commerce; such are those established by European nations in several parts of Asia, Africa, and America.

COLOPHONY, in pharmacy, black resin, or turpentine, boiled in water, and afterwards dried; or, which is still better, the caput mortuum remaining after the distillation of the etherial oil, being further urged by a more intense and long continued fire.

COLOQUINTIDA, in botany. See Cucumis.

COLORATURA, in music, denotes all manner of variations, trilios, diminutions, &c. serving to make a song agreeable.

COLORATURA, in music, denotes all manner of variations, trilios, diminutions, &c. serving to make a song agreeable.

COLORATURA, in music, denotes all manner of variations, trilios, diminutions, &c. serving to make a song agreeable.

COLOUR, in painting, is applied both to the drugs, and to the tints produced by those drugs variously mixed and applied.

The principal colours used by painters are red and white lead, or cerufs; yellow and red ochres; several kinds of earth, umbre, orpiment, lamp-black, burnt ivory, black lead, cinnabar or vermilion, gumboige, laccis, blue and green ives, verdigris, bistre, bice, saint, carmine, ultra marine: each of which, with their uses, &c, are to be found under their proper articles.

Of these colours some are used tempered with gum-water, some ground with oil, others only in fresco, and others for miniature.

Painters also distinguish colours into simple and mineral.

Under simple colours they rank all those which are extracted from vegetables, and which will not bear the fire; as the yellow, made of saffron, French berries, laccis, and other tinctures extracted from flowers, used by limners, illuminers, &c.

Under light colours are comprehended white, and all that approach nearest to it.

Painters also distinguish colours into simple and mineral.

The mineral colours are those which being drawn from metals, &c. are able to bear the fire, and therefore used by enamellers. Changeable and permanent colours is another division, which, by some, is made of colours.

Changeable colours are such as depend on the situation of the objects with respect to the eye, as that of a pigeon's neck, taffeties, &c. the first however being attentively viewed by the microscope, each fibre of the feathers appears composéd of several little squares, alternately red and green, so that they are fixed colours.

Local Colours. See Local.

Water Colours. See Water.

Water Colours. See Water.
Here it is to be observed, that they give the name crimson to all colours made with cochineal.

Colours, in heraldry. The colours generally used in heraldry are red, blue, black, green, and purple, which the heralds call gules, azure, fable, vert or sable, and purpure; tenne or tawny, and fanguine, are not fo common: as to yellow and white, called or and argent, they are metals, not colours.

The metals and colours are sometimes expressed in blazon by the names of precious stones, and sometimes by those of planets or stars. See Blazoning.

Oenomaus is said to have first invented the distinction of colours, to distinguish the gundilas of combattants of the Circenian games; the green for those who represented the earth, and blue for those who represented the sea.

Colours, in the military art, include the banners, flags, ensigns, &c. of all kinds, borne in the army or fleet. See Flag, and Standard.

Field-Colour. See Field.

Colours, in the Latin and Greek churches, are used to distinguish several mysteries and fealties, celebrated therein.

Five colours only are regularly admitted into the Latin church; these are white, green, red, violet, and black: the white is for the mysteries of our Saviour, the feallets of the virgin, those of the angels, saints, and confessors; the red is for the mysteries and solemnities of the holy sacrament, the feallets of the apostles and martyrs; the green for the time between pentecost and advent, and from epiphany to septuagesima; the violet in advent and Christmas, in vigils, rogations, &c. and in votive masses in time of war; lastly, the black is for the dead, and the ceremonies thereto belonging.

In the Greek church, the use of colours is almost abolished, as well as among us; red was, in the Greek church, the colour for Christmas, and the dead, as black among us.

To Colour strangers goods, is when a freeman allows a foreigner to enter goods at the custom-house in his name.

COLOURING, among painters, the manner of applying and conducting the colours of a picture; or the mixtures of light and shades, formed by the various colours employed in painting. See Painting.

COLOURING of glafs. See Glass.

COLOURING of porcelain. See Porcelain.

COLT, in zoology. See Equus.

COLT-EVIL, among farriers, a swelling of the yard and scrotum, incident both to stock bred horses and geldings; for which, after washing the part with lukewarm vinegar, it is usual to anoint them with juice of rue, mixed with honey, and boiled in hog's grease, adding bay-leaves and the powder of fenugreek.

COLT'S FOOT, in botany. See Tussilago.

COLTIE, a term used by timber-merchants for a defect, or blemish, in some of the annular circles of a tree, whereby its value is much diminished.

COLUMBER, in zoology, a genus of serpents belonging to the class of amphibia. The characters are these:

They have a number of scuta, or hard crofts, on the belly; and scutelle, or scales, on the tail. Linnaeus enumerates no less than 97 species under this genus, distinguished solely by the number of scuta and scutelle. For the sake of brevity, we shall give the numbers in figures, the first denoting the number of scuta, and the second the number of scutelle, thus, 140-22.

The first species is the vipera, 118-22. This is the viper of the shops, the flesh of which has been much recommended in scrophulous, leprous, and other oblitinate chronic disorders: but its virtues in these states have been too much exaggerated: the flesh of the viper is however highly nutritious, and is therefore properly esteemed to be a good restorative: but, to answer any good purpose, even when given with this intention, it ought to be used liberally, and for a considerable time, as food. This animal is a native of Egypt. The body is very short, and of a pale colour, with brownish spots; and the head is gibbous, and covered with small scales. 2. The atrobas, 131-22, is a native of America; the body is white, and the eyes are brown, with a white iris. 3. The berus, 110-50, is a native of Canada, and has many linear black rings. 4. The ammodites, 142-32, is about six inches long, and has an erect fleasy protuberance on its nose. It is a native of the East. 5. The berus, 146-39, or common British viper, is a native of Sweden, and rather less than the alp. 7. The prester, 152-32, is found in the northern parts of Europe, and the whole body is black. 8. The alpis, 140-46, is a native of France, and is of a reddish colour, with dusky spots on the back. 9. Lebetinus, 155-46, is a native of Asia, and is of a cloudy colour, with red spots on the belly. 10. The feverus, 170-42, is likewise a native of Asia, and is ash-coloured, with white belts. 11. The flolatus, 143-76, is a native of Asia, and is of a greyish colour, with two white fillets. 12. The lacetus, 203-32, is a native of the Indies; the colour is white, with black spots. 13. The naja, 193-60, is a native of the East Indies; and is the most poisonous of all serpents; they are eat by the ichneumon. 14. The atrobas, 196-69, is a native of Asia; it is of a hoary colour; and the head is compressed and covered with small scales. 15. The nivus, 209-62, is white, without any spots. It is a native of Africa. 16. The corallinus, 193-82, is a native of Asia: it is greyish, with three brown fillets. 17. The dipfas, 152-135, is a native of America: it is of a blueish colour, with the margins of the scales white. 18. The myzerizans, 192-167, is a native of America; the flout is stretched out, and triangular. Although this genus comprehends 97 species, the above 18 are all whose bite is supposed to be poisonous. The poison is contained in a little bag at the base of their long fangs. See Natural History.

The 19th species is the latius, 134-27; the back and belly are yellow: and the fides are blueish. It is a native of the Indies. 20. The calamarius, 140-22, is of a livid colour interperpered with dusky spots and
and lines, and is found in America. 21. The finus, 124-46, is a native of Carolina; the head is roundish, flat, and gibbous; the body is interperfed above with black and white; and the belly is black. 22. The striatus, 126-45, is likewise a native of Carolina; the back is dusky and striated; and the belly is pale. 23. The ceratites, 150-25, is a native of Asia; the scales of the head are round and small: this is the horned viper of Haf
felquitt; but the horns are a mere imposition; the Arabs fix the spurs of a cock or other bird upon the head of the viper, in order to raise the admiration of travellers. 24. The plicatilis, 131-46, is of a li-vid colour, with dusky fides. 25. The domicella, 118-60, is a native of Asia; it is white, with black belts. 26. The aldras, 121-58, is a native of India, and is all white. 27. The punctatus, 136-43, is a native Carolina: it is ash-coloured, variegated with yellow spots. 28. The bucc tus, 107-72, is dusky-coloured, with white belts, and is a native of Asia. 29. The angulosus, 117-70, is a native of Asia; of a greyish colour, with black fillets. 30. The ceratites, 165-24, is bluish, with white scales on one side: it is a native of America. 31. The albus, 170-20, is entirely white, and is a native of Asia. 32. The typhlus, 140-53, is a native of the Indies, and of a blueish colour. 33. The faclatius, 128-67, is a native of Carolina: the scales are carinated, and the colour is blackish. 34. The melanoccephalus, 140-62, is a native of America; the body is very smooth; the colour is dusky, and the head is black. 35. The colba, 150-54, is very frequent in America: it is ash-coloured, interperfed with white lines. 36. The region, 137-70, is a native of the Indies; the body is dusky, and the belly is black and white. 37. The dohatus, 164-43, is a native of Carolina; this is a small serpent, of a whiteh colour, with black rings. 38. The ordinatus, 138-72, is likehwise found in Carolina: it is blueh, and clouded with black spots. 39. The Mexicanus, 134-77, is a native of America. 40. The aurora, 179-37, is a native of America: it is ash-coloured, variegated with yellow and white. 41. The ordinatus, 138-72, is likewise found in Carolina: it is ash-coloured, variegated with yellow and black. 42. The laticaudatus, 220-42, is a native of the Indies; and is blueh, with yellow spots. 43. The vitellus, 187-103, is a native of the Indies: it is yellow behind, and variegated with yellow and white. 44. The virgularis, 190-96, is a native of America: it is clouded with yellow and an ash colour, and the scales are the same colour. 45. The candidus, 220-50, is a native of the Indies: it is white, with yellow belts. 46. The scaber, 228-44, is a native of the Indies: it is clouded with black and yellow, and the scales are carinated. 47. The laticaudatus, 164-82, is a native of America; and the scales are yellowish iron-colour, variegated with white; and the belly is white, with yellow spots. 48. The nebulatus, 185-81, is a native of America: it is clouded with yellow and an ash colour, and the belly is variegated with yellow and white. 49. The fuscus, 149-117, is a native of America: it is of a greenish colour. 50. The laticaudatus, 164-82, is a native of America; the body is annulated, with three white spots on the collar. 51. The fulvius, 218-31, is a native of Carolina: it has 22 black rings, and as many yellow, placed alternately. 52. The pallidus, 156-96, is a native of the Indies, and is of a pale colour, with grey and yellow spots. 53. The lineata, 169-84, is a native of Asia: it is blueh, with four linear fillets. 54. The padera, 198-56, is a native of the Indies: it is white, with yellowh spots. 55. The canus, 188-70, is a native of the Indies: it is of a hoary colour, with yellowh bellels. 56. The geatus, 215-44, is a native of Carolina: it is of a blackish blue colour, with yellowh linear bellels. 57. The laticaudatus, 220-42, is a native of the Indies: it is ash-coloured, with yellowh bells; and the tail is obtuse and compressed. 58. The laticaudatus, 150-114, is a native of Canada: the body is of a dirty yellow colour, with three blueh green fillets. 59. The fuscus, 180-85, is a native of Africa: it is of a yellowh iron-colour, interperfed with white; and the belly is white, with yellow spots. 60. The laticaudatus, 220-42, is a native of the Indies: it is clouded with yellow and an ash colour, and the belly is variegated with yellow and white. 61. The fuscus, 149-117, is a native of Asia; it is yellow and ash-coloured, and there are yellow spots behind the eyes. 62. The candidus, 220-50, is a native of the Indies: it is white, with yellow belts. 63. The candidus, 157-115, is a native of the Indies: it is of a lead colour, and the edges of the scales are tipped with white; the belly is white, and the back is carinated. 64. The ovivorus, 218-31, is a native of Carolina: it has 22 black rings, and as many yellow, placed alternately. 65. The lemnifcatus, 236-90, is a native of Canada: it is of a paleh colour, with round yellow spots. 66. The candidus, 220-50, is a native of the Indies: it is white, with yellow belts. 67. The candidus, 157-115, is a native of the Indies: it is of a lead colour, and the edges of the scales are tipped with white; the belly is white, and the back is carinated. 68. The candidus, 138-72, is a native of America: it is of a greenish colour. 69. The constrictor, 186-92, is a native of America: it is white, with round yellow spots. 70. The candidus, 157-115, is a native of the Indies: it is of a lead colour, and the edges of the scales are tipped with white; the belly is white, and the back is carinated. 70. The candidus, 157-115, is a native of America: it is of a greenish colour. 71. The constrictor, 186-92, is a native of America: it is black and smooth; the belly is of a palfish green, and the nape of the neck is white. This species is so bold, that it even attacks men, twisting about their legs, and breaking their bones: it runs very quickly; but its bite is not poisonous. 72. The exoletus, 147-120, is a native of the Indies: it is blueh and ash-coloured. 73. The fiatus, 236-90, is a native of Egypt: It is greyh. 74. The tricalis, 145-86, is a native of the Indies: It is of an azure colour. 75. The guttatus, 227-60, is a native of Carolina: It is of a livid colour, with red and black spots on the back. 76. The lemnifcatus, 236-90, is a native of Carolina: It is of a paleh colour, with round yellow spots. 78. The pelias, 187-103, is a native of the Indies: It is yellow behind the eyes, and the rest is blackish. 79. The typhlus, 210-83, is a native of Egypt: It is white, with yellow spots. 80. The fulvius, 195-102, is a native
COLUBRINUM lignum, or Snake-wood. See COLUMBIA, pigeon, in ornithology, a genus belonging to the order of pæfræs. The characters of this genus are these: The bill is straight, and descends towards the point; the cultrils are oblong, and half covered with a soft, thin membraneous covering; and the tongue is entire, i.e., not cloven. There are 40 species, viz.: 1. The cenæ, or domestic pigeon, is blue, with a greenish shining neck; on the back, towards the tail, it is white, with a blackish streak on the point of the wings and tail. It is the flock-dove or wood-pigeon of Ray, and is a bird of Europe. The pigeon lays two eggs, and hatches them every month, for eight or nine months in the year, which, in the space of four years, amounts to about 18,000 descendants. They always bill before copulation: Their method of feeding their young is curious: they first macerate the leaves or other food, and then vomit it up into the mouths of the young ones. The male and female sit upon their eggs by turns. 2. The hispanica, with white, mealy wax on the bill. It is a small double the size of the common pigeon. 3. The dufpus, with rough feathered legs. 4. The gutturosa, or cropper, has a power of inflating its crop till it be as large as the animal's body. It is a native of Arabia Felix. 5. The cucullata has the feathers on the back part of the head erect and reflected; and the bill is short. 6. The hifpida, or rough pigeon, with the small feathers of the back and wings erect. It is a native of the East Indies. 7. The turbita, with the feathers on the breast bent backward, a short bill, and a plain vertex. 8. The laticauda, or broad-tailed pigeon, has an erect open tail consisting of many feathers. 9. The gyraæus turns itself round when flying: it is a little less than the common pigeon. 10. The lateæus, with the head and prime feathers of the wings and tail of the same colour, and always different from the rest of the body. 11. The turcica, with red papillous wax. It is a bird of Arabia. 12. The tabellaria has naked eye brows, and broad, white, fleshy wax on the bill. Although this bird be carried to a very great distance from home, it returns with vall specked; and hence the ancients employed it for the purpose of conveying back letters. 13. The montana has naked red orbits, a reddish body, and a yellow belly; the bill and feet are red. It is the mountain-partridge of Ray, and is a native of Jamaica. 14. The leucocephala, with the top of the head and the orbits red, and a blueish body. It is a native of North America. 15. The leucoptera, with naked blue orbits, and the prime wing-feathers white at the points, and the intermediate ones yellowish. It is the Indian turtle of Edwards, and is a native of Asia. 16. The guinea, with naked red orbits, a yellowish bill, triangular white spots on the wings, and the prime wing-feathers black at the points. It is a native of Africa. 17. The coronata has black orbits, a large crested crest on the head, and a blueish body. It is almost as large as a peacock, and is a native of Ban- da. 18. The striata, with hoary orbits, and the body variegated with black and ash-coloured belts. It is a native of the East Indies. 19. The palumbus, with the prime tail-feathers red behind, the prime wing-feathers edged with white, a white neck, and feathered legs. It is a native of Europe and Asia. 20. The cyanoccephala, with a blue head, and a white bill below the eye. It is a native of America. 21. The madagascarenis, with feathered legs, a violet tail, a greenish blue body, and the head and feet red. It is found in Madagascar. 22. The zenea, with feathered legs, greenish legs and bill, and a brassy-coloured body. It is a native of the Molucca Isles. 23. The viridis, with a brassy-coloured body, a violet belly, and red legs half covered with feathers. It is found at Ambon. 24. The martina, with a violet body, a yellowish belly, and the prime wing-feathers red on the inside. It is found in Martinico. 25. The ja- maicensis, with blueish tail-feathers terminated by a white line. It is found in Jamaica. 26. The Senegal, with the three outmost prime tail-feathers white, and the neck spotted with black. It is found in Senegal. 27. The nicobarica has a white tail, a black body, blue prime wing-feathers, a green-
in shining back, and long feathers on the neck. It is found in the island of Nicobar near Pegu. 28. The finica is yellowish, and banded with black; the belly is reddish, the wings yellow, the prime wing-feathers black, and a black bill. It is a native of China. 29. The indica, with a purple body, green shoulders, and the top of the head bluish. It is a native of the East Indies. 30. The canadenensis, with the prime wing-feathers yellow at the points, and the prime tail-feathers ash-coloured. It is a native of Canada. 31. The afra, with the exterior prime tail-feathers white at the points, and violet spots on the wing-feathers. It is a native of Senegal. 32. The turtur, with the prime tail-feathers white, a greyish back, and a flesh-coloured breast. It is a native of India. 33. The riorfia is clay-coloured above, and has a black crest on the neck. It is a native of India. 34. The poiffyrina, with a purple body, and a yellow bill and legs. It inhabits America within the tropics. 35. The minuta is the smallest of all pigeons, is of a dullish colour, with five flesh-coloured spots on the wings, and the outmost prime tail-feathers white. It is a native of America. 36. The migratoria has a wedge-shaped tail, red naked orbits, and a reddish breast. This species is very frequent in North America: They live upon the seeds of the elm, oak, wheat, &c. and they winter in Carolina. 37. The carolinensis has a wedge-shaped tail, blue orbits, and a red-bill. This species is very frequent in North America. 38. The migratoria has a wedge-shaped tail, a reddish body, and a white belly. It is a native of North America. 39. The capenensis has a wedge-shaped tail, blue orbits, and a reddish belly. It is a native of America. 40. The dominicus, with lobated feet, a smooth head, and the belly very much spotted. It is a native of Europe. 41. The auritus, with lobated feet, a black head, and the ears are crested and of an iron colour. It frequents the lakes of Europe and America. 42. The ardicus, with a miferable tone of voice. 4. The ardicus, with palmated three-toed feet, a hoary head, and a violet neck. It frequents the northern seas and lakes. 5. The glacialis, with palmated four-toed feet, and a violet head and neck. It inhabits the northern seas. 6. The immer, with palmated four-toed feet, the upper part of the body black and undulated with white, and a white belly. It inhabits the frozen seas. 7. The crysaleusus, with lobated feet, a red head, a black collar, and white secondary prime wing-feathers. It is a native of Europe. 8. The auritus, with lobated feet, a black head, and the ears are crested and of an iron colour. It frequents the lakes of Europe and America. 9. The urinator, with lobated feet, a smooth head, and white spots on the wings. It is a native of the southern parts of Europe. 10. The dominicus, with lobated feet, a smooth head, and the belly very much spotted. 11. The padiceps, with lobated feet and a yellowish body. It is a native of North America.
and the seeds are ovated, spongy, and persistent. There is but one species, viz. the palustris, a native of Europe.

COMB, an instrument to clean, untangle, and dress flax, wool, hair, &c.

Combs for wool are prohibited to be imported into Britain.

COM is also the crest or red feathery tuft growing upon a cock's head.

Lady's Comb, in botany. See Scandix.

Combs, in the history of shell-fish. See Ostrea.

COMBAT, in a general sense, denotes an engagement, or a difference decided by arms. See Battle.

Combats, in our ancient law, was a formal trial of some doubtful cause or quarrel by the swords or batons of two champions. This form of proceeding was very frequent not only in criminal but in civil causes; being built on a presumption, that God would never grant the victory but to him who had the best right.

The last trial of this kind in England, was between Donald lord Ray, appellant, and David Ramfay, esq; defendant; when, after many formalities, the matter was referred to the king’s pleasure.

Combant, in heraldry, a term for two beasts, as lions, &c. borne in a coat of arms in a fighting posture, with their faces to each other.

Combination, properly denotes an assemblage of several things two by two.

Combination, in mathematics, is the variation or alteration of any number of quantities, letters, or the like, in all the different manners possible.

COMEDY. See Epic and Dramatic Compositions.

COMET, an opake, spherical, and solid body like a planet, performing revolutions about the sun in elliptical orbits, which have the fun in one of the foci. See Astronomy, p. 444.

COMETARIUM, a curious machine exhibiting an idea of the revolution of a comet about the sun. See Plate XLVIII. fig. 2.

COMFREY, in botany. See Symphytum.

COMITIA, in Roman antiquity, an assembly of the people, either in the comitia or campus martius, for the election of magistrates, or consulting on the important affairs of the republic.

There were certain days fixed for these assemblies, called dies comitiales, marked with a C in Julius Caesar’s calendar.

There were three kinds of comitia, viz. curiata, centuriata, and tributa, so distinguished from the manner wherein the people voted, and gave their suffrages, viz. by curia, or parishes, tribes, or centuries. The comitia curiata, owe their original to the division which Romulus made of the people into thirty curiae, which answer in most respects to our parishes. The comitia centuriata were instituted by Servius Tullius. Comitatial assemblies held for the election of consuls, were called consular comitia. In like manner the other comitia were named from the officer to be created, whether a tribune, pontif, &c.

The power of calling these assemblies, belonged at first only to the kings; but on the establishment of the democracy, the same privilege was allowed to most of the chief magistrates, and sometimes to the pontif.

COMMITALIS MORBUS, an appellation given to the epilepsy, by reason the comitia of ancient Rome were dissolved, if any person in the assembly happened to be taken with this distemper.

COMITIUM, in Roman antiquity, a large hall in the forum, where the comitia were ordinarily held.

COMMA, among grammarians, a point or character marked thus (,) serving to denote a short stop, and to divide the members of a period.

Comma, in music, an interval equal to the difference of the tone major or minor, and expressed by the ratio 81:80.

COMMELINA, in botany, a genus of the triandria monogynia class. The corolla is divided into fix segments; it has three cross-like nectaria inferred by their proper filaments. The species are ten, none of them natives of Britain.

COMMEMORATION, in a general sense, the remembrance of any person or thing; or the doing any thing in honour of a person’s memory, or in remembrance of any past event. Thus the eucharist is a commemoration of the sufferings of Jesus Christ.

COMMENDAM, in the ecclesiastical law, the trust or administration of the revenues of a benefice, given either to a layman, to hold, by way of dispositum, for fix months, in order to repairs, &c. or to an ecclesiastic, or beneficed person, to perform the pastoral duties thereof, till once the benefice is provided with a regular incumbent.

COMMENSURABLE, among geometricians, an appellation given to such quantities as are measured by one and the same common measure.

COMMENSURABLE NUMBERS, whether integers or fractions, are such as can be measured or divided by some other number, without any remainder: such are 12 and 18, as being measured by 6 or 3.

COMMENSURABLE IN POWER, is said of right lines, when their squares are measured by one and the same space or superficies.

COMMENSURABLE SURDS, those that being reduced to their leaf terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational one.

COMMENTARY, or Comment, in matters of literature, an illustration of the difficult or obscure passages of an author.

COMMENTARY, or Commentaries, likewise denotes a kind of history, or memoirs of certain transactions, wherein the author had a considerable hand: such are the commentaries of Cæsar.
COMMERCIAL

Commerce is an operation, by which the wealth, or work, either of individuals, or of societies, may be exchanged, by a set of men called merchants, for an equivalent, proper for supplying every want, without any interruption to industry, or any check upon consumption.

We shall begin by tracing commerce to its source, in order to reduce it to its first principles.

The most simple of all trade, is that which is carried on by bartering the necessary articles of subsistence. If we suppose the earth free to the first possessor, this person who cultivates it will first draw from it his food, and the surplus will be the object of barter: he will give this in exchange to any one who will supply his other wants. This naturally supposes both a surplus quantity of food produced by labour, and also free hands; for he who makes a trade of agriculture cannot supply himself with all other necessaries, as well as food; and he who makes a trade of supplying the farmers with such necessaries, in exchange for his surplus of food, cannot be employed in producing that food. The more the necessities of man increase, the more free hands are required to supply them; and the more free hands are required, the more surplus food must be produced by additional labour, to supply their demand.

This is the least complex kind of trade, and may be carried on to a greater or less extent, in different countries, according to the different degrees of the wants to be supplied. In a country where there is no money, nor any thing equivalent to it, the wants of mankind will be confined to few objects; to wit, the removing the inconveniences of hunger, thirst, cold, heat, danger, and the like. A free man, who, by his industry, can procure all the comforts of a simple life, will enjoy his rest, and work no more: and, in general, all increase of work will cease, so soon as the demand for the necessaries mentioned comes to be satisfied. There is a plain reason for this. When the free hands have procured, by their labour, wherewithal to supply their wants, their ambition is satisfied: so soon as the husbandmen have produced the necessary surplus for relieving theirs, they work no more. Here then is a natural stop put to industry, consequent on bartering.

The next thing to be examined is, how bartering grows into trade, properly so called and understood, according to the definition given of it above; how trade comes to be extended among men; how manufactures, more ornamental than useful, come to be established; and how men come to submit to labour, in order to acquire what is not absolutely necessary for them.

This, in a free society, is chiefly owing to the introduction of money, and a taste for superfluities in those who possess it.

In ancient times, money was not wanting; but the taste for superfluities not being in proportion to it, the specie was locked up. This was the case in Europe four hundred years ago. A new taste for superfluity has drawn, perhaps, more money into circulation, from our own treasures, than from the mines of the new world. The poor opinion we entertain of the riches of our forefathers, is founded upon the modern way of estimating wealth, by the quantity of coin in circulation, from which we conclude, that the greatest part of the specie now in our hands must have come from America.

It is more, therefore, through the taste of superfluity, than in consequence of the quantity of coin, that trade comes to be established; and it is only in consequence of trade that we see industry carry things in our days to so high a pitch of refinement and delicacy. Let us illustrate this, by comparing together the different operations of barter, sale, and commerce.

When reciprocal wants are supplied by barter, there is not the smallest occasion for money: this is the most simple of all combinations.

When wants are multiplied, bartering becomes more difficult; upon this money is introduced. This is the common price of all things: it is a proper equivalent in the hands of those who want, perfectly calculated to supply the occasions of those who, by industry, can relieve them. This operation of buying and selling is a little more complex than the former; but still we have here no idea of trade, because we have not introduced the merchant, by whose industry it is carried on.

Let this third person be brought into play, and the whole operation becomes clear. What before we called wants, is here represented by the consumer; what we called industry, by the manufacturer; what we called money, by the merchant. The merchant here represents the money, by substituting credit in its place; and as the money was invented to facilitate barter, so the merchant, with his credit, is a new refinement upon the use of money. This renders it still more effectual in performing the operations of buying and selling. This operation is trade: it relieves both parties of the whole trouble of transportation, and adjusting wants to wants, or wants to money; the merchant represents by turns both the consumer, the manufacturer, and the money. To the consumer he appears as the whole body of manufacturers; to the manufacturers as the whole body of consumers; and to the one and the other class his credit supplies the use of money. This is sufficient at present for an illustration. We now return to the simple operations of money in the hands of the two contracting parties, the buyer and the seller, in order to show how men, in order to submit to labour in order to acquire superfluities.

So soon as money is introduced into a country, it becomes an universal object of want to all the inhabitants.

The consequence is, that the free hands of the state,
who before flop working, because all their wants were
provided for, having this new object of ambition before
their eyes, endeavour, by refinements upon their labour,
to remove the smaller inconveniences which result from
a simplicity of manners. People, who formerly knew
but one sort of clothing for all seasons, willingly part
with a little money to procure for themselves different
sorts of apparel properly adapted to summer and winter,
which the ingenuity of manufacturers, and their desire
of getting money, may have suggested to their invention.
Indeed these refinements seem more generally owing
to the industry and invention of the manufacturers, (who
by their ingenuity daily contrive means of softening or
relieving inconveniences, which mankind seldom perceive
to be such, till the way of removing them is contrived),
than to the taste of luxury in the rich, who, to indulge
their ease, engage the poor to become industrious.

Let any man make an experiment of this nature upon
himself, by entering into the first shop. He will no
where so quickly discover his wants as there. Every
thing he sees appears either necessary, or at least highly
convenient; and he begins to wonder how he could have
been so long without that which the ingenuity of the
workman alone had invented, in order that from the no-
velty it might excite his desire; for perhaps when it is
bought, he will never once think of it more, nor ever
apply it to the use for which it at first appeared so ne-
cessary.

Here then is a reason why mankind labour though not
in want. They become defirous of possessing the very
instruments of luxury, which their avarice or ambition
prompted them to invent for the use of others.

What has been said represents trade in its infancy, or
rather the materials with which that great fabric is
built.

We have formed an idea of the wants of mankind
multiplied even to luxury, and abundantly supplied by
the employment of all the free hands set apart for that
purpose. But if we suppose the workman himself dif-
pensing of his work, and purchasing with it food from the
farmer, cloaths from the clothier; and, in general, seek-
ing for the supply of every want from the hands of the
perfons directly employed for the purpose of relieving it;
this will not convey an idea of trade, according to our
definition.

Trade and commerce are an abbreviation of this long
process; a scheme invented and set on foot by merchants,
from a principle of gain, supported and extended among
men, from a principle of general utility to every indivi-
dual, rich or poor, to every society, great or small.

Instead of a pin-maker exchanging his pins with fifty
different perfons, for whose labour he has occasion, he
sells all to the merchant for money or for credit; and,
as occasion offers, he purchases all his wants, either di-
rectly from those who supply them, or from other mer-
chants who deal with manufacturers in the same way his
merchant dealt with him.

Another advantage of trade is, that industrious people
in one part of the country, may supply customers in an-
other, though distant. They may establish themselves
in the most commodious places for their respective bui-
ness, and help one another reciprocally, without making
the distant parts of the country suffer for want of their
labour. They are likewise exposed to no avocation from
their work, by seeking for customers.

Trade produces many excellent advantages; it marks
out to the manufacturers when their branch is under or
over stocked with hands. If it is understocked, they will
find more demand than they can answer; if it is over-
stocked, the sale will be slow.

Intelligent men, in every profession, will easily disco-
very when these appearances are accidental, and when they
proceed from the real principles of trade.

Poists, and correspondence by letters, are a confe-
quence of trade; by the means of which merchants are
regularly informed of every augmentation or diminution
of industry in every branch, in every part of the country.
From this knowledge they regulate the prices they offer;
and as they are many, they serve as a check upon one
another, from the principles of competition.

From the current prices the manufacturers are as well
informed as they kept the correspondence themselves:
the statesman feels perfectly where hands are wanting, and
young people destined to industry, obey, in a manner, the
call of the public, and fall naturally in to supply the de-
mand.

Two great afliftances to merchants, especially in the
infancy of trade, are public markets for collecting the
work of small dealers, and large undertakings in the ma-
ufacturing way by private hands. By these means the
merchants come at the knowledge of the quantity of work
in the market, as on the other hand the manufacturers
learn, by the sale of the goods, the extent of the de-
mand for them. These two things being justly known,
the price of goods is easily fixed.

Public sales serve to correct the small inconveniences
which proceed from the operations of trade. A set of
manufacturers got all together into one town, and entire-
ly taken up with their industry, are thereby as well in-
formed of the rate of the market as if every one of them
carried thither his work, and upon the arrival of the
merchant, who readily takes it off their hands, he has not
the least advantage over them from his knowledge of the
state of demand. This man both buys and sells in what
is called wholesale; and from him retailers purchase, who
distribute the goods to every consumer throughout the
country. These last buy from wholesale merchants in
every branch, that proportion of every kind of merchan-
dize which is suitable to the demand of their borough,
city, or province.

Thus all inconveniences are prevented, at some ad-
ditional cost to the consumer, who must naturally re-
imburse the whole expense. The distance of the
manufacturer, the obscurity of his dwelling, the ca-
price in selling his work, are quite removed; the re-
tailer has all in his shop, and the public buys at a cur-
rent price.

How the Prices of Goods are determined by Trade.

In the price of goods, two things must be considered
as really existing, and quite different from one another;
to wit, the real value of the commodity, and the profit upon alienation.

I. The first thing to be known of any manufacture, when it comes to be fold, is, how much of it a perfon can perform in a day, a week, a month, according to the nature of the work, which may require more or less time to bring it to perfection. In making such estimations, regard is to be had only to what, upon an average, a workman of the country in general may perform, without supposing him the best: or the word in his profession, or having any peculiar advantage or disadvantage as to the place where he works.

Hence the reason why some people thrive by their industry, and others not; why some manufactures flourish in one place, and not in another.

II. The second thing to be known, is the value of the workman's subsistence, and necessary expense, both for supplying his personal wants, and providing the instruments belonging to his profession, which must be taken upon an average as above; except when the nature of the work requires the presence of the workman in the place of consumption: for although some trades, and almost every manufacture, may be carried on in places at a distance, and therefore may fall under one general regulation as to prices; yet others there are which, by their nature, require the presence of the workman in the place of consumption; and in that case the prices must be regulated by circumstances relative to every particular place.

III. The third and last thing to be known, is the value of the materials, that is, the first matter employed by the workman; and if the object of his industry be the manufacture of another, the same process of inquiry must be gone through with regard to the first, as with regard to the second: and thus the most complex manufactories may be at last reduced to the greatest simplicity.

These three articles being known, the price of manufacture is determined. It cannot be lower than the amount of all the three, that is, than the real value; whatever it is higher, is the manufacturer's profit. This will ever be in proportion to demand, and therefore will fluctuate according to circumstances.

Hence appears the necessity of a great demand, in order to promote flourishing manufactures.

By the extensive dealings of merchants, and their constant application to the study of the balance of work and demand, all the above circumstances are known to them, and are made known to the industrious, who regulate their living and expense according to their certain profit.

Employ a workman in a country where there is little trade or industry, he proportions his price always to the urgency of your want, or your capacity to pay; but seldom to his own labour. Employ another in a country of trade, he will not impose upon you, unless perhaps you be a stranger, which supposes your being ignorant of the value; but employ the same workman in a work not used in the country, consequently not demanded, consequently not regulated as to the value, he will proportion his price as in the first supposition.

We may therefore conclude from what has been said, that in a country where trade has been established, manufactures must flourish; from the ready sale, the regulated price of work, and the certain profit resulting from industry. Let us next inquire into the consequences of such a situation.

How foreign Trade opens to an industrious People, and the Consequences of it to the Merchants who set it on foot.

The first consequence of the situation described in the preceding section is, that wants are easily supplied, for the adequate value of the thing wanted.

The next consequence is, the opening of foreign trade under its two denominations of passive and active. Strangers and people of distant countries, finding the difficulty of having their wants supplied at home, and the ease of having them supplied from this country, immediately have recourse to it. This is passive trade. The active is when merchants, who have executed this plan at home with success, begin to transport the labour of their countrymen into other regions, which either produce, or are capable of producing such articles of consumption, proper to be manufactured, as are most demanded at home; and consequently will meet with the readiest sale, and fetch the largest profits.

Here then is the opening of foreign trade, under its two denominations of active and passive.

What then are the consequences of this new commerce to our merchants, who have left their homes in quest of gain aboard?

The first is, that, arriving in any new country, they find themselves in the same situation, with regard to the inhabitants, as the workman in the country of no trade, with regard to those who employed him; that is, they proportion the price of their goods to the eagerness of acquiring, or the capacity of paying, in the inhabitants, but never to their real value.

The first profits then, upon this trade, must be very considerable; and the demand from such a country will be high or low, great or small, according to the spirit, not the real wants of the people: for these in all countries must first be supplied by the inhabitants themselves, before they cease to labour.

If the people of this not-trading country be abundantly furnished with commodities useful to the traders, they will easily part with them, at first, for the instruments of luxury and ease; but the great profit of the traders will insensibly increase the demand for the productions of their new correspondents; this will have the effect of producing a competition between themselves, and thereby of throwing the demand on their side. This is perpetually a disadvantage in traffic; the most unpolished nations in the world quickly perceive the effects of it; and are taught to profit by the discovery, in spite of the address of those who are the most expert in commerce.

The traders will therefore be very fond of falling upon every method and contrivance to inspire this people with a taste of refinement and delicacy. Abundance of fine presents, confiting of every instrument of luxury and finery, the best adapted to the genius of the people, will be given to the prince and leading men among them. Workmen will even be employed at home to study the
taste of the strangers, and to captivate their desires by every possible means. The more eager they are of presents, the more lavish the traders will be in bestowing and diversifying them. It is an animal put up to fatten, the more he eats the sooner he is fit for slaughter. When their taste for superfluity is fully formed, when the relish for their former simplicity is sophificated, poisoned, and obliterated, then they are surely in the fetters of the traders, and the deeper they go, the less possibility there is of their getting out. The presents then will die away, having served their purpose; and if afterwards they are found to be continued, it will probably be to support the competition against other nations, who will incline to share of the profits.

If, on the contrary, this not-trading nation does not abound with commodities useful to the traders, these will make little account of trading with them, whatever their turn may be; but, if we suppose this country inhabited by a laborious people, who, having taken a taste for refinement from the traders, apply themselves to agriculture, in order to produce articles of sufficiency, they will solicit the merchants to give them part of their manufactures in exchange for those; and this trade will undoubtedly have the effect of multiplying numbers in the trading nation. But if food cannot be furnished, nor any other branch of production found out to support the correspondence, the taste for refinement will soon die away, and trade will flop in this quarter.

Had it not been for the furs in those countries adjacent to Hudson's Bay, and in Canada, the Europeans never would have thought of supplying instruments of luxury to those nations; and if the inhabitants of those regions had not taken a taste for the instruments of luxury, furnished to them by the Europeans, they never would have become so indefatigable nor so dextrous hunters. At the same time we are not to suppose, that ever these Americans would have come to Europe in quest of our manufactures. It is therefore owing to our merchants, that these nations are become in any degree fond of refinement; and this taste, in all probability, will not soon exceed the proportion of the productions of their country. From these beginnings of foreign trade it is easy to trace its increase.

One step towards this, is the establishing correspondences in foreign countries; and these are more or less necessary in proportion as the country where they are established is more or less polished or acquainted with trade. They supply the want of polls, and point out to the merchants what proportion the productions of the country bear to the demand of the inhabitants for manufactures. This communicates an idea of commerce to the not-trading nation, and they insensibly begin to fix a determined value upon their own productions, which perhaps bore no determined value at all before.

Let us trace a little the progress of this refinement in the savages, in order to shew how it has the effect of throwing the demand upon the traders, and of creating a competition among them, for the productions of the new country.

Experience shews, that, in a new discovered country, merchants constantly find some article or other of its productions, which turns out to a great account in commerce; and we see that the longer tunc a trade subsists, and the more the inhabitants take a taste for European manufactures, the more their own productions fall in value, and the less profit is made by trading with them, even in cafes where the trade is carried on by companies; which is a very wise institution for one reason, that it cuts off a competition between our merchants.

This is the best means of keeping prices low in favour of the nation; however it may work a contrary effect with respect to individuals who must buy from these monopolies.

When companies are not established, and when trade is open, our merchants, by their cageries to profit by the new trade, betray the secrets of it, they enter into competition for the purchase of the foreign produce, and this raises prices, and favours the commerce of the most ignorant savages.

Consequences of the Introduction of a passive foreign Trade among a People who live in Simplicity and Idleness.

We now suppose the arrival of traders, all in one interest, with instruments of luxury and refinement, at a port in a country of great simplicity of manners, abundantly provided by nature with great advantages for commerce, and peopled by a nation capable of adopting a taste for superfluities.

The first thing the merchants do is, to expoe their goods, and point out the advantages of many things, such as wines, spirits, instruments of agriculture, arms, and ammunition for hunting, nets for fishing, manufactures for clothing, and the like. The advantages of these are presently perceived, and such commodities are eagerly sought after.

The natives on their side produce what they most esteem, generally something superfluous or ornamental. The traders, after examining all circumstances, determine the object of their demand, giving the least quantity possible in return for this superfluity, in order to impress the inhabitants with a high notion of the value of their own commodities; but as this parsimony may do more hurt than good to their interest, they are very generous in making presents, from the principles mentioned above.

When the exchange is completed, and the traders depart, regret is commonly mutual; the one and the other are sorry that the superfluities of the country fall short. A return is promised by the traders, and assurances are given by the natives of a better provision another time.

What are the first consequences of this revolution? It is evident, that, in order to supply an equivalent for this new want, more hands must be set to work than formerly. And it is evident also, that this augmentation of industry will not essentially increase numbers: Why? Because the produce of the industry is, in this case, intended to be exported. But, if we can find out any additional consumption at home, even implied by
this new trade, it will have the effect of augmenting numbers. An example will make this plain.

Let us suppose the superfluity of this country to be the skins of wild beasts, not proper for food; the manufacture fought for, brandy. The brandy is sold for furs. He who has furs, or he who can spare time to hunt for them, will drink brandy in proportion: but there is no reason to conclude from this simple operation, that one man more in the country must necessarily be fed, or that any augmentation of agriculture must of consequence ensue from this new traffic.

But let us throw in a circumstance which may apply an additional consumption at home, and then examine the consequences.

A poor creature who has no equivalent to offer for food, who is miserable, and ready to perish for want of subsistence, goes a hunting, and kills a wolf; he comes to a farmer with the skin, and says, You are well fed, but you have no brandy; if you will give me a loaf, I will give you this skin, which the strangers are so fond of, and they will give you brandy. But, says the farmer, I have no more bread than what is sufficient for my own family. As for that, replies the other, I will come and dig in your ground, and you and I will settle our account as to the small quantity I defire of you. The bargain is made; the poor fellow gets his loaf, and lives at least; perhaps he marries, and the farmer gets a dram. But had it not been for this dram, that is, this new want, which was purchased by the industry of this poor fellow, by what argument could he have induced the farmer to part with a loaf?

Here the sentiment of charity is excluded. This alone is a principle of multiplication; but as true it is, on the other hand, that the poor fellow have got bread by begging, he would not probably have gone a-hunting.

Here then it appears, that the very dawning of trade, in the most unpolished countries, implies a multiplication. This is enough to point out the first step, and to connect the subject of our present inquiries with what has been already discussed in relation to other circumstances.

So soon as all the furs are disposed of, and a taste for superfluity is introduced, both the traders and the natives will be equally interested in the advancement of industry in this country. Many new objects of profit for the first will be discovered, which the proper employment of the inhabitants, in reaping the natural advantages of their soil and climate, will make effectual. The traders will therefore endeavor to let on foot many branches of industry among the savages, and the allures of brandy, arms, and clothing, will animate these in the pursuit of them.

When once this revolution is brought about; when those who formerly lived in simplicity become industrious; manners put on a new face.

That is to say, we now find two trading nations instead of one, with this difference, however, that as hitherto we have supposed the merchants all in one interest, the compound demand, that is, the competition of the buyers, has been, and must still continue on the side of the natives. This is a great prejudice to their interest; but as it is not supposed sufficient to check their industry, nor to restrain their consumption of the manufactures, let us here examine a little more particularly the consequences of the principle of demand in such a situation; for although we allow, that it can never change sides, yet it may admit of different modifications, and produce different effects, as we shall presently perceive.

The merchants we suppose all in one interest, consequently there can be no competition among them; consequently no check can be put upon their raising their prices, as long as the prices they demand are complied with. So soon as they are raised to the full extent of the abilities of the natives, or of their inclination to buy, the merchants have the choice of three things, which are all perfectly in their option; and the preference to be given to the one or the other, depends entirely upon themselves, and upon the circumstances we are going to point out.

First, they may support they high demand; that is, not lower their price; which will preserve a high estimation of the manufactures in the opinion of the inhabitants, and render the profits upon their trade the greatest possible. This part they may possibly take, if they perceive the natives doubling their diligence, in order to become able, in time, to purchase considerable cargoes at a high value; from which supplication is implied a strong disposition in the people to become luxurious, since nothing but want of ability prevents them from complying with the highest demand; but still another circumstance must concur, to engage the merchants not to lower their price. The great proportion of the goods they seek for in return, must be found in the hands of a few. This will be the case if slavery be established; for then there must be many poor, and few rich: and they are commonly the rich consumers who proportion the price they offer, rather to their desires, than to the value of the thing.

The second thing which may be done is, to open the door to a great demand; that is, to lower their prices. This will link the value of the manufactures in the opinion of the inhabitants, and render profits less in proportion, although indeed, upon the voyage, the profits may be greater.

This part they will take, if they perceive the inhabitants do not incline to consume great quantities of the merchandise at a high value, either for want of abilities or inclination; and also, if the profits upon the trade depend upon a large consumption, as is the case in merchandise of a low value, and suited chiefly to the occasions of the lower sort. Such motives of expediency will be sufficient to make them neglect a high demand, and prefer a great one; and the more, when there is a likelihood that the consumption of low-priced goods in the beginning may beget a taste for others of a higher value, and thus extend in general the taste of superfluity.

A third part to be taken, is the least politic, and perhaps the most familiar. It is to profit by the competition between the buyers, and encourage the rising of demand as long as possible; when this comes to a stop, to make a kind of auction, by first bringing down the prices
to the level of the highest bidders, and so to descend by
degrees, in proportion as demand sinks. Thus we may
say with propriety, that demand commonly becomes
great, in proportion as prices sink. By this operation,
the traders will profit as much as possible, and fall off as
much of their goods as the profits will permit.

But this plan, in a new discovered country, is not po-
litic, as it both discovers a covetousness and a want of
faith in the merchants, and also throws open the secrets
of their trade to those who ought to be kept ignorant of
them.

Let us next suppose, that the large profits of our mer-
chants shall be discovered by others, who arrive at the
same ports in a separate interest, and who enter into no
combination which might prevent the natural effects of
competition.

Let the rate of demand among the natives be suppo-
sed the same as formerly, both as to height and great-
ness; in consequence of the operation of the different
principles, which might have induced our merchants to
follow one or other of the plans we have been descri-
bining; we must however still suppose, that they have
been careful to preserve considerable profits upon every
branch.

If we suppose the inhabitants to have increased in
numbers, wealth, and taste for superfluity, since the last
voyage, demand will be found rather on the rising-hand.
Upon the arrival of the merchants in competition with
the former, both will offer to sell: but if both stand to
the same prices, it is very natural to suppose, that the
former dealers will obtain a preference; as, ceteris pari-
bus, it is always an advantage to know and to be known.
The last comers, therefore, have no other way left to
counter-balance this advantage, but to lower their prices.

This is a new phenomenon: here the fall of prices is
not voluntary as formerly; nor confined to from expe-
diency; not owing to a failure of demand, but to the in-
fluence of a new principle of commerce, to wit, a dou-
ble competition, which we shall now examine.

Of Double Competition.

When competition is much, stronger on one side of
the contract than on the other, it is called simple. This is
the species of competition which is implied in the term
high demand, or when it is said that demand raises
prices.

Double competition is, when, in a certain degree, it
takes place on both sides of the contract at once, or vi-
brates alternately from one to the other. This is what
restrains prices to the adequate value of merchandize.

The great difficulty is to distinguish clearly between
the principles of demand, and those of competition; here then follows the principal differences between the
two, relatively to the effects they produce separately in
the mercantile contract of buying and selling, which we
here express shortly by the word contract.

Simple demand is what brings the quantity of a com-
modity to market. Many demand, who do not buy; many
offer, who do not sell. This demand is called
great or small; it is said to increase, to augment, to
rise, to fall, to mount, to sink, and is expressed by these and
other synonymous terms.

Compound demand is the principle which raises prices,
and never can make them sink; because in this case more
than one demands the very same thing, but a part of the same thing, or things quite alike.

Compound demand is the principle which raises prices,
and never can make them sink; because in this case more
than one demands the very same thing, but a part of the same thing, or things quite alike.

We therefore say, with regard to prices, demand is
high or low. With regard to the quantity of merchan-
dize, demand is great or small. With regard to com-
petition, it is always called great or small, strong or
weak.

Competition is, with equal propriety, applicable to
both parties in the contract. A competition among buyers
is a proper expression; a competition among sellers, who
have the merchandize, is fully as easily understood, tho'
it be not quite so striking, for reasons which an example
will make plain.

You come to a fair, where you find a great variety of
every kind of merchandize, in the possession of different
merchants. Thence, by offering their goods to sale, con-
stitute a tacit competition; every one of them wishes to
fall in preference to another, and at the same time with the
best advantage to himself.

The buyers begin, by cheapning at every shop. The
first price asked marks the covetousness of the seller; the
first price offered, the avarice of the buyer. From this
operation competition begins to work its effects on both
sides, and so becomes double. The principles which in-
fluence this operation are now to be deduced.

It is impossible to suppose the same degree of eagerness,
either to buy or to sell, among several merchants; be-
cause the degree of eagerness is exactly in proportion to
their view of profit; and as these must necessarily be in-
fluenced and regulated by different circumstances, that
buyer, who has the best prospect of selling again with
profit, obliges him, whose prospect is not so good, to
content himself with less; and that seller, who has
bought to the best advantage, obliges him, who has paid
dearer
It is from these principles, that competition among buyers and sellers must take place. This is what confines the fluctuation of prices within limits which are compatible with the reasonable profits of both buyers and sellers; for we must constantly suppose the whole operation of buying and selling to be performed by merchants; the buyer cannot be supposed to give too high a price as that which he expects to receive, when he distributes to the consumers, nor can the seller be supposed to accept of a lower than that which he paid to the manufacturer. This competition is properly called double, because of the difficulty to determine upon which side it stands; the same merchant may have it in his favour upon certain articles, and against him upon others; it is continually in vibration, and the arrival of every post may lend or more pull down the heavy scale.

In every transaction between merchants, the profit resulting from the sale must be exactly distinguished from the value of the merchandize. The first may vary, the last never can. It is this profit alone which can be influenced by competition; and it is for that reason we find such uniformity every where in the prices of goods of the same quality.

The competition between sellers does not appear so striking, as that between buyers; because he who offers to sale, appears only passive in the first operation; whereas the buyers present themselves one after another; they make a demand when the merchandize is refused to one at a certain price, a second either offers more, or does not offer at all: but as soon as another seller finds his account in accepting the price the first had refused, then the first enters into competition, providing his profits will admit his lowering the first price, and thus competition takes place among the sellers, until the prices upon their trade prevent prices from falling lower.

In all markets this competition is varying, though insensibly, on many occasions; but in others, the vibrations are very perceptible. Sometimes it is found strongly on the side of the buyers; and in proportion as this grows, the competition between the sellers diminishes. When the competition between the former has raised prices to a certain standard, it comes to a stop; then the competition changes sides, and takes place among the sellers, eager to profit of the highest price. This makes prices fall, and according as they fall, the competition among the buyers diminishes. They still wait for the lowest period. At last it comes; and then perhaps some new circumstance, by giving the balance a kick, disappoints their hopes. If therefore it ever happens, that there is but one interest upon one side of the contract, as in the example in the former section, where we supposed the sellers united, you perceive, that the rise of the price, occasioned by the competition of the buyers, and even its coming to a stop, could not possibly have the effect of producing any competition on the other side; and therefore, if prices come afterwards to sink, the fall must have proceeded from the prudential considerations of adapting the price to the faculties of those who, from the height of it, had withdrawn their demand.

From these principles of competition, the foresaying of markets is made a crime, because it diminishes the competition which ought to take place between different people, who have the same merchandize to offer to sale. The forester buys all up, with an intention to sell with more profit, as he has by that means taken other competitors out of the way, and appears with a sly interest on one side of the contract, in the face of many competitors on the other. This person is punished by the state, because he has prevented the price of the merchandize from becoming justly proportioned to the real value; he has robbed the public, and enriched himself; and in the punishment he makes reparation. Here occur two questions to be resolved, for the sake of illustration.

Can competition among buyers possibly take place, when the provision made is more than sufficient to supply the quantity demanded? On the other hand, can competition take place among the sellers, when the quantity demanded exceeds the total provision made for it?

We think it may in both cases; because in the one and the other, there is a competition implied on one side of the contract, and the very nature of this competition implies a possibility of its coming on the other, provided separate interests be found upon both sides. But to be more particular:

1. Experience shews, that however justly the proportion between the demand and the supply may be determined in fact, it is still next to impossible to discover it exactly, and therefore the buyers can only regulate the prices they offer, by what they may reasonably expect to sell for again. The sellers, on the other hand, can only regulate the prices they expect, by what the merchandize has cost them when brought to market. We have already shown, how, under such circumstances, the several interests of individuals affect each other, and make the balance vibrate.

2. The proportion between the supply and the demand is seldom other than relative among merchants, who are supposing to buy and sell, not from necessity, but from a view to profit. What we mean by relative is, that their demand is great or small, according to prices; there may be a great demand for grain at 35s. per quarter, and no demand at all for it at 40s.; that is, among merchants.

It is essential to attend to the smallest circumstance in matters of this kind. The circumstance we mean, is the difference we find in the effect of competition, when it takes place purely among merchants on both sides of the contract, and when it happens, that either the consumers mingle themselves with the merchant buyers, or the manufacturers, that is, the furnishers, mingle themselves with the merchant-sellers. This combination we shall illustrate, by the solution of another question, and then conclude with a few reflections upon the whole.

Can there be no case formed, where the competition upon one side may subserve, without a possibility of its ta-
king place on the other, although there should be separate interests upon both?

The cafe is hardly supposable among merchants, who buy and sell with a view to profit; but it is absolutely supposable, and that is all, when the direct consumers are the buyers; when the circumstances of one of the parties is perfectly known; and when the competition is so strong upon one side, as to prevent a possibility of its becoming double, before the whole provision is sold off, or the demand satisfied. Let us have recourse to examples.

Grain arriving in a small quantity, at a port where the inhabitants are starving, produces so great a competition among the consumers, who are the buyers, that their necessity becomes evident; all the grain is generally bought up before prices can rise so high as to come to a stop; because nothing but want of money, that is, an impossibility of complying with the prices demanded by the merchants, can restrain them: but if you suppose, even here, that prices come naturally to a stop; because nothing but want of money, that is, an impossibility of complying with the prices demanded by the merchants, can restrain them: but if you suppose, even here, that prices come naturally to a stop; or that, after some time, they fall lower, from prudential considerations; then there is a possibility of a competition taking place among the sellers, from the principles above deduced. If, on the contrary, the stop is not natural, but occasioned by the interposition of the magistrate, from humanity, or the like, there will be no competition, because then the principles of commerce are suspended; the sellers are restrained on one side, and they restrain the buyers on the other. Or rather, indeed, it is the magistrate, or companion, who in a manner fixes the price, and performs the office of both buyer and seller.

A better example may be found, in a competition among sellers; where it may be so strong, as to render a commodity in a manner of no value at all, as in the case of an uncommon and unexpected draught of fish, in a place of small consumption, when no preparations have been made for taking them. There can be then no competition among the buyers; because the market cannot last, and they find themselves entirely masters, to give what price they please, being sure the sellers must accept of it, or lose their merchandise. In the first example, humanity commonly flops the activity of the principle of competition; in the other it is sloped by a certain degree of fair-dealing, which forbids the accepting of a merchantize for nothing.

In proportion therefore as the rising of prices can stop demand, or the sinking of prices can increase it, in the same proportion will competition prevent either the rise or the fall from being carried beyond a certain length: and if such a cafe can be put, where the rising of prices cannot stop demand, nor the lowering of prices augment it, in such a cafe double competition has no effect; because these circumstances unite the most separate interests of buyers and sellers in the mercantile contract; and when upon one side there is no separate interest, there can then be no competition.

From what has been said, we may form a judgment of the various degrees of competition. A book not worth a shilling, a shilling of a few pounds weight, are often sold for considerable sums. The buyers here are not merchants. When an ambassador leaves a court in a hurry, things are sold for less than the half of their value: he is no merchant, and his situation is known. When, at a public market, there are found consumers, who make their provision; or manufacturers, who dispose of their goods for present subsistence; the merchants, who are respectively upon the opposite side of the contract to these, profit of their competition; and those who are respectively upon the same side with them, stand by with patience, until they have finished their business. Then matters come to be carried on between merchant and merchant, and then profits may rise and fall, in the proportion of quantity to demand; that is to say, if the provision is less than the demand, the competition among the demanders, or the rise of the price, will be in the compound proportion of the falling short of the commodity, and of the prospect of selling again with profit. It is this combination which regulates the competition, and keeps it within bounds. It can affect but the profits upon the transaction; the intrinsic value of the commodity remains immovable: nothing is ever sold below the real value; nothing is ever bought for more than it may probably bring. We mean in general. Whereas, so soon as consumers and needy manufacturers mingle in the operation, all proportion is lost. The competition between them is too strong for the merchants; the balance vibrates by jerks. In such markets merchants seldom appear: the principal objects there, are the fruits and productions of the earth, and articles of the first necessity for life, not manufactures strictly so called. A poor fellow often sells, to purchase bread to eat; not to pay what he did eat while he was employed in the work he dispenses of. The consumer often measures the value of what he is about to purchase, by the weight of his purse, and his desire to consume.

Of what is called Expence, Profit, and Loss.

The term expence, when simply expressed, without any particular relation, is always understood to be relative to money. This kind is distinguished under the three heads of private, public, and national.

1. Private expence is, what a private person, or private society, lays out, either to provide articles of consumption, or something more permanent, which may be conducive to their ease, convenience, or advantage. Thus we say, a large domestic expence, relative to one who spends a great income. We say, a merchant has been at great expence for magazines, for living, for clerks, &c., but never that he has been at any in buying goods. In the same way a manufacturer may expend for building, machines, horses, and carriages, but never for the matter he manufactures. When a thing is bought, in order to be sold again, the sum employed is called money advanced; when it is bought not to be sold, it may be said to be expended.

2. Public expence is, the employment of that money, which has been contributed by individuals, for the current service of the state. The contribution, or gathering it together, represents the effects of many articles of private expence; the laying it out when collected, is public expence.

3. National
3. National expense, is what is expended out of the country: this is what diminishes national wealth. The principal distinction to be here attended to, is between public expense, or the laying out of public money, and national expense, which is the alienating the nation’s wealth in favour of strangers. Thus the greatest public expense imaginable, may be no national expense; because the money may remain at home. On the other hand, the smallest public, or even private expense, may be a national expense; because the money may go abroad.

Profit and loss is divided into positive, relative, and compound. Positive profit, implies no loss to any body; it results from an augmentation of labour, industry, or ingenuity, and has the effect of swelling or augmenting the public good.

Positive loss, implies no profit to any body; it is what results from the cessation of the former, or of the effects resulting from it, and may be said to diminish the public good.

Relative profit, is what implies a loss to some body; it marks a vibration of the balance of wealth between parties, but implies no addition to the general stock.

Relative loss, is what, on the contrary, implies a profit to some body; it also marks a vibration of the balance, but takes nothing from the general stock.

The compound is easily understood; it is that species of profit and loss which is partly relative, and partly positive.

The general consequences resulting to a trading Nation, upon the opening of an active foreign Commerce.

A nation which remains passive in her commerce, is at the mercy of those who are active, and must be greatly favoured, indeed, by natural advantages, or by a constant flux of gold and silver from her mines, to be able to support a correspondence, not entirely hurtful to the augmentation of her wealth.

When we look upon the wide field which here opens to our view, we are perplexed with too great a variety of objects. In one part, we see a decent and comely beginning of industry; wealth flowing gently in, to compensate ingenuity; numbers both augmenting, and every one becoming daily more useful to another; agriculture proportionally extending itself; no violent revolutions; no exorbitant profits; no insolvency among the rich; no excessive misery among the poor; multitudes employed in producing; great oeconomy upon consumption; and all the instruments of luxury, daily produced by the hands of the diligent, going out of the country for the service of strangers; not remaining at home for the gratification of sensuality. In one part, we see a decent and comely beginning of industry; wealth flowing gently in, to compensate ingenuity; numbers both augmenting, and every one becoming daily more useful to another; agriculture proportionally extending itself; no violent revolutions; no exorbitant profits; no insolvency among the rich; no excessive misery among the poor; multitudes employed in producing; great oeconomy upon consumption; and all the instruments of luxury, daily produced by the hands of the diligent, going out of the country for the service of strangers; not remaining at home for the gratification of sensuality.

of any great advantage or inconvenience; the change of their circumstances will even be imperceptible.

The immediate effects of the violent revolution will, in this example, be flattering to some, and disagreeable to others. Wealth will be found daily to augment, from the rising of prices, in many branches of industry. This will encourage the industrious classes, and the idle consumers at home will complain. We have already dwelt abundantly long upon the effects resulting from this to the lower classes of the people, in providing them with a certain means of subsistence. Let us now examine in what respect even the higher classes will be made likewise to feel the good effects of this general change, although at first they may suffer a temporary inconvenience from it.

Farmers, as has been observed, will have a greater difficulty in finding servants, who, instead of labouring the ground, will chuse to turn themselves to manufactures. This we have considered in the light of purging the lands of superfluous mouths; but every consequence in this great chain of politics draws other consequences after it, and as they follow one another, things put on different faces, which affect classes differently. The purging of the land is but one of the first; here follows another.

The defection of the lands employed in a trifling agriculture will at first, no doubt, embarras the farmers; but in a little time every thing becomes balanced in a trading nation, because every industrious man must advance in prosperity, in spite of all general combinations of circumstances.

In the cafe before us, the relative profits upon farming must soon become greater than formerly, because of this additional expence which must affect the whole classes of farmers; consequently, this additional expence, instead of turning out to be a loss to either landlord or farmer, will, after some little time, turn out to the advantage of both: because the produce of the ground, being indispensably necessary to every body, must in every article increase in its value. Thus in a short time accounts will be nearly balanced on all hands; that is to say, the same proportion of wealth will, ceteris paribus, continue the same among the industrious. We say among the industrious; for those who are either idle, or even negligent, will be great losers.

A proprietor of land, inattentive to the causes of his farmer's additional expence, may very imprudently suffer his rents to fall, instead of affisting him on a proper occasion, in order to make them afterwards rise the higher.

Those who live upon a determined income in money, and who are nowise employed in traffic, nor in any scheme of industry, will, by the augmentation of prices, be found in worse circumstances than before.

In a trading nation every man must turn his talents to account; or he will undoubtedly be left behind in this universal emulation, in which the most industrious, the most ingenious, and the most frugal will constantly carry off the prize.

This consideration ought to be a spur to every body. The richest men in a trading nation have no security against poverty; we mean proportional poverty; for though they diminish nothing of their income, yet, by not increasing it in proportion to others, they lose their rank in wealth, and from the first class in which they stand they will slide insensibly down to a lower.

There is one consequence of an additional beneficial trade, which raises demand and increases wealth; but if we suppose no proportional augmentation of supply, it will prove at best but an airy dream which lasts for a moment, and when the gilded scene is passed away, numberless are the inconveniences which are seen to follow.

We shall now point out the natural consequences of this augmentation of wealth drawn from foreign nations, when the statesman remains inattentive to increase the supply both of food and manufactures, in proportion to the augmentation of mouths, and of the demand for the produce of industry.

In such a situation profits will daily swell, and every scheme for reducing them within the bounds of moderation, will be locked upon as a hurtful and unpopular measure: be it so; but let us examine the consequences.

We have said, that the rise of demand for manufactures naturally increases the value of work: now we must add, that under such circumstances, the augmentation of riches, in a country, either not capable of improvement as to the soil, or where precautions have not been taken for facilitating a multiplication of inhabitants, by the importation of subsistence, will be productive of the most calamitous consequences.

On one side, this wealth will effectually diminish the mafs of the food before produced; and on the other, will increase the number of useless consumers. The first of these circumstances will raise the demand for food; and the second will diminish the number of useful free hands, and consequently raise the price of manufactures here are shortly the outlines of this progress.

The more rich and luxurious a people are, the more delicate they become in their manner of living; if they fed on bread formerly, they will now feed on meat; if they fed on meat, they will now feed on fowl. The same ground which feeds a hundred with bread, and a proportional quantity of animal food, will not maintain an equal number of delicate livers. Food must then become more scarce; demand for it rises; the rich are always the strongest in the market; they consume the food, and the poor are forced to starve. Here the wide door to modern distress opens; to wit, a hurtful competition for subsistence. Further, when a people become rich, they think less of economy; a number of useless servants are hired, to become an additional dead weight on consumption; and when their flattering countrymen cannot supply the extravagance of the rich to cheaply as other nations, they either import instruments of foreign luxury, or seek to enjoy them out of their own country, and thereby make restitution of their gains.

Is it not therefore evident, that if, before things come to this pass, additional subsistence be not provided by one method or other, the number of inhabitants must diminish; although riches may daily increase by a balance of additional matter, supposed to be brought into the country
in consequence of the hitherto beneficial foreign trade. This is not all. We say farther, that the beneficial trade will last for a time only. For the infallible consequence of the rise of prices at home will be, that those nations which at first consumed your manufactures, perceiving the gradual increase of their price, will begin to work for themselves; or finding out your rivals who can supply them cheaper, will open their doors to them. These again, perceiving the great advantages gained by your traders will begin to supply the market; and since every thing must be cheaper in countries where we do not suppute the concurrence of all the circumstances mentioned above, these nations will supplant you, and be enriched in their turn.

Here comes a new revolution. Trade is come to a stop; what then becomes of all the hands which were formerly employed in supplying the foreign demands?

Were revolutions so sudden as we are obliged to represent them, all would go to wreck; in proportion as they happen by quicker or slower degrees, the inconveniences are greater or smaller.

Prices, we have said, are made to rise by competition. If the competition of the strangers was what raised them, the distress upon the manufacturers will be in proportion to the suddenness of their deserting the market. If the competition was divided between the strangers and the home-consumers, the inconveniences which ensue will be less; because the desertion of the strangers will be in some measure made up by an increase of home-consumption which will follow upon the fall of prices. And if, in the third case, the natives have been so imprudent, as not only to support a competition with the strangers, and thereby disgust them from coming any more to market, but even to continue the competition between themselves, the whole has sustained by the revolution will be national. Wealth will cease to augment; but the inconveniences, in place of being felt by the manufacturers, will only affect the state; those will continue in affluence, extolling the generosity of their countrymen, and defiring the poverty of the strangers who had enriched them.

Domestic luxury will here prove an expedient for preserving from ruin the industrious part of a people, who in subsisting themselves had enriched their country. No change will follow in their condition; they will go on with a painful alacrity to labour, and if the consequences of it become now hurtful to one part of the state, they must at least be allowed to be essentially necessary for the support of the other.

But that luxury is no necessary concomitant of foreign trade, in a nation where the true principles of it are understood, will appear very plain, from a contrast we are now going to point out, in the example of a modern state, renowned for its commerce and frugality. The country is Holland.

A set of industrious and frugal people were assembled in a country by nature subject to many inconveniences, the moving of which necessarily employed abundance of hands. Their situation upon the continent, the power of their former masters, and the ambition of their neighbours, obliged them to keep great bodies of troops. These two articles added to the numbers of the community, without either enriching the state by their labour exported, or producing food for themselves or countrymen.

The scheme of a commonwealth was calculated to draw together the industrious; but it has been still more useful in subsisting them: the republican form of government being there greatly subdivided, vests authority sufficient in every part of it, to make sufficient provision for their own subsistence; and the tie which unites them, regards only matters of public concern. Had the whole been governed by one sovereign, or by one council, this important matter never could have been effectuated.

It would be impossible for the most able minister that ever lived, to provide nourishment for a country so extended as France, or even as England, supposing these as fully peopled as Holland is: even although it should be admitted that a sufficient quantity of food might be found in other countries for their subsistence. The enterprize would be too great, abuses would multiply; the consequence would be, that the inhabitants would die for want. But in Holland the case is different, every little town takes care of its own inhabitants; and this care being the object of application and profit to so many persons, is accomplished with success.

When once it is laid down as a maxim in a country, that food must of necessity be got from abroad in order to feed the inhabitants at home, the corn-trade becomes considerable, and at the same time certain, regular, and permanent. This was the case in Holland: as the inhabitants were industrious, the necessary consequence has been, a very extraordinary multiplication; and at the same time such an abundance of grain, that, instead of being in want themselves, they often supply their neighbours. There are many examples of England's being supplied with grain from hence, and, which is still more extraordinary, from the re-exportation of the very produce of its own fruitful soil.

It is therefore evident, that the only way to support industry, is to provide a supply of subsistence, constantly proportional to the demand that may be made for it. This is a precaution indispensably necessary for preventing hurtful competition. This is the particular care of the Dutch; so long as it can be effectual, their state can fear no decline; but whenever they come to be disinterested in the markets, upon which they depend for subsistence, they will sink into ruin. It is by mere diet of frugality, cheap and parsimonious living, that the navigation of this industrious people is supported. Constant employment, and an accumulation of almost impregnable gains, fills their coffers with wealth, in spite of the large outgoings to which their own proper nourishment yearly forces them. The large profits upon industry in other countries, which are no proof of generosity, but a fatal effect of a scanty subsistence, is far from dazzling their eyes. They seldom are found in the list of competitors at any foreign port; if they have their cargo to dispose of, they wait with pleasure in their own vessels, continuing their own provisions, and at full accept of what others have left.

It may be said, that many other circumstances concur in favour of the Dutch, besides the article of subsistence.
Without disputing this matter, it may be observed, that if a computation be made of the hands employed in providing subsistence, and of those who are severally taken up in supplying every other want, their numbers will be found nearly to balance one another in the most luxurious countries. From this we may conclude, that the article of food, among the lower classes, must bear a very high proportion to all the other articles of their consumption; and therefore a diminution upon the price of subsistence, must be of infinite consequence to manufacturers, who are obliged to buy it. From this consideration, let us judge of the consequence of such augmentations upon the price of grain as are familiar to us; 30 or 40 per cent. seems nothing. Now this augmentation operates upon two thirds, at least, of the whole expense of a labouring man; let any one who lives in tolerable affluence make the application of this to himself, and examine how he would manage his affairs if, by accidents of rains or winds, his expenses were to rise 30 per cent. without a possibility of restraining them; for this is unfortunately the case with all the lower classes. From whence it may be concluded, that the keeping food cheap, and still more the preferring it at all times at an equal standard, is the fountain of the wealth of Holland; and that any hurtful competition in this article must beget a disorder which will affect the whole of the manufacturers of a state.

COMMISSARY, in the ecclesiastical law, an officer of the church, who has the charge of all the stores, for which he is accountable to the office of ordnance. See Scots Law, title, Division of rights.

COMMISSION, in common-law, the warrant or letter-patent, or other lawful warrant, to examine any matters, or execute any public office, &c.

Besides those relating to judicial proceedings, there are Commissioners of the customs, See Customs.

Commissioners of excise, See Excise.

Commissioners of the navy, See Navy.

Lords Commissioners of the treasury, See Treasury and Exchequer.

COMMITTEE, one or more persons, to whom the confideration or ordering of a matter is referred, either by some court, or by the consent of parties, to whom it belongs.

COMMITTEE of parliament, a certain number of members appointed by the house, for the examination of a bill, making a report of an inquiry, proceeds of the house, &c.

When a parliament is called, and the speaker and members have taken the oaths, there are committees appointed to sit on certain days, viz. the committee of privileges and elections, of religion, of trade, &c., which are standing committees.

Sometimes the whole house resolves itself into a committee; on which occasion each person has a right to speak and reply as often as he pleases, which is not the case when a house is not in a committee.

COMMISSARY, in a military sense, is of three sorts.

COMMISSARY-general of the mullers, an officer appointed to muster the army, as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact state of the strength of the army.

COMMISSARY-general of stores, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

COMMISSARY-general of provisons, an officer who has the inspection of the bread and provisions of the army.

COMMISSION, in common-law, the warrant or letter-patent which all persons exercising jurisdiction have to empower them to hear or determine any cause or suit, as the commission of the judges, &c.

COMMISSION of bankruptcy, is the commission that issues from the lord chancellor, on a person's becoming a bankrupt within any of the statutes, directed to certain commissioners appointed to examine into it, and to secure the bankrupt's lands and estates for the satisfaction of his creditors.

COMMISSION of lunacy issues out of the court of chancery, to inquire whether a person represented to be a lunatic be so or not.

COMMISSION, in commerce, See Factorage.

COMMISSIONER, a person authorized by commission, letters-patent, or other lawful warrant, to examine any matters, or execute any public office, &c.

COMMODATE, in Scots law, is a gratuitous loan, wherein the property of the thing but continues with the lender, and only the use of it given to the borrower, who must restore the individual thing borrowed. See Scots Law, title, Obligations and contracts in general.

COMMODITY, in a general sense, denotes all sorts of wares and merchandizes whatsoever that a person deals in.

Staple Commodities, such wares and merchandizes as
are commonly and readily fold in a market, or export-
ed abroad: being, for the most part, the proper pro-
duce or manufacture of the country.

COMMODORE, in maritime affairs, an officer of the
British navy, commissioned by the lords of the admiral-
ty, or by an admiral, to command a squadron of men
of war in chief.

COMMON, something that belongs to all alike, in
contradistinction to proper, peculiar, 

COMMON COUNCIL. Council.

COMMON LAW, that body of rules received as law in
England, before any statute was enacted in parlia-
ment to alter the same. See Law.

COMMON PLACE BOOK, is a register of what things oc-
cur, worthy to be noted, in the course of a man's
thinking or study, so disposed, as that, among a number
of subjects, any one may be easily found. The ad-
vantages of making a common-place book are many:
it not only makes a man read with accuracy and at-
tention, but induces him infensibly to think for him-
self, provided he considers it not so much as a regi-
ger of sentiments that strike him in the course of read-
ing, but as a register of his own thoughts upon vari-
ous subjects. Many valuable thoughts occur even to
men of no extraordinary genius. These, without the
assistance of a common place-book, are generally lost
both to himself and others. There are various me-
ths of arranging common-place books; that of Mr
Locke is as good as any that have hitherto been con-
trived.

The first page of the book you intend to take down
their common place in, is to serve as a kind of index
to the whole; and to contain references to every place
or matter therein: in the commodious contrivance of
which index, so as it may admit of a sufficient copia
or variety of materials, without any confusion, all the
secret of the method confines.

In order to this, the first page, as already mention-
ed, or, for more room, the two first pages that front
each other, are to be divided, by parallel lines, into
25 equal parts; whereas, every fifth line to be distin-
guished, by its colour or other circumstance. These
lines are to be cut perpendicularly by others, drawn
down from top to bottom; and in the several spaces thereof,
the several letters of the alphabet, both capital and
minuscule, are to be duly wrote.

The form of the lines and divisions, both horizon-
tal and perpendicular, with the manner of writing the
letters therein, will be conceived from the following
specimen; wherein, what is to be done in the book
for all the letters of the alphabet, is here shown in the
first four, A, B, C, and D.

<table>
<thead>
<tr>
<th>A</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>o u</td>
</tr>
</tbody>
</table>

The index of the common-place book thus formed,
matters are ready for the taking down any thing
therein.

In order to this, consider to what head the thing
you would enter is most naturally referred; and under
which one would be led to look for such a thing:
in this head, or word, regard is had to the initial let-
ter, and the first vowel that follows it; which are the
characteristic letters whereon all the use of the index
depends.

Suppose, (e. gr.) I would enter down a passage that
refers to the head Beauty; B, I consider, is the initial
letter, and e the first vowel; then, looking upon the
index for the partition B, and therein the line e, (which is the place for all words whose initial letter
is B, and first vowel e; as Beauty, Benevolence,
Bread, Breeding, Blemishes,) and finding no num-
bers already down to direct me to any page of the
the book where words of this characteristic have been
entered, I turn forward to the first blank page I find,
which, in a fresh book, as this is supposed to be, will
be page 2, and here write what I have occasion for on
the head Beauty; beginning the head in the margin,
and indenting all the other subordinate lines, that the
head may stand out and show itself: this done, I en-
ter the page where it is wrote, viz. 2, in the index,
in the space, B e; from which time, the class B e
becomes wholly in possession of the 2d and 3d pages,
which are consigned to letters of this characteristic.

Had I found any page or number already entered in
the space B e, I must have turned to the page, and
have wrote my matter in what room was left therein:
so, if after entering the passage on beauty, I should
have occasion for benevolence, or the like, finding the
number 2 already possessed of the space of this cha-
acteristic, I begin the passage on benevolence in the
remainder of the page, which not containing the whole,
I carry it on to page 3, which is also for B e; and
add the number 3 in the index.

COMMON PLEAS is one of the king's courts now held
constantly
Common, in law, that foil, the use of which is composite in that of common prayer in the church of England. The chief judge of this court is called lord chief justice of the common pleas, who is assisted by three other judges: the other officers of the court are the custos breviarium, who is the chief clerk; three prothonotaries, and their secondaries; the clerk of the warrants, clerk of the seals, clerk of the outlawries, clerk of the journals, forty exchequers, a clerk of the juries, the chirographer, the clerk of the king's silver, clerk of the treasury, clerk of the seal, clerk of the outlawries, clerk of the inrolment of fines and recoveries, and clerk of the errors. Common, in grammar, denotes the gender of nouns, which are equally applicable to both sexes: thus parent, a parent, is of the common gender. Common, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures. Common divisor, a quantity or number which exactly divides two or more other quantities or numbers, notwithstanding any remainder. COMMONER, or Gentleman Commoner, in the universities, a student entered in a certain rank. COMMONS, or House of Commons a denomination given to the lower house of parliament. See Parliament. Commons, or Commonalty, likewise signifies the whole body of the people under the degree of a baron, whether knights, gentlemen, burgesses, yeomen, &c. Doctors Commons, See College of Civilians. Proctor of the Commons. See Proctor. COMMONTY, in Scots law, sometimes signifies lands belonging to two or more common proprietors; sometimes a heath or moor though it should belong in property to one, if there has been a promissory possession upon it by pasturage: and the act 1605 mentions commonits belonging in property to the king and to royal boroughs. See title, Obligations arising from consent. COMMONWEALTH. See Republic. COMMUNICATION, in a general sense, the act of imparting something to another. Communication is also used for the connection of one thing with another, or the passage from one place to another: thus a gallery is a communication between two apartments. COMMUNICATION of idioms, in theology, the act of imparting the attributes of one of the natures in Jesus Christ to the other. COMMUNICATION of motion, the act whereby a body at rest is put into motion by a moving body; or, it is the acceleration of motion in a body already moving. See Mechanics. Lines of Communication, in military matters, trenches made to continue and preserve a safe correspondence between two forts or posts; or at a siege, between two approaches, that they may relieve one another. COMMUNION, in matters of religion, the being united in doctrine and discipline; in which sense the word, different churches are said to hold communion with each other. In the primitive Christian church, every bishop was obliged, after his ordination, to send circular letters to foreign churches, to signify that he was in communion with them. The three great communions into which the Christian church is at present divided, is that of the church of Rome, the Greek church, and the Protestant church: but originally all Christians were in communion with each other, having one common faith and discipline. Communication is also used for the act of communicating in the sacrament of the eucharist, or the Lord's supper. See Religion. Communication service, in the liturgy of the church of England, the office for the administration of the holy sacrament, extracted from several ancient liturgies, as those of St Basil, St Ambrose, &c. By the last rubric, part of this service is appointed to be read every Sunday and holyday, after the morning prayer, even though there be no communicants. COMMUNITY, a society of men living in the same place, under the same laws, the same regulations, and the same customs. Commutation, in law, the change of a penalty or punishment from a greater to a less; as when death is commuted for banishment, &c. COMORIN, or Cape Comorin, the most southerly point of the hither India, lying north-west of the island of Ceylon. COMPACT, in physiology, is said of bodies which are of a clofe, dense, and heavy texture, with few pores, and very small. Company, in a commercial sense, is a society of merchants, mechanics, or other traders, joined together in one common interest. When there are only two or three joined in this manner, it is called a partnership; the term company being restrained to societies consisting of a considerable number of members associated together by a charter obtained from the prince. The mechanics of all corporations, or towns incorporated, are thus erected into companies, which have charters of privileges and large immunities. We
We shall here give some account of the principal companies of merchants, some of which trade with joint flocks, and all of them enjoy by charter many exclusive privileges: for however injurious these companies may, at this time of day, be reckoned to the nation in general, yet it is certain, that they were the original parents of all our foreign commerce; private traders upon their own bottom being discouraged from hazarding their fortunes in foreign countries, till the methods of traffic had been settled by joint-flock companies: and from this very principle it is, that we find several nations at present endeavouring to extend their trade by the same means. The most ancient trading company, in Britain, is the Hamburgh company, originally called merchants of the staple, and afterwards merchant-adventurers: they were incorporated by king Edward IV. from which time they traded with success till the reign of queen Elizabeth, who, for a farther encouragement of their industry, not only confirmed, but enlarged their privileges. However, it ought to be observed, that this trade is now open to private merchants, upon paying the small sum to the company. The company of this kind, next incorporated, was that of the Russian merchants, who, having improved their trade and commerce in those remote parts, were incorporated by Edward VI. greatly encouraged by queen Mary, and had their confirmation, with an enlargement of their privileges, from Elizabeth. This company is not very considerable at present; the trade of those parts being mostly carried on by private merchants, on paying the sum of 5l. to the company.

The Eastland company, formerly called merchants of Elbin, were incorporated by queen Elizabeth, and by her greatly encouraged; but, like the former company, it is now become inconsiderable, the trade of Norway and Sweden being laid open by act of parliament.

The Turkey, or Levant company, was likewise incorporated by the same princes, and its charter confirmed and enlarged by king James I. who impowered them to trade to the Levant, or eastern parts of the Mediterranean; particularly to Smyrna, Aleppo, Alexandria, Grand-Cairo, and the other parts of the Turkish dominions. But this trade is now also laid open to private merchants, upon paying a small consideration.

The next in order is the East-India company, first incorporated in the year 1600, and impowered to trade to all countries lying eastward of the cape of Good Hope. Towards the end of king William's reign, an act of parliament passed, granting all private merchants, who should raise a certain sum for the supply of the government, the privilege of trading to those parts. Accordingly, a great many subscribed, and were called the new East-India company; which soon found it necessary to unite with the old one, and trade with one joint flock: since which time, they have been styled the united East-India company; and are at present in a flourishing condition, and in possession of many considerable forts and factories on the coast of Malabar, the Coromandel-coast, the bay of Bengal, &c.

The royal African company was first created in the year 1661, with an exclusive privilege to trade from cape Blanc, on the coast of Africa, in 20° N. lat. as far as the cape of Good Hope. But this trade is now laid open by act of parliament.

The Eastland company, the Greenland company, the Hudson's-bay company, the South-sea company, have likewise their several charters and privileges for trading to the places from which they take their denominations.

These are the principal trading company's belonging to the crown of Great Britain; and of a similar nature are the Dutch East and West India companies, the French East and West India companies, &c.

Concerning these companies, it may be proper to remark, that however necessary they might be in the infancy of trade, they are now looked upon by most men in the light of monopolies: hence it is, that their privileges have from time to time been lessened, in order to establish an absolutely free and general trade; and experience hath shewn, that the trade of the nation has advanced in proportion as monopolies have been laid aside. Indeed, to carry on trade with distant countries, where forces and forts are to be maintained, a company with a joint flock seems necessary; or, at least, certain duties ought to be paid by all who trade therewith, towards defraying the said expenses: for not to speak of the East-India, Hudson's bay, &c. companies, the expense of maintaining whole forts must be very considerable, even the Turkey, Hamburgh, Muscovy, and Eastland companies, which do not trade with a joint flock, are nevertheless obliged to be at considerable charges, in making presents to the grand seignior and his ministrers, maintaining consuls, &c. It would therefore be unjust that any should trade to the places within their charters, without paying the same duties towards the company's charge, as the present adventurers pay; but then there appears to be no reason why any of the king's subjects should be barred from trading to those places, or forced to pay a great fine for admission, that are willing to pay the company's duties, and submit to their regulations and orders in other respects.

On the whole, as all restrictions of trade are found to be hurtful, nothing can be more evident than that no company whatsoever, whether they trade in a joint flock, or only under regulation, can be for the public good, except it may be easy for all or any of his majesty's subjects to be admitted into all or any of the said companies, at any time, and for a very inconsiderable fine.

Company, in military affairs, a small body of foot, commanded by a captain, who has under him a lieutenant and ensign.

The number of centinels or private soldiers in a company, may be from 50 to 80; and a battalion consists of thirteen such companies, one of which is always grenadiers, and posted on the right: next them stand the eldest company, and on the left the second company;
the youngest one being always posted in the centre.

Companies not incorporated into regiments are call-
ed irregulars, or independent companies.

Artillery Company. See Artillery.

Company of Ships, a fleet of merchantmen, who make
a charter-party among themselves; the principal con-
ditions whereof usually are, that certain vessels shall
be acknowledged admiral, vice-admiral, and rear-
admiral; that such and such signals shall be observed;
that those which bear no guns, shall pay so much per
cent. of their cargo; and in case they be attacked,
that what damages are sustained, shall be reimbursed
by the company in general. In the Mediterranean, such
companies are called conserves.

Comparative Anatomy, is that branch of anatomy
which considers the secondary objects, or the bodies
of other animals; serving for the more accurate dif-
finitions of several parts, and supplying the defect of
human subjects.

It is otherwise called the anatomy of beasts, and
sometimes zootomy; and stands in contradistinction to
human anatomy, or that branch of the art which con-
siders the human body, the primary object of anatomy.
See Anatomy.

Comparative Degree, among grammarians, that be-
tween the positive and superlative degrees, expressing
any particular quality above or beneath the level of
another.

Comparison, in a general sense, the consideration of
the relation between two persons or things, when oppo-
sed and set against each other, by which we judge
of their agreement or difference.

Instructiion is the principal, but not the only end of
comparison. It may be employed with success in put-
ing a subject in a strong point of view. A lively idea
is formed of a man's courage by likening it to that of
a lion; and eloquence is exalted in our imagination by
comparing it to a river overflowing its bank, and in-
volving all in its impetuous course. The same effect
is produced by contrast: A man in prosperity becomes
more feizable of his happiness, by comparing his con-
dition with that of a person in want of bread. Thus
comparison is subservient to poetry as well as to phi-
losophy.

Comparisons serve two purposes: when addressed
to the understanding, their purpose is to instruct; when
to the heart, their purpose is to please. Various
means contribute to the latter: first, the suggesting
some unusual resemblance or contrast; second, the
setting an object in the strongest light; third, the
associating an object with others that are agreeable;
fourth, the elevating an object; and, fifth, the de-
pressing it. And that comparisons may give pleasure
by these various means, will be made evident by ex-
amples, which shall be given, after premising some ge-
neral observations.

Objects of different senses cannot be compared to-
gether; for such objects are totally separated from
each other, and have no circumstance in common to
admit either resemblance or contrast. Objects of hear-
ing may be compared together, as also of taste, of
smell, and of touch: but the chief fund of comparison
are objects of sight: because, in writing or speaking,
things can only be compared in idea, and the ideas of
sight are more distinct and lively than those of any
other sense.

When a nation emerging out of barbarity begins to
think of the fine arts, the beauties of language cannot
long lie concealed; and when discovered, they are ge-
nerally, by the force of novelty, carried beyond all
bounds of moderation. Thus, in the earliest poems of
every nation, we find metaphors and similes founded on
the lightest and most distant resemblances, which, losing
their grace with their novelty, wear gradually out of re-
pute; and now, by the improvement of taste, no meta-
phor nor simile is admitted into any polite composition
but of the most-striking kind. To illustrate this obser-
vation, a specimen shall be given; after which several
metaphors as we have been describing; with respect to similes
take the following specimen.

"Behold, thou art fair, my love: thy hair is as a
flock of goats that appear from Mount Gilead: thy
teeth are like a flock of sheep from the wailing, e-
evone bearing twins: thy lips are like a thread
of scarlet: thy neck like the tower of David built
for an armoury, whereon hang a thousand shields of
mighty men: thy two breasts like two young roes
that are twins, which feed among the lilies: thy
eyes like the fifth pools in Hebron, by the gate of
Bath-rabbim: thy nose like the tower of Lebanon,
looking toward Damascus." Song of Solomon.

"Thou art like snow on the heath; thy hair like
the mist of Cromla, when it curls on the rocks and
shines to the beam of the west: thy breasts are like
two smooth rocks seen from Branno of the streams:	hy arms like two white pillars in the hall of the
mighty Fingal." Fingal.

It has no good effect to compare things by way of fi-
mile that are of the same kind; nor to contrast things of
different kinds.

A numerous brigade hasten'd: as when bands
Of pioneers with spade and pick-ax arm'd,
Forerun the royal camp to trench a field
Or call a rampart.

Milton.

The following is of things contrasted that are of dif-
ferent kinds.

Queen. What, is my Richard both in shape and
mind
Transform'd and weak? Hath Bolinbrooke depos'd
Thine intellect? Hath he been in thy heart?
The lion, dying, thrusteth forth his paw,
And wounds the earth, if nothing else, with rage
To be o'erpower'd: and wilt thou, pupil like.
Take thy correction mildly, kiss the rod,
And fawn on rage with base humility?

Richard II. act 5. sc. 1.

This comparison has scarce any force: a man and a
lion are of different species, and therefore are proper sub-
jects for a simile; but there is no such resemblance be-
tween them in general, as to produce any strong effect by
contrasting particular attributes or circumstances.

A third general observation is, That abstract terms
can
can never be the subject of comparison, otherwise than by being personified. Shakespeare compares adversity to a road, and flander to the bite of a crocodile; but in such comparisons these abstract terms must be imagined sensible beings.

To have a just notion of comparisons, they must be distinguished into two kinds; one common and familiar, as where a man is compared to a lion in courage, or to a horse in speed; the other more distant and refined, where two things that have in themselves no resemblance or opposition, are compared with respect to their effects.

There is no resemblance between a flower-plot and a cheerful song; and yet they may be compared with respect to their effects, the emotions they produce in the mind being extremely similar. There is as little resemblance between fraternal concord and precious ointment; yet observe how successfully they are compared with respect to their effects. The emotions they produce in the mind being extremely similar.

For illustrating this sort of comparison, we shall add some more examples:

"Delightful is thy presence, O Fingal! it is like the fun on Cromla, when the hunter mourns his absence for a season, and sees him between the clouds.

"Did not Oflian hear a voice? or is it the sound of days that are no more? Often, like the evening-fun, comes the memory of former times on my soul.

"His countenance is settled from war; and is calm as the evening-beam, that from the cloud of the west looks on Cona's silent vale." Fingal.

We now proceed to illustrate by particular instances the different means by which comparisons, whether of the one sort or the other, can afford pleasure; and, in the order above established, we shall begin with such instances as are agreeable by suggesting some unusual resemblances or contrasts.

Sweet are the ures of Adversity,
Which, like the road, ugly and venomous,
Wears yet a precious jewel in her head.

As you like it, act 2. sc. 1.

See, how the Morning opes her golden gates,
And takes her farewell of the glorious sun;
How well resembles it the prime of youth,
Tripp'd like a yonker prancing to his love.

Second Part Henry VI. act 2. sc. 1.

Thus they their doubtful consultations dark
Ended, rejoicing in their matchless chief:
As when from mountain tops, the dusky clouds
Ascending, while the North-wind sleeps, o'erneath
Heav'n's cheerfull face, the rising element
Scowls o'er the darken'd landscape, snow, and shower;
If chance the radiant fun with farewell sweet
Extends his evening-beam, the fields revive,

The birds their notes renew, and bleating herds
Attein their joy, that hill and valley rings.

Paradise Lost, book 2.

None of the foregoing similes tend to illustrate the principal subject: and therefore the chief pleasure they afford must arise from suggesting resemblances that are not obvious: for undoubtedly a beautiful subject introduced to form the simile affords a separate pleasure, which is felt in the similes mentioned, particularly in that cited from Milton.

The next effect of a comparison in the order mentioned, is to place an object in a strong point of view; which effect is remarkable in the following similes.

As when two scales are charg'd with doubtful loads,
From side to side the trembling scale doth nod,
(While some laborious matron, just and poor,
With nice exactness weighs her woollen store),
Till pois'd aloft, the resting beam suspends
Each equal weight; nor is this nut that descends:
So flood the war, till Hector's matchless might,
With fates prevailing, turn'd the scale of fight.
Fierce as a whirlwind up the wall he flies,
And fires his hoft with loud repeated cries.

Iliad, b. xii. 522.

Out, out, brief candle!
Life's but a walking shadow, a poor player,
That struts and frets his hour upon the stage,
And then is heard no more.

Macbeth, part 5. sc. 5.

O thou Goddefe,
Thou divine nature! how thyfelf thou blazon'd
In these two princely boys! they are as gentle
As zephyrs blowing below the violet,
Not wagging his sweet head; and yet as rough,
(Their royal blood inchaf'd) as the rudest wind,
That by the top doth take the mountain-pine,
And make him ftoop to th' vale.

Cymbeline, act 4. sc. 4.

"Why did not I pass away in secret, like the flower of the rock that lifts its fair head unseen,

Fingal.

"endless, when the sun is setting in the west, and then is heard no more.

Paradise Lost, book 2.

As words convey but a faint and obscure notion of great numbers, a poet, to give a lively notion of the object he describes with regard to number, does well to compare it to what is familiar and commonly known. Thus Homer compares the Grecian army in point of number to a swarm of bees: in another passage he compares it to that profusion of leaves and flowers which appear in the spring, or of insects in a summer's evening: and Milton,

As when the potent rod
Of Amram's son in Egypt's evil day
Wav'd round the coaft, up call'd a pitchy cloud
Of locusts, warping on the easterne wind,
That o'er the realm of impious Pharaoh hung
Like night, and darken'd all the land of Nile:
So numberless were those bad angels seen,
How did not I pass away in secret, like the flower of the rock that lifts its fair head unseen,
And then is heard no more.

Fingal.
Thus Milton, in his description of the rout of the rebel-angels, happily expresses their terror and dismay in the following simile:

As a herd
Of goats or timorous flock together throng'd,
Drove them before him thunder-struck, purfu'd
With terrors and with furies to the bounds
And crystal wall of heav'n, which op'ning wide,
Row'd inward, and a spacious gap difclo's'd
Into the waffeful deep; the moniftous fight
Strock them with horror backward, but far worfe
Urg'd them behind; headlong themselves they threw
Down from the verge of Heav'n.

By this time the different purposes of comparison, and the various impressions it makes on the mind, are sufficiently illustrated by proper examples. This was an easy work. It is more difficult to lay down rules about the propriety or impropriety of comparisons; in what circumstances they may be introduced, and in what circumstances they are out of place. It is evident, that a comparison is not proper upon every occasion: a man in his cool and sedate moments, is not disposed to poetical flights, nor to sacrifice truth and reality to the delusive operations of the imagination; far less is he so disposed, when - press'd with care, or interested in some important transaction that occupies him totally. On the other hand, it is observable, that a man, when elevated or animated by any passion, is disposed to elevate or animate all his subjects; he avoids familiar names, exalts objects by circumlocution and metaphor, and gives even life and voluntary action to inanimate beings. In this warmth of mind, the highest poetical flights are indulged, and the boldest similes and metaphors refined. But without fearing so high, the mind is frequently in a tone to regard chaste and moderate ornament; such as comparisons that let the principal subject in a strong point of view, or that embellish and diversify the narration. In general, when by any animating passion, whether pleasant or painful, an impulse is given to the imagination; we are in that condition disposed to every fort of figurative expression, and in particular to comparisons. This in a great measure is evident from the comparisons already mentioned; and shall be further illustrated by other instances. Love, for example, in its infancy, routing the imagination, prompts the heart to display itself in figurative language, and in similes:

Troilus. Tell me, Apollo, for thy Daphne's love,
What Crefclid is, what Pandar, and what we?
Her bed is India, there she lies, a pearl:
Between our Ilium, and where she resides,
Let it be call'd the wild and wandering flood;
Ourself the merchant, and this failing Pandar
Our doubtful hope, our convoy, and our bark.

Troilus and Crefcida, act 1. sc. 1.

Again:
Come, gentle Night; come, loving black-brow'd
Night!
Give me my Romeo; and, when he shall die,
Take him, and cut him out in little stars,
And he will make the face of heav'n so fine,

As rufheth a foamy flream from the dark shady
sleepe of Cromla, when thunder is rolling above,
and dark brown night reits on the hill: so fierce,
so vast, so terrible, rush forward the sons of Erin.
The chief, like a whale -of Ocean followed by all
its billows, pours valour forth as a flream, rolling
its might along the shore.

Richard II. act 3. sc. 5.

As when a vulture on Imaus bred,
Whole snowy ridge the roving Tartar bounds,
Dilodging from a region scarce of prey
To gorge the fleth of lambs, or yeading kids,
On hills where flocks are fed. flies toward the springs
Of Ganges or Hydapses, Indian streams,
But in his way lights on the barren plains
Of Sericana, where Chinefes drive
With fails and winds their cany waggons light:
So on this windy sea of land, the fiend
Walk'd up and down alone, bent on his prey.

Milton  b. 3.

Next of comparifons that aggrandize or elevate. Those affect us more than any other fort: the reason of which will be evident from the following similes.

As when a flame the winding valley fills,
And runs on crackling flubs between the hills,
Then o'er the fluffy up the mountain flies,
Fires the high woods, and blazes to the skies,
This way and that, the fpreading torrent roars;
And runs on crackling fhiubs between the hills,
As when a flame the winding valley fills,
Next of comparifons that aggrandize or elevate. The last article mentioned, is that of kindling or de-

Methinks, King Richard and myself should meet
With no lefs terror than the elements
Of fire and water, when their thundering ftruck,
At meeting tears the cloudy checks of heaven.

Richard II. act 3. sc. 5.

The laft article mentioned, is that of lightening or de-

Fingal, b. 1.
That all the world shall be in love with Night,
And pay no worship to the garish sun.

Rome and Juliet, act 3, sc. 4.

But it will be a better illustration of the present head, to give examples where comparisons are improperly introduced. Simes are not the language of a man in his ordinary state of mind, dispatching his daily and usual work; for that reason, the following speech of a gardener to his servant, is extremely improper:

Go bind thou up yon dangling apricocks,
Which, like unruly children, make their fire
Stoop with oppression of their prodigal weight:
Go thou, and, like an executioner,
Cut off the heads of too-fall-growing sprays,
That look too lofty in our commonwealth;
All must be even in our government.

Richard II. act 3, sc. 7.

The fertility of Shakespeare’s vein betrays him frequently into this error.

Rooted grief, deep anguish, terror, remorse, despair, and all the severe dispiriting passions, are declared enemies, perhaps not to figurative language in general, but undoubtedly to the pomp and solemnity of comparison.

Upon this account, the simile pronounced by young Rutland, under terror of death from an inveterate enemy, and not disposed to heighten or illustrate his discourse by similes,

So looks the pent-up lion o’er the wretch
That trembles under his devouring paws;
And fo he comes to rend his limbs afunder.

The latter of the two similes is good: the former, because of the faintness of the resemblance, produces no good effect, and crowds the narration with an useless interlude.

A man spent and dispirited after losing a battle, is not disposed to heighten or illustrate his discourse by similes.

York. With this we charg’d again; but out! alas,
We bodg’d again; as I have seen a swan
With bootless labour swim against the tide,
And spend her strength with over-matching waves.
Ah! hark, the fatal followers do pursue;
And I am faint and cannot fly their fury.
The sands are number’d that make up my life;
Here must I stay, and here my life must end.

Third part Henry VI. act 1, sc. 6.

Similes thus unseasonably introduced, are finely ridiculed in the Rehearsal.

“Bayes. Now here the must make a simile.

“Smith. Where’s the necessity of that, Mr Bayes?

“Bayes. Because she’s surpriz’d; that’s a general rule; you must ever make a simile when you are surpriz’d; ’tis a new way of writing.”

A comparison is not always faultless even where it is properly introduced: A comparison, like other human productions, may fall short of its end; of which defects inferences are not rare even among good writers: and to complete the present subject, it will be necessary to make some observations upon such faulty comparisons. Nothing can be more erroneous than to institute a comparison too faint; a distant resemblance or contrast falsifies the mind with its obscurity, instead of amusing it; and tends not to fulfil any one end of a comparison. The following similes seem to labour under this defect.

K. Rich. Give me the crown.—Here, coufin, seize the crown.

Here, on this side, my hand; on that side, thine.
Now is the golden crown like a deep well,
That owes two buckets, filling one another;
The emptier ever dancing in the air,
The other down, unseen and full of water;
That bucket down, and full of tears, am I,
Drinking my griefs, whilst you mount up on high.

Richard II. act 4, sc. 3.

K. John. Oh! cousin, thou art come to let mine eye;
The tackle of my heart is crack’d and burnt;
And all the strings wherewith my life should fail,
Are turned to one thread, one little hair:
My heart hath one poor string to stay it by,
Which holds but till thy news be uttered.

King John, act 5, sc. 10.

Tork. My uncles both are slain in relieving me;
And all my followers to the eager foe
Turn back, and fly like ships before the wind,
Or lambs pursu’d by hunger starved wolves.

Third part Henry VI. act 1, sc. 6.

The latter of the two similes is good: the former, because of the faintness of the resemblance, produces no good effect, and crouds the narration with an useless image.

In an epic poem, or in any elevated subject, a writer ought to avoid raising a simile upon a low image, which never fails to bring down the principal subject. In general, it is a rule, that a grand object ought never to be resembled to one that is diminutive, however delightful the resemblance may be; for it is the peculiar character of a grand object to fix the attention, and swell the mind; in which state, it is disagreeable to contract the mind to a minute object, however elegant. The resembling an object to one that is greater, has, on the contrary, a good effect, by raising or swelling the mind:

Meanwhile the troops beneath Patroclus’ care,
Invade the Trojans, and commence the war.
As wasps, provok’d by children in their play,
Pour from their manlions by the broad highway,
In swarms the guiltless traveller engage.
As wafps, provok’d by children in their play,
Pour from their manlions by the broad highway,
All rise in arms, and with a general cry
Assail their waxen domes and buzzing progeny:
Thus from the tents the fervent legion swarms,
So loud their clamours, and so keen their arms.

IIIad, xvi. 312.

So burns the vengeful hornet (fool all o’er)
Reign’d in vain, and thirty fill of gore; (Bold son of air and licent)
on angry wings
Untam’d, untir’d, he turns, attacks, and slings.

3 R Fir’d
Sir'd with like ardour, fierce Atrides flew,
And sent his foul with ev'ry lance he threw.

An error opposite to the former, is the introducing a
refembling image, fo elevated or great as to bear no propor-
tion to the principal subjéct. Their remarkable dif-
parity, being the most striking circumstance, feizes the
mind, and never fails to deprefs the principal subjéct by
contrast, instead of raifing it by refemblance; and if the
difparity be exceeding great, the fimile takes on an air
of burlefque; nothing being more ridiculous than to
force an object out of its proper rank in nature, by e-
qualling it with one greatly superior or greatly inferior.
This will be evident from the following comparifon.

Loud as a bull makes hill and valley ring,
So roar'd the lock when it releas'd the spring.

Such a fimile upon the fimpleft of all actions, that of o-
pening a lock, is pure burlefque.

A writer of delicacy will avoid drawing his compar-
fions from any image that is naufeous, ugly, or remarka-
ibly difagreeable; for however strong the refemblance
may be, more will be loft than gained by such compar-
ifon. Therefore we cannot help condemning, though
with some reluctance, the following fimile, or rather me-
taphor.

O thou fond many! with what loud applause
Did't thou beat hear'n with bleffing Bolingbroke
Before he was what thou would'lt have him be?
And now being trimm'd up in thine own defires,
That thou provok'dst thyself to cast him up.
And fo, thou common dog, didst thou difgorge
Thy glutton bofom of the royal Richard,
And now thou would'lt eat thy dead vomit up,
And how'lft to find it.

Second part Henry IV. at 1. fe. 6.

The strongeft objection that can lie againft a compar-
is, that it conflits in words only, not in fenfe.
Such falfe coin, or baftard wit, does extremely well in
burlefque; nothing being more ridiculous than to
force an object out of its proper rank in nature, by e-
qualling it with one greatly superior or greatly inferior.
This will be evident from the following comparifon.

Where the subjéct is burlefque or ludicrous, such
fimiles are far from being improper. Horace fays plea-
santly,

Quamquam tu levis cortice.

And Shakefpear,

In breaking oaths he's stronger than Hercules.
And this leads to obferve, that besides the foregoing
comparifons, which are all ferious, there is a fpecies, the
end and purpofe of which is to excite gaiety or mirth.
Take the following examples.

Falstaff, fpeaking to his page:

"I do here walk before thee, like a few that hath
"overwhelmed all her litter but one."

Second part Henry IV. at 1. fe. 10.

"I think he is not a pick-purfe, nor a horfe steal-
er; but for his verity in love, I do think him as
"concave as a cover'd goblet, or a worm-eaten nut."

As you like it, at 3. fe. 10.

This word a dagger had his page,
That was but little for his age;
And therefore waited on him fo,
As dwarfs upon knights-errant do.

Hudibras, canto 1.

"Books, like men, their authors, have but one
"way of coming into the world; but there are ten
"thousand to go out of it, and return no more."

Tale of a Tub.

"The moft accomplifhed way of uſing books at
"prefent is, to serve them as fome do lords, learn
"their titles, and then brag of their acquaintance."

Ibid.

"He does not confider, that fincerity in love is as
"much out of fashion as sweet snuff; no body takes
"it now."

Carelfa's Husband.

Comparison of ideas, that operation of the mind
whereby it compares its ideas one with another, in
regard of extent, degree, time, place, or any other
circumftance, and is the ground of relations.

Comparison, in grammar, the infledtion of the compa-
rative degree.

COMPARTITION, in architecture, denotes the com-
pative degree.

COMPARTIMENT, in general, is a design compro-
of
A compartment of tiles, or bricks, is an arrangement of different colours, and varnished, for the decoration of a building. Compartments, in gardening, are an assemblage of beds, plots, borders, walks, &c. disposed in the most advantageous manner that the ground will admit of. Compartments, in heraldry, are otherwise called partitions.

COMPASS, or mariner's Compass, an instrument whereby the ship's course is determined. See Navigation.

Azimuth Compass. See Navigation.

Compass dials, are small horizontal dials, fitted in brass or silver boxes, for the pocket, to shew the hour of the day, by the direction of a needle, that indicates how to place them right, by turning the dial about, till the cock or style stand directly over the needle, and point to the northward: but these can never be very exact, because of the variations of the needle itself. See Dialing.

COMPASSES, or pair of COMPASSES, a mathematical instrument for describing circles, measuring figures, &c.

The common compasses consist of two sharp-pointed branches, or legs, of iron, steel, brass, or other metal, joined at top by a rivet, whereon they move as on a centre.

The principal perfection of this, as of all other compasses, consists in the easy and uniform opening and shutting of their legs; one of which may be taken out, in order to make room for others.

There are now used compasses of various kinds and contrivances, accommodated to the various uses they are intended for.

COMPEIGN, a city of France, situated on the river Oyse, about forty-five miles north-east of Paris: Long. 3°, N. lat. 49° 30'.

COMPENDIUM, in matters of literature, denotes much the same with epitome or abridgment. See ABRIDGMENT.

COMPENSATION, in a general sense, the uniting or compounding of several things. See Term, and Idea.

COMPLEXION, among physicians, the temperament, habit, and natural disposition of the body, but more often the colour of the face and skin.

Complex terms, or ideas, in logic, are such as are compounded of several simple ones. See Term, and Idea.

Complexion, in Scots law: In echeats, fee title, Extinction in moveables.

Compitalia, or Compitalitia, in Roman antiquity, feasts instituted by Servius Tullius in honour of the Lares. See LAKES.

These feasts were obsered on the 12th of January, and 6th of March.

COMPLEMENT, in geometry, is what remains of a quadrant of a circle, or of 90°, after any certain arch has been taken away from it. Thus, if the arch taken away be 40°, its complement is 50°: because 50+40=90. The fine of the complement of an arch is called the co-fine, and that of the tangent the cotangent, &c.

COMPLEX, in a more general sense, a term synonymous with compound; though, in strictness of speech, there is some difference. See Compound.

COMPOSITION, in a general sense, the blending, or rather interweaving, of several different things together: thus a person afflicted with several disorders at the same time, is said to labour under a complication of diseases.

Compound, Compone, or Gobony, in heraldry, is said of a bordure made up of angular parts, or chequers, of two different colours. See Plate LXV.

Composite, in general, denotes something compounded, or made up of several others united together. Thus, Composite numbers, are such as can be measured exactly by a number exceeding unity: as 6 by 2 or 3, or 10 by 5, &c. so that 4 is the lowest composite number.

Composition of ideas, an act of the mind, whereby it unites several simple ideas into one conception or complex idea.

When we are provided with a sufficient stock of simple ideas, and have by habit and use rendered them familiar to our minds, they become the component parts of other ideas still more complicated, and form what we may call a second order of compound notions. This process may be continued to any degree of composition we please, mounting from one stage to another, and enlarging the number of combinations.

Composition, in grammar, the joining of two words together; or prefixing a particle to another word, to augment, diminish, or change its signification.

Composition, in logic, a method of reasoning, where-
by we proceed from some general self-evident truth, to other particular and singular ones.

In disposing and putting together our thoughts, there are two ways of proceeding, equally within our choice: for we may propose the truths, relating to any part of knowledge, as they presented themselves to the mind, in the manner of investigation; carrying on the series of proofs in a reverse order, till they, at last, terminate in first principles: or, beginning with these principles, we may take the contrary way, and from them deduce, by a direct train of reasoning, all the several propositions we want to establish.

This diversity, in the manner of arranging our thoughts, gives rise to the twofold division of method established among logicians; the one called analytic method, or the method of resolution, inasmuch as it traces things back to their source, and resolves knowledge into its first and original principles. This method stands in contradistinction to the method of composition; or, as it is otherwise called, the synthetic method: for here we proceed by gathering together the several scattered parts of knowledge, and combining them into one system, in such a manner, as that the understanding is enabled distinctly to follow truth through all the different stages of gradation.

Composition, in music, the art of disposing musical sounds into airs, songs, &c. either in one or more parts, to be sung by a voice, or played on instruments. See Music, and Song.

Under composition are comprehended the rules, 1. Of melody, or the art of making a single part; that is, contriving and disposing the simple sound, so as that their succession and progression may be agreeable to the ear. See Melody.

2. Of harmony, or the art of disposing and concerting several single parts together, so as that they make one agreeable whole. See Harmony.

COMPOSITION, in literature, the art of forming and arranging sentiments, and cloathing them with language suitable to the nature of the subject or discourse. We shall first give a few thoughts on original composition; and, 2dly, by way of example, unfold the nature of epic and dramatic compositions.

1. On Original Composition.

The mind of a man of genius is a fertile and pleasant field; pleasant as Elysium, and fertile as Tempe; it enjoys a perpetual spring. Of that spring, originals are the fairest flowers; imitations are of quicker growth, but fainter bloom. Imitations are of two kinds; one of nature, one of authors: the first we call originals, and confine the term imitation to the second. We shall not enter into the curious inquiry of what is, or is not, strictly speaking, original, content with what all must allow, that some compositions are more so than others; and the more they are so, the better. Originals are, and ought to be, great favourites, for they are benefactors; they extend the republic of letters, and add a new province to its dominion: imitators only give us a sort of dupe of what we had, possibly much better, before; increasing the mere drug of books, while all that makes them valuable, knowledge and genius, are at a stand. The pen of an original writer, like Armida's wand, out of a barren waste calls a blooming spring: out of that blooming spring an imitator is a transplantor of laurels, which sometimes die on removal, always languish in a foreign soil.

But suppose an imitator to be most excellent (and such there are), yet still he but nobly builds on another's foundation; his debt is, at least, equal to his glory; which therefore, on the balance, cannot be very great. On the contrary, an original, though but indifferent (in originality being let aside), yet has something to boast; it is something to lay with him in Horace,

Meo jum pasper in arce;

and to share ambition with no less than Caesar, who declared he had rather be the first in a village, than the second at Rome.

Still farther: an imitator shares his crown, if he has one, with the chosen object of his imitation; an original enjoys an undivided applause. An original may be said to be of a vegetable nature; it rises spontaneously from the vital root of genius; it grows, it is not made: imitations are often a sort of manufacture wrought by those mechanics, art and labour, out of pre-existent materials not their own.

Again: we read imitation with somewhat of his language who listens to a twice-told tale: our spirits rose at an original: that is a perfect stranger, and all through to learn what news from a foreign land: and though it comes, like an Indian prince, adorned with feathers only, having little of weight; yet of our attention it will rob the more solid, if not equally new: thus every telescope is lifted at a new-discovered star; it makes a hundred astronomers in a moment, and denies equal notice to the sun. But if an original, by being as excellent, as new, adds admiration to our prize, then are we at the writer's mercy; on the strong wing of his imagination, we are snatched from Britain to Italy, from climate to climate, from pleasure to pleasure; we have no home, no thought, of our own; till the magician drops his pen; and then falling down into ourselves, we awake to flat realities, lamenting the change, like the beggar who dreamt himself a prince.

It is with thoughts, as it is with words; and with both, as with men; they may grow old and die. Words tarnished, by falling through the mouths of the vulgar, are laid aside as inelegant and obsolete. So thoughts, when become too common, should lose their currency; and we should fend new metal to the mint, that is, new meaning to the press. The division of tongues at Babel did not more effectually debar men from making themselves a name (as the scripture speaks) than the too great concurrence or union of tongues will do for ever. We may as well grow good by another's virtue, or fat by another's food, as famous by another's thought. The world will pay its debt of praise but once; and instead of applauding, explode a second demand, as a cheat.

If it is said, that most of the Latin classics, and all the Greek, except, perhaps, Homer, Pindar, and Anacreon,
creon, are in the number of initiators, yet receive our highest applause; our answer is, that they, though not real, are accidental originals; the works they imitated, few excepted, are lost: they, on their father's decease, enter as lawful heirs on their estates in fame: the fathers of our copyists are still in possession; and secured in it, in spite of Goths, and flames, by the perpetuating power of the press. Very late must a modern imitator's enter as lawful heirs on their estates in fame: the real, are accidental originals; the works they imitated, harvest is over, the great reapers of antiquity having left nothing to be gleaned after them; nor because the human mind's teeming time is past, or because it is incapable of putting forth unprecedented births; but because illustrious examples engross, prejudice and intimidate. They engross our attention, and so prevent a due inspection of ourselves; they prejudice our judgment in favour of their abilities, and so lessen the sense of our own; and they intimidate us with the splendor of their renown, and thus under difficulty bury our strength. Nature's impossibilities, and those of difference, lie wide asunder.

After all, the first ancients had not merit in being originals: they could not be initiators. Modern writers have a choice to make; and therefore have a merit in their power. They may move in the regions of liberty, or more in the loft fitters of early imitation; and imitation has as many plausible reasons to urge, as pleasure had to offer to Hercules. Hercules made the choice of an hero, and so became immortal.

Yet let not afficients of classic excellence imagine, that we deny the tribute it so well deserves. He that admires not ancient authors, betrays a secret he would conceal, and tells the world, that he does not understand them. Let us be as far from neglecting, as from copying, their admirable compositions: sacred be their rights, and inviolable their fame. Let our understanding feed on theirs; they afford the noblest nourishment: but let them nourish, and annihilate, our own. When we read, let our imagination kindle at their charms; when we write, let our judgment shut them out of our thoughts; treat even Homer himself, as his royal admirer was treated by the cynic; bid him stand aside, nor shade our composition from the beams of our own genius: for nothing original can rise, nothing immortal, can ripen, in any other sun.

Must we, then, not imitate ancient authors? Imitate them, by all means; but imitate aright. He that imitates the divine Iliad, does not imitate Homer; but he who takes the same method, which Homer took, for arriving at a capacity of accomplishing a work so great. Tread in his steps to the sole fountain of immortality; drink where he drank, at the true Helicon, that is, at the breast of nature. Imitate; but imitate not the composition, but the nian. For may not this paradox pass into a maxim? viz. "The less we copy the renowned ancients, we shall resembale them the more."

But possibly it may be replied, that we must either imitate Homer, or depart from nature. Not so: for suppose you were to change place, in time, with Homer; then, if you write naturally, you might as well charge Homer with an imitation of you. Can you be said to imitate Homer for writing so, as you would have written if Homer had never been? As far as a regard to nature, and found sense, will permit a departure from your great predecessors; so far, ambitiously, depart from them; the farther from them in similitude, the nearer are you to them in excellence; you rise by it into an original; become a noble collateral, not an humble descendant from them. Let us build our compositions with the spirit, and in the taste of the ancients; but not with their materials: thus will they resemble the structures of Pericles at Athens, which Plutarch commends for having had an air of antiquity as soon as they were built. All eminence, and distinction, lies out of the beaten road; excursions, and deviation, are necessary to find it; and the more remote your path from the highway, the more reputable; if, like poor Gulliver, you fall not into a ditch, in your way to glory.

What glory to come near, what glory to reach, what glory (presumptuous thought!) to surpass our predecessors? And is that then in nature absolutely impossible? or is it not rather contrary to nature to fail in it? Nature herself sets the ladder, all wanting is our ambition to climb. For by the bounty of nature we are as strong as our predecessors; and by the favour of time (which is but another round in nature's scale) we stand on higher ground. As to the first, were they more than men? or are we less? Are not our minds caged in the same mould with those before the flood? The flood affected matter: mind escaped. As to the second, though we are moderns, the world is an ancient; more ancient far, than when they, whom we most admire, filled it with their fame. Have we not their beauties, as stars, to guide; their defects, as rocks, to be shunned; the judgment of ages on both, as a chart to conduct, and a sure helm to steer us in our passage to greater perfection than theirs? And shall we stop in our rival pretensions to fame by this just reproof?

Stat contra, dicitque tibi tua pagina, Fur er.

It is by a fort of noble contagion, from a general familiarity with their writings, and not by any particular fortdid theft, that we can be the better for those who went
went before us. Hope we, from plagiarism, any domination in literature; as that Rome role from a nest of thieves?

Rome was a powerful ally to many states; ancient authors are our powerful allies; but we must take heed, that they do not succour till they inflame, after the manner of Rome. 'Too formidable an idea of their superiority, like a spectre, would fright us out of a proper use of our wits; and dwarf our understanding, by making a giant of theirs. Too great aw for them lays genius under restraint, and denies it that free scope, that full elbow-room, which is requisite for striking its most masterly strokes. Genius is a master-workman, learning is but an instrument, and an instrument, though most valuable, yet not always indispensable. Heaven will not admit of a partner in the accomplishment of some favourite spirits; but rejecting all human means, assumes the whole glory to itself. Have not some, though not famed for erudition, f written, as almost to persuade us, that they shine brighter, and soared higher, for escaping the boated aid of that proud ally?

Nor is it strange; for what, for the most part, mean we by genius, but the power of accomplishing great things without the means generally reputed necessary to that end? A genius differs from a good understanding, as a magician from a good architect; that raises his structure by means invisible; this by the skilful use of common tools. Hence genius has ever been supposed to partake of something divine.

Learning, deitute of this superior aid, is fond, and proud of what has cost it much pains; is a great lover of rules, and boastful of famed examples. As beauties less perfect, who owe half their charms to cautious art, learning inveighs against natural unfstudied graces, and small harmless inaccuracies, and lets rigid bounds to that liberty to which genius often owes its supreme glory; but the no genius its frequent ruin. For unpreferred beauties, and unexamined excellence, which are characteristics of genius, lie without the pale of learning's authorities, and laws; which pale, genius must leap to come at them: but by that leap, if genius is wanting, we break our necks; we lose that little credit, which possibly we might have enjoyed before. For rules, like crutches, are a needful aid to the lame, though an impediment to the strong. A Homer calls them away; and, like his Achilles,

Jura negat foia nata, nihil non arregat,
by native force of mind. There is something in poetry beyond-profe-reason: there are mysteries in it not to be explained, but admired; which render mere prose-men indels to their divinity. And here may be offered a second paradox: erit. "Genius often then deserves merit to be praised, when it is most sure to be condemned; that is, when its excellence, from mounting high, to weak eyes is quite out of sight."

If we might speak farther of learning and genius, we would compare genius to virtue, and learning to riches. As riches are most wanted where there is least virtue; so learning where there is least genius. As virtue without much riches can give happiness; so genius without much learning can give renown. As it is said in Terence, pecuniis negligis interdum maximum est lucrum; so to neglect of learning, genius sometimes owes its greater glory. Genius, therefore, leaves but the second place, among men of letters, to the learned. It is their merit, and ambition, to fling light on the works of genius, and point out its charms. We must greatly reverence their informing radius for that favour; but we must much more admire the radiant stars pointed out by them.

A flare of the first magnitude among the moderns was Shakespeare; among the ancients, Pindar; who, (as Voisin tells us) boasted of his no-learning, calling himself the eagle, for his flight above it. And such genius as these may, indeed, have much reliance on their own native powers. For genius may be compared to the natural strength of the body; learning to the superinduced accoutrements of arms: if the first is equal to the professed exploit, the latter rather encumbers, than assists; rather retards, than promotes, the victory. Saecer no-bis inest Deus, says Seneca. With regard to the moral world, confidence, with regard to the intellectual, genius, is that god within. Genius can let us right in composition, without the rules of the learned; as confidence sets us right in life, without the laws of the land: this, ignis, can make us good, as men: that, fings, as writers, &c., sometimes, make us great.

As too great admirers of the fathers of the church have sometimes set up their authority against the true sense of scripture; so too great admirers of the classical fathers have sometimes set up their authority, or example, against reason.

Neve minor, neve sit qunito produtor aucta fabula.
So says Horace, so says ancient example. But reason has not subscribed. We know but one book that can justify our implicit acquiescence in it: and (by the way) on that book a noble disdain of undue deference to prior opinion has lately call, and is still calling, a new and illuminating light.

But, superition for our predecessors set aside, the classics are for ever our rightful and revered matters in composition; and our understandings bow before them. But when? When a master is wanted; which sometimes is not the case. Some are pupils of nature only, nor go farther to school. From such we reap often a double advantage; they not only rival the reputation of the great ancient authors, but also reduce the number of mean ones among the moderns. For when they enter on subjects which have been in former hands, such is their superiority, that, like a tenth wave, they overwhelm, and bury in oblivion all that went before: and thus not only enrich and adorn, but remove a load, and lessen the labour, of the letter'd world.

"But it may be said, since originals can arise from genius only, and since genius is so very rare, it is scarce worth while to labour a point to much, from which we can reasonably expect so little." To show that genius is not so very rare as you imagine, we shall point out strong instances of it, in a far distant quarter from that mentioned above. The minds of the schoolmen were almost as much cloistered as their bodies: they had but little learning, and few books; yet may the most learned be struck with...
with some alinement at their so singular nature's sagacity, and most exquisite edge of thought. Who would expect to find Pindar and Scoto, Shakespear and Aquinas, of the same party? Both equally shew an original, unindebted, energy: the vigour igneus, and calcis origo, burns in both; and leaves us in doubt whether genius is more evident in the sublime flights and beauteous flowers of poetry, or in the profound penetrations, and marvelously keen and minute distinctions, called the thorns of the schools. There might have been more able confus called from the plough, than ever arrived at that honour: many a genius, probably, there has been, which could neither write nor read. So that genius, that supreme lafrus of literature, is less rare than is generally conceived.

By the praise of genius we detract not from learning; we detract not from the value of gold, by saying that diamond has greater fill. He who disregards learning, shows that he wants its aid; and he that overvalues it, shows that its aid has done him harm. Over-valued indeed it cannot be, if genius as to composition, is valued more. Learning, we thank; genius, we revere; that gives us pleasure, this gives us rapture; that informs, this inspires; and is itself inspired; for genius is from heaven, learning from man: this sets us above the low, and illiterate; that, above the learned, and polite. Learning is borrowed knowledge; genius is knowledge innate, and quite our own. Therefore, as Bacon observes, it may take a nobler name, and be called wisdom; in which sense of wisdom, some are born wise.

Having put in a caveat against the most fatal of errors, from the too great indifference of genius, return we now to that too great suppression of it, which is detrimental to composition; and endeavour to rescue the writer, as well as the man. We have said, that some are born wise; but they, like those that are born rich, by neglecting the cultivation and produce of their own poffessions, and by running in debt, may be beggared at last; and lose their reputations, as younger brothers elates, not by being born with less abilities than the rich heir, but at too late an hour.

Many a great man has been lost to himself, and to the public, purely because great ones were born before him. Hermaeus, in his collections on Homer's blindness, says, that Homer requelling the gods to grant him a sight of Achilles, that hero rose, but in armour so bright, that it struck Homer blind with the blaze. Let not the blaze of even Homer's muse darken us to the discernment of our own powers; which may possibly fet us above the rank of imitators; who, though most excellent, and even immortal, (as some of them are), yet are still but dii minorum gentium, nor can expect the largeft share of incense, the greatest profusion of praise, on their secondary altars.

But farther still: a spirit of imitation hath many ill effects; we shall confine ourselves to three. First, It deprives the liberal and polite artists of an advantage which the mechanic enjoy: in thefe, men are ever endeavouring to go beyond their predeceffors; in the former, to follow them. And since copies surpass not their originals, as streams rife not higher than their spring, rarely so high; hence, while arts mechanical are in perpetual progress and increase, the liberal are in retrogradation and decay. These re semble pyramids, are broad at bottom, but lessen exceedingly as they rife; those resemble rivers, which, from a small fountain head, are spreading ever wider and wider, as they run. Hence it is evident, that different portions of understanding are not (as some imagine) allotted to different periods of time; for we see, in the fame period, understanding rising in one fet of artists, and declining in another. Therefore nature stands aboveling, and our inferiority in composition must be charged on ourselves.

Nay, so far are we from complying with a necessity which nature lays under, that, secondly, by a spirit of imitation we counteract nature, and thwart her design. She brings us into the world all originals. No two faces, nor two minds, are just alike; but all bear nature's evident mark of separation on them. Born originals, how comes it to pass that we die copies? That meddling ape imitation, as soon as we come to years of indiffen tion, (if we may so speak), matches the pen, and blots out nature's mark of separation, cancels her kind intention, destroys all mental individuality; the letter'd world no longer consists of singulars, it is a medly, a mass; and a hundred books, at bottom, are but one. Why are monks such masters of mimicry? why receive they such a talent at imitation? Is it not as the Spartan slaves received a license for ebulition, that their betters might be ashamed of it?

The third fault to be found with a spirit of imitation is, that with great incongruity it makes us poor and proud: makes us think little, and write much; gives us hopes folly, which are little better than more reputable eclipsions to promote our repose. Have not some seven fold volumes put us in mind of Ovid's seven fold channels of the Nile at the conflagration?

Oftia septem Pulverulenta vacant septem fine flutnine valles.

Such labours are like Lyceurgus's iron money, which was so much less in value than in bulk, that it required barns for strong boxes, and a yoke of oxen to draw five hundred pounds.

But notwithstanding these disadvantages of imitation, imitation must be the lot (and often an honourable lot it is) of most writers. If there is a famine of invention in the land, like Joseph's brethren, we must travel far for food; we must visit the remote and rich ancients: but an inventive genius may safely stay at home; that, like the widow's cruse, is divinely replenished from within, and affords us a miraculous delight. Whether our own genius be such or not, we diligently should inquire, that we may not go a-begging with gold in our purse. For there is a mine in man, which must be deeply dug ere we can conjecture its contents. Another often fees that in us, which we fee not ourselves; and may there not be that in us which is unseen by both? That there may, chance often discovers, either by a luckily chosen theme, or a mighty premium, or an absolute necessity of exertion, or a noble stroke of emulation from another's glory; as that on Thucydides from hearing Herodotus repeat part of his history at the Olympic games. Had there been no Herodotus, there might have been no Thucydides, and the world's
world's admiration might have begun at Livy for excellence in that province of the pen. Demosthenes had the same connexion on hearing Callistatus; or Tully might have been the first of consummate renown at the bar.

Quite clear of the dispute concerning ancient and modern learning, we speak not of performance, but powers. The modern powers are equal to those before them; modern performance in general is deplorably short. How great are the names just mentioned? Yet who will daily affirm, that as great may not rise up in some future, or even in the present age? Reafons there are why talents may not appear, none why they may not exist, as much in one period as another. An evocation of vegetable fruits depends on rain, air, and fun; an evocation of the fruits of genius no less depends on externals. What a marvellous crop bore it in Greece and Rome? And encouragement from the nature of their governments, painting, sculpture, and architecture, a tax levied for the support of a war. Cæfar drops his papers when Tully spoke; and Philip trembled at the voice of Demosthenes. And has there arisen but one Tully, one Demosthenes, in so long a course of years? The powerful eloquence of them both in one stream, should never bear us down into the melancholy persuasion, that several have not been born, though they have not emerged. The fun as much exists in a cloudy day, as in a clear; the first beamings of their yet unsuspected genius on at a lucid meteor in the night; is much surprized; can scarce believe it true. During this happy confusion, it may be said to him, as at Eve at the lake,

What there thou shalt, fair creature, is thyself.

Milton.

Genius, in this view, is like a dear friend in our company under disguise; who, while we are lamenting his absence, drops his mask, striking us at once with equal surprize and joy. This sensation, which we speak of in a writer, might favour, and so promote, the fable of poetic inspiration. A poet of a strong imagination, and stronger vanity, on feeling it, might naturally enough resolve the world's mere compliment, and think himself truly inspired. Which is not improbable; for enthusiasm of all kinds do no left.

Since it is plain, that men may be strangers to their own abilities; and by thinking meanly of them without just cause, may possibly lose a name, perhaps a name immortal; we would find some means to prevent these evils. Whatever promotes virtue, promotes something more, and carries its good influence beyond the mortal man: to prevent these evils we borrow two golden rules from ethics, which are no less golden in composition, than in life. 1. Know thyself; 2. Revere thyself.

If, Know thyself. Of ourselves it may be said, as Martial says of a bad neighbour,

Nil tam praepe, proculque nobis.

Therefore dive deep into thy bosom; learn the depth, extent, bias, and full fort of thy mind; contract full intimacy with the stranger within thee; excite and cherish every spark of intellectual light and heat, however smothered under former negligence, or scattered through the dull, dark maze of common thoughts; and collecting them into a body, let thy genius rise (if a genius thou hast) as the sun from chaos; and if we should then say, like an Indian, Worship it, (though too bold) yet should we say little more than the second rule enjoins, viz. Reverence thyself.

That is, let not great examples, or authorities, bow-beat thy reason into too great a diffidence of thyself: thyself so reverence, as to prefer the native growth of thy own mind to the richest import from abroad; such borrowed riches make us poor. The man who thus reverence himself, will soon find the world's reverence to follow his own. His works will stand distinguished; his the sole property of them; which property alone can confer the noble title of an author; that is, of one who, to speak accurately, thinks, and composes; while other invaders of the press how voluminous, and learned forever, with due respect be it spoken, only read and write.

This is the difference between those two luminaries in literature, the well-accomplished scholar, and the divinely-inspired enthusiast; the first is, as the bright morning star; the second, as the rising sun. The writer who neglects those two rules above will never stand alone; he makes
makes one of a group, and thinks in wretched unanimity with the throng. Incumbered with the notions of others, and impoverished by their abundance, he conceives not the least embryo of new thought; opens not the least viâta through the gloom of ordinary writers, into the bright walks of rare imagination, and singular design, while the true genius is crossing all public roads into fresh untried ground, he, up to the knees in antiquity, is treading the sacred footsteps of great examples, with the blind veneration of a bigot fainting at the papal shade, and a beggar to the last. Such is that inimitable flow, through the various modulations of masculine melody, into those grandeur of solemn sound, which are in-

But supposing Pope's Iliad to have been perfect in its kind; yet it is a translation still; which differs as much from an original, as the moon from the sun. But as nothing is more easy than to write originally wrong; originals are not here recommended, but under the strong guard of the first rule.—Know thyself. Lucian, who was an original, neglected not this rule, if we may judge by his reply to one who took some freedom with him. He was at first an apprentice to a flatatury; and when he was reflected on as such, by being called Prometheus, he replied, "I am indeed the inventor of a new work, the model of which I owe to none; and, if I do not execute it well, I deferve to be torn by twelve vultures, instead of one."

Bacon says, "Men seek not to know their own stock, and abilities; but fancy their possessions to be greater, and their abilities less, than they really are." Which is in effect saying, "That we ought to exert more than we do; and that, on exertion, our probability of success is greater than we conceive."

Nor have we Bacon's opinion only, but his assistance too, in favour of originals. His mighty mind travelled round the intellectual world; and, with a more than eagle's eye, saw, and has pointed out, blank spaces, or dark spots in it, on which the human mind never shone: some of these have been enlightened since; some are benighted still. Moreover, no boundless are the bold excursions of the human mind, that in the vast void beyond real existence, it can call forth shadowy beings, and unknown worlds, as numerous, as bright, and perhaps as lasting as the stars; such quite-original beauties we may call paradisaical.

Natos fine femine flores.

When such an ample area for renowned adventure in original attempts lies before us, shall we be mere leaden pipes, conveying to the present age small streams of excellence from its grand reservoir in antiquity; and those too perhaps muddled in the pass? Originals shine like comets; have no peer in their path; are rivalled by none, and the gaze of all: all other compositions (if they shine at all) shine in clusters; like the stars in the galaxy; where, like bad neighbours, all suffer from all; each particular being diminished, and almost lost in the throng.

If thoughts of this nature prevailed; if ancients and moderns were no longer considered as masters and pupils,
but as hard-matched rivals for renown; then moderns, by the longevity of their labours, might one day become ancients themselves: and old time, that beft weight of merits, to keep his balance even, might have the golden weight of an Augustan age in both his scales: or rather, our scale might defend; and that of antiquity (as a modern match for it strongly speaks) might kick the beam.

Why condemned Maro his admirable epic to the flames? Was it not because his differing eye saw some length of perfection beyond it? And what he saw, may not others reach? And who bid fairer than our countrymen for that glory? Something new may perhaps be expected from Britons particularly; who feem not to be more fevered from the rest of mankind by the surrounding sea, than by the current in their veins; and of whom little more appears to be required, in order to give us originals, than a confidency of character, and making their compositions of a piece with their lives. May our genius shine; and proclaim us in that noble view!

—and so do; for in polite composition, in natural and mathematical knowledge, we have great originals already: Bacon, Boyle, Newton, Shakespeare, Milton, have showed us, that all the winds cannot blow the British flag farther, than an original spirit can convey the British fame; their names go round the world; and what foreign genius strikes not as they pass? Why should not their pofterity embark in the fame bold bottom of new enterprife, and hope the fame fuccefs? Hope it they may; or we muft aflert, either that those originals, which we already enjoy, were written by angels, or deny that we are men. As Simonides faid to Paufanias, rea- fon should fay to the writer, “Remember thou art a man.” And for man flot to graft at all which is laudable within his reach, is a difhonour to human nature, and a disobedience to the divine; for as Heaven does nothing in vain, its gift of talents implies an injuncion of their ufe.

Johnson, in the ferious drama, is as much an imitator as Shakespeare is an original. He was very learned, as Sampfon was very strong, to his own hurt. Blind to the nature of tragedy, he pulled down all antiquity on his head, and buried himself under it; we fee nothing of Johnson, nor indeed of his admired (but also murdered) ancients; for what fhone in the historian is a cloud on the poet; and Catiline might have been a good play if Salluit had never written.

Dryden, deftitute of Shakespeare’s genius, had almost as much learning as Johnson, and, for the bulkin, quite as little taste. He was a stranger to the pathos, and, by numbers, expression, sentiment, and every other dramatic cheat, ftove to make amends for it; as if a faint could make amends for the want of confcioufness; a soldier, for the want of valour; or a vefal, of modefly. The noble nature of tragedy disclaims an equivalent; like virtue, it demands the heart; and Dryden had none to give. Let epic poets think, the tragedian’s point is rather to feel; such diftant things are a tragedian and a poet, that the latter indulged, deftroys the former. Look on Barnwell, and Eflax, and fee how as to these diftant characters Dryden excels, and is excel-

Multi rhyme then, it may be said, be banifhed? It is to be wished the nature of our language could bear its entire expulfion; but our leffer poetrystands in need of a toleration for it; it raises that, but links the great; as spangles adorn children, but expofe men.

Among the brighteft of the moderns, Mr Addifon muft take his place. Who does not approach his character with great respect? They who refuge to clofe with the public in his præfule, refuge at their peril. But, if men will be fond of their own opinions, some hazard muft be run. He had, what Dryden and Johnson wanted, a warm, and feeling heart; but, being of a grave and pious nature, through a philofophic referve, and a fort of moral prudery, he concealed it, where he should have let loofe all his fire, and have showed the moft tender fensibility of heart. At his celebrated Cato, few tears are shed, but Cato’s own; which indeed are truly great, but unaffecting, except to the noble few who love their country better than themselves. The bulk of mankind want virtue enough to be touched by them. His strength of genius has reared up one glorious image, more lofty, and truly golden, than that in the plain of Dura, for cool admiration to gaze at, and warm patriotism (how rare!) to worship; while thofe two-throbbing pulses of the drama, by which alone it is (hown to live, terror and pity, neglected through the whole, leave our unmolefted hearts at perfect peace. Thus the poet, like his hero, through mistaken excellence, and virtue overstrained, becomes a fort of suicide; and that which is moft dramatic in the drama, dies. All his charms of poetry are but as funeral flowers which adorn, all his noble sentiments, but as rich spices which embalm, the tragedy deceafed.

Socrates frequented the plays of Euripides; and, what living Socrates would decline the theatre, at the representation of Cato? Tully’s affaflins found him in his litter, reading the Mea of the Grecian poet, to prepare himfelf for death. Part of Cato might be read to the fame end. In the weight and dignity of moral refection, Adi- donf resembles that poet, who was called the dramatic philofopher; and is himfelf, as he fays of Cato, ambitiously fenfations. But as to the fingular talent fo remarkable in Euripides, at melting down hearts into the tender freams of grief and pity, there the refeemblance fails. His beauties sparkle, but do not warm; they sparkle as flars in a frowly night. There is, indeed, a conftellation in his play; there is the philofopher, patriot, orator, and poet; but where is the tragedian? And, if that is wanting,

Car in theatrum Cato fevere veniit? Mart.

2. Of epic and dramatic Compositions.

Tragedy and the epic poem differ little in substantials:
in both the same ends are proposed, viz. instruction and amusement; and in both the same means are employed, viz. imitation of human actions. They differ in the manner only of imitating: epic poetry deals in narration; tragedy represents its facts as palling in our sight: in the former, the poet introduces himself as an historian; in the latter, he presents his actors, and never himself.

This difference, regarding form only, may be thought slight: but the effects it occasions, are by no means so; for what we see, makes a stronger impression than what we learn from others. A narrative poem is a story told by another: facts and incidents palling upon the stage, come under our own observation; and are before much enlivened by action and gesture, expressive of many sentiments beyond the reach of language.

A dramatic composition has another property, independent altogether of action; which is, that it makes a deeper impression than narration: in the former, persons express their own sentiments; in the latter, sentiments are related at second hand. For that reason, Aristotle, the father of critics, lays it down as a rule, That in an epic poem the author ought to take every opportunity to introduce his actors, and to confine the narrative part within the narrowest bounds. Homer underestimates perfectly the advantage of this method; and his poems are both of them in a great measure dramatic. Lycur runs to the opposite extreme; and is guilty of a still greater fault, in stuffing his Pharsalia with cold and languid reflections, the merit of which he assumes to himself, and deigns not to share with his personages.

Aristotle, from the nature of the fable, divides tragedy into simple and complex: but it is of greater moment, with respect to dramatic as well as epic poetry, to found a distinction upon the different ends attained by such compositions. A poem, whether dramatic or epic, that has nothing in view but to move the passions, and to exhibit pictures of virtue and vice, may be distinguished by the name of pathetic: but where a story is purposely contrived to illustrate some moral truth, by showing that disordered passions naturally lead to external misfortunes, such composition may be denominated moral. Besides making a deeper impression than can be done by any moral discourse, it affords conviction equal to that of the most accurate reasoning. To be satisfied of this, we need but reflect, that the natural connection which vice hath with misery, and virtue with happiness, may be illustrated by stating a fact as well as by urging an argument. Let us assume, for example, the following moral truths: That discord among the chiefs renders inefficient all common measures; and that the consequences of a slightely-founded quarrel, fostered by pride and arrogance, are not less fatal than those of the grossest injury: these truths may be inculcated, by the quarrel between Agamemnon and Achilles at the siege of Troy. In this view, probable circumstances must be invented, such as furnish an opportunity for the turbulent passions to exert themselves in action: at the same time, no accidental nor unaccountable event ought to be admitted; for the necessary or probable connection between vice and misery, is not learned from any events but what are naturally occasioned by the characters and passions of the persons represented, acting in such and such circumstances. A real event of which we see not the cause, may be a lesson to us; because what hath happened may again happen: but this cannot be inferred from a story that is known to be a fiction.

Many are the good effects of such compositions. A pathetic composition, whether epic or dramatic, tends to a habit of virtue, by exciting us to do what is right, and restraining from what is wrong. Its frequent pictures of human woe produce, besides, two effects extremely salutary: they improve our sympathy, and at the same time fortify us in bearing our own misfortunes. A moral composition must obviously produce the same good effects, because by being moral it doth not cease to be pathetic: it enjoys besides an excellence peculiar to itself; for it not only improves the heart, as above mentioned, but instructs the head by the moral it contains. For our part, we cannot imagine any entertainment more suited to a rational being, than a work thus happily illusrating some moral truth; where a number of persons of different characters are engaged in an important action, some retarding, others promoting, the great catastrophe; and where there is dignity of style as well as of matter. A work of this kind has our sympathy at command, and can put in motion the whole train of the social affections: our curiosity is by turns excited and gratified; and our delight is consummated at the close, upon finding, from the characters and situations exhibited at the commencement, that every incident down to the final catastrophe is natural, and that the whole in conjunction make a regular chain of causes and effects.

Considering that an epic and a dramatic poem are the same in subsistence, and have the same aim or end, one would readily imagine, that subjects proper for the one must be equally proper for the other. But considering their difference as to form, there will be found reason to correct that conjecture, at least in some degree. Many subjects may indeed be treated with equal advantage in either form: but the subjects are still more numerous for which they are not equally qualified; and there are subjects proper for the one and not at all for the other. To give some slight notion of the difference, as there is no room here for enlarging upon every article, we observe, that dialogue is the best qualified for expressing sentiments, and narrative for displaying facts. Heroism, magnanimity, undaunted courage, and the whole tribe of the elevated virtues, figure best in action: tender passions, and the whole tribe of sympathetic affections, figure best in sentiment: what we feel is the most remarkable in the latter; what we perform is the most remarkable in the former. It clearly follows, that tender passions are more peculiarly the province of tragedy, grand and heroic actions of epic poetry.

The subject best fitted for tragedy is a story where a man has himself been the cause of his misfortune. But this man must neither be deeply guilty, nor altogether innocent: the misfortune must be occasioned by a fault incident to human nature, and therefore venial. Misfortunes of this kind call forth the social affections, and warmly interest the spectator. An accidental misfortune, if not extremely singular, doth not greatly move:
our pity: the person who suffers, being innocent, is freed from the greatest of all torments, that anguish of mind which is occasioned by remorse.

An atrocious criminal, on the other hand, who brings misfortunes upon himself, excites little pity, for a different reason: his remorse, it is true, aggravates his distress, and swells the first emotions of pity; but then our hatred of him as a criminal blending with pity, blinds its edge considerably. Misfortunes that are not innocent, nor highly criminal, partake the advantages of each extreme: they are attended with remorse to embitter the distress, which raises our pity to a great height; and the flight indignation we have at a venial fault, detaches not sensibly from our pity. For this reason, the happiest of all subjects for raising pity, is where a man of integrity falls into a great misfortune by doing an action that is innocent, but which by some singular means he conceives to be criminal: his remorse aggravates his distress; and our compassion, unrestrained by indignation, rises to its highest pitch. Pity comes thus to be the ruling passion of a pathetic tragedy; and by proper representation, may be raised to a height far beyond any thing felt in real life. A moral tragedy takes in a larger field; for, beside exercising our pity, it raises another passion, selfish indeed, but which deserves to be cherished equally with the social affections. The passion we have in view is fear or terror; for when a misfortune is the natural consequence of some wrong bias in the temper, every spectator who is conscious of such a wrong bias in his own temper, takes the alarm, and dreads his falling into the same misfortune: and it is by this emotion of fear or terror, frequently reiterated in a variety of moral tragedies, that the spectators are put upon their guard against the disorders of passion.

The commentators upon Aristotle, and other critics, have been much gravelled about the account given of tragedy by this author: "That by means of pity and terror, it refines or purifies us in all sorts of passion." But no one who has a clear conception of the end and effects of a good tragedy, can have any difficulty about Aristotle's meaning: our pity is engaged for the persons represented; and our terror is upon our own account. Pity indeed is here made to stand for all the sympathetic emotions, because of these it is the capital. There can be no doubt, that our sympathetic emotions are refined or improved by daily exercise; and in what manner our other passions are refined by terror, we have just now said.

With respect to subjects of this kind, it may indeed be a doubtful question, whether the conclusion ought not always to be fortunate. Where a person of integrity is represented as suffering to the end under misfortunes purely accidental, we depart discontented; and with some obscure sense of injustice: for seldom is man so submissive to providence, as not to revolt against the tyranny and vexations of blind chance; he will be inclined to say, This ought not to be. We give for an example the Romeo and Juliet of Shakespeare, where the fatal catastrophe occasioned by Friar Laurence's coming to the monument a minute too late. We are vexed at the unlucky chance, and go away dissatisfied. Such impressions, which ought not to be cherished, are a sufficient reason for excluding stories of that kind from the theatre. The misfortunes of a virtuous person, arising from necessary causes, or from a chain of unavoidable circumstances, will be considered in a different light: chance affords always a gloomy prospect, and in every instance gives an impulsion of anxiety and misrule: a regular chain, on the contrary, of causes and effects, directed by the general laws of nature, never fails to suggest the hand of Providence; to which we submit without resentment, being conscious that submission is our duty. For that reason, we are not displeased with the distresses of Voltaire's Mariamne, though redoubled on her till the moment of her death, without the least fault or failing on her part: her misfortunes are owing to a cause extremely natural, and not unfrequent, the jealousy of a barbarous husband. The fate of Delfdemona in the Moor of Venice, affects us in the same manner. We are not so easily reconciled to the fate of Cordelia in King Lear: the causes of her misfortune are by no means so evident, as to exclude the gloomy notion of chance. In short, a perfect character suffering under misfortunes, is qualified for being the subject of a pathetic tragedy, provided chance be excluded. Nor is a perfect character altogether inconsistent with a moral tragedy: it may successfully be introduced as an under-part, supposing the chief place to be filled with an imperfect character from which a moral can be drawn. This is the case of Delfdemona and Mariamne just now mentioned; and it is the case of Monimia and Belvidera, in Otway's two tragedies, the Orphan, and Venice Preserved.

Fable operates on our passions, by representing its events as passing in our sight, and by deluding us into a conviction of reality. Hence, in epic and dramatic compositions, it is of importance to employ means of every sort that may promote the delusion, such as the borrowing from history some noted event, with the addition of circumstances that may answer the author's purpose: the principal facts are known to be true; and we are disposed to extend our belief to every circumstance. But in choosing a subject that makes a figure in history, greater precaution is necessary than where the whole is a fiction. In the latter case there is full scope for invention: the author is under no restraint other than that the characters and incidents be just copies of nature. But where the story is founded on truth, no circumstances must be added, but such as connect naturally with what are known to be true: history may be supplied, but must not be contradicted: further, the subject chosen must be distant in time, or at least in place; for the familiarity of personages and events nearly connected with us, ought by all means to be avoided. Familiarity ought more especially to be avoided in an epic poem, the peculiar character of which is dignity and elevation: modern manners make but a poor figure in such a poem.

After Voltaire, no writer, it is probable, will think of rearing an epic poem upon a recent event in the history of his own country. But an event of this kind is perhaps not altogether unqualified for tragedy: it was admitted in Greece; and Shakespeare has employed it successfully
cerefully in several of his pieces. One advantage it po-
sesses above fiction, that of more readily engaging our be-
lief, which tends above any other particular to raise our sympa-
thy. The scene of comedy is generally laid at home: familiarity is no objection; and we are pecu-
liarily sensible of the ridicule of our own manners.

After a proper subject is chosen, the dividing it into
parts requires some art. The conclusion of a book in an
epic poem, or of an act in a play, cannot be altogether arbitrary; nor be intended for so flight a purpose as to
make the parts of equal length. The supposed pause at
the end of every book, and the real pause at the end of
every act, ought always to coincide with some pause in
the action. In this respect, a dramatic or epic poem
ought to resemble a sentence or period in language, di-
vided into members that are distinguished from each other
by proper pauses; or it ought to resemble a piece of
music, having a full close at the end, preceded by im-
perfect cloises that contribute to the melody. Every act in a dramatic poem ought therefore to close with some incident that makes a pause in the action; for otherwize
there can be no pretext for interrupting the representa-
tion: it would be absurd to break off in the very heat of
action; against which every one would exclaim: the ab-
surdity still remains, though the action relents, if it be
not actually suspended for some time. This rule is also
applicable to an epic poem: though there, a deviation
from the rule is less remarkable; because it is in the rea-
der's power to hide the absurdity, by proceeding infant-
ly to another book. The first book of the Paradise
Lolit ends without any regular close, perfect or imper-
fect: it breaks off abruptly, where Satan, seated on his
throne, is prepared to make a speech to the convocated
host of the fallen angels; and the second book begins
with the speech. Milton seems to have copied the Æneid,
of which the two first books are divided much in the
same manner. Neither is there any proper pause at the
end of the fifth book of the Æneid. There is no pro-
per pause at the end of the seventh book of Paradise
Lolit, nor at the end of the eleventh.

This branch of the subject shall be closed with a gen-
eral rule, That action being the fundamental part of
every composition whether epic or dramatic, the senti-
ments and tone of language ought to be subservient to the
action, so as in every respect to appear natural, and
proper for the occasion. The application of this rule to
our modern plays, would reduce the bulk of them to a
skeleton.

After carrying on together epic and dramatic com-
positions, we proceed to handle them separately, and to
mention circumstances peculiar to each, beginning with
the epic kind. In a theatrical entertainment, which em-
ploy both the eye and the ear, it would be a gross ab-
surdity to introduce upon the stage superior beings in a
visible shape. There is not place for this object in an
epic poem; and Boileau, with many other critics, de-
clares strongly for this sort of machinery in an epic poem.
But waving authority, which is apt to impose upon the
judgment, let us draw what light we can from reason.
This matter is but indifferently handled by critics: the
poetical privilege of animating insensible objects for en-
livening a description, is very different from what is
termed machinery, where deities, angels, devils, or o-
ther supernatural powers, are introduced as real per-
were beings elevated one step only above mankind, actuated by the same passions, and directed by the same motives; therefore not altogether improper to mix with men in an important action. In our creed, superior beings are placed at such a mighty distance from us, and are of a nature so different, that with no propriety can they appear with us upon the same stage: man is a creature so much inferior, that he loses all dignity when set in opposition.

There can be no doubt, that an historical poem admits the embellishment of allegory, as well as of metaphor, simile, or other figure. Moral truth, in particular, is finely illustrated in the allegorical manner: it amuses the fancy to find abstract terms, by a sort of magic, turn to useful purposes. But allegorical beings should be confined within their own sphere, and never be admitted to mix in the principal action, nor to operate in retarding or advancing the catastrophe, which would have a still worse effect than invisible powers, and we are ready to affign the reason. The impression of real existence, essential to an epic poem, is inconsistent with that figurative existence which is essential to an allegory; and therefore no method can be more effectual to prevent the impression of reality, than to introduce allegorical beings, co-operating with those whom we conceive to be really existing. The love-episode in the Henriade, is unfufferable by the discordant mixture of allegory with real life, is copied from that of Rinaldo and Armida in the Gierusalemme liberata, which hath no merit to intitle it to be copied. An allegorical object, such as Fame in the Aeneid, and the Temple of Love in the Henriade, may find place in a description; but to introduce Discord as a real perfonage, imploring the affiance of Love as another real perfonage, is to sacrifice the interest of the hero, is making these figurative beings act beyond their sphere, and creating a strange jumble of truth and fiction.

What is the true notion of an episode? or how is it to be distinguished from the principal action? Every incident that promotes or retards the catastrophe, must be a part of the principal action. This clears the nature of an episode; which may be defined, "An incident connected with the principal action, but contributing neither to advance nor retard it." The defect of Aeneas into Hell doth not advance nor retard the catastrophe; and therefore is an episode. The story of Nysus and Euryalus, producing an alteration in the affairs of the contending parties, is a part of the principal action. The family scene in the fifth book of the Iliad is of the same nature: by Hector's retiring from the field of battle to visit his wife, the Grecians had liberty to breathe, and even to press upon the Trojans. Such being the nature of an episode, the unavoidable effect of it must be, to break in upon the unity of action; and therefore it ought never to be indulged, unless to unbend the mind after the fatigue of a long narration. This purpose of an episode demands the following conditions: it ought to be well connected with the principal action: it ought to be lively and interesting: it ought to be short: and a time ought to be chosen when the principal action commences.

Next, upon the peculiarities of a dramatic poem. And the first we shall mention is a double plot; one of which must be of the nature of an episode in an epic poem; for it would distract the spectator, instead of entertaining him, if he were forced to attend, at the same time, to two capital plots equally interesting. And even supposing it an under-plot, of the nature of an episode, it seldom hath a good effect in tragedy, of which simplicity is a chief property: for an interesting subject that engages our warmest affections, occupies our whole attention, and leaves no room for any separate concern. Variety is more tolerable in comedy, which pretends only to amuse, without totally occupying the mind. But even here to make a double plot agreeable, is no flight effort of art: the under plot ought not to vary greatly in its tone from the principal; for discordant passions are unpleasant when jumbled together; which, by the way, is an insuperable objection to tragi-comedy. Upon this account, we blame the Provoked Husband: all the scenes that bring the family of the Wrongheads into action, being ludicrous and farcical, agree very ill with the principal scenes; displacing severe and bitter expostulations between lord Townly and his lady. The same objection touches not the double plot of the Careless Husband; the different subjects being sweetly connected, and having only so much variety as to resemble shades of colours harmoniously mixed. But this is not all. The under plot ought to be connected with that which is principal, so much at least as to employ the same persons: the under-plot ought to occupy the intervals or pauses of the principal action; and both ought to be concluded together. This is the case of the Merry Wives of Windsor.

Violent action ought never to be represented on the stage. While the dialogue runs on, a thousand particulars concur to delude us into an impression of reality, genuine sentiments, passionate language, and persuasive gesture: the spectator once engaged, is willing to be deceived, loses sight of himselfi, and without scruple enjoys the spectacle as a reality. From this absurd state, he is roused by violent action: he wakes as from a pleasing dream, and gathering his senses about him, finds all to be a fiction.

The French critics join with Horace in excluding from the stage the shedding blood; but they have overlooked the most substantial objection, that above-mentioned, urging only that it is barbarous, and shocking to a polite audience. But the Greeks had no notion of such delicacy, or rather effeminacy; we witness the murder of Clytemnestra by her son Orestes, passing behind the scene, as represented by Sophocles: her voice is heard calling out for mercy, bitter expostulations on his part, loud shrieks upon her being flayed, and then a deep silence. We appeal to every person of feeling, whether this scene be not more horrible, than if the deed had been committed in sight of the spectators upon a sudden gust of passion. If Corneille, in representing the affair between Horatius and his sister upon which murder ensues behind the scene, had
had no other view but to remove from the spectators a shocking action; he certainly was in a capital mistake: for murder in cold blood, which in some measure was the cafe as represented, is more shocking to a polite audience, even where the conclusive stab is not seen, than the same act performed in their presence, when it is occasioned by violent and unpurged paffion, as suddenly repented of as committed. We heartily agree with Addison, that no part of this incident ought to have been represented, but reserved for a narrative, with every alleviating circumstance in favour of the hero. This is the only method to avoid the difficulties that unqualify this incident for representation, a deliberate murder performed on the one hand, and on the other a violent action performed on the self, which must route the spectator from his dream of reality.

A few words upon the dialogue, which ought to be so conducted as to be a true representation of nature. Every single speech, short or long, ought to arise from what is said by the former speaker, and furnish matter for what comes after, till the end of the scene. In this view, the whole speeches, from first to last, represent too many links, all connected together in one regular chain. No author, ancient or modern, possesses the art of dialogue equal to Shakespeare. Dryden in this particular may justly be placed as his opposite: he frequently introduces three or four persons speaking upon the same subject, each throwing out his own sentiments separately, without regarding what is said by the rest; take for an example the first scene of Aurengzebe: sometimes he makes a number club in relating an event, not to a stranger, supposed ignorant of it, but to one another, for the sake merely of speaking: of which notable form of dialogue, we have a specimen in the first scene of the first part of the Conquest of Granada. In the second part of the same tragedy, scene second, the king, Abenamar, and Zulema, make their separate observations, like so many soliloquies, upon the fluctuating temper of the mob: a dialogue so uncouth, puts one in mind of two shepherds in a pastoral, excited by a prize to pronounce verses alternately, each in praise of his own mistress.

The bandying sentiments in this manner, beside an unnatural air, has another bad effect: it plays the course of the action, because it is not productive of any consequence. In Congreve's comedies, the action is often suspended to make way for a play of wit.

No fault is more common among writers, than to prolong a speech after the impatience of the person to whom it is addressed ought to prompt him or her to break in. Consider only how the impatient actor is to behave in the mean time. To express his impatience in violent action without interrupting, would be unnatural; and yet to dissemble his impatience by appearing cool where he ought to be highly inflamed, would be no less unnatural.

Rhyme being unnatural and disagreeful in dialogue, is happily banished from our theatre: the only wonder is, that it ever found admittance, especially among a people accustomed to the more manly freedom of Shakespeare's dialogue. By banishing rhyme, we have gained so much as never once to dream that there can be any further improvement. And yet, however suitable blank verse may be to elevated characters and warm passions, it must appear improper and affected in the mouths of the lower sort. Why then should it be a rule, that every scene in tragedy must be in blank verse? Shakespeare, with great judgment, has followed a different rule; which is, to intermix prose with verse, and only to employ the latter where the importance or dignity of the subject requires it. Familiar thoughts and ordinary facts ought to be expressed in plain language; and if it appear not ridiculous to hear a footman deliver a simple message in blank verse, a vail must be drawn over the ridiculous appearance by the force of custom. In short, that variety of characters and of situations, which is the life of a play, requires not only a suitable variety in the sentiments, but also in the diction.

**Composition, in painting, consists of two parts, invention and disposition; the first whereof is the choice of the objects which are to enter into the composition of the subject the painter intends to execute, and is either simply historical or allegorical.**

**Composition, in commerce, a contract between an involvent debtor and his creditors, whereby the latter accept of a part of the debt in compensation for the whole, and give a general acquittance accordingly.**

**Composition, in printing, commonly termed composing, the arranging of several types, or letters, in the composing-ditch, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several pages, to make a form. See Printing.**

**Composition, in husbandry and gardening, several sorts of soils, or earthy matter, mixed together, in order to make a manure, for affisting the natural earth in the work of vegetation, by way of amendment or improvement. See Agriculture.**

**Compostella, the capital of Galicia, in Spain, remarkable for the devotion paid there by pilgrims from all countries to the relics of St James.**

**Compound, in a general sense, an appellation given to whatever is composed, or made up of different things: thus we say, a compound word, compound sound, compound tale, compound force, &c.**

**Compound-interest. See Interest.**

**Compound-numbers, those which may be divided by some other number besides unity, without leaving any remainder: such are 2, 6, or 9; and the second by the numbers 2, 4, 5, 10.**

**Comprehension, in logic, the same with apprehension.**

**Comprehension, the act of pressing or squeezing some matter, so as to set its parts nearer to each other, and make it possess less space.**

**Compriint, among bookellers, signifies a surreptitious printing of another's copy, in order to gain thereby, which is expressly contrary to statute 14 Car. II.**

**Compromise, a treaty, or contract, whereby two contending parties agree to a mutual adjustment of their respective claims.**

Conception is also the capital of the province of Ve-

Concentration, in general, signifies the bringing

Concentric, in mathematics, something that has

Concatenation, a term chiefly used in speaking

Concave, a term chiefly used in speaking of the mutual dependence of second causes upon one another.

Concave glasses, such as are ground hollow, and are usually of a spherical figure, though they may be of any other, as parabolic, &c. All objects seen through concave glasses, appear erect and diminished. See Optics.

Concentration, in general, signifies the bringing things nearer a center. Hence the particles of air, in sea-water, are said to be concentrated; that is, brought nearer each other, by evaporating the watery part. See Chemistry.

Concentric, in mathematics, something that has the same common center with another; it stands in opposition to excentric.

Conception, among physicians, &c. denotes the first formation of an embryo in the womb of its parent, who from that time becomes pregnant. See Generation.

Conception, in logic. See Abstraction.

Conception, in geography, a city of Chili, in South America, situated on the Pacific Ocean, in 79° W. long. and 37° S. lat.

Conception is also the capital of the province of Viquegua, in Mexico, about 100 miles west of Porto Bello: W. long. 83°, and N. lat. 10°.

Concert, or Concerto, in music, a number or company of musicians, playing or singing the same piece of music or song at the same time. See Music.

Concertato intimates the piece of music to be composed in such a manner, as that all the parts may have their recitatives, be it for two, three, four, or more voices or instruments.

Concerto grosso, the grand chorus of a concerto, or those places where all the several parts perform or play together.

Concha, in zoology, a synonyme of the Mytilus, Solen, &c. See these articles.

CONDOM, the capital of the Condomois, in the province of Gascony, in France, about sixty miles south-east of the city of Bordeaux. It is a bishop's see, and situated in 20° E. long., and 44° 5' N. lat.

CONCORDIA, in geography, a town of the duchy of Mantua in Italy, about fifteen miles south-east of the city of Mantua: E. long. 11° 20', and N. lat. 45°.

CONCRETE, in the school-philosophy, an assemblage or compound.

CONCRETION, the uniting together several small particles of a natural body into sensible masses, or concretes, whereby it becomes so and so figured and determined, and is ended with such and such properties.

CONDITIONAL, in the civil law, a clause of obligation properly disposed. See Pneumatics.

CONDITIONALS, something not absolute but subject to conditions.

CONDITION, in the civil law, a clause of obligation stipulated as an article of a treaty or contract or in a donation of testament, legacy, &c., in which last case a donee does not lose his donative, if it be charged with any dishonest or impossible conditions.

CONDITIONALS, something not absolute but subject to conditions.

CONDAMIN, in botany. See Cinchona.

CONDENSATION, the act whereby soft bodies are rendered hard; or an insensible motion of the particles of a fluid or a soft body, whereby they come to a condensation. It is indifferently used for induration, congelation, and coagulation.

CONCESSIONAL, according to divines, an irregular appetite, or lust after carnal things, inherent in the nature of man ever since the fall.

CONCESSIONAL, something preserved, especially dry substances. It also signifies a liquid or soft electuary, of which there are various sorts directed in dispensatories.

CONCESSIONAL, a denomination given to fruits, flowers, herbs, roots, &c., when boiled or prepared with sugar or honey, to dispose them to keep, and render them more agreeable to the taste. Also signifies a liquid or soft electuary, of which there are various sorts directed in dispensatories.

CONCESSIONAL, something not absolute but subject to conditions.

CONDUCTOR, in surgery, an instrument which serves to conduct the knife in the operation of cutting for the stone, and in laying up fistulous fistulas. See Surgery.

CONDUIT, a canal or pipe for the conveyance of water, or other fluid.

CONFESSION, in a legal sense, an acknowledgment of sins to God in the name of the whole people: but, in a more limited sense, it signifies the declaration which a Christian makes of his sins.

CONFESSION, among divines, the verbal acknowledgement which a Christian makes of his sins. Among the Jews it was a custom, on the annual feast of expiation, for the high-priest to make confession of sins to God in the name of the whole people: besides this general confession, the Jews were enjoined, if their sins were a breach of the first table of the law, to make confession of them to God; but violations offered the second table, were to be acknowledged to their brethren. The confessions of the primitive Christians...
frians were all voluntary, and not imposed on them by any laws of the church; yet private confession was not only allowed, but encouraged.

The Romish church requires confession not only as a duty, but has advanced it to the dignity of a sacrament: this confession is made to the priest, and privately and auricularly; and the priest is not to reveal them under pain of the highest punishment.

**Confession of faith**, a list of the several articles of belief in any church.

**Confessional, or Confessionary**, a place in churches, under the great altar, where the bodies of deceased saints, martyrs, and confessors, were deposited.

**Confessor**, in the Romish church, a priest who is empowered to receive the confession of penitents, and to give them absolution.

**Configuration, the outward figure which bounds bodies, and gives them their external appearance; being that which, in a great measure, constitutes the specific difference between bodies**.

**Confirmation by a superior.** See Scots Law, title, *Transfer of rights by confirmation*.

**Confirmation of a testament.** See Scots Law, title, *Succession in moveables*.

**Confirmation, in theology, the ceremony of laying on of hands, for the conveyance of the Holy Ghost.**

The antiquity of this ceremony is, by all ancient writers, carried as high as the apostles, and founded upon their example and practice. In the primitive church, it used to be given to Christians immediately after baptism, if the bishop happened to be present at the solemnity. Among the Greeks, and throughout the East, it still accompanies baptism: but the Romans make it a distinct independent sacrament. Seven years is the stated time for confirmation: however, they are sometimes confirmed before, and sometimes after that age. The person to be confirmed has a godfather and godmother appointed him, as in baptism. The order of confirmation in the church of England, does not determine the precise age of the persons to be confirmed.

**Confiscation, in law, the adjudication of goods to the public treasury; as the bodies and effects of criminals, traitors, &c.**

**Conflagration, the general burning of a city, or other considerable place.**

This word is commonly applied to that grand period or catastrophe of our world, when the face of nature is to be changed by fire, as formerly it was by water.

**Confident, among physicians, &c.** An appellation given to that kind of small-pox wherein the pustules run into each other. See Medicine.

**Conformation, the particular conformation and texture of the parts of any body, and their disposition to compose a whole.**

**Conformation, in medicine, that make and construction of the human body, which is peculiar to every individual.**

**Conformity, among schoolmen, the relation of agreement between one thing and another; as that between any thing and the division thereof, the object and the understanding, &c.**

**Confusion, in Scots law, is a method of extinguishing and suspending obligations.** See Scots Law, title, *Extinction of obligations*.

**Conge' d'ivre, in ecclesiastical policy, the king's permission royal to a dean and chapter in the time of a vacancy, to chuse a bishop; or to an abbey, or priory, of his own foundation, to chuse their abbot or prior.**

The king of England, as sovereign patron of all archbishoprics, bishoprics, and other ecclesiastical benefices, had of ancient time free appointment of all ecclesiastical dignities, whenever they chanced to be void; investing them first per baculum & annulum, and afterwards by his letters-patent; and in course of time he made the election over to others, under certain forms and limitations, as that they should at every vacation, before they chuse, demand the king's congé d'ivre, and after the election crave his royal assent, &c.

**Congé, in architecture, a mould in form of a quarter round or a cavetto, which serves to separate two members from one another, such as that which joins the shaft of the column to the cincture, called also apophyge.**

**Conges are also rings or ferrels formerly used in the extremities of wooden pillars, to keep them from splitting, afterwards imitated in stone-work.**

**Congelation, freezing, or such a change produced by cold in a fluid body, that it quits its former state, and becomes congealed.** See Freezing.

**Conger, in zoology. See Murjena.**

**Congeries, a constellation or aggregate of several particles or bodies united into one mass.**

**Congius, a liquid measure of the ancient Romans, containing the eighth part of the amphora, or the fourth of the urna, or Ex sextarii.** The congius in English measure contains 2,070 676 solid inches; that is, seven pints, 4942 solid inches.

**Conglobate gland, in anatomy.** See Vol. I, p. 265.

**Conglomerate gland, in anatomy.** See Vol. I, p. 265, bottom.

**Conglutination, the gluing or fastening any two bodies together by the intromission of a third, whose parts are intusuous and tenacious, in the nature of glue.** See Glue.

**Congo, a large country on the western coast of Africa, between 10° and 20° E. long. and 20° S. long. comprehending the countries of Loango, Angola, and Benguella. It is bounded by the kingdom of Benin on the north; by Mataram, a part of Caffaria, on the south; and by the Atlantic ocean, on the west; and is sometimes called the lower Guinea.**

**Congregation, an assembly of several ecclesiastics united, so as to constitute one body; as an assembly of cardinals; in the constitution of the pope's court, met for the dispatch of some particular business.** These assemblies, being sixteen in number, are distributed
flributed into several chambers, after the manner of our offices and courts: the first whereof is the pope's congregation, whose business it is to prepare the most difficult beneficiary matters to be afterward debated in the consistory: the second is the congregation of the holy office, or the inquisition: the third is the congregation de propaganda fide: the fourth is the congregation for explaining the council of Trent: the fifth is the congregation of the index, deputed to examine into pernicious and heretical books: the sixth is the congregation of immunities, established to obviate the congregation of the index, deputed to examine into pernicious and heretical books: the seventh is the congregation of bishops and regulars: the eighth is the congregation for the examination of bishops, &c. It is also used for a company or society of religious, cantoned out of any order, so as to make a subdivision of the order itself; as the congregation of Cluny, &c. among the Benedictines. It is likewise used for assemblies of pious persons, in manner of fraternities.

CONGREGATIONALISTS, in church-history, a sect of protestants who reject all church-government, except that of a single congregation.

CONGRESS, in political affairs, an assembly of commissioners, envoys, deputies, &c. from several courts meeting to concert matters for their common good.

Congress, in a judicial sense, the trial made by appointment of a judge, before surgeons and matrons, in order to prove whether or no a man be impotent, before sentence is passed for the dissolution of a marriage, solicited upon such a complaint.

CONGRUITY, a fituableness or relation of agreement between things.

The terms congruity and propriety are not applicable to any single object: they imply a plurality, and obviously signify a particular relation between different objects. Thus we say currently, that a decent garb is suitable or proper for a judge, modest behaviour for a young woman, and a lofty style for an epic poem: and, on the other hand, that it is unsuitable or incongruous to see a little woman sunk in an overgrown farthingale, a coat richly embroidered covering coarse and dirty linen, a mean subject in an elevated style, an elevated subject in a mean style, a first minister darning his wife's stockings, or a reverend prelate in lawn sleeves dancing a hornpipe.

The perception we have of this relation, which seems peculiar to man, cannot proceed from any other cause, but from a sense of congruity or propriety; for, supposing us destitute of that sense, the terms would be to us unintelligible.

It is a matter of experience, that congruity or propriety, where-ever perceived, is agreeable; and that incongruity or impropriety, where-ever perceived, is disagreeable. The only difficulty is, to ascertain what are the particular objects that in conjunction suggest these relations; for there are many objects that do not: the sea, for example, viewed in conjunction with a picture, or a man viewed in conjunction with a mountain, suggest not either congruity or incongruity. It seems natural to infer, what will be found true by induction, that we never perceive congruity nor incongruity but among things that are connected together by some relation; such as a man and his actions, a principal and its accesories, a subject and its ornaments. We are indeed so framed by nature, as among things so connected, to require a certain suitableness or correspondence, termed congruity or propriety; and to be displeased when we find the opposite relation of incongruity or impropriety.

If things connected be the subject of congruity, it is reasonable beforehand to expect, that a degree of congruity should be required proportioned to the degree of the connection. And upon examination we find this to hold in fact: where the relation is intimate, as between a cause and its effect, a whole and its parts, we require the strictest congruity; but where the relation is slight, or accidental, as among things jumbled together in the same place, we require little or no congruity: the strictest propriety is required in behaviour and manner of living; because a man is connected with these by the relation of cause and effect: the relation between an edifice and the ground it stands upon, is of the most intimate kind, and therefore the situation of a great house ought to be lofty; its relation to surrounding hills, rivers, plains, being that of propinquity only, demands but a small share of congruity: among members of the same club, the congruity ought to be considerable, as well as among things placed for show in the same niche: among passengers in a stage-coach, we require very little congruity; and least full at a public spectacle.

Congruity is so nearly allied to beauty, as commonly to be held a species of it; and yet they differ so essentially, as never to coincide: beauty, like colour, is placed upon a single subject; congruity upon a plurality: further, a thing beautiful in itself, may, with relation to other things, produce the strongest sense of incongruity.

Congruity and propriety are commonly reckoned synonymous terms; but they are distinguishable; and the precise meaning of each must be ascertained. Congruity is the genus, of which propriety is a species; for we call nothing propriety, but that congruity or suitableness, which ought to subsist between sensible beings and their thoughts, words, and actions.

In order to give a full view of these secondary relations, we shall trace them through some of the most considerable primary relations. The relation of a part to the whole, being extremely intimate, demands the utmost degree of congruity; even the slightest deviation is disgusting.

Examples of congruity and incongruity are furnished in plenty by the relation between a subject and its ornaments. A literary performance intended merely for amusement, is susceptible of much ornament, as well as a music-room, or a play-house; for in gaiety, the mind hath a peculiar relish for show and decoration. The most gorgeous apparel, however improper in tragedy, is not unsuitable to opera-actors: the truth is, an opera, in its present form, is a mighty fine thing; but as it deviates from nature in its capital circumstances, we look not for nature
nor propriety in those which are crieffory. On the oth-
er hand, a serious and important subject admits not
much ornament; nor a subject that of itself is extremely
beautiful: and a subject that fills the mind with its lofty-
ness and grandeur, appears best in a dress altogether plain.

To a perfon of a mean appearance, gorgeous apparel
is unsuitable; which, besides the incongruity, has a bad
effect; for by contrariety it shows the meanness of appear-
ance in the strongest light. Sweetness of look and man-
ner, requires simplicity of dress joined with the greatest
elegance. A flately and majestic air requires sumptuous
apparel, which ought not to be gaudy, nor crowded with
little ornaments. A woman of consummate beauty can
bear to be highly adorned, and yet shows best in a plain
dress:

For loveliness
Needs not the foreign aid of ornament,
But when unadorn’d, adorn’d the more.

Thomson’s Autumn, 208.

Congruity regulates not only the quantity of orna-
ment, but also the kind. The ornaments that embellish
a dancing-room ought to be all of them gay. No picture
is proper for a church, but what has religion for its sub-
ject. All the ornaments upon a shield ought to relate
to war; and Virgil, with great judgment, confines the
carvings upon the shield of Æneas to the military his-
tory of the Romans: but this beauty is overlooked by Ho-
mer; for the bulk of the sculpture upon the shield of A-
chilles, is of the arts of peace in general, and of joy and
festivity in particular: the author of Telemachus betrays
the same inattention, in describing the shield of that
young hero.

In judging of propriety with regard to ornaments, we
must attend, not only to the nature of the subject that is
to be adorned, but also to the circumstances in which it
is placed: the ornaments that are proper for a ball, will
appear not altogether so decent at public worship; and
the same person ought to dress differently for a marriage-
feast and for a burial.

Nothing is more intimately related to a man, than his
sentiments, words, and actions; and therefore we re-
quire here the strictest conformity. When we find what
we thus require, we have a lively sense of propriety: when we find the contrary, our sense of impropriety is
not less lively. Hence the universal dislike of affecta-
tion, which consists in making a show of greater delicacy
and refinement than is suited either to the character or
circumstances of the person.

Congruity and propriety, where-ever perceived, ap-
pear agreeable; and every agreeable object produces in
the mind a pleasant emotion: incongruity and impro-
priety, on the other hand, are disagreeable; and of course
produce painful emotions. These emotions, whether
pleasant or painful, sometimes vanish without any con-
sequence; but more frequently occasion other emotions,
which we proceed to exemplify.

When any slight incongruity is perceived, in an acci-
dental combination of persons or things, as of passengers
in a stage-coach, or of individuals dining at an ordinary;
the painful emotion of incongruity, after a momentary
existence, vanishes without producing any effect. But
this is not the case of propriety and impropriety; volun-
tary acts, whether words or deeds, are imputed to the
author; when proper, we reward him with our esteem;
when improper, we punish him with our contempt. Let
us, suppose, for example, a generous action suited to the
character of the author, which raises in him and in every
spectator the pleasant emotion of propriety: this emotion
generates in the author both self-esteem and joy; the
former when he considers his relation to the action, and
the latter when he considers the good opinion that others
will entertain of him: the same emotion of propriety
produced in the spectators esteem for the author of the
action; and when they think of themselves, it also pro-
duces, by means of contrast, an emotion of humility.

To discover the effects of an unsuitable action, we must
invert each of these circumstances: the painful emotion
of impropriety generates in the author of the action both
humbly and shame; the former when he considers his
relation to the action, and the latter when he considers
what others will think of him: the same emotion of im-
propriety produced in the spectators esteem for the au-
thor of the action; and it also produces, by means of
contrast, when they think of themselves, an emotion of self-esteem. Here then are many different emotions, de-
rived from the same action considered in different views
by different persons; a machine provided with many
springs, and not a little complicated. Propriety of ac-
ton, it would seem, is a chief favourite of nature, when
such care and solicitude is bestowed upon it. It is not
left to our own choice: but, like justice, is required at
our hands; and, like justice, is enforced by natural re-
wards and punishments: a man cannot, with impurity,
do anything unbecoming or improper; he suffers the
shame of contempt inflicted by others, and of shame
inflicted by himself. An apparatus so complicated, and
so singular, ought to arouse our attention: for nature
doth nothing in vain; and we may conclude with great
certainty, that this curious branch of the human con-
stitution is intended for some valuable purpose.

A gross impropiety is punished with contempt and in-
dignation, which are vented against the offender by cor-
responding external expressions: nor is even the slightest
impropriety suffered to pass without some degree of con-
tempt. But there are improprieties, of the lighter kind,
that provoke laughter; of which we have examples with-
out end, in the blunders and absurdities of our own spe-
cies: such improprieties receive a different punishment,
as will appear by what follows. The emotions of con-
tempt and of laughter occasioned by an impropriety of
this kind, uniting intimately in the mind of the spectator,
are expressed externally by a peculiar sort of laugh, term-
ed a laugh of derision or scorn. An impropriety that
thus moves not only contempt but laughter, is distingui-
shed by the epithet of ridiculous; and a laugh of deri-
son or scorn is the punishment provided for it by nature.
Nor ought it to escape observation, that we are so fond of
inflicting this punishment, as sometimes to exert it
even against creatures of an inferior species: witness a
turkey-cock swelling with pride, and strutting with dis-
played feathers; a ridiculous object, which in a gay mood
is apt to provoke a laugh of derision.
We must not expect, that these different improprieties are separated by distinct boundaries: for of improprieties, from the slightest to the most gross, from the most ribble to the most serious, there are degrees without end. Hence it is, that in viewing some unbecoming actions, too ribble for anger, and too serious for derision, the spectator feels a sort of mixed emotion, partaking both of derision and of anger; which account for an expression, common with respect to the impropriety of some actions, that we know not whether to laugh or be angry.

It cannot fail to be observed, that in the case of a ribble impropriety, which is always allowed, the contempt we have for the offender is extremely faint, though derision, its gratification, is extremely pleasant. This disproportion between a passion and its gratification, seems not conformable to the analogy of nature. In looking about for a solution, we must reflect upon what is laid down above, that an improper action not only moves our contempt for the author, but also, by means of contrast, swelling the good opinion we have of ourselves. This contributes, more than any other article, to the pleasure we have in ridiculing follies and absurdities; and accordingly, it is well known, that they who put the greatest value upon themselves are the most prone to laugh at others. Pride, which is a vivid passion, pleasant in itself, and not less so in its gratification, would singly be sufficient to account for the pleasure of ridicule, without borrowing any aid from contempt. Hence appears the reason of a noted observation, That we are the most disposed to ridicule the blunders and absurdities of others, when we are noted observers. That we are the most inclined to ridicule the follies and absurdities of others, when we are noted observers.

With regard to the final causes of congruity and impropriety; one, regarding congruity, is pretty obvious, that the sense of congruity, as one principle of the fine arts, contributes in a remarkable degree to our entertainment. Congruity, indeed, with respect to quantity, coincides with proportion: when the parts of a building are nicely adjusted to each other, it may be said indifferently, that it is agreeable by the congruity of its parts, or by the proportion of its parts. But propriety, which regards voluntary agents only, can never be the same with proportion: a very long nose is disproportioned, but cannot be termed improper. In some instances, it is true, impropriety coincides with disproportion in the same subject, but never in the same respect; for example, a very little man buckled to a long toledo: considering the man and the sword with respect to size, we perceive a disproportion; considering the sword as the choice of the man, we perceive an impropriety.

The sense of impropriety with respect to mistakes, blunders, and absurdities, is happily contrived for the good of mankind. In the spectators, it is productive of mirth and laughter, excellent recreation in an interval from business. But this is a trifle in respect of what follows. It is painful to be the subject of ridicule; and to punish with ridicule the man who is guilty of an absurdity, tends to put him more upon his guard in time coming. Thus even the most innocent blunder is not committed with impunity; because, were errors licensed where they do no hurt, inattention would grow into a habit, and be the occasion of much hurt.

The final cause of propriety as to moral duties, is of all the most illustrious. To have a just notion of it, the moral duties that respect others must be distinguished from those that respect ourselves. Fidelity, gratitude, and the forbearing injury, are examples of the first sort; temperance, modesty, firmness of mind, are examples of the other: the former are made duties by the sense of justice; the latter by the sense of propriety. Here is a final cause of the sense of propriety, that must route our attention. It is undoubtedly the interest of every man, to suit his behaviour to the dignity of his nature, and to the station allotted him by Providence; for such rational conduct contributes in every respect to happiness, by preferring health, by procuring plenty, by gaining the esteem of others, and, which of all is the greatest blessing, by gaining a justly-founded self-esteem. But in a matter so essential to our well-being, even self-interest is not relied on: the powerful authority of duty is superadded to the motive of interest. The God of nature, in all things essential to our happiness, hath observed one uniform method: to keep us steady in our conduct, he hath fortified us with natural laws and principles, which prevent many aberrations, that would daily happen were we totally surrendered to so fallible a guide as is human reason. Propriety cannot rightly be considered in another light, than as the natural law that regulates our conduct with respect to ourselves; as justice is the natural law that regulates our conduct with respect to others. We call propriety a law, not less than justice; because both are equally rules of conduct that ought to be obeyed: propriety includes this obligation; for to say an action is proper, is, in other words, to say, that it ought to be performed; and to say it is improper, is, in other words, to say that it ought to be forbore. It is this very character of ought and should that makes justice a law to us; and the same character is applicable to propriety, though perhaps more faintly than to justice: but the difference is in degree only, not in kind; and we ought, without hesitation or reluctance, to submit equally to the government of both.

But it must, in the next place, be observed, that to the sense of propriety, as well as to justice, are annexed the functions of rewards and punishments; which evidently prove the one to be a law as well as the other. The satisfaction a man hath in doing his duty, joined with the esteem and good will of others, is the reward that belongs to both equally. The punishments also, though not the same, are nearly allied; and differ in degree more than in quality. Disobedience to the law of justice, is punished with remorse; disobedience to the law of propriety, with shame, which is remorse in a lower degree. Every transgression of the law of justice raises indignation in the beholder; and so doth every flagrant transgression of the law of propriety. Slighter improprieties receive a milder punishment: they are always rebuked with some degree of contempt, and frequently with derision. In general, it is true, that the rewards and punishments annexed to the sense of propriety, are
CONIC SECTIONS.

CONIC SECTIONS are curve lines formed by the interferences of a cone and plane.

If a cone be cut by a plane through the vertex, the section will be a triangle ABC, Plate LXVII. fig. 1.

If a cone be cut by a plane parallel to its base, the section will be a circle. If it be cut by a plane DEF, the section is a parabola; if it be cut by a plane DR, fig. 2, meeting AC extended beyond A, it is an hyperbola.

If any line HG, fig. 1, be drawn in a parabola perpendicular to DP, the square of HG will be to the square of AC, the section is an ellipse; and if it be cut by a plane DMO, fig. 3, which would meet AC extended beyond A, it is an hyperbola.

If any line HG, fig. 1, be drawn in a parabola perpendicular to DP, the square of HG will be to the square of AC, the section is an ellipse; and if it be cut by a plane DMO, fig. 3, which would meet AC extended beyond A, it is an hyperbola.

If any two points, as A and B, fig. 5, be taken in any plane, and in them are fixed the extremities of a thread, whose length is greater than the distance between the points, and the thread extended by means of a small pin C, and if the pin be moved round from any point until it return to the place from whence it began to move, the thread being extended during the whole time of the revolution, the figure which the small pin by this revolution describes is called an Ellipse.

The points AB are called the foci; D, the centre; EF, the transverse axis; GH, the lesser axis; and any other line passing through D, a diameter.

HYPERBOLA.

"If to the point A, fig. 6, in any plane, one end of the rule AB be placed, in such a manner, that about that point, as a center, it may freely move; and if to the other end B, of the rule AB, be fixed the extremity of the thread BDC, whose length is smaller than the rule AB, and the other end of the thread being fixed in the point C, coinciding with the side of the rule AB, which is in the same plane with the given point A; and let part of the thread, as BD, be brought close to the side of the rule AB, by means of a small pin D; then let the rule be moved about the point A, from C towards T, the thread all the while being extended, and the remaining part coinciding with the side of the rule being ftopt from going from it by means of the small pin, and by the motion of the small pin D, a certain figure is described which is called the semi-hyperbola."

The other semi-hyperbola is described in the same way, and the opposite HKF, by fixing the ruler to C, and the thread to A, and describing it in the same manner. A and C are called foci; the point G, which bisects AC, the center; KE, the transverse axis; a line drawn through the center meeting the hyperbolas, a transverse diameter; a line drawn through the center, perpendicular to the transverse axis, and cut off by the circle MN, whose center is E, and radius equal to CG, is called the second axis.

If a line be drawn through the vertex E, equal and parallel to the second axis GF, and GO be joined, they are called asymptotes. Any line drawn through the center, not meeting the hyperbolas, and equal in length to the
part of a tangent parallel to it, and intercepted between the asymptotes, is called a second diameter.

An ordinate to any section is a line bisected by a diameter and the abscissa, the part of the diameter cut off by the ordinate.

Conjugate diameters in the ellipse and hyperbola are such as mutually bisect lines parallel to the other; and a third proportional to two conjugate diameters is called the latus rectum of that diameter, which is the first in the proportion.

In the parabola, the lines drawn from any point to the focus are equal to perpendiculars to the directrix; being both equal to the part of the thread separated from the ruler.

In the ellipse, the two lines drawn from any point in the curve to the foci are equal to each other, being equal to the length of the thread; they are also equal to the transverse axis. In the hyperbola the difference of the lines drawn from any point to the foci is equal, being equal to the difference of the lengths of the ruler and thread, and is equal to the transverse axis.

From these fundamental properties all the others are derived.

The ellipse returns into itself. The parabola and hyperbola may be extended without limit.

Every line perpendicular to the directrix of a parabola meets it in one point, and falls afterwards within it; and every line drawn from the focus meets it in one point, and falls afterwards without it. And every line that passes through a parabola, not perpendicular to the directrix, will meet it again, but only once.

Every line passing through the center of an ellipse is bisected by it; the transverse axis is the greatest of all these lines; the lesser axis the least; and these nearer the transverse axis greater than those more remote.

In the hyperbola, every line passing through the center is bisected by the opposite hyperbola, and the transverse axis is the least of all these lines; the second axis is the least of the first and second diameters. Every line drawn from the center within the angle contained by the asymptotes, meets it once, and falls afterwards within it; and every line drawn through the center without that angle never meets it; and a line which cuts one of the asymptotes, and cuts the other extended beyond the center, will meet both the opposite hyperbolas in one point.

If a line GM, fig. 4, be drawn from a point in a parabola perpendicular to the axis, it will be an ordinate to the axis, and its square will be equal to the rectangle under the abscissa and latus rectum; for, because GMC is a right angle, GM is equal to the difference of GC and CM; but GC is equal to GE, which is equal to MB; therefore GM is equal to BM - CM; which, because CI and IB are equal, is (5 Enc. 2) equal to four times the rectangle under MI and IB, or equal to the rectangle under MI and the latus rectum.

Hence it follows, that if different ordinates be drawn to the axis, their squares being each equal to the rectangle under the abscissa and latus rectum, will be to each other in the proportion of the abscissas, which is the same property as was shown before to take place in the parabola cut from the cone, and proves those curves to be the same.

This property is extended also to the ordinates of other diameters, whose squares are equal to the rectangle under the abscissas and parameters of their respective diameters.

In the ellipse, the square of the ordinate is to the rectangle under the segments of the diameter, as the square of the diameter parallel to the ordinate to the square of the diameter to which it is drawn, or as the first diameter to its latus rectum; that is, \( LK^2 \) (fig. 5) is to \( EK^2 \) as \( EF^2 \) to \( GH^2 \).

In the hyperbola, the square of the ordinate is to the rectangle contained under the segments of the diameters between the vertices, as the square of the diameter parallel to the ordinate to the square of the diameter to which it is drawn, or as the first diameter to its latus rectum; that is, \( SX^2 \) is to \( EXK^2 \) as \( MN^2 \) to \( KE^2 \).

Or if an ordinate be drawn to a second diameter, its square will be to the sum of the squares of the second diameter, and of the line intercepted between the ordinate and centre, in the same proportion; that is, \( RZ^2 \) (fig. 6) is to \( ZG^2 \) added to \( GM^2 \), as \( KE^2 \) to \( MN^2 \). These are the most important properties of the conic sections: and, by means of these, it is demonstrated, that the figures are the same described on a plane as cut from the cone; which we have demonstrated in the case of the parabola.

**Equations of the Conic Sections.**

The equations of the conic sections are derived from the above properties. The equation of any curve is an algebraic expression, which denotes the relation between the ordinate and abscissa; the abscissa being equal to \( x \), and the ordinate equal to \( y \).

If \( p \) be the parameter of a parabola, then \( y^2 = px \); which is an equation for all parabolas.

If \( a \) be the diameter of an ellipse, \( p \) its parameter; then \( y^2 = ax - xx : : p : a \); and \( y^2 = \frac{p}{a} - ax + xx \); an equation for all ellipses.

If \( a \) be a transverse diameter of a hyperbola, \( p \) its parameter; then \( y^2 = a x + xx : : p : a \), and \( y^2 = \frac{p}{a} x + xx \).

If \( a \) be a second diameter of an hyperbola, then \( y^2 = aa + xx : : p : a \); and \( y^2 = \frac{p}{a} x + aa + xx \); which are equations for all hyperbolas.

As all these equations are expressed by the second powers of \( x \) and \( y \), all conic sections are curves of the second order; and conversely, the locus of every quadratic equation is a conic section, and is a parabola, ellipse, or hyperbola, according as the form of the equation corresponds with the above ones, or with some other deduced from lines drawn in a different manner with respect to the section.

**General Properties of Conic Sections.**

A tangent to a parabola bisects the angle contained by the lines drawn to the focus and directrix; in an ellipse.
ellipre and hyperbola, it bisefts the angle contained by
the lines drawn to the foci.

In all the sections, lines parallel to the tangent are
ordinates to the diameter passing through the point of
contact; and in the ellipse and hyperbola, the diameters
parallel to the tangent, and those passing through the
points of contact, are mutually conjugate to each other.
If an ordinate be drawn from a point to a diameter and a
tangent from the same point which meets the diameter pro-
duced; in the parabola the part of the diameter betwixt
the ordinate and tangent will be bifeñted in the vertex;
and in the ellipse and hyperbola, the diameter betwixt
the vertices of any conjugate diameters, in the same el-

Properties peculiar to the Hyperbola.

As the hyperbola has some curious properties arising
from its asymptotes, which appear at first view almost
incredible, we shall briefly demonstrate them.
1. The hyperbola and its asymptotes never meet: if
not, let them meet in S, fig. 6.; then by the property of
the curve the rectangle KXE is to SX as GE to GM
or EP; that is, SX to SX'; wherefore, KXE will
be equal to the square of GX; but the rectangle
KXE, together with the square of GE, is also equal to
the square of GX; which is absurd.
2. If a line be drawn through a hyperbola parallel to
its second axis, the rectangle, by the segments of that
line, bifefts the point in the hyperbola and the asymp-
totes, will be equal to the square of the second axis.
For, if SQ, fig. 6. be drawn perpendicular to the second
axis, by the property of the curve, the square of MG, that
is, the square of PE, is to the square of GE, as the
quares of ZG and MG are equal to the square of GE, together, to the
square of ZG or GX; and the squares of RX and GX
are in the same proportion, because the triangles RXG,
PEG are equiangular; therefore the squares ZG and
MG are equal to the square of RX; from which taking
the equal squares of SX and ZG, there remains the
rectangle RSV, equal to the square of MG.
3. Hence, if right lines be drawn parallel to the second
axis, cutting an hyperbola and its asymptotes, the rec-
tangles contained betwixt the hyperbola and points where
the lines cut the asymptotes will be equal to each o-
her; for they are severally equal to the square of the
second axis.
4. If from any points, d and S, in a hyperbola, there
be drawn lines parallel to the asymptotes dS and Sb dc,
the rectangle under dS and dc will be equal to the rect-
angle under GS and SB; also the parallelograms dS, GS,
and SQGB, which are equiangular, and consequently
proportional to the rectangles, are equal.
For draw YW RV parallel to the second axis, the
rectangle YdW is equal to the rectangle RSV; where-
fore, WD is to SV as RS is to dY. But because

the triangles RQS, AYD, and GSV c dW, are
equivangular, Wd is to SV as cd to SB, and RS
is to AD as SQ to dS; wherefore, dS is to SB as
SQ to dS; and the rectangle dc, dS, is equal to the
rectangle QS, SB.
5. The asymptotes always approach nearer the hyper-

For, because the rectangle under SQ and Sb, or QG,
is equal to the rectangle under dS and dc, or AG, and
QG is greater than aG; therefore dS is greater than QS.
6. The asymptotes come nearer the hyperbola than any
able distance.
Let X be any small line. Take any point, as d, in the
hyperbola, and draw dS, dc, parallel to the asymp-
totes; and as X is to dS, so let aG be to QG. Draw
QS parallel to dS, meeting the hyperbola in S, then
QS will be equal to X. For the rectangle SQG will be
equal to the rectangle dS aG, and consequently SQ is to
da as AG to QG.
If any point be taken in the asymptote below Q, it

can easily be shown that its distance is less than the
line X.

Areas contained by Conic Sections.

The area of a parabola is equal to 
the area of a
circumscribed parallelogram.

The area of an ellipse is equal to the area of a
circle whose diameter is a mean proportional betwixt its great-

If two lines, ad and QS, be drawn parallel to one of
the asymptotes of an hyperbola, the space aQ s, d, bounded
by these parallel lines, the asymptotes and the hy-
perbola will be equal to the logarithm of aQ, whose
module is ad, supposing aG equal to unity.

Curvature of Conic Sections.

The curvature of any conic section, at the vertices of
its axis, is equal to the curvature of a circle whose dia-

If a tangent be drawn from any other point of a conic
section, the curvature of the section in that point will be
equal to the curvature of a circle to which the fame line
is a tangent, and which cuts off from the diameter of
the section, drawn through the point, a part equal to
its parameter.

Uses of Conic Sections.

Any body, projected from the surface of the earth,
describes a parabola, to which the direction wherein it
is projected is a tangent; and the distance of the direc-
tix is equal to the height from which a body must fall to ac-
quire the velocity whereby it is projected; hence the
properties of the parabola are the foundation of gunnery.

All bodies acted on by a central force, which decrea-
ses as the square of the distances increases, and impre-

fors of any projectile motion, making any angle with
the direction of the central force, must describe conic
sections, having the central force in one of the foci, and
will
CONIC SECTIONS.

Uses of Conic Sections in the Solution of Geometrical Problems.

Many problems can be solved by conic sections that cannot be solved by right lines and circles. The following theorems, which follow from the simpler properties of the sections, will give a specimen of this.

A point equally distant from a given point and a given line, is situated in a given parabola.

A point, the sum of whose distances from two given points is given, is situated in a given ellipse.

A point, the difference of whose distances from two given points is given, is situated in a given hyperbola.

CONIC SECTIONS.

weft; being about 100 miles in length, and 80 in breadth.

CONNECTION, or Connexion, the relation or dependence of one thing upon another.

CONNECTION, or Continuity, in the drama, consists in the joining of the several scenes together. The connection is said to be observed, when the scenes of an act succeed one another immediately, and are so joined as that the stage is never left empty.

CONNOISSEUR, a French word much used of late in English, to signify a person well versed in any thing; whence it is used for a critic, or a person who is a thorough judge of any subject.

CONNOR, a city of Ireland, in the county of Antrim, and province of Ulster, situated about six miles north of Antrim, in 6° 30' W. long. and 54° 50' N. lat.

CONCARPODENDRON, in botany. See Protea.

CONCARPUS, the button-tree, in botany, a genus of the pentandria monogynia class. The corolla consists of four petals; the seeds are naked, solitary, and below the flower; and the flowers are aggregated. There are three species, all natives of the Indies.

CONOID, in geometry, a solid body, generated by the revolution of a conic section about its axis. See Conic Sections.

CONOIDES, in anatomy, a gland found in the third ventricle of the brain, called pinealis, from its resemblance to a pine-apple.

CONQUEST. See Scots Law, title, Succession in heritable rights.

CONSANGUINITY, the relation subsisting between persons of the same blood, or who are sprung from the same root.

Consanguinity and affinity, degrees of, forbidden in marriage; see Scots Law, title, Marriage. Confanguinity or affinity, an objection against a judge; see title, Jurisdiction and judges: Against a witness; see title, Probation.

CONSCIENCE, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil. See Morals.

CONSCRIPT, in Roman antiquity, an appellation given to the senators of Rome, who were called conscript-fathers on account of their names being entered all in one register.

CONSECRATION, the act of devoting any thing to the service and worship of God. In England, churches have been always consecrated with particular ceremonies, the form of which was left to the discretion of the bishop.

CONSENT, in a general sense, denotes much the same with assent. See Assent.

Consent of parts, in the animal economy. See Sympathy.

CONSEQUENCE, in logic, the conclusion, or what results from reason or argument.

CONSERVATOR, an officer ordained for the security and preservation of the privileges of some cities and communities, having a commission to judge of and determine the differences among them.

CONSERVATORY, a term sometimes used for a green-house, or ice-house.

CONSERVE, in pharmacy, a form of medicine, contrived to preserve the flowers, herbs, roots, pills, or fruits, of several simples, as near as possible to what they are when fresh gathered. Conerves are made by beating up the thing to be preserved, with sugar, viz. a triple quantity thereof to those that are most moist, and a double quantity to those that are least so.

CONSIGNATION of money; see Scots Law, title, Obligations and contracts in general: Of redemption-money; see title, Redeemable rights.

CONSISTENCE, in physics, that state of a body from which its component particles are so connected or entangled among themselves, as not to separate or recede from each other. It differs from continuity in this, that it implies a regard to motion or rest, which continuity does not, it being sufficient to denominate a thing continuous that its parts are contiguous to each other.

CONSISTORIAL, or Commissionary court. See Scots Law, title, Ecclesiastical persons.

CONSISTORY, at Rome, is an ecclesiastical assembly held in the presence of the pope, for the reception of princes or their ambassadors, for the canonization of saints, for the promotion of cardinals, and other important affairs.

CONSOLE, in architecture, an ornament cut upon the key of an arch, which has a projection, and, on occasion, serves to support little cornices, figures, bulbs, and vases. See Architecture.

CONSOLIDA, in botany. See Ajuga.

CONSOLIDATION, in medicine, the action of uniting broken bones, or the lips of wounds, by means of conglutinating medicines.

CONSONANCE, in music, is ordinarily used in the same sense with concord, viz. for the union or agreement of two sounds produced at the same time, the one grave and the other acute; which mingling in the air in a certain proportion, occasion an accord agreeable to the ear. See Music.

CONSONANT, a letter that cannot be sounded without some single or double vowel before or after it, as b, c, d, &c.

CONSPIRACY, in law, signifies an agreement between two or more, falsely to indict, or procure to be indicted, an innocent person, of felony.

CONSPIRATORS are, by statute, defined to be such as bind themselves by oath, covenant, or other alliance, to affit one another falsely and maliciously to indict persons, or falsely to maintain pleas.

Conspirators in treason are those that plot against the king and the government.

CONSTABLE, Lord High Constable, an ancient officer of the crowns both of England and France, whose authority was so very extensive, that the office has been laid aside in both kingdoms, except upon particular occasions.
Constitution also denotes an ordinance, decision, regulation, or law, made by authority of any superior, ecclesiastical or civil.

Apostolical Constitutions, a collection of regulations attributed to the apostles, and supposed to have been collected by St. Clement, whose name they likewise bear.

It is the general opinion, however, that they are spurious, and that St. Clement had no hand in them. They appeared first in the IVth age, but have been much changed and corrupted since that time. They are divided into eight books, consisting of a great number of rules and precepts, relating to the duties of Christians, and particularly the ceremonies and discipline of the church. Mr. Whifton, in opposition to the general opinion, afferts them to be a part of the sacred writings, dictated by the apostles in their meetings, and wrote down from their own mouths by St. Clement, and intended as a supplement to the New Testament, or rather as a systém of Christian faith and polity. The reason why the Constitutions are suspected by the orthodox, and, perhaps, the reason also why their genuineness is defended by Mr. Whifton, is, that they seem to favour Arianism.

Constitution, in a physical sense, signifies the particular temperature of the body.

Constrictor, an appellation given to several muscles on account of their constricting or closing some of the orifices of the body. See Anatomy.

Construction, in grammar, the connecting the words of a sentence according to the rules of the language.

Constitution, in a physical sense, denotes the part, in physiology, an essential part in the composition of any thing, differing little from what is otherwise called element or principle.

Constitution, in matters of policy, signifies the form of government established in any country or kingdom.

Constitution also denotes an ordinance, decision, regulation, or law, made by authority of any superior, ecclesiastical or civil.
the head of the senate: they commanded the armies, and were supreme judges of the differences between the citizens; but as they had made some abuse of this power, it was allowed by the Valerian law for the party aggrieved to appeal from their tribunal to the people, especially in cases where the life of a citizen was concerned. Under the emperors, consul was little more than an honourable title, and at last it became absolutely extinct in the time of Justinian. From the establishment of the republic to the consulate of Bassil, that is, from the year of Rome 244, to the year of Rome 1294, the years are accounted by the consuls; but after that period, the time was computed by the years of the emperors reigns and the indictions. Consul, at present, is an officer established by virtue of a commission from the king and other princes, in all foreign countries of any considerable trade, to facilitate and dispatch business, and protect the merchants of the nation. The consuls are to keep up a correspondence with the ministers of England residing in the courts wherein their confulate depends. They are to support the commerce and the interest of the nation; to dispose of the sums given and the preffents made to the lords and principals of places, to obtain their protection, and prevent the insults of the natives on the merchants of the nation.

Consummation, the end or completion of the work. Thus we say, the consummation of all things, meaning the world.

Consumption, in medicine, a word of very extensive signification, implies all disorders that bring any decay or waste upon the constitution; but is most used for the phthisia pulmonalis. See Medicine.

Contact, is when one line, plane, or body, is made to touch another, and the parts that do thus touch, are called the points or places of contact.

Contagion, in physic, the communicating a disease from one body to another. In some diseases it is only effected by an immediate contact or touch, as the venom of the pox; in others, it is conveyed by infected cloaths, as the itch; and in others, it is transmitted through the air at a considerable distance, by means of fumes or effluvia expiring from the sick. as in the plague and other pestilential disorders, in which the air is said to be contagious.

Contemplation, an act of the mind, whereby it applies itself to consider and reflect upon the works of God, nature, &c.

Contemporary, a person or thing that existed in the same age with another. Thus, Socrates, Plato, and Aristophanes, were contemporaries.

Content, in geometry, the area or quantity of matter or space included in certain bounds. See Geometry.

Contessa, a port-town of Turkey, in Europe, in the province of Macedonia, situated on a bay of the Archipelago, about 200 miles south-west of Constantinople: E. long. 25°, and N. lat. 41°.

Context, among divines and critics, that part of scripture or of a writing that precedes and follows the text.

Conti, a town of Picardy in France, about fifteen miles south-west of Amiens: E. long. 2° 20', N. lat. 49° 40'.

Continuity, is defined by some schoolmen the immediate cohesion of parts in the same quantum; by others, a mode of body, whereby its extremities become one; and by others, a state of body resulting from the mutual implication of its parts. There are two kinds of continuity, mathematical and physical. The first is merely imaginary, since it supposes real or physical parts where there are none.

Physical continuity is that state of two or more particles, in which their parts are so mutually implicated as to constitute one uninterrupted quantity or continuum.

Continuo, in music, signifies the thorough bass, as basso continuo is the continual or thorough bass, which is sometimes marked in music books by the letters B, C.

Continuation, in medicine, has many significations.

1. It denotes the iliac position. 2. An incomplete dislocation, when a bone is in part, but not entirely, forced from its articulation. 3. A dislocation of the vertebrae of the back side-ways, or a crookedness of these vertebrae. And, 4. A dislocation of the head, in which it is drawn towards one side, either by a spasmodic contraction of the muscles on the same side, or a palsy of the antagonist muscles on the other.

Contour, in painting, the out-line, or that which defines a figure.

A great part of the skill of the painter lies in managing the contours well. Contour, with the Italian painters, signifies the lineaments of the face.

Contourne, in heraldry, is used when a beast is represented standing or running with its face to the sinister side of the escutcheon. they being always supposed to look to the right, if not otherwise expressed.

Contourniated, a term among antiquaries applied to medals, the edges of which appear as if turned in a lath. This sort of work seems to have had its origin in Greece, and to have been designed to perpetuate the memories of great men, particularly those who had bore away the prize at the solemn games. Such are
are those remaining of Homer, Solon, Euclid, Pythagoras, Socrates, and several athletes.

CONTRABAND, in commerce, a prohibited commodity, or merchandise bought or sold, imported or exported, in prejudice to the laws and ordinances of a state, or the public prohibitions of the sovereign. Contraband goods are not only liable to confiscation themselves, but also subject all other allowed merchandise found with them in the same box, bale or parcel, together with the horses, waggon, &c. which conduct them. There are contrabands likewise, which, besides the forfeiture of the goods, are attended with several penalties and disabilities.

CONTRACT, in a general sense, a mutual consent of two or more parties, who voluntarily promise and obligate themselves to do something, pay a certain sum, or the like. All donations, exchanges, leases, &c. are so many different contracts.

CONTRACTILE force, that property or power inherent in certain bodies, whereby, when extended, they are enabled to draw themselves up again to their former dimensions.

CONTRACTION, in grammar, is the reducing of two syllables into one, as can't for cannot, should'nt for shouldn't, &c.

CONTRACTION, in physics, the diminishing the extent or dimensions of a body, or the causing its parts to approach nearer to each other, in which sense it stands opposed to dilatation or expansion.

CONTRA-FISSURE, in surgery, a kind of fissure, in the cranium, which sometimes happens on the side opposite to that which received the blow; or, at least, at some distance from it. See Surgery.

CONTRARIETY, an opposition between two things, which imports their being contrary to one another; and consists in this, that one of the terms implies a negation of the other, either mediately or immediately; so that contrariety may be said to be the contrary, or opposition of two things, one of which imports the absence of the other, as love and hatred.

CONTRARY, a positive opposite, which, subduing by turns in the same subject with its opposite, is as remote from it as possible, expels it, and is mutually expelled by it. Blackness and whiteness, cold and heat, are such contraries.

CONTRAST. See Resemblance.

CONTRATE-wheel, in watch-work, that next to the crown, the teeth and hoop whereof lie contrary to those of the other wheels, from whence it takes its name. See Watch Making.

CONTRAVALLATION, or the line Contravallation, in fortification, a trench guarded with a parapet, and usually cut round about a place by the besiegers, to secure themselves on that side, and to stop the fallies of the garrison. See Fortification.

CONTRAVENTION, in law, a man's failing to discharge his word, obligation, duty, or the laws or customs of the place.

CONTRAYERVA, in botany. See Dorstenia.

CONTRÉ, in heraldry, an appellation given to several bearings, on account of their cutting the shield contrary and opposite ways: thus we meet with contre-bend, contre-chevron, contre-pale, &c. when there are two ordinaries of the same nature opposite to each other, so as colour may be opposed to metal, and metal to colour. See Counter.

CONTRITION, in theology, a sorrow for our sins, resulting from the reflection of having offended God, from the sole consideration of his goodness, without any regard to the punishment due to the trespass, and attended with a sincere resolution of reforming them.

CONTROL is properly a double register kept of acts, issues, &c. of the officers or commissioners in the revenue, army, &c. in order to perceive the true state thereof, and to certify the truth, and the due keeping of the acts subject to the engraffement.

CONTROLLER, an officer appointed to control or oversee the accounts of other officers, and, on occasion, to certify whether or no things have been controlled or examined.

In Britain we have several officers of this name, as controller of the king's house, controller of the navy, controller of the customs, controller of the mint, &c.

CONTROLLER of the hanaper, an officer that attends the lord chancellor daily, in term and in real-time, to take all things sealed in leathern bags from the clerks of the hanaper, and to make the number and effect thereof, and enter them in a book, with all the duties belonging to the king and other officers for the same, and to charge the clerk of the hanaper with them.

CONTROLLER of the pipe, an officer of the exchequer, that makes out a summons twice every year, to levy the farms and debts of the pipe. See Pipe, and Exchequer.

CONTROLLERS of the pells, two officers of the exchequer, who are the chamberlain's clerks, and keep a control of the pell of receipts, and goings out.

CONTRUSION, in medicine and surgery, any hurt of the body that is inflicted by a blunt instrument. See Surgery.

CONVALLARIA, or Lilly of the valley, in botany, a genus of the hexandria monogynia class. The corolla is divided into six segments; and the berry is spotted, and has three cells. The species are eight, three of which are natives of Britain, viz. the majalis, or may-lily; the multiflora, or Solomon's-seal; and the polygonatum, or sweet smelling Solomon's-seal.

CONVENT, in church-history. See Monastery.

CONVENTICLE, a private assembly or meeting, for the exercise of religion. The word was first attributed as an appellation of reproach to the religious assemblies of Wickliffe, in this nation, in the reigns of Edward III. and Richard II. There were several statutes made in former reigns, for the suppression of conventicles; but, by 1 William and Mary, it is ordered, that dissenters may assemble for the performance of religious worship, provided their doors be not locked, barred, or bolted.

CONVENT, a treaty, contract, or agreement between two or more parties.

CONVENTION is also a name given to an extraordinary assembly of parliament, or the estates of the realm, held...
CONVERGING, or Convergent lines, in geometry, are such as continually approach nearer one another, or whose distances become still less and less. These are opposed to divergent lines, the distances of which become continually greater: those lines which converge one way, diverge the other.

Converging rays, in optics, those rays that, issuing from divers points of an object, incline towards another, till, at last, they meet and cross, and then become diverging rays. See Optics.

Converse, in mathematics. One proposition is called the converse of another, when, after a conclusion is drawn from something supposed in the converse proposition, that conclusion is supposed; and then, that which in the other was supposed, is now drawn as a conclusion from it: thus, when two sides of a triangle are equal, the angles under these sides are equal; and, on the converse, if these angles are equal, the two sides are equal.

Conversion, in a moral sense, implies a repentance for a temper and conduct unworthy our nature, and unbecoming our obligations to its Author, and a resolution to act a wiser and a better part for the future.

Conversion, in war, a military motion whereby the front of a battalion is turned where the flank was, in case the battalion is attacked in the flank.

Convex, an appellation given to the exterior surface of gibbous or globular bodies, in opposition to the hollow inner surface of such bodies, which is called concave: thus we say, a convex frieze, lens, mirror, superficies, &c.

Convexity, that configuration or shape of a body, on account of which it is denominated convex.

Conveyance, in law, a deed or instrument that conveys by land into a town, army, or the like, in the presence of men, money, ammunition, or provisions, conveyed by land into a town, army, or the like.

Convoy, in marine affairs, one or more ships of war, employed to accompany and protect merchant ships, and prevent their being insulted by pirates, or the enemies of the state in time of war.

Convoy, in military matters, a body of men that guard any supply of men, money, ammunition, or provisions, conveyed by land into a town, army, or the like, in time of war.

Convulsion, in medicine, a preternatural and violent contraction of the membranous and muscular parts of the body. See Medicine.

Conway, a market-town of Carnarvonshire in North Wales, situated near the mouth of a river of the same name, fifteen miles west of St Asaph: W. long. 3° 50', and N. lat. 53° 20'.

Conyza, or Flea-bane, in botany, a genus of the syngeenia polygama superflua class. The receptacle is naked; the pappus is simple; the calix is roundish and imbricated; and the rays of the corolla are divided into three segments. There are nineteen species, only one of which is a native of Britain, viz. the squarrosa, or glowman's spikenard.

Conza, a town of the kingdom of Naples in Italy, situated on the farther Principate, on the river Offanto, fifty miles south-east of the city of Naples: E. long. 16°, N. lat. 41°. It is the seat of an archbishop.

Cooper, in geography, the name of a river in Carolina in North America.

Cooper, on board a ship, he that looks to the casks, and all other vessels for beer, water, or any other liquor. He has a mate under him.

Co-ordinate, something of equal order, rank, or degree with another. See Order.

Copaiba
COPAIBA, or balsam of Copaiba, a liquid resinous juice, flowing from incisions made in the trunk of the fera, a large tree which grows in the Spanish West Indies, and is used as a corroborating and detergent medicine.

COPAL, in the materia medica, a resin obtained from several forts of large trees in New Spain. It is brought to us in irregular lumps; but it has never come into use as a medicine, and is rarely to be met with in the shops.

COPENHAGEN, the capital of the kingdom of Denmark, situated on the eastern shore of the island of Zealand, upon a fine bay of the Baltic sea, not far from the strait called the Sound: E. long. 13°, and N. lat. 55° 30'.

COPERNICAN, in general, something belonging to Copernicus. Hence, Copernican system or hypothesis, that system of the world, wherein the sun is supposed to rest in the centre, and the planets, with the earth, to move in ellipses round him. See Vol. I. p. 434.

Copernicus, the name of an astronomical instrument, invented by Mr Whiston, to exhibit the motion and phenomena of the planets, both primary and secondary. It is built upon the Copernican system, and for that reason called by his name.

COPHTS, Cophti, or Copts, a name given to such of the Christians of Egypt as are of the sect of Jacobites.

The Cophts have a patriarch, who is styled the patriarch of Alexandria, having eleven or twelve bishops under him, but no archbishop. The rest of the clergy, whether secular or regular, are of the order of St Anthony, St Paul, and St Macarius, each of whom have their monasteries. The Cophts have seven sacraments, viz. baptism, the eucharist, confirmation, ordination, faith, fasting, and prayer.

Cophtic, or Coptic language, is that spoke by the Cophts, being the ancient language of the Egyptians, intermixed with the Greek, and the characters of it being those of the Greek.

The ancient Cophtic is now a dead language, to be met with no where but in books, and those only translations of the scriptures, and of ecclesiastical offices, or others that have a relation thereto; the language now used over all the country being that of the Arabic.

COPPER, a chemical vessel made of earth, pretty thick, and of the form of a platter or dish.

COPPERAS, a name given to the factitious green vitriol. See Chemistry.

The English copperas is made at Deptford, in the following manner, from pyrite. See Pyrite.

A heap of these stones, two or three foot thick, is laid in a bed well rammed; where being turned once in six months, in five or six years, by the action of the air and rain, they begin to dissolve, and yield a liquor which is received in pits, and thence conveyed into a cistern, in a boiling house. The liquor at length being pumped out of the cistern into a leaden boiler, and a quantity of iron added thereto; in two or three days the boiling is completed; care having been taken all along to supply it with fresh quantities of iron, and to restore the boiling, whenever it seems to abate. When boiled sufficiently, it is drawn off into a cooler, with sticks across, where it is left 14 or 15 days to sot. The nies of copperas are numerous. It is the chief ingredient in the dying of wool, cloths, and hats, black; in making ink, in tanning and dressing leather, &c. and from hence is prepared oil of vitriol, and a kind of Spanish brown for painters. In medicine it is rarely prescribed under the name of copperas, but it is a true salt of iron, and often prescribed under that name, and used instead of the genuine preparation; our chemists in general giving themselves no further trouble about the making of that salt, than to dissolve and purify the common copperas, and sot it again into crystals.

COPPER, or Copse, a little wood, consisting of under-woods, or such as may be raised either by sowing or planting.

COPY-HOLD, a tenure for which a tenant has nothing to sot but the copy of the rolls made by the steward of the lords court.

It is called a base tenure, because the tenant holds the land at the will of the lord. However, it is not simply at the will of the lord, but according to the custom of the manor by which such estate is descen
dible, and the tenants heirs may inherit it; and a copyholder, so long as he does his services, and does not break the custom, cannot be ejected by the lord; and if he be, he shall have trespas against him.

COPY-HOLDER, one who is admitted tenant of lands or tenements within a manor, which time out of mind, by use and custom of the manor, and custom of the lords court.

COQUIMBO, a port-town of Chili, on South America, situated at the mouth of a river of the same name, which discharges itself into the pacific ocean: W. long. 75° 10', and N. lat. 30°.

COR caroli, in astronomy, an extraconfellated star in the northern hemisphere, situated between the comas beroenices, and ura major, so called by Dr Halley in honour of king Charles.

COR HYDRAE, a fixed star of the first magnitude, in the constellation of hydra.
COR Leonis, or Regulus, in astronomy, a fixed star of the first magnitude in the constellation Leo.

CORACOMANTES, in antiquity, persons who foretold events from their observations on crows.

CORALLINA, or Coral, in zoology, a genus belonging to the order of vermes zoophyta. The trunk is radicated, jointed, and calcareous. The species are eight, distinguished by the form of their branches, and are found in the ocean adhering to stones, bones, shells, etc. The corals were formerly believed to be vegetable substances hardened by the air; but are generally believed to be composed of a congeries of animals, which are even endowed with the faculty of moving spontaneously. Linnaeus's order of zoophyta is composed of animals of this kind, as the spongia, fterculia, etc. See Natural History.

CORALLODENDRON, in botany. See Erythrina.

CORAL FISHERY. Red coral is found in the Mediterranean, on the shores of Provence, from Cape de la Couronne to that of St Tropez; about the isles of Majorca and Minorca; on the south of Sicily; on the coasts of Africa; and, lastly, in the Ethiopian ocean, about Cape Negro. The divers say, that the little branches are found only in the caverns whose situation is parallel to the earth's surface, and open to the south. The manner of fishing being nearly the same wherever coral is found, it will suffice to illustrate the method used at the baftion of France, under the direction of the company established at Marseilles for that fishery. Seven or eight men go in a boat commanded by the patron or proprietor, and when the net is thrown by the caller, the rest work the vessel, and help to draw the net in. The net is composed of two rafts of wood tied cross-wise, with leads fixed to them: to these they fasten a quantity of hemp twisted loosely round, and intermingled with some large netting. This instrument is let down where they think there is coral, and pulled up again, when the coral is strongly intangled in the hemp and netting. For this purpose, six boats are sometimes required; and if in hauling in, the rope happens to break, the fishermen run the hazard of being loft. Before the fishers go to sea, they agree for the price of the coral, which is sometimes more, sometimes less a pound; and they engage, on pain of corporal punishment, that neither they nor their crew shall embezze any, but deliver the whole to the proprietors. When the fishery is ended, which amounts one year with another to twenty-five quintals for each boat, it is divided into thirteen parts, of which the proprietor hath four, the callers two, and the other six men one each, the thirteenth belongs to the company for payment of the boat furnished them.

CORAN, or Alcoran. See Alcoran.

CORAX, in ornithology, the trivial name of a species of corvus. See Corvus.

CORBAN, a scripture term of an offering which had life, in opposition to the minchab which had no life.

CORBAN is also a ceremony which the Mahometans perform at the foot of mount Ararat, in Arabia, near Mecca. It consists in killing a great number of sheep, and distributing them among the poor.

CORBEL, in architecture, a representation of a basket, sometimes seen on the heads of the caryatides.

CORBY, a town of Germany, thirty miles east of Paderborn, in Westphalia: East long. 9° 20', N. lat. 51° 40'.

CORCHORUS, Jewish ballad, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals; the calix is deciduous, and consists of five leaves; and the capsule has many cells and valves. The species are six, none of them natives of Britain.

CORD OF WOOD, a certain quantity of wood for burning, so called because formerly measured with a cord. The dimensions of a flat cord of wood are eight feet long, four feet high, and four feet broad.

CORD-WOOD, is new wood, and such as, when brought by water, comes on board a vessel, in opposition to that which is floated.

CORDAGE, a term used, in general, for all sorts of cord, whether small, middling, or great. See Rope.

CORDATED, an appellation frequently given by naturalists to things somewhat resembling a heart.

CORDED, in heraldry. A cross corded some authors take for a cross wound or wrenched about with cords. See Cabled Cross.

CORDS, others, with more probability, take it for a cross made of two pieces of cord.

CORDELIER, in church-history, a Franciscan or religious of the order of St Francis.

CORDIA, in botany, a genus of the pentandria monogynia class. The corolla is trun£i-shaped, and has but one petal; the stylum is dichotomous; and the fruit is a bilocular drupa. The species are five, none of them natives of Britain.

CORDIAL, in medicine, whatever raises the spirits, and gives them a sudden strength and cheerfulness, as wine, spirits, the effluvia of flowers, fruit, and many other substances.

CORDON, in fortification, a row of stones, made round on the outside, and set between the wall of the fortres which lies aloof, and the parapet which stands perpendicular, after such a manner, that this difference may not be offensive to the eye: whence the cordons serve only as an ornament, ranging round about the place, being only used in fortification of stone-work. For in those made with earth, the void space is filled up with pointed flakes.

CORDERAS, mountains of South America, other-wise called Andes. See Andes.

CORDERAS, mountains of South America, otherwise called Andes. See Andes.

CORDOUA, Cordova, a city of Andalufsia, in Spain, situated
sufficient on the river Guadalquivir, seventy-two miles north-east of Seville, and seventy-five north of Malaga: W. long. 4° 45', and N. lat. 37° 45'.

COREA, an island or peninsula on the north-east coast of China, between 36° and 47° N. lat.

CORDWAINERS, a term whereby shoemakers are denominated in figurative. By a statute of Jac. I. the masters and wardens of the cordwainers' company, &c. are to appoint searchers and triers of leather; and no leather is to be sold before searched, sealed, &c.

CORDYLINE, in botany. See Yucca.

CORDYLYUS, the trivial name of a species of Lacerta. See Lacerta.

COREA, an island or peninsula on the north-east coast of China, between 36° and 47° N. lat.

CORFU, an island subject to the Venetians, situated in the Mediterranean, near the entrance of the gulf of Venice.

CORFU, an island subject to the Venetians, situated in the Mediterranean, near the entrance of the gulf of Venice.

CORFUS, in botany, a genus of the Linné digynia class of plants, whose corolla consists of two compressed, crooked, pointed petals, equal in size, and placed opposite one another: its fruit is a roundish capsule, compressed, bilocular, and having a furrowed edge; the seeds are of an oblong figure, and stand single. There are two species, none of them natives of Britain.

CORK, or CORK-TREE, in botany. See Quercus.

CORK, in geography, the capital of a county of the same name, in Ireland, and province of Munster, situated on the river Lee, about fifty miles south of Limerick: W. long. 8° 25, and N. lat. 51° 40'.

CORMANDEL-COAST, comprehends the eastern coast of the hither India, bounded by Golconda on the east, the bay of Bengal on the east, Madura on the south, and Bimnar on the west: it lies between 10° and 20° N. lat.

CORMORANT, in ornithology. See Tantalus.

CORK, in antiquity, a festival in honour of Prosperine.

COREOPSIS, in botany, a genus of the syngeenia class of plants, whose corolla consists of two compressed, crooked, pointed petals, equal in size, and placed opposite one another: its fruit is a roundish capsule, compressed, bilocular, and having a furrowed edge; the seeds are of an oblong figure, and stand single. There are two species, none of them natives of Britain.

CORK, or CORKING of a faddle, the pieces to which the bolliers are made fast; so called as having formerly been made of cork.

CORK, in geography, the capital of a county of the same name, in Ireland, and province of Munster, situated on the river Lee, about fifty miles south of Limerick: W. long. 8° 25, and N. lat. 51° 40'.

CORMANDER-COAST, comprehends the eastern coast of the hither India, bounded by Golconda on the east, the bay of Bengal on the east, Madura on the south, and Bimnar on the west: it lies between 10° and 20° N. lat.

CORMORANT, in ornithology. See Tantalus.

CORINTH, a city of European Turkey, situated near the isthmus into the Morea, about fifty miles west of Athens, in 23° E. long. and 37° 30' N. lat.

CORIS, in botany, a genus of the Linné digynia class of plants. The corolla has but one irregular leaf; the calyx is prickly, and the capsule has five valves. There is but one species, a native of Montpelier.

CORYSPERMUM, in botany, a genus of the monogynia class of plants, whose corolla consists of two compressed, crooked, pointed petals, equal in size, and placed opposite one another: its fruit is a roundish capsule, compressed, bilocular, and having a furrowed edge; the seeds are of an oblong figure, and stand single. There are two species, none of them natives of Britain.

CORK, or CORKING of a faddle, the pieces to which the bolliers are made fast; so called as having formerly been made of cork.

CORK, in geography, the capital of a county of the same name, in Ireland, and province of Munster, situated on the river Lee, about fifty miles south of Limerick: W. long. 8° 25, and N. lat. 51° 40'.

CORMADEC-COAST, comprehends the eastern coast of the hither India, bounded by Golconda on the east, the bay of Bengal on the east, Madura on the south, and Bimnar on the west: it lies between 10° and 20° N. lat.

CORMORANT, in ornithology. See Tantalus.

CORINTH, a city of European Turkey, situated near the isthmus into the Morea, about fifty miles west of Athens, in 23° E. long. and 37° 30' N. lat.

CORIS, in botany, a genus of the Linné digynia class of plants. The corolla has but one irregular leaf; the calyx is prickly, and the capsule has five valves. There is but one species, a native of Montpelier.

CORISPERMUM, in botany, a genus of the monogynia class of plants, whose corolla consists of two compressed, crooked, pointed petals, equal in size, and placed opposite one another: its fruit is a roundish capsule, compressed, bilocular, and having a furrowed edge; the seeds are of an oblong figure, and stand single. There are two species, none of them natives of Britain.

CORK, or CORKING of a faddle, the pieces to which the bolliers are made fast; so called as having formerly been made of cork.

CORK, in geography, the capital of a county of the same name, in Ireland, and province of Munster, situated on the river Lee, about fifty miles south of Limerick: W. long. 8° 25, and N. lat. 51° 40'.

CORMADEC-COAST, comprehends the eastern coast of the hither India, bounded by Golconda on the east, the bay of Bengal on the east, Madura on the south, and Bimnar on the west: it lies between 10° and 20° N. lat.
the depth of two or three fingers, and indoles them with an incrustation, through which neither air nor insects can penetrate.

Corn not exceeding the under mentioned prices have the following bounties per quarter, viz.

<table>
<thead>

Wheat 2 8 5
Rye 1 12
Barley and Malt 1 4
Oat-meal 0 15

In France corn of the growth of the kingdom is reckoned a contraband commodity.

**Corn-mill**, a water-engine for grinding of corn. See Mechanics.

Corn, in medicine and surgery, a hard tubercle like a flat wart, growing in several parts of the feet, especially upon the joints of the toes. See Medicine.

**Corn-machine-powder**, the same with what is sometimes called the earl of Warwick's powder, and pulvis de tribus. It is prepared thus: Take four ounces of calcined harthorn prepared, three ounces; grind them together into a powder. It is given as a purge.

**Cornage**, an ancient tenure, the service whereof was this: The foldiers were to move without the soldiers; whereas, when the trumpet on the lookout, and the cornets and trumpets sounded the charge or retreat, and the comets and trumpets sounded duello, the care and valour of the latter.

**Cornelia**, in botany. See Cornus.

**Cornet**, in the military art of the moderns, the third instrument much in the nature of a trumpet, which when the cornets and trumpets sounded the charge or retreat, and the cornets and trumpets sounded during the course of the battle.

**Corner**, in a general sense, the same with angle.

See Angle.

**Cornet**, in the military art of the ancients, an instrument much in the nature of a trumpet, which when it only sounded, the enligns were to march alone, without the soldiers; whereas, when the trumpet only sounded, the soldiers were to move without the enligns. The cornets and bucinses sounded the charge and retreat, and the cornets and trumpets sounded during the course of the battle.

**Corner**, in the military art of the moderns, the third commision-officer in a troop of horse or dragoons.

This is a very honourable post; he commands in the lieutenant's absence; his principal duty being to carry the standards, near the middle of the first rank of the squadron.

**Corneus**, the name by which Linneus calls a kind of tin-ore, found in black columns, with irregular sides, and terminating in prisms.

**Corniche, Cornish, or Cornice**, in architecture. See Architecture.

**Corniche** is also used, in general, for all little projections in masonry or joinery, even where there are no columns, as the corniche of a chimney, beaufet, &c.

**Corniche-ring**, of a piece of ordnance, that is next from the muzzle-ring, backward.

**Cornicularius**, in Roman antiquity, an officer of the army, appointed to assist the military tribune in quality of lieutenant.

**Cornix**, in ornithology, the trivial name of a species of corvus. See Corvus.

**Cornu.** See Horn.

**Cornu ammonis**, in natural history, fossil shells, called also serpent-stones, or snake-stones. They are found of all sizes, from the breadth of a sixpence to more than two feet in diameter; some of them rounded, others greatly compressed, and lodged in different strata of stones and clays; some again are smooth, and others ridged in different manners, their NGA and ridges being either straight, irregularly crooked, or undulated.

**Cornu cervi.** See Hartshorn.

**Cornucopia, or Horn of plenty, among painters, &c.** is represented under the figure of a large horn, out of which issue fruits, flowers, &c. Upon medals the cornucopia is given to all deities, genii, and heroes, to mark the felicity and abundance of all the wealth procured by the goodnes of the former, or the care and valour of the latter.

**Cornucopia**, in botany, a genus of the triandria dioica class. The involucrum consists of one tunnel-shaped crenated leaf, containing many flowers; and the calices are double-valved. There is but one species, viz., the cucullatum, a native of Smyrna.

**Cornus, or Cornel-tree**, in botany, a genus of the tetrandria monogyia class. The involucrum consists mostly of four leaves; the petals are four, and above the fruit, which is a bilocular gluma. There are five species, none of them natives of Britain.

**Cornutia**, in botany, a genus of the didynamia class. The involucrum consists of one tunnel-shaped crenated leaf, containing many flowers; and the calices are double-valved. There is but one species, viz., the cucullatum, a native of Smyrna.

**Corona borealis**, the Northern cross, in astronomy. See Vol. I. p. 486.

**Corona**, among botanists, denotes that edge of the corolla which gives the title of duke to the prince of Wales. It sends forty-four members to parliament.

**Corolla**, among botanists, the most conspicuous part of a flower, surrounding the organs of generation, and composed of one or more flower-leaves, most commonly called petals, to distinguish them from the leaves of the plant; according as there is one, two, or three of these petals, the corolla is said to be monopetalous, dipetalous, tripetalous, &c.

**Corollary** is a consequence drawn from something already advanced or demonstrated.

**Corollula**, a term used by botanists, to express the little partial flowers, which together make up the compound ones.

**Corona**, among anatomists, denotes that edge of the glans penis where the preputium begins. See Anatomy.

**Corona**, among botanists. See Pappus.

**Corona borealis**, the Northern crown, in astronomy. See Vol. I. p. 486.

**Corona imperialis**, in zoology, a synonyme of a species of conus. See Conus.

**Corona imperialis**, in botany. See Frutillaria.

**Corona**
COR 

CORONA solis, in botany. See Helianthus.

CORONA. See Jus.

CORONALE, in anatomy, the same with the os frontis. See Vol. I. p. 152.

CORONARIA, in botany. See Agrostema.

CORONARY vessels, in anatomy. See Anatomy, Part III. and IV.

CORONELLA, in botany. See Lysimachia.

CORONER, an ancient officer of this kingdom, so called because he is wholly employed for the king and crown.

The office of coroners especially concerns the pleas of the crown; and they are conservators of the peace in the county where elected, being usually two for each county. Their authority is judicial and ministerial: judicial, where a present comes to a violent death; to take and enter appeals of murder, pronounce judgment on outlawries, &c. and to inquire into the lands, goods, and escape of murders, treasure trove, wreck of the sea, deodands, &c. The ministerial power is when coroners execute the king's writs, on exception taken to the sheriff, as being party in a suit, of kin to either of the parties, or on the default of the sheriff, &c. The authority of the coroner does not terminate on the demise of the king, as that of judges, &c. does, who act by the king's commission. On default of sheriffs, coroners are to impanel juries, and to return issues on juries not appearing, &c.

CORONET. See Crown.

CORONET, or Cronet of a horse, the lowest part of the postern, which runs round the coffin, and is distinguished by the hair joining and covering the upper part of the hoof.

CORONILLA, in botany, a genus of the diadelphia decandria class. The calix is bilabiated, and the vexillum is hardly longer than the alic. There are three species, none of them natives of Britain.

CORONOPUS, in botany. See Plantago.

CORPUS reticulare. See Reticulare.

CORPUS Sibylli, a festival of the church, kept on the next Thursday after Trinity-Sunday, instituted in honour of the eucharist; to which also one of the colleges in Oxford is dedicated.

CORPUSCULE, in physics, a minute particle, or physical atom, being such as a natural body is made up of. By this word is not meant the elementary particles, nor the hypothetical principles of chemists; but such particles, whether of a simple or compound nature, whose parts will not be dissolved nor disintegrated by ordinary degrees of heat.

CORPUSCULAR philosophy, that way of philosophy which endeavours to explain things, and to account for the phenomena of nature by the motion, figure, rel, position, &c. of the corpuscles, or the minute particles of matter.

Mr Boyle fumes up the chief principles of the corpuscular hypothesis, which now flourishes under the mechanical philosophy, in these particulars:

1. They suppose that there is but one catholic or universal matter, which is an extended, impenetrable, and divisible substance, common to all bodies, and capable of all forms. 2. That this matter, in order to form the vast variety of natural bodies, must have motion in some or all its divisible parts; and that this motion was given to matter by God the Creator of all things, and has all manner of directions and tendencies. 3. Matter must also be actually divided into parts, and each of these primitive particles, fragments, or atoms of matter, must have its proper magnitude or size, as also its peculiar figure or shape. 4. They suppose also, that these differently sized and shaped particles may have as different orders and positions, whereof great variety may arise in the composition of bodies.

CORRECTION, in printing, the pointing out or discovering the faults in a printed sheet, in order to be amended by the compositor before it be printed off. See Printing.

CORRECTOR, in general, denotes something that mends the faults or bad qualities of others. CORRECTOR of the staple, a clerk belonging to the staple, whose business is to write down and record the bargains that merchants make there.
CORRECTOR, in medicine and pharmacy, an ingredient in a composition, which guards against or abates the force of another.

CORRELATIVE, something opposed to another in a certain relation. Thus, father and son are correlative.

CORROBORANTS, or Corroborative medicines.

CORRIGIOLA, in botany. See Illecebrum.

CORROSION, in a general sense, the addition of gnawing away, by degrees, the continuity of the parts of bodies.

CORRUPTION, the destruction, extinction, or, at least, cessation for a time, of the proper mode of existence of any natural body. See Putrefaction.

CORRUPTION of blood, in law, an infection accruing to a man's estate, attained of felony and treason, and to his issue; for as he loses all to the prince, &c. his issue cannot be heirs to him, or to any other ancestor by him: and if he were noble, his heirs are rendered ignoble.

CORSICA, an island in the Mediterranean, between 8° and 10° E. long. and between 41° and 43° N. lat. about one hundred miles south of Genoa, and subject to that republic; though the natives for many years disputed their right. This island is now in the hands of the French, after a glorious struggle for liberty under General Paoli.

CORTEX, or Cortex Peruvianus. See Cinchona.

CORTONA, a city of Tuscany, in Italy, about thirty-five miles south-east of Sienna: E. long. 13°, and N. lat. 43° 15'.

CORTUSA, in botany, a genus of the pentandria monogynia class. The corolla is rotated, with an open limbus; and the capsule has two valves. There are two species, none of them natives of Britain.

CORUNNA, or Corun, a port-town of Gallicia in Spain, situated on a fine bay of the Atlantic ocean, about thirty-two miles north of Compostella: W. long. 0°, and N. lat. 43°.

CORUS, in Jewish antiquity. See Homer.

Corus, in our old writers, denotes eight bushels, or a quarter.

Corus is also a wind, so called by the Jews, rising in the summer in the west; and is that at present called the north east-wind.

CORUSCATION, a glittering, or gleam of light issuing from any thing. It is chiefly used for a flash of lightening darting from the clouds in time of thunder.

CORVUS, the Raven, or Crow-kind, in ornithology, a genus of birds, of the order of picce, the distinguishing characteristics of which are these: The beak is convex and culatted; the nostrils are covered with bristly feathers; the tongue is forked and cartilaginous; and the feet are of the walking kind. The species are nineteen, viz. 1. The hottentottus, is of a greenish black colour, with long myrtaches, and an equal tail. It is found at the Cape of Good Hope. 2. The corax, or raven of English authors, is black, with a blueish back, and a roundish tail. It is a native of Europe, and feeds upon carrion: it is much given to theft, and may be taught to utter articulate sounds. 3. The corone, or carrion-crow, is of a black bluish colour, with the prime wing-feathers sharp, and a round tail; it lives upon carrion and fruits, and is a native of Europe. 4. The frugilegus, or rook, is black, with an ah-coloured forehead, and a roundish tail. The rocks assemble in flocks, and infest the corn-fields: many of them sleep together in the same tree, by which means they are easily taken. 5. The corvus, or roylon-crow, is ah-coloured, with the throat, wings, and tail black. It feeds upon worms, snails, frogs, caterpillars, &c. 6. The monedula, or Jack-daw, is of a dull-coloured forehead, and a roundish tail. The rocks assemble in flocks, and infest the corn-fields: many of them sleep together in the same tree, by which means they are easily taken. 7. The glandularius, or jay, has blueish wings, with transverse black and white lines; and the body is variegated with an iron-colour. It is a native of Europe, and feeds upon nuts, corn, and sometimes small birds. 8. The criptatus, or blue-crested jay, has the covert feathers of the wings marked with transverse black lines, a blueish body, and a black collar. It is a native of North America. 9. The cayanus, is of a violet colour above, and white below, with a black front and throat, and the point of the tail white: the feathers of the hind head are erect and rigid. It is a native of Cayenne. 10. The caryocatactes, is brown, and spotted with white; the wings and tail are black; the prime tail-feathers are white at the points, but the intermediate ones have a worn appearance. It is a native of Europe, and feeds upon nuts. 11. The bairdius is of a greenish black colour, with a forked tail.
It is found on the Philippine isles. 12. The afer, is of a violet blackish colour, and has a wedge-like tail. It is a native of Africa. 13. The pica, or magpie, is variegated with black and white, and its tail is shaped like a wedge. They build their nests in trees in a very artificial manner; the outside consists of thorns both above and below; leaving only a hole for their entrance. They lay five or six eggs, which are pale and spotted: they feed upon small birds, &c. and carefully lay up superfluous food till they become hungry again. They may be learned to talk pretty distinctly.

14. The senegalensis, is of a blackish violet colour, with black legs, and a wedge-shaped tail. It is a native of Senegal. 15. The brachyurus, is green below, with yellow lines on the head, and white spots on the wings. It is found in the Molucca isles. 16. The canadenfis, is of a dusky colour, with a yellow fore-head, and white below: it has a roundish tail, and is a native of Canada. 17. The pyrrhocorax, is blackish, with a yellow beak, and black legs. 18. The graculus, is of a blackish violet colour, with a yellow back and legs. 19. The eremita, is greenish, with a yellowish head, a small crest on the back part of the head, and a red beak and legs. The three last are natives of Switzerland.

Corvus, in Roman antiquity, a military engine, or rather a gallows, moveable at pleasure by means of pulleys, chiefly used in boarding the enemy's ships, to cover the men.

Corybantes, in antiquity, priests of the goddess Cybele, who, inspired with a sacred fury, danced up and down, toasting their heads, and beating on cymbals or brazen drums. They inhabited mount Ida, in the island of Crete, where they nourished the infant Jupiter, keeping a continual rattling with their cymbals, that his father Saturn, who had resolved to devour all his male offspring, might not hear the child's cries.

Corybantica, in Grecian antiquity, a festival kept in honor of the Corybantes.

Corycomachia, among the ancients, was a fort of exercise in which they pulled forwards a ball, suspended from the ceiling, and at its return either stopped it with their hands, or suffered it to meet their body. Orisbafus informs us it was recommended for extenuating too gross bodies.

Corydalis, in botany. See Fumaria.

Corylus, the Hazle, in botany, a genus belonging to the order of palmæ flabelliformis. The corolla consists of three petals; it has six stamens, and one pistillum; and the fruit is a drupa containing one seed. There is but one species, a native of India.

Corypha, in botany, a genus belonging to the order of palmæ flabelliformis. The corolla consists of three petals; it has six stamens, and one pistillum; and the fruit is a drupa containing one seed. There is but one species, a native of Africa.

Coryphæa, in ichthyology, a genus belonging to the order of thoracici. The head is declined and truncated; the branchiostegæ membrane has six rays; and the back fin runs the whole length of the back. There are twelve species, most of them found in foreign seas.

Coryza, in medicine, a catarrh of the nose. See Catarrh.

Corzola, or Corscola, an island in the gulf of Venice, divided from Ragusa in Dalmatia, by a narrow strait: E. long. 16°, and N. lat. 42° 35'.

COS, the Whet-stone, in natural history, a genus of vitreous flones, consisting of fragments of an indeterminate figure, sub opaque, and granulated.

Of this genus there are several species, some consisting of rougher, and others of smoother, or even of altogether impalpable particles; and used not only for whet-stones, but also for mill-stones, and other the like purposes.

Co-secant, in geometry, the secant of an arch which is the complement of another to 90°. See Geometry.

Cosenza, the capital of the hither Calabria, in the kingdom of Naples: E. long. 16° 35', and N. lat. 39° 15'. It is an archbishop's see.

Cosine, in trigonometry, the sine of an arch, which is the complement of another to 90°. See Geometry.

Cosmetic, in physic, any medicine or preparation which renders the skin soft and white, or helps to beautify and improve the complexion; as lip-salves, cold creams, cerufs, &c.

Cosmical, a term in astronomy, expressing one of the poetical risings of a star: thus a star is said to rise cosmically, when it rises with the sun, or with that point of the ecliptic in which the sun is at that time: and the cosmical setting is when a star sets in the west at the same time that the sun rises in the east.

Cosmography, a description of the several parts of the visible world; or the art of delineating the several bodies according to their magnitudes, motions, relations, &c.

Cosmography consists of two parts, astronomy and geography. See Astronomy, and Geography.

Cossacks, people inhabiting the banks of the rivers Neiper and Don, near the Black Sea and frontiers of Turkey. Their country is commonly called the Ukraine, and is mostly subject to Russia.

Cosset, among farmers, a colt, calf, lamb, &c. brought up by hand, without the dam.

Costal, an appellation given by anatomists to several parts belonging to the sides: thus we meet with colar muscles, vertebrae, &c.
COSTA RICA, a province of Mexico, bounded by the North sea on the north-east, and by the Pacific ocean on the south-west. Its chief town is New-Carthage.

COSTIVENESS, in medicine, a preternatural detention of the faces, with an unual dryness and hardness thereof, and thence a suppresion of their evacuation. See Medicine.

COSTMARY, the English name of a species of tanzy.

COSTUSTRANDULA, in botany. See Scrophularia.

COSTUS, in botany, a genus of the monandria monogynia class. The interior part of the corolla is inflated and ringent; the inferior lip being trifid. There is but one species, viz. the arabicus, a native of both the Indies. The root of the costus is said to attenuate acid humours, and to promote expectoration, perspiration, and urine; but is now rarely to be met with in the shops.

COTICE, or Cotise, in heraldry, is the fourth part, or quarter of an escutcheon. See Bend.

COTINUS, in botany, the trivial name of a species of rhus. See Rhus.

COTONASTER, in botany. See Cratægus.

COTRONA, a town of the further Calabria, in the kingdom of Naples, situated on the Mediterranean, about fifteen miles south-east of St. Severino: E. long. 17° 40', and N. lat. 38° 50'. It is the seat of a bishop.

COTTON, in commerce, a soft downy substance found on the bombax, or cotton tree. See Bombax.

Cotton is separated from the seeds of the plant by a mill, and then spun and prepared for all sorts of fine works, as stockings, waistcoats, quilts, tapestry, curtains, &c. With it they likewise make muslin, and sometimes it is mixed with wool, sometimes with silk, and even with gold leaf. The finest sort comes from Bengal and the coast of Coromandel.

Cotton makes a very considerable article in commerce, and is distinguished into cotton-wool, and cotton thread. The finest is brought chiefly from Cyprus, St. John d'Acre, and Smyrna: the most esteemed is white, long, and soft. Those who buy it in bales should see that it has not been wet, moisture being very prejudicial to it. The price of the finest is usually from six to seven piastras the quintal of forty-four oces.

Of cotton thread, that of Damas, called cotton d'ounce, and that of Jerusalem, called bazas, are the most esteemed; as also that of the Antilles islands. It is to be chosen white, fine, very dry, and evenly spun. The other cotton-threads are the half bazas, the names, the beledin, and gondezel; the payas and montafiri, the geneguins, the baquins, the dadalars. They are sold in bags, with a deduction of one pound and a half on each of those of Tutucorin, which are the dearest, and two pounds on each bag of the other sorts. For those of Fielbas, Smyrna, Aleppo, and Jerusalem, the deduction at Amsterdam is six in the hundred for the tare, and two in the hundred for weight, and on the value one per cent. for prompt payment.

Cotton of Siam, is a kind of silky cotton in the Antilles, so called because the grain was brought from Siam. It is of an extraordinary fineness, even surpassing flax in softness. They make hose of it there preferable to silk ones, for their lustre and beauty. They fell from ten to twelve and fifteen crowns a pair, but there are very few made, unless for curiosity.

The manner of packing cotton, as practised in the Antilles. The bags are made of coarse cloth, of which they take three ells and a half each: the breadth is one ell three inches. When the bag has been well soaked in water, they hang it up, extending the mouth of it to crofs pieces of timber nailed to posts fixed in the ground seven or eight feet high. He who packs it goes into the bag, which is six feet nine inches deep, or thereabouts, and presses down the cotton, which another hands him, with hands and feet; observing to tread it equally every where, and putting in but little at a time. The best time of packing is in rainy moist weather, provided the cotton be under cover. The bag should contain from 300 to 320 pounds. The tare abated in the Antilles is three in the hundred.

Cotton being a production applicable to a great variety of manufactures, it cannot be too much cultivated in our own plantations that will admit of it.

Cotton-wool, not of the British plantations, pays on importation 10d. the pound, and draws back on exportation 6d. the pound, and draws back 58d. the pound, and draws back 4d. on 100.

East Indies, pays 21d. the pound, and draws back 258d. the pound.

Cotton yarn the pound, of the East Indies pays 10d. and draws back 4d.

Lavender Cotton. See Santolina.

Philosophic Cotton, a name given to the flowers of zinc, on account of their white colour, and resemblance to cotton.

Cotton-Weed. See Gnaphalium.

COTTUS, in ichthyology, a genus belonging to the order of thoraci. The head is broader than the body, and the gill-membrane has fix rays. There are
COVERTURE, in law, is applied to the estate and condition of a married woman, who is under the power of her husband, and therefore called *femme covert.*

COVENANT, a contract or agreement, made between two or more persons, to perform something.

COVENNT, in botany, a genus of the decandria pentagynia class. The calyx is divided into five segments; the corolla consists of one petal; there are five nectariferous scales at the base of the germen; and it has five capsules. Thus, species are eight, only one of which is a native of Britain, *viz.* the umbellatus, or navel-wort.

COXOGLINES, in botany, are certain glandular bodies, adhering to the chorion of some animals.

COXULAS, or COXYTA, in antiquity, a liquid measure among the Greeks, equal to the hemina of the Romans, containing half a sextarius, or four acetabula: hence it appears that it contained ten ounces of wine, and nine of oil.

COYTURNIX, in ornithology. See Tetrao.

COYTEDDEN, in botany, a genus of the decandria pentagynia class. The calyx is divided into five segments; the corolla consists of one petal; there are five nectariferous scales at the base of the germen; and it has five capsules. Thus, species are eight, only one of which is a native of Britain, *viz.* the umbellatus, or navel-wort.

COYOLEDON, or COYLEDONES, in anatomy, are certain glandular bodies, adhering to the chorion of some animals.

COYLODON, in botany, a genus of the decandria pentagynia class. The calyx is divided into five segments; the corolla consists of one petal; there are five nectariferous scales at the base of the germen; and it has five capsules. Thus, species are eight, only one of which is a native of Britain, *viz.* the umbellatus, or navel-wort.

COYLY, in heraldry, denotes any thing lying along.

COYLY, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHÉ, in heraldry, denotes any thing lying along: thus, chevron couché, is a chevron lying sideways, with the two ends on each side of the shield, which should properly rest on the base.

COUCHING of a cataract, in surgery. See Surgery.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised, which distinguishes the posture of couchant from other beasts, when lying down, but with his head raised, wherein he is supposed quite stretched out and asleep. See Plate LXV. fig. 9.
Julianian, condemned the three chapters taken out of the book of Theodorus of Mopseulia, having first decided that it was lawful to anathematize the dead. Some authors tell us, that they likewise condemned the several errors of Origen about the Trinity, the plurality of worlds, and pre-existence of souls. 6. The third council of Constantinople, held by the command of Constantinus Pogonatus the emperor, in which they received the definitions of the five first general councils, and particularly that against Origen and Theodorus of Mopseulia. 7. The second Nicene council. 8. The fourth council of Constantinople, assembled when Lewis II. was emperor of the west. The regulations which they made are contained in twenty-seven canons, the heads of which are set down by M. du Pin, to whom the reader is referred.

COUNSELLOR, in general, a person who advises another; thus we say, a counsellor at law, a privy counsellor, &c.

COUNSELLOR at law, a person retained by a client to plead his cause in a public court of judicature.

COUNT, a nobleman who possesses a domain erected in- 

Counter-alley, in gardening. See Alley.

Counter approaches, in fortification, lines and trenches made by the besieged in order to attack the works of the besiegers, or to hinder their approaches.

Counter battery, is a battery raised to play upon another to dismount the guns.

Counter changed, in heraldry, is when any field or charge is divided or parted by any line or lines of partition, confessing all interchangeably of the same tinctures. See Plate LXV. fig. 12.

Counter charge, a reciprocal charge or recrimination brought against an accuser.

Counter-chekoned, a shield chevrony, parted by one or more partition lines.

Counter-componded, in heraldry, is when the figure is compounded of two panes, as in Plate LXV. fig. 13.

Counter-drawing, in painting, is the copying of a design, or painting, by means of a fine linen-cloth, an oiled paper, or other transparent matter, where the lines appearing through are followed with a pencil, with or without colour. Sometimes it is done on glass, and with frames or nets divided into squares with silk or with thread, and also by means of instruments invented for the purpose, as the parallelogram.

Counter-ermine, in heraldry, is the contrary of ermine, being a black field with white spots. See Plate LXV. fig. 14.

Counterfeits, in law, are persons that obtain any money or goods by counterfeit letters or false tokens, who being convicted before justices of assize or of the peace, &c. are to suffer such punishment as shall be thought fit to be inflicted under death, as imprisonment, pillory, &c.

Counter-faced, or counter-face, in heraldry, is the name that we call barry per pale counterchanged; but then the number of panes into which the field is divided is always specified. See Barry.

Counter foil, or counter-stock, in the exchequer, that part of a tally which is kept by an officer of the court.

Counter-forts, spurs or buttresses serving as props to a wall subject to bulge or be thrown down.

Counter-fugue, in music, is when the fugues go contrary to one another. See Fugue.

Counter-guard, in fortification, is a work raised before the point of a bastion, confitting of two long faces parallel to the faces of the bastion, making a falliant angle; they are sometimes of other shapes, or otherwise situated.

Counter-light, of counter-jour, a light opposite to any thing, which makes it appear to disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

Counter-march, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear. It also signifies returning, or marching back again.

Counter-mine, in war, a well and gallery drove and sunk till it meet the enemy's mine, to prevent its effect.

Counter-paled, contre pale, in heraldry, is when another to dismount the arms, and the one seems to go quite the contrary way from the other.

Counter-part, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble.

Counter-passant, is when two lions are in a coat of arms, and the one seems to go quite the contrary way from the other.

Counter-part, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble.

Counter-fugue, in music, is when the fugues go contrary to one another. See Fugue.

Counter-guard, in fortification, is a work raised before the point of a bastion, confisting of two long faces parallel to the faces of the bastion, making a falliant angle: they are sometimes of other shapes, or otherwise situated.

Counter-light, of counter-jour, a light opposite to any thing, which makes it appear to disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

Counter-march, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear. It also signifies returning, or marching back again.

Counter-mine, in war, a well and gallery drove and sunk till it meet the enemy's mine, to prevent its effect.

Counter-paled, contre pale, in heraldry, is when another to dismount the arms, and the one seems to go quite the contrary way from the other.

Counter-part, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble.

Counter-guard, in fortification, is a work raised before the point of a bastion, consisting of two long faces parallel to the faces of the bastion, making a falliant angle: they are sometimes of other shapes, or otherwise situated.

Counter-light, of counter-jour, a light opposite to any thing, which makes it appear to disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

Counter-march, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear. It also signifies returning, or marching back again.

Counter-mine, in war, a well and gallery drove and sunk till it meet the enemy's mine, to prevent its effect.

Counter-paled, contre pale, in heraldry, is when another to dismount the arms, and the one seems to go quite the contrary way from the other.

Counter-part, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble.
COUNTER-POTENT, contre-potent, in heraldry, is reck- 
ed a for as well as vair and ermine, but composed of such pieces as represent the tops of crutches, called in French potences, and in old English potens.

COUNTER-PROOF, in rolling-press printing, a print taken off from another fresh printed; which by being passed through the press, gives the figure of the former, but inverted. To counter-prove, is also to pass a design in black lead, or red chalk, through the press, after having moistened with a sponge both that and the paper on which the counter-proof is to be taken.

COUNTER-QUARTERED, contre-cartere, in heraldry, denotes the escutcheon, after being quartered, to have each quarter again divided into two.

COUNTER-TAIL, in two beasts, are borne in coat leaping from each other directly contrary way.

COUNTER-SCARP, in fortification, is properly the exterior talus or top of the ditch; but it is often taken for the covered way and the glacis. In this sense we say, the enemy have lodged themselves on the counter-scarp.

Angle of the COUNTER-SCARP, is that made by the two sides of the counter-scarp meeting before the middle of the curtin.

COUNTER-SIGNING, the signing the writing of a superior in quality of secretary. Thus charters are signed by the king, and counter-signed by a secretary of state or lord chancellor.

COUNTER-SWALLOW-TAIL, in fortification, an outwork in form of an angle tenaille, wider at the gorge than the head.

COUNTER-TENOR, called by the French haut contre, one of the middle parts of music opposite to the tenor. See Tenor.

COUNTER-TIME, in the menage, is the defence or refuse of a horse that interrupts his cadence, and the measure of his menage, occasioned either by a bad horfeman, or by the malice of the horse.

COUNTER is also the name of a counting-board in a shop, and of a piece of metal with a stamp on it, used in playing at cards.

COUNTER of a horse, that part of a horse's forehead which lies between the shoulders and under the neck.

COUNTERS in a ship are two. 1. The hollow arching from the gallery to the lower part of the straight piece of the stern, is called the upper counter. 2. The lower counter is between the tranom and the lower part of the gallery.

COUNTER is also the name of two prisons in the city of London, viz. the Poultry and Woodstreet.

COUNTING. See Account.

COUNTY, in geography, originally signified the territory of a count or earl, but now it is used in the same sense with shire. See SHIRE.

COUNTY COURT, a court of justice, held every month in each county, by the sheriff or his deputy.

COUPED, in heraldry, is used to express the head, or any limb, of an animal, cut off from the trunk, smooth; distinguishing it from that which is called e-

raffled, that is, forcibly torn off, and therefore is rag-

ged and uneven.

COUPED is also used to signify such crosses, bars, bends, chevrons, &c. as do not touch the sides of the escutcheons, but are, as it were, cut off from them.

COUPER, the name of two towns of Scotland, the one situated about twelve miles north-east of Perth, in the shire of Angus, W. long. 3°, and N. lat. 56° 39'; and the other in the county of Fife, about ten miles south of St Andrews: W. long. 2° 40', and N. lat. 56° 20'.

COUPLE-CROSS, in heraldry, the fourth part of a chevron, never borne but in pairs, except there be a chevron between them, see Guillim, though Bloom gives an instance to the contrary.

COUPLE, a division of a hymn, ode, song, &c. where an equal number, or equal measure of verses is found in each part; which divisions, in odes, are called strophes.

COURBARIL, in botany. See Hymenaea.

COURIER, a messenger sent post, or express, to carry dispatches.

COURBARIL, in botany. See Hymenaea.

COURIER, a messenger sent post, or express, to carry dispatches.

COURT-BARON, a court that every lord of a manor has within his own precincts. This court must be held

by prescription, and is of two kinds, viz., by common law, and by custom: the former is where the barons or freeholders, being suitors, are the judges; the other is that where the lord, or his steward, is the judge.

**Court of chivalry, or the marshall's Court,** that whereof the judges are the lord high constable, and the earl marshal of England.

This court is the fountain of martial law; and the earl marshal is not only one of the judges, but is to see execution done.

**Court of conscience,** a court in the cities of London, Westminster, and some other places, that determines matters in all cases where the debt or damage is under forty shillings.

**Court of delegates,** a court where delegates are appointed by the king's commissiou, under the great seal, upon an appeal to him from the sentence of an archbishop, &c., in ecclesiastical causes; or of the court of admiralty, in any marine cause.

**Court of huftings,** a court of record held at Guildhall, for the city of London, before the lord mayor and aldermen, sheriffs and recorder, where all pleas, real, personal, and mixt, are determined; where all lands, tenements, &c., within the said city, or its bounds, are pleadable in two huftings; the one called the huftings of plea of lands, and the other the huftings of common pleas. The court of huftings is the highest court within the city, in which writs of exequat may be taken out, and outlawries awarded, wherein judgment is given by the recorder. There are also other courts called wardmotes, or meeting of the wards; and courts of holyment, or assemblies of the guilds and fraternities.

**Court-leet,** a court ordained for the punishment of offences under high treason against the crown.

**Court-martial,** a court appointed for the punishing offences in officers, soldiers, and sailors, the powers of which are regulated by the mutiny-bill.

**Court of requests,** was a court of equity, of the same nature with the chancery, but inferior to it.

**Courtsey, or Courtsey of England,** a certain tenor whereby a man marrying an heir of seised of lands of fee simple, or fee tail general, or seised as heir of the tail special, and geteth a child by her that cometh alive into the world, though both it and his wife die alive into the world, though both it and his wife die; yet, if she were in possession, he shall keep the land during his life, and is called tenant per legem Anglie, or tenant by the courtesy of England; because this privilege is not allowed in any country except Scotland, where it is called curialitas Scotiae.

**Courttsian,** a woman who prostitutes herself for hire, especially to people of superior rank.

**Courttray,** a town of the Austrian Netherland, situated on the river Ly, about twenty-three miles south-west of Ghent, and fourteen east of Ypres: E. long. 5° 10', and N. lat. 50° 45'.

**Cousin,** a term of relation between the children of brothers and sisters, who in the first generation are called cousin-german, and in the second generation second cousins, &c. If sprung from the relations of the father's side, they are denominated paternal cousins; if on the mother's, maternal.

**Cousin,** in heraldry, signifies a piece of another colour or metal placed on the ordinary, as if it were sewed on, as the word imports. This is generally of colour upon colour, or metal upon metal, contrary to the general rule of heraldry.

**Covert,** in heraldry, denotes something like a piece of hanging, or a pavilion falling over the top of a chief or other ordinary, so as not to hide, but only to be a covering to it.

**Cow,** in zoology. See Bos.

**Cecow,** in zoology. See Trichecus.

**Cowitch,** in botany. See Phaseolus.

**Cow's-lip,** in botany. See Primula.

**Cows-lip of Jerusalem,** See Pulmonaria.

**Coward,** in heraldry, a term given to a lion borne in an escutcheon with his tail doubled or turned in between his legs.

**Cowes,** a town and harbour on the northern coast of the isle of Wight, situated about eight miles south of Plymouth: W. long. 1° 25', and N. lat. 50° 45'.

**Cowl,** or **Coyle,** a habit worn by the Bernardines and Benediftines, of which there are two kinds; one white, very large, worn in ceremonies; the other black, worn on ordinary occasions, in the streets, &c.

**Friar's Cowl,** in botany. See Arisarum.

**Coxwold,** a market-town in the north riding of Yorkshire, about fourteen miles north of the city of York: W. long. 5° 50', and N. lat. 5° 20'.

**Cozumel,** an island near the western coast of Yucatan, where Cortez landed and refrefted his troops, before entering upon the conquest of Mexico: W. long. 89°, and N. lat. 15°.

**Crab,** in zoology. See Cancer.

**Crab's claws,** in the materia medica, are the tips of the claws of the common crab broken off at the verge of the black part, so much of the extremity of the claws only being allowed to be used in medicine as is tinged with this colour. The blacknefs, however, is only superficial; they are of a greyish white within, and when levigated furnish a tolerable white powder.

Crab's claws are of the number of the alkaline absorbets, but they are superior to the generality of them in some degree, as they are found on a chemical analysis to contain a volatile urinous salt.

**Crab's eyes,** in pharmacy, are a strong concretion in the head of the cray-fish. They are rounded on one side, and depressed and situated on the other, considerably heavy, moderately hard, and without smell. We have them from Holland, Muscovy, Poland, Denmark, Sweden, and many other places.

Crab's eyes are much used both in the shop-medicines and extemporaneous prescriptions, being accounted not only absorbent and drying, but also diffusive and diuretic.

**Crab,** an engine of wood, with three claws, placed on the ground like a capstan, and used at launching or heaving ships into the dock.
CRANGANOR, a Dutch factory on the Malabar-coast.

CRANCE, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRANE, in ornithology. See Ardea.

CRANAGE, the liberty of using a crane at a wharf.

CRACKER, in ornithology. See Anas.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMPFISH. See Torpedo.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMPER, in ichthyology. See Cyprinus.

CRAMPONE'E, in heraldry, an epithet given to a blazon.

CRAMPES, in the menage, a swelling on the pastern, where the bullet is put.

CRAPULA, among physicians. See Surfeit.

CRAPULA, in botany, a genus of the pinnatiadria monogynia class. The calyx has five segments, and the corolla of five petals; there are six nectariferous glands at the base of the germin; and it has six capsules. There are 17 species, none of them natives of Britain.

CRATÉGUS, in botany, a genus of the icofandria digynia claus. The calyx has five segments, and the corolla of five petals; the berry is below the flower, and contains two seeds. There are nine species, three of which are natives of Britain, viz. the aria, or white bean-tree; the terminalis, service-tree, or forb; and the oxyacantha, white-thorn, or hawthorn.

CRATCHES, in the menage, a swelling on the pastern, which serves to fallen together pieces of wood, stones, or other things.

CRAMPER, in ichthyology. See Cyprinus.

CRAMPONE'E, in heraldry, an epithet given to a blazon.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRABRO, in zoology, See Tenthredo.

CRACOW, by some accounted the capital city of Poland, is situated in the province of little Poland, and palatinate of Cracow, in a fine plane near the banks of the Vistula. It has an university, and is the seat of a bishop, and the seat of the supreme courts of justice: it stands about 140 miles south-west of Warsaw, in 19° 30' E. long. and 50° N. lat.

CRADLE, a well known machine in which infants are rocked to sleep.

CRADLE, in surgery, a case in which a broken leg is laid after being set.

CRADLE, among Shipwrights, a timber frame made along the outside of a ship by the bilge, for the convenience of launching her with ease and safety.

CRAG, in the sea language, signifies all manner of nets, lines, hooks, &c. used in fishing. Hence all such little vessels as ketches, hoys, and smacks, &c. used in the fishing trade, are called small craft.

CRAIL, or Care il, a parliament town of Scotland, situated on the sea-coast of the county of Fife, about seven miles south-east of St. Andrews: W. long. 2° 20' and N. lat. 56° 17'.

CRAMBE, wild sea-cabbage, in botany, a genus of the tetradynamia siliquos claus. The four long filaments are forked at the points, and the antherae are fixed upon one of them; the berry is dry, globular, and deciduous. The species are three, only one of which, viz. the maritima, or sea-celwovart, is a native of Britain.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.

CRAMP, in medicine, a convulsive contraction of a muscle part of the body.

CRAMP, in surgery, a case in which a broken leg is laid after being set.

CRAMP, in mechanics, a machine used in building and commerce for raising large stones and other weights.
CREAT, in she menage, an usher to a riding matter; CREAM, the fat part of the milk that swims upon the surface.

CRAYON, a name for all coloured stones, earths, or other minerals used in designing or painting in pastel. Crayons may be made of any colour, and adapted for the faces of men, women, landscapes, clouds, funbeams, buildings, and shadows, in the following manner: Take plaster of Paris, or alabaster calcined, and of the colour of which you intend to make your crayons, a sufficient quantity; grind them first afunder, and then together, and with a little water make them into a paste; then roll them with your hand upon the grinding stone into long pieces, and let them dry moderately in the air, when they are to be used, scrape them to a point like a common pencil. Crayons may be made of any colour, and adapted for any use of the colour of which you intend to make your crayons. They are used in the following manner: Take plaster of Paris, or alabaster calcined, and of the colour of which you intend to make your crayons, a sufficient quantity; grind them first afunder, and then together, and with a little water make them into a paste; then roll them with your hand upon the grinding stone into long pieces, and let them dry moderately in the air, when they are to be used, scrape them to a point like a common pencil.

CREATION, the producing something out of nothing, which is lost in the mind of God alone, all other creations being only transformations, or change of shape.

CREDIBLE, a species of evidence, less indeed than absolute certainty or demonstration, but greater than mere possibility; it is nearly allied to probability, and seems to be a mean between possibility and demonstration.

CREDIBILITY, a species of evidence, less indeed than absolute certainty or demonstration, but greater than mere possibility; it is nearly allied to probability, and seems to be a mean between possibility and demonstration.

CREDENTIALS, letters of recommendation, and power, especially such as are given to ambassadors, or public ministers, by the prince or state that sends them to foreign courts.

CREDITOR, a person to whom any sum of money is due, either by obligation, promise, or otherwise.

CREED, a brief summary of the articles of a Christian's belief. The most ancient form of creeds is that which goes under the name of the apostolic creed; besides this, there are several other ancient forms and scattered remains of creeds to be met with in the primitive records of the church. The first is a form of apostolical doctrine, collected by Origen; the second is a fragment of a creed preferred by Tertullian; the third remains of a creed, is in the works of Cyprian; the fourth, a creed composed by Gregory Thaumaturgus, for the use of his own church; the fifth, the creed of St. Lucian the martyr; the sixth, the creed of the apostles.

CREEDING, a gentleman bred in the academy, with intent to or, a gentleman bred in the academy, with intent to make himself capable of teaching the art of riding the great horse.

CREEK, the part of a haven where anything is landed.

CREEPER, in ornithology. See Certhia.

CREEK, the part of a haven where anything is landed from the sea.

CREEPER, a plant that grows along the ground or over other plants.

CREEPER, in botany, a genus of the synæneisia polygama class. The receptacle is naked; the calix is caliculated, with deciduous scales; and the pappus is plumose and furnished with a stipe. The species are fourteen, three of which are natives of Britain, viz. the tectorum, or smooth succory hawk-weed; the biennis, or rough succory hawk-weed; and the festida, or finking hawk-weed.

CREPIS, in botany, a genus of the synæneisia polygama class. The receptacle is naked; the calix is caliculated, with deciduous scales; and the pappus is plumose and furnished with a stipe. The species are fourteen, three of which are natives of Britain, viz. the tectorum, or smooth succory hawk-weed; the biennis, or rough succory hawk-weed; and the festida, or finking hawk-weed.

CREPUSCLE, in astronomy, a term used to express the difference to distinguish between elder and younger forms, as those of Jerusalem, Casarea, Antioch, &c.

CREPUSCLE, in astronomy, a term used to express the difference to distinguish between elder and younger forms, as those of Jerusalem, Casarea, Antioch, &c.

CREPUSCULAR, in botany. See Vol. L p 646.

CREMONA, a city and bishop's see of Italy, capital of a district of the Milanese, situated forty-five miles south-east of Milan, in 16° 30'. E. long. and 45° 20' N. lat.

CREPUSCULAR, in botany. See Vol. L p 646.

CREEPER, in botany. See Certhia.

CREEK, the part of a haven where anything is landed from the sea.
CRESTED, something furnished with a crest. See CREST.

CREST, in heraldry, the uppermost part of the helmet, in manner of a comb, or tuft of a cock, deriving its name from crijfa, a cock's comb.

The crest was for the most part made of feathers, or the hair of horses' tails or mains. The soldiers took great pride in adorning them.

CREST, in armoury, the top-part of the armour, for the head, mounting over the helmet, in manner of a comb.

The crest in heraldry is esteemed a greater mark of nobility than the armory; being borne at tournaments, to which none were admitted till such time as they had given proof of their nobility: sometimes it serves to distinguish the several branches of a family; and it has served, on occasion, as a distinguishing badge of factions: sometimes the crest is taken for the device; but more usually is formed of some piece of the arms. Families that exchange arms do not change their crest.

CREST, among carvers, an imagery, or carved work, to signify that kind of sculpture, where the lines and figures are cut and formed within the face or plan of the plate or matter engraved; and thus it stands in opposition to relief, where the lines and figures are embossed, and rise prominent above the face of the matter engraved on.

CREW, the company of sailors belonging to a ship, boat, or other vessel.

CREX, in ornithology. See Rallus.

CRESS, or Cresses, in botany. See Sisymbrium.

CRESSY, a port-town of Picardy in France, about forty-four miles south of Calais, and twenty-seven north-west of Abbeville, remarkable on account of the victory obtained there over the French, by Edward III. of England, in the year 1346: E. long. 2°, N. lat. 50° 20'.

CREST, in botany, a genus of the didynamia species, a native of Jamaica.

CRESS, in anatomy. See Crista galli, or Cock's comb. See Rhinanthus.

CRETA, or CHALK, in natural-history. See Chalk.

CREUX, a French term used among artists, and literally signifies a hollow cavity or pit, out of which something has been scooped or dug: whence it is used to signify that kind of sculpture, where the lines and figures are cut and formed within the face or plan of the plate or matter engraved; and thus it stands in opposition to relief, where the lines and figures are embossed, and rise prominent above the face of the matter engraved on.

CREW, the company of sailors belonging to a ship, boat, or other vessel.

CREX, in ornithology. See Rallus.

CIBBAGE, a game at cards, to be learnt only by practice.

CIBRATION, in pharmacy, the passing any substance through a sieve, or search, in order to separate the finer particles from the groffer.

CIBROSUM os, in anatomy, called also os ethmoides.

CICERO, in zoology. See Gryllus.

CICERUS, in anatomy. See Gryllotalpa.

CICLAD, a borough-town of Wiltshire, situated on the river Iffs, about twenty-six miles south-west of Oxford: W. long. 1° 55', and N. lat. 51° 35'.

CICERO, or CICRIO THYROIDIUS, in anatomy. See Vol. I. p. 300.

CRIM, or CRIM TARTARY, a peninsula in the Black sea, between 34° and 37° E. long. and between 44° and 46° N. lat. It is joined to Little Tartary by a narrow isthmus.

CRIM, in medicine, is used in different senses, both by the ancient and modern physicians. With some it means frequently no more than the excretion of any noxious substance from the body. Others take the word for a secretion of the noxious humours made in a fever. Others use it for the critical motion itself; and Galen defines a crisis in fevers, a sudden and instantaneous change, either for the better or the worse, productive of recovery or death.

CRISTA GALLI, or Cock's comb. See Rhinanthus.

CRISTA PAVONIS, in botany. See Poinciana.
CRITERIUM, a standard by which propositions and opinions are compared, in order to discover their truth or falsehood.

CRITHE; in surgery, commonly called the flye, is a tubercle that grows in different parts of the eye lids.

CRITTHUM, in botany, a genus of the pentandria digynia class. The fruit is oval and compressed.

There are two species, one of which, viz. the marinimum, or samare, is a native of Britain; the leaves are said to be fromachic, aperient, and diuretic.

CRITICAL days and symptoms, among physicians, are certain days and symptoms in the course of acute diseases, which indicate the patient's state, and determine him either to recover or grow worse. See Medicine.

CRITICISM, the art of judging with propriety concerning any object or combination of objects. But, in a more limited sense, the science of criticism is confined to the fine arts. The principles of the fine arts are best unfolded by studying the sensitive part of our nature, and by learning what objects are naturally agreeable, and what are naturally disagreeable.

The man who aspires to be a critic in these arts, must pierce still deeper: he must clearly perceive what objects are lofty, what low, what are proper or improper, what are manly, and what are mean or trivial. Hence a foundation for judging of taste, and for reasoning upon it: where it is conformable to principles, we can pronounce with certainty, that it is correct; otherwise, that it is incorrect, and perhaps whimsical. Thus the fine arts, like morals, become a rational science; and, like morals, may be cultivated to a high degree of refinement.

Manifold are the advantages of criticism, when thus studied as a rational science. In the first place, a thorough acquaintance with the principles of the fine arts, redoubles the entertainment these arts afford. To the man who resigns himself entirely to sentiment or feeling, without interpreting any sort of judgment, poetry, music, painting, are mere pastime; in the prime of life, indeed, they are delightful, being supported by the force of novelty, and the heat of imagination; but they lose their relish gradually with their novelty; and are generally neglected in the maturity of life, which disposes to more serious and more important occupations. To those who deal in criticism as a regular science, governed by just principles, and giving scope to judgment as well as to fancy, the fine arts are a favourite entertainment; and in old age maintain that relish which they produce in the morning of life.

In the next place, a philosophical inquiry into the principles of the fine arts, inures the reflecting mind to the most enticing sort of logic: the practice of reasoning upon subjects so agreeable tends to a habit; and a habit strengthening the reasoning faculties, prepares the mind for entering into subjects more difficult and abstract. To have, in this respect, a just conception of the importance of criticism, we need but reflect upon the common method of education; which, after some years spent in acquiring languages, hurries us, without the least preparatory discipline, into the most profound philosophy; a more effectual method to alienate the tender mind from abstract science, is beyond the reach of invention; and accordingly, with respect to such speculations, the bulk of our youth contract a fort of hobgoblin terror, which is seldom, if ever subdued. Those who apply to the arts, are trained in a very different manner: they are led, step by step, from the easier parts of the operation, to what are more difficult; and are not permitted to make a new motion, till they be perfected in those which regularly precede it. The science of criticism appears then to be a middle link, connecting the different parts of education into a regular chain. This science furniseth an inviting opportunity to execute the judgment: we delight to reason upon subjects that are equally pleasant and familiar; we proceed gradually from the simpler to the more involved cases: and in a due course of discipline, custom, which improves all our faculties, belows acuteness upon those of reason, sufficient to unravel all the intricacies of philosophy.

Nor ought it to be overlooked, that the reasonings employed upon the fine arts are of the same kind with those which regulate our conduct. Mathematical and metaphysical reasonings have no tendency to improve social intercourse; nor are they applicable to the common affairs of life: but a just taste in the fine arts, derived from rational principles, furnishes elegant subjects for conversation, and prepares us finely for acting in the social state with dignity and propriety.

The science of rational criticism tends to improve the heart not less than the understanding. It tends, in the first place, to moderate the selfish affections: by sweetening and harmonizing the temper, it is a strong antidote to the turbulence of passion and violence of pursuit: it procures to a man so much mental enjoyment, that in order to be occupied, he is not tempted in youth to precipitate into hunting, gaming, drinking; nor in middle-age, to deliver himself over to ambition; nor in old-age, to avarice. Pride and envy, two delightful passions, find in the constitution no enemy more formidable than a delicate and disinterested taste; the man upon whom nature and culture have bestowed this blessing, feels great delight in the virtuous dispositions and actions of others: he loves to cherish them, and to publish them to the world: faults and failings, it is true, are to him not less obvious; but these he avoids, or removes out of sight, because they give him pain. On the other hand, a man void of taste, upon whom the most striking beauties make but a faint impression, has no joy but in gratifying his pride or envy by the discovery of errors and blemishes. In a word, there may be other passions, which, for a season, disturb the peace of society more than those mentioned; but no other passion is so unwieldy an antagonist to the sweets of social intercourse: these passions, tending affiduously to their gratification, put a man perpetually in opposition to others; and dispose him more to relish bad than good qualities, even in a companion. How different that disposition of mind, where every virtue
CROCODILE, in zoology. See LACERTA.

CROCODES, an appellation given to pastils or troches.

CROCINUM, among physicians, denotes the oil of CROCCEUS, or Homeo, a large river of China, whereof crocus, or saffron, is the principal ingredient.

CROCKET, a little close adjoining to a dwelling-house, and enclosed for pasture or arable land, or any other particular use.

CROISADE, CRUSADE, or CRUZADO, a name given to the expeditions of the Christians against the infidels, for the conquest of Palestine; so called, because those who engaged in the undertaking wore a cross on their cloaths, and bore one on their standard. This expedition was also called the holy war, to which people flocked in great numbers out of pure devotion, the pope’s bulls and the preaching of the priests of those days making it a point of conscience. The several nations engaged in the holy war were distinguished by the different colours of their crosses: the English wore white, the French red, the Flemish green, the Germans black, and the Italians yellow. From this enterprise several orders of knighthood took their rise. They reckon eight croisades for the conquest of the holy land; the first begun in the year 1095, at the solicitation of the Greek emperor and the patriarch of Jerusalem.

CROISIERS, or CROIZES, in English antiquity, pilgrims bound for the holy land, or such as had been there; so called from a badge they wore in imitation of a cross. The knights of St John of Jerusalem, created for the defence and protection of pilgrims, were particularly called croisiers.

CROISIERS, a religious order founded in honour of the invention or discovery of the cross by the empress Helena.

They are dispersed in several parts of Europe, particularly in the Low Countries, France, and Bohemia, those in Italy being at present suppressed. Those religious follow the rule of St Augustine. They had in England the name of crouched friers.

CROMARTY, the capital of the shire of Cromarty in Scotland, with an excellent and safe harbour capable of containing the greatest fleets; W. long. 3° 40’, and N. lat. 57° 54’.

CRONENBURG, a fortress of Denmark, situated in the island of Zealand, at the entrance of the Sound, where the Danes take toll of ships bound for the Baltic; E. long. 12° 5’, and N. lat. 56°.

CRONSTAT, a town of Transylvania, situated near the frontiers of Moldavia, about fifty miles north-east of Hermanstat, and subject to the house of Austria; E. long. 25°, and N. lat. 47°.

CROPPER,
CROPPHER, in ornithology. See COLUMBA.

CROSIER, or CROZIER, a shepherd's crook; a symbol of pastoral authority, consisting of a gold or silver staff, crooked at the top, carried occasionally before bishops and abbots, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

CROSIER, or Crozier, a shepherd's crook; a symbol of pastoral authority, consisting of a gold or silver staff, crooked at the top, carried occasionally before bishops and abbots, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

CROPPER, in ornithology. See COLUMBA.

Exaltation of the Cross, a grand festival solemnized on September 14, in commemoration of Heraclius's recovery of the Holy Places in the Holy Land, the cross being the ensign of that war.

In these wars, the Scots carried St Andrew's cross; the French, a crescent; the English, a cross; and the Germans, a fable; the Italians, azure; the Spaniards, gules.

Cross-bar-shot, a bullet with an iron-bar passing through it, and flitting fix or eight inches out at both sides: it is used at sea, for destroying the enemy's rigging.

Cross-bill, in ornithology. See Loxia.

Cross-wort, in botany. See Valantia.

CROSLET, in heraldry, is when a cross is crossed at the ends. Upon the staff, held by the chief, in the possession of the chief, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

CROSLET, in heraldry, is when a cross is crossed at the ends. Upon the staff, held by the chief, in the possession of the chief, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

Invention of the Cross, a festival observed on May 3, by the Latin church, in memory of the empress Helena (the mother of Constantine) finding the true cross of Christ on Mount Calvary, where she caused it erected a church for the preservation of it.

Exaltation of the Cross, a grand festival solemnized on September 14, in commemoration of Heraclius's recovery of the Holy Places in the Holy Land, the cross being the ensign of that war.

In these wars, the Scots carried St Andrew's cross; the French, a crescent; the English, a cross; and the Germans, a fable; the Italians, azure; the Spaniards, gules.

Cross-bar-shot, a bullet with an iron-bar passing through it, and flitting fix or eight inches out at both sides: it is used at sea, for destroying the enemy's rigging.

Cross-bill, in ornithology. See Loxia.

Cross-wort, in botany. See Valantia.

CROSLET, in heraldry, is when a cross is crossed at the ends. Upon the staff, held by the chief, in the possession of the chief, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

CROTON, in botany, a genus of plants of the Monroea polyandria class. The calyx of the male is cylindrical,
Crow's feet, in a ship, small lines or ropes, sometimes called fmall lines or ropes.
Crown, an ornament worn on the head by kings, often called a diadem.
Crownland, a market-town of Lincolnshire: W: long. 1° 30', and N. lat. 50° 15'.
Croupade, in the menage, a leap, in which the horse jumps over an obstacle.
Crow, in mechanics, a kind of iron lever, with a claw.
Crow's bill, among surgeons, a kind of forceps, for removing foreign bodies.
Crow-flowers, in botany. See Lychnis.
Crow's feet, in botany. See Ranunculus.
Crowland, a market-town of Lincolnshire: W. long. 1° 30', and N. lat. 50° 15'.
Crown, an ornament worn on the head by kings, sovereign princes, and noblemen.

In scripture there is frequent mention of crowns, and the use of them seems to have been very common among the Hebrews. The high priest wore a crown, which was a fillet of gold placed upon the forehead, and tied with a ribbon of hyacinth colour, or azure blue. It seems also as if private priests, and even common Israelites, wore also a sort of crown, since God commands Ezekiel not to take off his crown, nor assume the marks of one in mourning.

The French Crown, is a circle of eight fleurs de lis, encompafled with six diadems, bearing at top a double fleurs de lis, which is the crest of France. (ibid. n°. 3.)
The Imperial Crown is a bonnet or tiara, with a semi-circle of gold, supporting a globe with a crofs at top. (See Plate LXVI. Fig. 9.)
The British Crown is adorned with four crofes, between which there are four fleurs de lis: it is covered with four diadems, which meet at a little globe supporting a crofs. (Ibid. n°. 1.)
The French Crown, is a circle of eight fleurs de lis, encompafled with fix diadems, bearing at top a double fleurs de lis, which is the crest of France. (Ibid. n°. 2.)
The Spanish Crown is adorned with large indented leaves, and covered with diadems terminating in a globe, surmounted with a crofs. (Ibid. n°. 4.)
CROWNS. The crowns of almost all other kings are adorned with large leaves, bordered with four, six, or eight diadems, with a globe and crofs at top.

The Papal Crown is composed of a tiara, and a triple crown encompassing it, with two pendants like the bishop's mitres. These crowns represent the pretended triple capacity of the pope, as high priest, supreme judge, and sole legislator of Christians. Ibid. n. 5.

An electoral Crown, or coronet, is a scarlet cap turned up with ermine, and closed with a femicircle of gold, all covered with pearls, with a globe at top, surmounted with a golden crofs. Ibid. n. 6.

Crowns of noblemen are, a duke's, composed of leaves and fleurs de lis, with one arch, in the middle of which is a ball and crofs, as in the royal diadem. 2. That of all the younger sons and brothers of the king, consists likewife of croffes and fleurs de lis alternately, but without any arch, or being surmounted with a globe and crofs at top. 3. That of the other princes of the blood consists alternately of croffes and leaves, like those in the coronet of dukes, &c. Ibid. fig. 10. n. 1. 2. 3.

Crowns of noblemen are, a duke's, composed of leaves and fleurs de lis, or parsley: that of a marquis, of flowers and pearls placed alternately: an earl's has no flowers about the circle, like the duke and marquis, but only points rising, and a pearl on every one of them: a viscount has neither flowers nor points rised above the circle, like the other superior degrees, but only pearls placed on the circle itself without any limited number: a baron's has only six pearls on the golden border, not raised, to distinguish him from the earl's; and the number of them limited, to shew he is inferior to the viscount. Ibid. fig. 11. n. 1. 2. &c.

Crown, in commerce, a general name for coins both foreign and domestic, which are of, or very near, the value of five shillings sterling.

Crown Office, an office belonging to the king's bench court, of which the king's coroner or attorney is commonly master. In this office, the attorney general and clerk of the crown severally exhibit informations for crimes and misdemeanors at common law, as in the case of batteries, conspiracies, libelling, &c. on which the offender is liable to pay a fine to the king.

Crown-glass, denotes the finest sort of window-glass. See Glass.

Crown-wheel of a watch, the upper wheel next the balance, which by its motion drives the balance, and in royal-pendulums is called the swinging-wheel.

Crown Imperial, in botany. See Fritillaria.

Croydon, a market-town in Surrey, about ten miles south of London.

Crucifixion, a capital punishment by nailing the criminal to a crofs. See Cross.

Cruceform, in general, something disposed crosswise; but more especially used by botanists, for flowers consisting of four petals disposed in the form of a crofs.

Crude, an epithet given to something that has not passed the fire, or had a proper degree of coction.

Crudity, among physicians, is applied to undigested substances in the stomack; to humours in the body which are unconcocted, and not prepared for expulsion; and to the excrements.

Cruise, in the sea-language, signifies to sail back and fore within a certain space of the sea, as well to annoy the enemy, as to protect our own trading vessels.

Crumentata, among zoologists, animals furnished with a pouch, or bag, wherein to receive their young in time of danger.

Cruor, sometimes signifies the blood in general; sometimes only the venous blood; and sometimes extravasated, or coagulated blood.

Crupper, in the menage, the buttocks of a horse, the rump; also a thong of leather put under a horse's tail, and drawn up by thongs to the buckle behind the saddle, fo as to keep him from casting the faddle forwards on his neck.

Crureus, or Crureus musculus, in anatomy. See Vol. I. p. 207.

Crural, in anatomy, an epithet given to the artery which conveys the blood to the crura, or legs, and to the calix and corolla. The species are five, none of them natives of Britain.

Crucifata, in botany. See Valentina.

Crucible, a chemical vessel made of earth, and so tempered and backed as to endure the greatest fire. They are used to melt metals, and to flux minerals, ores, &c.

The figure of a crucible is commonly that of an obfute conoid, with its base at the top, and obtuse apex at the bottom; whence this conical figure may be varied, till it comes to the hollow segment of a sphere.

The crucibles most generally used are those of Hefse and Autfria.
CRY (297) CUB

the vein by which this blood returns towards the heart. See Anatomy, Part III, IV.

CRUS, in anatomy, all that part of the body contained between the buttocks and the toes. See Anatomy, Part I.

CRUSCA, an Italian term signifying bran, is in use among us to denote that celebrated academy called della crusca, established at Florence, for purifying and perfecting the Tuscan language.

CRUSTACEOUS, an appellation given to animals composed of several pieces, in contradistinction to those confuting of a single piece.

CRUX, or St Croix, one of the Caribbee islands, situated about sixty miles south-east of Porto Rico, and subject to France: W. long. 64°, and N. lat. 17° 30'.

CRUZADO, in commerce, a Portuguese coin, (truck under Portugal on the other.

CRUSTACEOUS, an appellation given to animals composed of several pieces, in contradistinction to those consisting of a single piece.

CRUSTA lactea, in medicine, the same with achor.

CRYPTOGRAPHY, the art of writing in cipher, or with sympathetic ink. See Cipher and Ink.

CRYSTAL, the name of a very large class of substances; hard, pellucid, and naturally coloured; of regularly angular figures, composed of simple, not filamentous plates; not flexible nor elastic, giving fire with steel; not fermenting in acid menstrua, and calcining in a strong fire.

The orders of pure crystal are three; the first is perfect columnar crystals, with double pyramids, composed of eighteen planes, in an hexagonal column, terminated by an hexagonal pyramid at each end; the second order is that of perfect crystals, with double pyramids, without a column, composed either of twelve or of sixteen planes, in two hexagonal pyramids, joined closely, base to base, without the intervention of any column; the third order is that of imperfect crystals, with single pyramids, composed either of twelve or ten planes, in an hexagonal or pentagonal column, affixed irregularly, at one end, to some solid body, and terminated, at the other, by an hexagonal or pentagonal pyramid.

These are all the general forms into which crystal, when pure, is found concreted: but under these there are almost infinite varieties in the number of angles, and the length, thickness, and other accidents of the columns and pyramids.

When crystal is blended with metallic particles at the time of its formation, it assumes a variety of figures wholly different from these, constituting a fourth order, under the name of metalline crystals: when that metal is lead, the crystal assumes the form of a cube; when it is tin, of a quadrilateral pyramid, with a broad base; when iron, the crystal is found concreted in rhomboidal crystals: these crystals are very common about mines; but the common spars, which are liable to be influenced in the same manner by the metals, and to appear in the very same form, are to be carefully distinguished from them. There is one very easy test for this purpose, which is, that all spars are subject to be dissolved by aqua fortis, and effervescence violently only on its touching it: but it has no such effects on crystal.

The pebble crystal is common enough in all parts of the world; but that which is formed of hexagonal columns, affixed to a solid base at one end, and terminated by a hexagonal column at the other, is infinitely more so: this is what we call sprig or rock crystal, and is the species described by most authors under the name of crystal of the shops, or that kept for medicinal use.

It is to be chosen the clearest, purest, and most transparent that can be had: it should be proved to be no spar, by means of aquafortis, or by drawing a point of it along a pane of glass, which it cuts in the manner of a diamond. It is found in vast abundance in many parts of England and Ireland; and in Germany it is yet more frequent. It is found about Briftol of amethystine tinge; in Silesia and Bohemia it is stained to the colour of the ruby, sapphire, emerald, and topaz, in which case jewellers make great advantage of it, selling it under the name of accidental sapphire, &c.

Crystal is also used for a fictitious body, called glass-houses, called crystal-glass; being, in fact, no more than glass carried, in the composition and manufacture, to a greater perfection than the common glass.

The best kind of glass-crystal is that called Venice crystal, made at Moran, near Venice. See Glass.

CRYSTALS, in chemistry, salts or other matters, not or congealed, in the manner of crystal. See Chemistry.

CRYSTALLIZATION, in chemistry. See Chemistry.

CRYSTALLOMANCY, in antiquity, a kind of divination, performed by means of a mirror, wherein the figures of the things required are said to have been represented.

CUB, a bear's whelp. Among hunters, a fox and marten of the first year, are called cubs. See Ursus.

CUBA, an island of North America, situated in the Atlantic ocean, between 74° and 87° of W. long, and between 20° and 23° N. lat. being eight hundred miles and upwards in length from east to west, and generally about seventy miles broad. It lies about fifty miles west of Hispaniola, and seventy-five north of Jamaica.

CUBAGUA, an American island, situated between the island of Marguerita and Terra Firma, and subject to Spain: W. long. 64°, and N. lat. 10° 15'.
CUBIC, or CUBICAL EQUATION, in algebra. See Algebra.

CUBIT, in the menurcation of the ancients, a long measure, equal to the length of a man's arm, from the elbow to the tip of the fingers.

Dr Arbuthnot makes the English cubit equal to 18 inches; the Roman cubit equal to 1 foot, 5, 406 inches; and the cubit of the Scripture equal to 1 foot, 9, 888 inches.

CUCULUS, the Cuckow, in ornithology. See Cuculus.

CUBICUBUS, in the materia medica, a small dried fruit, CUBE, in geometry, a solid body, consisting of six equal square sides. See Geometry.

CUBEBS, in the materia medica, a small dried fruit, resembling a grain of pepper, but often somewhat longer, brought into Europe from the island of Java. In aromatic warmth and pungency, they are far inferior to pepper.

CUBICAL, or CUBICAL EQUATION, in algebra. See Algebra.

CUCUMBER, in botany. See Cucumis.

CUCUMIS, or Cucumber, in botany, a genus of the

In aromatic warmth and pungency, they are far inferior to pepper.

CUCULA, in botany, a genus of the decandria class. The calyx is inflated; the corolla has five petals with uncus, and the capsule has three cells. There are 13 species, five of which are natives of Britain, vix. the bacciferus, or berry-bearing chickweed; the beken, or white corn; the vifeo, or Dover campion; the olites, or Spanish catchfly; and the aculis, or moss campion.

CUCULUS, the CUCKOW, in ornithology, a genus belonging to the order of picae. The bill is somewhat cylindrical; the edges of the nostrils are a little prominent; the tongue is arrow-shaped, plain, and not divided, and the toes are of the climbing kind, i.e. two before and two behind. It is about the size of a pigeon. The cuckow is a migrating bird; it comes to Britain about the end of April, hatches its young, and disappears about St John's day. The cuckow neither builds a nest, nor sits upon its eggs; but takes possession of a nest built by small birds of the sparrow kind, in which it generally lays but one egg, which is hatched by the small bird along with its own eggs; during the time of hatching, the cuckow sits upon hedges or trees, and almost constantly sings. If the cuckow's egg be first hatched, she immediately throws out and destroys the eggs of the small bird; but if the small bird's eggs be first hatched, the cuckow allows the young to live till its own egg is hatched, and then destroys the young belonging to the small bird. The small bird feeds and brings up the young cuckow with as much care and attention as if it were its own, till it be able to procure its own food, when, none fay, it ungratefully kills and eats its nurse. The cuckow feeds upon caterpillars and small birds; but is never transformed into a hawk, as is vulgarly supposed. It is a native of Europe. Linneaus enumerates no less than 22 species, which inhabit different parts of the globe, and are chiefly distinguished by the shape of the tail and variations in colour.

CUCUMBER, in botany. See Cucumis.

CUCUMIS, or Cucumber, in botany, a genus of the monoecea syngenesia class. The calyx of the male has five teeth; the corolla is divided into five segments; and the filaments are three: The calyx and corolla of the female are the same with those of the male; the pistillum is trifid; and the seeds of the apple are short and slender. There are 11 species, none of them natives of Britain.

CUCURBIT, in chemistry. See Chemistry, Vol. II.

CUCURBITA, the gourd, in botany, a genus of the monoecea syngenesia class. The calyx has five teeth; the corolla is divided into five segments; and the filaments are three: The calyx and corolla of the female are the same with those of the male; the pistillum is quinquefid; and the seeds of the apple are turned at the edges. The species are five, none of them natives of Britain.

CUD sometimes means the inside of the throat in beasts, and sometimes the food that they keep there and chew over again: from whence, to chew the cud, signifies, to ponder, think, or ruminate upon a thing.

CUDWEED, in botany. See Gnaphalium.

CUENCA, a city and bishop's see of New Castile, in Spain, about eighty-five miles east of Madrid: W. long. 2° 40', and N. lat. 40° 12'.

CUIRASSE, a piece of defensive armour, made of iron plate, well hampered, serving to cover the body, from the neck to the girdle, both before and behind. Whence, CUIRASSIERS, cavalry armed with cuirasses, as most of the Germans are: the French have a regiment of cuirassiers; but we have had none in the British army since the revolution.

CULDEES, in church-history, a sort of monkifh priests, remarkable for the religious exercises of preaching and praying, they were called, by way of eminence, cultores Dei; from whence is derived the word culdees. They made choice of one of their own fraternity to be their spiritual head, who was afterwards called the Scots bishop.

CULMI-
CULMINATION, in astronomy, the passage of any heavenly body over the meridian, or its greatest altitude for that day.

CULMORE, a town of Ireland, in the county of Londonderry, and province of Ulster, about five miles north of Londonderry: W. long. 7° 40', and N. lat. 55°.

CULMUS. See CULM.

CUL-PRIT, a formal reply of a proper officer in court, in behalf of the king, after a criminal has pleaded not guilty, affirming him to be guilty, without which the issue to be tried is not joined.

The term culprit is a contraction of the Latin culpabilis, and the French prêst; importing that he is ready to prove the criminal guilty.

CULROSS, a parliament town of Scotland, situated on the river Forth, about twenty-three miles north-west of Edinburgh: W. long. 3° 34', and N. lat. 56° 8'.

CULVERIN, in the military art, a large cannon, or piece of artillery; for the kinds, weight, and proportions of which, see CANNON.

CULVERTAILED, among shipwrights, signifies the fastening, or letting, of one timber into another, so that they cannot slip out, as the carlings into the beams of a ship.

CUMBERLAND, one of the most northerly counties of England, separated from Scotland by the frith and river of Solway. It gives the title of duke to his royal highness William duke of Cumberland, &c.

CUMIN, in botany. See Cuminum.

CUMINUM, in botany, a genus of the pentandria diagnost clafs; of which there are three species, none of them natives of Britain.

CUNICULUS, in zoology. See Lepus.

CUNEIFORM, in general, an appellation given to whatever resembles a wedge.

CUNEUS, the wedge, in mechanics. See Mechanics.

CUNICULUS, in zoology. See Lepus.

CUNILA, in botany, a genus of the diandria monogynia clafs; of which there are three species, none of them natives of Britain.

CUNNINGHAM, one of the four bailiwicks of Scotland, separated from Scotland by the frith and river of Solway. It gives the title of duke to his royal highness William duke of Cumberland, &c.

CUP, among botanists, the same with calyx. See CALYX.

CUPANIA, in botany, a genus of the pentandria monandria monogynia clafs. There is but one species, natives of Britain.

CUPTHEM, or Coppel, in chemistry. See Coppel.

CUPPA, in architecture, a spherical vault; or the round top of the dome of a church, in form of a cup inverted.

CUPPING, in surgery, the operation of applying cupping-glaffes for the discharge of blood, and other humours, by the skin. See Surgery.

CUPRESSUS, the Cypress-tree, a genus of the monoecea monodelphia clafs. The calix of the male is a scale of the amentum; it has no corolla; and the anthers have no filaments: The calix of the female is a strobilus, and the squama contains a single flower; it has no corolla; the flylus is a concave point; and the nut is angular. The species are four, none of them natives of Britain.

CUPRUM, or Copper. See Chemistry, Vol. II. p. 80.

CURASSOW, or Curacao, one of the lesser Antillean islands, subject to the Dutch, and situated in 68° 30' W. long. and 12° 30' N. lat.

CURATE, properly signifies the parson or vicar of a parish, who has the charge or cure of the parishioners souls. See Cure.

CURATE, also signifies a person substituted by the incumbent, to serve his cure in his stead.

CURATOR, among civilians, a perfon regularly appointed to manage the affairs of minors, or persons mad, deaf, dumb, &c. See Law.

CURB, in the menage, a chain of iron, made fast to the upper part of the branches of the bridle, in a hole called the eye, and running over the horse's beard. It consists of these three parts; the hook, fixed to the eye of the branch; the chain of SS's, or links; and the two rings, or mailes. Large curbs, provided they be round, are always most gentle: but care is to be taken, that it rest in its proper place, a little above the beard, otherwise the bit-mouth will no have the effect that may be expected from it.

English watering bits have no curbs; the Turkish bits, called genettes, have a ring that serves instead of a curb. See Genettes.

CURCULIO, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are subclavated, and rest upon the snout, which is prominent and horny. There are no less than ninety-five species, principally distinguished by their colour.

CURCUMA, or Turmeric, in botany, a genus of the monandria monogynia clafs. It has four barren flamina, and only the fifth is fertile. There are two species, both natives of India. See Vol. I. p. 633.

CURDISTAN, a province of Persia, having Turcomania, or Armenia, on the north, and Eyraca-Arabic, or Chaldea, on the south.

CURDLING, the coagulating any fluid body, especially milk.

It is said, that at Florence they curdle their milk for the making of cheefe with artichoke-flowers, instead of the rennet used among us for that purpose.

CURFEW, or Curfew, a signal given in cities to advise the people to secure themselves from the robberies and debaucheries of the night.

The most eminent curfew in England was that established by William the Conqueror, who appointed, under
under severe penalties, that, at the ringing of a bell at eight o'clock in the evening, every one should put out their lights and fires, and go to bed: whence, to this day, a bell rung about that time is called a curfew-bell.

CURIA, in Roman antiquity, a certain division, or portion of a tribe. Romulus divided the people into thirty curiae, or wards, whereof there were ten in every tribe, that each might keep the ceremonies of their feasts and sacra1ices in the temple, or holy place, appointed for every curia. The priest of the curia was called curio.

CURIA, in the English law, generally signifies a court; and has been taken for the customary tenants, who do their suit and service at the court of the lord. See Court.

CURING, a term used for the preserving fish, flesh, and other animal substances, by means of certain additions of things, to prevent putrefaction. One great method of doing this, is by smoking the bodies with the smoke of wood, or rubbing them with salt, nitre, &c.

CURLEW, in ornithology. See Scolopax.

CURNOCK, a measure of corn, containing four bushels, or half a quarter.

CURRANTS, or Currants, the fruit of a species of Grossularia. See Grossularia.

The white and red sort are mostly used; for the black, and chiefly the leaves, upon first coming out, are in use to flavour English spirits, and counterfeit French brandy. Currants greatly affuage drought, cool and fortify the stomach, and help digestion.

Curtains, or Courtin, in fortification, is that part of the rampart of a place which is between the flanks of two bastions, bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way and into the moat.

CURVA, in navigation, are certain fetings of the stream, by which ships are compelled to alter their course or velocity, or both, and submit to the motion impressed upon them by the current. See Navigation.

CURRIERS, those who dress and colour leather after it comes from the tan yard. See Tanning.

CURRUCU, in ornithology. See Motacilla.

CURRYING, the method of preparing leather with oil, tallow, &c. See Tanning.

CURTATE distance, in astronomy, the distance of a planet from the sun to that point where a perpendicular let fall from the planet meets with the ecliptic.

CURTATION, in astronomy, is the interval between a planet's distance from the sun, and the currate distance.

CURTON, CURTAIN, or Courtin, in fortification, is that part of the rampart of a place which is between the flanks of two bastions, bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way and into the moat.

CURVATURE of a line, is the peculiar manner of its bending or flexure by which it becomes a curve of such peculiar properties.

CURVE, in geometry, a line which running on continually in all directions, may be cut by one right line in more points than one. See Conic Sections, and Flu8ctions.

CURVET, or Corvet, in the menage, an air in which the horse's legs are raised higher than in the demi volt; being a kind of leap up, and a little forwards, where-in the horse raises both his fore-legs at once, equally advanced, (when he is going straight forward, and not in a circle), and as his fore-legs are falling, he immediately raises his hind-legs, equally advanced, and not one before the other: so that all his four legs are in the air at once; and as he lets them down, he marks it twice with them.

CURVILINEAR, or Curvilinear, is said of figures bounded by curves, or crooked lines.

CURVILINEAR, in ornithology. See Loxia.

CURULE chair, in Roman antiquity, a chair adorned with ivory, wherein the great magistrates of Rome had a right to sit and be carried.

The curule magistrates were the aediles, the pretors, cen wors, and confuls. This chair was fitted in a kind of chariot, whence it had its name. The senators who had borne the offices of aediles, pretors, &c. were carried to the senate-house in this chair, as were also those who triumphed, and such as went to administer justice, &c. See Edile, &c.

CURZOLA, an island in the gulf of Venice, upon the coast of Dalmatia, about twelve miles from the island of Lefina.

CUSCO, the capital city of Peru, during the reigns of the Incas: it is still a fine city, and the see of a bishop, and stands about 350 miles east of Lima, in 7° W. long. and 13° S. lat.

CUSCUTA, or Dodder, a genus of the tetrandra digynia clafs. The calix consists of four segments; the corolla has but one petal; and the capsule is bilocular. The are two species, one of which is a native of Britain, viz. the Europaea, dodder, hell-weed, or devil's guts.

CUSPIDATED, in botany, are such plants whose leaves are pointed like a spear.

CUSTOM,
CUSTOM, a very comprehensive term, denoting the manners, ceremonies and fashions of a people, which having turned into a habit, and paffed into use, obtains the force of laws; in which fince it implies fuch ufages, as, though voluntary at first, are yet, by practice, become necessary.

Custom is hence, both by lawyers and civilians, defined lex non scripta, a law, or right, not written, establi{hed by long ufage, and the content of our ancestors: in which fince it stands opposed to the lex scripta, or the written law.

Customs, in commerce, the tribute or toll, paid by merchants to the king, for goods exported or imported: they are otherwife called duties. See Duty.

Custom house, an office establi{hed by the king's authority in the maritime cities, or port-towns, for the receipt and management of the customs and duties of importation and exportation, imposed on merchandifes, and regulated by books of rates.

Custos brevium, the principal clerk belonging to the court of common pleas, whose bu{inefs it is to receive and keep all the writs made returnable in that court, filing every return by itself; and, at the end of each term, to receive of the prothonotaries all the records of the nisi prius, called the po{tea.

Custos rotulorum, an officer who has the custody of the rolls and records, of the fessions of peace, and alfo of the commi{ion of the peace itself.

He usually is some perfon of quality, and always a justice of the peace, of the quorum, in the county where he is appointed.

Custos spiritualium, he that exercises the spiritual jurisdiction of a diocese, during the vacancy of any fee, which, by the canon law, belongs to the dean and chapter; but at prefent, in England, to the archbifhop of the province, by prescription.

Custos temporalium was the person to whom a vacant fee or abbey was given by the king, as supreme lord. His office was, as fteWARD of the goods and profits, to give an account to the escheator, who did the like to the eschequer.

Cutumbuli, certain worms, either under the skin, or upon it, which, by their creeping, caufe an uneafy fensation. It is alfo applied to wandering scorbutive pains.

Cut-A-Feather, in the fea-language. If a fhip has too broad a bow, it is common to fay, she will not cut a feather; that is, she will not pass through the water fo fwit, as to make it foam or frott.

Cutaneous, in general, an appellation given to whatever belongs to the cutis or skin.

Cuticular, the fame with cutaneous.

Cutis, the skin, in anatomy. See Vol. I. p. 254.

Cutler of the tallies, an officer of the eschequer, whose bu{inefs is to provide wood for the tallies, to cut or notch the sum paid upon them; and then to call them into court, to be written upon. See Tally.

Cuttle-Fish. See Sepia.

Cutzt, the moft eastern province of the kingdom of Fez, in Africa.

CYANUS, in botany. See Centauria.

CYATHUS, in Roman antiquity, a liquid measure, containing four ligulas, or half a pint English meafure, being 469½ solid inches.

CYCLAMEN, or Sow-bread, in botany, a genus of the pentandria monogyina class. The corolla is rotat{ed and reflected; the tube is very fhort, with a prominent fuxus; and the berry is covered with a capulce. There are two fpecies, none of them natives of Britain. The root is a powerful aperient and abftergent.

Cycliscus, in surgery, an instrument in the form of a half moon, used in scraping the skull, in cafe of fractures of that part.

Cycloid, a curve on which the doctrine of pendulums and time mea{uring inftruments in a great mea{ure de-pend: Mr Huygens demonstrated, that from whatever point or height a heavy body, oscillating on a fixed centre, begins to defend, while it continues to move in a cycloid, the time of its falls or oscillations will be equal to each other. It is like{wise demonstrable, that it is the curve of quickest defcent, i.e. a body falling in it, from any given point above, to another not exactly under it, will come to this point in a lefs time than in any other curve passing through those two points.

Cyclopedic, a term sometimes used for the meafuration of circles.

Cyclopedic, or Encyclopedic, denotes the circle or compafs of arts and sciences. A cyclopedic, fay the authors of the French Encyclopedia, ought to explain, as much as po{f{ible, the order and connection of human knowledge. See Dictionary.

Cyclopterus, the Lump-fish, in ichthyology, a genus belonging to the order of amphibia nantes. The head is obtufe, and furnished with faw-teeth; there are four rays in the gills; and the belly-fins are connected together in an orbicular form. There are three fpecies.

Cyder, an excellent drink made of the juice of apples. It conduces greatly to the goodness of the cyder, to let the apples lie a week or two in heaps, before they are pressed. After draining the liquor through a sieve, let it stand a day or two in an open tun, covered only with a cloth, or boards, to keep out the duff, that the more gross parts may fubfide. Then draw it off in pails into vessels, wherein it is intended to be kept, obferving to leave an eighth part of them empty. Set these ves-sels in your coldest cellars, with the bung open, or covered only with a loose cover, both that the volatile fteams may have free vent, and that the muf{t may be kept cool, otherwife it is apt to ferment too much. Having fermented in this manner for fifteen or twenty days, the ve{f{el may be stopped up clofe; and, in two or three months time, the cyder will be fit for drinking. But if you expe{t cyder in perfection, so as to flower in the glass, it must be glued as they call it, and drawn off into bottles, after it has been a short time in the cask: this is done by pouring into each ve-fel...
fel a pint of the infusion of sixty or seventy grains of the most transparent flint-glass, or flint-glace, in a little white-wine and river or rain water, stirred well together, after being strained through a linen cloth. When this viscous fluid is put into the cauldron, it spreads itself over the surface like a net, and carries all the dregs to the bottom with it.

Ginger added to cyder, not only corrects its windiness, but makes it more brisk; and a few drops of currant-juice, besides tingeing, adds a pleasant quickness to it. Honey, or sugar, mixed with some spices, and added to flat cyder, will very much revive it.

Some commend boiling of cyder-juice, which should be done as soon as it is pressed, scoriing it continually, and observing to let it boil no longer than till it acquires the colour of small beer: when cold, put it into a cauldron, leaving a small vent; and when it begins to bubble up out of the vent, bottle it for use.

CYDONIA, in botany. See Crataeva.

CYGNUS, in ornithology. See Anas.

Cylindrical, in geometry, a solid body, supposed to be generated by the rotation of a parallelogram. Rolling, or loaded Cylinder. See Mechanics.

Cylindroid, in geometry, a solid body, approaching to the figure of a cylinder, but differing from it in some respects, as having the bases elliptical, but parallel and equal.

Cylindrurus, in natural history. See Voluta.

CyMA, in botany, the tender stalks which herbs send forth in the beginning of the spring, particularly those of the cabbage-kind.

Cymatium, in architecture, a member or moulding, of the cornice, the profile of which is waved, that is, concave at top, and convex at bottom. See Architecture.

Cymbal, a musical instrument in use among the ancients. The cymbal was round, made of brass, like our kettle-drums, and, as some think, in their form, but smaller, and of different use.

Cymbalaria, in botany. See Antirrhinum.

Cymbaria, in botany, a genus of the didynamia angiospermia class of plants. The calix is divided into many parts; and the capsule is unilocular. There is but one species.

Cynædus, in ichthyology. See Sparus.

Cynanche, among physicians, denotes an inflammation of the larynx.

Cynanchum, in botany, a genus of the pentandria digynia class of plants. The nectarium is cylindrical, and has five teeth. There are five species, none of them natives of Britain.

Cynanthropia, in medicine, the distemper occasioned by the bite of a mad dog. See Medicine.

Cynapium, in botany. See Erythra.

Cynara, the Artichoke, in botany, a genus of the syngenesia polymagia equalis class. The calix is dilated and imbricated, with fleshy scales sharp at the points. There are four species, none of them natives of Britain. The use of the artichoke as a food is well known.

Cynics, a sect of ancient philosophers, who valued themselves upon their contempt of riches and flate, arts and sciences, and every thing, in short, except virtue or morality.

The cynic philosophers owe their origin and institution to Antisthenes of Athens, a disciple of Socrates, who, being asked of what use his philosophy had been to him, replied, "It enables me to live with myself." Diogenes was the most famous of his disciples, in whose life the system of this philosophy appears in its greatest perfection: he led a most wretched life, a tub having served him for a lodging, which he rolled before him wherever he went; yet he was, nevertheless, not the more humble on account of his ragged cloak, bag, and tub; for, one day, entering Plato's house, at a time that there was a splendid entertainment there for several persons of distinction, he jumped up upon a very rich couch, in all his dirt, saying, "I trample on the pride of Plato." "Yes (replied Plato,) but with great pride, Diogenes." He had the utmost contempt for all the human race, for he walked the streets of Athens, at noon-day, with a lighted lantern in his hand, telling the people, "He was in search of a man." Amongst many excellent maxims of morality, he held some very pernicious opinions; for he used to say, that the uninterrupted good fortune of Harsalus, who generally puffed for a thief and a robber, was a testimony against the gods. He regarded chastity and modesty as weaknesses; hence Laertius observes of him, that he did every thing openly, whether it belonged to Ceres or Venus, though he adds that Diogenes only ran to an excess of impudence to put others out of conceit with it: but impudence was the characteristic of these philosophers, who argued, that what was right to be done, might be done at all times, and in all places. The chief principle of this sect, in common with the fioes, was, that we should follow nature; but they differed from the Stoics in their explanation of that maxim, the cynics being of opinion that a man followed nature, that gratified his natural motions and appetites; while the Stoics understood right reason, by the word nature.

Cynic Spasm, a kind of convulsion, wherein the patient imitates the howlings of dogs.

Cynips, in zoology, a genus of insects belonging to the order of hymenoptera. The mouth consist of two jaws, without any proboscis; and the sting in the tail is spiral, and generally hid. There are nineteen species, distinguished by their colour, and the plants they inhabit.

Cynocepalus, in zoology, the trivial name of a species of Simia. See Simia.

Cynoglossum, in botany, a genus of the pentandria monogynia class. The corolla is tunnel-shaped; the seeds are depressed, and the stylus is fixed to the interior side of them. There are eight species, only one of which is a native of Britain; viz. the officinale, or hound's-tongue; the root is said to be pechoral and narcotic.

Cynometra, in botany, a genus of the decandria monogynia class. The calix consists of four segments,
DAC, in ichthyology, the English name of a species of pleuronectes. See Pleuronectes.

DACA, a city of the province of Bengal, in the East-Indies, situated on a branch of the river Ganges: E. long. 89° and N. lat. 23° 30'.

DA CAPO, in music, signifies from the head or beginning; intimating, that the air is to be begun again, and ended with the first part.

DACE, the English name of a species of cyprinus. See Cyprinus.

Vol. II. No. 42.
or smooth cock’s-foot grafts; and the glomeratus, or rough cock’s-foot grafts; both natives of Britain.

Dactylus, in zoology. See Pholas.

Dadouchi, in antiquity, priests of the goddesses Ceres, so called, became at the feasts and sacrifices of that goddess, they ran about the temple, carrying a lighted torch, which they delivered from hand to hand, till it had passed through them all. This they did in memory of Ceres’s searching for her daughter Proserpine, by the light of a torch, which she kindled in mount Etna.

Démon, a name given by the ancients to certain spirits, or genii, which appeared to men, either to do them service, or to hurt them. The Platonists distinguished between gods, demons, and heroes. The gods are those whom Cicero calls Dii majorum gentium. The demons are those whom we call angels. Christians, by the word demon, understand only evil spirits, or devils.

Démoniac, a word applied to a person supposed to be possessed with an evil spirit, or demon. See Demon.

Demoniacs, in church-history, a branch of the ana-baptists, whose distinguishing tenet is, that the devils shall be saved at the end of the world.

Dago, or Dagworth, the capital of an island of the same name in the Baltic, near the coast of Livonia, subject to Russia: E. long. 21° 30’, and N. lat. 58° 45’.

Dahgestan, a country of Asia, bounded by Circassia, on the north, by Servia on the east, by Georgia on the west, and by the Caspian sea on the south. Its chief towns are Tarku and Derbent, both situated on the Caspian sea.

Dahome, a kingdom of Africa, on the Guihea coast.

Daisy. See Bellis.

Dame, a kind of Africa, on the Guinea coast.

Dame, a kind of Africa, on the Guinea coast.

Daisy. See Leucanthemum.

Dox-eye Daisy. See Buphthalmum.

Daiea, in botany. See Psoralea.

Dalea, in botany. See Psoralea.

Daleburg, the capital of the province of Dalia, in Sweden, situated on the western side of the Wener-lake, fifty miles north-east of Gottenburg; E. long. 15°, and N. lat. 50°.

Dalecarlia, a province of Sweden, abounding with iron and copper mines.

Dalechampia, in botany, a genus of the monoeclisia monodelphia class. It has no corolla either in the male or female; and the seeds are roundish and solitary. There is but one species, viz. the scandens, a native of America.

Dalkith, a town of Scotland, in the county of Lothian, six miles south-east of Edinburgh: W. long. 2° 40’, and N. lat. 55° 50’.

Dala, a province of Sweden, bounded on the north by Dalecarlia, on the east by Wermeland and the Wener-lake, on the south by Gothland, and on the west by Norway.

Dalmatia, a frontier province of Europe, mostly subject to the Turks, but some towns on the sea-coast to the Venetians: it is bounded by Bosnia on the north, by Servia on the east, by Albania on the south, and by Morachia and the gulf of Venice on the west.

Dama, in zoology. See Cervus.

Damage, in law, is generally understood of a hurt, or hindrance attending a person’s estate.

Damaia, a sea port town of the Morea in Greece, at the entry of the gulf of Enega.

Daman, a port-town of the hither India, in the province of Guzarat or Cambay, situated on the west coast, about eighty miles south of Surat, in 72° 20’ E. long. and 20° N. lat. It is subject to the Portuguese.

Damascus, or Carman, the capital city of the south part of Syria, situated ninety miles north-east of Jerusalem, in a pleasant, extensive, and fruitful plain; E. long. 37° 20’, and N. lat. 33° 15’.

Damask, a silk stuff, with a raised pattern, so as that the right side of the damask is that which hath the flowers raised or fattened.

Damask, or Damasking, the art of operation of beautifying iron, steel, &c. by making incisions therein, and filling them up with gold and silver, wire; chiefly used for adorning sword-blades, guards and grips, locks of pistols, &c.

Damasonium, in botany. See Alisone.

Dambea, the capital of Abyssinia, or Ethiopia, situated at the head of a lake, to which it gives name: E. long. 34°, and N. lat. 15°.

Dame, a kind of bilander, used in Holland for conveying merchandise from one canal to another; being very commodious for passing under the bridges.

Damiants, in church-history, a branch of the ancient aetaphil-feveritae. They agreed with the catholics in admitting the IVth council, but disowned any distinctions of persons in the Godhead; and professed one single nature, incapable of any difference; and yet they called God, the Father, Son, and Holy Ghost.

Damieta, a port-town of Egypt, situated on the western mouth of the river Nile, four miles from the sea, and 100 miles north of Grand Cairo; E. long. 32°, and N. lat. 31°.

Daminata Terra, among chemists, the same with caput mortuum. See Caput.

Damps, in natural history, noxious streams and exhalations, frequently found in mines, pits, wells, and other subterraneous places. See Pneumatics.

Damsel, from the French damoisel, or dameoiseau, an appellation anciently given to all young people of either sex, that were of noble or genteel extraction; and professed one single nature, incapable of any difference; and yet they called God, the Father, Son, and Holy Ghost.

Damiëta, a port-town of Egypt, situated on the eastern mouth of the river Nile, four miles from the sea, and 100 miles north of Grand Cairo; E. long. 32°, and N. lat. 31°.

Damp, in natural history, noxious streams and exhalations, frequently found in mines, pits, wells, and other subterraneous places. See Pneumatics.

Damsel, from the French damoisel, or damoiseau, an appellation anciently given to all young people of either sex, that were of noble or genteel extraction, as the sons of princes, knaves, and barons: thus we read of Damfel Pepin, Damfel Louis le Gros, Damfel Richard prince of Wales.

From the sons of kings this appellation first passed to those of great lords and barons, and at length to those of gentlemen, who were not yet knights. At present, damsel is applied to all maids or girls, not yet married, provided they be not of the vulgar.

Damæ, in antiquity, a coin somewhat more than an obolus, used to be put into the mouths of the dead, to pay their passage over the river Acheron.

Dance,
DANCE, an agreeable motion of the body, adjusted by art to the measures or tune of instruments, or of the voice.

Atheneus concludes, that in the early ages of antiquity, they accounted dancing an exercise becoming perfons of honour and wisdom; and that, as such, it had been esteemed by the greatest men in all ages. Thus, Homer calls Merion a fine dancer; and says, that the graceful mein and great agility which he had acquired by that exercise, distinguished him above the rest in the armies of either Greeks or Trojans. Dancing was in very great esteem among the Greeks, even the Lacedemonians encouraged it; but, at Rome, we find the custom was quite otherwise; for there, to use the words of Cicero, no man dances unless he is mad or drunk: Cicero reproaches Gabinius with having danced: and we read, that Domitian excluded several members from the senate for having danced.

Dancing in general, was by the ancients divided into cubistic, spheristic, and orcheftic: the cubistic dance was performed with certain wrestlings and contortions of the body; the spheristic with a sort of ball, or bowl play; but the orcheftic was most usual, and what indeed was dancing properly so called.

Dancing is usually an effect and indication of joy; though Mr. Palleprat affures us, that there are nations in South America, who dance to shew their sorrow. It has been in use among all nations, civilized and barbarous; though held in esteem among some, and in contempt among others. It has often been, and still is, sometimes made an act of religion. Thus David danced before the ark to honour God, and express his excess of joy for its return into Sion. Among the pagans it made a part of the worship paid to the gods; it being usual to dance round the altars and statues; and at Rome, the falli, who were priests of Mars, danced through the streets in honour of that God. The poets made the gods themselves dance. The Christians are not free from this superstitition; for in popish countries certain festivals, particularly those of the sacrament, and passion of our Lord, are celebrated with dancing.

DANCETT, in heraldry, is when the outline of any bordure, or ordinary, is indented very largely, the spheristic with a sort of ball, or bowl play; but the orcheftic was most usual, and what indeed was dancing properly so called.

Dancing is usually an effect and indication of joy; though Mr. Palleprat affures us, that there are nations in South America, who dance to shew their sorrow. It has been in use among all nations, civilized and barbarous; though held in esteem among some, and in contempt among others. It has often been, and still is, sometimes made an act of religion. Thus David danced before the ark to honour God, and express his excess of joy for its return into Sion. Among the pagans it made a part of the worship paid to the gods; it being usual to dance round the altars and statues; and at Rome, the falli, who were priests of Mars, danced through the streets in honour of that God. The poets made the gods themselves dance. The Christians are not free from this superstitition; for in popish countries certain festivals, particularly those of the sacrament, and passion of our Lord, are celebrated with dancing.

DANETTE, in heraldry. See Dancette.

DANIELL, in botany. See Isnardia.

DANTZICK, the capital of regal Prufia, in the kingdom of Poland, situated on the western shore of the river Wefel, or Viitula, which a little below falls into the Baltic sea: E. long. 19°, and N. lat. 54°. It is an excellent harbour, and has the best foreign trade within the Baltic.

DANUBE, one of the largest rivers in Europe, which, taking its rise in the Black Foreft in Swabia, runs eastward through Bavaria, Austria, Hungary, and Turkey in Europe; discharging itself by several channels into the Pontus Euxinus, or Black Sea.

DAPHNE, in botany, a genus of the ocatandria monoga periods and the berry contains but one seed. There are 11 species, two of which are natives of Britain, viz. the laureola, or spurge olive: and the mezerium, or spurge olive. The laureola is a strong cathartic.

DAPPLE BAY, in the menage: when bay horses have marks of a dark bay, they are called dapple-bays.

DAPPLE-BLACK; when a black horse has got spots or marks, more black or shining than the rest of his skin, he is called a dapple-black.

DARPI, among logicians, one of the modes of syllogism of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

DAR- Every body is divisible.
AP- Every body is a substance.
TH- Therefore, some substance is divisible.

DARBY, the capital of Darbyshire, situated on the river Darwent: W. long. 1° 26', and N. lat. 53°.

DARDANELLS, two castles at the entrance of the Hellefsport, where all ships going to Constantinople are examined: E. long. 27°, and N. lat. 40° 5'.

DARIEN, a province of Terra Firma, in South America, being the narrow fithmus which joins North and South America.

DARIUS, in logic, one of the modes of syllogism of the first figure, wherein the major proposition is an universal affirmative, and the minor and conclusion particular affirmatives: thus,

DA- Every thing that is moved, is moved by another.
RI- Some body is moved.
TH- Therefore, some body is moved by another.

DARKING, a market-town of Surrey, situated ten miles east of Guildford: W. long. 20°, and N. lat. 51° 18'.

DARLINGTON, a market-town of the county of Durham, situated twenty miles south of the city of Durham: W. long. 1° 15', and N. lat. 54° 30'.

DARMSTAR, the capital of Helfi-Darmfit, in the circle of the upper Rhine in Germany, situated on a river of the same name, fourteen miles south of France, and thirteen south-east of Mentz: E. long. 8° 25', and N. lat. 49° 45'.

DARNEL, in botany. See Lolium.

DARTFORD, a market-town of Kent, in the Dover road, fourteen miles south-east of London: E. long. 16', and N. lat. 51° 25'.

DARTMOUTH, a borough and port town of Devonshire, situated on the English channel, twenty-six miles south of Dartmouth, a borough and port town of Devonshire, situated on the English channel, twenty-six miles south of Dartmouth.
South of Exeter, which sends two members to parliament: W. long. 4°, and N. lat. 50° 25'.

DARWENT, a river, which rising in the Peak of Darbyshire, runs from north to south through that county, and falls into the Trent.

DASYPUS, the Armadillo, in zoology, a genus of quadrupeds belonging to the order of bruta. The dafypus has neither fore-teeth nor dog-teeth; it is covered with a hard bony shell, intersected with distinct moveable zones or belts: This shell covers the head, the neck, the back, the flanks, and extends even to the extremity of the tail; the only parts to which it does not extend, are the throat, the breast, and the belly, which are covered with a whitish skin of a coarse grain, resembling that of a hen after the feathers are pulled off. The shell does not consist of one entire piece, like that of the tortoise, but is divided into separate belts connected to each other by membranes, which enable the animal to move it, and even to roll itself up like a hedge-hog. The number of these belts does not depend on the age of the animal, as some have imagined, but is uniformly the same at all times, and serves to distinguish the different species. All the species of this animal were originally natives of America: they were entirely unknown to the ancients; and modern travellers mention them as peculiar to Mexico, Brazil, and the southern parts of America; though some indeed have confounded them with two species of manis, or shell-lizard, which are found in the East Indies: Others report that they are natives of Africa, because some of them have been transported from Brazil to the coast of Guinea, where a few have since been propagated: but they were never heard of in Europe, Asia, or Africa, till after the discovery of America. — They are all endowed with the faculty of extending and contracting their bodies, and of rolling themselves up like a ball, but not into so complete a sphere as the hedge-hog. They are very inoffensive animals, excepting when they get into gardens, where they devour the melons, potatoes, and other roots. They walk quickly; but can hardly be said to run or leap; so that they seldom escape the pursuit either of men or dogs. But nature has not left them altogether defenceless. They dig deep holes in the earth; and seldom go very far from their subterraneous habitations: Upon any alarm, they immediately go into their holes; but, when at too great a distance, they require but a few moments to make one. The hunters can hardly catch them by the tail before they sink their body in the ground, where they tick so clofe, that the tail frequently comes away and leaves the body in the earth; which obliges the hunters, when they want to take them alive and immutilated, to dilate the sides of the hole. When they are taken, and find that there is no resource, they infantly roll themselves up, and will not extend their bodies, unless they are held near a fire. When in deep holes, there is no other method of making them come out, but by forcing in smoke or water. They keep in their holes through the day, and seldom go abroad in quest of subsistence but in the night. The hunters usually chase them with small dogs, which easily come up with them. When the dogs are near, the creatures instantly roll themselves up, and in this condition the hunters carry them off. However, if they be near a precipice, they often escape both the dogs and hunters; they roll themselves up, and tumble down like a ball, without breaking their shell or receiving any injury. The dafypus is a very fruitful animal; the female generally brings forth four young ones every month; which is the reason why the species is so numerous, notwithstanding they are so much sought after on account of the sweetness of their flesh. The Indians likewise make baskets, boxes, &c. of the shells which cover their heads.

Linnaeus enumerates six species of dafypus, principally distinguished by the number of their moveable belts.

1. The novemcenius, or dafypus, with nine moveable belts. (See Plate LXVIII. fig. 1.) The head is long and narrow; the muzzle extends a good way beyond the under lip; the mouth is large; the eyes are small, and placed on the sides of the head; the ears are long, and placed near each other; the tail is long and conical, and terminates in a sharp point. It has five toes on the hind-feet, and only four on the fore-feet; the claws are long, and of a yellowish colour. The length of the body, from the point of the muzzle, to the origin of the tail, is about eleven inches; and the length of the tail, about nine and a half.

2. The uncinius, or dafypus, with eighteen moveable belts; the other species have two large immovable pieces of shell, one on the shoulders, and another on the buttocks: this species has but one, which is on the shoulders, from that to the tail consisting entirely of moveable belts. The length of the body, from the point of the muzzle, to the origin of the tail, is about nine inches, and the tail about five.

3. The tricenius, or dafypus, with three moveable belts. The head is oblong, and covered with an entire piece of shell; the ears are short and roundish; it has five toes on all the feet, and the two middle claws of the fore-feet are remarkably larger than the rest; the tail is short, being about two inches in length; and the body is about one foot long.

4. The quadrincenius, or dafypus, with four moveable belts; Linnaeus is mistaken with regard to the trivial name and specific character of this animal; it ought to be called the sexcinius, or dafypus, with six moveable belts; for, according to Brissoulius, Bouffon, and most other natural historians, none of the species of this genus have four moveable belts. It has five toes on every foot.

5. The septemcinius, or dafypus, with seven moveable belts: Here Linneus is in another error of the same kind; for this animal has eight moveable belts. It has four toes on the fore-feet, and five on the hind-feet.

6. The dafypus with 12 moveable belts. This is the largest species, being about two feet in length.

DATA, among mathematicians, a term for such things or quantities as are given or known, in order to find other things thereby that are unknown. Euclid uses the word data (of which he hath a particular tract) for
DAV (307) DEA

anchor, and to fasten it at the ship's bow or loof. The
davit is shiftable from one side of the ship to the other,
as there is occasion.

DAUPHIN, a title given to the eldest son of France,
and heir presumptive of the crown. On account of the
province of Dauphiny, which, in 1343, was given to
Philip of Valois, on this condition, by Humbert dauph-
phin of the Viennois.

DAUPHIN-FORT, a fort built by the French, on the
eastern coaft of the island of Madagascar, E. long 45°,
and S. lat. 24°.

DAUPHINE, or Dauphiny, a province of France,
bounded by Burgundy on the north, by Piedmont on
the east, by Provence on the south, and by the river
Rhone, which separates it from Languedoc and the
Lyons, on the west.

Days of grace, are those granted by the court at the
prayer of the defendant, or plaintiff, in whole delay
it is.

Days of grace, in commerce, are a customary number
of days allowed for the payment of a bill of exchange,
&c. After the same becomes due.

Three days of grace are allowed in Britain; ten in
France and Dantzic; eight at Naples; six at Venice,
Amsterdam, Rotterdam, and Antwerp; four at Francc-
fort; five at Leipzig; twelve at Hamburg; six in Por-
tugal; fourteen in Spain; thirty in Genoa, &c.

Day's-man, in the north of England, an arbitrator or
perfon chosen to determine an affair in dispute.

DEACON, one of the three sacred orders of the Chri-
tian church.

As to the office of deacons, the most common and
ordinary was to be attendant on the bishops and pre-
byters in the service of the altar, to take care of the
holy table and all the ornaments and utensils belonging
thereunto; and, in the next place, to receive the offerings
of the people, and to present them to the priest; at
the same time reciting the names of those who offered.
In some churches, though not in all, the deacons read
the gospel both before and at the communion-service;
but their most peculiar office was to assist the bishop and
prebendaries in the administration of the eucharist, at
which their business was to distribute the elements to
the people who were present, and carry them to those
who were absent. That they were never allowed to
consecrate them at the altar, appears from the testimo-
nies of Hilary, Jerom, and the author of the constitu-
tions. They were permitted, however, to administer
solely the sacrament of baptism in some places. An-
other part of the office of deacons, was to be a sort
of monitors and directors to the people in the exercise
of their public devotions in the church; for which pur-
pose they made use of certain known forms of words,
to give notice when each part of the service began.
Whence they are sometimes called [eirokerukes,] the
the holy cryers of the church.

Deacons had, by licence and authority from the bi-
shop, a power to preach, to reconcile penitents and
grant them abolution, and to represent their bishops

for such spaces, lines, and angles as are given in mag-
itude, or to which we can assign others equal.

DATE, in law, is the description of the day, month,
year of our Lord, and year of the reign of the king,
in which a deed or other writing was made.

Dates, the fruit of the phoenix, or great palm-tree. See

Phoenix.

DATISI, in logic, a mode of syllogisms in the third fi-
gure, wherein the major is an universal affirmative, and
the minor and conclusion particular affirmative propo-
sitions. For example,

DA- All who serve God are kings;
TI- Some who serve God are poor;
SI- Therefore, some who are poor are kings.

DATIVE, among grammarians, the third case in the
descension of nouns, expressing the relation of a thing
to whose profit or loss some other thing is referred. It
is called dative, because usually governed by a verb,
implying something to be given to some person. In
English, the dative is expressed by the signs to or for.

DATURA, the Thorn-apple, in botany, a genus of
plants belonging to the pentandria monogyinia clas.
The corolla is plaited and tunnel-shaped; the calix is tubulous, angular, and
deciduous; and the capsule consists of four valves.
There are six species, all natives of warm climates.
The thorn-apple is a narcotic poison: It has lately
been recommended in cases of madness by Dr Stork,
but without answering any useful purpose.

DAUCUS,-the Carrot, in botany, a genus of plants
belonging to the pentandria digynia clas. The cor-
olla are subradiated, and all hermaphrodite; and the
seeds are rough and hairy. There are five species,
one of which, viz. the carota, wild-carrot, or
bird's-nest, is a native of Britain. The seeds are said
to be diuretic and carminative.

There are five species, all natives of warm climates.

DAVentry, a market-town of Northamptonshire, sit-
uated about ten miles north of Northampton: W.
long. 1° 15', and N. lat. 52° 12'.

DAVIDISTS, in church-history, a sect of Christian her-
etics in the XVth century; so called from David
George, their leader, who began by giving out that he
was the Messiah, and was sent into the world in order
to people the kingdom of heaven, which was quite
empty of inhabitants, for want of virtuous and good
men: he rejected marriage, and denied the resurrec-
tion.

They were permitted, however, to administer
solely the sacrament of baptism in some places. An-
other part of the office of deacons, was to be a sort
of monitors and directors to the people in the exercise
of their public devotions in the church; for which pur-
pose they made use of certain known forms of words,
to give notice when each part of the service began.
Whence they are sometimes called [eirokerukes,] the
the holy cryers of the church.

Deacons had, by licence and authority from the bi-
shop, a power to preach, to reconcile penitents and
grant them abolution, and to represent their bishops

Vol. II. No. 43.

DEACON, one of the three sacred orders of the Chri-
tian church.

As to the office of deacons, the most common and
ordinary was to be attendant on the bishops and pre-
byters in the service of the altar, to take care of the
holy table and all the ornaments and utensils belonging
to it; and, in the next place, to receive the offerings
of the people, and to present them to the priest; at
the same time reciting the names of those who offered.
In some churches, though not in all, the deacons read
the gospel both before and at the communion-service;
but their most peculiar office was to assist the bishop and
prebendaries in the administration of the eucharist, at
which their business was to distribute the elements to
the people who were present, and carry them to those
who were absent. That they were never allowed to
consecrate them at the altar, appears from the testimo-
nies of Hilary, Jerom, and the author of the constitu-
tions. They were permitted, however, to administer
solely the sacrament of baptism in some places. An-
other part of the office of deacons, was to be a sort
of monitors and directors to the people in the exercise
of their public devotions in the church; for which pur-
pose they made use of certain known forms of words,
to give notice when each part of the service began.
Whence they are sometimes called [eirokerukes,] the
the holy cryers of the church.

Deacons had, by licence and authority from the bi-
shop, a power to preach, to reconcile penitents and
grant them abolution, and to represent their bishops
in general councils. Their office out of the church was to take care of the necessitous, such as orphans, widows, prisoners, and all the poor and sick who had any title to be maintained out of the public revenues of the church; to inquire into the morals and conversation of the people, and to make their report thereof to the bishop. Whence, on account of the variety of business, it was usual to have several deacons in the same church.

In the Roman church, it is the deacons office to incense the officiating priest or prelate; to lay the corporal on the altar; to receive the pater or cup from the subdeacon, and present them to the person officiating; to incense the choir; to receive the ax from the officiating prelate, and carry it to the subdeacon; and at the pontifical masses, when the bishop gives the blessing, to put the mitre on his head, and to take off the archbishop’s pall, and lay it on the altar. In England, the form of ordaining deacons, declares that it is their office to assist the priest in the distribution of the holy communion; in which, agreeably to the practice of the ancient church, they are confined to the administering the wine to the communicants. A deacon, with us, is not capable of any ecclesiastical promotion, yet he may be a chaplain to a family, curate to a beneficed clergyman, or lecturer to a parish church. He may be ordained at twenty-three years of age, anno 1608. But it is expressly provided, that the bishop shall not ordain the same person a priest and deacon in the same day. Deacons, according to St. Paul, should be chaste, sincere, and blameless; neither great drinkers, nor given to filthy lucre; they should hold the mystery of the faith in a pure confidence, and should be well approved before they are admitted to the ministry.

DEACONESS, a female deacon, an order of women, who had their distinct offices and services in the primitive church. This office appears as ancient as the apocryphal age; for St. Paul calls Phebe a servant of the church of Cenchreae. The original word is [diakono], answerable to the Latin word ministra. Tertullian calls them viduæ, widows, because they were commonly chosen out of the widows of the church; and, for the same reason, Epiphanius, when the council of Laodicea, calls them [presbutidas], elderly women, because none but such were ordinarily taken into this office. For, indeed, by some ancient laws, these four qualifications were required in every one that was to be admitted into this order. 1. That she should be a widow. 2. That she should be a widow that had born children. 3. A widow that was but once married. 4. One of a considerable age, forty, fifty, or sixty years old. Though all these rules admitted of exceptions. Concerning their ordination, whether it was always performed by imposition of hands, the learned are much divided in their sentiments. Baronius and Valesius think they were not, and make no other account of them than as mere lay-perfons. But the author of the constitutions, speaking of their ordination, requires the bishop to use imposition of hands, with a form of prayer which is there recited. We are not, however, to imagine, that this ordination gave them any power to execute any part of the sacred office. They were only to perform some inferior services of the church, and those chiefly relating to the women for whose sakes they were ordained. One part of their office was to assist the minister at the baptizing of women, to undress them for immersion, and to dres them again, that the whole ceremony might be performed with all the decency becoming so sacred an action. Another part of their office was to be private catechists to the women-catechumens who were preparing for baptism. They were likewise to visit and attend women that were sick and in distress; to minister to the martyrs and confessors in prison; to attend the women’s gate in the church; and, lastly, to assign all women their places in the church, regulate their behavior, and preside over the rest of the widows, whence in some canons they are styled [prokathemenai] governesses. This order, which since the tenth or eleventh century has been wholly laid aside, was not abolished everywhere at once, but continued in the Greek church longer than in the Latin, and in some of the Latin churches longer than in others.

DEAD-MAN’S HEAD, in geography, a cape or promontory near Tregony in Cornwall, between St. Mawes and Fowey.

DEAD-MEN’S EYES, in the sea-language, a kind of blocks with many holes in them, but no sheevers, whereby the hrowds are fastened to the chains: the crow-feet reach above through these holes; and, in some ships, the main-flays are let tight in them; but then they have only one hole, through which the lanyards are fastened several times.

DEAD-SETTLE. See LAMIIUM.

DEAD-RECKONING, in navigation, the calculation made of a ship’s place by means of the compass and log; the first serving to point out the course she sails on, and the other the distance run. See Navigation.

DEAD-SEAS, in geography, a lake of Judea, into which the river Jordan discharges itself; being about seventy miles long, and twenty broad.

DEAD-TOPS, a disagreeable incident to young trees, and cured by cutting off the dead parts close to the next good twig or shoot, and laying them over as in grafting.

DEAD-WATER, at sea, the eddy-water just after a ship, so called, because it does not pass away so swiftly as the water running by her sides does. They say that a ship makes much dead water, when she has a great eddy following her stern.

DEADLY CARROT. See THAPSIA.

DEADLY NIGHTSHADE. See ATROPA.

DEADS, among miners, denotes the earth or other fertile substances which inclose the ore on every side. Hence, breaking up the deads, is the removing these substances for the convenience of carrying on their work.

DEAFNESS,
DEAFNESS, the state of a person who either wants the sense of hearing, or has it greatly impaired. See Dumb.

DEAL, a thin kind of fir-planks, of great use in carpentry: they are formed by sawing the trunk of a tree into a great many longitudinal divisions, of more or less thickness, according to the purposes they are intended to serve.

Deals are rendered much harder, by throwing them into salt water as soon as they are fawed, keeping them there three or four days, and afterwards drying them in the air or sun; but neither this nor any other method yet known, will prevent them from shrinking.

Deals called Burgendop deals, the hundred containing fix score, pay on importation 31. s. 6d. and draw back 31. s. 5d. the rate 12l. Meabro deals, fix score, pay 1l. 2s. 8d. and draw back 1l. 1s. 8d. the rate 1d. Norway deals, fix score, pay 1l. 8s. 7½d. and draw back 1l. 6s. 3d. the rate 5l. Spruce deals, fix score, pay 4l. 5s. 10fd. and draw back 3l. 18s. 9d. the rate 15l. Deals from Russia, and all other countries not particularly rated, exceeding twenty foot in length, pay 4l. 5s. 10½d. and draw back 3l. 18s. 9d. the rate 15l. Deals from Sweden, or any other country, of twenty feet in length or under, not otherwise rated, the 120, pay 1l. 8s. 7½d. and draw back 1l. 6s. 3d. the rate 5l.

DEAL, in geography, a port-town of the county of Kent, between which and the Goodwin-fands, the shipping usually rides in the Downs, in going out or coming home: it is about sixty-seven miles eastward of London: E. long. 1° 30', and N. lat. 51° 16'.

DEAN, an ecclesiastical dignitary in cathedral and collegiate churches, and heads of the chapter.

DEAN and CHAPTER, are the bishop's council to assist him in the affairs of religion, and to assist to every grant which the bishop shall make to bind his successors. As a deanery is a spiritual dignity, a man cannot be a dean and prebendary of the same church.

DEAN of GUILD, in Scots law, a magistrate of a royal borough, who has the cognizance of mercantile causes, and the inspection of buildings within borough. See Scots Law, title 4.

DEATH is generally considered as the separation of the soul and body; in which sense it stands opposed to life, which consists in the union thereof.

The law of DEATH-BED, in Scots law, the privilege which that law allows to an heir of reducing all deeds respecting the heritable estate of his predecessor, granted by him while on death-bed, in prejudice of the lawful heir. All deeds are liable to reduction except the legal estate of which he died, and that not afterwards recovered, so as to have gone to kirk or market unsupported. See Scots Law, title 27.

DEBENHAM, a market-town of Suffolk, about twenty miles east of Bury: E. long. 1° 20', and N. lat. 52° 20'.

DEBENTURE, a term of trade used at the custom-house for a kind of certificate signed by the officers of the customs, which intitles a merchant exporting goods to the receipt of a bounty or draw-back. All merchandises that are designed to be taken on board for that voyage being entered and shipped, and the ship being regularly cleared out, and failed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties, or premiums; which debentures for foreign goods are to be paid within one month after demand. And in making out these debentures, it must be observed, that every piece of velum, parchment, or paper, containing any debenture for drawing back customs or duties, must, before writing, be flamped, and pay a duty of 8d.

The forms of debentures vary, according to the merchandises exported. In the execution of debentures for tobacco, it must be particularly observed, 1. That debentures for the same quantity, may be made in one or more parchments. 2. That the exporter's oath must be printed, specifying whether he acts for himself or by commission. If exported to any other foreign ports than Ireland, the word Ireland must be added to the oath after Great Britain. 3. That no tobacco may be consumed on board ships of war in Europe, but what has paid full duties, and been manufactured in Great Britain, no drawback is to be allowed for tobacco exported in any man of war. 4. That the eight pounds per hoghead of 350 pounds, or more, allowed for draught at importation, must not be deducted on exportation. 5. That debentures for tobacco exported to Ireland, must not be paid till a certificate be produced, testifying the landing thereof. 6. That no perons may swear to the exportation, but such as are permitted to swear to debentures for other goods. In debentures for all other foreign goods, no peron may be admitted to swear to the exportation, but the true exporter, either as a proprietor, or who being employed by commission, is concerned in the direction of the voyage. All kinds of debentures before delivered or paid to the exporters, are entered into a separate book kept for that purpose by the collector and comptroller of the customs.

Debita fundi, in Scots Law. A debt is said to be a debitum fundi, when it is recoverable either by a personal action against the debtor himself, or by a real action against his lands.

Debita fructuum, in Scots law. Funds are debita fructuum not fundi; fo are not recoverable out of the lands themselves, but out of the fruits of the lands out of which they are payable. See Scots Law, title 17.

DEBILITY, among physicians, a relaxation of the solids, occasioning oftentimes weaknesses and faintings.

DEBRECHEN, a town of Upper Hungary, about seventy-seven miles east of Buda: E. long. 21° 10' N. lat. 47° 45'.

DEBRUIZED, in heraldry, a term peculiar to the Engifh, by which is intimated the grievous restraint of any animal, debarred of its natural freedom, by any of the ordnaries being laid over it.

DEBT, in law, any thing due to another, whether it be money,
money, goods, or services; or the action brought for recovering the same.

DEBTOR, a person who owes anything to another; in

contradistinction to creditor, which is he to whom the
debt is owing.

DEBTOR, in merchants accounts. See Book-keeping.

DECAGON, in geometry, a plane figure with ten sides
and ten angles.

DECLARQUE, the ten precepts or commandments
delivered by God to Moses, after engraving them on
two tables of stone.

The Jews, by way of excellence, call these com-
mandments the ten words, from whence they had af-
wards the name of decalogue: but it is to be ob-
erved, that they joined the first and second into one,
and divided the last into two: they understood that a-
gainst stealing, to relate to the stealing of men, or
killing; and, alleging, that the stealing one anothers
goods or property, is forbidden in the last command-
ment.

The emperor Julian objected to the decalogue, that
the precepts it contained (those only excepted which
concern the worship of false gods, and the observa-
tion of the sabbath) were already so familiar to all nations,
and so universally received, that they were unworthy,
for that very reason, to be delivered, by so great a
legislator, to so peculiar a people. The church of
Rome has struck the second commandment quite out
of the decalogue, and to make their number complete,
hath split the tenth into two. The reason of which
may be easily conceived.

DECAN, a province of the Hither India, bounded by
the province of Cambay, or Guzurat, on the north;
by Golconda and Berar, on the east; by Vifapur, on
the south; and by the Indian ocean on the west.

DECADEANIA, ancient Roman festivals celebrated by
the emperors, every tenth year of their reign, with
sacrifices, games, and largesses for the people. The
emperor Augustus first instituted these solemnities,
in which he was imitated by his successors.

DECADUS, in Roman antiquity, an officer who pre-
ofs over other ten officers, and was head of the con-
tumbrum, or quarter of a field of soldiers.

DECAPROTI, decemprimi, in Roman antiquity, offi-
cers for gathering the tributes and taxes.

Every language has, besides the form of its charac-
ters, something peculiar in the place, order, combina-
tion, frequency, and number of the letters; to all
which particular regard is to be had in deciphering.
In all languages, however, the following rules ought to
be observed: 1. One word is to be compared with
another, that their resemblance and difference may be
known. 2. No word can be without a vowel. 3. A
word of one letter is always a vowel, or a con-
sonant. 4. The vowels recur much more
frequently than the consonants. 5. Double vowels
may be at the beginning of a word, but not double
consonants. 6. Double characters at the beginning of
a word are always vowels. 7. Short words of two
or three letters have two or three, or one or two con-
sonants. 8. The vowels are therefore most easily
learned from the short words which are to be first
considered by the decipherer. 9. If double charac-
ters are preceded by a single letter, the letter is a
vowel. 10. In languages abounding with diphthongs
one
one vowel is of ten joined with another. 11. The letter that precedes or follows double consonants is, if a consonant, always one of the liquids, l, m, n, r, 12. If two different characters occur, of which the latter is often conjoined with various letters, and the former is never found either by itself, or followed by any other letter, those two are qu, 13. These letters qu are always followed by a vowel. 14. One vowel recurs more frequently than another, as do the consonants, according to the language, &c.

DECLARATION, in grammar, an inflexion of nouns according to their various cases. It is a different thing in the modern languages, which have not properly any cases, from what it is in the ancient Greek and Latin. With respect to languages, when the nouns admit of changes, either in the beginning, the middle, or ending; declension is properly the expression of all those changes in a certain order, and by certain degrees called cases. With regard to languages, where the nouns do not admit of changes in the same number, declension is the expression of the different classes a noun is in, and the different relations it has; which difference of relations is marked by particles, and called articles, as a, the, of, to, from, by, &c.

DECLINATION, in astronomy, the distance of any celestial object from the equinoctial, either northward or southward. It is either true or apparent, according as the real or apparent place of the object is considered. See Astronomy.

DECLAVATION of a wall or plane for dials. See Dialling.

DECLINATOR, or Declinatory, an instrument contrived for taking the declinations, inclinations, and reclinations of planes.

DECLARATION, in Scots law, declining the jurisdiction of a judge, or refusing to acquiesce in his judgment from any legal obligation to the judge himself, the incompetency of his jurisdiction to the nature of the action, or upon the privilege of the object or decliner. See Scots Law, title 2.

DECLIVITY denotes the reverse of acclivity. See Acclivity.

DECOCTION, in pharmacy, the boiling simples, or other drugs, in order to extract their virtues for some medicinal purpose. The general subjects of decoction are animals and vegetables, and sometimes minerals, as antimony and quicksilver. The liquors which serve to boil them, are water, wine, vinegar, milk, and whey.

DECOMPOSITION, in chemistry, the reduction of a body into its principles or component parts. See Chemistry.

DECORATION, in architecture, is used for whatever adorns a building, either without or within.

DECORUM, in architecture, is the suitableness of a body to its principles or component parts. See Architecture.

DECOURS, in heraldry, is the same as uncoupled: thus a chevron uncoupled, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DECOURSM, in architecture, is used for whatever adorns a building, either without or within.

DECREE, in the civil law, is a determination that the emperor pronounces upon hearing a particular cause between plaintiff and defendant.

DECREASE, an order made by a superior power, for the regulation of an inferior.

DECREET, or Decret, in Scots law, the decisive sentence or judgment of a court of law.

DECREET-arbitral, in Scots law, the sentence or judgment of one to whom parties voluntarily submit the determination of any question betwixt them. See Scots Law, title 32.

DECREMENT, in heraldry, signifies the wane of the moon from the full to the new. The moon in this state is called moon decrement, or in decreus; and when borne in coat-armour, faces to the left side of the escutcheon, as the does to the right side when in the increament. See Crescent.

DECREPITATION, in chemistry, the act of calcining salt over the fire, till it ceases to crackle. See Chemistry.
DEEMSTERS, or Demsters. All controversies in
Deeping, a market-town of Lincolnshire, about thirty-
deed, in Scots laws, any settlement, disposition, con-
deeds, an instrument written on paper or parchment,
Dedication, an anniversary festival among
DEDICATION, a solemn devoting or setting apart
called the decurio.
The Roman cavalry was divided into decuries,
which were subdivisions of a century, each century
containing ten decuries.
DECUSATION, a term in geometry, optics, and
anatomy, signifying the crossing of any two lines, rays,
or nerves, when they meet in a point, and then go on
separately from one another.
DECUSSORIUM, a surgeon's instrument, which, by
pressing gently on the dura mater, causes an evacuation
of the pus collected between the cranium and the
before mentioned membrane, through the perforation
made by the trepan.
DEDNINGTON, a market town of Oxfordshire, about
fifteen miles north of Oxford: W. long. 1° 20', and
N. lat. 51° 51'.
DEDHAM, a market-town in Essex, about thirty-five
miles north-east of Chelmsford: E. long. 1° 10', and
N. lat. 52° 4'.
DEDICATION, a solemn devoting or setting apart
any person or thing to the service of God and the
purposes of religion.
Feast of Dedication, an anniversary festival among
the Jews, in memory of Judas Maccabaeus, who re-
paired and dedicated anew the temple and altar, which
had been plundered and profaned by Antiochus Epif-
phanes. It was observed on the twenty-fifth of Cisfe,
and continued eight days.
DEE, the name of several rivers, as that on which Che-
fter stands, that whereon Aberdeen stands, &c.
DEED, in Scots laws, any settlement, disposition, con-
tract, or other legal writing.
DEED, an instrument written on paper or parchment,
comprehending some contract, bargain or agreement
between the parties thereto, in relation to the matter
therein contained.
DEEMSTERS, or Demsters. All controversies in
the Isle of Man are decided without process, writ-
ings, or any charges, by certain judges, chosen yearly
from among themselves, called deemsters; there being two
of them for each division of the ifland: they fit judges
in all courts, either for life or property; and with the
advice of twenty-four keys, declare what is law, in
uncommon emergencies.
DEEPING, a market-town of Lincolnshire, about thirty-
five miles south of Lincoln: W. long. 20°, and N.
latt. 52° 35'.
DEER, in zoology. See Cervus.
DEFAMATION, the speaking slanderous words of an-
other; for which the slanderer is punishable, according
to the nature of his offence, either by action upon the
case at common law, or by statute, in the ecclesiastical
court.
DEFAULT, in law, is generally taken for non-appear-
cance in court, at a day assigned; but imports any o-
million of that which we ought to do, for which
judgment may be given against the defaulter.
DEFASANCE. See Defeisance.
DEFECATE, or DefiEcate, in chemistry, a term ap-
p lied to a body freed and purged from faces and im-
purities.
DEFERENT, in law, a condition relating to some
certain deed, which being performed, the deed is de-
feated and rendered void, as if it had never been
made.
DEFENCE, in fortification, all sorts of works that co-
ver and defend the opposite posts, as flanks, cafemens,
parapets, and fauffebrays. See Fortification.
Line of Defence, a supposed line drawn from the angle
curin; or from any other part in the curin,
to the flanked angle of the opposite baflion. See Forti-
fication.
Defender of the faith, a peculiar title, belonging
to the king of Great Britain, as Catholic does to the
king of Spain, Chriftian to the king of France, &c.
This title was first given by pope Leo X. to king
Henry VIII., for writing against Luther.
DefereR, in anatomy, a term applied to certain
vessels in the body, that serve for the conveyance of
humours from one part to another. See Anatomy.
DefereNT, in the Ptolemaic astronomy, a circle invent-
ed to account for the eccentricity, perige, and apogee
of the planets.
DEFILE, in fortification, a strait narrow passage, thro'
which a company of horse or foot can pass only in file,
by making a small front.
DEFINITE, in grammar, is applied to an article that
has a precise determinate signification; such as the
article the in English, le and la in French, &c. which
fix and ascertain the noun they belong to, to some particu-
lar, as the king, le roy; whereas in the quality of
kings, de roy, the articles of and de mark nothing pre-
cile, and are therefore indefinite.
DEFINITION, an idea of any science, subject, &c.
conveyed in a few words.
DEFINITIVE, a term applied to whatever terminates
a process, question, &c. in opposition to provisional
and interlocutory.
DEFLAGRATION, in chemistry, the kindling or set-
ing fire to a salt or mineral, &c. either alone, or mix-
ed for that purpose with a sulphurous one in order to
purify it. See Chemistry.
DEFLUXION, in medicine, the falling of humours
from a superior to an inferior part of the body.
DEFORCEMENT,
DEISTS, in the modern sense of the word, are those who deny the existence of an eternal, infinite, independent, intelligent Being; and who teach, that this supreme Being made the world, though they fancy he does not at all concern himself in the management of it. 2. Those who believe not only the being, but also the providence of God with respect to the natural world; but who, not allowing any difference between moral good and evil, deny that God takes any notice of the morally good or evil actions of men; these things depending, as they imagine, on the arbitrary constitutions of human laws. 3. Those who having right apprehensions concerning the natural attributes of God, and his all governing providence, and some notion of his moral perfections also; yet, being prejudiced against the notion of the immortality of the human soul, believe that men perish entirely at death, and that one generation shall perpetually succeed another, without any future restoration or renovation of things. 4. Such as believe the existence of a supreme Being, together with his providence in the government of the world, as also the obligations of natural religion; but so far only as these things are discoverable by the light of nature alone, without believing any divine revelation. These last are the only true deists; but as the principles of these men would naturally lead them to embrace the Christian revelation, the learned author concludes there is now no consistent scheme of deism in the world.

DEITY, a term frequently used in a synonymous sense with God.

DELEGATES, commissioners appointed by the king under the great seal to hear and determine appeals from the ecclesiastical court.

DELEGATION, in Scots law, a method of extinguishing obligations by the creditor's discharging his former debtor upon another becoming bound in his place.

DELETERIOUS, an appellation given to things of a destructive or poisonous nature. See Poison.

DELF, in heraldry, is by some supposed to represent a square rod or turf, and to be so called from delving, or digging. A defter tenne is due to him that revokes his own challenge, or in any way goes from his word; and to such this is given as an abatement to the honour of their arms, and is always placed in the middle of the escutcheon. However, if two or more defets are found in an escutcheon, they are not then to be looked upon as signs of an abatement, but of honour. Also, if it be of metal, or charged upon, it then becomes a charge of perfect bearing.

DELT, a city of the United Netherlands, in the province of Holland, eight miles north-east of Rotterdam, and thirty-four miles south-west of Amsterdam: E. long. 4° 5', and N. lat. 52° 6'.

DELA, in antiquity, feasts celebrated by the Athenians in honour of Apollo, surnamed Delius.

DELIA was also a quinquennial festival in the island of Delos, instituted by Theseus at his return from Crete, in honour of Venus, whose statue, given him by Ariadne, he erected on that place, having by her assistance met with success in his expedition.

DELIBERMENTA, in antiquity, a libation to the infernal gods, always offered by pouring downwards. See Libation.

DELIBERANDI, in Scots law, an apparent heir is allowed a year after his predecessor's death, called annus deliberandi, to deliberate whether he will enter and represent him or not, during which time he cannot be pur sued for the debts of his predecessor. See Scots Law, title 27.
DELICT, in Scots law, signifies such small offences or breaches of the peace as are punishable only by fine or short imprisonment. See Scots Law, title 33.

DELIQUENT, a guilty person, or one who has committed some fault or offence, for which he is punishable.

DELIQUIUM, or Animi Deliquium. See Lipothyria.

DELIQUIUM, in chemistry, signifies the solution of any body, when exposed to a cool and damp place, by the humidity it attracts from the air.

DELIRIUM, in medicine, the production of ideas not answerable to external causes, from an internal indisposition of the brain. See Medicine.

DELIVERY, or Child-birth. See Midwifery.

DELLY, the capital of a province of the same name, and at present of all the Hither India: E. long. 79°, and N. lat. 28°.

DELOS, the principal of the Cyclades islands, in the Archipelago: E. long. 25° 50', and N. lat. 37° 26'.

DELPHINIUM, or Lark's-spur, in botany, a genus of the polyandria trigynia class. It has no calix; the corolla consists of five petals; and the nectarium is bifid, and horned behind. There are seven species, only one of which, viz. the consolida, or wild lark's-spur, is a native of Britain.

DELPHINUS, or Dolphin, in ichthyology, a genus belonging to the order of cetes; the characters of which are these: they have teeth in each jaw; and a fiftula or pipe in the head. There are three species, viz. 1. The phocaena, with a conical body, a broad and horned behind. There are seven species, only one of which, viz. the consolida, or wild lark’s-spur, is a native of Britain. 2. The delphus, or dolphin of the ancients, is of an oblong cylindrical shape, and the snout is sharp and tapering; the teeth are serrated. It likewise frequents the European ocean. 3. The orca, or lesser whale of Ray, has the upper part of the snout waved, and broad serrated teeth. The inferior jaw is much longer than the superior one.

DELPHINUS, in astronomy, a constellation of the northern hemisphere. See Astronomy.

DELSBERG, or Desberg, a town of Switzerland, about seventeen miles south-west of Basl.

DELUGE, an inundation or overflowing of the earth, either wholly or in part, by water.

We have several deluges recorded in history, as that of Ogyges, which overflowed almost all Attica; and that of Deucalion, which drowned all Thessaly in Greece: but the most memorable was that called the universal deluge, or Noah's flood, which overflowed and destroyed the whole earth, and out of which only Noah, and those with him in the ark, escaped. See Ark.

Many attempts have been made to account for the deluge by means of natural causes: but these attempts have only tended to discredit philosophy, and to render their authors ridiculous.

DEMAIN, or Demesne, in its common acceptation, is used for the lands round a manor-house, occupied by the lord.

DEMAIN, or Demesne, in law, is commonly underfoot to be the lord's chief manor-place, with the lands thereto belonging, which he and his ancestors have time out of mind kept in their own manual occupation.

DEMEMBRE', in heraldry, is said of dismembered animals, or those with their limbs cut off.

DEMEMBRATION, in Scots law, signifies either the crime of depriving another of any member of his body, or the punishment of a crime by cutting off any member of the criminal's body. See Scots Law, title 33.

DEMER, a river in the Austrian Netherlands, on which the city of Mechlin stands.

DEMESNE. See Demain.

DEMETRIA, a festival celebrated by the Greeks in honour of Ceres, wherein it was usual for the devotees to fast themselves.

DEMTRIOWITZ, a city of the dutchy of Smolentko, in the Russian empire, situated upon the river Ugra, in 37° E. long. and 52° 30' N. lat.

DEMI, a word used in composition with other words to signify half.

DEMI-CULVERIN, a piece of ordnance usually 4½ inches bore, 2700 pound weight, ten feet long, and carrying point blank 175 paces.

DEMI-CULVERIN, of the least size, is 4½ inches bore, young with milk; and they live about thirty years. They live several days out of the water, provided they be not wounded. See Plate LXVIII. fig. 2. It is about four feet long, and two and a half thick.

2. The delphus, or dolphin of the ancients, is of an oblong cylindrical shape, and the snout is sharp and tapering; the teeth are serrated. It likewise frequents the European ocean. 3. The orca, or lesser whale of Ray, has the upper part of the snout waved, and broad serrated teeth. The inferior jaw is much longer than the superior one.
DENARIUS, in Roman antiquity, the chief silver coin among the Romans, worth in our money about sevenpence three farthings. As a weight, it was the seventh part of a Roman ounce.

DENARIUS is also used in our law-books for an English penny.

DENDROCHATES, in natural history, the name used by the ancients for an extremely elegant and beautiful species of agate, the ground of which is whitish, variegated with veins of a brighter white. These veins are beautifully disposed in a number of various figures, but generally in many concentric irregular circles, drawn round one or more points. It is common also, in various parts of this stone, to find very beautiful delineations of trees, mosses, sea-plants, and the like, so elegantly expressed, that many have erroneously taken them for real plants included in the substance of the stone; whence the name dendrachates.

DENEB, an Arabic term signifying tail, used by astronomers to denote several fixed stars. Thus deneb eleet, signifies the bright star in the lion's tail. Deneb adigege, that in the swan's tail, &c.

DENS CANIS, or dog's-tooth, in botany. See Erythonium.

DENS LEONIS. See LEONTODON.

DENSITY of bodies, is that property directly opposite to rarity, whereby they contain such a quantity of matter under such a bulk.

Accordingly, a body is said to have double or triple the density of another body, when their bulk being equal, the quantity of matter is in the one double or triple the quantity of matter in the other.

DENSITY of the air. See PNEUMATICS.
DENTALIUM, in natural history, a shell-fish belonging to the order of vermes teflacea. The shell consists of one tubulous straight valve, open at both ends. There are eight species, distinguished by the angles, frirs, &c. of their shells.

DENTARIA, or toothwort, in botany, a genus of the tetradyomia filiquofa class. The filiqua or pod bursts open by elastic valves; the stigma is emarginated; and the calyx is conivnent. There are three species, only one of which, viz. the bulbifera, or coralwort, is a native of Britain.

DENTATES LEAF. See botany, p. 640.

DENTEX, in ichthyology. See Sparus.

DENTILES, or Dentils, in architecture, an ornament in corniches bearing some resemblance to teeth, particularly used in the Ionic and Corinthian orders. See Architecture, p. 352.

DENTIFRICE, in medicine, a remedy for rubbing the teeth, and purging them from fordes; and for cleaning and abating the gums, when replete with humours. There are dentifrices of various kinds and forms; some in form of a powder composed of corals, pumice-flone, salt, allum, egg-shells, crabs-claws, hartsthorn, &c. others in form of an elixery, confisting of the same powders mixt up with honey; others are in form of a liquor drawn by distillations from drying herbs. &c. See Medicine.

DENTILLARIA. See Plumbago.

DENTISCALPRA. See Plumbago.

DENTIFRICA, in surgery, an instrument for scouring yellow, livid, or black teeth; to which being applied, near the gums, it scrapes off the foul morbid crust. See Medicine.

DENTIFICATION, the breeding or cutting the teeth in children. See Medicine.

DENUCTION, a solemn publication or promulgation of any thing.

All vessels of enemies are lawful prizes, after denunciation or proclamation of war. The design of the denunciation of excommunicated persons, is that the sentence may be the more fully executed by the person's being more known.

Denunciation at the horn, in Scots law, is that form by which a debtor, after the expiry of a charge to make payment upon letters of horning, is denounced rebel to the king for disobedience. No caption for apprehending and imprisoning the debtor can be obtained upon an expired charge of horning till he is first denounced rebel, and the horning with the executions of charge and denunciation registered. As to the other legal effects of denunciation, see Scots Law, title 12.

DEOBSTRUENTS, in pharmacy, such medicines as open obstructions. See Detergent.

DEODAND, in our customs, implies a thing devoted or consecrated to God, for the pacification of his wrath, in case of any misfortune; as a person's comage to a violent end, without the fault of any reasonable creature; as if a horse should strike his keeper, and so kill him. In this case, the horse is to be a deodand; that is, he is to be sold, and the price distributed to the poor, as an expiation of that dreadful event.

DEONENT, in Latin grammar, a term applied to verbs which have active significations, but passive terminations or conjugations, and want one of their particles passive.

DEONENT, in the law of Scotland, a person who makes a deposition. See Deposition.

DEPOPULATION, the act of diminishing the number of people in any country, whether by war or bad politics.

DEPORTATION, a sort of banishment used by the Romans, whereby some island or other place was allotted to a criminal for the place of his abode, with a prohibition not to flir out of the same on pain of death.

DEPOSIT, among civilians, something that is committed to the custody of a person, to be kept without any reward, and to be returned again on demand.

DEPOSITORY, in law, a person intrusted as keeper or guardian of a deposit.

DEPOSITION, in Scots law, is a contract by which one commits the custody or possession of any thing to another, to be kept for behoof of the owner, and returned on demand, or at any period specified in the contract. The owner is called the depofitor, and the person to whom custody the thing is committed the depositary. See Scots Law, title 20.

DEPOSITION, in law, the testimony given in court by a witness upon oath.

DEPRECATORY, or Deprecative, in theology, a term applied to the manner of performing some ceremonies in the form of prayer.

The form of abforlution is deprecative in the Greek church, being conceived in these terms, May God absolve you: whereas it is in the declarative form in the Latin church, and in some of the reformed churches, I absolve you.

DEPRESSION of the pole. See Astronomy, and Geography.

DEPRESSOR, or Deprimens, in anatomy, a name applied to several muscles, because they depress the parts they are fastened to.

DEPRIVATION, in the canon-law, the depofing a bishop, parson, vicar, &c. from his office and preferment.

DEPTFORD, a town three miles east of London, on the southern banks of the Thames; chiefly considerablc for its fine docks for building ships, and the king's yard.

DEPURATION. See Clarification.

DEPURATORY FEVER, a name given by Sydenham to a fever which prevailed much in the years 1661, 1662, 1663, and 1664. He called it depuratory, because he observed, that nature regulated all the symptoms in such a manner, as to fit the febrile matter, prepared by proper concoction, for expulsion in a certain time, either by a copious sweat, or a freer perspiration.

DEPUTATION, a million of select persons out of a company
company or body, to a prince or assembly, to treat of matters in their name.

DEPUTY, a person sent upon some business, by some community.

DEPUTY is also one that exercises an office in another's right; and the forfeiture or misdemeanor of such deputy shall cause the person whom he represents to lose his office.

DEPUTATUS, among the ancients, a name applied to

DERIVATIVE, in grammar, a word which is derived from another called its primitive. See Primitive.

Thus, manhood is derived from man, deity from Deus, and lawyer from law.

DERMESTES, in zoology, a genus of insects belonging to the order of coleoptera. The antennae are elevated, with three of the joints thicker than the rest; the breast is convex; and the head is inflected below the breast. There are thirty species, distinguished by their colour, &c.

DERNIER ressort. See Ressort.

DEROGATORY, a clause importing derogation. A derogatory clause in a testament, is a certain sentence, derogatory clause is not inserted expressly, and word for word. It is a precaution invented by lawyers against latter-wills extorted by violence, or obtained by suggestion.

DERPT, a town of Livonia, situated on the river Em- bec: E. long. 28° 10', and N. lat. 58° 10'.

DERVIS, a name given to all Mahomedan monks, though of various orders. The most noted among them are the Bektaşi, the Mevelevi, the Kadri, and the Seyah. The Bektaşi, who are allowed to marry and live in cities and towns, are obliged, by the rules of their order, to visit remote lands, and to salute every one they meet with gazel, or love-songs, and with fma, or the invocation of the names of God, and humbly to wish him prosperity, which they do by repeating the word sivallah, a solemn exclamation of the wretflers, by which the conqueror yields the palm to the conqueror. The Mevelevi, so called from Mevelava their founder, are used to turn round for two or three hours together, with such swiftness that you cannot see their faces; they are great lovers of music: in their monasteries they profess great humility and poverty, and when visited make no distinction of persons; they first bring their guests coffee to drink; and if the ways have been dirty, they wash their feet and sandals. The Kadri, with a peculiar superstition, emaciate their bodies; they go quite naked, except their thighs, and often join hands and dance, sometimes a whole day, repeating with great vehemence, bu! bu! bu! (one of the names of God) till, like madmen, they fall on the ground, foaming at the mouth, and running down with sweat: the prime vizir Kupruli Ahmed Pasha, thinking this feast unbecoming the Mahomedan religion, ordered it to be suppressed; but, after his death, it revived, and is at present more numerous than ever, especially at Constantinople. The Seyah are wanderers, and though they have monasteries, yet they often spend their whole life in travelling; when they are sent out, their superiors impose upon them such a quantity of money or provisions, forbidding them to come back till they have procured it, and sent it to the monastery: wherefore when a Seyah comes into a town, he cries aloud in the market-place, Ta allah fenden, &c. O God! give me, I pray, five thousand crowns, or a thousand measures of rice. Many of these dervises travel over the whole Mahomedan world, entertaining the people where-ever they come, with agreeable relations of all the curiosities they have met with. There are dervises in Egypt, who live with their families, and exercise their trades, of which kind are the dancing dervises at Damascus. They are all distinguished among themselves by the different forms and colours of their habits; those of Persia wear blue; the solitaries and wanderers wear only rags of different colours; others carry on their heads a plume made of the feathers of a cock; and those of Egypt wear an octagonal badge of a greenish white alabaster at their girdles, and a high stiff cap, without any thing round it.

DERWENT, a river, which, taking its rise in the north riding of Yorkshire, runs south, and falls into the Ouse.

DERWENT-WATER, a river of Cumberland, which falls into the Irish sea below Cockermouth.

DESART, a large extent of country entirely barren, and producing nothing. In this sense some are sandy desarts, as those of Lop, Xamo, Arabia, and several others in Asia; in Africa, those of Lybia and Zara: others are stony, as the desart of Plia an in Arabia, and producing nothing. In this sense some are sandy desarts, as those of Lop, Xamo, Arabia, and several others in Asia; in Africa, those of Lybia and Zara: others are stony, as the desert of Pharan in Arabia Petraea.

The DESART, absolutely so called, is that part of Arabia, south of the Holy Land, where the children of Israel wandered forty years.

DESCANT, in music, the art of composing in several parts. See Music.

DESCENDENTS, in Scots law. The issue of a common parent in infinitum are called his descendants.

DESCENSION, in astronomy, is either right or oblique.

Right DESCENSION is an arch of the equinoctial, intercepted between the next equinoctial point and the intersection of the meridian, passing through the centre of the object, at its setting, in a right sphere.

Oblique DESCENSION, an arch of the equinoctial, intercepted;
Descend, in general, is the tendency of a body from a higher to a lower place; thus all bodies, unless otherwise determined by a force superior to their gravity, descend towards the centre of the earth. See Mechanics.

Descent, or Discent, in law, an order or method whereby lands or tenements are derived to any man from his ancestors.

Descent, in genealogy, the order or succession of descendants in a line or family; or their distance from a common progenitor: thus we say, one descent, two descendants, &c.

Descent, in heraldy, is used to express the coming down of any thing from above; as, a lion en descent, is a lion with his head towards the base points, and his heels towards one of the corners of the chief, as if he were leaping down from some high place.

Description, is such a strong and beautiful representation of a thing, as gives the reader a distinct view and satisfactory notion of it. See Narration and Description.

Desedada, or Desiderada, one of the Caribbee-illands, subject to France, lying eastward of Guadaloupe. See Caribbee.

Deserter, in a military sense, a soldier who, by running away from his regiment or company, abandons the service. A deserter is, by the articles of war, punishable by death, and, after conviction, is hanged at the head of the regiment he formerly belonged to, with his crime writ on his breast.

Desertion, in Scots Law, when one of the married persons deserts or forsakes the other. Wilful desertion for four years together is a ground of divorce. See Scots Law, title 6.

Deshache', in heraldry, is where a bead has its setting, in an oblique sphere.

Desertion, or Discretion, in Scots Law, when one of the married persons deserts or forsakes the other. Wilful desertion for four years together is a ground of divorce. See Scots Law, title 6.

Desertion, in Scots Law, when one of the married persons deserts or forsakes the other. Wilful desertion for four years together is a ground of divorce. See Scots Law, title 6.

Design is also used, in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large.

Design, in a general sense, the plan, order, representation, or construction of a building, book, painting, &c.

Design, in the manufactories, expresses the figures with which the workman enriches his stuff, or silk, and which he copies after some painter, or eminent draughtsman, as in diaper, damask, and other figured silk and tapestry, and the like.

In undertaking of such kinds of figured stuffs, it is necessary, says Monf. Savary, that, before the first stroke of the shuttle, the whole design be represented on the threads of the warp; we do not mean in colours, but with an infinite number of little pack-threads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle for woof. This method of preparing the work is called reading the design, and reading the figure, which is performed in the following manner: a paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented thereon. This they divide lengthwise, by as many black lines as there are intended threads in the warp; and crosses these lines, by others drawn breadthwise, which, with the former, make little equal squares: on the paper thus squared, the draughtsman designs his figures, and heightens them with colours, as he sees fit. When the design is finished, a workman reads it, while another lays it on the fimblo.

To read the design, is to tell the person who manages the loom, the number of squares, or threads, comprised in the space he is reading, intimating at the same time, whether it is ground or figure. To put what is read on the fimblo, is to fasten little figure-stitches to the several packthreads, which are to raise the threads named; and thus they continue to do till the whole design is read.

Every piece being composed of several repetitions of the same design, when the whole design is drawn, the drawer, to re-begin the design afresh, has nothing to do but to raise the little figure-stitches, with flip-knots, to the top of the fimblo, which he had let down to the bottom: this he is to repeat as often as is necessary till the whole be manufactured.

The ribbon-weavers have likewise a design, but far more simple than that now described. It is drawn on paper with lines and squares, representing the threads of the warp and woof. But instead of lines, whereof the figures of the former consist, these are constituted of points only, or dots, placed in certain of the little squares, formed by the intersecion of the lines. These points mark the threads of the warp that are to be raised, and the spaces left blank denote the threads that are to keep their situation: the rest is managed as in the former.
times the design is coloured, that is, colours are laid on much like those intended for the grand work.

The essential requisites of a design are correctness, good taste, elegance, character, diversity, expression, and perspective. Correctness depends on the justness of the proportions, and knowledge of anatomy. Taste is a certain manner of correctness peculiar to one's self, derived either from nature, matters, or studies, or all of them united. Elegance gives a delicacy that not only strikes persons of judgment, but communicates an agreeableness to pleases universally. The character is what is peculiar to each thing, wherein there must be diversity, inomuch that every thing has its peculiar character to distinguish it. The expression is the representation of an object, according to the circumstances it is supposed to be in. Perspective is the representation of the parts of a painting or a figure, according to the situation they are in with regard to the point of sight. The design or draught, is a part of the greatest import and extent in painting. It is acquired chiefly by genius and application, rules being of less avail here than in any other branches of the art, as colouring, &c.

The principal rules that regard design are, that novices accustom themselves to copy good originals at first sight; not to use squares in drawing, lest they dampen and confine their judgment; to design well from life, before they practise perspective; to learn to adjust the size of their figures to the visual angle, and the distance of the eye from the model or object; to mark out all the parts of their design before they begin to shade; to make their contours in great pieces, without taking notice of the little muscles, and other breaks; to make themselves masters of the rules of perspective; to observe the perpendicular, parallel, and distance of every stroke; to compare and oppose the parts that meet and traverse the perpendicular, so as to form a kind of square in the mind, which is the great and almost the only rule of designing justly; to have a regard not only to the model, but to the parts already designed, there being no such thing as designing with strict justice, but by comparing and proportioning every part to the first. All the other rules relate to perspective. See Perspective.

DESIGN, the Macedonian name of the month called by the Athenians anthesterion.

DESISE, a town of France, situated on the river Loire, fifteen miles south-east of Nevers: E. long. 3° 32', N. lat. 46° 48'.

DESPOTICAL, in general, denotes anything that is uncontrollable and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turkey, Persia, and most of the eastern governments; and even those of Europe, if we except the republics, our own, and the Swedish government.

DESPOUILLÉ, in heraldry, the whole cafe, skin, or flough of a beast, with the head, feet, tail, and all appurtenances, so that being filled and stuffed it looks like the entire creature.

DESSAW, a city of upper Saxony, in Germany, situated on the river Elbe, sixty miles north-west of Dref-

DESSERT, or Dessert, a service of fruits and sweet-meats, usually served up last to table.

DESSICCATIVE, or Desiccative, in pharmacy, an epithet applied to such topical medicines as dry up the humours flowing to a wound or ulcer.

DESTINIES, in mythology. See Parcae.

DESTINY, among philosophers and divines. See Fate.

DESTRUCTION, in general, an alteration of any thing from its natural state to one contrary to nature; whereby it is deemed the same with corruption. See Corruption.

A chemical destruction, or corruption, is nothing but a resolution of the whole naturally mixt body into its parts.

DESDURATION, in medicine, a profuse and inordinate sweat, succeeded by an eruption of pustules, called furdamina, or heat pimples.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scour the country.

DETERGENTS, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade and carry along with them such particles as they lay hold on in their passage.

DETERIORATION, the impairing or rendering a thing worse: it is just the reverse of melioration. See Melioration.

DETERMINATION, in mechanics, signifies much the same with the tendency or direction of a body in motion. See Mechanics.

DETERMINATION, among school-divines, is an act of divine power, limiting the agency of second causes, in every instance, to what the Deity predestinated concerning them. See Predestination.

DETESIVES, in pharmacy. See Detergents.

DETHMOLD, a town of Westphalia, in Germany, fifteen miles north of Paderborn: E. long. 8° 35', N. lat. 52°.

DETINUE, in law, a writ or action that lies against one who has got goods or other things delivered to him to keep, and afterwards refuses to deliver them.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination. See Chemistry.

DETRANCHE, in heraldry, a line bendwise, proceeding to compare and oppose the parts that meet and traverse the perpendicular, parallel, and distance of every stroke; to observe the perpendicular, parallel, and distance of every stroke; to compare and oppose the parts that meet and traverse the perpendicular, so as to form a kind of square in the mind, which is the great and almost the only rule of designing justly; to have a regard not only to the model, but to the parts already designed, there being no such thing as designing with strict justice, but by comparing and proportioning every part to the first. All the other rules relate to perspective. See Perspective.

DEVIL, among painters. See Devise.
DEUUUM (420) DIA

DEVIL, an evil angel, one of those celestial spirits cast down from heaven for pretending to equal himself with God. The Ethiopians paint the devil white, to be even with the Europeans who paint him black. There is no mention of the word devil in the Old Testament, but only of the word Satan and Belial: nor do we meet with it in any heathen authors, in the sense it is taken among Christians, that is, as a creature revolting from God. Their theology went no farther than to evil genii, or demons.

Some of the American idolaters have a notion of two collateral independent beings, one of whom is good, and the other evil; which last they imagine has the direction and superintendence of this earth, for which reason they chiefly worship him: whence that account of the religion of these savages give out, with some impropriety, that they worship the devil. The Chaldeans, in like manner, believed both a good principle and an evil one, which last they imagined was an enemy to mankind.

Isaiah, speaking, according to some commentators, of the fall of the devil, calls him Lucifer, from his former elevation and state of glory: but others explain this passage of Isaiah in reference to the king of Babylon, who had been precipitated from his throne and glory. The Arabians call Lucifer, Eblis, which some think is only a diminutive or corruption of the word Diabolus.

DEVIL’S BIT. See Scabrasa.

DEVINCTION, in antiquity, a kind of love-charm, described by Virgil in his eighth eclogue: it consisted in tying certain knots, and repeating a formula of words.

DEVISE, or Device, in heraldry, painting, and sculpture, any emblem used to represent a certain family, person, action, or quality; with a suitable motto, applied in a figurative sense. See Motto.

DEVISE, in law, the act whereby a person bequeaths his lands or tenements to another by his last will and testament.

DEVISES, a borough town in Wiltshire, eighteen miles south-west of Salisbury: W. long. 2° 6’, and N. lat. 51° 25’. It sends two members to parliament.

DEUNX, in Roman antiquity, eleven ounces, or 1/4 of their libra. See Libra.

DEVOLUTION, in law, a right acquired by succession from one to another.

DEVONSHIRE, a county in the west of England, bounded by the Bristol channel, on the north; by Somersetshire and Dorsetshire, on the east; by the English channel, on the south; and by Cornwall, on the west. From this county the noble family of Cavendish take the title of duke.

DEVOTION, a sincere ardent worship of the deity. See Prayer, Adoration, Worship, &c.

DEUERONOMY, a canonical book of the Old Testament, and the last of the pentateuch of Moses. See Bible.

DEUTEROPOTMI, in Grecian antiquity, a designation given to such of the Athenians as had been thought dead, and, after the celebration of the funeral rites, unexpectedly recovered. It was unlawful for the deceased to enter into the temple of the Eumenides, or to be admitted to the holy rites, till after they were purified, by being let through the lap of a woman’s gown, that they might seem to be new born.

DEUTEROSIS, the Greek name by which the Jews called their Mischnah, or second law. See Mischnah.

DEUX PONTS, a city of Germany, in the palatinate of the Rhine, sixty miles north-east of Nancy: E. long. 7° 15’, and N. lat. 49° 25’. DEW, a dense moist vapour, falling on the earth in form of a misting rain, while the sun is below the horizon. See Pneumatics.

DEW-BORN, in country affairs, a diffemper in cattle, being a swelling in the body, as much as the skin can hold, so that some beasts are in danger of bursting. This distemper proceeds from the greediness of a beast to feed, when put into a rank pasture: but commonly when the grass is full of water. In this case the beast should be hilled up and down, and made to purge well: but the proper cure is bleeding in the tail; then take a grated nutmeg, with an egg, and breaking the top of the shell, put out so much of the white as you may have room to slip the nutmeg into the shell; mix them together, and then let the all be put down the beast’s throat; that done, walk him up and down, and he will soon mend.

DEXTANTS, in Roman antiquity, ten ounces, or 1/4 of their libra. See Libra.

DEY, in matters of government, the sovereign prince of Algiers, answering to the bay of Tunis. See Bey.

DEYNSE, a town of Flanders, nine miles south-west of Ghent: E. long. 3° 30’, N. lat. 51° 15’. DEYSE, a town of Flanders, nine miles south-west of Ghent: E. long. 3° 30’, N. lat. 51° 15’. DIABETES, in physic, an excessive discharge of urine, which comes away crude, and exceeds the quantity of liquids drank. See Medicine.

DIABOLUS. See Devil.

DIABOLUS MARINUS. See Raia.

DIABOLUS METELLORUM, a title given by chemists to jupiter or tin, because, when incorporated with other metals, it renders them incapable of reduction, or at least very difficult to undergo that operation.

DIABROSIS, in medicine. See Anabrosis.

DIACARYON, in pharmacy. See Dianucum.

DIACASTIC CURVE, a species of the caulis curves formed by refraction.

DIACHYLON, in pharmacy, an emollient digestive plaster, composed of mucilages or viscous juices drawn from certain plants.

DIACODIUM, in pharmacy, a syrup prepared from poppy heads. It is also called the syrupus de meconio. As it is of consequence that all the circumstances in the directions

DIABROSIS, in medicine. See Anabrosis.
DIA (421) DIA

directions for compounding this medicine, be exactly followed, we here give the method of preparing it from the London Dispensatory. Take the heads of dried white poppies without their seeds, three pounds and a half; of water, six gallons. Slice the heads, and boil them in the water, often skirmishing them that they may not burn, till about a third only of the liquor is left, which will be almost all imbible by the poppy heads: then take all from the fire, and press the liquor strongly out from the heads; in the next place, boil the liquor by itself, to about two quarts, and strain it while hot, stril through a sieve, and then through a thin flannel: set it by for a night, that what scates have passed the strainers, may subside; next morning pour off the clear liquor, and boil it with fix pounds of double refined sugar, till the whole comes to the weight of nine pounds, or a little more, that it may become a syrup of a just consistence. This syrup partakes of all the virtues of the poppy.

DIACOUSTICS, called also diaphonics, the consideration of the properties of refracted sound, as it passes through different mediums.

DIADELPHIA, in the Linnaean system of botany. See Vol. I. p. 635.

DIADEM, in antiquity, a head-band, or fillet, worn on the body, and forehead, the ends being tied behind, and let fall of silk, thread, or wool, and tied round the temples and rims, serving to inclose the crowns of sovereign princes, and to bear the globe and cross, or the flower de luces and to administer justice without partiality.

DIAGLYPHICE, the art of cutting or engraving figures on metals, such as seals, intaglias, matrices of letters, &c. or coins for medals.

DIAGNOSTIC, in medicine, a term given to those signs which indicate the present state of a disease, its nature and cause.

DIAGONAL, in geometry, a right line drawn across a quadrilateral figure, from one angle to another, by some called the diameter, and by others the diametral figure. See Geometry.

DIAGRAM, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c. See Geometry.

DIAGRAM, among ancient musicians. See Scale.

DIAPASON, or Diapente, among farriers, a compound medicine, so called from its containing six ingredients, viz. birthwort and gentian roots, juniper-berries, bay-berries, myrrh, and ivory flavings. It is commended for colds, consumptions, purges, and many other disorders in horses.

DIAL. A dial is a plane, upon which lines are descried in such a manner, that the shadow of a wire, or of the upper edge of another plane, erected perpendicularly on the former, may shew the true time of the day.

The edge of the plane by which the time of the day is found, is called the stile of the dial, which must be parallel to the earth's axis; and the line on which the said plane is erected, is called the subtitle.

The angle included between the subtitle and stile, is called the elevation, or height of the stile.

Those dials whose planes are parallel to the plane of the horizon, are called horizontal dials; and those dials whose planes are perpendicular to the plane of the horizon, are called vertical, or erect dials.

Those erect dials, whose planes directly from the north or south, are called direct north or south dials; and all other erect dials are called decliners, because their planes are turned away from the north or south.

Those dials whose planes are neither parallel nor perpendicular to the plane of the horizon, are called inclining, or reclining dials, according as their planes make acute or obtuse angles with the horizon; and if their planes are also turned aside from facing the south or north, they are called declining-inclining, or declining-reclining dials.

The interfeclion of the plane of the dial, with that of the meridian, passing through the stile, is called the meridian of the dial, or the hour-line of XII.

Those meridians, whose planes pass through the stile, and make angles of 15, 30, 45, 60, 75, and 90 degrees with the meridian of the place (which marks the hour-line of XII.) are called hour circles; and their interfeclions with the plane of the dial are called hour-lines.

In all declining dials, the subtitle makes an angle with
with the hour line of XII; and this angle is called the
distance of the subtyle from the meridian.
The declining plane’s difference of longitude, is the
angle formed at the intersection of the plane of the
dial, by two meridians; one of which passes through
the hour-line of XII, and the other through the sub-
tyle.
This much being premised concerning dials in general,
we shall now proceed to explain the different methods
of their construction.
If the whole earth was, (Plate LXIX. fig. 1.) were it
transparent, and hollow, like a sphere of glasts, and had
its equator divided into 24 equal parts by fo many meri-
dian semicircles, a, b, c, d, e, f, g, &c. one of which is
the geographical meridian of any given place, as London
(which is supposed to be at the point a1) and if the
hours of XII were marked at the equator, both upon
that meridian and the opposite one, and all the rest of
the hours in order on the rest of the meridians, those
meridians would be the hour-circles of London: then, if
the sphere had an opaque axis, as PEp, terminating in
the poles P and p, the shadow of the axis would fall
upon every particular meridian and hour, when the sun
came to the plane of the opposite meridian, and would
consequently shine the time at London, and at all other
places on the meridian of London.
If this sphere was cut through the middle by a solid
plane ABCD, in the rational horizon of London, one
half of the axis EP would be above the plane, and the
other half below it; and if straight lines were drawn
from the centre of the plane, to those points where its
circumference is cut by the hour-circles of the sphere,
those lines would be the hour-lines of a horizontal dial
for London: for the shadow of the axis would fall up-
on each particular hour-line of the dial, when it fell upon
the like hour-circle of the sphere.
If the plane which cuts the sphere be upright, as
ACFG, fig. 2. touching the given place (London) at F,
and directly facing the meridian of London, it will then
become the plane of an erect direct south dial: and if
right lines be drawn from its center E, to those points of
its circumference where the hour-circles of the sphere
cut it, these will be the hour-lines of a vertical or direct
south dial for London, to which the hours are to be set
as in the figure (contrary to those on a horizontal dial),
and the lower half EP of the axis will cast a shadow on
the hour of the day in this dial, at the same time that it
would fall upon the like hour-circle of the sphere, if the
dial-plane was not in the way.
If the plane (still facing the meridian) be made to in-
cline, or recline, any given number of degrees, the hour-
circles of the sphere will still cut the edge of the plane in
those points to which the hour-lines must be drawn
straight from the center; and the axis of the sphere will
cast a shadow on these lines at the respective hours. The
like will still hold, if the plane be made to decline by
any given number of degrees from the meridian toward
the east or west: provided the declination be less than 90
degrees, or the reeination be less than the co-latitude of
the place: and the axis of the sphere will be a gnomon,
or stile, for the dial. But it cannot be a gnomon, when
the declination is quite 90 degrees, nor when the reeleina-
tion is equal to the co-latitude; because in these two
cases, the axis has no elevation above the plane of the
dial.
And thus it appears, that the plane of every dial repre-
sents the plane of some great circle upon the earth; and
the gnomon the earth’s axis, whether it be a small wire,
as in the above figures, or the edge of a thin plate, as in
the common horizontal dials.
The whole earth, as to its bulk, is but a point, if
compared to its distance from the sun: and therefore, if
a small sphere of glass be placed upon any part of the
earth’s surface, so that its axis be parallel to the axis
of the earth, and the sphere have such lines upon it, and
such planes within it, as above described; it will show
the hours of the day as truly as if it were placed at the
earth’s center, and the shell of the earth were as tran-
parent as glass.
But because it is impossible to have a hollow sphere of
glass perfectly true, blown round a solid plane; or if it
was, we could not get at the plane within the glass to
set the hour in any given position: we make use of a wire-sphere
for explaining the principles of dialing, by joining 24 semi-
circles together at the poles, and putting a thin flat plate
of brass within it.
A common globe, of 12 inches diameter, has generally
24 meridian semicircles drawn upon it. If such a globe
be elevated to the latitude of any given place, and turn-
ed about until one of these meridians cut the horizon in the
north point, where the hour of XII is supposed to be
marked, the rest of the meridians will cut the horizon at
the respective distances of all the other hours from XII.
Then if these points of distance be marked on the horizon,
and the globe be taken out of the horizon, and a flat
board or plate be put into its place, even with the sur-
fate of the horizon; and if straight lines be drawn from
the center of the board, to those points of distance on the
horizon, and the plane be drawn through the middle of the
same, the edge of the plane will be parallel to the axis
of a horizontal dial; for the plane of every dial represents
the plane of some great circle, and the gnomon is the
axis of the earth, and the sphere have such planes upon it,
as in the above figure, or the edge of a thin plate, as in
the common horizontal dials.
But if your globe have more than 24 meridian semi-
circles upon it, you must take the following method for
making horizontal and south dials.
Elevate the pole to the latitude of your place, and
turn the globe until any particular meridian (suppose the
first) comes to the north point of the horizon, and the
opposite meridian will cut the horizon in the south.
Then, set the hour-index to the uppermost XII on its
circle;
circle; which done, turn the globe westward until 15
degrees of the equator pafs under the brazen meridian,
and then the hour-index will be at I (for the sun
moves 15 degrees every hour) and the first meridian
will cut the horizon in the number of degrees from the
north point, that I is distant from XII. Turn on,
until other 15 degrees of the equator pafs under the brazen
meridian, and the hour-index will then be at II, and
the first meridian will cut the horizon in the number of
degrees that II is distant from XII: and so, by making
15 degrees of the equator pafs under the brazen meridian
for every hour, the first meridian of the globe will cut
the horizon in the distances of all the hours from XII to VI,
which is distant just 90 degrees; and then you need go no
farther, for the distances of XI, X, IX, VIII, VII, and VI,
in the forenoon, are the same from XII, as the distances of
I, II, III, IIII, V, and VI, in the afternoon: and
these hour-lines continued through the center, will give
the opposite hour-lines on the other half of the dial.
Thus, to make a horizontal dial for the latitude of
London, which is 51° degrees north, elevate the north
pole of the globe 51° degrees above the north point of
the horizon, and then turn the globe, until the first meri-
idian (which is that of London on the English terre-
tricial globe) cuts the north point of the horizon,
and set the hour-index to XII at noon.
Then turning the globe westward until the index points
successively to I, II, IIII, IIIII, V, and VI, in the
afternoon, or until 15, 30, 45, 60, 75, and 90 degrees of the
equator pafs under the brazen meridian, you will find
that the first meridian of the globe cuts the horizon in the
following numbers of degrees from the north towards
the east, viz. II°, 24°, 38°, 53°, 71°, and 90; which
are the respective distances of the above hours from XII
upon the plane of the horizon.
To transfer these, and the rest of the hours, to a ho-
izontal plane, draw the parallel right lines a c and d b,
(Plate LXIX. fig. 3.) upon that plane, as far from each other
as is equal to the intended thickness of the gnomon or
stile of the dial, and the space included between them
will be the meridian or twelve o'clock line on the dial.
Cross this meridian at right angles with the fix o'clock
line g h, and setting one foot of your compasses in the
intersection a, as a center, describe the quadrant g e with
any convenient radius or opening of the compasses: then,
setting one foot in the intersection b, as a center, with
the same radius describe the quadrant f i h, and divide
each quadrant into 90 equal parts or degrees, as in the
figure.
Because the hour-lines are less distant from each other
about noon, than in any other part of the dial, it is best
to have the centers of these quadrants at a little distance
from the center of the dial-plane, on the side opposite
to XII, in order to enlarge the hour-distances there-
abouts, under the same angles on the plane. Thus, the
center of the plane is at C, but the centers of the qua-
drants are at a and b.
Lay a ruler over the point b (and keeping it there for
the center of all the afternoon hours in the quadrant f i h)
and draw the hour-line of I through 11° degrees in the qua-
Drant; the hour-line of II, through 24° degrees; of
Vol. II. No. 43.
III, through 38°, degrees; IIII, through 53°; and V,
through 71°; and because the sun rises about four in
the morning, on the longest days at London, continue
the hour-lines of III and V in the afternoon through
the center b to the opposite side of the dial.—Thus done,
lay the ruler to the center a of the quadrant g e, and
through the like divisions or degrees of that quadrant,
viz. 11°, 24°, 38°, 53°, and 71°, draw the fore-
noon hour-lines of XI, X, IX, VIII, and VII; and be-
cause the sun sets not before eight in the evening on the
longest days, continue the hour-lines of VII and VIII in
the forenoon, through the center a, to VII and VIII in
the afternoon; and all the hour-lines will be finished on
this dial; to which the hours may be set, as in the
figure.
Lastly, through 51° degrees of either quadrant, and
from its center, draw the right line a g for the hypo-
themuse or axis of the gnomon a g i; and from g, let fall
the perpendicular g i, upon the meridian line a i, and
there will be a triangle made, whose sides are a g, g i,
and i a. If a plate similar to this triangle be made as
thick as the distance between the lines a c and b d, and
set upright between them, touching at a and b, its hypo-
themuse a g will be parallel to the axis of the world,
when the dial is truly set; and will cast a shadow on
the hour of the day.
N. B. The trouble of dividing the two quadrants
may be saved, if you have a scale with a line of chords
upon it, such as that on the top of Plate LXX.: for if
you extend the compasses from 0 to 60 degrees of the line
of chords, and with that extent, as a radius, describe
the two quadrants upon their respective centers, the a-
bove distances may be taken with the compasses upon the
line, and set off upon the quadrants.
To make an erect direct south dial, Plate LXIX. fig. 4.
Elevate the pole to the co-latitude of your place, and
place in all respects as above taught for the horizontal
dial, from VI in the morning to VI in the afternoon,
only the hours must be reverled, as in the figure; and
the hypotenuse a g of the gnomon a g i, must make an
angle with the dial-plane equal to the co-latitude of the
place. As the sun can shine no longer on this dial than
from six in the morning until six in the evening, there is
no occaion for having any more than twelve hours upon
it.
To make an erect dial, declining from the south to-
wards the east or west. Elevate the pole to the latitude
of your place, and screw the quadrant of altitude to the
zenith. Then, if your dial declines towards the e'ast
(which we shall suppose it to do at present) count in the
horizon the degrees of declination, from the east point to-
wards the north, and bring the lower end of the quadrant
to that degree of declination at which the reckoning ends.
This done, bring any particular meridian of your globe
(as suppose the first meridian) directly under the gradua-
ted edge of the upper part of the brazen meridian, and set
the hour-index to XII at noon. Then, keeping the qua-
drant of altitude at the degree of declination in the hori-
zon, turn the globe eastward on its axis, and observe the
degrees cut by the first meridian in the quadrant of alti-
tude (counted from the zenith) as the hour index comes
D I A  (  423  )  D I A

4 N to
Thus, we have finished our declining dial; and in so doing, we made four dials, *viz.*

1. A north dial, declining eastward by the same number of degrees. 2. A north dial, declining the same number west. 3. A south dial, declining east. And, 4, a south dial declining west. Only, placing the proper number of hours, and the slit or gnomon respectively, upon each plane. For (as above mentioned) in the south-west plane, the subtile-line falls among the afternoon hours; and in the south east, of the same declination, among the afternoon hours, at equal distances from XII. and so, in all the morning hours on the west decliner, will be like the afternoon hours on the east decliner: the south-east decliner will produce the north-west decliner; and the south-west decliner, by only extending the hour-lines, slit and subtile, quite through the center; the axis of the slit (or edge that casts the shadow on the hour of the day) being in all dials whatever parallel to the axis of the world, and consequently pointing towards the north pole of the heaven in north latitudes, and towards the south pole in south latitudes.

But because every one who would like to make a dial, may perhaps not be provided with a globe to afflict him, and may probably not understand the method of doing it by logarithmic calculation; we shall show how to perform it by the plain dialing lines, or scale of latitudes and hours; such as those on the top of Plate LXX. and which may be had on scales commonly sold by the mathematical instrument makers.

This is the easiest of all mechanical methods, and by much the best, when the lines are truly divided: and not only the half hours and quarters may be laid down by all of them, but every fifth minute by most, and every single minute by those where the line of hours is a foot in length.

Having drawn your double meridian line $ab$, $cd$, (Plate LXIX. fig. 5.) on the plane intended for a horizontal dial, and crossed it at right angles by the fix o'clock line $fe$ (as in fig. 5.) take the latitude of your place with the compasses, in the scale of latitudes, and set that extent from $c$ to $e$, and from $a$ to $f$, on the fix o'clock line: then, taking the whole six hours between the points of the compasses in the scale of hours, with that extent set one foot in the point $c$, and let the other foot fall where it will upon the meridian line $cd$, as at $d$. Do the same from $f$ to $b$, and draw the right lines $ed$ and $fb$, each of which will be equal in length to the whole scale of hours. This done, let one foot of the compasses in the beginning of the scale at XII, and extending the other to each hour on the scale, lay off these extents from $d$ to $e$ for the afternoon hours, and from $b$ to $f$ for those of the forenoon: this will divide the lines $de$ and $bf$ in the same manner as the hour-scale is divided at 1, 2, 3, 4, and 6; on which the quarters may also be laid down, if required. Then, laying a ruler on the point $c$, draw the first five hours in the afternoon, from that point, through the dots at the numerical figures 1, 2, 3, 4, and 5; on the line $de$; and continue the lines of IIII and V through the center $c$ to the other side of the dial, for the like hours of the morning: which done, lay the ruler on the point $a$, and draw the last five hours in the forenoon through the dots 5, 4, 3, 2.
2, 1, on the line \( f b \); continuing the hour-lines of VII and VIII through the center \( a \) to the other side of the dial, for the like hours of the evening; and set the hours to their respective lines, as in the figure. Lastly, make the gnomon the same way as taught above for the horizontal dial, and the whole will be finished.

To make an erect south dial, take the co-latitude of your place from the scale of latitudes, and then proceed in all respects for the hour-lines, as in the horizontal dial; only reverting the hours, as in fig. 4, and making the angle of the stile's height equal to the co-latitude.

But let the young dialist should have neither globe nor wooden scale, we shall now shew him how he may make a dial without any of these helps. Only, if he has not a line of chords, he must divide a quadrant into 90 equal parts or degrees for taking the proper angle of the stile's elevation; which is easily done.

With any opening of the compasses, as \( Z L \), describe the two semicircles \( LFk \) and \( LQk \), upon the centers \( Z \) and \( x \), where the fix o'clock line crosses the double meridian line, and divide each semicircle into 12 equal parts, beginning at \( L \) (though, strictly speaking, only the quadrants from \( L \) to the fix o'clock line need be divided); then connect the divisions which are equidistant from \( L \), by the parallel lines \( K M, IN, HO, GP \), and \( FQ \). Draw \( VZ \) for the hypotenuse of the stile, making the angle \( VZE \) equal to the latitude of your place; and continue the line \( VZ \) to \( R \). Draw the line \( RR \) parallel to the fix o'clock line, and set off the distance \( aK \) from \( Z \) to \( T \), the distance \( bL \) from \( Z \) to \( X \), \( cH \) from \( Z \) to \( W \), \( dG \) from \( Z \) to \( T \), and \( eF \) from \( Z \) to \( S \). Then draw the lines \( Ss, Tt, Ww, Xx, \) and \( Yy \), each parallel to \( RR \). Set off the distance \( YX \) from \( a \) to \( 11 \), and from \( f \) to \( 10 \); the distance \( XX \) from \( b \) to \( 10 \), and from \( g \) to \( 2 \); \( wW \) from \( e \) to \( 9 \), and from \( h \) to \( 3 \); \( IT \) from \( d \) to \( 8 \), and from \( i \) to \( 4 \); \( S \) from \( e \) to \( 7 \), and from \( n \) to \( 5 \). Then laying a ruler to the center \( Z \), draw the forenoon hour-lines through the points \( 11, 10, 9, 8 \); and laying it to the center \( Z \), draw the afternoon lines through the points \( 1, 2, 3, 4, 5 \); continuing the forenoon lines of VII and VIII through the center \( Z \), to the opposite side of the dial, for the like afternoon hours; and the afternoon lines IIII and V through the center \( Z \), to the opposite side, for the like morning hours. Set the hours to these lines as in the figure, and then erect the stile or gnomon, and the horizontal dial will be finished.

To construct a south dial, draw the line \( VZ \), making an angle with the meridian \( Z L \) equal to the co-latitude of your place; and proceed in all respects as in the above horizontal dial for the same latitude, reverting the hours as in fig. 4, and making the elevation of the gnomon equal to the co-latitude.

Perhaps it may not be unacceptable to explain the method of constructing the dialing lines, and some others; which is as follows.

With any opening of the compasses, (Plate LXX. fig. 1.) as \( E A \), according to the intended length of the scale, describe the circle \( ADCB \), and cross it at right angles by the diameters \( CE \) and \( DE \). Divide the quadrant \( AB \) into 9 equal parts, and then each part into 10; so shall the quadrant be divided into 90 equal parts or degrees. Draw the right line \( AFB \) for the chord of this quadrant, and setting one foot of the compasses in the point \( A \), extend the other to the several divisions of the quadrant, and transfer these divisions to the line \( AFB \) by the arcs 10, 10, 20, 20, &c., and this will be a line of chords, divided into 90 unequal parts; which, if transferred from the line back again to the quadrant, will divide it equally. It is plain by the figure, that the distance from \( A \) to \( 60 \) in the line of chords, is just equal to \( AE \), the radius of the circle from which that line is made; for if the arc \( 60, 60 \) be continued, of which \( A \) is the center, it goes exactly through the center \( E \) of the arc \( AB \).

And therefore, in laying down any number of degrees on a circle, by the line of chords, you must first open the compasses so, as to take in just 60 degrees upon that line, as from \( A \) to \( 60 \); and then, with that extent, as a radius, describe a circle, which will be exactly of the same size with that from which the line was divided: which done, set one foot of the compasses in the beginning of the chord line, as at \( A \), and extend the other to the number of degrees you want upon the line; which extent, applied to the circle, will include the like number of degrees upon it.

Divide the quadrant \( CD \) into 90 equal parts, and from each point of division draw right lines, as \( i, k, l, &c. \) to the line \( CE \); all perpendicular to that line, and parallel to \( DE \), which will divide \( EC \) into a line of lines; and although these are seldom put among the dialing lines on a scale, yet they assist in drawing the line of latitudes. For if a ruler be laid upon the point \( D \), and over each division in the line of lines, it will divide the quadrant \( CB \) into 90 unequal parts, as \( Ba, Bb, &c. \), shown by the right lines 10a, 20b, 30c, &c. drawn along the edge of the ruler. If the right line \( BC \) be drawn, subtending this quadrant, and the nearest divisions \( Ba, Bb, Bc. &c. \) be taken in the compasses from \( B \), and set upon this line in the same manner as directed for the line of chords, it will make a line of latitudes \( BC \), equal in length to the line of chords \( AB \), and of an equal number of divisions, but very unequal as to their lengths.

Draw the right line \( DCA \), subtending the quadrant \( DA \); and parallel to it, draw the right line \( rs \), touching the quadrant \( DA \) at the numeral figure 3. Divide this quadrant into six equal parts, as \( i, 2, 3, &c. \) and through these points of division draw right lines from the centre \( E \) to the line \( rs \), which will divide it at the points where the six hours are to be placed, as in the figure. If every sixth part of the quadrant be subdivided into four equal parts, right lines drawn from the centre through these points of division, and continued to the line \( rs \), will divide each hour upon it into quarters.

In Fig. 2. Plate LXX. we have the representation of a portable dial, which may be easily drawn on a card, and carried in a pocket-book. The lines \( ad, ab, \) and \( bc \) of the gnomon must be cut quite through the card; and as the end \( a b \) of the gnomon is raised occasionally above the plane of the dial, it turns upon the uncut line \( cd \) as on a hinge. The line dotted \( AB \) must be fit quite through the card, and the thread \( G \) must be put through the slot, and have a knot tied behind, to keep it from being easily drawn out. On the other end of this thread
thread is a small plummet $D$, and on the middle of it a small bead for shewing the hour of the day.

To rectify this dial, set the thread in the slit right against the day of the month, and stretch the thread from the day of the month over the angular point where the curve-lines meet at XII; then shift the bead to that point on the thread, and the dial will be rectified.

To find the thread in the day of the month, raise the gnomon (no matter how much or how little) and hold the edge of the dial next the gnomon towards the sun, so as the uppermost edge of the shadow of the gnomon may just cover the shadow-line; and the bead then playing, freely on the face of the dial, by the weight of the plummet, will shew the time of the day among the hour-lines, as it is forenoon or afternoon.

To find the time of sun-rising and setting, move the thread among the hour-lines, until it either covers some one of them, or lies parallel between any two; and then it will cut the time of sun-rising among the forenoon hours; and of sun-setting among the afternoon hours, for that day of the year to which the thread is set in the scale of months.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII, and it will cut the sun's declination, as it is north or south, for that day, in the proper scale.

To find on what days the sun enters the signs: when the bead, as above rectified, moves along any of the curve-lines which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

The construction of this dial is very easy, especially if the reader compares it all along with fig. 3, as he reads the following explanation of that figure.

Draw the occult line, (Plate LXX. fig. 9.) $AB$ parallel to the top of the card, and cross it at right angles with the fix o'clock line $ECD$; then upon $C$, as a centre, with the radius $CA$, describe the semicircle $AEL$, and divide it into 12 equal parts (beginning at $A$) as $Ar$, $As$, &c. and from these points of division draw the hour-lines $r, s, t, u, v, E, w, x$, all parallel to the fix o'clock line $E$. If each part of the semicircle be subdivided into four equal parts, they will give the half-hour lines and quarters, as in fig. 2. Draw the right-line $ASDo$, making the angle $SAB$ equal to the latitude of your place. Upon the centre $A$ describe the arch $RST$, and set off upon it the arcs $SR$ and $ST$, each equal to $23\frac{1}{2}$ degrees, for the sun's greatest declination; and divide them into $23\frac{1}{2}$ equal parts, as in fig. 2. Through the intersection $D$ of the lines $ECD$ and $ADo$, draw the right line $FDG$ at right angles to $ADo$. Lay a ruler to the points $A$ and $R$, and draw the line $ARF$ through $23\frac{1}{2}$ degrees of south declination in the arc $SR$; and then laying the ruler to the points $A$ and $T$, draw the line $ATG$ through $23\frac{1}{2}$ degrees of north declination in the arc $ST$: so shall the lines $ARF$ and $ATG$ cut the line $FDG$ in the proper length for the scale of months. Upon the centre $D$, with the radius $DE$, describe the semicircle $FGC$; which divide into six equal parts, $Fm$, $m\,n$, $n\,q$, &c. and from these points of division draw the right lines $mh$, $ni$, $pk$, and $ql$, each parallel to $OD$. Then setting one foot of the compasses in the point $F$, extend the other to $A$, and describe the arc $A\,z\,H$ for the tropic of $\varphi$; with the same extent, setting one foot in $G$, describe the arc $A\,e\,D$ for the tropic of $\varphi$. Next setting one foot in the point $b$, and extending the other to $A$, describe the arc $AGl$ for the beginnings of the signs $\alpha$ and $\beta$; and with the same extent, setting one foot in the point $i$, describe the arc $AN$ for the beginnings of the signs $\Pi$ and $\Omega$. Set one foot in the point $i$, and having extended the other to $A$, describe the arc $AK$ for the beginnings of the signs $\chi$ and $\pi$; and with the same extent, set on foot in $A$, and describe the arc $HM$ for the beginnings of the signs $\chi$ and $\pi$. Then setting one foot in the point $D$, and extending the other to $A$, describe the curve $AM$ for the beginnings of $\gamma$ and $\alpha$; and the signs will be finished. This done, lay a ruler from the point $A$ over the sun's declination in the arch $RST$; and where the ruler cuts the line $FDG$, make marks; and place the days of the months right against these marks, in the manner shewn by fig. 2. Lastly, draw the shadow-line $BP$ parallel to the arc-line $AB$; make the gnomon, and set the hours to their respective lines, as in fig. 2, and the dial will be finished.

There are several kinds of dials, which are called universal, because they serve for all latitudes. Of these, the belt is Mr. Pardié's, (Plate LXX. fig. 4.) which consists of three principal parts; the first of which is called the horizontal plane ($A$), because in practice it must be parallel to the horizon. In this plane is fixed an upright pin, which enters into the edge of the second part $BD$, called the meridional plane; which is made of two pieces, the lowest whereof ($B$) is called the quadrant, because it contains a quarter of a circle, divided into 90 degrees; and it is only into this part, near $B$, that the pin enters. The other piece is a semicircle ($D$) adjusted to the quadrant, and turning in it by a groove, for raising or depressing the diameter ($EF$) of the semicircle, which diameter is called the axis of the instrument. The third piece is a circle ($C$), divided on both sides into 24 equal parts, which are the hours. This circle is put upon the meridional plane so, that the axis ($EF$) may be perpendicular to the circle, and the point $C$ be the common centre of the circle, semicircle, and quadrant.

The straight edge of the semicircle is chamfered on both sides to a sharp edge, which passes through the centre of the circle. On one side of the chamfered part, the first six months of the year are laid down, according to the sun's declination for their respective days, and on the other side the last six months. And against the days on which the sun enters the signs, there are straight lines drawn upon the semicircle, with the characters of the signs marked upon them. There is a black line drawn along the middle of the upright edge of the quadrant, over which hangs a thread ($H$), with its plummet ($I$), for levelling the instrument. N. B. From the twenty-third of September to the twentieth of March, the upper surface of the circle must touch both the centre $C$ of the semicircle, and the line of $\gamma$ and $\alpha$; and from the twentieth of March to the twenty-third of September, the lower surface of the circle must touch that centre and line.
To find the time of the day by this dial. Having set it on a level place in sun-shine, and adjusted it by the leveling screws \( k \) and \( l \), until the plumb-line hangs over the black line upon the edge of the quadrant, and parallel to the said edge; move the semicircle in the quadrant; then turn the whole meridional plane \( BD \), with its circle \( G \), upon the horizontal plane \( A \), until the edge of the shadow of the circle falls precisely on the day of the month in the semicircle; and then, the meridional plane will be due north and south, the axis \( EF \) will be parallel to the axis of the world, and will cast a shadow upon the true time of the day, among the hours on the circle.

\[ N. B. \text{ As, when the instrument is thus rectified, the quadrant and semicircle are in the plane of the meridian, so the circle is then in the plane of the equinoctial.} \]

Therefore, as the sun is above the equinoctial in summer (in northern latitudes) and below it in winter; the axis of the semicircle will cast a shadow on the hour of the day, on the upper surface of the circle, from the twenty-first of March to the twenty-third of September; and from the twenty-third of September to the twentieth of March, the hour of the day will be determined by the shadow of the semicircle, upon the lower surface of the circle. In the former case, the shadow of the circle falls upon the day of the month, on the lower part of the diameter of the semicircle; and in the latter case, on the upper part.

The method of laying down the months and signs upon the semicircle is as follows. Draw the right line \( ACB \), equal to the diameter of the semicircle \( ADB \), and crofs it in the middle at right angles with the line \( EGD \), equal in length to \( ADB \); then \( EC \) will be the radius of the circle \( FCG \), which is the same as that of the semicircle. Upon \( E \), as a centre, describe the circle \( FCG \), on which set off the arcs \( CB \) and \( CI \), each equal to 23\(^\circ\) degrees, and divide them accordingly into that number, for the sun's declination.

Then, laying the edge of a ruler over the centre \( E \), and also over the sun's declination for every fifth day of each month (as in the card-dial) mark the points on the diameter \( AB \) of the semicircle from \( a \) to \( g \), which are cut by the ruler; and there place the days of the months accordingly, answering to the sun's declination. This done, setting one foot of the compasses in \( C \), and extending the other to \( a \) or \( g \), describe the semicircles \( abcd \) \( efg \); which divide into six equal parts, and through the points of division draw right lines, parallel to \( CD \), for the beginning of the lines (of which one half are on one side of the semicircle, and the other half on the other) and set the characters of the signs to their proper lines, as in the figure.

Having shown how to make fun-dials by the assistance of a good globe, or of a dialing-scale, we shall now proceed to the method of constructing dials arithmetically; which will be more agreeable to those who have learned the elements of trigonometry, because globes and scales can never be so accurate as the logarithms in finding the angular distances of the hours. Yet, as a globe may be found exact enough for some other requisites in dialing, we shall take it in occasionally.

The construction of sun-dials on all planes whatever, may be included in one general rule: intelligible, if that of a horizontal dial for any given latitude be well understood. For there is no plane, however obliquely situated with respect to any given place, but what is parallel to the horizon of some other place; and therefore, if we can find that other place by a problem on the terrestrial globe, or by a trigonometrical calculation, and construct a horizontal dial for it; that dial, applied to the plane where it is to serve, will be a true dial for that place.—Thus, an erect direct south dial in 51\(^\circ\) degrees north latitude, would be a horizontal dial on the same meridian, 90 degrees southward of 51\(^\circ\) degrees north latitude; which falls in with 38\(^\circ\) degrees of south latitude. But if the upright plane declines from facing the south at the given place, it would still be a horizontal plane 90 degrees from that place, but for a different longitude, which would alter the reckoning of the hours accordingly.

**CASE I.**

1. **Let us suppose** that an upright plane at London declines 36 degrees westward from facing the south; and that it is required to find a place on the globe, to whose horizon the said plane is parallel; and also the difference of longitude between London and that place.

Rectify the globe to the latitude of London, and bring London to the zenith under the brazen meridian, then that point of the globe which lies in the horizon at the given degree of inclination (counted westward from the south point of the horizon) is the place at which the above-mentioned plane would be horizontal.——Now, to find the latitude and longitude of that place, keep your eye upon the place, and turn the globe eastward, until it comes under the graduated edge of the brazen meridian, then, the degrees of the brazen meridian that stands directly over the place, is its latitude; and the number of degrees in the equator, which are intercepted between the meridian of London and the brazen meridian, is the place's difference of longitude.

Thus, as the latitude of London is 51\(^\circ\) degrees north, and the declination of the place is 36 degrees west; elevate the north pole 51\(^\circ\) degrees above the horizon, and turn the globe until London comes to the zenith, or under the graduated edge of the meridian; then count 36 degrees on the horizon westward from the south point, and make a mark on that place of the globe over which the reckoning ends, and bringing the mark under the graduated edge of the brazen meridian, it will be found to be under 30\(^\circ\) degrees in south latitude: keeping it there, count in the equator the number of degrees between the meridian of London and the brazen meridian (which now becomes the meridian of the required place) and you will find it to be 42\(^\circ\). Therefore an upright plane at London, declining 36 degrees westward from the south, would be a horizontal plane at that place. whose latitude is 30\(^\circ\) degrees south of the equator, and longitude 42\(^\circ\) degrees west of the meridian of London.
DIA

Which difference of longitude being converted into
time, is 2 hours 51 minutes.

The vertical dial declining westward 36 degrees at
London, is therefore to be drawn in all respects as a
horizontal dial for south latitude 30 degrees; save only,
that the reckoning of the hours is to anticipate the
reckoning on the horizontal dial, by 2 hours 51 minutes:
for so much sooner will the sun come to the meridian
of London, than to the meridian of any place whose lon-
gitude is 42 degrees west from London.

2. But to be more exact than the globe will shew us,
we shall use a little trigonometry.

Let N E S W (Plate LXX. fig. 6.) be the horizon of
London, whose zenith is Z, and P the north pole of
the sphere; and let Z b be the position of a vertical plane
at Z, declining westward from S (the south) by an angle
of 36 degrees; on which plane an erect dial for London
at Z is to be described. Make the semidiameter Z D
perpendicular to Z b, and it will cut the horizon in D,
36 degrees west of the south S. Then a plane, in the
tangent H D, touching the sphere in D, will be parallel
to the plane Z b; and the axis of the sphere will be
equally inclined to both these planes.

Let W Q E be the equinoctial, whose elevation above
the horizon of Z (London) is 38 degrees; and PRD
be the meridian of the place D, cutting the equinoctial
in R. Then it is evident, that the arc RD is the lati-
tude of the place D (where the plane Z b would be ho-
izontal) and the arc R Q is the difference of longitude
of the planes Z b and D H.

In the spherical triangle W D R, the arc WD is given,
for it is the complement of the plane's declination from S
to south; which complement is 54 degrees (viz. 90 degrees
— 36 degrees); the angle at R, in which the meridian of the place D
cuts the equator, is a right angle; and the angle RWD
measures the elevation of the equinoctial above the hori-
zon of Z, namely, 38 degrees. Say therefore, as ra-
dius is to the co-fine of the plane's declination from the
south, so is the co-fine of the latitude of Z to the sine of RD
the latitude of D; which is of a different denomination
from the latitude of Z, because Z and D are on different
fides of the equator.

As radius — — — — — 10.00000
To co-fine 36° 0 = R Q 9.90796
So co-fine 51° 30' = R Q 9.79415

To fine 30° 14' = DR (9.70211) = the lat. of D,
whose horizon is parallel to the vertical plane Z b at Z.

N. B. When radius is made the first term, it may be
omitted, and then, by subtracting it mentally from the
sum of the other two, the operation will be shortened.
Thus, in the present case,
To the logarithmic fine of WR = * 54° 0' 9.90796
Add the logarithmic fine of RD = † 36° 30' 9.79415

Their sum — radius 10.13874

* The co-fine of 36° 0, or of R Q.
† The co-fine of 51° 30', or of R Q.

give the same solution as above. And we shall keep to
this method in the following part of this article.

To find the difference of longitude of the places D
and Z, say, as radius is to the co-fine of 38 degrees,
the height of the equinoctial at Z, so is the co-tangent
of 36 degrees, the plane's declination, to the co tangent
of the difference of longitudes. Thus,
To the logarithmic fine of * 51° 30' 9.89354
Add the logarithmic tang of † 54° 0' 10.13874

Their sum — radius 10.01328

This is the nearest tangent of 47° 8' = WR; which is the
co-tangent of 42° 52' = R Q, the difference of lon-
gitude sought. Which difference, being reduced to time,
is two hours 51 minutes.

3. And thus having found the exact latitude and lon-
gitude of the place D, to whose horizon the vertical plane
at Z is parallel, we shall proceed to the construction
of a horizontal dial for the place D, whose latitude is
30° 14' south; but anticipating the time at D by 2 hours
51 minutes (neglecting the 4 minute in practice) because
D is so far westward in longitude from the meridian
of London; and this will be a true vertical dial at London,
declining westward 36 degrees.

Assume any right line CSL, (Plate LXX. fig. 7.) for the
subtile of the dial, and make the angle KCP equal to the
latitude of the place (viz. 30° 14') To whose hori-
zone the plane of the dial is parallel; then CRP will be
the axis of the fiddle, or edge that casts the shadow on the
hours of the day, in the dial. This done, draw the con-
tingent line EQ, cutting the subtilar line at right angles
in K; and from K make KR perpendicular to the axis
CRP. Then KG (= KR) being made radius, that is,
equal to the chord of 60° or tangent of 45° on a good
fector, take 42° 52' (the difference of longitude of the
places Z and D) from the tangents, and having set
it from K to M, draw CM for the hour-line of XII.
Take KN, equal to the tangent of an angle less by 15
degrees than A/IZ; that is, the tangent 27° 52'; and
this set off from K towards £9 on the

* The co-fine of 38° 30', or of WR.
† The co-tangent of 36° 0, or of DW.
In all erect dials, $CM$, the hour-line of XII, is perpendicular to the horizon of the place for which the dial is to serve: for that line is the intersection of a vertical plane with the plane of the meridian of the place, both which are perpendicular to the plane of the horizon: and any line $HO$, or $h_5$, perpendicular to $CM$, will be a horizontal line on the plane of the dial, along which line the hours may be numbered; and $CM$ being let perpendicular to the horizon, the dial will have its true position.

If the plane of the dial had declined by an equal angle toward the east, its description would have differed only in this, that the hour-line of XII would have fallen on the other side of the subtile line $CL$, and the line $HO$ would have had a subcontrary position to what it has in this figure.

And these two dials, with the upper points of their stiles turned toward the north pole, will serve for other two planes parallel to them; the one declining from the north toward the east, and the other from the north toward the west, by the same quantity of angle. The like holds true of all dials in general, whatever be their declination and obliquity of their planes to the horizon.

CASE II.

If the plane of the dial not only declines, but also reclines, or inclines. Suppose its declination from fronting the south $S$ (Plate LXXXI, fig. 1.) equal to the arc $SD$ on the horizon; and its inclination equal to the arc $DD$ on the vertical circle $DZ$: then it is plain, that if the quadrant of altitude $ZD$ on the globe cuts the point $D$ in the horizon, and the inclination is counted upon the quadrant from $D$ to $d$; the intersection of the hour circle $Pd$, with the equinoctial $WdE$, will determine $Rd$, the latitude of the place $d$, whose horizon is parallel to the given plane at $Z$; and $RQ$ will be the difference in longitude of the planes at $d$ and $Z$.

Trigonometrically thus: let a great circle pass through the three points $N$, $d$, $E$; and in the triangle $WDd$, right-angled at $D$, the sides $WD$ and $DD$ are given; and thence the angle $DdW$ is found, and so is the hypotenuse $Wd$. Again, the difference, or the sum, of $DdW$ and $DWR$, the elevation of the equinoctial above the horizon of $Z$, gives the angle $dWR$; and the hypotenuse of the triangle $WRd$ was just now found; whence the sides $Rd$ and $WR$ are found, the former being the latitude of the place $d$, and the latter the complement of $RQ$, the difference of longitude sought.

Thus, if the latitude of the place $Z$ be $52^\circ 10'$ north; the declination $SD$ of the plane $Zd$ (which would be horizontal at $d$) be $30^\circ$, and the inclination be $15^\circ$, or equal to the arc $DD$; the fourth latitude of the place $d$, that is, the arc $Rd$, will be $15^\circ 9'$; and $RQ$, the difference of longitude, $36^\circ 2'$. From these data, therefore, let the dial (fig. 2.) be described, as in the former example.

There are several other things requisite in the practice of dialing; the chief of which shall be given in the form of arithmetical rules, simple and easy to those who have learned the elements of trigonometry. For in practical arts of this kind, arithmetick should be used as far as it can go; and scales never trufted to, except in the final construction, where they are absolutely necessary in laying down the calculated hour-distances on the plain of the dial.

**Rule I. To find the angles which the hour-lines on any dial make with the subtile.**

To the logarithmic sine of the given latitude, or of the file's elevation above the plane of the dial, add the logarithmic tangent of the hour *st* distance from the meridian, or from the + subtile; and the sum minus radius will be the logarithmic tangent of the angle sought.

For, in fig. 7. Plate LXXX. $KC$ is to $KM$ in the ratio compounded of the ratio of $KC$ to $KG$ ($=KR$) and of $KG$ to $KM$; which, making $CK$ the radius 10,000,000, or 10,000, or 10, or 1, are the ratio of 10,000,000, or of 10,000, or of 10, or of 1, to $KG \times KM$.

Thus, in a horizontal dial, for latitude $51^\circ 30'$, to find the angular distance of XI in the forenoon, or I in the afternoon, from XII.

To the logarithmic sine of $51^\circ 30'$ = 9.89354, Add the logarithmic tang. of $15^\circ 0'$ = 0.94255

The sum — radius is = 9.32159 = the logarithmic tangent of $11^\circ 50'$, or of the angle which the hour-line of XI or I makes with the hour of XII.

And by computing in this manner, with the sine of the latitude, and the tangents of $30, 45, 60$, and $75^\circ$, for the hours of II, III, IIII, and V in the afternoon or of X, IX, VIII, and VII in the forenoon; you will find their angular distances from XII to be $24^\circ 18', 38^\circ 3', 53^\circ 35'$ and $71^\circ 6'$; which are all that there is occasion to compute for. — And these distances may be set off from XII by a line of chords; or rather, by taking 1000 from a scale of equal parts, and setting that extent as a radius from $C$ to XII; and then, taking 200 of the same parts (which, in the tables, are the natural logarithmic tangent of the hour sought.

To the logarithmic sine of the given latitude, or of the file's elevation above the plane of the dial, add the logarithmic tangent of the hour $st$ distance from the meridian, or from the + subtile; and the sum minus radius will be the logarithmic tangent of the angle sought.

Thus, in a horizontal dial, for latitude $51^\circ 30'$, to find the angular distance of XI in the forenoon, or I in the afternoon, from XII.

To the logarithmic sine of $51^\circ 30'$ = 9.89354, Add the logarithmic tang. of $15^\circ 0'$ = 0.94255

The sum — radius is = 9.32159 = the logarithmic tangent of $11^\circ 50'$, or of the angle which the hour-line of XI or I makes with the hour of XII.

And by computing in this manner, with the sine of the latitude, and the tangents of $30, 45, 60$, and $75^\circ$, for the hours of II, III, IIII, and V in the afternoon or of X, IX, VIII, and VII in the forenoon; you will find their angular distances from XII to be $24^\circ 18', 38^\circ 3', 53^\circ 35'$ and $71^\circ 6'$; which are all that there is occasion to compute for. — And these distances may be set off from XII by a line of chords; or rather, by taking 1000 from a scale of equal parts, and setting that extent as a radius from $C$ to XII; and then, taking 200 of the same parts (which, in the tables, are the natural tangent of $11^\circ 50'$) and setting them from XII to XI and to I, on the line $h_5$, which is perpendicular to $CXII$; and so for the rest of the hour-lines, which, in the table of natural tangents, against the above distances, are $45^1$, $782, 1355$, and $2920$, of such equal parts from XII, as the radius $C$ XII contains 1000. And lastly, set off $1257$ (the natural tangent of $51^\circ 30'$) for the angle of the file's height, which is equal to the latitude of the place.

**Rule II. The latitude of the place, the sun's declination, and his hour-distance from the meridian, being given; to find (1.) his altitude; (2.) his azimuth.**

1. Let
1. Let \( d \) (Plate LXXI. fig. 1.) be the sun's place, \( dR \), his declination; and in the triangle \( Pzd \), \( Pd \) the sun, or the difference, of \( dR \), and the quadrant \( PR \), being given by the supposition, as also the complement of the latitude \( PZ \), and the angle \( dPz \), which measures the hourly distance of \( d \) from the meridian; we shall (by Cale's, of Keil's oblique spherical Trigonometry) find the base \( Zd \), which is the sun's distance from the zenith, or the complement of his altitude.

And (2.) As fine \( Zd \): fine \( Pd \) :: \( dPz \): : \( ZP \), or of its supplement \( DzS \), the azimuthal distance from the fourth.

Or, the practical rule may be as follows.

Write \( A \) for the sign of the sun's altitude, \( L \) and \( d \) for the sine and co-sine of the latitude, \( D \) and \( d \) for the sine and co-sine of the sun's declination, and \( H \) for the sine of the hourly distance from VI.

Then, the relation of \( H \) to \( A \) will have three varieties.

1. When the declination is toward the elevated pole, and the hour of the day is between XII and VI; it is

\[ A = LD + Hl \]

2. When the hour is after VI, it is

\[ A = LD - Hl \]

3. When the declination is toward the depressed pole, we have

\[ A = Hl - LD \]

Which theorems will be found useful, and expedient enough for solving those problems in geography and dialling, which depend on the relation of the sun's altitude to the hour of the day.

**Example I.**

Suppose the latitude of the place to be 51\( \frac{1}{2} \) degrees north: the five hours distant from XII, that is, an hour after VI in the morning, or before VI in the evening; and the sun's declination 20\( \circ \) north. Required the sun's altitude?

Then to log. \( L = \) log. sin. 51\( \circ \) 30' 1.89354*

add log. \( D = \) log. sin. 20\( \circ \) 90 1.52409

Their sum 1.42769 gives

\( LD = \) logarithm of 0.267664, in the natural lines.

And, to log. \( H = \) log. sin. 15\( \circ \) 90 1.41300

Add \( \frac{1}{2} \) log. \( d = \) log. sin. 38\( \circ \) 90 1.79415

Add \( \frac{1}{2} \) log. \( d = \) log. sin. 70\( \circ \) 90 1.97300

Their sum 1.18015 gives

\( Hl = \) logarithm of 0.151408, in the natural lines.

And these two numbers (0.267664 and 0.151408) make 0.419072 = \( A \), which, in the table, is the nearest natural line of 24\( \circ \) 47', the sun's altitude sought.

The same hour-distance being assumed on the other side of VI, then \( LD - Hl = 0.116256 \), the sine of 60\( \circ \), which is the sun's altitude at V in the morning, or VII in the evening, when his north declination is 20\( \circ \).

But when the declination is 20\( \circ \) south (or towards the depressed pole) the difference \( Hl - LD \) becomes negative, and thereby shews that, an hour before VI in the morning, or past VI in the evening, the sun's center is 60\( \circ \) 40\( \frac{1}{2} \) below the horizon.

**Example II.**

From the same data to find the sun's azimuth.

If \( H \), \( L \) and \( D \) are given, then (by par. 3. of Rule II.) from \( H \) having found the altitude and its complement \( Zd \); and the arc \( Pd \) (the distance from the pole) being given; say, As the co-sine of the altitude is to the sine of the distance from the pole, so is the sine of the hour-distance from the meridian to the sine of the azimuth distance from the meridian.

Let the latitude be 51\( \circ \) 30' north, the declination 15\( \circ \) south, and the time II h. 24. m. in the afternoon, when the sun begins to illuminate a vertical wall, and it is required to find the position of the wall.

Then, by the foregoing theorems, the complement of the altitude will be 85\( \circ \) 30' north, and the time II h. 24. m. in the afternoon, when the sun begins to illuminate a vertical wall, and it is required to find the position of the wall.

This praxis is of singular use on many occasions; in finding the declination of vertical planes more exactly than in the common way, especially if the tranits of the sun's center is observed by applying a ruler with sights, either plain or telescopic, to the wall or plane, whose declination is required.—In finding the bearings of places in terrestrial surveys; the tranits of the sun over any place, or his horizontal distance from it being observed, together with the altitude and hour.—And thence determining small differences of longitude.—In observing the variation at sea, &c.

Of the double horizontal dials, and the Babylonian and Italian dials.

To the gnomonic projection, there is sometimes added a stereographic projection of the hour-circles, and the parallels of the sun's declination, on the same horizontal plane; the upright side of the gnomon being sloped into an edge, standing perpendicularly over the center of the projection: so that the dial, being in its due position, the shadow

---

* Here we consider the radius as unity, and not 10,00000, by which, instead of the index 9, we have 1, as above; which is of no farther use, than making the work a little easier.

† The distance of one hour from VI.

* The co-declination of the sun.
shadow of that perpendicular edge is a vertical circle passing through the sun, in the stereographic projection.

The months being duly marked on this dial, the sun's declination, and the length of the day at any time, are had by inspection (as also his altitude, by means of a scale of tangents.) But its chief property is, that it may be placed true, whenever the sun shines, without the help of any other instrument.

Let $d$ (Plate LXXI. fig. 1.) be the sun's place in the stereographic projection, $x y z$ the parallel of the sun's declination. $Z d$ a vertical circle through the sun's center, $P d$ the hour-circle; and it is evident, that the diameter $NS$ of this projection being placed duly north and south, these three circles will pass through the point $d$. And therefore, to give the dial its due position, we have only to turn its gnomon toward the sun, on a horizontal plane, until the hour on the common gnomonic projection coincides with that marked by the hour-circle $P d$, which passes through the intersection of the shadow $Z d$ with the circle of the sun's present declination.

The Babylonian and Italian dials reckon the hours, not from the meridian, as with us, but from the sun's rising and setting. Thus, in Italy, an hour before sun-set is reckoned the 23rd hour; two hours before sun-set, the 22nd hour; and so of the rest. And the shadow that marks them on the hour-lines, is that of the point of a file. This occasions a perpetual variation between their dials and clocks, which they must correct from time to time, before it arises to any sensible quantity, by letting their clocks so much faster or slower. And in Italy, they begin their day, and regulate their clocks, not from sun-set, but from about mid-twilight, when the Ave Maria is said; which corrects the difference that would otherwise be between the clock and the dial.

The improvements which have been made in all sorts of instruments and machines for measuring time, have rendered such dials of little account. Yet, as the theory of them is ingenious, and they are really, in some respects, the best contrived of any for vulgar use, a general idea of their description may not be unacceptable.

Let fig. 5. represent an erect south wall, on which a Babylonian dial is to be drawn, shewing the hours from sun-rising; the latitude of the place, whole horizon is parallel to the wall, being equal to the angle $KCR$. Make, as for a common dial, $KG = KR$ (which is perpendicular to $CR$) the radius of the equinoctial $AE$, and draw $RS$ perpendicular to $CK$ for the file of the dial; the shadow of whose point $R$ is to mark the hours, when $SR$ is set upright on the plane of the dial.

Then it is evident, that, in the contiguous line $AE$, the spaces $K I, K 2, K 3, &c.$ being taken equal to the tangents of the hour-distances from the meridian, to the radius $KG$, one, two, three, &c. hours after sun-rising, on the equinoctial day; the shadow of the point $R$ will be found, at these times; respectively in the points, 1, 2, 3, &c.

Draw, for the like hours after sun-rising, when the sun is in the tropic of Capricorn $y V$, the like common lines $CD, CE, CF, &c.$ and at these hours the shadow of the point $R$ will be found in these lines respectively. Find the sun's altitudes above the plane of the dial at these

Vol. II. No. 44.
the plate will face the sun directly at noon on the equinoctial days. Let the sun shine freely through the hole into the room; and hang a plumb-line to the ceiling of the room, at least five or six feet from the window, in such a place as that the sun’s rays, transmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the said place on the ceiling, take away the line.

Having adjusted a sliding bar to a dovetail groove, in a piece of wood about 18 inches long, and fixed a hook in the middle of the bar, nail the wood to the above-mentioned place on the ceiling, parallel to the side of the room in which the window is; the groove and bar being towards the floor. Then, hang the plumb-line upon the hook in the bar, the weight or plummet reaching almost to the floor; and the whole will be prepared for farther and proper adjustment.

This done, find the true solar time by either of the two last methods, and thereby regulate your clock. Then, at the moment of next noon by the clock, when the sun shines, move the sliding-bar in the groove, until the shadow of the plumb-line bisects the image of the sun (made by his rays transmitted through the hole) on the floor, wall, or on a white screen placed on the north side of the room, at least five or six feet from the window, in such a place as that the sun’s rays, transmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the said place on the ceiling, take away the line.

But because this may not be quite correct for the first time, on account that the plummet will not settle immediately, even in water; it may be farther corrected on the following days, by the above method, with the sun and clock; and so brought to a very great exactness.

N. B. The rays transmitted through the hole, will cast but a faint image of the sun, even on a white screen, unless the room be so darkened that no sunshine may be allowed to enter, but what comes through the small hole in the plate. And always, for some time before the observation is made, the plummet ought to be immersed in a jar of water, where it may hang freely; by which means the line will soon become steady, which otherwise would be apt to continue swinging.

An universal dial, showing the hours of the day by a terrestrial globe, and by the shadows of several gnomons, at the same time; together with all the places of the earth which are then enlightened by the sun; and those to which the sun is then rising; or on the meridian, or setting.

This dial (see Plate LXXII.) is made of a thick square piece of wood, or hollow metal. The sides are cut into semicircular hollows, in which the hours are placed; the file of each hollow coming out from the bottom thereof, as far as the ends of the hollows project. The corners are cut out into angles, in the infides of which the hours are also marked; and the edge of the end of each side of the angle serves as a file for calling a shadow on the hours marked on the other side.

In the middle of the uppermost file, or plane, there is an equinoctial dial; in the centre whereof an upright wire is fixed, for calling a shadow on the hours of that dial, and supporting a small terrestrial globe on its top.

The whole dial stands on a pillar, in the middle of a round horizontal board, in which there is a compass and magnetic needle, for placing the meridian file toward the south. The pillar has a joint with a quadrant upon it, divided into 90 degrees (supposed to be hid from sight under the dial in the figure) for setting it to the latitude of any given place; the same way as already described in the dial on the crofs.

The equator of the globe is divided into 24 equal parts, and the hours are laid down upon it at these parts. The time of the day may be known by these hours, when the sun shines upon the globe.

To rectify and use this dial, set it on a level table, or sole of the window, where the sun shines, placing the meridian file due south, by means of the needle; which will be, when the needle points as far from the north fleur-de-lis toward the well, as it declines westward, at your place. Then bend the pillar in the joint, till the black line on the pillar comes to the latitude of your place in the quadrant.

The machine being thus rectified, the plane of its dial-part will be parallel to the equator, the wire or axis that supports the globe will be parallel to the earth’s axis, and the north pole of the globe will point toward the north pole of the heavens.

The same hour will then be shewn in several of the hollows, by the ends of the shadows of their respective files; the axis of the globe will cast a shadow on the same hour of the day, in the equinoctial dial, in the centre of which it is placed, from the 20th of March to the 23d of September; and, if the meridian of your place on the globe be set even with the meridian file, all the parts of the globe that the sun shines upon, will answer to those places of the real earth which are then enlightened by the sun. The places where the shade is just coming upon the globe, answer to all those places of the earth to which the sun is then setting; as the places where it is going off, and the light coming on, answer to all the places of the earth where the sun is then rising. And lastly, if the hour of VI be marked on the equator in the meridian of your place (as it is marked on the meridian of London in the figure) the division of the light and shade on the globe will shew the time of the day.

The northern file of the dial (opposite to the southern or meridian one) is hid from sight in the figure, by the axis of the globe. The hours in the hollow to which that file belongs, are also supposed to be hid by the oblique view of the figure: but they are the same as the hours in the front-hollow. Those also in the right and left hand semicircular hollows are mostly hid from sight; and so also are all those on the sides next the eye of the four acute angles.

The construction of this dial is as follows: (See Plate LXXI. fig. 4.)

On a thick square piece of wood, or metal, draw the lines ae and bd, as far from each other as you intend for the thickenss of the file abcd; and in the same manner, draw the like thickenss of the other three files, efgb, iklm, and npq, all standing outright as from the centre.

With any convenient opening of the compasses, as aA (so as to leave proper strength of stuff when X I is equal to
to a $A$) set one foot in $a$, as a centre, and with the other foot describe the quadrantal arc $Ac$. Then, without altering the compasses, set one foot in $b$ as a centre, and with the other foot describe the quadrant $dB$. All the other quadrants in the figure must be described in the same manner, and with the same opening of the compasses, on their centres $e, f; i, k$; and $n, o$: and each quadrant divided into six equal parts, for so many hours, as in the figure; each of which parts must be subdivided into 4, for the half hours and quarters.

At equal distances from each corner, draw the right lines $Ip$ and $Kp$, $Lq$ and $Mq$, $Nr$ and $Or$, $Ps$ and $Qs$; to form the four angular hollows $IpK$, $LqM$, $NrO$, and $PsQ$; making the distances between the tips of these hollows, as $IK$, $LM$, $NO$, and $PsQ$; each equal to the radius of the quadrants; and leaving sufficient room within the angular points $p,q,r$, and $s$, for the equinoctial dial in the middle.

To divide the insides of these angles properly, for the hour-spaces thereon; take the following method.

Set one foot of the compasses in the point $I$, as a centre, and open the other to $K$, and with that opening describe the arc $Kt$: then, without altering the compasses, set one foot in $K$, and with the other foot describe the arc $It$. Divide each of these arcs, from $I$ and $K$ to their intersection at $t$, into four equal parts; and from their centres $I$ and $K$, through the points of division, draw the right lines $I_3$, $I_4$, $I_5$, $I_6$, $I_7$, and $K_2$, $K_1$, $K_{12}$, $K_{11}$; and they will meet the sides $Kp$ and $Ip$ of the angle $IpK$ where the hours thereon must be placed. And these hour-spaces in the arcs must be subdivided into four equal parts, for the half hours and quarters.—Do the like for the other three angles, and draw the dotted lines, and set the hours in the insides where those lines meet them, as in the figure: and the like hour-lines will be parallel to each other in all the quadrants and in all the angles.

Mark points, for all these hours on the upper side; and cut out all the angular hollows, and the quadrantal ones quite through the places where their four gnomons must stand; and lay down the hours on their insides, as in Plate LXII. and then set in their gnomons, which must be as broad as the dial is thick; and this breadth and thickness must be large enough to keep the shadows of the gnomons from ever falling quite out at the sides of the hollows, even when the sun’s declination is at the greatest.

Lastly, draw the equinoctial dial in the middle, all the hours of which are equidistant from each other; and the dial will be finished.

As the sun goes round, the broad end of the shadow of the flile $abcd$ will show the hours in the quadrant $Ac$, from sun-rise till VI in the morning; the shadow from the end $M$ will show the hours on the side $Lg$ from $V$ to $IX$ in the morning; the shadow of the flile $efbo$ in the quadrant $Dp$ (in the the long days) will show the hours from sun-rise till VI in the morning; and the shadow of the end $N$ will show the morning hours, on the side $Or$, from III to VII.

Just as the shadow of the ‘northern’ flile $abc$ goes off the quadrant $Ac$, the shadow of the southern flile $kln$ begins to fall within the quadrant $Fl$, at VI in the morning; and shows the time, in that quadrant, from VI till XII at noon; and from noon till VI in the evening in the quadrant $mE$. And the shadow of the end $O$, shows the time from XI in the forenoon till III in the afternoon, on the side $rN$; as the shadow of the end $P$ shows the time from IX in the morning till I o’clock in the afternoon, on the side $Qs$.

At noon, when the shadow of the eastern flile $efhb$ goes off the quadrant $Ac$ (in which it showed the time from VI in the morning till noon, as it did in the quadrant $gD$ from sun-rise till VI in the morning) the shadow of the western flile $nopq$ begins to enter the quadrant $Hp$; and shows the hours thereon from XII at noon till VI in the evening; and after that till sun set, in the quadrant $gC$: and the end $Q$ casts a shadow on the side $Ps$ from $V$ in the evening till IX at night, if the sun be not set before that time.

The shadow of the end $I$ shows the time on the side $Kp$ from III till VII in the afternoon; and the shadow of the flile $abcd$ shows the time from VI in the evening till the sun sets.

The shadow of the upright central wire, that supports the globe at top, shows the time of the day, in the middle or equinoctial dial, all the summer half year, when the sun is on the north side of the equator.

DIALECT, an appellation given to the language of a province, in so far as it differs from that of the whole kingdom. The term, however, is more particularly used in speaking of the ancient Greek, whereof there were four dialects, the Attic, Ionic, Æolic, and Doric, each of which was a perfect language in its kind, that took place in certain countries, and had peculiar beauties.

DIALOGISM, in rhetoric, is used for the soliloquy of perfons deliberating with themselves. See Soliloquy.

DIALOGUE, in matters of literature, a conversation between two or more persons, either by writing or by word of mouth.

Dialogue appears to be the most ancient form of writing, and is greatly recommended by several authors. The archbishop of Cambrey, at the head of his pastoral instruction, gives an account of the advantages of dialogue.

DIALTHAEA, in pharmacy, an unguent much used as a resolvent, so called from althaea, or marsh-mallows, which is the principal ingredient in it. See Althaea.

DIALYSIS, in grammar, a mark or character, consisting of two points, `·' placed over two vowels of a word, in order to separate them, because otherwise they would make a diphthong, as Mofaic, &c. See Diphthong.

DIAMETER, in geometry, a right line passing through the center of a circle, and terminated at each side by the circumference thereof. See Geometry.

DIAMOND, in natural history, a genus of precious stones, of a fine pellucid fulfillance, of great hardness, never fouled by any admixture of earthy or any other coarse matter, susceptible of elegant tinges from metallic.
line particles, giving fire with steel, not fermenting
with acid menstruums, scarcely calcinable by any de-
cree of fire, and of one simple and permanent appear-
ance in all lights.

This is the most valuable and hardest of all gems;
and though found of different shapes, and sometimes ac-
cidentally tinged to several colours, yet ever carries the
same distinguishing characters, and is very evidently in
all those states the same body. It is, when pure, per-
cfectly clear and pellucid as the purest water, and is e-
minently distinguished from all other substances, by its
vivid splendor, and the brightness of its reflections.
It is extremely various in shape and size, being found
in the greatest quantity very small, and the larger opals
extremely seldom met with; the largest diamond cer-
tainly known ever to have been found is that in the po-
session of the Great Mogul, which weighs 279 carats,
and is computed to be worth 779,244l.

The diamond has certainly one proper and determin-
ate figure, into which it naturally willl concretc, when
in a state of rest and impeded by no other ac-
cident in its formation: the true figure then is an equilateral octahedron; and where ever it has concre-
ted in a perfect manner, and without any interrupting
accidents, it has always formed itself into this figure;
and often in this its several surfaces are as bright as if
polished by art: but, as in common fact, though its
figure be pyramidal, yet very easy accidents can de-
termine it into cubes and parallelopipeds; so the dia-
mond has often, in the state of formation, been thrown
into two other figures, both also seeming regular ones;
the one a prismatic columnar one of six angles some-
what emulating the figure of crystal, the other an ob-
long quadrilateral column with two truncated ends:
these seem the only regular figures of this gem; but
besides these, it is every day found in numberless other
misshapen forms, often roundish, emulating the shape
of pebbles, but full of small flat planes or faces; fre-
fquently oblong, very often flat, and as often tapering,
either from one end to the other, or else from the
middle to both ends. A diamond bears the force of
the strongest fire, except the concentrated solar rays,
without hurt; and even that infinitely fierceft of all
fires does it no injury, unlefs directed to its weaker parts.

It is a common thing for diamonds to be too thick
or deep for the extent of their surface, and there is
a certain proportion of depth, beyond which the gem
should not be allowed: in this cafe two diamonds are
often made, by the regularly dividing one: this, when
the mafs is of an angular figure, is done by cutting
it through with a wire, wetted with oil, and covered
with diamond-powder; but in the flat or more com-
mon mafs, it is done much more expeditiously by
finding the grain of the ftone, and introducing the
point of a fine flat chifel between them. This is not
the only use of the splitting; for when a diamond has
a flaw or blemish in it, which greatly debases its value,
the plates may be separated at a proper breadth, and
the flaw removed; in which case the thinner crest,
struck off, is of value in proportion to its size, and
the remainder, being now freed from its flaw, is of
much more value than it was at firft. The places
whence we have the diamonds are the East-Indies, in
the island of Borneo, and in the kingdoms of Vifapour,
Golconda, Bengal; and the Brazils in the Weft-
Indies. They are not unfrequently found yellowifh,
blueifh, and reddifh, but more rarely greenifh.

Valuation of Diamonds, among jewellers, is thus cal-
culated: they suppose the value of a rough diamond
to be 2l. per carat; then to find the value of those
of greater weight, they multiply the fquare of their
weight by 2, and this laft product is the value of the
diamonds in their rough state: thus, the value of a
rough diamond weighing 4 carats, is equal $4 \times 2 = 8$; and so in other cafes, to find the value of wrought diamonds, they suppose half
their weight loit in the manufacturing them, and there-
fore multiply the fquare of double their weight by 2;
thus the value of a wrought diamond, weighing 3 car-
rats, is equal $6 \times 6 \times 2 = 72$.

Ref-Diamond is that quite flat underneath, with its
upper part cut in divers little facles, ufually triangles,
the uppermoll of which terminate in a point.

Table-Diamond is that which has a large fquare face at
top, encompassed with four leffer.

Brilliant Diamond is that cut in faces both at top and
bottom; and whose table, or principal face at top, is
flat.

Diamond, in the glafs-trade, an instrument used for
squaring the large plates or pieces; and, among gla-
izers, for cutting their glafs.

These fur of diamonds are differently fitted up;
that used for large pieces, as looking-glaifes, &c. is
set in an iron ferril, about two inches long, and a quar-
ter of an inch in diameter; the cavity of the ferril
being filled up with lead, to keep the diamond firm:
there is alfo a handle of box, or ebony, fitted to the
ferril, for holding it by.

Diamond, in heraldry, a term used for exprefling the
black colour in the achievements of peerage.
Guillim does not approve of blazoning the coats of
peers by precious ftones instead of metals and colours;
but the English practice allows it. Morgan says the
diamond is an emblem of fortitude.
DIANA1 arbor, or Arbor luna:, in chemiftry, the
beautiful cryftallizations of silver, difolved in aqua
fortis, to which fome quickfiver is added; and fo cal-
led from their refembling the trunk, branches, leaves,
&c. of a tree. See CHEMISTRY.

DIANDRIA, in the Linnaean fystem of botany. See
BOTANY, p. 625.

DIANO, a town of the Genoese, about three miles from
the fea. The country about produces great numbers
of olives.

DIANTHERA, in botany, a genus of the diandria
gynia class. The corolla is rinfent; and the
capule has two elaftic valves. There are two fpecies,
both natives of America.

DIANTHUS, in botany, a genus of the decandria di-
gynia class. The calix is cylindrical, and conifls of
one leaf, with four scales at the bafe; the corolla con-
ifls of five clawed petals; and the capule is cylindrical,
and has but one cell. There are seventeen species, five of which are natives of Britain, viz. the armeria, or Deptiorid pink; the prolifer, or linewort; the deltoide, or maiden pinks; the glaucus, or mountain pink; and the arenarius, or stone pink.

Diapason, among the musical instrument makers, a kind of rule or scale, whereby they adjust the pipes of their organs, and cut the holes in their flutes, hautboys, &c.; in due proportion, for performing the tones, semitones, and concords just.

Diapason diapente, in music, a kind of compound concord, whereof there are two sorts; the greater, which is in the proportion of 10:3; and the less, in that of 16:5.

Diapason diatessaron, in music, a compound concord, founded on the proportion of 8:3. To this interval, Martianus Capella allows eight tones and a semitone, seventeen semitones, and thirty-eight dieses. It is a symphony made when the voice proceeds from the first to the twelfth sound.

Diapason diatessaron, in music, a compound concord, founded on the proportion of 8:3. To this interval, Martianus Capella allows eight tones and a semitone, seventeen semitones, and thirty-eight dieses. It is a symphony made when the voice proceeds from the first to the twelfth sound.

Diapason ditone, in music, a compound concord, whose terms are as 10:4, or 5:2.

Diapason semiditone, in music, a compound concord, whose terms are in the proportion of 12:5.

Diapason semiditone, in music, a compound concord, whose terms are in the proportion of 12:5.

Diapheresis, in rhetoric, a figure of oratory, expressing the uncertainty of the speaker how he shall proceed in his discourse.

Diarbecc, or Diarbeck, the capital of a province of the same name, answering to the ancient Mesopotamia; it is situated on the river Tigris, near its source, in 42° E. long. and 27° 30' N. lat.

Diarrhoea, or Loseness, in medicine, is a frequent and copious evacuation of liquid excrement, by stool. See Medicine.

Diary, among traders, denotes a day-book containing the proceedings of one day.

Diachism, among musicians, denotes the difference between the comma and enharmonic dieses, commonly called the lesser comma.

Diascordium, in pharmacy, a celebrated composition, so called from scordium, one of its ingredients. It is otherwise termed confettio fracafloris, and is thus directed by the college.

Take of cinnamon and cassia-wood, of each half an ounce; of true scordium, one ounce; of Cretan dittany, tormentil, bifort, galbanum, and gum-arabic, of each half an ounce; of florax, four drams and an half; of opium, and seeds of forred, of each one dram and an half; of gentian, half an ounce; of American bole, one ounce and an half; of Lemnian sealed earth, half an ounce; of long pepper and ginger, of each two drams; of clarified honey, two pounds and an half; of sugar of roxes, one pound; of generous canary, eight ounces; make into an electuary. It is excellent in all kinds of fluxes, and a great strengthener both of the stomach and bowels.

Diasbesten, in pharmacy, a soft purgative electuary, whereof sebelets are the principal ingredients. The other ingredients are prunes, tamarinds, juices of iris, anguria and mercurialis, penidies, simple diaprunum, violet seeds, and diargrydium. It is good in remitting and continued fevers, &c.

Diaessenia, in pharmacy, the name of a medicine in which fenna is the principal ingredient. The other ingredients are sugar-candy, cinnamon, lapis lazuli, silk, cloves, galanga minor, black pepper, nardus indica, seed of basilicum, flowers of cloves, cardamoms, saffron, ginger, zedoary, &c.

This electuary is taken against melancholy and spleen, and against difeases arising from an atrabilis.

Diasole, among physicians, signifies the dilatation of the heart, auricles and arteries; and stands opposed to the systole, or contraction of the same parts. See Circulation.

Diasole, in grammar, a figure of prosody, whereby a syllable naturally short is made long: such is the first syllable of Priamides, in the following verse of Virgil.

Aque hic Priamides i nihil d tibi, amice, relitum.

Diayrmus, in rhetoric, a kind of hyperbole, being an exaggeration of some low ridiculous thing.

Diatessaron, among ancient musicians, a concord, or harmonical interval, composed of a greater tone, a
DICHOTOMY, a term used by astronomers for that phasis, or appearance of the moon, wherein she is bisected, or looks just half her disk. In this situation the moon is said to be in a quadrat aspect, or to be in her quadrature.

DICHOTOMY, in botany. See Botany, p. 641.

DIC (434) DIC

DICHTOMY, a term used by astronomers for that phasis, or appearance of the moon, wherein she is bisected, or looks just half her disk. In this situation the moon is said to be in a quadrat aspect, or to be in her quadrature.

DICHTOMY, in botany. See Botany, p. 641.
this in the most accurate manner, is the most complete. Therefore the principal study of a lexicographer ought to be, to discover a method which will be best adapted for that purpose. Dr. Johnson, with great labour, has collected the various meanings of every word, and quoted the authorities: But, would it not have been an improvement if he had given an accurate definition of the precise meaning of every word; pointed out the way in which it ought to be employed with the greatest propriety; shewed the various deviations from that original meaning, which custom had so far established as to render allowable; and fixed the precise limits beyond which it could not be employed without becoming a vicious expression? With this view, it would have been necessary to exhibit the nice distinctions that take place between words which are nearly synonymous. Without this, many words can only be defined in such a manner, as that they must be considered as exactly synonymous. We omit giving any quotations from Johnson to point out these defects; but shall content ourselves with giving that they must be considered as exactly synonymous.

We omit giving any quotations from Johnson to point out these defects; but shall content ourselves with giving that they must be considered as exactly synonymous. We omit giving any quotations from Johnson to point out these defects; but shall content ourselves with giving that they must be considered as exactly synonymous.
3. Great, when applied to the human species, never
denotes the size or largeness of body, but is applied
solely to the qualities of the mind. Thus, when we
say, that Socrates was a great man, we do not
mean that he was a man of great size, but that he
was a man who excelled in the endowments of the
mind. The terms which denote largeness of size
in the human body are, big, bulky, huge, &c.
4. Great is sometimes applied to the human species,
as denoting high rank. In this case it is often em-
ploied in the plural number than otherwise. Thus we
say simply, the great, meaning the whole body of
men in high estimation, as opposed to mean. It should
seldom be employed in this sense, as it tends to
confound dignity of rank with elevation of mind.
5. As this is a general term of augmentation, it may
be joined with all nouns which denote quantity,
quality, number, excellence, or defect; or such as
imply praise, blame, anger, contempt, or any oth-
er affection of the mind.
6. It is employed to denote every step of ascending
or descending confanguinity; as, great-grandfather,
great-grandson. See.
HIGH. adj. Exalted in a perpendicular direction at
a distance from the surface of the earth. Opposed to
low.
1. High is a term altogether indefinite, and is em-
ployed to express the degree of elevation of any an-
imate body. Thus, we say, a high mountain,
a high house, steeple, tower, pillar, &c. nor is
there any other word that can here be considered as
fynonymous; lofty being employed only to denote
a very eminent degree of elevation.
2. To express the perpendicular elevation of vegeta-
bles, either high or tall may be employed, as being
in this case nearly fynonymous, we may therefore
say, a high or tall tree, a high or tall man, &c.
but with this difference between these two expre-
sions, that tall can be more properly applied to
those that are much elevated and of small dimen-
sions; and high, to such as are more bulky, and of
greater size.
3. The perpendicular height of man can never be ex-
pressed by the word high; tall being here the pro-
per expression. And although high is sometimes
used to express the height of other animals, yet it
seems to be an improper expression. See Tall.
4. High, when applied to the human species, always
refers to the mind; and denotes haughtiness, state-
liness, pride, &c.; and, when combined with the
expressions of any energy of the mind, it denotes
that in a higher degree. In this sense, it is oppo-
sed to meanness, abjectness, and humility.
5. As this is an indefinite term, tending to denote a-
ny thing that is elevated above us, it may be com-
bined with almost every noun which admits of this
elevation. And as objects high above us are always
out of our reach, it is in a metaphorical sense used
to denote any thing that seems to be above the or-
dinary condition of mankind; or those qualities or
endowments of mind that are not easily acquired;
as, dignity or elevation of sentiment, dignity of
rank, acuteness in reasoning on difficult subejets;
pride, haughtiness, or any other quality which
seems beyond the ordinary level of mankind; dear-
ness of price, &c.
6. In the same manner we employ this term to time;
which having a metaphorical refemblance to a river,
flowing on with an unceasing current through all
successive ages, any thing of remote antiquity is de-
noted by the term high.
7. Likewise those degrees of latitude far removed from
the line, where the pole becomes more elevated.
8. And to some particular crimes, as being at-
tended with peculiar degrees of guilt; as, high trea-
fon.
TALL. adj. Something elevated to a considerable
degree in a perpendicular direction. Opposed to
low.
1. This term is chiefly employed to express the height
of man, and other animals; and is applied to de-
note the height of the body only, without having
any reference to the mind. When applied to man,
no other word can be substituted in its stead: when
applied to other animals, high is sometimes con-
fidered as nearly fynonymous. See High.
2. It is likewise employed to denote the perpendicular
height of vegetables; and in this case it is nearly
fynonymous with high. See High.
3. It can in no case be employed to express the height
of merely inanimate objects; as we can never say a
tall steeple, tower, or pillar, but a high steeple,
&c. For the distinctions in these cases, see High.
LONG. adj. A relative term, denoting the di stance
between the extremes of any body, which is extend-
ed more in one of its geometrical dimensions than
another. Opposed to short.
1. This term may be applied to all inanimate objects,
of whatever kind, whose dimensions in one way ex-
ceed the other, and when not in an erect posture,
whatever be the other circumstances attending them;
whether it relates to superficialities alone, or to solid
bodies; whether thebe be bounded or open, straight or
crooked, flexible or rigid, or in any other circum-
stances whatever; thus we say a long or short line,
a long or short ridge, street, ditch, rope, chain, flaff,
&c. But it is to be observed, that although long is,
in the strict sense only, opposed to short; yet as it ex-
presses the extension of matter in one of its geo-
metrical proportions, it is often contrasted by those
words which express the other proportions when we
mean only to describe the several proportions; as, a
table long and broad: and as these several dimen-
sions are expressed by different words, according to the
various forms, modifications, and circumstances, in
which bodies are found; therefore it is in this sense
contrasted by a great diversity of terms; as, a long
and
and broad, or wide, narrow, or strait street or lane, a long and thick, or small rope, chain, staff, &c.

For the distinctions in these cases, see Broad, Wide, &c.

2. Objects necessarily fixed in an erect position can never have this term applied to them; and therefore we cannot say a long, but a high tower or steeple. And for the same reason, while trees are growing and fixed in an erect position, we cannot apply this term to them; but when they are felled and laid upon the ground, it is quite proper and necessary. Thus, we do not say a long, but a tall or high tree, while it is growing; but we say a long, not a tall log of wood; and in the same manner we say a tall mast, when it is fixed in the ship; but a long mast, while it lies upon the beech. See Tall and High.

3. Those vegetables which are of a tenderpliant nature, or so weak as not to be able to retain a fixed position, being considered as of a middle nature between erect and prostrate bodies, admit of either of the terms long, tall, or high; as, a long or tall rush or willow wand, or a long, tall, or high stalk of corn. See High and Tall.

4. The parts of vegetables, when considered as distinct from the whole, even when growing and erect, assume the term long; for we do not say a tall, but a long shoot of a tree; and a tree with a long stem, in preference to a tree with a high stem.

5. For the same reason, a staff, and pole, even when fixed in a perpendicular direction, assume the word long, in preference to tall or high.

6. With regard to animals, the general rule is applied, without any exceptions; tall, and not long, being employed to denote the height of the human body, when in an erect posture; and long and not tall, to denote its length when in an incumbent situation. Long, applied to all other animals which do not walk erect, always denotes their greatest length in a horizontal position from head to tail.

7. In a figurative sense, it denotes, with regard to time, any thing at a great distance from us.

8. As also, any thing that takes up much time before it is finished; as, a long discourse, a protracted note in music, &c.

BROAD. adj. The distance between the two nearest sides of any body, whose geometrical dimensions are larger in one direction than in another; and has a reference to superficies only, and never to the solid contents. Opposed to narrow.

1. Broad, in the strictest acceptation, is applied to denote those bodies only whose sides are altogether open and unconfined; as, a broad table, a broad wheel, &c. and in these cases it is invariably contrived by the word narrow; nor is there any other word which in these cases can be considered as synonymous with it, or used in its stead.

2. When any object is in some sort bounded on the sides, although not quite closed up, as a road, street, ditch, &c. either broad or wide may be employed, but with some difference of signification; broad being most properly used for those that are more open, and wide to those which are more confined; nor can this term be ever applied to such objects as are close bounded all around, as a house, church, &c. wide being here employed. For the more accurate distinctions in these cases, see the article Wide.

WIDE. adj. A term employed to denote relative extent in certain circumstances. Opposed to narrow and strait.

1. This term is in its proper sense applied only to denote the space contained within any body closed all round on every side, as a house, gate, &c. and differs from broad in this, that it never relates to the superficies of solid objects, but is employed to express the capaciousness of any body which contains vast vacant space; nor can capaciousness in this sense be expressed by any other word but wide.

2. As many bodies may be considered either with respect to their capaciousness, or superficial extent; in all these cases, either the term broad or wide may be used; as, a broad or wide street or ditch, &c. but with a greater or less degree of propriety, according to the circumstances of the object, or the idea we wish to convey. In a street where the houses are low, and the boundaries open, or in a ditch of small depth and large superficies, this largeness of superficies bears the principal proportion, broad would be more proper; but if the houses are of great height, or the ditch of great depth, and capaciousness is the principal property that affects the mind, we would naturally say a wide street or ditch; and the same may be said of all similar cases; but there are some cases in which both these terms are applied, with a greater difference of meaning; thus we say, a broad, or a wide gate; but as the gate is employed to denote either the aperture in the wall, or the matter which closes that aperture, these terms are each of them used to denote that particular quality to which they are generally applied: and as the opening itself can never be considered as a superficies, the term wide, in this case, denotes the distance between the sides of the aperture; while, on the contrary, broad denotes the extent of matter fitted to close that aperture; nor can these two terms in any case be subordinated to one another.

3. As a figurative expression, it is used as a cant phrase for a mistake; as, you are wide of the mark; that is, not near the truth.

NARROW. adj. A relative term, denoting a proportional smallness of distance between the sides of the superficies of plain bodies. Opposed to broad.

1. As this is only applied to superficies, it is exactly contrived by broad, and is applied in all cases where the term broad can be used, (see Broad); and in no other case but as a contralt to it, except the following.

2. It sometimes is employed to describe the smallness of space circumscribed between certain boundaries, as opposed to wide, and nearly synonymous with
STRAIT, adj. A relative term, denoting the extent of space in certain circumstances. Opposed to wide.

1. This term is employed, in its proper sense, to denote only space, as contained between surrounding bodies in such circumstances as to denote some degree of confinement; and is exactly opposed to wide; as, a wide or a slight gate, &c. See WIDE.

2. So necessary is it that the idea of confinement should be connected with this word, that in all those cases where the space contained is large, as in a church or house, we cannot express a smaller proportional width by this term. And as we have no other word to express space in these circumstances, we have been obliged to force the word narrow from its natural signification, and make it express this. See Narrow.

3. In some particular cases narrow or slight may be employed to the same object; as, a narrow or a slight lane; but here slight is never employed but where an idea of confinement is suggested, and where it is exactly contrasted to wide; nor can narrow be employed but in such circumstances where broad would be a perfect contrast to it. Therefore, these two terms may be always employed in the same circumstances as those which contrast them may be. For an account of which, see WIDE.

4. The term slight is likewise in a peculiar manner used to denote the smallness of the internal diameter of those small bodies which are fitted to receive or contain others as, any kind of bag, tube, body-cloths, mortuaries, and others of the same kind; and in all these cases this term may be employed to denote the smallness of their lesser diameter, and never the term narrow. But in certain circumstances the word tight may be substituted for it. See Tight.

5. Strait, in a figurative sense, denotes any sort of confinement of sentiment or disposition. TIGHT. adj. A term employed in certain circumstances to denote the internal capacity of particular bodies. Nearly synonymous with slight.

This term is confined entirely to denote the smallness of the internal dimensions of such objects as are formed to cover or to receive or contain other solid bodies, and can be employed in no other case. And although it agrees with slight, in always denoting confinement, and by being applicable to the same species of objects, yet it differs in the following respects: 1. If there be any difference of the diameter of the objects to which the term slight can be employed, it always has reference to the smaller; yet tight may be employed to any sort of confinement, whether it regards the length or breadth.

2. Strait can be applied to all bodies of capacity when of small diameter, without any sort of reference to the nature of the substance which it may be capable of containing. For we can say a slight bag, a slight sleeve, a slight mortuary, a slight gate, &c. whereas tight can only be applied to any body when it is considered as having reference to another body which is intended to be contained in it and is pinched for want of room. Thus, we say, the sleeve of a coat is too tight for the arm, the mortuary is too tight for the tenon, &c. but we cannot say, the bag, or the gate is too tight, because these are fitted to receive any sort of objects. And hence it happens, that, in many cases, the dimensions of the same body may be expressed by tight or slight when considered in different circumstances. Thus, we may say, this sleeve is too slight, when we look at a coat when lying on the table, and consider its proportions; but it is not till we have tried it upon the arm that it is intended to cover, that we call it tight. And we may say, a gate is too slight, or too tight; but in the first case we consider it as being too confined for admitting objects to pass through it, and in the last as being too confined with respect to the leaves that are to shut the aperture, not allowing them space to move with freedom.

These examples may serve to give some idea of the plan of an English dictionary composed upon philosophical principles: But, besides the circumstances above enumerated, there are many others which would require particular attention in the execution of a work of this kind. In the English language, a great variety of terms occur, which denote matter under certain general forms or circumstances, without regarding the minute diversities that may take place; as the word cloth, which denotes matter as manufactured into a particular form, including under it all the variety of stuffs manufactured in that particular way, of whatever materials, colours, texture, or fineness they may be. The same may be said of wood, iron, yarn, and a great variety of terms of the same nature, some of which cannot assume any plural; while others admit of it in all cases; and others admit or refuse it according to the different circumstances in which they are considered. In a dictionary, therefore, all the variety of cases ought to be clearly and distinctly pointed out under each particular article: this is the more necessary, as some of these words have others formed from them, which might be readily mistaken for their plurals, although they have a very different signification; as cloths which does not denote any number of pieces or different kinds of cloth, but wearing apparel. The following example will illustrate this head.

WOOD: sub. A solid substance of which the trunks and branches of trees consist.

1. This term is allowed to denote the solid parts of vegetables of all kinds, in whatever form or circumstances they are found. Nor does this term admit of plural with propriety, unless in the circumstances after mentioned: for we say, many different kinds of wood, in preference to many kinds of woods; or, we say, oak, ash, or elm wood; not woods.

2. But where we want to contrast wood of one quality,
lity or country with that of another, it admits of a plural; for we say, *white woods are in general softer than red*; or *West-Indian woods are in general of greater specific gravity than the European woods*. But unless where the colour, or some quality which distinguishes it from growing wood, is mentioned, this plural ought as much as possible to be avoided, as it always suggests an idea of growing wood. 

3. *Wood* likewise denotes a number of trees growing near one another; being nearly synonymous with *forest*: See *Forest*. In this sense it always admits of a plural; as, *Ye woods and wilds whose solitary gloom, &c.*

A dictionary cannot be reckoned complete without explaining obsolete words; and if the terms of the several provincial provincial dialects were likewise given, it would be of great utility; nor would this take much time; because a number of these words need no other explanation than to mark along with them the words which had come in their place, when there happened to be one perfectly synonymous: and in these cases where the same idea could not be expressed in modern language without a paraphrase, it would be of use to explain them distinctly; so that, when a writer found himself at a loss for a term, and obliged to search for one beyond the bounds of our own language, he might take one of these, when he found that it was expressive and energetic; in preference to an other drawn from a foreign language. This would at least have one good effect: it would make our language more fixed and stable; not to say more accurate and precise, than by borrowing from foreign languages. The following examples may serve to give some idea of the manner of treating this part of the work.

*Mae*, or *mo*. adj. An obsolete term still employed in the Scotch dialect, and by them pronounced *mae*: denoting a greater number, and nearly synonymous with *more*; but it differs in this respect, that, in the Scotch dialect, *mae and mair* (English, *more*) are each employed in their distinct sphere, without encroaching upon one another; *mae* being employed to denote number, but never quantity or quality; and *mair*, to denote quantity and quality, but never number: thus they say *mae*, not *mair apples*, *men*, &c. and they say *mair*, not *mae cloth*, *earth*, *courage*, &c. See *Mair*. Both of these terms are supplied by the word *more*; which, in the English language, is applied indiscriminately to denote quantity, quality, and number. See *More*.

*Thir* pron. Obsolete; still employed in the Scotch dialect: the plural of *this*; and contrasted to *thee*, in the same manner as *that* is to *this*.

As there is no word in the English language equivalent to this, we thus shew the manner in which it is employed. In the English language we say, *that stone or house*, pointing at one at a distance, is *larger or more commodious than this stone or this house*, which is supposed to be at hand. In the same manner, in the Scotch dialect, they say, *thefe* (or as it is pronounced, *thae*) *flones are whiter than thir floes*; denoting, that the former are at a distance, and the latter at hand. And, in the same manner, it is invariably applied to denote any present object in the plural number, as opposed to *thee*; as *thee* or *thir apples*, as at hand or at a distance; *thefe* or *thir trees*, &c.; but never in the singular number, as it is always *this* or *that tree*, *bye*, &c.

As the English language is so exceedingly irregular in the pronunciation, the same letter in the same situation often assuming sounds totally different in different words, it is impossible to establish any general rules on this subject, which do not admit of many exceptions: therefore, a dictionary is the best means of ascertaining and pointing out the proper pronunciation of words. For, if the writer first pointed out all the different sounds that the same letter could ever be made to express, and assigned to every particular sound which each letter could be made to assume, a particular mark, which was appropriated to denote that particular sound of the letter whenever it occurred; by placing these particular marks above the letters in the dictionary, the found of each letter would be pointed out in all cases with the utmost certainty. It would be impossible for us to illustrate this by examples, without first ascertaining all the sounds of each letter; which would lead us into a discussion too long for this place; and this is at present the more unnecessary, as the public have been long in expectation of a dictionary, by a very able hand, in which this particular will be attended to.

We shall only further observe, that, besides having the accented syllable of every word *properly* distinguished in a dictionary to assist in the pronunciation, the English language requires another essential improvement, viz. the use of accents to distinguish the meaning of words and *phrases*; which, although it is not so properly confined to a lexicographer, yet it is not quite without its sphere. Thus the word *as* admits of two very different sounds, as well as different significations; as in this example, "Cicero was nearly *as* eloquent *as* Demosthenes;" in which the first *as* is pronounced *afs*, and the last is pronounced *az*. Now, it often happens, that, in reading, the particular word in which it ought to be understood is not pointed out by the context, till after the word itself is pronounced, which has an equal chance at least of being pronounced wrong; whereas, if it were always accented when employed in the one sense, and not in the other, it would free the reader from this perplexity. There are other cases in which the use of proper accents in writing would be of great consequence; as at the beginning of a sentence, when it was put as a question, or used ironically, &c. the want of which every one must have observed. But as this does not so properly belong to the lexicographer as the grammarian, we shall here take no further notice of it.

The above examples, we hope, will be sufficient to give the reader some idea of the plan that we would propose; and enable him to determine, whether or not a dictionary, executed upon this plan, would convey, to his mind a more perfect knowledge of the English language, than those dictionaries that have hitherto published.
DIDELPHIS, in zoology, a genus of quadrupeds belonging to the order of feræe, the characters of which are these: they have ten fore teeth in the upper jaw, and eight in the under one; the dog-teeth are long; the tongue is somewhat ciliated; and they have a pocket, formed by a duplicature of the skin of the belly, in which the dugs are included. There are five species, viz. 1. The marfupialis, with eight dugs inclosed in the abdominal pocket. He is about fifteen inches long from the snout to the root of the tail, which is about twelve inches long: he has five toes on the fore-feet, with crooked claws and five toes on the hind-feet, only four of them furnished with claws; the fifth, which is a kind of thumb, is at a distance from the others, and has no claw; the tail is bare from a little below the root: The ears and legs are likewise bare; the eyes are small, prominent, of a black colour, and very lively. The body is of a greyish colour, with some small tufts of black and white hairs upon the back and sides. Under the belly of the female there is a large bag or pocket, formed by a remarkable duplicature of the skin, in which the dugs are contained. This pocket the animal can flunt or open at pleasure, by means of a couple of dugs, pendulous ears, and a tail bushy at the base. The more accurate writers, however, restrain the term of diet to what regards eating and drinking, or solid aliments and drinks. See Medicine.

DIDACTIC, in the schools, signifies the manner of speaking, or writing, adapted to teach or explain the nature of things.

DIDAPPER, in ornithology, See Colymbus.

DIDELPHIS, in zoology, a genus of quadrupeds belonging to the order of feræe, the characters of which are these: they have ten fore teeth in the upper jaw, and eight in the under one; the dog-teeth are long; the tongue is somewhat ciliated; and they have a pocket, formed by a duplicature of the skin of the belly, in which the dugs are included. DIDYNAMIA, in the Linnaean system of botany. See otany, p. 635.

DIE, in geography, a town of France, in the province of Dauphiné, situated on the river Drôme, twenty-two miles south of Grenoble: E. long. 5° 20', N. lat. 44° 50'.

DIEGEM, a town of the Austrian Netherlands, in the province of Brabant, about three miles north of Brufels: E. long. 4° 20', and N. lat. 51°.

DIEPE, a port-town of France, situated on the British channel, about thirty miles north of Rouen, and opposite to port Rye in England: E. long. 1° 15', and N. lat. 49° 55'.

DIEPHOLT, a city of Westphalia in Germany, situated at the north end of the Dummer lake, thirty-five miles south of Bremen: E. long. 8°, and N. lat. 53°.

DIERVILLA, in botany. See Lanicera.

DIES MARCHI, was the day of congress, or meeting of the English and Scotch, annually appointed to be held on the marches, or borders, in order to adjust all differences between them.

DIESIS, in music, is the division of a tone less than a semi-tone; or an interval consisting of a less or imperfect semi-tone.

DIESIS is the smallest and softest change or inflexion of the voice imaginable: it is called a faint, expressed thus X, by a St Andrew's cross, or falter.

DIE, in medicine, according to some, comprehends the whole regimen, or rule of life, with regard to the fix non-naturals, air, meats and drinks, sleep and watching, motion and repose, passions of the mind, tendencies and excretions.

The more accurate writers, however, restrain the term of diet to what regards eating and drinking, or solid aliments and drinks. See Medicine.

DIEF-DRIKKS, a form in phytic, including all the medicated wines, ales, and wheys, used in chronic cafes. They require a course or continuation to answer any intention of moment.

DIEF OF APPEARANCE, in Scots law, the day to which a defendant is cited to appear in court, and every other day to which the court shall afterwards adjourn the consideration of the question.
DIFFUSE, an epithet applied to such writings as are wrote in a prolix manner. Among historians, Sallust;

DIEU ET MON DROIT, i.e. God and my right, the motto of the royal arms of England, first assumed by king Richard I. to intimate that he did not hold his empire in vassalage of any mortal. It was afterwards taken up by Edward III. and was continued without interruption to the time of the late king William, who used the motto Je main-tien-dray, though the former was still retained upon the great seal. After him queen Anne used the motto Semper eadem, which had been before used by queen Elizabeth; but ever since queen Anne, Dieu et mon droit continues to be the royal motto.

DIGEST, in matters of literature, a collection of the decisions of the Roman lawyers properly digested, or arranged under distinct heads, by order of the emperor Justinian. It constitutes the first part or volume of the civil law.

DIGESTION, in medicine, is the dissolution of the aliment into such minute parts as are fit to enter the lacteal vessels, and circulate with the mafs of blood. Various are the systems and hypotheses framed by physicians and philosophers to account for digestion. Some contend, that it is done by a kind of elixation of the solid and grosser parts of the food in the liquid by the heat of the stomack, and of the adjacent parts, the liver, spleen, &c. Others will have it done by attrition, as if the stomack, by those repeated motions, which are the effects of respiration, rubbed off the minute particles from the grosser matters, and digested the rest against each other, attenuated and dissoloved them.

Others think the bilious juice, others the spirits, chiefly concerned in digestion. Others will have the food dissoloved by a menstruum; but then they are greatly divided as to the nature and origin of this menstruum; some supposing it an acid furnished by the glands of the stomack; others, a nitro-aerial spirit, which, by penetrating the mafs of food, breaks the connexion of the molt solid parts; and others, a saline juice, which divides and volatilizes the parts of the food. Others, again, suppose digestion to be performed by means of a ferment or leaven, which mixing with the aliment, excites an invisible motion in the parts thereof, by which means the parts are attenuated and dissoloved. But these likewise differ in their opinion of this ferment; some taking it to be the remains of the food last digested, which, by its continuance in the stomack, has contracted an acid quality and become a ferment: others take the principles of fermentation to be contained in the aliment itself, which when inclosed in the stomack, heated there, and put in motion, enters on its office of fermentation: others suppose the matter of the ferment supplied by the glands of the stomack; and lastly, others contend for the saliva, and make that the ferment serving principally for the digestion of the food.

Some suppose digestion owing to gentle heat and motion. By this heat and motion, say they, the texture of the nourishment is changed in the bodies of animals; and then the conffuent solid parts are indued with peculiar attractive powers of certain magnitudes, by which they draw, out of the fluids moving through them, like parts in certain quantities, and thereby preserve their forms and just magnitudes.

DIGESTION, in physics, is the dissolution of the aliment into such minute parts as are fit to enter the lacteal vessels, and circulate with the mafs of blood. Various are the systems and hypotheses framed by physicians and philosophers to account for digestion. Some contend, that it is done by a kind of elixation of the solid and grosser parts of the food in the liquid by the heat of the stomack, and of the adjacent parts, the liver, spleen, &c. Others will have it done by attrition, as if the stomack, by those repeated motions, which are the effects of respiration, rubbed off the minute particles from the grosser matters, and digested the rest against each other, attenuated and dissoloved them.

Others think the bilious juice, others the spirits, chiefly concerned in digestion. Others will have the food dissoloved by a menstruum; but then they are greatly divided as to the nature and origin of this menstruum; some supposing it an acid furnished by the glands of the stomack; others, a nitro-aerial spirit, which, by penetrating the mafs of food, breaks the connexion of the molt solid parts; and others, a saline juice, which divides and volatilizes the parts of the food. Others, again, suppose digestion to be performed by means of a ferment or leaven, which mixing with the aliment, excites an invisible motion in the parts thereof, by which means the parts are attenuated and dissoloved. But these likewise differ in their opinion of this ferment; some taking it to be the remains of the food last digested, which, by its continuance in the stomack, has contracted an acid quality and become a ferment: others take the principles of fermentation to be contained in the aliment itself, which when inclosed in the stomack, heated there, and put in motion, enters on its office of fermentation: others suppose the matter of the ferment supplied by the glands of the stomack; and lastly, others contend for the saliva, and make that the ferment serving principally for the digestion of the food.

Some suppose digestion owing to gentle heat and motion. By this heat and motion, say they, the texture of the nourishment is changed in the bodies of animals; and then the conffuent solid parts are indued with peculiar attractive powers of certain magnitudes, by which they draw, out of the fluids moving through them, like parts in certain quantities, and thereby preserve their forms and just magnitudes.
And, to mention no more, Boerhaave ascribes digestion to the joint action of several of the above-mentioned causes, aided by the expansion of the air contained in the aliment.

Want of Digestion, a diffuse attended with pain, and a sense of weight, with eruptions and copious flatulences from corrupt humours in the stomach.

Digestive, in medicine, such remedies as strengthen and increase the tone of the stomach, and assist in the digestion of foods. To this class belong all stomachics and strengtheners, or corroborants.

Digit, in arithmetic, the twelfth part of the diameter of the fun or moon, is used to express the quantity of an eclipse. Thus an eclipse is said to be of fix digits, when six of these parts are hid.

Dignity, as applied to the titles of noblemen, signifies honour and authority. Such is a dignity which parties are bound to give, in implementing certain contracts or trulls, and which varies according to the nature of the contract; as to which, see Scots Law, title 7. 20. and 28.: Or it signifies certain forms of law, whereby the creditor endeavours to operate his payment, either by affecing the person or estate of the debtor; see title 18.

Dillemburg, a city of the circle of the Upper Rhine in Germany, about forty miles north of Frankfort, and subject to the house of Nassau: E. long. 8° 8', and N. lat. 50° 45'.

Dillenburg, a city of Swabia, in Germany, situated on the Danube, about twenty miles north-east of Ulm: E. long. 10° 26', and N. lat. 48° 40'.

Dillenia, in botany, a genus of the polyandria polygynia class. The calyx consists of five leaves, and the corolla of five petals; and the capsule contains many seeds. There is but one species, a native of Malabar.

Dilute. To dilute a body is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors.

Diphtheria, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus, cellule is a diminutive of cell, globule of globe, hillock of hill.

Dine Violence, in algebra, a kind of imperfect triglyph, console, or the like, with two channels or engravings, either circular or angular.

Digne, a city and bishop's see of Provence in France, fifty-five miles north of Toulon: E. long. 6° 59', and N. lat. 44° 56'.

Dignity, in the canon law, a person who holds a dignity, is a benefice which gives him some pre-eminence over mere priests and canons. Such is a bishop, dean, arch-deacon, prebendary, &c.

Dignity, as applied to the titles of noblemen, signifies honour and authority.

Dijon, the capital of the province of Burgundy, in France, situated on the river Ouche, 140 miles south-east of Paris: E. long. 5° 2', and N. lat. 47° 15'.

Dilatation, in physics, a motion of the parts of a body, by which it is so expanded as to occupy a greater space. This expansive motion depends upon the elastic power of the body, whence it appears that dilatation is different from rarefaction, this last being produced by the means of heat. See Mechanics.

Dilatatores, in anatomy, a name given to several muscles in the human body. See Anatomy, Part II.

Dilemma, in logic, an argument consisting of two or more propositions, which divides the whole into all its parts, or members, by a disjunctive proposition, and then infers something concerning each part, which is finally referred to concerning the whole. See Logic.

Diligence, in Scots law, signifies either that care and attention which parties are bound to give, in implementing certain contracts or trulls, and which varies according to the nature of the contract; as to which, see Scots Law, title 7. 20. and 28.: Or it signifies certain forms of law, whereby the creditor endeavours to operate his payment, either by affecing the person or estate of the debtor; see title 18.

Dillemburg, a city of the circle of the Upper Rhine in Germany, about forty miles north of Frankfort, and subject to the house of Nassau: E. long. 8° 8', and N. lat. 50° 45'.

Dillenburg, a city of Swabia, in Germany, situated on the Danube, about twenty miles north-east of Ulm: E. long. 10° 26', and N. lat. 48° 40'.

Dillenia, in botany, a genus of the polyandria polygynia class. The calyx consists of five leaves, and the corolla of five petals; and the capsule contains many seeds. There is but one species, a native of Malabar.

Dilute. To dilute a body is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors.

Dimension, in geometry, is either length, breadth, or thickness; hence, a line hath one dimension, viz. length; a superficies two, viz. length and breadth; and a body, or solid, has three, viz. length, breadth, and thickness.

Dilute. To dilute a body is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors.

Diligence, in Scots law, signifies either that care and attention which parties are bound to give, in implementing certain contracts or trulls, and which varies according to the nature of the contract; as to which, see Scots Law, title 7. 20. and 28.: Or it signifies certain forms of law, whereby the creditor endeavours to operate his payment, either by affecing the person or estate of the debtor; see title 18.

Dillemburg, a city of the circle of the Upper Rhine in Germany, about forty miles north of Frankfort, and subject to the house of Nassau: E. long. 8° 8', and N. lat. 50° 45'.

Dillenburg, a city of Swabia, in Germany, situated on the Danube, about twenty miles north-east of Ulm: E. long. 10° 26', and N. lat. 48° 40'.

Dillenia, in botany, a genus of the polyandria polygynia class. The calyx consists of five leaves, and the corolla of five petals; and the capsule contains many seeds. There is but one species, a native of Malabar.

Dilute. To dilute a body is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors.

Dimension, in geometry, is either length, breadth, or thickness; hence, a line hath one dimension, viz. length; a superficies two, viz. length and breadth; and a body, or solid, has three, viz. length, breadth, and thickness.

Dilutive, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus, cellule is a diminutive of cell, globule of globe, hillock of hill.

Diorphotheca, in botany. See Calandula.

Dinant, a town of Germany in the bishopric of Liege, situated on the river Meuse, about twelve miles south of Namur: E. long. 4° 50', and N. lat. 50° 18'.

Dingwel, or Dingwal, a parliament-town of Scotland, situated at the west-end of the Cromarty-bay, in the county of Ross: W long. 4° 15', and N. lat. 57° 36'. It classes with Domrock, Wick, and Kirkwall.

Dinkelspiehl, a city of Swabia, about forty miles north of Ulm, E. long. 10° 12', and N. lat. 49° 0'.

Diocese, denotes a particular district, or division, under the direction and government of a bishop.

 Dioctahedria, in natural history, a genus of pentagonal pyramids, joined base to base, without any intermediate column. Of these some have long pyramids, others short and sharp-pointed ones, and others short and obtuse pointed ones; the two former species being found in the hartz-forest, and the last in the mines of Cornwall.

Diodia, in botany, a genus of the tetrandria monogynia class. The corolla consists of one tunnel-shaped petal; and the capsule has two cells, containing as many seeds. There is but one species, a native of Virginia.

Diodon, in ichthyology, a genus belonging to the order of amphibia nantes. The jaws are bony, forked out, and undivided; the aperture or mouth is a transverse
transverse line. The body is every way befet with sharp moveable prickles. It has no belly-fins. There are two species, viz. 1. The atringa, which is spherical, and has triangular prickles. It is a native of India. 2. The tryphex, which is oblong, with cylindrical prickles, and is a native of the Cape of Good Hope.

DIOMEDEA, in ornithology, a genus belonging to the order of anseres. The bill is strait; the superior mandible is crooked at the point, and the lower one is truncated; the nostrils are oval, open, a little prominent, and placed on the sides. There are two species, viz. 1. The exulans, has pennated wings, and three toes on each foot. It is the abbatros of Edwards, and is found in the ocean betwixt the tropics, and at the Cape of Good Hope. It flies pretty high, feeds upon flying fish, and is about the size of a pelican. 2. The demersa, has no quill-feathers on the wings; and the feet have four toes, connected together by a membrane. It is the black penguin of Edwards, about the size of a goose, and is found at the Cape of Good Hope.

DIONYSIA, in Grecian antiquity, solemnities in honour of Bacchus, sometimes called by the general name of orgia; and by the Romans bacchanalia, and libertinia. See Bacchanalia.

DIOMEDES AVIS, in ornithology. See Procellaria.

DIOPTRICS, the science of refractive vision. See Optics.

DIOSCOREA, in botany, a genus of the dioecia class. The calix both of the male and female consists of six segments, and they have no corolla. The female has three styli; the capsule is compressed, has three cells, and contains two membranaceous seeds. There are eight species, none of them natives of Britain.

DIOSMA, in botany, a genus of the pentandria monogynia class. The corolla has five petals; and the nectarary is shaped like a crown, is divided into five segments, and situat above the germen; it has five united capsules; and the seeds are furnished with calyptra. There are nine species, none of them natives of Britain.

DIPSACE, or Teasel, in botany, a genus of the dicotyledon class. The common calix consists of many leaves, and the proper one is above the fruit; and the receptacle is pellucid. There are three species, all natives of Britain, viz. the fullo, or manured teasel; the sylvestris, or wild teasel; and the pilosus, or small wild teasel.

DIPSAS, in zoology. See Coluber.

DIPTOTES, in grammar, are such nouns as have only two cafes, as suspexit, suspexit, &c.

DIPYCHS, in antiquity, a public register, in which were written the names of the consuls and other magistrates among the heathens; and among the Christians, they were a sort of tablets, on one of which were written the names of the deceased, and on the other those of the living patriarchs, bishops, &c. or those who had done any service to the church, for whom prayers were offered, the deacon reading the names at mass.

DIRECTION, in mechanics, signifies the line or path of a body's motion, along which it endeavours to proceed, according to the force impressed upon it. See Mechanics.

DIRECTOR, in commercial polity, a person who has the management of the affairs of a trading company: thus we say, the directors of the India-company, South Sea company, &c. See Company.

The directors are considerable proprietors in the flocks of their respective companies, being chosen by plurality of votes from among the body of proprietors. The Dutch East India company have sixty such directors; that of France, twenty-one; the British East India company, has twenty-four, including the chairman, who may be re-elected for four years successively. These last have salaries of 150l. a-year each, and the chairman 200l. They meet at least once a week, and commonly oftener, being summoned as occasion requires.

DIRECTOR, in surgery, a grooved probe, to direct the edge.
edge of the knife or scissors, in opening sinuses, or fissures, that by this means the adjacent vessels, nerves, and tendons may remain unharmed. See Surgery.

DIRIGENT, or Directrix, a term in geometry, signifying the line of motion, along which the described line or surface is carried in the genesis of any plane or solid figure.

DIS, an infparable article prefixed to divers words, the effect whereof is either to give them a signification contrary to what the simple words have as disoblige, disfavour, &c. or to signify a separation, detachment, &c. as disjoining, distributing.

DISC, in antiquity, a quoit made of stone, iron, or copper, five or six fingers broad, and more than a foot long, inclining to an oval figure, which they hurled in form of a bowl, to a vast distance, by the help of a leathern thong tied round the person's hand and furnished with a handle. Homer has made Ajax and Ulysses great artists at this sport.

Disc, in optics, is the width of the aperture of telescopic glasses, whatever their form be, whether plain, convex, concave, &c.

DISCERNING, or Discrimination, among logicians, a faculty of the mind, whereby it distinguishes between ideas.

DISCIPLE, one who learns any thing from another: thus, the followers of any teacher, philosopher, &c. are called disciples. In the Christian sense, they were followers of Jesus Christ, in general; but in a more restrained sense, the disciples denote those alone who were the immediate followers and attendants on his person, of which there were seventy or seventy-two. The names disciple and apostle are often synonymously used in the gospel-histories; but sometimes the apostles are distinguished from disciples, as perons selected out of the number of disciples, to be the principal ministers of his religion; of these there were only twelve. The Latins kept the festival of the seventy or seventy-two disciples on July 15th, and the Greeks on January 4th.

DISCIPLINE, in a general sense, denotes instruction and government; as military discipline, ecclesiastical discipline, &c.

DISCLAMATION, in Scots law, is that casualty whereby a vassal forfeited his feu to his superior, by disowning or declaiming him as such without sufficient reason. See Scots Law, title 12.

DISCORD, in music, the relation of two sounds which are always and of themselves disagreable, whether applied in succession or concomitance.

DISCOUNT, in commerce, a term among traders, merchants, and bankers. It is used by the two former on occasion of their buying commodities on the usual time of credit, with a condition that the seller shall allow the buyer a certain discount at the rate of so much per cent. per annum, for the time for which the credit is generally given, upon condition that the buyer pays ready money for such commodities, instead of taking the time of credit.

DISCRETE, or Disjunct Proportion, is when the ratio of two or more pairs of numbers or quantities is the same, but there is not the same proportion between all the four numbers. Thus if the numbers 3:6:8:16 be considered, the ratio between 3:6, is the same as that between 8:16, and therefore the numbers are proportional; but it is only discreetly or disjunctly, for 3 is not to 6 as 6 to 8; that is, the proportion is broken off between 8 and 3, and is not continued as in the following continuant proportional,

DISCUS, in antiquity. See Disc.

DISCUSSION, in matters of literature, signifies the clear treating or handling of any particular point, or problem, so as to shew off the difficulties with which it is embarrassed; thus we say, such a point was well discussed, when it was well treated of and cleared up.

DISCUTIENTS, in medicine, are such remedies, as, by their subtlety, dissolve a stagnating or coagulated fluid, and disperse the same without an external solution of continuity.

DISSIDIAPASON, or Diapason, in music, a compound concord, described by F. Parran, in the quadruple ratio of 4:1, or 8:2.

DISSIPATION, or Diapason, a concord in a sextuple ratio of 1:6.

DISDIAPASON-Semi-diapente, a compound concord in the proportion of 16:3.

DISDIAPASON-Diitone, a compound consonance in the proportion of 10:2.

DISEASE, in medicine, that state of a living body, wherein it is deprived of the exercise of any of its functions, whether vital, natural, or animal. See Medicine.

DISFRANCHISING, among civilians, signifies the depriving a person of the rights and privileges of a free citizen or subject.

DISJUNCTIVE, something that separates or disjoins. Thus, or, neither, &c. which in connecting a discourse yet separates the parts of it, are called disjunctive conjunctions.

DISLOCATION, in surgery. See Luxation.

DISMA, a town of Japan, separated from Nanquefaque, only by a narrow canal. The Dutch have a very fine magazine there.

DISPENSARY, or Dispensatory, denotes a book containing the method of preparing the various kinds of medicines used in pharmacy. Such are those of Bauderon, Quercetan, Zwelfer, Charas, Bates, Me-fue, Salmon, Lemery, Quincy, &c. but the latest and most esteemed are the Edinburgh and London Dispensatories.

DISPENSARY, or Dispensatory, is likewise a magazine or office for selling medicines at prime cost to the poor.
**DISPENSATION**, in law, the granting a license of doing some certain action that otherwise is not permitted.

**DISPLAYED**, in heraldry, is understood of the disposition of any affair, in order to discourse clearly about it.

**DISPOSITION**, in rhetoric, the placing words in such an order as contributes most to the beauty and sometimes even to the strength of a discourse.

**DISPOSITION**, in Scots law, is that deed or writing by which a person conveys his lands or tenements.

**DISPONDEE**, in the Greek and Latin poetry, a double spondee or foot, consisting of four long syllables, as μακενατος κολαζευμένος.

**DISPOSITION**, in law, a unlawful disposing a person of his lands or tenements.

**DISTANCE** is measured by the chain, by reason of some river, or the like, extending a thing to its full length or breadth.

**DISTILLATION**, in chemistry, the act of drawing off the spirituous, aqueous, oleaginous, or saline parts of a mixed body from the greater and more terrestrial parts by means of fire, and collecting and condening them again by cold. The end of distillation is of two kinds: the first, and by far the most general, is for the separation of some acquired bodies from others with which they were mixed, as in the case of vinous and volatile spirits, and essential oils; the other is for the quicker and more effectual combination of such bodies, whose mixture is alighted by a boiling heat, as in the case of spirit nitrat. dulce. See Chemistry.

The method of distilling malt-wath, or a fermented mixture of meal and malt, for spirit. Fill two thirds of a still, first moistened by the steam of boiling water, with malt-wath; immediately clap on the head, and lute it down; there will soon run a spirituous inflammable liquor. Thus is obtained what the malt-distillers call a malt low-wine; what comes over after the spirit falls off from being proof, is called faults. This experiment may be rendered general, with flight variation; for any wine, beer, or fermented liquor from sugar, treacle, or fruits, &c. be thus treated, it affords a spirit differing only according to the nature of the subject; but none of them will afford the least inflammable spirit without a previous fermentation. The requisite cautions for succefs are, 1. That the fermentation be well performed, 2. That it be gently distilled, with a soft well regulated fire. 3. That the greater oil, apt to rise along with the spirit, be let out by flannel under the nose of the worm. These cautions observed, the low-wines will be pure and vinous.

The method of distilling the lower wines into proof spirits for sale. The lower wines of the last processes, distilled in a bath-heat, give a higher rectified spirit than before, which being let down with fair water to a certain size or standard, called proof, is what the malt-distillers understand by proof-goods, or their rectified malt-spirit.

The inconveniences of this art, on account of the many large vessels required, which increase the labour and price of the commodity, might perhaps be remedied by the introduction of a new art, subervient to the malt-distillers, and confined to the boiling down the malt-wort to a rob; whereas it was to be wished, that those who were filled in this branch of distillation...
DISTRICT, in geography, a part of a province, divided into equal parts. See Arithmetic.

DITTONY, in botany. See Dictamnus.

DITTO, usually written D°, in books of accounts, an Italian word, signifying the aforementioned.

DIVAL, in heraldry, the herb nightshade, used by such as blazon by flowers and herbs, instead of colours and metals, for fable, or black.

DIVALLIA. See Angeronalia.

DIVAN, a council-chamber, or court of justice, among the eastern nations, particularly the Turks.

DIVAN-BEGHI, the superintendent of justice in Persia, whose place is the last of the six ministers of the second rank, who are all under the athenaumader, or first minister. To this tribunal of the divan-beghi he appeals from sentences passed by the governors: he has a fixed stipend of 50,000 crowns for administering justice; all the serjeants, uffers, &c. of the court, are in his service; he takes cognizance of the criminal causes of the chams, governors, and other great lords of Persia, when accused of any fault. There are divan-beghis not only at court and in the capital, but also in the provinces and other cities of the empire. The aherman is the sole rule of his administration of justice, which also he interprets at pleasure. He takes no cognizance of civil causes, but all differences arising between the officers of the king’s household, and between foreign ministers, are determined by him.

DIVANDUROW, the name of seven islands which lie a league north of the Maldives, and twenty-four from the coast of Malabar, almost opposite to Cananor.

DIVER, in ornithology. See Colymbus.

DIVERGENT, or DIVERGING LINES, in geometry, are those which continually recede from each other.

DIVERGENT RAYS, in optics, are those which going from a point of the visible object, are difpersed, and continually depart one from another, in proportion as they are removed from the object: in which sense it is opposed to convergent. See Optics.

DIVERSION, in military affairs, is, when an enemy is attacked in one place where they are weak and unprovided, in order to draw off their forces from another place where they have made or intend to make an incursion. Thus the Romans had no other way in their power of driving Hannibal out of Italy, but by making a diversion in attacking Carthage.

DIVESTING, or DIVESTITURE, in law, is used for the act of surrendering one’s effects.

DIVIDEND, in arithmetic, the number proposed to be divided into equal parts. See Arithmetic.

DIVIDEND of stocks, is a share or proportion of the interest of stocks erected on public funds, as the southsea, &c. divided among and paid to the adventurers half yearly.

DIVINATION, the knowledge of things obscure, or future, which cannot be obtained by any natural means. It was a received opinion among the heathens, that the gods were wont to converse familiarly with some men, whom they endowed with extraordinary powers, and admitted to the knowledge of their councils and designs. Plato, Aristotle, Plutarch, Ciceron and others, divide divination into two sorts or species, viz. natural and artificial. The former was so called, because not attained by any rules or precepts of art, but inspired or inspired into the diviner, without his taking any further care about it, than to purify and prepare himself for the reception of the divine affluence. Of this kind were all those who delivered oracles, and foretold future events by inspiration, without observing external signs or accidents. The second species of divination was called artificial, because it was not obtained by immediate inspiration, but was the effect of experience and observation.
obervation. Such was southsaying, as depending up
on human art and invention, which however was sup-
pofed not to be altogether destitute of divine direction
and concurrence, and such was divination by lots. Of
this sort there were various kinds, as by facrifices, en-
trails, flame, cakes, flour, wine, water, augury, birds,
lots, verfes, omens, &c.
DIVINE, fomething relating to God.
DIVING, the art of defcending under water, to con-
derate depths, and abiding there a competent time; the
ufes of which are confiderable, particularly in fhilling for
pearls, corals, fponges, wrecks of fhips, &c. See
Pneumatics.
DIVINITY, properly fignifies the nature, quality, and
offence of God.
DIVINITY is alfo ufed in the fame fenfe with theo-
logy.
DIVISIBILITY, that property by which the particles
of matter in all bodies are capable of feparation or
difunion from each other. See Mechanics.
DIVISION, in general, is the separating a thing into
two or more parts.
DIVISION, in algebra. See Vol. I. p. 82.
DIVISION, in algebra. See Vol. I. p. 82.
DIU RESIS, in medicine, an excretion of urine.
whence,
DIURETICS, in pharmacy, fuch simples as increase
the dicharge of urine, or which are suppofted to have
a power of removing obftruftions in the urinary paffages.
DIURNAL, in altronomy, fomething relating to the
day; in opposition to nocturnal, which regards the
night.
DIURER, or St. Diuier, a city of Champaign in France,
situated on the river Marne, about forty-five miles
north-eaft of the city of Troy: E. long. 5°, and N. lat.
25° 15'.
DIVORCE, is the legal dissolution of a marriage
which can be obtained at the fuit of the injured party, upon
the grounds of adultery or wilful defeftion proved a-
gainft the other. See Scots Law, title 6.
DIURESIS, in medicine, an excretion of urine:
whence,
DIURETICS, in pharmacy, fuch simples as increase
the dicharge of urine, or which are suppofted to have
a power of removing obftruftions in the urinary paffages.
DIURNAL, in altronomy, fomething relating to the
day; in opposition to nocturnal, which regards the
night.
DIURNAL, in altronomy, fomething relating to the

night.
DIVORCE, is the legal dissolution of a marriage
which can be obtained at the fuit of the injured party, upon
the grounds of adultery or wilful defeftion proved a-
gainft the other. See Scots Law, title 6.
DIVORCE, is the legal dissolution of a marriage
which can be obtained at the fuit of the injured party, upon
the grounds of adultery or wilful defeftion proved a-
gainft the other. See Scots Law, title 6.
DIVORSBURG, a town of the United Netherlands, in
the province of Guelderland, situated on the river Yf-
fel, about nine miles south of Zutphen: E. long. 6°,
and N. lat. 52°.
DO, in music, a note of the Italian fcale, correfponding
to ut of the common gamut. See Music.
DOB-CHICK, in ornithology. See Cylamus.
DOB-CHICK, in ornithology. See Cylamus.
DOBLAC, a town of the Tyrolefe, in Germany, fitua-
ted on the river Marne, about forty-five miles
north-eaft of Troyes: E. long. 5°, and N. lat. 48°
32'.
DIZIER, or St Dizier, a city of Champaign in France,
situated on the river Marne, about forty-five miles
north-eaft of the city of Troyes: E. long. 5°, and N. lat.
48°
32'.
DIZOSTOS, in botany. See Euphorbia.
DIZINESS, in medicine, See Verrigo.
DO, in music, a note of the Italian fcale, correfponding
to ut of the common gamut. See Music.
DOB-CHICK, in ornithology. See Cylamus.
DOB-CHICK, in ornithology. See Cylamus.
DOB-CHICK, in ornithology. See Cylamus.
DODARTIA, in botany, a genus of the didynarriia an-
capfule is roundifh, and has two ceils; There ate
two fpecies, none of them natives of Britain.
DODDER, in botany. See Cuscuta.
DODCAGON, in geometry, a regular polygon con-
ffitting of twelve equal fides and angles.
DODCEHEDRON, in geometry, one of the platonic
bodies, or regular fol's, contained under twelve e-
qual and regular pentagons.
DODCANDRIA, in the Linnasan fyftem of botany.
The calix has five teeth: the inferior labium is much lefs than the superior; and the
capsule is roundifh, and has two ceils. There ate
two fpecies, none of them natives of Britain.
DODDER, in botany. See Cuscuta.
DODCAGON, in geometry, a regular polygon con-
ffitting of twelve equal fides and angles.
DODCEHEDRON, in geometry, one of the platonic
bodies, or regular fol's, contained under twelve e-
qual and regular pentagons.
DODCANDRIA, in the Linnasan fyftem of botany.
The calix has five teeth: the inferior labium is much lefs than the superior; and the
capsule is roundifh, and has two ceils. There ate
two fpecies, none of them natives of Britain.
DODDER, in botany. See Cuscuta.
DODCAGON, in geometry, a regular polygon con-
ffitting of twelve equal fides and angles.
DODCEHEDRON, in geometry, one of the platonic
bodies, or regular fol's, contained under twelve e-
qual and regular pentagons.
DODCANDRIA, in the Linnasan fyftem of botany.
The calix has five teeth: the inferior labium is much lefs than the superior; and the
capsule is roundifh, and has two ceils. There ate

bodies, or regular fol's, contained under twelve e-
qual and regular pentagons.
DODCANDRIA, in the Linnasan fyftem of botany.
DOG-DAYS. See Canicular.
Dog’s fennel, in botany. See Cotula.
Dog’s mercury, in botany. See Mercurialis.
Dog’s rose. See Rosa.
Dog’s stones, in botany. See Orchis.
Dog’s tail, in botany. See Cynosurus.
Dog’s tongue, in botany. See Cynoglossum.
Dog’s tooth, in botany. See Erythronium.

DOGMATISTS, a fed of ancient physicians, of which

DOGMATICAL, something belonging to a doctrine or opinion. A dogmatical philosopher is one who asserts things positively; in opposition to a sceptic, who doubts of every thing.

DOGMATISTS, a sect of ancient physicians, of which Hippocrates was the first author. They are also called logici, logicians, from their using the rules of logic in subjects of their profession. They laid down definitions and divisions reducing diseases to certain genera, and those genera to species, and furnishing remedies for them all; supposing principles, drawing conclusions, and applying those principles and conclusions to particular diseases under consideration: in which sense the dogmatists stand contradistinguished from empirics and methodists. They reject all medicinal virtues that they think not reducible to manifest qualities: but Galen hath long ago observed of such men, that they must either deny plain matter of fact, or assign but very poor reasons and causes of many effects they pretend to explain.

DOLE, in our ancient customs, signified a part or portion, most commonly of a meadow, where several persons have shares. It also still signifies a distribution or dealing of alms, or a liberal gift made by a great man to the people.

DOLE, in Scots law, signifies a malevolent intention. It is essential in all crimes that it be committed intentionally, or by an act of the will; hence the rule, Crimen dolo contrariatur. See SCOTS LAW, title 33.

DOLICHOS, in botany, a genus of the diadelphous dcandria class of plants, the corolla of which is papilionaceous; the vexillum is roundish, large, emarginated, and wholly reflected; the fruit is a large, acuminate, oblong pod, composed of two valves, and containing two cells; the seeds are numerous, elliptical, and frequently compressed. There are twenty-five species, none of them natives of Britain.

DOLLAR, a silver coin current in several parts of Germany and Holland. There are various species of dollars, as the rix-dollar, the semi-dollar, the quarter-dollar, &c.

DOLPHIN, in ichthyology. See Delphinus.

DOM, or Don, a title of honour, invented and chiefly used by the Spaniards, signifying, sir, or lord.

This title, it seems, was first given to Pelayo, in the beginning of the VIIIth century. In Portugal no person can assume the title of don, without the permission of the king, since it is looked upon as a mark of honour and nobility.

DOMAIN, the inheritance, estate, or possession of any one. See Demesne.

DOME, in architecture, a spheric roof, or a roof of a spheric form, raised over the middle of a building, as a church, hall, pavilion, vestibule, stair-case, &c. by way of crowning.

DOME, or DOOM, signifies also a sentence, judgment, or decree.

DOMESDAY, or DOOMSDAY-BOOK, a very ancient record made in the time of William the Conqueror, which now remains in the exchequer, and consists of two volumes, a greater and a less; the greater contains a survey of all the lands in most of the counties in England, and the less comprehends some counties that were then surveyed. The book of domesday was begun by five justices, assigned for that purpose in each county, in the year 1081, and finished in 1086. It was of that authority, that the conqueror himself submitted, in some cases wherein he was concerned, to be determined by it. Camden calls this book the tax-book of king William; and it was farther called Magna rolla.

There is likewise a third book of Domeday, made by command of the conqueror; and also a fourth, being an abridgment of the other books.

DOMESTIC, any man who acts under another, serving to compose his family; in which he lives, or is supposed to live, as a chaplain, secretary, &c. Sometimes domestick is applied to the wife and children, but very seldom to servants, such as footmen, lackeys, porters, &c.

DOMICILE, in Scots law, is the dwelling place where a person lives with an intention to remain. See SCOTS LAW, title 2.

DOMIFYING, in astrology, the dividing or distributing the heavens into twelve houes, in order to erect a theme, or horoscope, by means of six great circles, called circles of position.

There are various ways of domifying: that of regi-montanus, which is the most common, makes the circles
DONATISTS, Christian schismatics in Africa, who
were a voluntary gift. DOCTRINE, in Scots law, signifies a voluntary gift.
DOMINO, or St Domingo, the capital of the island of Hispaniola, the fee of an archbishop, and the most
ancient royal audience in America: W. long. 70°, N. lat. 19° 20'.
DOMINICA, one of the Caribbee-islands, subject to
Britain: W. long. 61° 20', N. lat. 16°.
DOMINICAL LETTER. See Astronomy, p. 495.
DOMINICANS, an order of religious, called in France
Jacobsins, and in England Black-friers, or preaching-friers. This order founded by St Dominic, a native
of Spain, was approved of by Innocent III. in 1215, and
confirmed by a bull of Honorius III. in 1216. The
design of their institution was to preach the gospel,
convert heretics, defend the faith, and propagate
Christianity. They embraced the rule of St Augustin,
to which they added statutes and constitutions, which
had formerly been observed either by the Carthusian or
Premonstratenses. The principal articles enjoined
perpetual silence, abstinence from flesh at all times,
habits of woolen, rigorous poverty, and several o-
other austerities. This order has spread into all the
parts of the world. It has produced a great number
of martyrs, confessors, bishops; and they reckon three
cardinals, 150 abbots, and 800 bishops of their order, besides the masters of the sacred
palace, who have always been Dominicans. They are
inquirers in many places.
DOMINION, in the civil law, signifies the power to
use or dispose of a thing as we please.
DOMINIUM eminent, in Scots law, the right which a
superior retains in the lands, notwithstanding the feudal
grant to his vassal. See Scots Law, title 8.
DOMINIUM directum, in Scots law, the right which a
superior retains in the lands, notwithstanding the feudal
grant to his vassal. See Scots Law, title 12.
DOMINIUM utile, in Scots law, the right which the
vassal acquires in the lands by the feudal grant from
his superior. See Scots Law, title 13.
DON, the name of two rivers; one very large, which,
after dividing Asia from Europe, falls into the Palus
Meotis; the other in the county of Aberdeen in Scot-
land.
DONATION, in Scots law, signifies a voluntary gift.
Donation between husband and wife; see Scots Law,
title 6.—When revocable; Not presumed in du-
bio;—Donations mortis causa: See title 22.
DONATISTS, Christian schismatics in Africa, who
took their name from their leader Donatus. A scert
hatred against Caecilian, elected bishop of Carthage ab-
out the year 311, excited Donatus to form this sect.
He accused Caecilian of having delivered up the sacred
books to the Pagans, and pretended that his election
was void, and all his adherents heretics. He taught
that baptism administered by heretics was null, that
every church but the African was become prostituted,
and that he was to be the restorer of religion. Some
accuse the Donatists of Arianism. Constantius and
Honorius made laws for their banishment, and Theode-
lius and Honorius condemned them to grievous
maltreatment.
DONATIVE, a gratuity, or present made to any per-
son.
Donative among the Romans was properly a gift
made to the soldiers, as congiarium was that made to
the people.
DONATORY, in Scots law, that person to whom the
king bequeaths his right to any forfeiture that has fallen
to the crown.
DONAWERT, a city of Bavaria in Germany, forty
miles north-west of Ulm: E. long. 10° 40', N. lat.
48° 40'.
DONAX, a genus of insects belonging to the order
of vermif tegnata. It is an animal of the oyster kind;
and the shell has two valves, with a very obtuse mar-
gin in the fore-part. There are ten species, principi-
ally distinguished by the figure of their shells.
DONCASTER, a market-town of Yorkshire, thirty
miles south of York. See York.
DONOR, in law, the person who gives lands or ten-
ements to another in tail, &c. to whom such lands,
&c. are given is the donee.
DONZY, a town of France in the Orleannois: E. long.
3° 16', N. lat. 47° 17'.
DOOR, in architecture. See Architecture, p. 356.
DORCHESTER, the capital of Dorsetshire, situated on
the river Frome, six miles north of Weymouth: W.
long. 2° 35', and N. lat. 50° 40'. It gives the title
to the crown.
DORDONNE, a river of France, which runs through
the province of Guienne, and falls into the Garonne,
twelve miles below Bourdeaux.
DOR, or JOHN DORE, in ichthology. See ZEUS.
DORIA, in botany. See Solidago.
DORIC, in general, any thing belonging to the Dori-
ans, an ancient people of Greece, inhabiting near
mount Parnassus.
DORIC DIALECT, one of the five dialects, or manners of
speaking which were principally in use among the
Greeks.
It was first used by the Lacedemonians, particularly
those of Argos; afterwards it passed into Epirus, Lyb-
ia, Sicily, and the islands of Rhodes, Crete, &c.
DORIC MODE, in music, the first of the authentic modes
of the ancients; its character is to be severe, temper-
ed with gravity and joy, and is proper upon religious
occasions, as also to be used in war. It begins D, la,
fol, re. Plato admires the music of the doric mode,
ing masculine; and on this account allows it in his commonwealth. The ancients had like-wis their sub-doric or hypodoric mode, which was one of the plagal modes. Its character was to be very grave and fol-lem: it began with re, a fourth lower than the doric.

DORMANT, in heraldry, is used for the posture of a lion, or any other beast, lying along in a sleeping-at-titude, with the head on the fore-paws; by which it is distinguished from the couchant, where though the beast be lying, yet he holds up his head.

DORMER, in architecture, signifies a window made in the roof of an house, or above the entablature, being raised upon the rafters.

DORMITORY, a gallery in convents or religious houses, divided into several cells, in which the religious sleep or lodge.

DORONICIS affinis, in botany. See Gerbera.

DORONICUM, leopard's bane, in botany, a ge-

DORSAL, an appellation given to whatever belongs to the posterior part of the trunk of the body, from the neck to the buttocks. See Anatomy.

DORT, or DORPAT, a city of Livonia, about fifty miles south of Narva: E. long. 27° 25', and N. lat. 58°.

DORSAL muscles. See Anat. Part. II.

DORSIFEROUS plants, among botanists, such as are of the capillary kind, without stalks, and which bear their seeds on the back-side of their leaves.

DORSTENIA, in botany, a genus of the tetrandra monogynia class. The common receptacle consists of one fleshly leaf, in which the solitary seeds are contained. There are four species, none of them natives of Britain.

DORPT, or Dorpat, a city of Livonia, about fifteen miles south of Narva: E. lon. 27°, and N. lat. 50° 25'.

DORSAL muscles. See Anatomy.

DOUBTING, the act of withholding our assent from any proposition, on suspicion that we are not thoroughly apprised of the merits thereof; or from not being able peremptorily to decide between the reasons for and against it.

DOUCINE, in architecture, a moulding concave above and convex below, serving commonly as a cymatium to a delicate cornice. It is likewise called guila.

DOVE, in ornithology. See Columba.

Dove, in geography, the name of a river dividing Derbyshire

ver married. Dositheus, their founder, being diffati-

fied among the Jews, retired to the Samaritans, who were reputed heretics, and invented another sect; and to make it more authentic, he went into a cave, where, by too long abstinence, he killed himself. The name of Dositheans was also given to some of the disciples of Simon Magus.

DOTTEREL, in ornithology. See Charadrius.

DOUY, a fortified city of the French Netherlands, situated on the river Scrape, about fifteen miles south of Lille: E. lon. 5°, and N. lat. 50° 25'.

DOUBLE FISHY, or FISCE, in heraldry, the denomina-
tion of a cross, when the extremity has two points, in contradistinction to FICHE, where the extremity is sharpened away to one point. See Plate LXVIII. fig. 8.

DOUBLETS, a game on dice within tables: the men, which are only fifteen, being placed thus: upon the ace, nine, and quater points, there stand three men a-piece; and upon the trey, duce, and ace, only two.

He that throws highest hath the benefit of throwing first, and what he throws he lays down, and doth the other: what the one throws, and hath not, the other lays down for him, but on his own account; and thus they do till all the men are down, and then they bear. He that is down first bears first, and will double the game, if the other throws not doublets to overtake him; which he is sure to do, since he advances or bears as many as the doublets make, viz. eight for two fours.

DOUBLING, in the military art, is the putting two ranks or files of soldiers into one. Thus, when the word of command is, double your ranks, the second, fourth, and fifth ranks march into the first, third, and fifth, so that the six ranks are reduced to three; and the intervals between the ranks become double what they were before.

Doubling, among hunters, who say that a hare doubles, when the keeps in plain fields, and winds about to deceive the hounds.

Doubling, in the menage, a term used of a horse, who is said to double his reins, when he leaps several times together, to throw his rider: thus we say, the rame-"g" doubles his reins, and makes pontevis.

Doubling a cape or point, in navigation, signifies the coming up with it, passing by it, and leaving it behind the flip.

Doubling, in heraldry, the linings of robes and mant-les of state, or of the mantlings in achievements.

DOUBLON, or Dubloon, a Spanish and Portuguese coin, being the double of a pistole. See Pistole.

DOUBTING, the act of withholding our assent from any proposition, on suspicion that we are not thoroughly apprised of the merits thereof; or from not being able peremptorily to decide between the reasons for and against it.

DOUCINE, in architecture, a moulding concave above and convex below, serving commonly as a cymatium to a delicate cornice. It is likewise called guila.

DOVE, in ornithology. See Columba.

Dove, in geography, the name of a river dividing Derbyshire
byshire from Staffordshire: also of a town of the Or-
leansois, in France, about twenty miles south east of
Angers.

**Dove-tailing**, in carpentry, is the manner of fatten-
ing boards together by letting one piece into another,
in the form of the tail of a dove. The dove-tail is the
strongest of the assemblages or jointings, because
the tenon, or piece of wood which is put into the o-
ther, goes widening to the extreme, so that it cannot
be drawn out again, by reason the extreme or tip is
bigger than the hole.

**DOVER**, a borough and port-town of Kent, situated
on a rock, opposite to Calais in France, with a strong cas-
tle: E. long. 25°, and N. lat. 51° 10'.

Dover gives the title of duke to the dukes of Queens-
bury, a branch of the noble family of Douglas; and
fends two members to parliament, styled barons of the
cinque ports, whereby Dover is the chief.

**DOUGLAS**, a port-town, and the best harbour in the
Down, in geography, the capital of a county of the
Down, in geography, the capital of a county of the
dowry, that portion which the law allows a widow out
of the lands of her husband, after his decease.

**DOVER*, a widow endowed, is a title applied to the
widows of princes, dukes, earls, and persons of high
rank only.

**DOWER**, that portion which the law allows a widow out
of the lands of her husband, after his decease.

**DOWN**, in geography, the capital of a county of the
fame name in the province of Ulster, in Ireland: W.
long. 5° 50', and N. lat. 54° 23'.

**DOWNETON**, or Dunkton, a borough-town of
Downham, a market-town of Norfolk, ten miles
south of Lynn, famous for its good butter; there be-
sends two members to parliament.

**DOWNHAM**, a market-town of Norfolk, ten miles
south of Lynn, famous for its good butter; there be-
ing a thousand, and sometimes two thousand firkins
bought here every Monday, and sent up the river
Ouse to Cambridge, from whence it is conveyed to
London, in the Cambridge wagons.

**DOWNS**, a famous road near Deal, in Kent, whereboth
the outward and homeward bound ships frequently
make some stay; and squadrons of men of war ren-
devous in time of war.

It affords excellent anchorage, and is defended by
the castles of Deal, Dover, and Sandwich.

**DOWRY**, the money or fortune which the wife brings
her husband in marriage: It is otherwise called
marriage goods, and differs from dower.

**DOXOLOGY**, an hymn used in praise of the Almighty,
distinguished by the title of greater and lesser.

The lesser doxology was anciently only a single sen-
tence, without refponse, running in these words, Glory
be to the Father, and to the Son, and to the Holy
Ghost, world without end. Amen. Part of the latter
clause, As it was in the beginning, is now, and ever
shall be, was infected some time after the first com-
position. Some read this ancient hymn, Glory be to the
Father, and to the Son with the Holy Ghost. Others,
Glory be to the Father in or by the Son, and by the
Holy Ghost. This difference of expression occasioned
no disputes in the church, till the rife of the Arian he-
rely; but when the followers of Arius began to make
use of the latter as a distinguishing character of their
party, it was entirely laid aside by the catholics, and
the use of it was enough to bring any one under sus-
picion of heterodoxy. The doxology was used at the
close of every solemn office. The western church re-
peated it at the end of every psalm, and the eastern
church at the end of the last psalm. Many of their
prayers were also concluded with it, particularly the
solemn thanksgiving, or consecration prayer at the eu-
charist. It was also the ordinary conclusion of their
sermons. The greater doxology, or angelic hymn, was like-
wise of great note in the ancient church. It began
with these words, which the angels sung at our Savi-
our's birth, Glory be to God on high, &c. It was chiefly
used in communion service, and in mens private devo-
tions. Both the doxologies have a place in the church
of England, the former being repeated after every
psalm, and the latter used in the communion ser-
vice.

**DRABA**, in botany, a genus of the tetradynd nium sili-
culofa class. The pod is entire and somewhat oval, with
plain valves, and a parallel diffepimentum; it has
no stylos. There are five species, three of them natives
of Britain, viz. the verna, or common whitlow-grafs;
the muralis, or speedwell-leaved whitlow-grafs; and
the incana, or wreathen-podded whitlow-grafs.

**DRABS**, in the salt-works, a kind of wooden boxes for
holding the salt when taken out of the boiling pan, the
bottoms of which are made thriving or inclining for-
wards, that the briny moisture of the salt may drain off.

**DRACHIM**, a Grecian coin of the value of seven pence
three farthings.

**DRACO**, the dragon, in zoology, a genus belonging
to the order of amphibia reptilia. The characters of
which are these: It has four legs, a cylindrical tail,
and two membranaceous wings, radiated like the fins of a
fish, by which he is enabled to fly, but not to any
great distance at a time. There are two species, 1. The
volans, or flying dragon, with the wings entirely di-
flected from the fore-legs; it is found in Africa and the
East Indies. 2. The praepus, with the wings fixed to
the fore-legs; it is a native of America. They are
both harmless creatures, and feed upon flies, ants, and
small insects.

**DRACO VOLANS**, in meteorology, a fiery exhalation, fre-
fquent in marshy and cold countries.

It is most common in summer, and though princi-
pally seen playing near the banks of rivers, or in bag-
gy places, yet sometimes mounts up to a considerable
height in the air, to the no small terror of the amazed
beholders; its appearance being that of an oblong,
sometimes roundish, fiery body, with a long tail. It is
entirely harmless, frequently flicking to the hands and
cloaths of people without injuring them in the least.

**DRACO**, in astronomy, a constellation of the northern

**DRACOCEPHALUM**, dragon's head, in botany,
a genus of the didynamia gymnospermia class. The
faux of the corolla is inflated, and the superior labium is concave. There are 13 species, none of them natives of Britain.

DRACONIC MONTH, the time of one revolution of the moon, from her ascending node, called caput draconis, to her return thither.

DRACONIUM, DRAGONS, in botany, a genus of the gynandria polyandria class. The spatha is shaped like a boat; the spadix is covered; it has no calix; the corolla consists of five petals; and the berry contains many seeds. There are five species, all natives of the Indies.

DRACUNULI, in medicine, small long worms, which breed in the muscular parts of the arms and legs, called Guine worms. See Medicine.

DRACUNULUS, in botany. See Arum.

DRAGOMAN, DROGMAN, or DRUGMAN, a name given in the Levant to the interpreters kept by the ambassadors of Christian nations, residing at the Porte, to assist them in treating of their master's affairs.

DRAGON, in zoology. See Draco.

DRAGON'S BLOOD, in pharmacy, a resin brought from the East-Indies, either in oval drops, wrapped up in flag leaves, or in large masses composed of smaller tears. The fine dragon's blood of either sort breaks smooth, free from any visible impurities, of a dark red colour, which changes upon being powdered into an elegant bright crimson. It diffolves in pure spirit, and tinges a large quantity of the menstruum of a deep red colour; it is also soluble in oils. It is usually looked upon as a gentle astringent, and is sometimes prescribed against seminal gleet, the fluor albus, and other fluxes.

DRAGON-FLY. See Libella.

DRAGON-HELL. See Patella.

DRAGONS, in botany. See Dracuncium.

DRAGONNE'E, in heraldry; a lion dragonné is where a dragon is placed on horseback, who sometimes fights or marches on foot, as occasion requires.

Dragoons are divided into brigades, as the cavalry, and each regiment into troops; each troop having a captain, lieutenant, cornet, quarter-mater, two sergeants, three corporals, and two drums. Some regiments have hautboys: they are very useful on any expedition that requires dispatch, for they can keep pace with the cavalry, and do the duty of infantry: they encamp generally on the wings of the army, or at the passes leading to the camp; and sometimes they are brought to cover the general's quarters: they do duty on the generals of horse and dragoons, and march in the front and rear of the army.

DRAGS, in the sea-language, are whatever hangs over the ship in the sea, as shirteri, coats, or the like; and boats, when towed, or whatever else that, after this manner, may hinder the ship's way when the sails, are called drags.

DRAINS, a name given, in the ten countries, to certain large cuts or ditches of twenty, thirty, forty, fifty, or upwards, cut through the marshy ground to some river or other place capable of discharging the water they carry out of the fen-lands. See Agriculture.

DRAKE, in ornithology, the male of the duck-kind. See Anas.

DRAMA, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind.

The principal species of the drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See Composition.

DRAMATIC, an epithet given to pieces written for the stage. See Composition.

DRANK, among farmers, a term used to denote wild oats, which never fail to infest worn-out lands; so that when plowed lands run to these weeds and shuffles, the farmer knows it is high time to follow them, or else to sow them with hay-feed, and make pasture of them.

DRAPERY, in sculpture and painting, signifies the representation of the clothing of human figures, and also hangings, tapestry, curtains, and most other things that are not carnations or landscapes. See Painting.

DRAUGHT, in trade, called also cloff or clouch, is a small allowance on weighable goods, made by the king to the importer, or by the seller to the buyer, that the weight may hold out when the goods are weighed again.

The king allows 1 lb draught for goods weighing no less than 1 Cwt. 2 lb for goods weighing between 1 and 2 Cwt. 3 lb for goods weighing between 2 and 3 Cwt. 4 lb from 3 to 10 Cwt. 7 lb from 10 to 18 Cwt. 9 lb from 18 to 30, or upwards.

DRAUGHT-HOOKS, are large hooks of iron, fixed on the cheeks of a cannon-carriage, two on each side, one near the trunnion hole, and the other at the train, distinguished by the name of fore and hind draught-hooks. Large guns have draught-hooks near the middle trun- tum, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forwards, by men with strong ropes, called draught-rope. See Agriculture.

DRAUGHT-HORSE, in farming, a sort of coarse-made horse, defined for the service of a cart or plough. See Equus.

DRAW, in the sea-language. A ship is said to draw so much water, according to the number of feet the finks into it; so that if a ship sink into the water eighteen feet perpendicularly, she is said to draw eighteen feet water; and according as the draws more or less, she is said to be of more or less draught.

DRAW-BACK, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandise, that have paid duty on importation.
The oaths of the merchants importing and exporting are required to obtain the drawback of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and these may be made by the agent or husband of any corporation or company, or by the known servant of any merchant usually employed in making his entries and paying his customs. In regard to foreign goods entered outward, if less quantity or value be fraudulently shipped out than is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no drawback to be allowed for the same. Foreign goods exported by certificate, in order to obtain the drawback, not shipped or exported, or re-landed in Great Britain, unless in case of necessity to serve the benefit of the drawback, and are forfeited, or their value, with the vessels, horses, carriages, &c. employed in the re-landing thereof; and the persons employed in the re-landing them, or by whose privilege they are re-landed, or into whose hands they shall knowingly come, are to forfeit double the amount of the drawback. Officers of the customs conniving at, or assisting in any fraud relating to certificate-goods, besides other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail or mainprice; as are also nailers, or persons belonging to the ships employed therein. Bonds given for the exportation of certificate-goods to Ireland, must not be delivered up, nor drawback allowed for any goods, till a certificate under the hands and affeals of the collector or comptroller, &c. of the customs be produced, testifying the landing.

The computation of what is to be drawn back upon the exportation of foreign goods, may be seen under their respective heads.

**Draw-bridge.** A bridge made after the manner of a floor, to draw up, or let down, as occasion serves, before the gate of a town or castle.

**Drawing.** In general, denotes the action of pulling out, or haling along: thus, we read of tooth-drawing, wire-drawing, &c.

**Drawing,** the art of representing the appearances of objects by imitation, or copying without the assistance of mathematical rules.

The general precepts for drawing are as follow:

1. Begin with plain geometrical figures, as lines, angles, triangles, polygons, arches, circles, ovals, cones, cylinders, and the like, being the foundation of all other proportions. The circle is of use in the several orbicular forms, as the sun, moon, globes, &c. the oval, in giving a just proportion to the face and mouth; and the square, confines a picture you are to copy, &c. the triangle is of use in drawing a side or half face; angles and arches, in perspective; and the polygon, in ground-plots, fortifications, &c. the cone, in spires, steeles, tops of towers, &c. the cylinder, in columns, pillars, pilasters, &c. See Perspective.

2. Having brought your hand to be fit and ready in general proportions, accustom yourself to give every object its due shade, according to its concavity or convexity, and to elevate or depress the same, as the object appears either nearer or farther off the light.

3. The second practice of drawing consists in forming fruits, as apples, pears, cherries, &c. with their leaves; the imitation of flowers, as roses, tulips, carnations, &c. herbs, trees, &c. of different kinds.

4. The third, in the imitation of beasts, fowls, fishes, &c.

5. The fourth practice of drawing consists in the imitation of the body of man, with all its lineaments, as head, nose, eyes, ears, cheeks, arms, and shadows, all exactly proportioned both to the whole and to one another.

6. The fifth is in the drapery, in the imitation of cloathing, and artificially setting off the outward coverings, habit, and ornaments of the body, either of cloth, stuff, silk, or linen, in their natural and proper folds.

7. In drawing of all the forms before-mentioned, it is requisite to be first perfect in the laying down the exact proportions; secondly, in the general or outward lines, before you proceed to shadowing, or trimming the work within.

8. In mixed and uncertain forms, where the circle, square, &c. will be of no use, but only in the idea thereof in your own fancy, as horses, oxen, and the like, you must do it by judgment, and to gain the true proportions by diligent practice: thus having the shape of the thing in your mind, first draw it rudely with a coal; then, with more exactness, with a lead or pencil; then peruse it well, and mend it in those parts you have erred in, according to the idea you carry in your mind. When it is mended by your own judgment, compare it with some good pattern of the same kind, and amend it by that.

9. Having good copies to draw after, learn to reduce them to other proportions, either larger or smaller; and this by frequent practice.

10. Let a perfection in drawing be attained by diligent exercise, and the infliction of a good matter, before there be any attempts as to colouring and painting; for the former being attained, the rest will be easily understood, and gained by frequent practice.

**Particular observations with regard to Drawing, are as follows.** 1. If you draw after a print or picture, place it in such a light, that the gloss of the colours may not interrupt your light, and that the light and your eye may equally and obliquely fall upon the piece, which should be placed at such a distance, that, upon opening your eye, you may view it at once: the larger the picture is, the greater distance off it should be placed: it should also be right before you, and a little reclining.

2. Draw your out-lines at first very faint, and with a coal; and let them be drawn agreeable to the pattern, before you begin to shadow any part of it. When you have drawn one feature, it should, in some measure, be a direction for you to draw the other, by observing the distance from that to the next feature; making a small mark at the place with your coal, then draw it, and so to the next, till you have drawn the whole figure.

3. Then
3. Then observe the middle of the picture you would copy, and touch upon the paper with the point of your coal: afterwards, observe the more conspicuous and uppermost figures, if there are more than one, which you are to touch lightly in their proper places: thus, running over the whole draught, you will see, as it were, the skeleton of the piece to draw.

4. Having made out these sketches, view them diligently, if they answer your pattern or not; for the gesticulations of the life ought to shew themselves eminently in the first rudolf draughts thereof: correct and mend whatever you perceive amiss, adding and diminishing as it varies from the pattern; by which method it will be brought nearer and nearer to the life.

5. Observe the distance of one limb, joint, or muscle, from another, and the same in all other accidents of the figure, their length, breadth, turnings, &e. shadow next to the light very faintly; and where you see bold and free touches, be not timorous in expressing the same. In drawing a head by the life, or otherwife, take care to place the features exactly right upon the crofs-lines, whether it be a full face, or three-quarter face. In fore-shortening you must make the crofs-lines to fly upwards, where they look upwards; but where the alpeck is downwards, they must be made downwards, in a circular manner. Having drawn the out-lines true, with a coal, you are to proceed to trace the same lines again with a pen, Indian ink, &c. drawing them with more exactness, and by imitating all the hatches with their exact distances one from another, their croffings, turnings and windings, with more boldness and freedom perfect your design.

6. In drawing after a naked body, all the muscles are not to be so plainly expressed as in anatomical figures; but that side whose parts are most apparent, and of signification in the performance of any action, must be made to appear more or less, according to the force of that action.

7. In drawing young persons, the muscles must not appear manifestly so hard as in older and full-grown persons: the same is to be observed as to fat and flabby persons, and such as are very delicate and beautiful; and in women, feare any muscles at all are to be expressed, or but very little, unless it be in some very terrible action, and then too they are to be represented very faintly; the like is also to be observed as to little children.

8. The motion of the whole body must be considered in drawing of the muscles; as in the rising and falling of the arms, the muscles of the breast do appear more or less; the hips do the like according as they are bent outward or inward; and it is the same chiefly in the shoulders, sides, and neck, according to the several actions of the body.

9. The proportion of the figure ought to be multiplied by degrees, in proportion of one to two, three, four, &c. for herein the chief skiff confists: the diameter of the biggest place, between the knee and the foot, is double to the leaf; and the largest part of the thigh, triple.

DRAY, a kind of cart used by brewers, for carrying barrels of beer, or ale; also a sledge drawn without wheels.

Dry, among sportmen, denotes squirrel-nefts, built in the tops of trees.

Dryatone, a market-town of Shropshire, fourteen miles north-east of Shrewsbury.

Dreg, or dredge, among farmers, denotes oats and barley mingled together.

Dreggers, the term used in the admirality-court for the oifer-filters.

Drench, among farriers, a physical potion for horses. The ingredients for this purpose are to be beat coarfly, and either mingled with a decoction, or with wine. Then let all infufe about a quarter of an hour, and give it to the horse with a horn, after he has been tied up two hours to the rack.

Dresden, the capital of Upper Saxony, in Germany, situated on the river Elbe, fifty-five miles north-west of Prague, and eighty-five south of Berlin: E. long. 15° 36′, N. lat. 51°.

It is one of the largest and strongest towns in Germany, and is the usual residence of the elector of Saxony.

Dreux, a town of Orleans, in France, seventeen miles north of Chartres, and thirty-five west of Paris.

Drift, a term used at sea. Thus, any thing that floats upon the water, is said to run a-drift.

Drift-sail, a sail used under water, veered out right a-head by sheets, as other falls are. It serves to keep the ship's head right upon the sea in a storm, and to hinder her driving too fast in a current.

Drill, in mechanics, a small instrument for making such holos as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners.

Drill, or Drill-box, a name given to an instrument for fowing land in the new method of horse-hoeing husbandry. See Agriculture.

Drink, a part of our ordinary food in a liquid form, serving to dilute and moisten the dry meat.

The drinks in different countries are different. The common drink in England is either water, malt liquor, wine, or mixtures of these.

The first drinks of mankind were certainly water and milk, but the love of luxury and debauchery soon introduced the art of preparing intoxicating and inebriating drinks out of vegetables. The vine gave the first of these liquors; after this, wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after these the juices drained from the pine, sycamore, and maple tree, were brought to this use: in latter times, roots, berries, and the pith of the sugar-cane, have been employed for the same purposes.

Drivers, among sportmen, a machine for driving phelant-powrs, consisting of good strong oxen-wagons, such as...
such as the basket-makers use; these are to be set in a handle, and twilled or bound with small oziers in two or three places.

With this instrument, the sportsman drives whole eyes of young poults into his nets. See the next article.

DRIVING, among sportsmen, a method of taking pheasant-poults. It is thus: the sportsman finds out the haunts of these birds; and having fixed his nets there, he calls them together by a pheasant-call, imitating the voice of the dam: after this he makes a noise with his driver, which will make them run a little way forward in a cluster; and this he is to repeat till he has made sure of them, which an expert sportsman never fails to do, by driving them into his nets.

Driving, in metallurgy, is said of silver, when in the operation of refining, the lead being burnt away, the remaining copper rises upon its surface in red fiery bubbles.

Driving, in the sea-language, is said of a ship when an anchor being let fall will not hold her fast, nor prevent her falling away with the tide or wind. The best help in this case is to let fall more anchors, or to veer out more cable; for the more cable she has out, the safer she rides. When a ship is a-hull, or a-try, they say she drives to leeward.

DROGHEDA, a port-town of Ireland, twenty-three miles north of Dublin.

DROGMAN. See Dragoman.

DROITWICH, a borough six miles north of Worcester, which sends two members to parliament.

DROMEDARY. See Camelus.

DRONE, in the history of insects. See Apis.

DRONE-FLY, a two-winged insect, extremely like the common drone-bee, whence also the name.

DROPS, in meteorology, small spherical bodies which the particles of fluids spontaneously form themselves into when let fall from any height.

DROPS, in medicine, a liquid remedy, the dose of which is regulated by a certain number of drops.

DROPSY, in medicine, an unnatural collection of watery humours in any part of the body. See Medicine.

DROPSY, in medicine, an unnatural collection of watery humours in any part of the body. See Medicine.

DROP-WORT, in botany. See Filipendula.

DROSERA, Sun-dew, in botany, a genus of the pentandria pentagynia class of plants, with a funnel-fashioned flower, consisting of five obtusely-ovated petals: the fruit is an unilocular suboval capsule, containing a great many very small seeds.

DROWNING, the act of suffocating, or being suffocated, by water.

Naturalists and physicians furnish us with divers well attested instances of surprising recoveries of persons drowned. It is certain from repeated dissections made on persons drowned, that they generally have less water in their stomachs than if they had voluntarily drunk a considerable quantity: whence it does not seem expedient to hang the drowned person by the heels, a position that must prove uneasy as soon as the humours of the body should resume their ordinary motion. In order to know whether the person has swallowed too much water or not, and to make him vomit it up if he has, it is proper to put him in a tun, open at both ends, which is to be rolled in different directions: or the bearded end of a feather should be introduced into the cæophagus. After taking off the cloaths of the drowned person, we ought, with the utmost expedition, to shelter him from the impressions of the cold air, and begin to warm him, by wrapping him up with cloaths and coverings: to do this more effectually, he is afterwards to be put into a pretty warm bed, applying also to his body hot napkins and cloths. A hot forcouring fun, to which drowned persons have been exposed, and hot baths, have produced the fame happy effects.

The great intention to be pursued is, to put the solid parts of the machine in action, that thus they may restore the motion of the fluids: in order to this, the drowned person should be agitated in various directions, in a bed, in the arms of persons of sufficient strength.

Spirituos liquors should be poured into his mouth, or warm urine; and some persons prescribe a decoction of pepper and vinegar, as a gargalism: we must also attempt to irritate the internal fibres of the nose, either by volatile spirits, and by the liquors used in apoplectic cafes; or by tickling the nerves of the nostrils with a bearded feather; or by blowing, through a quill, snuff, or some other more powerful stimulatory. One of the means frequently used with success, is to blow warm air, by means of a pipe, into their mouths; or to introduce it by a pair of bellows; or, by injecting warm clysters, to irritate the intestines: the smoke of tobacco conveyed into the intestines, by means of a tobacco pipe, is much recommended. Venesection is by no means to be neglected; and perhaps most successfully in the jugular vein.

DRUG, a general term for goods of the druggist and grocery kinds, especially for those used in medicine and dying.

DRUGGET, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded, but usuallly plain.

Those that have the woof of wool, and the warp of thread, are called threaded-druggets; and those wrought with the flutto on a loom of four marches, as the serges of Moui, Beauvois, and other like stuffs corded, are called corded druggets. As to the plain, they are wrought on a loom of two marches, with the shuttle, in the same manner as cloth, camlets, and other like stuffs not corded.

DRUIDS, the priests or ministers of religion of the ancient Britons and Gauls. The druids were chosen out of the best families; and were held, both by the honours of their birth, and their office, in the greatest veneration. They are said to have understood astrology, geometry, natural history, politics, and geography: they had the administration of all sacred things, were the interpreters of religion, and the judges of all affairs indifferentely.

Whoever refused obedience to them, was declared implious and accursed: they held the immortality of the
the soul, and the transmigration of souls. They are divided by some into several classes, as the vacant, bardi, bugais, femonthii. They had a chief, or archdruid, in every nation: he was a sort of high-priest, having an absolute authority over the rest, and was succeeded by the most considerable among his survivors. The youth was to be instructed by them, retiring with them to caves and desolate forests, where they were sometimes kept twenty years. They preferred the memory and actions of great men by their verses; but are said to have sacrificed men to Mercury. Cæsar imagined that the druids came from Britain into Gaul, but several among the modern writers are of a different opinion.

**DRUM**, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or slackened at pleasure by the means of small cords or sliding knots: It is beat upon with sticks. Some drums are made of brass, but they are commonly of wood.

**Kettle Drums**, are two sorts of large basins of copper or brass, rounded in the bottom, and covered with vellum, or goat-skin, which is kept fast by a circle of iron, and several holes fastened to the body of the drum, and a like number screws to screw up and down. They are much used among the horfe, as also in operas, oratorios, concerts, &c.

**Drum**, or **Drummer**, he that beats the drum; of the drum, and a like number screws to screw up and down. They are much used among the horse, as also in operas, oratorios, concerts, &c.

**DRUM, or Drummer**, he that beats the drum; of whom each company of foot has one, and sometimes two. Every regiment has a drum-major, who has the command over the other drums. They are distinguished from the soldiers, by cloaths of a different fashion: their pofl, when a battalion is drawn up, is on the flanks, and on a march it is betwixt the divifions.

**Drum Lanerk**, a town of Scotland, fifteen miles north of Dumfries.

**Drunkenness**, a well known disorder in the brain, occasioned by drinking too freely of spirituous liquors. Drunkenness appears in different forms, in different constitutions: some it makes gay, some fullen, and some furious.

**Drusenheim**, a town of Alsace, in Germany, four miles south-east of Hagenau.

**Duck**, in ornithology. See Anas.

**Ducking at the main-yard**, among seamen, is a way of punishing offenders on board a ship; and is performed by binding the malefactor, by way of exercise; but among the Celts, Franks, and ancient Germans, it was a sort of punishment for persons of scandalous lives.

They were shut up, naked to the skirt, to the yard of a thallop, and ducked several times.

**Ducking at the main-yard**, among seamen, is a way of punishing offenders on board a ship; and is performed by binding the malefactor, by way of exercise; but among the Celts, Franks, and ancient Germans, it was a sort of punishment for persons of scandalous lives.

They were shut up, naked to the skirt, to the yard of a thallop, and ducked several times.

**Duck**, in general, denotes any tube or canal. It is a term much used by anatomists.

**Air-Duct**, among ichthyologists, a canal reaching from the air-bladder in fishes to their stomach.

**Ductility**, in physics, a property of certain bodies, whereby they are capable of being expanded, or stretched forth, by means of a hammer, presses, &c. See Chemistry, and Mechanics.

**Duderstadt**, a town of Upper Saxony, thirty-five miles north-east of Caffel.

**Duel**, a single combat, at a time and place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and the accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes, and Franks, that none were excluded from it but women, sick people, cripples, and such as were under twenty-one years of age, or above sixty. Even ecclesiastics, priests, and monks, were obliged to find champions to
DULL, in the menage. The marks of a dull horse, called by the French marquis de ladre, are white spots round the eye and on the tip of the nose, upon which, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil ones for the maintenance of rights to estates, and the like: in latter times, however, before they were entirely abolished, they were restricted to these four cases. 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must, by common fame, be supposed guilty. And, 4. The matter not capable of proof by witnesses. At present it is used for a single combat on some private quarrel, and must be premised, otherwise it is called a retournement. If a person be killed in a duel, both the principals and seconds are guilty of murder, whether the seconds engage or not. It is also a very high offence to challenge a person, either by word or letter, or to be the messenger of a challenge. The severe edicts made by Lewis XIV. against duels have, in a great measure, put a stop to the custom in France.

DUELLING, in Scots law. See title 33.

DUERO, or Duro, a large river, which, rising in Old Castile in Spain, runs from east to west, crosses the province of Leon, and, after dividing Portugal from Spain by a southerly course, turns westward, crosses Portugal, and falls into the Atlantic Ocean at Porto.

DUKE is either the title of a sovereign prince, as the duke of Savoy, Parma, &c. the grand duke of Tuscany, Muscovy, &c. or it is the title of honour and nobility next below princes. The commanders of armies in time of war, the governors of provinces and wardens of marches in times of peace, were called dukes under the later emperors. The Goths and Vandals divided all Gaul into dutyshes and counties, the governors of which they sometimes called dukes, and sometimes comites. In France, under the second race of kings, though they retained the name and form of ducal government, there were scarce any dukes except those of Burgundy, Aquitain, and France. In England, among the Saxons, the commanders of armies, &c. were called dukes, dukes, without any addition, till Edward III. made his son, the Black Prince, duke of Cornwall; after whom there were more made in the same manner, the title depending to their poverties. Duke then, at present, is a mere title of dignity, without giving any domain, territory, or jurisdiction over the place from whence the title is taken. A duke is created by patent, cincture of sword, mantle of state, imposition of a cap and coronet of gold on his head, and a verge of gold put into his hand. His title is Grace; and, in the style of the heralds, Most high, potent, high-born, and noble prince.

DULCIFYING, in chemistry, is the sweetening any matter impregnated with salts, by frequently washing it in pure water.

DULL, in the menage. The marks of a dull horse, called by the French marquis de ladre, are white spots round the eye and on the tip of the nose, upon which, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil ones for the maintenance of rights to estates, and the like: in latter times, however, before they were entirely abolished, they were restricted to these four cases. 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must, by common fame, be supposed guilty. And, 4. The matter not capable of proof by witnesses. At present it is used for a single combat on some private quarrel, and must be premised, otherwise it is called a retournement. If a person be killed in a duel, both the principals and seconds are guilty of murder, whether the seconds engage or not. It is also a very high offence to challenge a person, either by word or letter, or to be the messenger of a challenge. The severe edicts made by Lewis XIV. against duels have, in a great measure, put a stop to the custom in France.

DULWICH, a village near London, remarkable for its mineral waters, which are said to contain a bitter cathartic fault, but no iron.

DUM BLAIN, a town of Scotland, about five miles north of Stirling.

DUMBNESS, the privation of the faculty of speech. The most general, or rather the sole cause of dumbness, is the want of the sense of hearing. The use of language is originally acquired by imitating articulate sounds. From this source of intelligence, deaf people are entirely excluded: they cannot acquire articulate sounds by the ear; unless, therefore, articulation be communicated to them by some other medium, these unhappy people must for ever be deprived of the use of language; and as language is the principal source of knowledge, whoever has the misfortune to want the sense of hearing, must remain in a state little superior to that of the brute creation. Deafness has in all ages been considered as such a total obstruction to speech, or written language, that an attempt to teach the deaf to speak or read has been uniformly regarded as impracticable, till Dr Wallis and some others have shown that deaf people cannot learn to speak or read by the direction of the ear, that there are other sources of imitation, by which the same effect may be produced. The organs of hearing and of speech have little or no connection. Persons deprived of the former generally possess the latter in such perfection, that nothing further is necessary, in order to make them articulate, than to teach them how to use these organs. This indeed is no easy task; but experience shows that it is practicable. Mr Thomas Braidwood, of Edinburgh, is perhaps the first who ever brought this surprising art to any degree of perfection. For these some years past, he has taught many people born deaf, to speak distinctly, to read, to write, to understand figures, the principles of religion and morality, &c. This, at first sight, may appear to be altogether incredible; but the fact is certain. Mr Braidwood has, at present, ten or a dozen of deaf pupils, some of them above twenty years of age, all making a rapid and amazing progress in those useful branches of education.

Mr Braidwood's principal difficulty, after he had discovered this art, was to make people believe in the practicability of it. He advertised in the public papers; he exhibited his pupils to many noblemen and gentlemen; still he found the generality of mankind unwilling to believe him. A remarkable instance of this incredulity occurred some years ago. A gentleman in England lent a deaf girl of his to Mr Braidwood's care. A year or two afterwards, Mr Braidwood wrote to the father, that his daughter could speak, read, and write distinctly. The father returned an answer, begging Mr Braidwood's excuse, as he could not believe it; however, he defired a friend of his, who was oc-
casionally going to Edinburgh, to call at Mr Braidwood, and inquire into the truth of what he had wrote him: he did so; conversed with Mr Braidwood, saw the young lady, heard her read, speak, and answer any questions he put to her. On his return, he told the father the surprising progress his child had made; but still the father thought the whole an imposition: the girl herself wrote to her father, but he looked upon the letter as a forgery. About this time the father died, and the mother sent an uncle and cousin of the deaf lady's from Shrewsbury, in order to be satisfied of the truth. When they arrived, Mr Braidwood told the girl her uncle and cousin were in the parlour, and desired her to go and ask them how they did, and how her mother and other friends did. The friends were astonished, and could hardly credit their own ears and eyes.

We have conversed with Mr Braidwood, concerning the nature and method of teaching this wonderful art: he seems to be very desirous of communicating and answering any questions he put to her. On his return, he told the father the surprising progress his child had made; but still the father thought the whole an imposition: the girl herself wrote to her father, but he looked upon the letter as a forgery. About this time the father died, and the mother sent an uncle and cousin of the deaf lady's from Shrewsbury, in order to be satisfied of the truth. When they arrived, Mr Braidwood told the girl her uncle and cousin were in the parlour, and desired her to go and ask them how they did, and how her mother and other friends did. The friends were astonished, and could hardly credit their own ears and eyes.

We have conversed with Mr Braidwood, concerning the nature and method of teaching this wonderful art: he seems to be very desirous of communicating and transmitting his discovery to posterity. He speaks in his instructions that he cannot communicate it so fully in writing as to enable any other person to teach it. He pronounces the sound of a slowly, pointing out the figure of the letter at the same time; makes his pupil observe the motion of his mouth and throat; then he puts his finger into the pupil's mouth, depresses or elevates the tongue, and makes him keep the parts in that position; then he lays hold of the outside of the wind-pipe, and gives it some kind of squeeze, which it is impossible to describe: all the while he is pronouncing a, the pupil is anxiously imitating him, but at first seems not to understand what he would have him to do. In this manner he proceeds, till the pupil has learned to pronounce the sounds of the letters. He goes on in the same manner to join a vowel and a consonant, till at length the pupil is enabled both to speak and read.

It is altogether in vain for us to attempt to say any more concerning the mode of operation. Mr Braidwood undertakes every deaf person, who is not at the same time foolish or idiotical. The greatest misfortune is, that this art is confined to a single man, and that his pupils must live in the house with him for some years. The expense necessarily attending education of this kind, excludes all but people in opulent circumstances from deriving any advantage from it. Mr Braidwood says, that the only way for preferring the art, and communicating it to a number, is to take people in the way of apprentices: this he is unable to do at his own expence. What a pity, that such a curious and useful art should live and die with a single man! There are many sums mortified in this kingdom, both by government and private persons, for less important purposes, than the preservation and extension of the art of raising a great number of our fellow-creatures from the rank of brutes, to that of reasonable beings, and useful members of society.

DUMFRIES, the capital of a county of the same name, in Scotland, lying northwards of the Solway frith: W. long. 3° 20', and N. lat. 54° 45'.

DUNBAR, a parliament and port-town of Scotland, about twenty-five miles east of Edinburgh.

DUNBARTON, the capital of a county of the same name in Scotland, called by some Lenox; it is a parliament-town, situated at the confluence of the rivers Clyde and Leven; sixteen miles north-west of Glasgow.

DUNCANNON, a town of the county of Wexford, in Ireland, six miles east of Waterford.

DUNDALK, a port-town of Ireland, eighteen miles north of Drogheda.

DUNDEE, a large parliament-town of Angus, in Scotland, situated on the north side of the frith of Tay, fourteen miles north-west of St Andrews: W. lon. 2° 42', and N. lat. 56° 32'.

DUNG, in husbandry, is of several sorts, as that of horses, cows, sheep, hogs, pigeons, geese, hens, &c. See Agriculture.

DUNGANNON, a town of Ireland, eleven miles north of Armagh.

DUNGING of lands. See Agriculture.

DUNKELD, a town of Perthshire in Scotland, formerly a bishop's see, situated about twelve miles north of Perth.

DUNSTABLE, a market-town, fifteen miles south of London.
DURSWICK, a borough of Suffolk, forty miles east of Bury. It sends two members to parliament.

DUO, in music, a song or composition to be performed in two parts only, one sung, the other played on an instrument, or by two voices.

Duo is also when two voices sing different parts, as accompanied with a third, which is a thorough bass. It is seldom that unisons and octaves are used in duos, except at the beginning and end.

DUODECIMA, in music, is the twelfth or the fifth doubled. See Fifth.

DUODECIMAL SYSTEM, an appellation given to magistrates, commissioners, and officers: from their sentence it was lawful to appeal to the senate to death. Thefe judges were taken from the body of the people, who only had the power of condemning a citizen to death. Therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries: they should be so laid as to make the exports of this nation at least equal to our imports from those nations with whom we trade, so that a balance in money should not be issued out of Great Britain, to pay for the goods and merchandise of other countries: to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exports to such countries. These are the national principles on which all our treaties of commerce with other countries are to be grounded.

DUTY, in the military art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guards and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy directly to be engaged, is called going on service.

DUUMVIRATE, the office or dignity of the duumvirs: from their sentence it was lawful to appeal to the senate to death. Thefe judges were taken from the body of the people, who only had the power of condemning a citizen to death. Therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries: they should be so laid as to make the exports of this nation at least equal to our imports from those nations with whom we trade, so that a balance in money should not be issued out of Great Britain, to pay for the goods and merchandise of other countries: to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exports to such countries. These are the national principles on which all our treaties of commerce with other countries are to be grounded.

DUTY, in polity and commerce, signifies the impost laid on merchandise, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp-duties, &c. See Customs, Excise, &c.

The principles on which all duties and customs should be laid on foreign merchandise, which are imported into these kingdoms, are such as tend to cement a mutual friendship and traffic between one nation and another; and therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries: they should be so laid as to make the exports of this nation at least equal to our imports from those nations with whom we trade, so that a balance in money should not be issued out of Great Britain, to pay for the goods and merchandise of other countries: to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exports to such countries. These are the national principles on which all our treaties of commerce with other countries are to be grounded.

DUTY, in general, denotes any thing that one is obliged to perform.

DUROC, in Roman antiquity, a general appellation given to the duumvirs: from their sentence it was lawful to appeal to the senate to death. Thefe judges were taken from the body of the people, who only had the power of condemning a citizen to death. Therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries: they should be so laid as to make the exports of this nation at least equal to our imports from those nations with whom we trade, so that a balance in money should not be issued out of Great Britain, to pay for the goods and merchandise of other countries: to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exports to such countries. These are the national principles on which all our treaties of commerce with other countries are to be grounded.

DUTY, in the military art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guards and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy is called going on service.

DUMVIRATE, the office or dignity of the duumvirs: See the next article.

The duumvirate lasted till the year of Rome 388, when it was changed into a decemvirate.

DUUMVIRI, in Roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

DUUMVIRI CAPITALES were the judges in criminal cases: from their sentence it was lawful to appeal to the people, who only had the power of condemning a citizen to death. These judges were taken from the body of
of the decuriones; they had great power and authority, were members of the public council, and had two lictors to walk before them.

Duumviri municipales, were two magistrates in some cities of the empire, answering to what the consuls were at Rome: they were chosen out of the body of the decuriones; their office lasted commonly five years, upon which account they were frequently termed quinquennales magistrates. Their jurisdiction was of great extent: they had officers walking before them, carrying a small switch in their hands; and some of them allowed the privilege of having lictors, carrying axes and the fasces, or bundles of rods, before them.

Duumviri navales were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duty of their office consisted in giving orders for the fitting of ships, and giving their commissions to the marine officers, &c.

Duumviri sacrorum were magistrates created by Tarquinus Superbus, for the performance of the sacrifice, and keeping of the fasces books. They were chosen from among the patricians, and held their office for life: they were exempted from serving in the wars, and from the offices imposed on the other citizens, and without them the oracles of the sibyls could not be consulted.

Duyveland, or Diveland, one of the islands of Zealand, in the United Provinces, lying easterly of Schonen, from which it is only separated by a narrow channel.

Dwal, in heraldry, the herb nightshade used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

Dwarf, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds: thus there are dwarfs of the human species, dwarf-dogs, dwarf-trees, &c.

The Romans were so passionately fond of dwarfs, that they often used artificial methods to prevent the growth of boys designed for dwarfs, by inclosing them in boxes, or by the use of tight bandages. In Italy, several kinds: thus there are dwarfs of the human species, dwarf-dogs, dwarf-trees, &c.

Dwina, the name of two large rivers, one of which rises in Lithuania, and, dividing Livonia from Courland, falls into the Baltic sea a little below Riga: the other gives name to the province of Dwina, in Russia, discharging itself into the White sea, a little below Archangel.

Dye, in architecture, any square body, as the trunk or notched part of a pedestal: or it is the middle of the pedestal, or that part included between the base and the cornice, so called because it is often made in the form of a cube or dye. See Architecture.

Dyer, a person who professes the art of dyeing all manner of colours. See Dyeing.

Dyer’s weed, in botany. See Reseda.

Dyeing, the art of giving a lasting colour to silks, clothes, and other substances, whereby their beauty is much improved, and value enhanced.

This art depends chiefly on three things, viz. 1. Dipping the surface of the stuffs to receive and retain the colours; which is performed by washing them in different lyres, digesting, beating them, &c. in which human urine putrifed, a sharp salt of ashes, divers soaps, and galls of animals, are of principal use; by means whereby the supefluous gluten of the silk-worms naturally adhering to their threads, is washed and cleansed from them, and thus they become fitted gradually to imbibe the colours. By these also the greasy foulnefs adhering to wool and flax is secured off.

2. To grind the colours, so that they may enter the body duly prepared, and preserve their brightness uniminished.

3. The third consists in having beautiful colours.

According to Sir W. Petty, the account of what is done in particular trades by the art of dyeing, 1. There is a whitening of wax, and several sorts of linen and cotton cloths, by the fun, air, and reciprocal effusions of water. 2. Colouring of wood and leather, by lime, salt and liquors, as in flosses, canes, and marble leathers. 3. Colouring of paper, viz. the marbled paper, by deliming the colours with ox-gall, and applying them upon a fliff gummned liquo. 4. Colouring, or rather discolouring, the colours of silks, taffies, &c. by brimstone. 5. Colouring of several iron and copper-works into black with oil. 6. Colouring of leather into gold-colour, or rather silver-leaves into gold by varnishes, and in other cases by urine and sulphur. 7. Dyeing of marble and alabaster, with heat and coloured oils. 8. Colouring silver into the brass-colour, with brimstone or urine. 9. Colouring the barrels and locks of guns into blue and purple, with the temper of small-coal heat. 10. Colouring of glafs (made of sands, flints, &c.) as also of cryftals and earthen ware, with the rubs and solutions of metals. 11. The colouring of live hair, as in Poland, horse and man’s hair: as also the colouring of furs. 12. Enameling and annealing. 13. Applying colours, as in the printing of books and pictures, and in making of playing cards, being each of them performed in a different way. 14. Gilding and tinning with mercury, block-tin, fal amnoniac. 15. Colouring of metals, as copper with calamy, into brass, and with zinc or fperiter into a golden colour, or into a silver one with arsenic; and of iron into a resemblance of copper with Hungarian vitriol. 16. Making painters colours by preparing of earth, chalk, and flates; as in umber, ochre, cullen-earth, &c. as also out of calces of lead, as cerule and minium; by sublimates of mercury and brimstone, as in vermilion; by tinging whole earths variously, as in verdeter, and some of the lakes; by concrete juices, or feculae, as in gambogium, indigo, pinks, sap-green, and lakes; as also of rubs, as in verdigris, &c. 17. The applying these colours by the adhesion of ox-gall, as in the marbled paper aforesaid; or by gun-water, as by liming; or by clammy drying oils, such as the oils of limifced, nuts, &c. 18. The watering of tabbies. 19. The colouring of wool, linen, cotton, silk, hair, feathers, horn, leather, and the threads.
threads and webs of them with woods, roots, herbs, seeds, leaves, salts, limes, lixiviums, waters, heats, fermentations, macerations, and other great variety of management: an account of all which is a short history of dyeing.

The materials used in the art of Dyeing, are iron and steel, or what is produced from them in all true blacks, called Spanish blacks, though not in Flanders blacks, viz. they use copperas, steel-filings, and flippes; they also use pewter for Bow-dye scarlet, viz. they dissolve bars of pewter in aquafortis; litharge is also used by some, though acknowledged by few to add weight to dyed silk. Antimony is much used to the same purpose. Arsenic is used in crimson upon pretence of giving lustre, although those who pretend not to be wanting in giving lustre to their silks disown its use. Verdigrase is also used by linen-dyers in their yellow and greenish colours; though, of itself, it strikes no deeper colour than that of a pale straw. Of mineral salts used in dyeing, the chief is alum; the true use whereof seems to be in regard to the fixation of colours. The next mineral salt is salpetre, not used by ancient dyers, and but by few of the modern; nor is it yet used but to brighten colours, by back boiling of them, for which argol is more commonly used: lime is much used in working blue vats.

Of the animal tribes are used cochineal, urine of labouring men kept till it be flate and flinking, honey, yolks of eggs, and ox gall; the use of the urine is to colour, and help the fermenting and heating of woad; and is used also in blue vats instead of lime; it discharges the yellow, and therefore is used to spend the matter with.

Dyers use two sorts of water, viz. river and well-water; the last, which is harsh, they use in reds and other colours wanting refringency, and dyeing materials of the flacker contexts, as in callicoe, suftian, and the several species of cotton-works; but is not good for blues, and makes yellows and greens look ruddy. River-water is more fat and oily, and is therefore used in most cases, and must be had in great quantities for washing and rinsing their cloths after dyeing. Water is called by dyers white liquor; but a mixture of one part bran and five of river-water, boiled an hour and put into leaden cisterns to settle, is what they call liquor absolutely.

Gums have been used by dyers about silk, viz. gum arabic, tragacanth, mastic, dragon's blood. Those teed little to the tincture, any more than gum in writing-ink, which only gives it a confidence; so gum may give the filk a glossiness; and, lastly, to increase the weight. The three peculiar ingredients for black are copperas, filings of steel, and flippes: the refringent binding materials are alder-bark, pomegranate-peels, walnuts, and roots of oak and maple bark, and saw -dust of the same, crab -tree bark, galls, and sumac.

The salts are alum, salt petre, salt armoniac, pot -ash, and flone -lime; among which urine may be enumerated as a liquid salt.

The liquors are well and river water, urine, aquavitae, vinegar, lemon juice, aquafortis, honey, and molasses. Ingredients of another class are bran, wheaten flour, yolks of eggs, leaven, cummin feed, fenugreek feed, agaric, and leenna.

The smeltics, or ableftives, are fuller's earth, soap, linseed -oil, and ox gall.

The metals and minerals are pewter, verdigrase, antimony, litharge, and arsenic.

The colourings are of three sorts, viz. blue, yellow, and red; of which logwood, old suffic, indigo, and madder, are the chief.

General observations upon Dyeing.

1. All materials which of themselves do give colour are either red, yellow, or blue; so that out of them, and the primitive fundamental colour white, all that great variety which we see in dyed stuffs doth arise.

2. That few of the colouring materials, as cochineal, foot, wood-wax, woad, &c. are in their outward and first appearance of the same colour, which by the flightest distempers and solutions in the weakest menstrua, they dye upon cloth, silk, &c.

3. That many of them will not yield their colours without much grinding, steeping, boiling and fermenting, or corrosion by powerful menstrua, as redwood, weld, woad, arnottro, &c.

4. That many of them will of themselves give no colouring at all, as copperas or galls, or with much disadvantage, unless the cloth or other stuff to be dyed be as it were first covered, or incrusted with some other matter, though colourles aforehand, as madder, weld, brazil, with alum.

5. That some of them, by the help of other colourless ingredients, do strike different colours from what they would of themselves, as cochineal, brazil, &c.

6. That some colours, as madder, indigo, and woad, by reiterated tinctures, will at last become black.

7. That although green be the most frequent and the most common of natural colours, yet there is no simple ingredient now used alone to dye green with upon any material; sap-green being the nearest, which is used by country people.

8. There is no black thing in use which dyes black, though both the coal and foot of coal things burnt or scorched be of that colour, and the blacker, by how much the matter before being burnt was whiter, as in ivory black.

9. The tincture of some dyeing stuffs will fade even with lying, or with the air, or will stain with water only, but very much with urine, vinegar, &c.

10. Some of the dyeing materials are used to bind and strengthen a colour; some to brighten it; some to give lustre to the stuff; some to discharge and take off the colour, either in whole or in part; and some out of fraud, to make the material dyed, if costly, heavier.

11. That some dyeing ingredients, or drugs, by the coarcseness of their bodies, make the thread of the dyed stuff seem coarser; and some, by shrinking them, smaller; and some, by smoothing them, finer.
12. Many of the same colours are dyed upon several fluffs with several materials, as red-wood is used in cloth, not in silks: arnatto in silks, not in cloth, and may be dyed at several prices.

13. That scouring and washing of fluffs to be dyed, is done with special materials, as sometimes with ox-galls, sometimes with fuller's-earth, and sometimes soap; this latter being, in some cafes, pernicious, where pot-ashes will stain, or alter the colour.

14. Where great quantities of fluffs are to be dyed together, or where they are to be done with any speed, and where the pieces are very long, broad, thick, or otherwise, they are to be differently handled, both in respect to the vessels and ingredients.

15. In some colours and fluffs the tincting liquor must be boiling, in other cafes blood-warm, and in some it may be cold.

16. Some tincture liquors are fitted for use by long keeping, and in some the virtues wear away by the keeping.

17. Some colour or fluffs are best dyed by reiterated dippings in the same liquor, some by continuing longer, and others a lesser time therein.

18. In some cafes, the matter of the vessel wherein the liquors are heated, and the tincture prepared, must be regarded, as the kettles must be pewter for Bow-dye.

19. There is little reckoning made how much liquor is used in proportion to the dyeing drugs, it being rather adjusted to the bulk of the fluffs, as the vessels are to their breadth; the quantity of dyeing drugs being proportioned both to the colour, higher or lower, and to the fluffs; as likewise the faults are to the dyeing drugs. Concerning the weight that colours give to silk, (in which it is most taken notice of, being sold by weight, and a commodity of great price) it is observed, that one pound of raw silk loses four ounces by washing out the gums and the natural fordes; that the same scoured silk may be raised to above thirty ounces from the remaining twelve, if it be dyed black with some materials.

Of a thing very useful in dyeing, especially of black, nothing increases weight so much as galls, by which black silks are restored to as much weight as they lost by washing out their gum: nor is it counted extraordinary that blacks should gain about four or six ounces in the dyeing upon each pound. Next to the galls, old mustard increases the weight about \( \frac{1}{2} \) in \( \frac{1}{2} \); madder, about one ounce; weld, half an ounce. The blue vats in deep blues of the fifth stall, give no considerable weight; neither doth logwood, cochineal, nor even copperas, where galls are not: flippie adds much to the weight, and giveth a deeper black than copper-as itself, which is a good excuse for the dyers that use it.

**Dyeing of wool and woollen manufactures.**

For black in woollen manufactures, it is begun with a strong decoction of woad and indigo, that communicate a deep blue; after which the fluffs being boiled with alum and tartar, or pot-ash, are to be maddered with common madder, then dyed black with Aleppo galls, copperas, and fumac, and finisht by back-boiling in wold. Woolls for tapestry are only to be washed, and then put in black. For scarlet, wool and woollen manufactures are dyed with kermes and cochineal, with which may also be used aegric and arsenic. Crimson scarlet is dyed with cochineal, mastic, aquafortis, sal armoniac, sublimate, and spirit of wine. Violet scarlet, purple, amaranth, and panfy-scarlets, are given with woad, cochineal, indigo, brazlletto, brazil, and orchal. Common reds are given with pure madder, without any other ingredient. Crimson reds, carnations, flame and peach-colours, are given, according to their several hues, with cochineal, mastic, without madder, or the like. Crimson-red is prepared with Roman alum, with cochineal.

Orange aurora, brick-colour, and onion-peel colour, are dyed with woad and madder, mixed according to their several shades. For blues, the dark are dyed with a strong tincture of woad; the brighter with the same liquor, as it weakens in working. Dark browns, minims, and tan colours, are given with woad, weaker in decoction than for black, with alum and pot-ashes, after which they are madderred higher than black: for tan-colours, a little cochineal is added. Pearl-colours are given with galls and copperas; some are begun with walnut-tree roots, and finisht with the former; though to make them more useful, they generally dip them in a weak tincture of cochineal.

Greens are begun with woad, and finisht with weld, pale-yellows, lemon-colour, and sulphur colour, are given with weld alone. Olive colours of all degrees are first put in green, and taken down with foot, more or less, according to the shade that is required. Feuemort, hair-colour, mulk, and cinnamon colour, are dyed with weld and madder. Nacaret, or bright orange, is given with weld and goats-hair boiled with pot-ashes.

**Dyeing of silks.** is begun by boiling them in soap, &c., then scouring and washing them in water, and steeping them in cold alum-water. For crimson, they are scoured a second time, before they are put into the cochineal-vat. Red-crimson is given with pure cochineal, mastic, adding galls, turmeric, arsenic, and tartar, all mixed in a copper of fair water, almost boiling: with thefe the silk is to be boiled an hour and a half, after which it is allowed to stand in the liquor till next day. Violet-crimson is given with pure cochineal, arsenic, tartar, and galls; but the galls in less proportion than in the former. When taken out, it is washed and put in a vat of indigo. Cinnamon crimson is begun like the violet, but finisht by back-boiling; if too bright, with copperas; and if dark, with a dip of indigo. Light blues are given in a back of indigo. Sky-blues are begun with oschal, and finisht with indigo. For citron colours, the silk is first alumed, then welded with indigo. Pale yellows, after aluming, are dyed in weld alone. Pale and brown aurora's, after aluming are welded strongly, then taken down with rouch and dissolved with pot-ashes. Flame-colour is begun with rouch, then alumed, and afterwards dipped
DYN (463) DYV

The Egyptians reckon thirty dynasties within the space of 36,250 years; but the generality of chronologists look upon them as fabulous. And it is very certain, that these dynasties are not continually successful, but collateral.

DYSCARCY, among physicians denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

DYSENTRY, in medicine, a diarrhoea or flux, wherein the stools are mixed with blood, and the bowels miserably tormented with gripes. See Medicine.

DYSERT, a parliament-town of Scotland, in the county of Fife, situated on the northern shore of the frith of Forth, about eleven miles north of Edinburgh.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach.

DYSPEPSY, a difficulty of digestion.

DYSPEA, a difficulty of breathing, usually called asthma.

DYSERY, in medicine, a difficulty of making urine, attended with a sensation of heat and pain. See Medicine.

DYSUS, in zoology, a genus of insects of the order of the coleoptera; the antennae of which are slender and setaceous, and the hind feet are hairy, and formed for swimming. There are twenty-three species, distinguished by their antennae, the colour of the elytra, &c.

DYVOUR’S HABIT, in Scots law, a party-coloured habit which fraudulent bankrupts, or bankrupts who have been dealers in illicit trades, are directed to wear, as a mark of ignominy, upon their being liberated from prison on a cession bonorum. See Scots Law, title 32.

E

EAGLE, in ornithology. See Falco.

Eagle, in heraldry, is accounted one of the most noble bearings in armoury, and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or for having done singular services to their sovereigns; in which cases they may be allowed a whole eagle, or an eagle naissant, or only the head or other parts thereof, as may be most agreeable to their exploits.

EAGLE-OWL. See Bubo.

EAGLE-STONE. See Etites.

Black Eagle, an order of knighthood, instituted by the elefactor of Brandenburgh, in 1701, on his being crowned king of Prussia.

The knights of this order wear an orange-coloured ribband suspending a black eagle.

White Eagle, a like order in Poland, instituted in 1325, by Uladislaus V. on occasion of the marriage of his son Casimir to the daughter of the great duke of Lithuania.

The knights of this order wear a chain of gold, suspending a silver eagle crowned.

EAGLET, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed eaglets.

EAR-WIG, in zoology. See FORFICULA.

EARING, in the sea language, is that part of the bolt-rod which at the four corners of the sail is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard-arms, and so the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are fixed or bent at the clew.

EARL, a British title of nobility, next below a marquis, and above a viscount. Earls were anciently called comites, because they were wont comitari regem, to wait upon the king for council and advice. The Germans call them graves, as landgrave, margrave, palgrave, rheingrave; the Saxons called them unefts, that title might be more properly applied to their dukes; the Danes, ealdors; and the English, earls. The title, originally, died with the man. William the conqueror first made it hereditary, giving it in fee to his nobles, and allotting them for the support of their state the third penny out of the sheriff's court, issuing out of all pleas of the shire whence they had their title. But now the matter is quite otherwise; for whereas heretofore comes and comitatus were correlatives, and there was no comes or earl but had a county or thire for his earldom, of later years the number of earls increasing, and no more counties being left, divers have made choice of some eminent part of a county, as Lindley, Holland, Cleveland, &c. Some of a lesser part, as Stafford, &c. others have chosen for their title some eminent town, as Marlborough, Exeter, Bristol, &c. and some have taken for their title the name of a small village; their own seat or park, as Godolphin, Clarendon, &c. An earl is created by cinature of sword, mantle of state put upon him by the king himself, a cap and a crown put upon his head, and a charter in his hand. All the earls of England are denominated from some shire, town or place, except three; two of whom, viz. earl Rivers, and earl Paulet, take their denomination from illustrious families: the third is not only honorary, as all the rest, but also officiary, as the earl-marshall of England.

EARL-MARSHAL OF ENGLAND, is a great officer who had ancienly several courts under his jurisdiction, as the court of chivalry, and the court of honour. Under him is also the herald's office or college of arms. He hath some pre-eminence in the court of Marlaffa, where he may sit in judgment against those who offend within the verge of the king's court. This office is of great antiquity in England, and anciently of greater power than now; and has been for several ages hereditary in the most noble family of Howard.

EARNEST, in Scots law, a piece of money sometimes given by a buyer, in evidence that the sale or contract is completed. See tit. 22.

EARTH, a solid, or terrestrial matter, whereof our globe partly consists. See Vol. I. p. 67.

EARTH, in astronomy and geography, one of the primary planets, being this terraqueous globe whereon we inhabit. See ASTRONOMY and GEOGRAPHY.

EARTHWATER, in natural history, a violent agitation of some considerable part of the earth generally attended with a terrible noise like thunder, and sometimes with an eruption of fire, water, wind, &c. See PNEUMATICS.

EASEL PIECES, a denomination given by painters to such pieces as are contained in frames, in contradistinction from those painted on cieilings, &c.

EASEMENT, in law, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit; such are a way through his lands, a sink, or the like. These, in many cases, may be claimed.

EASING, in the sea-language, signifies the slackening a rope, or the like: thus, to ease the bow-line or sheet, is to let them go flacker; to ease the helm is to let the ship go more large, more before the wind, or more larboard.

EASLOW, a borough of Cornwall, twenty-two miles south of Launceston, which sends two members to parliament.

EAST, one of the four cardinal points of the world; being that point of the horizon, where the sun is seen to rise when in the equinoxial.

EASTER, a festival of the christian church, observed in memory of our Saviour's resurrection.

The Greeks call it pascha, the Latins passa, an Hebrew word signifying pascha, applied to the Jewish feast of the passover. It is called easter in the English, from the goddes Eostre, worshipped by the Saxons with peculiar ceremonies in the month of April.

The Asiatic churches kept their Easter upon the very same day the Jews observed their passover; and others, on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that Easter should be kept upon one and the same day, which should always be a Sunday, in all Christian Churches in the world.

For the method of finding Easter by calculation, see Vol. I. p. 492.

EASTERN, an appellation given to whatever relates to the east: thus we say, eastern amplitude, eastern church. &c.

EATON, a town of Buckinghamshire, situated on the north side of the Thames, opposite to Windsor, and famous for its collegiate school, founded by king Henry VI being a seminary for king's college Cambridge, the fellows of which are all from this school.

EAVVS, in architecture, the margin or edge of the roof of an house; being the lowest tiles, slates, or the like, that hang over the walls, to throw off water to a distance from the wall.

EBDOMARIUS, in ecclesiastical writers, an officer formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, &c.

EBOMUS, the EBONY TREE, in botany, a genus of the diadema decandria class. The eilix has a number of small hairy teeth, as long as the corolla; the corolla
EBIONITES, in church-history, heretics of the first century, so called from their leader Eben.

They held the same errors with the Nazarenes, united the ceremony of the Mosaic institution with the precepts of the gospel, observed both the Jewish fasts and Christian Sunday, and, in celebrating the eucharist, made use of unleavened bread. They abstained from the flesh of animals, and even from milk. In relation to Jesus Christ, some of them held, that he was born like other men, of Joseph and Mary, and acquired sanctification only by his good works. Others of them allowed, that he was born of a virgin, but denied that he was the Word of God, or had any existence before his human generation. They said, he was indeed the only true Prophet; but yet a mere man, who, by his virtue, had arrived at being called Christ, and the Son of God. They also supposed, that Christ and the devil were two principles, which God had opposed to each other. Of the New Testament they only received the gospel of St. Matthew, which they called the gospel according to the Hebrews.

EBRO, anciently Iberus, a large river of Spain, which taking its rise in Old Catalonia, runs through Biscay and Arragon, passes by Saragofa, and, continuing its course through Catalonia, discharges itself with great rapidity into the Mediterranean, about twenty miles below the city of Tortofa.

EBULLITION. See Boiling.

EBULUS, in botany. See Syrhumus.

ECBOLIUM, in botany. See Apocynoda.

ECCHYMOSIS, in surgery, an extravasation of the blood from a vein in the arm between the flesh and skin.

ECHELON, in ichthyology, a genus belonging to the order of thoracis. The head is flat, naked, depressed, and marked with a number of transverse ridges; it has ten rays in the branchiotege membrane; and the body is naked. There are two species, viz. 1. the remora, with a forked tail, and eighteen frizes on the head. It is found in the Indian ocean. 2. The penates, with an undivided tail, and twenty-four frizes on the head. It is likewise a native of the Indian ocean.

ECHEVIN, in the French and Dutch polity, a magistrate elected by the inhabitants of a city or town, to take care of their common concerns, and the decoration and cleanliness of the city.

At Paris, there is a prevot, and four echevins; in other towns, a mayor and echevins. At Amsterdam, there are nine echevins; and, at Rotterdam, seven.

In France, the echevins take cognizance of rents, taxes, and the navigation of rivers, &c. In Holland, they judge of civil and criminal causes; and if the criminal confesses himself guilty, they can see their sentence executed without appeal.

ECHINATE, or Echinated, an appellation given to whatever is prickly, thereby resembling the hedgehog.

ECHINITES, in natural history, the name by which authors call the foible centronia, frequently found in our chalk-pits. See Centronia.

ECHINOPHORA, in botany, a genus of the pentandria digynia class. The fruit has foppled pedicels. There are two species, one of which, viz. the fringina, or prickly sapphure, is a native of Britain.

ECHINOPS, Glove-thistle, in botany, a genus of the pentandria monogynia class. The fruit has foppled pedicels. The proper calyx is erect, imbricated, and contains but a single flower. There are three species, none of them natives of Britain.

ECHINUS, in zoology, a genus of insects belonging to the order of vermes mollusca. The body is roundish, covered with a bony crust, and often beset with movable prickles; and the mouth is below, and consists of five valves. There are seventeen species, all natives of the sea.

ECHINUS, in architecture, a member or ornament near the bottom of the Ionic, Corinthian, and composite capitals.

ECHIUM, Viper's bugloss, in botany, a genus of the pentandria monogynia class. The corolla is irregular, with a naked frue. There are seven species, three of which are natives of Britain, viz. the vulgar, or viper's bugloss; the anglicum, or English viper's bugloss; and the italicum, or wall-viper's bugloss.

ECHIUM, in architecture, a term applied to certain kinds of

ECHO, a sound reverberated or reflected to the ear from some solid body. See Pneumatics.

ECHO, in architecture, a term applied to certain kinds of
ECTHIPSIS, among Latin grammarians, a figure of
prophy whereby the \( m \) at the end of a word, when the
following word begins with a vowel, or elided, or cut
off, together with the vowel preceding it, for the fake
of the measure of the verfe: thus they read mult' ille.
ECTROPIUM, in surgery, is when the eye-lids are in-
verted, or retracted so as to shew their internal or red
surface, and cannot sufficiently cover the eye.
ECTYLOTICS, in pharmacy, remedies proper for con-
fuming callofities.
ECU, or Escu, a French crown, for the value of which,
see Money.
EDDISH, or Eadish, the latter pasture, or grafs that
comes after moving or reaping; otherwise called ea-
grafs, or earfh, and etch
EDDY TIDE, or Eddy-water, among feamen, is
where the water runs back contrary to the tide; or
that which hinders the free pafsage of the stream, and
so caufes it to return again.
EDDY-WIND is that which returns, or is beat back from a
fail, mountain, or any thing that may hinder its pafsage.
EDESSA. See Orfa.
EDICT, in matters of polity, an order or inftrument,
which hinders the free pafsage of the ftre-am, and
continues duly balanced be-
tween the heels, without throwing to either fide. This
happens when a horfe has a fine fenfe of the aids of the
hand and heel.
ECTHFRACTICS. in medicine, remedies which atte-
nuate and remove obfractions. See Attenuants,
and Deobrants.
ECTHESMA, in surgery, a fort of fracture of the cra-
nium, when the bones are much shattered, and, preff-
ing inwardly, affect the membranes of the brain.
ECTHIESMA, in pharmacy, signifies the mafs remaining af-
after the juices of vegetable/s have been pressed out: and,
in this fene, is the fame as magma. It sometimes fur-
ther imports the juice pressed out.
ECTHIESMUS, in the ancient writers of medicine, a
word ufed to exprefs a diftemperature of the eye, con-
fting in a very great prominence of the entire globe of
the eye, which is, as it were, thruf out of its focket or orbit, by a great flux of humours, or an in-
flammation.
ECTHPISTICA, in pharmacy. See Incrassants.
ECTHISIS, in church-hiftory, a confession of faith, in
the form of an edict, published in the year 639, by the
emperor Heraclius, with a view to pacify the troubles
occasioned by the Eutychian heresy in the easterm
church. However, the fame prince revoked it, on
being informed that pope Severinus had condemned it,
as favouring the Monothelites; declaring at the fame
time, that Sergius, patriarch of Conftantinopole, was
the author of it.
EDINBURGH, the capital city of the kingdom of
Scotland, fituated W. long. 3°, and N. lat. 56°.
We fhall not fpend time in fruitlefs inquiries into
the antiquity of this city, or the etymology of its name;
both of which feem to be fabulous and uncertain. It
is conjectured by fome to have owed its origin and
name to Edwin king of Northumberland, about the
year 600; is taken notice of by authors in the 854
as a small and inconsiderable village, and only about the
middle of the 14th century as the capital of Scotland.
Edinburgh is fituated upon a fteep hill, rifing from
caft to weft, and terminating in a high and inaccefsible
rock, upon which the caftle flands. At the caft end,
or lower extremity of this hill, flands the abbey of
Holyrood-houfe, or king's palace, distant from the
caftle upwards of a mile; and betwixt which, along
the top of the ridge, and almoft in a ftraight line, runs
the high-freet of Edinburgh. On each fide, and pa-

ECTOMETER, among musicians, a kind of scale or
rule, with several lines thereon, ferving to meafure the
duration and length of sounds, and to find their inter-
vals and ratios.
ECCLIPTICS, ancient philofophers, who, without at-
taching themselves to any particular fect, fcelcted
whatever appeared to them the belt and moft rational,
from each.
Potamon of Alexandria was the firft of the eclectics:
he lived in the reigns of Augustus and Tiberius; and
being tired with the fcepticism of the Pyrrhonians, he
resolved upon a scheme that would allow him to believe
something, but without being fo implicit as to swallowing
any entire hypothesis.
ECLEOTOS. See Lintus.
ECLIPTISE, in astronomy, the deprivation of the light
of the sun, or of fome heavenly body, by the inter-
pofition of another heavenly body between our fight
and it. See Vol. I. p. 476.
ECLIPTIC, in astronomy, a great circle of the fphere,
supposed to be drawn through the middle of the zo-
dic, making an angle with the equinoctial of about
23° 30', which is the fun's greateft declination; or,
more ftridly fpeaking, it is that path or way among
the fixed liars, that the earth appears to defcribe to
an eye placed in the fun. See Astronomy, and
Geography.
ECLOGUE, in poetry, a kind of pastoral composition,
or a small elegant poem, in a natural fimple style.
The models in this fort of poetry are Theocritus
and Virgil.
ECOUTE', in the menage, a pace or motion of a horfe,
when he rides well upon the hands and the heels, is
named after moving or reaping; otherwise called ea-
grafs, or earfh, and etch
The models in this fort of poetry are Theocritus
and Virgil.
ECOUTE', in the menage, a pace or motion of a horfe,
when he rides well upon the hands and the heels, is
named after moving or reaping; otherwise called ea-
grafs, or earfh, and etch
The models in this fort of poetry are Theocritus
and Virgil.
rall to this ridge or hill, is another ridge of ground lower than that in the middle, and which does not extend so far to the east; that on the south being intercepted by Salisbury-rocks, and Arthur’s-seat, a hill of about 650 feet of perpendicular height; and that on the north by the Calton-hill, considerably lower than Arthur’s-seat; so that the situation of this city is most singular and romantic; the east or lower part of the town lying between two high hills; and the west or higher part rising up towards a third hill, little inferior in height to the highest of the other two, upon which, as has been observed, the castle is built, and overlooks the town.

The buildings of the town terminate at the distance of about 200 yards from the castle-gate; which space affords a most delightful as well as convenient and healthful walk to the inhabitants. The prospect from this spot is perhaps the finest any where to be met with, for extent, beauty, and variety. In the valley or hollow betwixt the mid and south ridge; and nearly parallel to the high-street, is another street called the Cowgate; and the town has now extended itself over most part of that south ridge also. Betwixt the mid and north ridge was a loch, which, till recently, terminated the town on that side. From the high-street towards the loch on the north, and Cowgate on the south, run narrow crofs streets or lanes, called wynds and cloysters, which grow deeper and deeper the farther west or nearer the castle; so that, were it not for the closeness and great height of the buildings, this city, from its situation and plan, might naturally be expected to be the best aired, as well as the most healthy place in Europe. The first, notwithstanding these disadvantages, it enjoys in an eminent degree; but we cannot compliment it upon the latter, notwithstanding every possible means has been used by the magistrates for that purpose.

The steepness of the ascent makes the access to the high-street from the north and south very difficult; and has no doubt greatly retarded the enlargement of this city. To remedy this inconvenience on the north, and with a view to extend the town on that quarter, a most elegant bridge is presently throwing over the north loch, which will join the north ridge to the middle of the high-street, by so easy an ascent as one in sixteen; and in pursuance of this design a plan of a new town to the north is fixed upon, and is actually carried into execution with surprising rapidity, and with an elegance and taste that does honour to this country.

The principal public buildings in Edinburgh may be reduced to four, viz. St Giles’s church, the palace of Holyrood house, Herriot’s hospital, and the Royal Infirmary.—St Giles’s church is the most ancient church in Edinburgh, in so much that it is not known when or by whom it was founded. It stands on the south-side of the high-street, about a quarter of a mile below the castle. It is a very large, irregular, and heavy building, except the steeple, which runs with a square front from the middle of the structure, and terminates in the form of an imperial crown, and is reckoned the finest in Britain for elegance and symmetry.

The abbey of Holyrood-house was erected by David I. anno 1128, in memory, as is said, of his deliverance from the horns of an enraged hart, by the interposition of heaven in the form of a crofs. It was first made a royal palace by James V. about the year 1528, who built the north wing of the present front, which evidently appears older than the rest. It was completed in the present form by Charles II. in the year 1674; and is justly reckoned a most magnificent and elegant building.

Herriot’s hospital was founded, July 1, 1628, by the magistrates of Edinburgh, in virtue of a donation of £43,608:11:3, bequeathed to them by George Herriot, goldsmith and jeweller to James VI. for the “maintenance, relief, bringing up, and education of so many poor fatherless boys, freemens sons of the “town of Edinburgh,” as the above sum should be sufficient for. This hospital contains at present about a hundred and forty boys, who are well educated and taken care of. It has, notwithstanding the large sum laid out in building the house, a great annual revenue; which, as it consists mostly of lands, must always keep pace with the nominal value of money. This hospital is finely situated on the west end of the south ridge, almost opposite to the castle; and is perhaps the most magnificent building of that kind in Britain.

The Royal Infirmary was founded in August 1738, by the magistrates of Edinburgh, in virtue of a charter from the crown, for the reception of poor diseased persons; and by conduct in the management of its funds, which are mostly from the public contributions, and were but very scanty, has proved an inestimable blessing to this country. This hospital stands near the east end of the south ridge; and is thought by some to be rather too magnificent, considering the purpose for which it is designed, and the narrowness of the original funds.

Edinburgh, as not being properly a sea-port town, has never been remarkable for trade. The chief advantages it enjoys arise from the supreme courts of justice, which are there held; and from its college, which has become famous over Europe, particularly for physic.

EDITOR: a person of learning, who has the care of an impression of any work, particularly that of an ancient author: thus Erasmus was a great editor; the louvain doctors, Scaliger, Petavius, F. Sirmond, bishop Walton, Mr Hearne, Mr Ruddiman, &c. are likewise famous editors.

EDUCATION, the instructing children, and youth in general, in such branches of knowledge and polite exercises, as are suitable to their genius and station.

Education is a very extensive subject, that has employed the thoughts and pens of the greatest men: Locke, the archbishop of Cambay, Tanaquili Faber, M. Crousaz, Rollin, and Roullet, may be consulted on this head.

The principal aim of parents should be, to know what sphere of life their children are designed to act in.
in; what education is really suitable to them; what will be the consequence of neglecting that; and what chance a superior education will give them, for their advancement in the world. Their chief study should be to give their children such a degree of knowledge, as will qualify them to fill some certain post or station in life: in short, to fit them for an employment suited to their condition and capacity, such as will make them happy in themselves and useful to society.

EDULCORATION, in chemistry, the separating, by a washing or solution in water, the salt that any body may be impregnated with, or those that may be left adhering to a body after any operation. See Chemistry.

EEL, in ichthyology, a species of murena. See Murena.

EEL-SPEAR, a forked instrument with three or four jagged teeth, used for catching of eels: that with the four teeth is best, which they strike into the mud at the bottom of the river, and if it strike again it never fails to bring them up.

EFFARE, or EFFRAVE, in heraldry, a term applied to a beast rearing on its hind-legs, as if it were frightened or provoked.

EFFECT, in a general sense, is that which results from, or is produced by, any cause. See Cause.

EFFECTS, in commerce, law, &c. the goods possessed by any person, whether moveable or immovable.

EFFERINGD, a town of Upper Austria, about ten miles west of Lintz.

EFFERVESCENCE, in a general sense, signifies a flight degree of ebullition in liquids exposed to a due degree of heat: but the chemists apply it to that insensible motion excited in various fluids, either by the mixture of fluids with others of a different nature; or by dropping salts or powders of various kinds into fluids. See Powders.

EFFIGY, the portrait, figure, or exact representation of a person.

EFFLORESCENCE, among physicians, the name with exanthema. See Exanthema.

EFFLUVIIUM, in physiology, a term much used by philosophers and physicians, to express the minute particles which exhale from molt, if not all, terrestrial bodies in form of insensible vapours.

EFFUSION, in a general sense, the pouring out of any thing liquid, and that with some violence.

EGG, in physiology, a body formed in certain females, in which is contained an embryo, or fetus of the same species, under a cortical surface or shell. The exterior part of an egg is the shell, which in a hen, for instance, is a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined everywhere with a very thin but a pretty tough membrane, which dividing at, or very near, the obtuse end of the egg, forms a small bag, where only air is contained. In new laid eggs this folliculus appears very little, but becomes larger when the egg is kept.

Within this are contained the albumen or white, and the vitellus or yolk; each of which have their different virtues.

The albumen is a cold, viscid, white liquor in the egg, different in consistence in its different parts. It is observed, that there are two different albumens, each of which is inclosed in its proper membrane; of these, one is very thin and liquid, and the other more dense and viscous, and of a somewhat whiter colour; but, in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg, is as sweet and free from corruption, during all the time of incubation, as it is in new-laid eggs; as is also the vitellus. As the eggs of hens consist of two liquors separated from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; so it is very probable that they are of different natures, and consequently appointed for different purposes.

When the vitellus grows warm with incubation, it becomes more humid, and like melting wax, or fat; whence it takes up more space; for as the fetus increases, the albumen insensibly waxes away, and condenses: the vitellus, on the contrary, seems to lose little or nothing of its bulk when the fetus is perfected, and only appears more liquid and humid when the abdomen of the fetus begins to be formed.

The chick in the egg is first nourished by the albumen; and when this is consumed, by the vitellus, as with milk. If we compare the chalaza to the extremities of an axis pining through the vitellus, which is of a spherical form, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg.

The yellowish white round spot, called cicatricula, is placed on the middle of the smaller portion of the yolk; and therefore, from what has been said in the last paragraph, must always appear on the superior part of the vitellus.

Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the small guts by a small duct.

Eggs differ very much according to the birds that lay them, according to their colour, form, bigness, age, and the different way of dressing them: those most used in food are hens eggs: of these, such as are new-laid are best.

As to the preservation of eggs, it is observed that
the egg is always quite full when it is first laid by the hen, but from that time it gradually becomes leeks and licks to, to its decay; and however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute for the discernment of our eyes, the effect of which is a daily decrease of matter within the egg, from the time of its being laid; and the perspiration is much quicker in hot weather than in cold.

To preserve the egg fresh, there needs no more than to preserve it full, and stop its transpiration; the method of doing which is, by flooding up those pores with matter which is not soluble in watery fluids; and on this principle it is, that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresh for a long time, if they are carefully rubbed all over the shell: tallow, or mutton fat, is also good for this purpose, for such as are rubbed over with this will keep as long as those coated over with varnish.

Artificial method of hatching Eggs. See Hatching.

EGLANTINE, in botany. See Rosa.

EJECTA, a term used by lawyers, for a woman deflowered, or cast from the virtuous.

EJECTION, in the animal economy, evacuation, or discharging any thing through some of the excreto-ries, as by stool, vomit, &c.

EJECTION, in Scots law, is the turning out the possessor of any heritable subject by force; and is either legal or illegal.—Legal ejection is where a person having no title to posses, is turned out by the authority of law: See Removing. Illegal ejection, is one person's violently turning another out of possession without lawful authority. See Law, title 29.

EIBENHOVFN, a town of Dutch Brabant, fifteen miles south of Boisduc.

EFIELD or ELFIELD, a town of lower Saxony, six miles north-west of Mentz.

EIGHT, or PIECE OF EIGHT. See Money.

EIMBECK, a town of lower Saxony, belonging to the Elector of Hanover, twenty-five miles south of Hildesheim.

EISLEBEA, a town of Upper Saxony, five miles east of Mansfield, remarkable for being the birth-place of Luther.

ELAGNUS, Dutch myrtle, in botany, a genus of the tetrandria-monogynia class. It has no corolla; the calyx is bell-shaped above the fruit, and has four segments; and the drupe is bell-shaped, and below the calyx. There are three species, none of them natives of Britain.

ELAEOTHESIUM, in antiquity, the anointing room, as by stool, vomit, &c.

ELAPHEBOLIUM, in Grecian antiquity, the ninth valent of the Athenian year, answering to the latter part of February and beginning of March. It consisted of thirty days, and took its name from the felvial elaphelobia, kept in this month, in honour of Diana the huntress; on which occasion, a cake made in the form of a deer, was offered to her.

ELASMIS, in natural history, a genus of talcs, composed of small plates in form of spangles; and either single, and not farther fiflile; or, if complex, only fiflile to a certain degree, and that in somewhat thick laminae.

Of these talcs there are several varieties, some with large and others with small spangles, which differ also in colour and other peculiarities.

ELASTIC, in natural philosophy, an appellation given to all bodies endowed with the property of elastickness. See the next article.

ELASTICITY, or ELASTIC FORCE, that property of bodies wherewith they resile to their former figure, after any external pressure. See Mechanics.

ELATERIUM, in pharmacy, imports, in general, any purging medicine; but is particularly applied to those which operate with violence.

ELATINE, in botany, a genus of the octandria-tetra-gynia class. The calix consists of four leaves, and the corolla of four petals; the capsule has four cells and two.
ELBE, a large river in Germany, which, rising on the confines of Silesia, runs through Bohemia, Saxony, and Brandenburg; and afterwards dividing the duchy of Lunenburg from that of Mecklenburg, as also the duchy of Bremen from Holstein, it falls into the German ocean, about seventy miles below Hamburg.

It is navigable for great ships higher than any river in Europe.

ELBOW, in anatomy, the juncture of the cubitus and radius; or the outer angle made by the flexure or bend of the arm. See Anatomy.

ELCESAITES, in church-history, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elcefas. The elcesaites kept a mean between the Jews, Christians, and Pagans; they worshipped but one God, observed the Jewish Sabbath, circumcision, and the other ceremonies of the law. They rejected the pentateuch, and the prophets; nor had they more respect for the writings of the apostles, particularly those of St. Paul.

ELDERS, or SENIORS, in Jewish history, were persons the most considerable for age, experience, and wisdom. Of this sort were the seventy men whom Moses associated to himself in the government of his people; such, likewise, afterwards were those who held the first rank in the synagogue, as presidents.

In the first assemblies of the primitive Christians, those who held the first place were called elders. The word presbyter, often used in the New Testament, is of the same signification: hence the first councils of Christians were called presbyterias, or councils of elders.

Elder is also a denomination still preferred in the presbyterian discipline. See Presbyterian.

Elder, or alder, in botany. See Alnus.

ELECT, among ecclesiastical writers, those whom God has chosen, or predestinated to be saved.

ELECTION, the choice that is made of a person, or thing, in preference of any other; as in the election of an emperor, of a pope, of a bishop, of members of parliament, &c.

ELECTION, in theology, signifies the choice which God makes of angels and men for the objects of his grace and mercy. See Grace, and Predestination.

ELECTOR, a person who has a right to elect or chuse another to an office, honour, &c.

Elector is particularly, and by way of eminence, applied to those princes of Germany in whom lies the right of electing the emperor: being all sovereign princes, and the principal members of the empire.

The electoral college, consisting of all the electors of the empire, is the most illustrious and august body in Europe. Bellarmine and Baronius attribute the institution of it to pope Gregory V and the emperor Otho III. in the tenth century; of which opinion are the generality of historians, and particularly the canonists: however, the number of electors was unsettled, at least, till the thirteenth century. In 1356 Charles IV. by the golden bull, fixed the number of electors to seven; three ecclesiastics, viz. the archbishops of Mentz, Treves, and Cologne; and four seculars, viz. the king of Bohemia, count Palatine of the Rhine, duke of Saxony, and marquis of Brandenburg. In 1648 this order was changed, the duke of Bavaria being put in the place of the count Palatine, who having accepted the crown of Bohemia was outlawed by the emperor; but being at length restored, an eighth electorate was erected for the duke of Bavaria.

In 1692, a ninth electorate was created, by the emperor Leopold, in favour of the duke of Hanover, of the house of Brunswick Lunenburg.

There is this difference between the secular and ecclesiastical electors, that the first have an active and passive voice, that is, may chuse and be choven; the last, an active only. The three archbishops are to be thirty years old, before they can be advanced to the dignity; the seculars, eighteen, before they can perform the office themselves. These last have each their vicars, who officiate in their absence.

Besides the power of chusing an emperor, the electors have also that of capitulating with, and deposing him; so that, if there be one suffrage wanting, a protest may be entered against the proceedings. By the right of capitulation, they attribute to themselves great privileges, as making of war, coined, and taking care of the public interest and security of the states; and the emperor promises, upon oath, to receive the empire upon these conditions.

The electors have precedence of all other princes of the empire, even of cardinals and kings; and are addressed under the title of electoral highness.

Their several functions are as follow: the elector of Mentz is chancellor of Germany, convokes the states, and gives his vote before any of the rest. The elector of Cologne is grand chancellor of Italy, and conserves the emperor. The elector of Treves is chancellor of the Gauls, and conserves impoffion of hands upon the emperor. The count Palatine of the Rhine is great treasurers of the empire, and presents the emperor with a globe at his coronation. The elector of Bavaria is great master of the imperial palace, and carries the golden apple. The marquis of Brandenburg is grand chamberlain, and puts the ring on the emperor's finger. The elector of Saxony is grand marshal, and gives the sword to the emperor. The king of Bohemia is grand butler, and puts Charlemagne's crown on the emperor's head. Lastly, the elector of Hanover, now king of Great Britain, is arch-treasurer, though first erected under the title of flandard-bearer of the empire.

ELECTORATE, a term used as well to signify the dignity of, as the territories belonging to, any of the electors of Germany; such are Bavaria, Saxony, &c.
The word ELECTRICITY signifies, in general, the effects of a very subtile fluid matter, different in its properties from every other fluid we are acquainted with. This fluid is capable of uniting with almost every body, but unites more readily with some particular bodies than with others: its motion is amazingly quick, is regulated by peculiar laws, and produces a vast variety of singular phenomena, the principal of which shall be enumerated in this article.

As we are entirely ignorant of the nature of the electrical fluid, it is impossible to define it but by its principal properties: that of repelling and attracting light bodies, is one of the most remarkable. The ancients were only acquainted with this property in amber. William Gilbert, a native of Colchester, and physician at London, in his treatise De Magnete, in the year 1600, was the first person who discovered, that sulphur, wax, resinous substances, glas, and precious stones, when dried and rubbed a little, were endowed with the same property of attracting and repelling straws and other light substances. Sir Francis Bacon, in his physiological remains, gives a catalogue of electrical bodies; but it differs in nothing worth mentioning from that of Gilbert. Mr Boyle, about the year 1670, made some addition to the catalogue of electric substances; but all his experiments on this subject relate only to a few circumstances attending the simple property of electrical attraction: he had never seen the electric light, and little imagined what astonishing effects would be afterwards produced by this wonderful power.

Contemporary with Mr Boyle was Otto Guericke, burgomaster of Magdeburg, and inventor of the air-pump, who was likewise one of the first improvers of electricity. He made his experiments with a globe of sulphur, which he mounted on an axis, and whirled it in a wooden frame, rubbing it at the same time with his hand. He first discovered, that a body once attracted by an excited electre was repelled by it, and not attracted again till it had been touched by some other body: that bodies immersed in electrical atmospheres are themselves electrified: that threads suspended within a small distance of his excited globe, were often repelled by his finger brought near them: that a feather, repelled by the globe, always turned the same face towards it, like the moon with respect to the earth; and that the excitation of his globe produced both light and sound, though in a very inconsiderable degree. A much finer electric light was afterwards observed by Dr Wall, and an account of it was published in the Philosophical Transactions: Dr Wall likewise compares the light and the crackling of his excited amber to thunder and lightning.

Sir Isaac Newton, in 1675, was the first who discovered that excited glas attracted light bodies on the side opposite to that on which it was rubbed.

After Gilbert, Boyle, and Otto Guericke, Mr Hawkef...
472

ELECTRICITY.

or in a very inconsiderable degree: such bodies are called non-electrics, or conductors, viz.

1. Water, and all aqueous and spirituous liquors, which are incapable of being thickened, and subjected to friction.

2. All metals, perfect and imperfect, and the greatest part of minerals; as, the load-stone, antimony, zinc, bismuth, the agat, the jasper, marble, free-stone, flate, &c.

3. All living creatures, excepting their hair. To which may be added most animal-solutions; as, leather, parchment, bone, ivory, horn, shells, &c.

4. Trees and plants of all kinds; thread, ropes, linen-cloth, paper, &c.

These two classes of bodies have been called by the name of electrics and non-electrics: but as the electrical matter is not contained in the electrical bodies themselves, but collected from them by the earth; and as non-electric allow the electrical matter to penetrate and flow through them, or to spread equally on their surfaces, the terms conductor and non-conductor are more proper.

Metals and water are the only perfect conductors; other bodies conducting only as they contain a mixture of these, without more or less of which they will not conduct at all.

Although conductors cannot be electrified by heat or friction, they may be charged with electricity, or made non-conductors, by an easy operation; but then they retain this property no longer than they are kept from communicating with other conductors. A bar of iron will become an electric or non-conductor, by being suspended by a silk cord, or laid upon a piece of rosin or other non-conductor, and at the same time having one end of it in contact with a well rubbed glass tube, or globe. In the same manner, water and metals of all kinds may be charged with electricity.

It is absolutely necessary, in exciting electricity by friction, that the glass, or other body, be perfectly dry; the least moisture detains, or at least diminishes the effect. A moist atmosphere, a burning candle, &c. are extremely unfavourable in making electrical experiments.

Hollow glass globes, of about a foot in diameter, and the 12th part of an inch thick, are now used in place of tubes, because it lessens the labour of friction, and accumulates a greater quantity of electrical matter. This globe is turned rapidly by a large wheel like those used by the cutlers. When the globe is rubbed, it soon acquires a considerable degree of electrical virtue, which is discovered by light bodies, at the distance of two or three feet, flying towards it. In approaching the globe with the hand or face, you will likewise feel the electric matter surrounding it like a gentle breeze of wind. These subtle emanations continue to be diffused round the globe as long as the friction is continued; and when the friction is stopped, they gradually diminish, till they are no longer perceptible. The application of non-conductors to the globe does not diminish the electrical matter: on the contrary, the application of conductors almost instantly annihilates the whole quantity previously collected by the friction. But this effect is not produced, unless when the conductor at the same time has a communication with the floor or earth where the machine stands. For, as above observed, if the conductor has no communication with the earth, it charges with electricity, and becomes a non-conductor. But non-conductors, as a piece of glass, sulphur, or wax, though they do not diminish the virtue of the globe, yet they do not acquire, like iron, &c., the property of attraction or repulsion. Hence it appears, that the electrical matter passes freely along conductors, and dissipates in the earth; but, on the contrary, that non-conductors do not receive any matter from the globe, and are incapable of transmitting it. The following experiments will make this more plain.

1. If a piece of iron be placed on a glass standard, and unconnected with any other body, as soon as the electrical matter is communicated to it, it attracts and repels pieces of gold leaf or other light bodies, and preserves this virtue even for some minutes after its communication with the globe is cut off. But, if a piece of glass, rosin, or any other non-conductor, be placed in the same circumstances, they do not discover any such effect.

2. If a person touches the piece of iron above mentioned with his hand, no friction is capable of making it attract or repel, or exhibit any marks of electricity. The same thing happens, if a chain of any metal touch the iron, and at the same time there has a communication with the ground. In both these cases, the electrical matter passes along the iron, and dissipates in the earth.

3. In place of touching the piece of iron with the finger, if a piece of amber, wax, or any other non-conductor be applied to it, the communication with the earth being interrupted by the non-conductor, the iron, in that case, retains the electrical matter as before.

From these experiments we learn, that metals and other conductors receive the electrical matter, and transmit it to other conductors till it diffuses and is lost in the earth; but that, if wax, glases, or any other non-conductor be applied to the conductor, the motions of the matter is instantly flopt, and accumulates and charges the conductor, at the same time that the non-conductor itself is not all affected. It is for this reason that conductors, as silk-cords, hair-ropes, &c. are always employed to suspend or support such bodies as we want to charge with electricity.

The following experiments will throw further light on this subject.

1. If a man stands upon a piece of rosin about five inches in diameter, and seven or eight inches thick, touching softly the globe, while the operator is rubbing it, his whole body, in a few seconds, will be charged with electrical matter; and the following phenomena will take place.

1. His loose hand, and indeed every part of his body, will mutually attract and repel light bodies at the distance of three or four feet.

2. All conductors which he takes in his hand, will become electrified in the same manner with himself, provided they touch nothing else, or be supported upon non-conductors: and this communication to other conductors, let
E L E C T R I C I T Y. 473

Let their number and extension be ever so great, instead of diminishing the electrical virtue in the body of the man, will rather augment its strength and quantity.

3. If this person gives his hand to another likewise standing on a similar piece of rosin, he too will be charged with electrical matter; and the same thing will happen to any number of persons, provided they stand upon rosin, and communicate with one another by an iron chain or other conductor. But the whole company will instantaneously lose the whole of their electrical virtue, if any non-electrified person touch a single man, or if any communication between one of them and a conducting substance.

4. If the first man removes his hand from the globe, and at the same time keep his former station, he and all the rest will preserve the power of attracting and repelling light substances for some time; but it gradually diminishes, till its effects totally disappear.

5. If a non-electrified person puts his hand near the first man’s face, he will feel a kind of atmosphere surrounding the electrified person; if he advances his hand still nearer any part of the face, for example the nose, both the point of the finger and the nose will appear luminous in the dark: Lastly, if he touches the nose, a spark of fire instantly explodes with a crack and strikes both parties equally with a shock more or less painful in proportion as the electrified person was charged. It is by the explosion of this spark, that the electrical matter instantly transmits itself from one body to another.

6. When we approach near an electrified person, we perceive an extraordinary smell proceeding from his body, similar to that of the phosphenus of urine.

II. An iron wire, 12,000 feet in length, was suspended about five feet from the ground by silk cords; one end of it was connected to the globe of an electrical machine, and at the other a lead ball was hung in order to perceive when the matter reached it.

1. After five or six turns of the wheel, the matter had passed along the whole wire, and communicated its virtue to the ball, which instantly attracted and repelled light bodies.

2. As this ball was equally electrified with every part of the wire, it is probable that the electric matter would instantly pervade a wire of a still greater length, provided we had a proper apparatus for the purpose.

3. Several metals and other conductors were substituted in place of the ball, and all received the electricity in the same manner.

4. The ball and other non-conductors, when touched with the finger, gave a luminous spark and as smart a shock, as when the end of the wire next the globe was touched.

5. All these effects instantly ceased whenever any person not electrified touched any part of the wire, and commenced again a few seconds after his hand was withdrawn.

6. The same effects are produced, though with more difficulty, when hair or woolen ropes were substituted in place of the silk ones: But they were entirely flopped by hemp-ropes, or when the silk ones were wetted.

7. When a hempen rope was substituted in place of the wire, the ball at the end of it was electrified with greater difficulty than when it hung at the wire, especially when the rope was dry; but when the rope was wet, the matter passed with more ease.

8. When, in place of the wire, a dry silk cord, or long glass tube, were used, they received but a very small quantity of the matter, which was not perceivable in the glass tube above 12 feet, nor in the cord above 25, beyond the globe.

9. When the wire was cut in several places, and the cut ends kept at the distance of somewhat less than a foot from each, the electrical matter darted through all these interruptions, and appeared in the ball at the farthest end. A strong blast made by a bellows across one of the interruptions, did not obstruct the passage of the matter; neither did the interposition of a piece of glass, wax, and other non-conductors: but all conductors, as the hand of a man, the point of a sword, and even a moist vapour, obstructed its course towards the ball.

10. When a man stood on a piece of rosin, and put a point of a sword in one of the interruptions, he was instantly filled with the matter, although neither he nor the sword touched the wire: neither was the course of the matter towards the ball obstructed by the interposition of the sword.

11. When a ring of brass wire, about three feet in diameter, was suspended in a vertical direction, and the iron wire was made to pass nearly through its centre, without touching any part of the circumference, the ring, in whatever part of the wire it was tried, was sensibly electrified. This shows that the electrical matter expands to a considerable distance on all sides of the electrified body.

12. The same iron wire suspended by silk cords was extended 6000 feet, (just half of its length), in a straight line; the other half was turned back in a parallel direction towards the globe, leaving about nine or ten inches of interval between the two halves of the wire: Each extremity of the wire was supported by a dry silk cord about seven or eight feet from the globe, and the lead ball was hung at one of them. An iron chain was then fixed with another silk cord above the globe, in order to receive the matter at one of its extremities; the other end of the chain was fixed to a rod of glass about five feet long, in such a manner that the matter received from the globe might be transmitted at pleasure to the wire, by applying the end of the fixed chain to the glass rod. Matters being thus prepared, after five or six turns of the wheel, the chain was applied to one end of the wire; at the same instant the ball at the other end attracted and repelled bits of gold-leaf. The same experiment was repeated, and a finger applied to the ball, and a spark issued out, and a shock was received at the very instant that the chain was applied to the other end of the wire: A spark likewise proceeded from the chain, which afforded an easy opportunity of discovering that the two sparks were perfectly synchronous.

From these experiments it appears,

1. That the electrical matter communicates itself to all non-electrics, or conductors, whatever be their bulk or extension.
2. That the quantity of this matter diffused is always in proportion to the magnitude and extension of the bodies into which it passes; and that it is uniformly diffused, no part of the body retaining more than any other part.

3. That, after being thus communicated to any body, it escapes with equal facility, as soon as it finds a communication with the earth.

4. That small interruptions in the continuity of electrified bodies do not interrupt the motion of the electrical matter.

5. That the motion of the electrical matter is so amazingly swift, that it runs over a space of 12,000 feet in an undefinable instant of time.

6. That it moves with equal rapidity either backward or forward, upon the application of a conductor.

7. Lastly, That an indefinitely large quantity of this matter may be accumulated by applying the globe or tube to conducting bodies of very large dimensions. Of late other methods of condensing a large quantity of electrical matter into a small space have been invented, as will afterwards appear when we come to treat of the Leyden phial.

The attraction and repulsion of light bodies, is the first thing that discovers to us the presence of the electrical matter. This motion is always reciprocal: If the electrified body be lighter than the conductor, and both are at liberty, the motion of the former is quicker than that of the latter; if the one be fixed, and the other at liberty, the unixed one constantly goes to the one that is fixed, and, at the same, takes the shortest road. The following experiments will illustrate these motions.

1. Prefent an electrified tube to small pieces of gold-leaf placed on a well-polished plate of copper, they will instantly fly towards the tube.

2. Suspend an electrified tube by two silk cords; take a piece of gold-leaf, and, holding it firm between your fingers, bring it near the tube; and the tube will be attracted and move toward the leaf.

3. If an electrified person, standing on a piece of rosin, holds in his hand a plate of copper, upon which pieces of gold-leaf are placed; and another person, who is not electrified, holds his finger above the plate; the gold-leaf will instantly rise from the plate, and fly towards his finger.

4. Lastly, If two balls of gilt paper be suspended six inches asunder, the one by a silk thread three feet in length, and the other by a small silver wire of the same length; when the ball suspended by the silk thread is electrified by the tube, both balls advance with equal quickness towards one another, though only one of them was electrified.

The most favourable circumstances for exhibiting the attraction of light bodies are the following:

1. They should be perfect conductors.

2. They ought to be of a small size.

3. They should be supported by a non-conductor, and raised four or five feet from the ground.

4. No other non-conductor should be nearer the bodies than the tube with which the experiments are making; otherwise the attraction will be disturbed.

Repulsion generally succeeds attraction; that is, a piece of gold-leaf is no sooner attracted by the tube than it is repelled and driven off from it. This repulsion is not very perceptible: when the tube is slightly electrified: but, when the electricity is brisk, the gold-leaf never fails to be repelled as soon as it has touched the tube. Again, if the electricity be very strong, the gold-leaf, though strongly attracted by the tube, never touches it; the repulsive power beginning to operate two or three inches before the leaf reaches the tube: from that instant the leaf is electrified; and, when it begins to be repelled, it has acquired as dense an electrical atmosphere as the tube: it then flies off, and remains suspended above the tube until it loses the electric virtue it had acquired, either by the moist vapours in the air, or till it loses it suddenly by touching some conductor. Hence it appears, that attraction precedes repulsion, only because it is necessary that the pieces of gold-leaf should acquire as dense an atmosphere as that of the globe before they can be repelled by it.

When the tube has repelled a piece of gold-leaf, if another tube, nearly equally electrified, be suddenly substituted in place of the former tube, the leaf will continue to be repelled at an equal distance. But if the substituted tube be much less electrified than the original one, the leaf will be attracted by that tube.

When two or more pieces of gold-leaf are presented at the same time to a well electrified tube, they are all equally attracted and repelled; but then they mutually repel one another, so that it is impossible to make any two of them join; and the distance at which they repel one another is equal to the distance to which each of them were repelled from the tube.

If a circular piece of gold-leaf, cut into small fringes, near the centre of the leaf, be presented to an electrified tube, it will first be attracted, and then repelled: in the time of repulsion, all the fringes repel each other, and diverge more or less in proportion to the strength of electricity in the tube.

If a small metal vessel filled with water, and furnished with a capillary siphon, having the longer leg hanging over the outside of the vessel, be touched with an electrified iron rod; the water, which could not run out of the siphon but drop by drop, will instantly fly out a strong jet, and divide itself into very fine threads; and these threads continue sometimes suspended in the air, repelled from each other to a considerable distance.

From these influences of attraction and repulsion it appears,

1. That light bodies are attracted by electrified substances until they be equally electrified by communication, and until they acquire as dense an atmosphere as the electrified substances themselves.

2. That, from the moment they acquire this atmosphere, attraction ceases and repulsion begins.

3. That no repulsion takes place but betwixt bodies electrified.

4. That repulsion continues only as long as the density of the two atmospheres are equal; that it ceases whenever the one or the other is diminished; that a new attraction
traction commences, and continues till an equality in the atmospheres is again restored; and that, immediately upon this, a new repulsion takes place.

5. That repulsion may subsist between two bodies which have never mutually been attracted, provided their atmospheres be equally dense.

6. That the distance to which bodies are repelled is always in proportion to the strength of the electricity they contain. This fact first suggested the notion of an electrometer, or a machine for measuring the different degrees of electricity.

Of Electrical Machines and Apparatus.

The improvement of electrical machines has kept pace with the improvements in the science. While nothing more than electrical attraction and repulsion was known, every phenomenon might be exhibited by means of a piece of amber, sealing wax, or glass, which the philosopher rubbed against his coat, and presented to bits of paper, feathers, and other light bodies.

To give a greater degree of friction to electric substances, Otto Guericke and Mr Hawkesbee contrived to whirl sulphur and glass in a spherical form. The first conductors were nothing more than hempen-cords supported by silken lines. In place of these, bars of metal, or gun-barrels, were foon substituted; and a rubber was employed to supply the place of a human hand. The discovery of the Leyden bottle, (to be afterwards described) occasioned more additions to the electrical apparatus; and the discoveries of Dr Franklin have made proportional additions necessary. No philosopher can now be satisfied, if he be not able to supply a conductor from the clouds, as well as from the friction of his glass globes or tubes.

Although globes or cylinders are now of the most extensive use in electrical experiments, glass-tubes are still most convenient for several purposes; they should be about three feet long, and as wide as a person can conveniently grasp, (Plate LXXIII. fig. 1 a.) The thickness of the glass is not material; perhaps the thinner they are, the better, if they can bear sufficient friction.

The belt rubber for a smooth glass is the rough side of black oiled silk, especially when a little amalgam of mercury or other metal is put upon it.

Glas-globes are in general preferable to cylinders. The globe should have its neck inclosed in a pretty deep brass cap, ending in a dilated brim, of about half an inch broad, if the globe be a large one. It has not been determined what kind of glass is the best; but flint is commonly used. Perhaps globes of twelve or thirteen inches diameter are the best size.

The form of the plate is immaterial with respect to the shock; and, for different experiments, both plates of glass, and jars of various forms and sizes, must be used. For common uses, the most commodious form is that of a jar, as wide as a person can conveniently hold in his hand by grasping, and as tall as it will stand without any danger of falling; perhaps about 3½ inches in diameter, and 8 inches in height. The mouth should be pretty open, that it may be the more conveniently inverted, which is requisite in many experiments. Brass-dust, however, or leaden dust, is very convenient for small phials. The tin-foil may be put on either with paste, gum-water, or bees-wax. To coat the insides of vessels which have narrow mouths, moisten the inside with gum-water, and then pour some brass-dust upon it: Enough will stick to make an exceeding good coating.

In the construction of an electrical battery, a number...
number of small jars are preferable to large ones. If
one of them should break by an explosion or any other
accident, the loss is less considerable; besides, by means
of narrow jars, a greater force (that is, a greater quan-
tity of coated surface) may be contained in less room.
The largest jars are about 17 inches in height, and
should not be more than 3 in diameter; and of the same
width throughout. Thus they may be easily coated both
within and without, and a box of a moderate size will
contain a prodigious force; for the jars being coated
within two inches of the top, each will contain a square
foot of coated glass. The battery (Plate LXIII. fig. 3.)
consists of 64 jars, each 8 inches long, and 24 in dia-
cmeter, coated within an inch and a half of the top. The
coated part of each is half a square foot; so that the
whole battery contains 32 square feet. The wire of each
jar has a piece of very small wire twisted about the lower
cord of it, to touch the inside coating in several places;
and it is put through a pretty large piece of cork within
the jar, to prevent any part of it from touching the side,
which would tend to promote a spontaneous discharge.
Each wire is turned round, so as to make a hole or ring
at the upper end; and through these rings a pretty thick
brafs rod with knobs is put, one rod serving for one row
of the jars. The communication between these rods is
made by laying a chain over them all : this chain is not
represented in the plate, left the figure should appear con-
 fused. When only a part of the battery is to be used,
the chain should be laid over as many rods as you want
rows of jars. The bottom of the box in which all the
jars stand is covered with tinfoil and brafs-dust; and a
bent wire touching this tinfoil is put through the box,
and appears on the outside, as in the plate. To this wire
is fastened whatever is intended to communicate with the
outside of the battery, as the piece of small wire in the
figure; and the discharge is made by bringing the brafs
knob to any of the knobs of the battery.

To discover the kind and degree of electricity, many
forms of ELECTROMETERS have been thought of. Mr
Canton’s balls A, represented on a glass standing on the
floor c, (Plate LXIII. fig. 1.) serve to discover small
degrees of electricity, to observe the changes of it from
positive to negative, and to estimate the force of a shock
before the discharge. These balls are two pieces of
cork, or pith of elder, nicely turned in a spout to about
the size of a small pea, and suspended on small linen
threads. These balls repel one another to distances ex-
actly proportioned to the quantity of electricity contained
in the vessel or other substance with which they are con-
ected; and by this work the operator knows pretty ex-
actly the force of the charge, and the shock that will be
given.

In order to repeat the experiment tending to shew
that the electric fluid is the same with the matter of
lightning, and to make observations on the electricity of
the atmosphere, the electrician should be provided with
A MACHINE FOR DRAWING ELECTRICITY FROM THE
CLOUDS. The best construction of which is the follow-
ing: On the top of any building erect a pole a, (Plate
LXXIV. fig. 2.) as tall as a man can well manage, ha-
vng on the top of it a solid piece of glass, or baked
wood, a foot in length. Let this be covered with a tin
or copper vessel (b) shaped like a funnel, to prevent its
ever being wetted; above this, let there rise a long slender
rod e, terminating in a pointed wire, and having a small wire
twisted round its whole length, the better to conduct the
electricity to the funnel. From the funnel make a wire (d)
defend along the building, about a foot distance from it,
and conducted through an open sash into any room that
shall be most convenient for making the experiment. In
this room, let a proper conductor be insulated, and con-
ected with the wire coming in at the window. This
wire and conductor, being completely insulated, will be
electrified whenever there is a considerable quantity of
electricity in the air. And notice will be given when it
is properly charged, either by Mr Canton’s balls hung to
it, or by a set of bells dispofed in the following manner.
Take three bells; suspend the two outermost from the
conductor by chains, and in the middle by a filken
string, while a chain connects it with the floor; and
hang two small knobs of brafs by filken strings, one be-
tween each two bells, to serve instead of clappers. In
consequence of this disposition, when the two outermost
bells, communicating with the conductor, are electrified,
they will attract the clappers, and be struck by them.
The clappers being thus loaded with electricity, will be
repelled, and fly to discharge themselves upon the middle
bell. After this, the clappers will be again attracted
by the outermost bells; and thus, by striking the bells
alternately, a continual ringing may be kept up as long
as the operator pleases. In the dark a continual flashing
of light will be seen between the clappers and the bells.
But when the electrification is very strong, these flashes of
light will be so large, that they will be transmitted by
the clapper from one bell to the other, without its ever
coming to actual contact with either of them, and the
ringing will consequently cease.

With regard to the construction of machines for elec-
trical experiments in general, that of Dr Priestly, repre-
sented on Plate LXIII. fig. 2, is perhaps the best.
The FRAME consists of two strong boards of mahogany,
(aa), of the same length, parallel to one another, about
four inches asunder, and the lower one is an inch on
each side broader than the upper: in the upper board is a
groove reaching almost its whole length. One of the
pillars b, which are of baked wood, is immovable, be-
ing let through the upper board, and firmly fixed in the
lower; while the other pillar slides in the groove above-
mentioned, in order to receive globes or cylinders of diffe-
rent sizes; but it is only wanted when an axis is used.
Both the pillars are perforated with holes at equal di-
fances from the top to the bottom; by means of which,
globes may be mounted higher or lower according to
their size; and they are made tall, to admit the use of
two or more globes at a time, one above another. Four
of a moderate size may be used, if two be fixed on one
axis; and the wheel has several grooves for that purpose.
If a globe with only one neck be used, as in the
Plate, a brafs arm, with an open socket c, is necessary
to support the axis beyond the pulley; and this part is
also contrived to be put higher or lower, together with
the brafs socket in which the axis stands. The axis d
is made to come quite through the pillar, that it may be turned by another handle without the wheel, if the operator chuses. The frame, being screwed to the table, may be placed nearer to, or farther from, the wheel, as the length of the string requires in different states of the weather. The Wheel is fixed in a frame by itself, by which it may have any motion with respect to the pulley, and be turned to one side, so as to prevent the string from cutting itself.

The Rubber (/) consists of a hollow piece of copper, filled with horse-hair, and covered with a basil-skin. It is supported by a socket, which receives the cylindrical axis, of a round and flat piece of baked wood, the opposite part of which is inserted into the socket of a bent steel-spring. These parts are easily separated; so that the rubber, or piece of wood that serves to insulate it, may be changed at pleasure. The spring may be either flipped along the groove, or moved in the contrary direction, so as to give it every desirable position with respect to the globe. It is besides furnished with a screw i, which makes it press harder or lighter on the globe, as the operator chuses.

The Prime Conductor (A) is a hollow vessel of polished copper in the form of a pear, supported by a pillar and a firm basis of baked wood; and it receives the electrical matter by means of a long arched wire or rod of very soft brass k, easily bent into any shape, and raised higher or lower as the globe requires. It is terminated by an open ring, in which are hung some sharp-pointed wires m, playing lightly on the globe when it is in motion. The body of the conductor is furnished with holes and sockets for the insertion of metallic rods to convey the fire where-ever it is wanted.
